Introduction: Expression of inflammatory cytokines' genes may take part in pathophysiology of different forms of gastroesophageal reflux disease (GERD). However, its role in local inflammatory response and association with types and number of gastroesophageal refluxes is poorly studied yet¹.

Aims & Methods: To explore the expression of inflammatory cytokines' genes in esophageal mucosa in patients with erosive esophagitis and non-erosive forms of gastroesophageal reflux disease and its association with data of esophageal multichannel intraluminal pH-impedance measurements.

This was a single-center prospective study. Esophageal mucosa samples were taken from lower part of the esophagus during endoscopy. Expression of IL-1 β , IL-10, IL-18, TNFA, TLR4, GATA3, CD68 and beta-2 macroglobulin genes in esophageal mucosa was assessed with ImmunoQuantex assays.

Multichannel intraluminal esophageal pH-impedance (MII-pH) studies were performed to all the participants.

Diagnosis of GERD was confirmed by the results of MII-pH data. Based on the endoscopy, patients were allocated to the group of erosive esophagitis (EE) and non-erosive GERD (NERD).

The control group consisted of non-symptomatic subjects with normal endoscopy and MII-pH results. We used non-parametric statistics to compare the differences between the groups. Association of expression of the mentioned genes and the results of MII-pH data was assessed with Spearman rank method.

Results: Data of 60 patients with GERD and 10 subjects of the control group were available for the analysis. Higher expression of IL-18 (5.89 $\pm$ 0.4 vs 5.28 $\pm$ 1.1, p=0.04) and GATA3 (2.92 $\pm$ 0.86 vs 2.23 $\pm$ 0.96, p=0.03) genes was found in EE group compared to NERD.

Expression of IL-1 β , IL-18, TNFA, and TLR4 genes was lower (P<0.05) in the control group compared to EE and NERD. Esophageal acid exposure correlated with the expression of IL-1 β (Spearman rank R = 0.29), IL-18 (R=0.31), TNFA (R=0.35), GATA3 (R=0.34), TLR4 (R=0.29), CD68 (R=0.37) genes.

Mean esophageal pH correlated inversely with the expressions of IL-18, TNFA, GATA3, TLR4, CD68 genes. No association between genes expression and number of gastroesophageal refluxes was found (Table 1).

	Number of GERs	Acid GERs	Weak-acid GERs	Non-acid GERs	High GERs	Mean pH	AET
IL-1 β	-0.02	0.14	-0.11	0.04	-0.03	-0.24	0.29 ^a
IL-10	-0.15	-0.02	-0.16	0.02	0.01	-0.21	0.18
IL-18	0.01	0.06	-0.02	0.01	0.01	-0.28 ^a	0.31 ^a
TNFA	-0.03	0.08	-0.12	0.01	-0.12	-0.33 ^a	0.35 ^a
GATA3	0.04	0.15	-0.13	-0.1	0.02	-0.28 ^a	0.34 ^a
TLR4	-0.05	0.04	-0.15	0.06	-0.04	-0.28 ^a	0.29 ^a
CD68	0.01	0.05	-0.03	-0.01	-0.08	-0.39 ^a	0.37 ^a
B2M	0.04	0.10	-0.04	0.17	0.09	-0.26	0.34 ^a

Notes: ^a - marked values are statistically significant (P<0.05); GERs – gastroesophageal refluxes; AET – acid exposure time (proportion of time with pH<4 per 24 hours at 5 cm above upper border of lower esophageal sphincter); mean pH – mean values of pH at 5 cm above upper border of lower esophageal sphincter.

Table 1. Correlation coefficients (by Spearman rank R) between the results of between the data of 24-hours multichannel intraluminal pH-impedance records and local expression of inflammatory cytokines.

Conclusion: In patients with erosive esophagitis, local expression of interleukin 18 and GATA3 transcription factor genes was higher compared to subjects with non-erosive form of gastroesophageal reflux disease. Esophageal acid exposure correlated directly with expression of IL-1 β , IL-18, TNFA, TLR4, CD68 and B2M genes. Inverse correlation revealed between expression of IL-18, TNFA, GATA3, TLR4 CD68 genes and mean esophageal pH.

Introduction: Molecular signature of the oesophageal mucosa of patients with gastro-oesophageal reflux disease (GORD) is yet to be clearly established. We recently identified expression of transient receptor potential vanilloid subfamily member-1 on superficial sensory nerves in patients with non-erosive reflux disease (NERD), alongside increased epithelial cell expression of acid-sensing ion channel-3 in erosive esophagitis and NERD, collectively highlighting mucosal mechanisms for heartburn sensation in different reflux phenotypes.

However, acid reflux-induced alterations to epithelial barrier integrity, mucosal inflammation and sensitivity are likely to have an overlapping role in heartburn pathogenesis in GORD.

Aims & Methods: We sought to better understand why some patients with heartburn symptoms develop oesophagitis while others develop NERD, using a bulk RNA sequencing approach.

19 patients with heartburn symptoms were phenotyped endoscopically and with objective reflux studies into erosive oesophagitis (N=10) and NERD (N=9) groups. Erosive oesophagitis patient biopsies were collected from a non-macroscopically inflamed segment of the distal oesophagus. RNA extracted from distal oesophageal mucosal biopsies taken at endoscopy from 19 GORD patients and 8 healthy volunteers were sequenced using NEBNext Ultra II Directional RNA Kit. Differential expression analysis and downstream functional enrichment analysis were performed with DESeq2 and goseq R packages, respectively.

Results: Compared with the oesophageal mucosa of healthy controls, erosive oesophagitis patients had 1665 significantly differentially expressed (DE) genes which were highlighted in 147 molecular pathways including, an enriched immune response, cytokine-mediated signalling, and leukocyte migration, as statistically significant ($p < 0.01$). NERD patients had 945 significantly differentially expressed (DE) genes compared to healthy controls, enriched in 84 molecular pathways including increased neutrophil degranulation, regulation of axon regeneration, and keratinocyte differentiation in NERD.

Interestingly, DESeq2 analysis between oesophageal mucosa of patients with erosive oesophagitis and NERD revealed only 10 significantly DE genes which were implicated in enriched extracellular matrix organisation, cell proliferation, and nerve growth factor signalling in erosive oesophagitis compared to NERD. None of the 10 DE genes identified were critically involved in barrier function.

Conclusion: Although the oesophageal mucosal gene expression signature is heterogeneous between healthy controls and heartburn patients, in erosive and non-erosive reflux disease it is strikingly similar at a molecular level. This suggests it is more likely that mucosal differences between erosive oesophagitis and NERD result from differences in severity of reflux or the chemical composition of refluxate damaging the oesophageal mucosa in these patients.

THE ACTIVITY OF THE JAK/ STAT PATHWAY IS DECREASED IN PATIENTS WITH ACHALASIA

S. Kipcak^{1,2}, P. Ergun^{2,3}, N. Selvi Gunel¹, S. Bor²,
Ege Reflux Study Group

¹Ege University, School of Medicine, Department of Medical Biology, Izmir, Turkey, ²Ege University, School of Medicine, Department of Gastroenterology, Izmir, Turkey, ³Ege University, School of Medicine, Department of Medical Biochemistry, Izmir, Turkey

Contact E-Mail Address: kipcaksezgi@gmail.com

Introduction: The pathogenesis of achalasia is not well characterized. The disease is localized in the muscle and effects neurons however data is limited at the esophageal epithelium (EE). EE is particularly important because therapeutic procedures such as POEM increases the risk of gastroesophageal reflux disease (GERD).

It is not known that long-term stasis and other effects predispose the EE to GERD. Jak/STAT is the main signaling mechanism for various cytokines and growth factors and its role within the EE.

Aims & Methods: The aim of the study is to determine the activation states of JAK/STAT pathway in achalasia. 37 (23 female) achalasia patients and 15 (6 female) healthy volunteers (HV) were included in the study. Epithelial esophageal biopsies taken by endoscopy were used to determine the

expression levels of JAK STAT-related genes and phosphorylated proteins. Gene expression levels were determined by the qRT-PCR method, protein levels were examined by Multiplex ELISA method.

Results: In our results, JAK1, JAK2, STAT1, STAT2 (-3.02, -2.43, -5.72, -4.31 fold, respectively) gene expression levels, which are important genes of the JAK/STAT pathway, expressed at lower levels in achalasia patients compared to HVs. The SOCS family activated by cytokines, is a negative regulator of the JAK-STAT pathway (1).

We determined that the SOCS1 and SOCS3 (8.15, 2.99 fold, respectively) genes are expressed at higher levels in achalasia patients compared to HVs. MAPK/ERK pathway is involved in the downstream regulation of the JAK-STAT pathway (2).

We also studied the levels of important proteins involved in MAPK/ERK pathway. Erk1/2 (Th202/Tyr204), MEK1 (Ser217/Ser221), c-Jun (Ser63) were low expressed in achalasia compared to HVs.

Conclusion: The low expression of the important genes of the JAK-STAT pathway and the high expression of the genes of the SOCs family, which is the negative regulator of this pathway, are important evidence of the low activity of the JAK-STAT pathway in achalasia patients. In addition, low expression of the proteins which are downstream of the JAK/STAT pathway supported the gene expression data. Long-term stasis and other effects in the achalasia EE do not cause activation of inflammation pathways like JAK/STAT, therefore achalasia EE may not be predisposed to GERD before the achalasia treatment.

Introduction: Gastric cancer is a major health burden worldwide. It is the second cause of cancer deaths after lung cancer. The literature is reviewed for evidence concerning the relation between calorie intake or body weight and cancer formation. Yet, various forms of reduced calorie intake such as caloric restriction or fasting demonstrate a wide range of beneficial effects able to help prevent malignancies and increase the efficacy of cancer therapies. It is known that Sirtuins (SIRT), are NAD(+)-dependent histone deacetylases regulating important metabolic pathways. The seven members of this family of enzymes play also fundamental roles in carcinogenesis.

They are key factors in maintenance of the malignant phenotype, mainly participating in cancer cell viability, apoptosis, metastasis, and tumorigenesis. So far, there are no data describing the impact of caloric restriction on the production of the entire SIRT family in gastric cancer cells.

Aims & Methods: The aim of our study was to perform SIRT's expression profiles in an established gastric cancer line CRL-1739 under caloric restriction.

We used AGS (ATCC®, CRL-1739™) adenocarcinoma cell line. The cells were cultured in two types of caloric restriction models:

1. RPMI +10% FBS (fetal bovine serum) with glucose limitation (0 mg/mL; 1mg/mL; 4,5mg/mL and 10mg/mL) and
2. RPMI without any glucose (0 mg/mL) and with different concentration of FBS (0%, 10%), to see if glucose or nutrients restriction are more shocking for cancer cells. Profile of SIRT's expression was assessed in 6 time points between 0-96h of incubation, using qRT-PCR method.

Results: For the first time, all sirtuins family expression analysis was performed in gastric cancer cell line. The results showed: 1. Large production of SIRT's (especially 1 and 7) during the caloric restriction period. The highest increase in SIRT's expression was noticed at the first time points (1h and 24h). After 48h the level of SIRT's expression returned to the values recorded in non-conditioned cells (without limitation of FBS or glucose).

Conclusion: These results prove a strong impact of caloric restriction in the production of SIRT in gastric cancer cells. We also noticed correlations in SIRT expression, caloric restriction and gastric cancer cell proliferation.

HEPATITIS B REPLICATION MARKERS ALONG WITH ENTRY RECEPTOR ON PLACENTA INDICATE: ANOTHER HOME FOR THE VIRUS

G. Garg¹, K. Patel¹, S. Purwar¹, S. Mukhopadhyay², N. Mishra³, D. Biswas¹, A. Singh¹, A.K. Vyas¹

Introduction: Hepatitis B chronic infection due to mother-baby vertical transmission of HBV is one of the major causes of HCC worldwide 1,2,3. The role of sodium taurocholate co-transporting polypeptide (NTCP), in facilitating the binding of the virus on the surface of hepatocytes is well documented 4.

Expression of NTCP in extrahepatic cells may make these cells susceptible to HBV infection and support cellular proliferation akin to hepatocytes. *Placental replication of HBV is not well explored/studied*.

Aims & Methods: In this study, our aim is to investigate the role of the placenta in HBV mother-to-baby vertical transmission. We have assessed the expression of NTCP and HBV replication markers (HBeAg, HBcAg, and HBV DNA) in placental cells, to investigate if these cells act as host/reservoir for HBV and which could be one of the causes of HCC in the pediatric population.

Results: Twenty HBsAg+ve pregnant women along with 10 healthy controls were enrolled after obtaining informed consent. The HBV DNA in the placenta was detected by qPCR using primers for X and core ORF. The expression of NTCP in the placenta was analyzed by qRT-PCR and was further investigated by immunohistochemistry (IHC) along with HBV replication biomarkers, HBsAg, HBeAg, and HBcAg.

HBV-infected females showed increased expression of NTCP in trophoblasts of the placenta compared to the control group (3.62±0.96 Vs 1.44±0.81). Furthermore, a significant difference in NTCP expression was also observed between HVL and LVL groups (3.62±0.96 Vs 2.06±1.3) and it was correlated with the maternal HBV DNA load. Membranous and/or Cytoplasmic immunostaining of NTCP, and cytoplasmic staining of HBeAg and HBcAg in trophoblasts along with the presence of HBV DNA indicated that trophoblasts are not only susceptible to HBV infection but may also be a probable site for viral replication.

Conclusion: This is the pioneer study, which demonstrates the expression of NTCP on the placenta which may facilitate the entry of HBV. Furthermore, the study establishes the presence of HBeAg in trophoblasts indicating these cells may act as replication host/reservoirs. The correlation of NTCP expression with maternal viral load and the presence of HBeAg in the placenta indicates its probable role in the vertical transmission of HBV and which could be one of the causes of HCC in a pediatric population. Our preliminary findings suggest that NTCP blocking strategy may be used for therapeutic intervention of vertical transmission.

MODERN STUDY ABOUT THE ROLE OF MACROPHAGES AND TRANSFORMING FACTOR B1 IN THE PATHOGENESIS OF PRIMARY SCLEROSING CHOLANGITIS AND ITS ASSOCIATION WITH INFLAMMATORY INTESTINAL DISEASES

G. Goyibova¹, A. Umarov², F. Alyaviya²

¹Tashkent Pediatric Medical Institute, Department of Gastroenterology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Department of Gastroenterology, Tashkent, Uzbekistan

Contact E-Mail Address: miss_gulinoza@mail.ru

Introduction: Macrophages are cells capable of absorbing and digesting foreign or harmful particles for the body: bacteria, the remains of destroyed cells, etc. It is important to investigate their new features.

Aims & Methods: To study the role of macrophages (CD68+) and transforming factor β1 (TGF-β1) in the pathogenesis of primary sclerosing cholangitis (PSC) and its association with inflammatory bowel diseases (IBD) in the interests of searching for new differential diagnostic markers of isolated and combined PSC and IBD. Immunohistochemical study of samples

(4 biopsies each) of the lamina propria (SO) of the ileum, the colon was carried out in 18 patients with PSC, of which 11 had active IBD. The control group consisted of 24 patients with moderate and severe isolated IBD (14 and 10 patients with ulcerative colitis (UC) and Crohn's disease (CD), respectively).

When evaluating liver biopsies (17 patients with PSC, of which 9 people with IBD/PSC), the counting was carried out in 3 sections of the hepatic lobule. Quantification of CD68+ and TGF- β 1 expression (absolute number of cells) was performed in 5 fields of view for each marker in 1 mm².

Results: Expression of CD68+ and TGF- β 1 in intestinal mucosa was high in all patients with PSC, regardless of the presence of active inflammation. The presence of CD68+ and TGF- β 1 in the intact intestinal mucosa is most likely due to their involvement in maintaining homeostasis. It is possible that we observed preclinical manifestations of IBD or predictors of their development. Expression of macrophages CD68+ and TGF- β 1 was higher ($p < 0.05$) in intestinal mucosa with active inflammation than in PSC without endoscopic and morphological signs of colitis. This is consistent with literature data and indicates that hyperproduction of CD68+ and TGF- β 1 inactive IBD. The expression of CD68+ in our study was higher in patients with isolated UC than in IBD/PSC, and the expression of TGF- β 1 did not differ statistically.

These changes may be explained by the higher morphological activity of UC in our work. High expression of CD68+ and TGF- β 1 in nonparenchymal liver cells confirms their key role in the pathogenesis of PSC. According to our data, increased expression of CD68+ occurred in all parts of the hepatic lobule, however, we recorded the predominance of CD68+ expression in the periportal zone, which is explained by the localization of inflammation in PSC. This may be of great practical importance in differential diagnosis with others, including autoimmune, liver diseases.

Conclusion: CD68+ and TGF- β 1 play an important role in the pathogenesis of PSC and its association with IBD. A promising diagnostic marker of PSC may be an increased expression of TGF- β 1 in the periportal zone of the hepatic lobule. CD68+ is probably important for the diagnosis of isolated and associated IBD. Further research is required.

Introduction: Gastric ulcer is one of the most common gastrointestinal system diseases, affecting approximately 10% of the world population. It mainly develops due to an imbalance between aggressive and protective factors. For years, the main targets of the treatment have been accepted as gastric acid secretion and H2RA blockers, PPIs are used to treat stomach ulcer cases.

However, there are adverse effects such as hypersensitivity, arrhythmia, hypomagnesemia, gynecomastia, and gastric cancer that restrict the clinical usage of most medications, in addition to a lack of complete recovery

in the treatment of gastric ulcers. It has become a research target to determine a new treatment that is safe, effective, and non-toxic derived from vegetables and fruits with gastric protective effects.

Aims & Methods: The present study aimed to evaluate the gastroprotective potential of ferulic acid on indomethacin-induced gastric ulcers in rats. Adult male Sprague-Dawley rats (200–250 g) were randomly divided into five groups: the control group, the ulcer group, and the FA groups (100, 250, and 500 mg/kg, respectively). After 24-h starvation, all the groups received subcutaneous indomethacin at a dose of 25 mg/kg dissolved in 5% NaHCO₃, except for the control group. Fifteen minutes later, the rats in the control and ulcer groups were given vehicle (10% tween 80) with oral gavage, and the rats in the FA groups were treated with 100, 250, and 500 mg/kg FA (suspended in 1 mL of 10% tween 80). On the 4th hour, rats were euthanized by exsanguination under isoflurane anesthesia.

Gastric samples were collected for macroscopic and microscopic examination. To assess the oxidative and inflammatory state, stomach samples were also analyzed for malondialdehyde (MDA), glutathione (GSH), and superoxide dismutase (SOD), myeloperoxidase (MPO), tumor necrosis factor (TNF)- α , interleukin (IL)-1 β , IL-6, and nuclear factor kappa-B-p65 (NF- κ B-p65) levels.

Results: In the ulcer group, indomethacin injection significantly increased the macroscopic and microscopic damage scores, gastric levels of the MDA, MPO, TNF- α , IL-1 β , IL-6, and NF- κ B p65 levels, but reduced the SOD and GSH content of gastric tissues. Treatment with FA significantly improved gastric injury both macroscopically and microscopically. FA displayed a marked decrease in the gastric levels of MDA, MPO, TNF- α , IL-1 β , IL-6, and NF- κ B p65 and a significant increase in the gastric levels of SOD and GSH when compared to the indomethacin group. While the 100 mg/kg dose had no significant effect, 250 mg/kg FA was the most effective dose.

Conclusion: This study showed that FA has considerable anti-ulcer activity. Our results revealed that the gastroprotective effect of FA against indomethacin-induced gastric ulcers in rats might be attributed to its antioxidant and anti-inflammatory properties. In conclusion, FA is a potential treatment choice for indomethacin-induced gastric ulcers.

Disclosure: This work was financially supported by Scientific Research Projects Commission of Acibadem Mehmet Ali Aydinlar University, Istanbul (Project No. 2021/03/02).

Introduction: Immune checkpoint inhibitors (ICI; anti-PD1 and/or anti-CTLA-4) can induce immune-related adverse events (irAEs). Upper gastrointestinal (GI) irAEs have been reported but data are scarce.

Aims & Methods: We aimed to describe upper GI irAEs in patients treated with ICI. In this retrospective study we included patients with upper GI symptoms and endoscopic erosions or ulcerations of the esophagus, stomach or duodenum during or up to 6 months after ICI discontinuation, in hospitals of the Paris area.

We excluded patients who had upper gastrointestinal symptoms unrelated to ICI (gastroesophageal reflux disease, *Helicobacter pylori* infection, Crohn's disease, amyloidosis, metastasis).

Results: Between January, 2013 and December, 2021, 35 patients were included. Twenty-three (66 %) were men, their median age was 63 years (range 27-89). Patients were treated with anti-PD1 (n=19, 54%), anti-CTLA-4 (n=4, 11%) or both (n=12, 34%). Twenty-eight patients had a melanoma (80.0%), 4 had a Non-Small Cell Lung Cancer (11.4%), 3 (8.6%) had another cancer. Symptoms occurred 3.3 months (0.10-23.80) after the initiation of ICI. These were epigastric pain (n=25, 71%), nausea (n=22, 63%), weight loss (n=23, 66%), diarrhoea (n=20, 57%), and early satiety (n=12, 34%). Twenty-six (74%) had others irAEs including 18 (51%) with gastrointestinal irAEs (ileitis or colitis).

Twenty-eight (80%) patients had a severe gastritis. Main endoscopic findings were erosions in 8 (23%), ulcerations in 9 (26%), hemorrhage in 9 (26%), and necrotic gastritis in 2 (6%) patients. Endoscopic biopsies showed chronic gastritis in 3 (11%) patients (lymphoplasmacytic infiltrate without activity), and active gastritis in 25 (89%) patients (periglandular inflammation, lymphoplasmacytic infiltrate and neutrophils).

Fourteen patients (40%) had a severe duodenitis. Eight (23%) patients had erosions, 5 (14%) had ulcers, and 1 (3%) had a hemorrhagic duodenitis. Endoscopic biopsies showed active duodenitis (lymphoplasmacytic infiltrate and neutrophils in the lamina propria and in the epithelium), with (n=2, 17%) or without (n=10, 83%) villus atrophy.

Three patients (9%) had an esophagitis associated with gastritis or duodenitis: 1 patient had superficial erosive lesions of the esophagus, 2 patients had ulcerated lesions of the esophagus.

The median follow-up was 15 months (1-80). Thirty-one patients (89%) were treated with corticosteroids. Among them, 26 patients (84%) responded and 18 (58%) reached clinical remission. Fourteen patients had a new upper gastro-intestinal endoscopy after corticosteroids; 12 (86%) had an endoscopic response; including two patients (14%) with mucosal

healing. Seven patients were treated with infliximab, 5 responded (71%), including 2 (29%) who reached clinical remission. One patient was treated with vedolizumab and had clinical response without remission.

Conclusion: ICI can induce severe esophagitis, gastritis and duodenitis. Corticosteroids and infliximab induce clinical response in the majority of patients.

Introduction: Achalasia is a rare motility disorder of the esophagus caused by the gradual degeneration of myenteric neurons. Immune-mediated ganglionitis has been proposed to underlie the loss of myenteric neurons. We aimed to map the immune cell transcriptional landscape and identify disease-associated transcriptional changes in achalasia using single-cell RNA sequencing (scRNA-seq).

Aims & Methods: Nine achalasia patients and 4 controls with paired tissue and blood samples, and 2 achalasia patients with only peripheral blood samples were included in this study. Patients with benign leiomyomas originating from LES served as controls. Immune cells in tissue were dissociated from smooth muscle in LES. Transcripts of 137,346 cells were determined using scRNA-seq and coupled T cell receptor and B cell receptor sequencing. Results were confirmed by multicolor immunohistochemistry.

Results: In achalasia, we identified a pattern of expanded immune cells and a unique transcriptional phenotype, especially in LES tissue. The C1QC⁺ macrophages, ZNF683⁺ CD8⁺ tissue-resident memory T (Trm), and XCL1⁺ CD4⁺ Trm clusters were significantly expanded and localized surrounding the myenteric plexus in LES tissue of achalasia. C1QC⁺ macrophages were functionally similar to microglia of the central nervous system and exhibited a neurodegenerative dysfunctional phenotype in achalasia. ZNF683⁺ CD8⁺ Trm and XCL1⁺ CD4⁺ Trm clusters also expressed transcripts of an inflammatory phenotype in achalasia. Moreover, inflammation increased with disease progression since immune cells were more activated in type I compared with type II achalasia.

Conclusion: We identified the C1QC⁺ macrophages, ZNF683⁺ CD8⁺ Trms, and XCL1⁺ CD4⁺ Trms as distinct immune cell clusters that underlie the mechanism of the inflammatory process in achalasia.

Introduction: Esophageal stricture formation is known as a very challenging complication of endoscopic submucosal dissection (ESD) for wide spread superficial esophageal cancer. It is caused by hyper fibrosis on the esophageal epithelium. Topical triamcinolone acetonide (TCA) injection to the ulcer base after ESD is partly effective for the stricture. However, it still has limitations to manage the disease completely. Tissue adhesive

materials to wet and dynamic surfaces such as gastrointestinal tract have great benefits for sustained release of drug. Based on these stories, we hypothesized that tissue adhesive material which has stability to the esophagus and controlled-releases TCA could be helpful to manage the disease. Here, we designed highly adhesive polyacrylamide hydrogel with controlled-releasing TCA and predicted that the local administration of the hydrogel could effectively prevent fibrosis in the esophagus.

Aims & Methods: The objective of this study is to examine the efficacy of the tissue adhesive polyacrylamide hydrogel incorporating TCA for preventing fibrosis in rats' esophagus.

Methods (1) Making the tissue adhesive polyacrylamide hydrogel : Solution of acrylamide, ammonium persulfate, tannic acid, TCA drug crystal, and N,N'-methylene bisacrylamide were mixed with tetramethylethylenediamine to synthesize the hydrogel. The hydrogel was characterized by FT-IR, scanning electron microscope, and tensile test. (2) Controlled-release of TCA from the hydrogel : The hydrogel was placed in 2 mL of PBS containing collagenase D. The release test was carried out at 37°C and the PBS was exchanged at different time points. The amount of TCA in the supernatant was determined by High Performance Liquid Chromatography. (3) In vivo stability test in rats' esophagus : 647 ovalbumin solution was added while making the hydrogel for this stability study. 200 µL of PTA hydrogel was applied to the rats' esophagus. After that, rats were restricted water and food intake. 24 hours later, rats were euthanized and extracted esophagus was observed by fluorescent imaging. (4) In vivo rat esophageal fibrosis model : Rats were performed a median laparotomy and 1 cm segment of the distal esophagus was exposed. The isolated segment was distended by administering 0.1 mL of 30% NaOH for 90 secs. The rats were euthanized in three weeks and the histology of the esophagus was evaluated by Masson's trichrome staining.

Results: 1. Making the tissue adhesive polyacrylamide hydrogel : The hydrogel was obtained in 30 minutes and characterizations showed its high adhesiveness.

2. Controlled-release of TCA from the hydrogel : The amount of released TA increased gradually over time. $85.3 \pm 3.4\%$ of TCA in the PTA hydrogel was released in 24 h and 100% of TCA was released in 48h.

3. In vivo stability test in rat's esophagus : 24 hours after the PTA hydrogel administration, the fluorescent imaging showed that the hydrogel remained in the rat's esophagus.

4. In vivo rat esophageal fibrosis model : In histological analysis, Masson's trichrome staining positive area/whole area (Fibrosis area rate) with the hydrogel group was significantly smaller than that with the disease group ($9.04 \pm 0.62\%$ vs $18.91 \pm 1.82\%$, $p = 0.004$).

Conclusion: We developed tissue adhesive hydrogel incorporating TCA. It had stability in the rats' esophagus and its efficacy in preventing fibrosis was observed. This study implicates the potential of the hydrogel as a topical TCA treatment for the stricture formation after the ESD.

FUNCTIONAL DYSPEPSIA DUODEUM MUCOSAL ASSOCIATED MICROBIOTA: COMPARISON BETWEEN FRESH BIOPSY AND HISTORICAL FORMALIN-FIXED PARAFFIN-EMBEDDED BIOPSIES IS VIABLE

Introduction: Emerging evidence suggests there is a specific duodenal mucosal associated microbiota (MAM) signature for functional dyspepsia (FD), although study numbers are low and consensus on biomarkers have not been reached. Additionally, we now know that FD is associated with high duodenal eosinophil counts and this site-specific immune response is likely interacting or responding to the MAM.

Aims & Methods: As duodenal biopsies for research can be difficult to obtain, we aimed to investigate formalin-fixed paraffin-embedded (FFPE) biopsies, routinely collected for pathology, sequence the MAM and compare them to the MAM profiles of matched RNAlater preserved biopsies. Duodenal biopsies (n=4) stored in RNAlater were homogenized for 3 mins at 5,000 rpm using the Precellys 24 homogenizer after removal from RNAlater solution. The total DNA was then extracted and purified with the Promega Maxwell automated DNA recovery system following manufacturer's instructions. DNA from matched FFPE sections (40 µm) were extracted with Qiagen deparaffinization solution and FFPE DNA extraction kit following manufacturer's instructions. 16S amplicon sequencing was completed targeting the V6-V8 region. Reads were processed with QIIME2/DADA2 and referenced against the SILVA SSU r138 database. Analysis of microbiota diversity was performed in R packages and Calypso. Data was transformed using Cumulative Sum Scaling + log2.

Results: The mean sequencing depth of RNAlater biopsies was 4115 and FFPE was 20170. The alpha diversity was significantly greater for FFPE sequenced samples when compared to whole biopsies (Chao1 P=0.029). Additionally, RDA multivariate analysis demonstrated significant clustering (P=0.024) of FFPE communities compared to the patient matched whole biopsy extracts. Permutational multivariate analysis of variance (adonis function) and ANOSIM Bray-Curtis were also both significant when comparing the MAM of each extraction type (P=0.0297 and 0.023 (R =1), respectively). There were also fewer "unknown" taxonomic assignments for FFPE samples compared to the matched biopsies.

Conclusion: Here we have shown that MAM 16S sequencing from FFPE tissue sections (tested 2-4yrs old) is a viable option and means that single biopsies can be multi-functional (histopathology and viable DNA recovery). The viability of MAM sequence amplification from FFPE provides a tantalising opportunity as the historical catalogue of samples where there were previously no specific biopsies collected for microbial analysis is extensive and would substantially contribute to the integration of FD associated MAM profiles.

Introduction: Previous studies have shown that microbiome plays an important role in maintaining a healthy state, and their imbalance is associated with various diseases. Recently microbial DNA was detected in the circulated blood. It has been shown that bacterial DNA corresponds to various states of human health as well.

Aims & Methods: The aim of the current study was to perform a microbiome analysis and identify possible circulating biomarkers for GC. Plasma DNA samples from 35 GC patients and 43 controls were used. V1-V2 region of bacterial 16S rRNA gene was sequenced on an Illumina MiSeq platform. To construct sample-similarity matrices abundances of taxonomic ranks in each sample type were used by applying Bray-Curtis algorithm. For significant differences between the groups, PERMANOVA and Mann-Whitney test followed by false-discovery rate test were used. ROC curve analysis was performed to predicting outcome of study disease status.

Results: Analysis revealed Actinobacteriota, Proteobacteria, Firmicutes, Bacteroidota, and Patescibacteria as most abundant bacterial at phylum level in GC and control group. The depth of GC samples reads was statistically lower than control group samples. Analysis of alpha-diversity revealed differences by Simpson's diversity and Pielou evenness indices, GC group was statistically less diverse than control group. Abundance of *Escherichia-Shigella* at 4 taxonomic levels (order, family, genus, ASV) was increased and abundance of *Collinsella aerofaciens* decreased in GC patients' blood plasma.

The combination of *Escherichia-Shigella* and *C. aerofaciens* yielded AUC 0.833, while using these bacteria separately AUC was 0.803 and 0.633, respectively. No significant differences were identified between blood plasma microbiome and gastric cancer clinical data.

Conclusion: The global circulating microbiome profile of GC patients differs from that of the control group. GC patients' blood microbiome are less diverse than controls. *Escherichia-Shigella* and *Collinsella aerofaciens* could presumably be used as clinical biomarkers of GC.

Disclosure: Nothing to disclose.

Introduction: Functional gastrointestinal disorders such as functional dyspepsia (FD) are disorders of gut-brain interactions, characterized by unexplained, chronic and relapsing gastrointestinal symptoms. Low grade mucosal inflammation, altered gut motility and sensory function, and the microbiota of the proximal small intestine may be important to the onset and recurrence of these conditions.

While diet and herbal medicines have been shown to positively affect FD symptoms, the impact of these treatments on the duodenal microbiota is largely unknown.

Aims & Methods: Here, we have assessed how two formulations of herbal extracts (STW5 and STW5-II) affect the growth and inflammatory tenor of the secretomes produced by mixed cultures and individual isolates of duodenal bacteria. The microbial communities resident on duodenal biopsy tissue from 6 FD and 6 non-FD (healthy control) subjects were cultured using a habitat-simulating medium with no additions or supplemented with 2, 4, or 8 µL/mL of either STW5 or STW5-II for 24 hours.

Cell biomass from these microbial communities was harvested and characterized by 16S rRNA gene amplicon sequencing. The secretomes produced by these mixed cultures were also recovered by harvesting the spent culture fluids via centrifugation, followed by their filter-sterilization and storage at -80°C. The immunomodulatory potential of these secretomes was evaluated *in vitro*, by challenging a human monocyte-derived NF-κB reporter cell line (THP1-luciferase).

Here, the secretomes (or uninoculated bacterial medium as a control) were diluted 1:4 with cell culture medium and 0.1 vol added to the THP1-luciferase cultures. In parallel, heat-killed *Listeria monocytogenes*, or lipopolysaccharide as stimulators of a TLR2 or TLR4 response, respectively, were used alone or in combination with the secretomes. The magnitude of NF-κB signalling was measured via luciferase output using standard methods.

Separately, axenic isolates of duodenal bacteria affiliated with *Escherichia*, *Streptococcus*, and *Veillonella* were also cultured using brain heart infusion broth supplemented with hemin and vitamin K, with no additions or supplemented with STW5 or STW5-II, as described above. The growth of these axenic cultures was monitored by measurement of optical density at 600nm.

Results: The profiles of bacterial communities recovered from duodenal tissue were separable according to subject phenotype (i.e., FD and non-FD). In general terms, the within sample (alpha) diversity was greater for the FD group. However, neither STW5 nor STW5-II at concentrations tested appear to exert gross, condition-specific alterations to these microbial communities. Similarly, immunomodulatory effects of the secretomes prepared from these cultures as tested on the THP1-luciferase cultures were not significantly different from control mixed cultures (i.e., no ad-

dition of STW5 or STW5-II). Interestingly, the growth rates of some of the axenic isolates were affected by either or both formulations and effects varied both within and between genera.

Conclusion: Both STW5 and STW5-II can affect the growth of select duodenal bacteria. However, at the concentrations tested these effects were not readily observed in more complex communities of duodenal bacteria from either FD or non-FD subjects. The inflammatory tenor of the secretomes from these consortia also appear to be unaffected. As such, neither STW5 or STW5-II resulted in dramatic shifts in the microbial communities suggesting – when compared to numerous other medications – both are tolerated by the duodenal microbiota.

Introduction: The number of patients treated with direct oral anticoagulants (DOACs) has rapidly elevated in the last decade. Compared to Vitamin-K antagonists (VKA), DOACs were reported to have a better safety profile, except for gastrointestinal bleeding (GIB). After successfully managing GIB, a decision of therapy reintroduction has to be made carefully, although data addressing this topic is lacking.

Aims & Methods: We aim to determine the safety and efficacy of DOACs resumption after a GIB event.

Our protocol was registered in advance in PROSPERO (CRD42021284314). We performed our study according to the Cochrane Handbook's recommendations for Systematic Reviews of Interventions. Studies that reported rebleeding, thromboembolic events, and mortality after restarting DOACs or withholding therapy were selected as eligible articles.

The systematic research was conducted in five databases (MEDLINE, EMBASE, CENTRAL, Web of Science, and Scopus) without any restriction. Random effect model was implemented to calculate pooled odds ratio (OR) with 95% confidence interval (CI). ROBINS-I tool was used for risk of bias assessment, certainty of the evidence was evaluated with the GRADE approach.

Results: From 8577 articles, 3 retrospective cohort studies were included in the meta-analysis. We did not find a significant increase in the risk of rebleeding in patients restarting DOACs after index GIB (OR=1.09; CI: 0.72–1.64). The outcomes of thromboembolic events and mortality data were not suitable for meta-analytic calculations. Single studies comparing DOAC resumption and withdrawal did not show statistically significant

differences in these outcomes (OR=1.21, CI: 0.61–2.42; OR=2.36, CI: 0.52–10.78 respectively). Data quality assessment showed a serious overall risk of bias and very low quality of evidence (GRADE D).

Conclusion: Based on our results, DOAC resumption after a GIB episode may not elevate the risk of rebleeding. However, the need for high-quality randomized clinical trials focusing on this clinically relevant question is crucial.

References:

Based on our results, DOAC resumption after a GIB episode may not elevate the risk of rebleeding. However, the need for high-quality randomized clinical trials focusing on this clinically relevant question is crucial.

PREDICTIVE ABILITY OF AVAILABLE SCORES IN MASSIVE UPPER GASTROINTESTINAL BLEEDING

R. Jiménez-Rosales¹, M. López-Vico¹, J.M. López-Tobaruela¹, E.J. Ortega-Suazo¹, J.G. Martínez-Cara¹, E. Redondo-Cerezo¹

¹Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain

Contact E-Mail Address: ritajimenezrosales@gmail.com

Introduction: Massive Gastrointestinal Bleeding (MGIB) refers to patients with severe bleeding who require emergency intervention in order to prevent mortality and limit morbidity(1).

Aims & Methods: The aim of our study was to describe patients with Upper MGIB (UMGIB) and to analyze the predictive ability of available scores in these patients.

Although no consensus definition exists, for the purpose of this study we have used D'Amore and Swaminathan (1) definition of MGIB (gastrointestinal bleeding that results in hemodynamic instability, signs of poor perfusion, transfusion of >2 packed red blood cells during the initial resuscitation or significant hematemesis/hematochezia) supported by that offered by Nagata et al. (2) (who accept two transfused units both during the initial resuscitation and during the hospital stay and/or shock).

Ours was a prospective study on consecutive and unselected patients admitted to the emergency room of Virgen de las Nieves University Hospital with upper gastrointestinal bleeding (2013-2020). We only considered for the analysis patients who fulfill UMGIB criteria as described in the previous definition. Information regarding clinical, biochemical data and procedures was collected. The discriminative ability of risk scores was evaluated by the AUROC curve. Comparison of the scores was performed by the deLong test.

Results: A total of 1179 patients were recruited, 92 (7.8%) presented UMGIB, with a median age of 62.17±13.55, 41.3% were female.

The most common causes of UMGIB were duodenal ulcers (26.1%), esophageal varices (18.5%) and gastric ulcer (17.4%).

Patients with UMGIB presented higher rates of endoscopic (76.1% vs. 42.6%; p=0.000), radiological (8.7% vs. 0.9%; p=0.000) and surgical (9.8% vs. 3.3%; p=0.006) intervention. Furthermore, they had higher rates of rebleeding (23.9% vs. 9.1%; p=0.000), in hospital deaths (21.3% vs. 9.4%; p=0.002) and delayed hemorrhagic events within the ensuing 6 months (23.7% vs.14.7%; p=0.047).

No differences were found in sex, comorbidity, NSAIDs, anticoagulants and antiaggregant previous use, underlying etiology and 6 month-delayed mortality.

Using the threshold for a low risk of adverse events previously defined for MAP(AHS) and Glasgow-Blatchford (GB), no patient presented UMGIB (0% vs. 100%; p=0.000 and p=0.043, respectively). For those low-risk patients identified through ABC score, 11 presented UMGIB (13.8% vs. 86.3%; p=0.000).

Scores' ability for UMGIB prediction is shown in Figure 1, with MAP(ASH) performing better than ABC (difference 0.247; 95% CI 0.196-0.298; p<0.001) and GB (difference 0.088; 95% CI 0.051-0.124; p<0.001).

	AUROC	95% CI
MAP(ASH) score	0.951	0.936 – 0.964
ABC score	0.704	0.674 – 0.733
GB score	0.864	0.840 – 0.885

Conclusion: Being UMGIB uncommon, it has gloomy outcomes in terms of need for intervention, rebleeding and in-hospital mortality. Hence, it is especially important to identify patients with a potential risk of developing this event in order to treat earlier.

Although none of the scores has been constructed or validated to predict this event, the MAP(ASH) score, a simple calculated pre-endoscopy risk score created from a Spanish cohort, performs accurately. Indeed, it performed better when predicting UMGIB than the other available scores.

Introduction: The main prognostic indices for the study of upper gastrointestinal bleeding (UGB) have hemoglobin value as a common variable. The Rockall pre-endoscopic score (PreRock) does not include hemoglobin (Hb). We hypothesized that a modification of this score to include hemoglobin levels might perform as well as other current scoring systems in predicting outcomes in UGB.

Aims & Methods: The objective of the study was to determine: 1:The PreRock score plus Hb value (Modified PreRockall score -PreRockMod) can predict the outcome of peptic ulcer bleeding (PUB) and 2:To compare PreRockMod score with 2 other validated scores for PUB: Glasgow-Blatchford score (GBS) and PreRock score.

Prospective unicenter study conducted for 5 years in a university tertiary care. Patients with PUB were defined by:

1. Presence of hematemesis, maelenas, hematochezia;
2. Confirmed by endoscopy<24 horas after the onset of bleeding.

The adverse outcomes considered were:

1. Rebleeding,
2. Red blood cell transfusión,
3. Endoscopic treatment,
4. Mortality, and;
5. Clinical intervention (transfusion, endoscopic treatment, embolization and/or surgery, rebleeding and death).

Area under the receiver operating characteristic (AUROC) curve and its IC95% were calculated for the PreRockMod score and compared for each

adverse outcome with the others scores (GBS and PreRockall). AUROCs were compared with the DeLong method using Stata 14.1 Software (Stata Corp.2015).

Results: A total of 230 patients were identified consecutively. The mean age was 63.8 years, standard deviation (SD±18.2), 152 (51%) were men. Mean hemoglobin was 9.5 g/dL (SD±2.4); 93 (40.4%) patients with gastric ulcer. Forrest classification was: Forrest I 51 (22.2%), Forrest IIa 59 (25.7%);Forrest IIb 30 (13%);Forrest IIc 36 (15.6%) and Forrest III 54 (23.5%) patients. Twenty-six (11.3%) patients rebleeding 7 (3%) died, 101 (43.9%) required transfusion, 140 (60.9%) received endoscopic treatment, 9 (3.9%) received arterial embolization.

When comparing ROC curves, we found no differences between the 3 scores for the outcomes considered. The only difference found is for the need for transfusion*. PreRockMod and GBS have similar AUROCs for transfusion requirement and more accurate than PreRock (Table 1. AUROC and IC95% for PreRockMod an Ris Scores).

SCORE	REBLEEDING	TRANSFUSION *	ENDOSCOPIC TREATMENT	MORTALITY	CLINICAL INTERVENTION
PreRockMod	0.73 (0.64-0.81)	0.90 (0.85-0.94)	0.72 (0.65-0.79)	0.85 (0.66-1.00)	0.73 (0.64-0.81)
PreRock	0.72 (0.64-0.81)	0.78 (0.72-0.84)	0.71 (0.64-0.78)	0.82 (0.66-0.99)	0.72 (0.64-0.81)
GBS	0.68 (0.58-0.79)	0.88 (0.83-0.92)	0.65 (0.58-0.72)	0.77 (0.61-0.93)	0.68 (0.58-0.79)

Table.

Conclusion: The PreRockMod score is better at predicting transfusion than PreRock score, and equivalent to GBS. They are similar for the rest of the outcomes.

AN AUDIT OF LOCAL MANAGEMENT OF UPPER GASTROINTESTINAL BLEEDS IN A UNITED KINGDOM DISTRICT GENERAL HOSPITAL

A. Patel¹, K. Simpson¹, N. Duffy¹, W.K. Tan^{1,2}, R. Kassam¹

¹North West Anglia NHS Foundation Trust, Department of Gastroenterology, Huntingdon, United Kingdom, ²University of Cambridge, Early Cancer Institute, Cambridge, United Kingdom

Contact E-Mail Address: aamie.patel1@nhs.net

Introduction: Acute upper gastrointestinal bleed (AUGIB) is associated with a 10% in-patient mortality and this outcome has not significantly improved over the past 50 years (1).

The UK's National Institute for Health and Care Excellence (NICE) has developed guidance for the management of patients presenting with AUGIB, which highlights several priorities that should be addressed such as:

- risk assessment using the Blatchford and Rockall scores,
- the optimal timing of endoscopy,
- management of non-variceal bleeds,
- management of variceal bleeds, and;
- guidance on controlling bleeding and preventing re-bleeding in patients on NSAIDs, aspirin or clopidogrel (1).

Aims & Methods: This study aimed to assess the compliance of AUGIB management in a district general hospital against the NICE quality standards. In the first cycle, we retrospectively reviewed case notes from 52 patients who presented with AUGIB and were admitted between September 1 and December 31, 2019. A re-audit was performed between December 1, 2020 to March 31, 2021 where we reviewed the case notes of 22 patients. We allowed for a 1-year interval between the first and second cycle where we educated doctors about the NICE quality standards of AUGIB management. The primary outcome of the study was the compliance of local management of AUGIB in a district hospital compared to NICE quality standards.

Results: The indications for intervention in the first cycle of patients were haematemesis in 26.9% (14/52), melaena in 50% (26/52), and both haematemesis and melaena in 23.1% (12/52); indications for the second cycle were haematemesis in 64% (14/22), melaena in 18% (4/22), and both haematemesis and melaena in 8% (4/22). The compliance for the discontinuation of aspirin during an AUGIB was 60% (3/5) in the first cycle, increasing to 80% (4/5) in the second cycle. When we assessed the use of risk score in the risk stratification of AUGIB, Blatchford score was calculated in 12.5% (5/40) in the first cycle, increasing to 50% (11/22) in the second cycle. When we assessed the time to endoscopy among patients with haemodynamic instability at presentation, endoscopy was performed immediately after resuscitation in 100% of patients in both the first (4/4) and second (3/3) cycle. Among haemodynamically stable patients, 91.4% (32/35) had endoscopy within 24 hours in the first cycle, but only 53% (10/19) in the second cycle.

Parameter	Audit (Sept 1, 2019 - Dec 31, 2019)	Re-audit (Dec 1, 2020 - Mar 31, 2021)
Number of patients	52	22
Use of non-steroidal anti-inflammatory drugs (NSAIDs), aspirin, clopidogrel		
- Continue low dose aspirin once haemostasis achieved	60% (3/5)	80% (4/5)
- Stop NSAIDs/COX2 inhibitor during acute phase	100% (4/4)	100% (3/3)
- Specialist advice regarding clopidogrel	100% (1/1)	100% (2/2)
Resuscitation and initial management		
- Platelet transfusion if platelet count <50 x 10 ⁹ /L	N/A	100% (2/2)
- Fresh frozen plasma transfusion if prothrombin time/international normalized ratio/activated partial thromboplastin time >1.5 times normal	N/A	N/A
- Cryoprecipitate use	N/A	N/A
- Prothrombin complex use	100% (1/1)	100% (2/2)
Risk assessment		
- Blatchford score at first assessment	12.5% (5/40)	50% (11/22)
- Full Rockall score post-endoscopy	0% (0/40)	14% (3/22)
Timing of endoscopy		
- Post-resuscitation	100% (4/4)	100% (3/3)
- Within 24 hours	91.4% (32/35)	53% (10/19)
Management of non-variceal bleed		
- PPI use before endoscopy	74/4% (29/39)	77% (17/22)
- Endoscopic management: clips with or without adrenaline	100% (2/2)	100% (2/2)
- Endoscopic management: thermal coagulation with adrenaline	100% (1/1)	0% (0)
- Endoscopic management: fibrin or thrombin with adrenaline	N/A	0% (0)
- Treatment after first or failed endoscopy: endoscopy for re-bleed	N/A	100% (2/2)
- Treatment after first or failed endoscopy: endoscopy for re-bleed	100% (1/1)	100% (1/1)
Varices management		
- Terlipressin	100% (4/4)	100% (5/5)
- Antibiotics	100% (4/4)	100% (5/5)
- Band ligation	100% (4/4)	100% (5/5)
- Referral for transjugular intrahepatic portosystemic shunts (TIPS)	N/A	N/A

Table.

Among patients with non-variceal bleed, proton pump inhibitors (PPI) were used in 74.4% (29/39) in the first cycle and 77% (17/22) in the second cycle. Regarding endoscopic management for non-variceal bleed, we achieved 100% compliance for the use of clips with or without adrenaline in both the first and second cycles. Dual therapy of thermal coagulation with adrenaline was performed in 100% (1/1) of patients in the first cycle, and none in the second cycle. For variceal bleeds, 100% of patients in the first (4/4) and second (5/5) cycle were given terlipressin antibiotics, with band ligation.

Conclusion: In our district hospital, pre-endoscopic management of AUGIB such as PPI use, and time to endoscopy were adequate, but did not fully meet the quality standards stipulated by NICE. Endoscopic management for AUGIB, however, was fully compliant with NICE standards.

Introduction: Acute Upper gastrointestinal bleeding (UGIB) remains a common medical emergency in gastroenterology with significant mortality. The early use of risk stratification scores is recommended for follow up and treatment selection in patients with UGIB. The most widely used risk scoring systems are the Glasgow–Blatchford (GBS), the Rockall score (RS) and AIMS65.

Aims & Methods: We aimed to compare the performance of the Scoring Systems in predicting the need for blood transfusion, short-term mortality, and re-bleeding among Moroccan population with UGIB. This was a retrospective study conducted at university hospital between January 2020 and December 2021 including all patients hospitalized for acute UGIB. The diagnosis was based on patient presentations, including hematemesis, melena or both. Variables including demographic information, physical examination, laboratory values, medical treatment and endoscopic findings were recorded. GBS, RS and AIMS65 were calculated for all patients. The area under the receiver operating characteristic (AUROC) curve was determined to compare the predictive power of each scoring system.

Results: A total of 410 patients were included. The mean age was 55,6 years and 63,8% were males. Major comorbidities, including liver, heart and renal diseases and diabetes mellitus were present in 49,9% of patients. Blood transfusion was indicated in 40,6% of patients with a median transfusion requirement of 2 units.

The endoscopic findings included peptic ulcer in 33,5%, esophageal varices in 37,9%, gastric varices in 8,31% and upper gastrointestinal tumors in 5,6%. In 11 patients no evident cause of UGIB was identified. Endoscopic therapy was required in 36,7% in order to achieve haemostasis and 3,9% proceeded to surgery.

Short-term mortality occurred in 3,42% of the patients, and rebleeding was noted in 3.7% of the patients. The median risk scores were as follows: GBS: 11.4 (range 2–19); RS: 3,64 (range 1–11) and AIMS65: 1.08 (range 0–4). The scoring systems showed comparable results in predicting blood transfusion (GBS: AUC = 0.55, RS: AUC = 0.52, AIMS65: AUC = 0.51, p=0.05)

The RS (AUC = 0.67) was superior to GBS and AIMS65 for predicting endoscopic treatment (p = 0.016, p = 0.023; respectively) and the need of surgery (AUC = 0.60, p = 0.02, p = 0.013). RS was also significantly better in predicting rebleeding (AUC = 0.63) comparing with GBS (p < 0.001) and AIMS65 (p < 0.001).

The GBS (AUC=0.49), RS (AUC=0.50) and AIMS65 (AUC=0.58) were predictors of in-hospital mortality. No significant differences were noted (p=0,24) between the three scores in this outcome.

Conclusion: Finding from this study suggested that these three scoring systems might be acceptable to predict outcomes of patient with UGIB. However, The RS was superior to the GBS and AIMS65 for predicting endoscopic therapy, surgery and rebleeding while the three scoring system showed comparable results in predicting blood transfusion and in hospital mortality.

HEDONIC AND SOMATIC RESPONSES TO MEAL INGESTION IN FUNCTIONAL DYSPEPSIA

D.M. Livovsky^{1,2}, C. Barber Caselles², F. Azpiroz²

¹Shaare Zedek Medical Center, Digestive Diseases Institute, Jerusalem, Israel, ²University Hospital Vall d'Hebron, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (Ciberehd), Universitat Autònoma de Barcelona, Digestive System Research Unit, Bellaterra (Cerdanyola del Vallès), Spain

Contact E-Mail Address: danlivo@yahoo.com

Introduction: Introduction. In healthy subjects, ingestion of a comfort meal induces homeostatic sensations (satiety, fullness) and satisfaction (sensation of digestive well-being). Patients with functional dyspepsia and postprandial distress syndrome complain of early satiety and excessive fullness in response to meal ingestion, but their hedonic experience (whether and to what extent they enjoy the meal and experience satisfaction) has not been characterized.

Aims & Methods: Aim. To determine whether the hedonic response to meal ingestion is affected in patients with postprandial dyspepsia.

Methods. Randomized parallel trial in patients fulfilling Rome IV criteria of postprandial distress syndrome (n = 24) and age-and-gender-matched healthy controls (n = 18) comparing the responses to stepwise ingestion of a comfort meal up to full satiation. Homeostatic and hedonic sensations were measured (by 10-score scales) before, during and after meal ingestion; changes in girth (using adaptable belts) and diaphragmatic position (position of the hepatic border by ultrasonography) from pre- to post-ingestion were also measured.

Results: Results. Healthy subjects enjoyed the comfort meal and experienced sensation of digestive well-being (peak of 3.6± 0.2 score) up to a meal load of 856± 90 Kcal; well-being decreased at full satiation (0.2± 0.7 score with 1287± 54 Kcal), without abdominal discomfort (0.4± 0.2 score). As compared to healthy subjects, patients tolerated smaller meal loads and experienced early satiety (full satiation at 666± 57Kcal; p < 0.001), postprandial bloating (6.5± 0.4 score; p=0.052) and discomfort (5.9± 0.5 score; p<0.001).

Based on their hedonic response, two distinct categories of dyspepsia were recognized: a subpopulation of dyspeptic patients (n = 9) enjoyed the meal and experienced satisfaction during eating (3.0± 0.3 maximal well-being score at 450 ± 79 Kcal; p < 0.001), while the other subgroup (n

= 15) did not and experienced an aversive sensation (-0.6 ± 0.3 maximal well-being score at 187 ± 30 Kcal); to note, both subgroups exhibited similar levels of meal tolerance and postprandial discomfort. Interestingly, the group that enjoyed the meal (enjoyers) developed an abnormal somatic response (abdominophrenic dyssynergia with increase in girth by 3.9 ± 0.5 cm and diaphragmatic descent by 1.1 ± 0.3 cm; $p < 0.05$ vs. healthy subjects for both), but the others (non-enjoyers) did not (no significant differences vs. healthy subjects).

Conclusion: Conclusions. Differences in hedonic and somatic responses to meal ingestion in subgroups of functional dyspepsia indicate that their pathophysiology is heterogeneous. Postprandial bloating in some patients may be related to a somatic, rather than visceral dysfunction, without impairment of their capability to enjoy the meal.

PRECISION MEDICINE IN DYSPEPSIA. DEVELOPMENT AND INTERNAL VALIDATION OF A PREDICTIVE PROGNOSIS MODEL OF RESPONSE TO PROTON-PUMP INHIBITOR IN ADULT PATIENTS WITH FUNCTIONAL DYSPEPSIA

L. Osorio¹, S.F. Niño Ramirez², M. Santisteban¹, L.F. Roldan^{3,2}, A.L. Leon⁴, L.G. Guevara¹

²Gastroclinic Institute, Gastroenterology, Medellín, Colombia,

³Gastroclinic Institute, Medellín, Colombia, ⁴Hector Abad Gómez National Faculty of Public Health, Universidad de Antioquia, Medellín, Colombia

Contact E-Mail Address: sfnesp@gmail.com

Introduction: The expected prognosis, to the first-line management of functional dyspepsia can personalize the need for interventions and establish individualized management in the context of precision medicine (1,2).

Aims & Methods: Development and internal validation of a multivariable prognostic predictive model to establish the probability of symptomatic response to proton pump inhibitor (PPI) management in adult patients with functional dyspepsia.

A cross-sectional study was carried out in adults with functional dyspepsia consulting a gastroenterology center in Medellín, Colombia, between August 2021 and March 2022. Adults with functional dyspepsia according to ROME IV criteria (3) were included; biliary, pancreatic neoplastic disease, peptic ulcer or pregnancy were excluded.

A pilot study was conducted to identify the variables most related to treatment response: nausea, bloating, anxiety (defined as excessive worry) or depression symptoms (defined as permanent sad mood), fibromyalgia (according to criteria of the American College of Rheumatology), age, sex, sleep disorder (4).

The 6 variables with the highest association were selected to be evaluated in the model, the outcome was defined as complete resolution of dyspeptic symptoms after 8 weeks treatment with esomeprazole, partial resolution or no resolution of symptoms was defined as poor response. Sample size was established according to Freeman's formula (5), random missing values <5% were resolved with multiple imputation.

A multivariable logistic regression model was developed using the best subset for the number and selection of variables, internal validation was performed by splitting the sample, 70% for development and 30% for validation. Variables with a value of $p < 0.1$ in the bivariate analysis were included to be tested in the model.

The final model was transformed into a scoring rule. The scores assigned to each variable were obtained by dividing each regression coefficient by

half the smaller coefficient and rounding to the nearest integer (6). Predictive ability was evaluated with AUC (area under the curve) and Hosmer lemeshow statistic.

Results: 192 patients were included (134 development, 58 validation), the best subset method identified 4 variables, as the best performing variables in terms of Akaike information criteria. The logistic model demonstrated adequate calibration and discrimination with AUC of 0.89 and a Hosmer-Lemshow chi-square test result with $p=1$. The final scoring system assigned a score to each variable; for anxiety 3 points, fibromyalgia 2 points, depression 1, female sex subtracted 1 point. The sum of scores lower than 4 points was related to favorable response to PPI with a sensitivity of 96,5%, confidence interval (CI) 88,1% to 100%, specificity of 56,6%, CI 37,2% to 76%, positive predictive value of 68,2%, CI 52,8% to 83,7%, and negative predictive value of 94,4%, CI 81% to 100%.

Variable	Coefficient*	P-value	Score**
Intercept	3.13	0.000	
Sex	1.05	0.124	-1
Anxiety	-3.56	0.001	3
Fibromyalgia	-2.65	0.000	2
Depression	-1.40	0.01	1

*Logistic regression coefficient. **Scores <4 are selected with favorable response to PPI.

Table 1. Logistic model of the score in the validation sample.

Conclusion: This model represents an easy-to-use and novel tool which allows early identification of patients with better therapeutic response to first-line management of functional dyspepsia.

Introduction: Migraine headaches are associated with functional dyspepsia (FD) according to Rome IV criteria in the general population (prevalence of 43.6% vs. 20.0% in controls, OR 3.1 [95% CI = 2.2-4.3], $p < 0.005$) (1).

Indeed, common pathophysiological mechanisms have been reported in both disorders, especially alterations of the gut-brain axis (2).

Furthermore, patients with uninvestigated dyspepsia referred for an upper gastrointestinal endoscopy frequently have migraine headaches (3).

Aims & Methods: Our aim was therefore to assess the impact of the overlap with migraine in patients with FD. Consecutive patients with investigated dyspepsia were assessed with self-administered questionnaires. FD, its subtypes postprandial distress syndrome (PDS) and epigastric pain syndrome (EPS), and irritable bowel syndrome (IBS) were diagnosed according to Rome IV criteria.

Self-reported migraine was assessed by questioning patients for migraine headaches. Patients were also asked if they had fibromyalgia. Quality of life (QoL) was assessed by the *Gastrointestinal Quality of Life Index* (GIQLI).

Anxiety and depression levels were evaluated using the *Hospital Anxiety and Depression* (HAD) scale. Sleep was assessed using both the *Pittsburgh Sleep Quality Index* (PSQI) and the *Insomnia Severity Index* (ISI). Gastric half-emptying time was assessed using octanoic acid breath testing.

Results: 355 patients with Rome IV-based FD were identified. Overlap with migraine was present in 134 of the patients (37.7%). In univariate analysis, this comorbidity was associated with better QoL (GIQLI: 74.1 ± 18.6 vs. 80.9 ± 18.9 points, $p = 0.0011$), increased overlaps with IBS (52.2% vs. 40.3%, $p = 0.036$), fibromyalgia (12.7% vs. 5.9%, $p = 0.031$) and insomnia (70.9% vs. 54.3%, $p = 0.0024$), and a longer duration of FD (98.0 ± 109.8 vs. 62.9 ± 90.9 months, $p = 0.0011$).

On the contrary, age, body mass index, sex distribution, gastric half-emptying time, HADS score, FD subtypes distribution, and sleep quality ($p > 0.05$ for all). In multivariate analysis, independent predictors of the overlap with migraine in FD patients were FD duration (OR 1.003 [95% CI = 1.001-1.006]; $p = 0.0044$) and the presence of insomnia (OR 1.66 [95% CI = 1.01-2.76]; $p = 0.047$).

Conclusion: Migraine headaches affect more than one third of patients suffering from functional dyspepsia. Overlap with migraine is independently associated with a longer duration of the disorder and with the presence of insomnia.

INTRAVENOUS FERRIC CARBOXYMALTOSIDE TREATMENT IS SAFE, EFFECTIVE, AND LONG-LASTING IN PATIENTS WITH CORPUS ATROPHIC GASTRITIS

L. Dottori¹, D. Corleone Tsar'kov¹, E. Dilaghi¹, G. Pivetta¹, G. Esposito¹, B. Annibale¹, E. Lahner¹

¹Sapienza University of Rome, Department of Medical-Surgical Sciences and Translational Medicine, Sant'Andrea Hospital, Rome, Italy

Contact E-Mail Address: ludovica.dottori@uniroma1.it

Introduction: Corpus Atrophic Gastritis (CAG) is characterized by chronic inflammation of gastric mucosa leading to destruction of typical gastric glands which are replaced by intestinal metaplasia, pseudo-pyloric metaplasia or fibrosis. Oxyntic mucosa involvement leads to impairment of hydrochloric acid and intrinsic factor secretion, resulting in iron and cobalamin deficiency. Iron deficiency anemia (IDA) is one of the most common manifestations of CAG and, with iron deficiency (ID), affects more than 50% of the CAG patients (1).

Oral iron therapy is poorly effective and poorly tolerated. Ferric carboxymaltose (FCM) is an intravenous (iv) preparation shown to be safe and effective in many GI diseases, but its efficacy in CAG patients has not been investigated so far.

Aims & Methods: The aim of this study is to assess the safety and efficacy of iv FCM in treating IDA in patients with CAG.

CAG patients with IDA, irrespective of concomitant cobalamin deficiency, were included. Other not-CAG-related causes of IDA were accurately excluded. Since availability of FCM in our centre (March 2015) until July 2021, 100 patients were treated, 31 patients with incomplete follow-up were excluded. Three patients who interrupted FCM infusion due to mild side effects not requiring further treatment, were excluded too. The remaining 66 patients (77.7% females; mean age 58.6 ± 2.2 years) were included and evaluated for clinical characteristics, anemia and iron status, previous oral iron therapy, FCM dosage, timing of FCM therapy, efficacy at 4 and 12 weeks for ID and IDA, timing for required FCM retreatment.

Paired sample t-tests were used to compare Hb and ferritin at baseline (T0), 4 weeks (T4) and 12 weeks (T12). IDA was defined as Hb < 13 g/dl for men and Hb < 12 g/dl for women associated with ferritin < 45 ng/dl. Moderate and severe anemia were defined as Hb 8-10 g/dl and Hb < 8 g/dl, respectively. ID was defined as ferritin < 45 ng/dl in presence of normal Hb values. Cobalamin deficiency was defined as serum levels < 220 pg/ml.

Results: At T0, mean Hb was 10.7 ± 0.3 g/dl, 36.4% had moderate and 6% severe anemia. Mean time from CAG diagnosis to FCM treatment was 20 ± 3.5 months, with 59% of patients receiving FCM within 9 months from diagnosis. FCM dosage was 1000 mg in 58.2%, 700 mg in 18.2% and 500 mg in 23.6% of patients, based on Hb levels. Two patients reported mild side effects not requiring FCM interruption. At 4 and 12 weeks, 68% and 77.5% of patients, respectively, recovered from IDA; T4 Hb significantly increased compared to T0 (12.6 ± 0.2 g/dl vs 10.7 ± 0.3 g/dl; $p < 0.0001$). At T12 a further

increase of mean Hb was observed (13.1 ± 0.2 g/dl vs 12.6 ± 0.2 g/dl; $p < 0.05$). At T4, ferritin levels significantly increased with respect to T0, but significantly decreased at T12.

After a mean time of 23.7 ± 2.9 months, 56% of patients were retreated with iv FCM: in 4.5% IDA relapsed due to new causes unrelated to CAG, in the remaining ones IDA was due to CAG only. At multivariate analysis, female gender (OR, 95%CI: 6.2, 1.2–32.1) and mild-moderate atrophy (OR, 95%CI: 4.3, 1.2–15.3) were associated with IDA relapse, while other factors (age, NSAIDs, baseline severe anemia, cobalamin supplementation) had no role.

Conclusion: Iv FCM is effective and safe in CAG patients, recovering IDA in nearly 80% of cases at 12 months after treatment. Two years after FCM treatment about half of patients remained non-anemic, while IDA relapsed more frequently in females and in those with mild-moderate atrophy. These data show that FCM treatment in CAG patients should be considered as first line treatment to recover from IDA promptly and safely.

MECHANISMS OF ACTION OF AN HERBAL MULTI-COMPONENT PREPARATION IN FUNCTIONAL DYSPEPSIA: EFFECTS ON GASTRIC MOTILITY

M.-R. Piqué-Borràs¹, J. Röhl¹, M. Jaklin¹, A. Ammendola¹, G. Künstle¹

¹Weleda AG, Arlesheim, Switzerland

Contact E-Mail Address: mpiqueborras@weleda.ch

Introduction: Functional dyspepsia (FD) is amongst the most common functional gastrointestinal disorders. FD is mostly characterized by an impaired gastric accommodation and upper gastrointestinal symptoms such as epigastric pain, heartburn, bloating and vomiting.

However, the origin of these symptoms remains poorly understood and effective treatment options are limited. Therapeutic efficacy studies of phytotherapeutic combinations of herbal extracts such as STW-5 (Iberogast®) have demonstrated to improve dyspeptic symptoms in FD patients.

In this study, we investigated another herbal multi-component preparation (MCP): Weleda Amara oral drops (Amara-Tropfen). MCP is traditionally used to treat disturbances of gastrointestinal motility and contains nine bitter hydroethanolic herbal extracts (*Artemisia abstinthium*, *Centaurium erythraea*, *Cichorium intybus*, *Gentiana lutea*, *Juniperus communis*, *Millefolium herba*, *Peucedanum ostruthium*, *Salvia officinalis* and *Taraxacum*).

Aims & Methods: Our studies aimed to investigate the mode of action of MCP on gastric motility *ex vivo* / *in vitro*. The MCP dry extract was prepared from the commercial medicinal product Weleda Amara oral drops. Muscle strips from guinea-pig gastric fundus, corpus and antrum were set up in organ baths in circular orientation. Upon stabilization of the baseline tone, the muscle strips were exposed to ethanol-free MCP in a concentration-dependent manner ($3.5 - 1,000 \mu\text{g/mL}$).

Each concentration was applied for a minimum of 20 minutes or until plateau of response was reached. To understand the underlying mechanism of the effects of MCP on the muscle strips, we studied different G-protein-

coupled receptors (GPCRs) known to play a central role in the pathogenesis of gastrointestinal disorders: muscarinic M₃ receptor, serotonin 5-HT₄ receptor, opioid δ and opioid μ receptors. MCP was studied *in vitro* for binding affinities to muscarinic M₃ receptor and for agonist and antagonist activity on serotonin 5-HT₄, opioid δ and μ receptors. All assays were performed in CHO-K1 cell line.

Results: Addition of ethanol-free MCP caused relaxation of guinea-pig fundus circular muscle strips which was found to be significantly different compared to the vehicle group at the highest concentration tested ($850 \mu\text{g/mL}$). MCP also caused concentration-dependent relaxation of corpus and antrum circular muscle strips. This relaxation effect was significantly different compared to the vehicle group at concentrations ranging from 450 to 1,000 $\mu\text{g/mL}$ and 650 to 1,000 $\mu\text{g/mL}$, respectively.

To understand the relaxation mechanism, we investigated MCP activity on muscarinic M₃, opioid δ and μ and serotonin 5-HT₄ receptors. MCP inhibited the binding of 3H-4-DAMP to muscarinic M₃ receptors (IC₅₀: 380 $\mu\text{g/mL}$). In addition, MCP potentially inhibited the activity of opioid δ and μ receptors, shown by inhibition of intracellular cAMP release (IC₅₀: 304 & 256 $\mu\text{g/mL}$, respectively). However, MCP did not affect serotonin 5-HT₄ receptor activity.

Conclusion: This data demonstrates that the multi-component hydroethanolic extract MCP alters gastric motility by relaxing the three different parts of the stomach, most likely by inhibiting three motility-related receptors: muscarinic M₃ receptor, opioid δ and opioid μ receptors.

These findings suggest that MCP / Weleda Amara oral drops could be an efficient treatment for FD patients suffering from motility disorders with impaired gastric accommodation. However, additional studies are required to further characterize potential therapeutic advantages of Weleda Amara oral drops herbal preparations.

Disclosure: All authors are employees of Weleda AG.

Contact E-Mail Address: thomas.fairlie@uqconnect.edu.au

Introduction: Functional gastrointestinal disorders (FGIDs) are defined as distinct combinations of chronic or recurrent gastrointestinal symptoms, with no obvious structural or biochemical abnormalities offering explanation^{1,2}. While attributed to altered gastrointestinal motility, abnormal visceral sensory function, epithelial barrier disturbances, mucosal immune activation or alterations of gastrointestinal microbiota function, there is increasingly the notion of altered brain-gut-interactions in these patients². It has been suggested that overlap of FGIDs such as functional dyspepsia and irritable bowel syndrome (occurring simultaneously in a given subject) is linked to increased symptom burden, impaired quality of life, and increased healthcare utilisation^{3,4}.

Aims & Methods: We conducted a systematic review and meta-analysis to explore the prevalence of an overlap of FGIDs, the relationship with symptom severity, impaired quality of life and psychological comorbidities. MEDLINE(PubMed) and Embase electronic databases were searched until

Feb 2022 for studies reporting prevalence of overlapping FGIDs. Pooled prevalence (PP) reported as a proportion, pooled standardised mean difference (SMD), Odds Ratio (OR) and 95% confidence intervals (CI) of FGID overlapping patients and singular FGID patients were calculated, utilising a random effects model.

Results: 32 studies reporting 124,776 adult subjects and 47,160 patients with FGID diagnosis (PP: 0.3779, 95%CI:0.3753 – 0.3807) were identified. An increased number of females (PP: 0.5755, 95%CI: 0.5728 – 0.5783) were included in these studies.

Overall, the majority of subjects had one FGID diagnosed (PP: 0.6740, 95%CI:0.6698 – 0.6782), while smaller numbers of patients had two (PP: 0.2854, 95%CI:0.2764 – 0.2946), three PP: 0.1818, 95%CI:0.1726 – 0.1913), four (PP: 0.1145, 95%CI:0.1068 – 0.1225), five (PP: 0.1046, 95%CI:0.0949 – 0.1150), and six (PP: 0.0464, 95%CI:0.0374 – 0.0567) FGIDs. Quality of life was significantly reduced in patients with overlapping FGIDs as compared to patients with a single FGID in both mental (SMD: -0.250, 95%CI:-0.467, -0.033, $p=0.024$) and physical component scores (SMD:-0.634, 95%CI:-0.634, -0.335, $p=0.0001$). Patients with an overlap of FGIDs had both increased prevalence of anxiety (SMD:0.501, 95%CI:0.347-0.654, $p=0.0001$) and depression (SMD:0.532, 95%CI:0.366, 0.698, $p=0.0001$).

Conclusion: Based upon this meta-analysis a substantial proportion of patients have more than one FGID as defined by the Rome criteria. Patients with an overlap have more severe impairment of quality of life and are characterised by a significantly higher rate of anxiety or depression. All this points towards the possibility that disturbances of brain-gut interactions are in particular relevant for patients presenting with an overlap of different FGID.

ENRICHMENT OF PATIENTS WITH EHLERS DANLOS SYNDROME IN IDIOPATHIC GASTROPARESIS – A GENE SET ENRICHMENT ANALYSIS

S. Smieszek¹

¹Vanda Pharmaceuticals, Genetics, DC, United States

Contact E-Mail Address: sandra.smieszek@vandapharma.com

Introduction: Ehlers Danlos Syndrome (EDS) is a heritable disorder of the connective tissue. It is usually inherited as an autosomal dominant trait; however, recessive mode of inheritance has been documented¹. EDS comprises a genetically heterogeneous group of connective tissue disorders of which the main clinical features are joint hypermobility, skin hyperextensibility, delayed wound healing with atrophic scarring, and generalized connective tissue fragility^{2,3}.

The genetic etiology is not well explained and there are 100s of variants within the core genes. In the current gastroparesis study, we report 16 cases of EDS (confirmed by electronic medical records), specifically enriched in the cohort of idiopathic gastroparesis.

Aims & Methods: Assuming incidence rate of 1 in 5000 the enrichment is 160-fold ($p= 8.18743E-26$). In order to explore the genetic surrogates of EDS we have done gene set enrichment analysis. We focused our analysis on core genes: COL1A1,COL1A2,COL3A1,COL5A1, andCOL5A2 and ADAMTS2,FKBP14,PLOD1, andTNXB, as reported in LOVD⁵.

Results: All EDS cases are of Caucasian ancestry, females with idiopathic gastroparesis. All self-reported ancestry was verified by principal component analysis. We report all coding/splicing variants in the core genes with a minor allele frequency (MAF)<0.05. Most of our EDS cases for which we have whole genome sequencing available (n=13) with exception of 1, have at least one such nonsynonymous variant/or splicing variant within the core gene set. We report 2 duplicate variants across this set.

The first variant is COL5A1:NM_000093:exon13:c.G1588A:p.G530S (rs61735045). It has a global MAF in gnomAD of 0.03 (ranging from 0.04 NFE to 0.0009 amongst East Asian). The variant is reported in ClinVar as pathogenic and associated with EDS, classic type and has a high CADD score of 24.9. This variant has been previously reported in literature in association with EDS¹.

These findings suggested that heterozygosity for the Gly530Ser substitution is associated with mild ultrastructural abnormalities and variably subtle clinical signs and is disease modifying, while homozygosity for this mutation is associated with classical EDS¹. Furthermore, the variant is significant in association analysis of idiopathic versus diabetic gastroparesis patients. We report 5/128 diabetic versus 27/238 idiopathic, p -value<0.007 (EDS gene set). The other variant duplicated in our cohort is the TNXB:NM_019105:exon26:c.A9044G:p.K3015R, with a high CADD score of 23.3. Amongst the 19 variants (total 21) reported in the 13 EDS patients, 9 have been reported in association with EDS confirmed in ClinVar⁶.

Additionally, a gene enrichment analysis was performed on core genes, $MAF<5$, idiopathic versus diabetic gastroparesis, and led to a significant result, specifically enrichment of variants in COL5A1, COL5A2, TNXB and ADAMTS2.

Conclusion: These results suggest a statistically significant enrichment of EDS patients in this gastroparesis study, with confirmed known and novel variants in the EDS gene set. Furthermore, these results suggest an enrichment of such gene variants in the entire idiopathic cohort of patients with idiopathic gastroparesis.

Introduction: Rivastigmine is a pseudo-irreversible cholinesterase inhibitor used for therapy of Alzheimer's disease and non-Alzheimer dementia syndromes (including vascular and Parkinson disease dementia) [1]. Rivastigmine is a relatively weak, but long-lasting, cholinesterase inhibitor (IC₅₀ = 4.5 µM) that inhibits the action of both acetylcholinesterase and butyrylcholinesterase by reversible binding to them. In humans, rivastigmine can cause significant gastrointestinal side effects that can limit its clinical use.

Aims & Methods: The aim of this study was to assess the impact of rivastigmine on gastric motor function by means of electrogastrography (EGG) in experimental pigs.

Six experimental adult female pigs (*Sus scrofa* f. *domestica*, hybrids of Czech White and Landrace breeds; 3-month-old; mean weight 30.7 ± 1.2 kg) were enrolled into the study twice and created two experimental groups. In group A, a single intragastric dose of 6 mg rivastigmine hydrogen tartrate was administered in the morning to fasting pigs before EGG recording. In group B, rivastigmine was administered to overnight fasting animals in a dietary bolus in the morning for 7 days (6 mg per day).

On day 8, an intragastric dose of 12 mg rivastigmine was given in the morning to fasting pigs before EGG. EGG recording was accomplished by means of an EGG standalone system. Recordings from both groups were evaluated in dominant frequency and EGG power (areas of amplitudes).

Results: In total, 1,980 one-minute EGG intervals were evaluated. In group A, basal EGG power (median 1290.5; interquartile range 736.5 - 2330 µV²) was significantly higher in comparison with the power of intervals T6 (882; 577 - 1375; p = 0.001) and T10 (992.5; 385 - 2859; p = 0.032). In group B, the dominant frequency increased significantly from basal values (1.97 ± 1.57 cycles per minute) to intervals T9 (3.26 ± 2.16; p < 0.001) and T10 (2.14 ± 1.16; p = 0.012), respectively.

In group B, basal EGG power (median 1030.5; inter-quartile range 549 - 5093) was significantly higher in comparison with the power of intervals T7 (692.5; 434 - 1476; p = 0.002) and T8 (799; 435 - 1463 µV²; p = 0.004).

Conclusion: Both single as well as repeated intragastric administration of rivastigmine hydrogen tartrate caused a significant decrease of EGG power (areas of amplitudes) in experimental pigs. EGG power may serve as an indirect indicator of gastric motor competence. These findings provide a possible explanation of rivastigmine-associated dyspepsia in humans.

LONG-TERM OUTCOMES OF PER-ORAL ENDOSCOPIC MYOTOMY IN ESOPHAGEAL MOTILITY DISORDERS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Z. Nabi¹, H. Mandavdhare², R. Talukdar¹, D.N. Reddy¹

¹Asian Institute of Gastroenterology, Gastroenterology, Hyderabad, India, ²Post Graduate Institute of Medical Education and Research, Gastroenterology, Chandigarh, India

Contact E-Mail Address: zaheernabi1978@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) is an established treatment for achalasia with emerging data on long-term outcomes. In this systematic review and meta-analysis we aim to analyse the long-term outcomes of POEM in esophageal motility disorders.

Aims & Methods: In this systematic review and meta-analysis we aim to analyse the long-term outcomes of POEM in esophageal motility disorders.

Literature search was performed in the databases including PubMed, Embase, Cochrane databases and Google scholar from Jan 2010 to May 2021. The primary objective of the study was clinical success (Eckardt score ≤ 3 or < 4) after POEM at mean follow-up of more than 30 months. Secondary objectives included post POEM gastroesophageal reflux (GER) as evaluated by symptoms, increased esophageal acid exposure and reflux esophagitis.

Results: Seventeen studies with 3,591 patients were included in the review. The sub-types of motility disorders were type I in 952 (27%), type II in 1,926 (54.5%), type III in 378 (10.7%), DES/JHE 71 (2%), EGJOO 62 (17.5%). Pooled mean follow-up duration from nine studies was 48.9 months (95% CI 40.02 to 57.75).

Pooled rate of clinical success at 30-60 months follow-up was 87% (95% CI 81% to 91%; I²86%) and ≥ 60 months was 84% (95% CI 76% to 89%; I²47%). Pooled rate of clinical success in type I achalasia was 87% (95% CI 80%-92%; I²28%), type II achalasia 88% (95% CI 83%-91%; I²23%) and type III achalasia 76% (95% CI 64%-84%; I²10%).

In non-achalasia esophageal motility disorders (EGJOO, DES and JHE), the pooled rate of clinical success was 77% (95% CI 65% - 85%; I²0%). GER as estimated by symptoms was 23% (95% CI 19%-27%; I²74%), erosive esophagitis was 27% (95% CI 18%-38%; I²91%), and increased esophageal acid exposure was 41% (95% CI 30%-52%; I²88%).

Symptomatic reflux at short term (< 6 months) was 19% (95% CI 14 to 24; I² 77%), mid-term (1-2 years) was 16% (95% CI 9 to 27; I² 70%) and long-term (> 2 years) was 23% (95% CI 15% to 32%; I² 77%). Pooled rate of erosive esophagitis at short-term (< 6 months) from ten studies was 28% (95% CI 17%-41%; I² 91%) and long-term (≥ 2 years, five studies) was 13% (95% CI 6%-25%; I² 77%).

Conclusion: POEM is a durable treatment option in cases with achalasia. One-fourth patients suffer from erosive GER in long-term and success rates are lower in non-achalasia esophageal motility disorders.

Disclosure: Nothing to disclose.

CHICAGO CLASSIFICATION VERSION 3 VERSUS VERSION 4: WHAT ARE THE DIAGNOSTIC IMPLICATIONS?

M. Freitas^{1,2,3}, V. Macedo Silva^{1,2,3}, C. Arieira^{1,2,3}, J. Cotter^{1,2,3}

¹Hospital da Senhora da Oliveira, Gastroenterology Department, Guimarães, Portugal, ²Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal, ³ICVS/3B's, PT Government Associate Laboratory, Braga/Guimarães, Portugal

Contact E-Mail Address: martasfreitas@gmail.com

Introduction: The Chicago classification (CC) categorizes esophageal motility disorders according to the parameters obtained in esophageal high-resolution manometry (HRM). Recently, a new version of CC, CCv4.0, was published.

Aims & Methods: We aimed to compare esophageal motility disorders diagnosed according to the last two versions of CC (CCv3.0 vs CCv4.0). We performed a retrospective study that included consecutive patients undergoing esophageal HRM with 10 swallows in the supine position and 5 swallows in the upright position between February 2021 and February 2022. The manometric studies were reviewed, and motility disorders classified according to CCv3.0 and CCv4.0 by two operators.

Results: Fifty-nine patients were included, 50.8% were male, with mean age of 58±15 years. According to CCv3.0, 8 (13.6%) patients were diagnosed with esophagogastric junction (EGJ) relaxation disorders, 23 (39.0%) with peristalsis disorders: 8 (13.6%) major, 15 (25.4%) minor, and 28 (47.5%) were normal. According to CCv4.0, 7 (11.9%) patients were diagnosed with EGJ relaxation disorders, 19 (32.2%) with peristalsis disorders, and 33 (55.9%) were normal.

The diagnosis of motility disorders changed in 5 (8.5%) patients: 2 with EGJ outflow obstruction in CCv3.0 became normal in CCv4.0 because they had normal integrated relaxation pressure (IRP) in the upright position; 1 absence of contractility changed to achalasia in CCv4.0 by increased IRP in the upright position; 2 with ineffective esophageal motility in CCv3.0 became normal in CCv4.0.

Conclusion: EGJ relaxation disorders and peristalsis disorders were less frequently diagnosed with CCv4.0 comparing to CCv3.0. Ineffective esophageal motility and EGJ outflow obstruction had the greatest diagnostic variation between the two classifications. Future studies should assess the clinical implications of the new CC.

Disclosure: Nothing to disclose.

P0030

AUTONOMIC AUTOANTIBODIES IN ACHALASIA

D. Ben-Ami Shor¹, Y. Ron², N. Bar³, O. Shibolet¹, G. Halpert⁴, H. Heidecke⁵, Y. Shoenfeld⁶

¹Tel Aviv Medical Center, Gastroenterology, Tel Aviv, Israel, ²Tel Aviv Medical Center, Tel Aviv, Israel, ³Tel Aviv Sourasky Medical Center, Gastroenterology and Hepatology, Tel Aviv, Israel, ⁴Sheba Medical Center, Ramat Gan, Israel, ⁵CellTrend GmbH, Luckenwalde, Germany, ⁶Zabludowicz Center for Autoimmune Diseases, Ramat Gan, Israel

Contact E-Mail Address: benamidana@gmail.com

Introduction: Idiopathic achalasia is an esophageal motor disorder, characterized by loss of enteric neurons leading to absence of peristalsis and impaired relaxation of the lower esophageal sphincter (LES). The pathophysiology of achalasia is still unknown, although an autoimmune etiology is suspected.

Aims & Methods: We aimed to determine whether autoantibodies against the autonomic nervous system receptors can explain the enigmatic pathogenesis of achalasia.

This is an observational cross-sectional study using an ELISA method designed to identify the level of circulating autoantibodies against G protein-coupled receptors of the autonomic nervous system (adrenergic, muscarinic, endothelin and angiotensin receptors). Peripheral blood was obtained from forty achalasia patients diagnosed by an expert gastroenterologist based on esophageal manometry and upper endoscopy findings. The medical records of each patient was reviewed. Peripheral blood was also obtained from forty matched healthy donors (HDs) with no history of achalasia, no history of an autoimmune disease, as well as no symptoms suggestive for upper motility disorder.

Results: We herein report a significant reduction in the sera level of anti-muscarinic 2 receptor (anti-M2R) autoantibodies among achalasia patients as compared with aged matched HDs ($p < 0.009$).

Conclusion: Anti-M2R autoantibodies could be involved in the pathophysiological mechanism of achalasia. Further studies are needed in order to evaluate whether a higher expression of M2 receptor in the tissues among achalasia patients may lead to a high binding of the anti-M2R autoantibodies to these receptors and therefore a decreased level of these antibodies in the circulation.

Disclosure: Nothing to disclose.

PREVALENCE OF DELAYED GASTRIC EMPTYING IN DIABETIC PATIENTS WITH GASTROPARESIS-LIKE SYMPTOMS

I.-H. Huang^{1,2}, F. Carbone¹, L. Van Aelst¹, J. Schol¹, Y. Chen³, L. Michaja Balsiger¹, B. Broeders¹, T. Vanuytsel¹, J. Tack¹

¹Translational Research Center for Gastrointestinal Disorders, University of Leuven, Leuven, Belgium, ²Tri-Service General Hospital, National Defense Medical Center, Department of Gastroenterology and Hepatology, Taipei, Taiwan, ³Takeda Pharmaceuticals, GI TAU, Cambridge, United States

Contact E-Mail Address: alberttsggh@gmail.com

Introduction: Diabetes mellitus (DM) is a highly prevalent metabolic condition which is often associated with bothersome upper gastrointestinal symptoms. In some patients the dyspeptic symptoms are attributed to delayed gastric emptying, i.e. diabetic gastroparesis (GP). However, the distinction between patients with diabetic GP from those with dyspepsia is challenging because of large overlap.

The recent European consensus defined GP as a condition characterized by delayed gastric emptying in the absence of mechanical obstruction, with a symptom pattern of predominant nausea and/or vomiting and overlapping postprandial distress syndrome (PDS) (Schol, UEGJ 2021). So far, there is a paucity of data on the relationship between the symptom pattern and delayed gastric emptying in DM patients.

Aims & Methods: **Aim:** To investigate to what extent the symptom pattern may differentiate diabetic GP from dyspepsia in DM patients.

Methods: This retrospective study included 55 DM patients from the Leuven University Hospital, who underwent a ¹³C-octanoic acid gastric emptying breath test (GEBT) for clinical reasons and had no organic gastrointestinal disease, a history of abdominal surgery or medications that delay gastric emptying.

The severity of 6 epigastric symptoms (postprandial fullness, epigastric pain and burning, bloating, nausea, and belching) scored on a 5-point Likert scale, 0=Absent, 1=Very mild, 2=Mild, 3=Moderate, 4=Severe, was assessed every 15 minutes, before and 4h after the test meal (250 kCal), during the GEBT.

Included patients were defined as having gastroparesis-like symptoms (GPLS, i.e. total score of nausea ≥ 1 combined with total score of postprandial fullness ≥ 1), or dyspeptic symptoms (not fitting GPLS). We compared demographic and clinical variables as well as GEBT results in GPLS vs. dyspepsia patients by Mann-Whitney U and Pearson's chi-square tests. To investigate to what extent the symptom pattern may differentiate diabetic GP from dyspepsia in DM patients.

Results: Among 55 DM patients (median age of 50 years), 21 reported GPLS and 34 were DM with dyspepsia. The characteristics of the patients in both groups are shown in Table 1.

The prevalence of delayed gastric emptying (half gastric emptying time ($T_{1/2}$) > 109 min) in GPLS was significantly higher than in the dyspepsia group (33.2% (27.2-39.69) vs 8.8% (1.9-23.7), $p=0.02$). The $T_{1/2}$ was 73.0 (45.0-123.0) min in GPLS, compared to 63.0 (40.8-85.3) min in DM with dyspepsia ($p=0.19$). In the GPLS group, patients with type 2 DM (median age, 52 years) had a significantly higher prevalence of delayed gastric emptying than patients with type 1 DM (median age, 46 years) (71.4% (29.0-96.3) vs 14.3% (1.8-42.8), $p<0.01$).

When subgrouping GPLS patients into delayed ($n=7$) and normal ($n=14$) gastric emptying, we found no significant difference in age and body mass index (52 (36-55) vs 46 (27-55) years; 25.2 (22.5-30.8) vs 26.1 (20.0-29.0) kg/m^2 , respectively). There was no significant difference in severity of 6 epigastric symptoms and overall dyspepsia symptom severity (all $p>0.4$).

	Overall ($n=55$)	Dyspepsia ($n=34$)	GPLS ($n=21$)	P value
Female	38 (70.4%)	19 (55.9%)	19 (90.5%)	<0.01
Age (years)	50 (37.0-29.0)	51 (42.5-65.0)	46.0 (28.0-55.0)	0.09
BMI	25.9 (22.5-29.0)	25.8 (23.7-28.8)	25.9 (20.6-29.0)	0.69
Type 1 DM	37 (67.3%)	23 (67.6%)	14 (66.7%)	0.93
OSS	28.0 (6-57)	16.0 (0.8-35.0)	61.0 (30.0-119.0)	<0.01
$T_{1/2}$ (min)	68.0 (43-94)	63.0 (40.8-85.3)	73.0 (45.0-123.0)	0.19
Delayed gastric emptying	10 (29.4)	3 (8.8%)	7 (33.3%)	0.02

* Results expressed as median (interquartile range) for a continuous variable or count (%) for a categorical variable.

Table 1. Characteristics of diabetic patients indyspepsia and gastroparesis-like symptom group

Conclusion: In DM patients reporting upper gastrointestinal symptoms, the prevalence of delayed gastric emptying is associated with GPLS as defined by the recent European consensus. These findings are in favor of the symptom pattern proposed by the European consensus.

G-POEM FOR REFRACTORY GASTROPARSIS: BASAL SYMPTOM SEVERITY AND INTRAGASTRIC MEAL DISTRIBUTION DURING GASTRIC EMPTYING SCINTIGRAPHY MAY BE PREDICTORS OF 12-MONTH CLINICAL OUTCOME

S.G.G. Testoni¹, F.V. Mandarino¹, A. Barchi¹, G. Pepe², D. Esposito¹, E. Viale¹, L. Fanti¹, P. Biamonte¹, S. Danese¹, F. Azzolini¹

Introduction: Gastroparesis is a chronic disorder characterized by multiple different pathophysiological mechanisms beyond delayed gastric emptying, in the absence of mechanical obstruction. Gastric peroral endoscopic myotomy (G-POEM) represents a proven technique for treating refractory gastroparesis, with modest clinical effectiveness at 12-month [1,2]. Localized measurements at gastric emptying scintigraphy (GES) may represent a patient selection criterion for G-POEM. The Intra-gastric Meal Distribution (IMD), as measure of impaired fundic accommodation, has never been evaluated in patients treated with G-POEM

Aims & Methods: Patients with refractory gastroparesis prospectively treated with G-POEM from March 2019 to October 2020 (NCT04349670) were investigated regarding clinical and functional response up to 12-month follow-up. Inclusion criteria were: gastroparesis diagnosis through gastric emptying half time ($T_{1/2}$) ≥ 180 min and/or Percent Gastric Retention (PGR) after 2 hours $\geq 60\%$ at GES and Gastroparesis Cardinal Symptom Index (GCSI) [3] ≥ 1.5 ; GCSI < 1.5 with GES parameters below the abovementioned average after a good response to botulin injection (100UI); age ≥ 18 years; no response to medical therapy with symptoms from more than 6 months.

Main outcome was clinical success, defined as at least 1-score decrease in the total GCSI with decrease $> 25\%$ in at least 2 out of 3 symptomatic subscales (post-prandial fullness, nausea/vomiting, bloating) at 3-, 6-, and 12-month assessments. Secondary outcomes were: a) functional response, assessed with $T_{1/2}$, 2-hour PGR, IMD, and retention index (RI) at 3-month GES, defining functional success as decrease $\geq 30\%$ of 2-hour PGR [4]; b) identification of any baseline predictive factors of 3-month functional success and 12-month clinical success; c) G-POEM technical success and safety

Results: Eighteen patients with refractory gastroparesis (11 idiopathic, 6 post-surgical and 1 diabetic) were treated with G-POEM. Technical success was achieved in all procedures (100%). Clinical success was 66.7%, 52.9% and 62.5% at 3-, 6- and 12-month follow-up. Compared with baseline, the median total GCSI score reduced significantly up to 12-month ($p<0.0001$ at 3- and 6-month, $p=0.0013$ at 12-month), as well as all three median symptomatic GCSI subscales.

At 3-month GES, no significant changes compared with baseline were observed for the median $T_{1/2}$, and the mean 2-hour PGR, IMD and RI. At ROC analysis a significant predictive yield for functional success at 3-month GES was found for basal total GCSI and IMD ($p<0.0001$ and $p=0.045$), with sensitivity of 100% and 100% and specificity of 88.9% and 77.8% at the best cut-off values of ≤ 1.86 and ≤ 84 , respectively.

The basal total GCSI and IMD confirmed a significant predictive yield for the 12-month clinical success ($p=0.0297$ and $p=0.0152$). A significant decrease of the total GCSI up to 12-month was observed in patients with basal total GCSI > 2.7 and IMD ≤ 96.78 ($p=0.0156$ and $p=0.0126$), as the best

cut-off values with sensitivity of 54.55% and 87.51% and specificity of 100% and 75%, respectively. Whilst patients with basal GCSI ≤ 2.7 and IMD > 96.78 experienced a non-significant decrease of total GCSI.

Conclusion: G-POEM is an effective procedure for refractory gastroparesis-related symptoms. The pre-procedural symptom severity and IMD at GES might predict the long-term clinical response to G-POEM. Further studies on large samples are required to confirm these results and understand the correlation between symptoms and gastric motility localized patterns in gastroparesis.

GASTROESOPHAGEAL REFLUX DISEASE AFTER PERORAL ENDOSCOPIC MYOTOMY

R. Muñoz González¹, A. Ezquerro Durán¹, S. Casabona-Francés¹, T. Pérez Fernández¹, C. Santander¹, P. Miranda¹

¹Hospital Universitario de La Princesa, Gastroenterology, Madrid, Spain

Contact E-Mail Address: pmpablomiranda@gmail.com

Introduction: Concern about gastroesophageal reflux disease (GERD) after peroral endoscopic myotomy (POEM) exists since high rates of pathological acid exposure time (AET) in pHmetry have been described. However, in treated achalasia patients, most cases of esophageal acidification are not related to reflux but are due to acid fermentation or stasis induced by acidic foods (1). Few studies have evaluated the relevance of fermentation or stasis after POEM.

Aims & Methods: The aim of our study was to evaluate the clinical, endoscopic, manometric and pHmetric characteristics of GERD in patients undergoing POEM.

From June 2018 to April 2022, we prospectively evaluated GERD in patients undergoing POEM at Hospital Universitario La Princesa (Spain) at months 3 and 12 after myotomy.

Clinical GERD was defined as GerdQ ≥ 8 , erosive esophagitis was reported according to Los Angeles classification, and an AET $> 6\%$ was considered pathological in 24h pHmetry registry (off acid suppression). In patients with a pathological AET, manual analysis of the pHmetric records was performed by an experienced physician who classified patterns in acidic reflux, fermentation or stasis, as previously described (1).

Results: 45 patients (20-86 years) underwent POEM. The main indication was achalasia type II (75%). Clinical success rate was 95% (Eckardt score < 3).

At follow-up (4-46 months), only 3 patients presented clinical GERD. Esophagitis was present in 9/32 (28%) and the vast majority were mild. Normalization of IRP4 occurred in 26/29 patients (89%) and pathological AET in 15/28 (53%). Of these (n=15), 10 (66%) had "real" GERD with prolonged clearance, while 4 (26%) presented acid fermentation and one (6%) was due to distal esophageal stasis.

Conclusion: Post-POEM GERD is usually asymptomatic. Objective tests such as endoscopy and pH-metry are needed to rule out GERD.

Manual interpretation of pathological AET is recommended to distinguish real acid reflux from fermentation or stasis, which has management implications.

ASSOCIATION BETWEEN GASTRIC EMPTYING AND SYMPTOMS IN A LARGE COHORT OF PATIENTS WITH DYSPESIA

J. Keller¹, A. Buchholtz¹, V. Andresen¹, P. Layer¹

¹Israelitisches Krankenhaus Hamburg, Department of Medicine, Hamburg, Germany

Contact E-Mail Address: j.keller@ik-h.de

Introduction: The current European consensus postulates that nausea and vomiting are the cardinal symptoms of gastroparesis (Schol et al. UEG J 2021). However, the association between gastric emptying and dyspeptic symptoms remains controversial, and a recent study by Carbone et al. (Clin Gastroenterol Hepatol 2022) showed no correlation between gastric emptying rate and simultaneously assessed dyspeptic symptoms in functional dyspepsia. However, the test meal used in this study was small (250 kcal) and may have elicited less symptoms than the patients' regular meals.

Aims & Methods: To investigate the association between gastric emptying and dyspeptic symptoms in a large cohort of patients, consecutive patients undergoing a ¹³C-octanoic acid breath test (¹³C-OAT, Ghos et al. 1993) at our institution were asked to also rate symptom severity using the Gastroparesis Cardinal Symptom Index (GCSI, Revicki et al. Qual Life Res 2004) while performing the gastric emptying test. The index reflects symptoms during the past 2 weeks. It requires graduation of severity of 9 symptoms from 0 (absent) to 5 (very severe), which are summarized in subscales for nausea/vomiting (N/V), postprandial fullness/early satiety (F/ES) and bloating (B). The GCSI is constructed as the average of these subscales. Normal gastric emptying half time (T_{1/2}) as established at our institution ranges from 50 to 150 min (Keller et al. UEG J 2021).

Results: We included 643 patients (447 females) with a median age of 50 [IQR 33-63] years. 13.5% of these patients had accelerated, 9.0% had delayed gastric emptying. Women had a higher GCSI than men (2.22[1.44-2.88] vs. 1.78[1.44-2.22], $p < 0.001$) with similar T_{1/2} (81[61-107] vs. 78[60-105] min, $p = 0.38$). In the total group and independent of sex, accelerated, normal or delayed GE, symptom severity for B was always significantly higher than severity of F/ES and N/V, respectively (tab). For the total group, there was no significant association between GCSI and T_{1/2} ($p = 0.468$). By contrast, in patients with delayed gastric emptying, T_{1/2} was a significant predictor of symptom severity, independent of age and sex ($R = 0.326$, $p = 0.020$). With regard to individual symptoms, vomiting ($R = 0.232$, $p = 0.039$)

and stomach fullness ($R=0.353$, $p=0.003$) were significantly associated with $T\frac{1}{2}$. The subscale, which correlated best with gastric emptying velocity, was F/ES ($R=0.255$, $p=0.027$).

	Total group (N=643)	Males (N=196)	Females (N=447)	$T\frac{1}{2}<50$ min (N=87)	$T\frac{1}{2} 50-150$ min (N=498)	$T\frac{1}{2}>150$ min (N=58)
<i>N/V</i>	1.0[0.0-1.7]	0.7[0.0-1.7]	1.0[0.3-1.7]	1.0[0.0-2.0]	1.0[0.0-2.0]	0.7[0.0-1.7]
<i>F/ES</i>	2.3[1.3-3.5]*	2.0[1.0-3.0]*	2.3[1.5-3.8]*	2.3[1.5-3.8]*	2.0[1.3-3.8]*	2.5[1.0-3.8]*
<i>B</i>	3.5[1.5-4.5]§	2.5[1.0-4.0]§	3.5[2.0-4.5]§	3.5[2.0-4.5]§	3.5[1.5-5.0]§	3.0[1.5-4.5]§

Data given as median with IQR, * $p<0.001$ vs *N/V*, § $p<0.015$ vs *N/V* and *F/ES*

Table.

Conclusion: In a large cohort of patients, who underwent a ^{13}C -OAT because of dyspeptic symptoms, more than 20% showed gastric emptying disturbances, about 10% had gastroparesis. When asked for symptom severity during the past 2 weeks, women recorded more severe symptoms than men despite similar gastric emptying.

Bloating was always the most bothersome symptom, independent of sex and gastric emptying velocity. In patients with gastroparesis (but not in patients with normal or accelerated gastric emptying), the degree of gastric emptying disturbance was an independent predictor of symptom severity. However, *F/ES* - and not *N/V* as postulated by the European consensus - correlated best with GE velocity in gastroparesis.

Introduction: Per oral endoscopic myotomy (POEM) has been established as the modality of choice for treatment of esophageal motility disorders (EMD). Longitudinal incision is the commonly used incision for entry into the submucosal space during POEM. Transverse incision is another alternative for entry, however, it is less commonly used. Retrospective data suggests that transverse incision has less chance of gas related events. However, a randomized controlled trial comparing the 2 types of incisions is lacking.

Aims & Methods: We performed a randomized controlled trial comparing the transverse and longitudinal incision for entry into the submucosal space during POEM for EMD. The primary objective was to compare the time for entry into the submucosal space.

The secondary objectives were to compare the time needed to close the incision, number of clips required to close the incision and gas related events in the form of capnoperitoneum needing needle aspiration under water seal and capnotherax needing intercostal drain placement.

Diagnosed cases of EMD (achalasia cardia (AC) type I, II, III, esophagogastric junction outflow obstruction (EGJO) and other spastic motility disorder like distal esophageal spasm (DES) and jackhammer esophagus (JE) as per the Chicago V 3.0 classification were enrolled.

The patients who were willing to undergo POEM after written informed consent were randomized to group A (longitudinal incision) and group B (transverse incision). Two experts and 2 trainees performed the POEM procedures. The opaque sealed envelope for randomization was opened after creation of the mucosal bleb.

The longitudinal incision was taken in a linear fashion along the long axis of esophagus starting proximally over the bleb and extending 2-3 cm aborally. The transverse incision was taken perpendicular to the long axis of the esophagus on the proximal aspect of the bleb in a right to left direction extending upto 2-3 cm.

Time taken for entry into the submucosal space, tunneling time, myotomy time, tunnel length and myotomy length, incision closure time and number clips needed for closure were noted during the procedure. Intraoperative events in the form of bleeding, mucosal injury (type I/II), capnoperitoneum/capnotherax needing aspiration were also noted. The technical success was defined as successful entry in to the submucosal space along with completion of all steps of POEM including myotomy.

Results: Between September 2021 and March 2022, 60 patients were randomized (30 each in the longitudinal and the transverse incision group). The median age was 39 (30,47.8) and 33 (55%) were males. Types of EMD were AC-I-33, II-16, III-2, DES-2, EGJO-2 and unclassified 5.

On comparing the 2 types of incisions there was no difference in entry time [3 (2, 5) min vs 2 (1.75, 5) min, $p=0.39$], closure time [7 (4, 13.5) min vs 9 (6.75, 19) min, $p=0.15$] and number clips needed for closure [4 (4, 6) vs 5 (4,7) min, $p=0.15$]. Also, the gas related events were comparable between the 2 groups (capnoperitoneum needing needle aspiration-5 vs 2, $p=0.22$).

On subgroup analysis, experts (n=42) needed more time to close the transverse incision as compared to longitudinal incision [7 (5,12) vs 11 (7,19), $p=0.04$]. This comparison was not feasible among trainees due to small sample size.

Conclusion: On comparison of the longitudinal and transverse incisions in POEM, entry time, number clips needed to close and gas related events were comparable while closure time was more for transverse incision.

A BASELINE SEVERITY INFLATION ANALYSIS IN STUDY VP-VLY-686-3301 OF TRADIPITANT IN GASTROPARESIS

J.L. Carlin¹, C. Polymeropoulos¹, C. Xiao¹, G. Birznies¹, M.H. Polymeropoulos¹

¹Vanda Pharmaceuticals, Inc., Washington, United States

Contact E-Mail Address: Jesse.Carlin@vandapharma.com

Introduction: Tradipitant is a novel NK-1 receptor antagonist that has previously showed efficacy in improving nausea, vomiting and overall gastroparesis symptoms in a phase 2 study (VP-VLY-686-2301) in patients with diabetic and idiopathic gastroparesis. The efficacy of tradipitant in gastroparesis was further evaluated in a phase 3 randomized, double-blind, placebo-controlled study (VP-VLY-686-3301).

A large placebo effect was observed which may have masked the true size of tradipitant benefit. Large placebo responses can be driven by Baseline Severity Inflation (BSI) especially on parameters which patients are selected for inclusion into the study. Here we present such a BSI analysis at the prespecified endpoint of change of nausea severity in VP-VLY-686-3301.

Aims & Methods: Idiopathic and diabetic gastroparesis patients with delayed gastric emptying, moderate to severe nausea, and at least 1 vomiting episode in screening were randomized to 85mg tradipitant BID or placebo for 12 weeks. Nausea was assessed using the 5-point Gastroparesis Core Symptom Daily Diary (GCSDD).

Overall gastroparesis symptom improvement was evaluated using the Patient Global Impression of Change (PGI-C) and the Overall Patient Benefit (OPB) scales. The BSI analysis subgroup included ITT (Intent-to-Treat) subjects with at least 1 but less than 7 average vomiting episodes and similarly excluded subjects whose vomiting severity was zero or highest severity category at baseline. This baseline threshold allows for censoring of patients with minimal or very high frequency of vomiting.

This method uses a symptom scale for censoring other than the scale used for the primary endpoint, is an accepted strategy to minimize placebo effect, and allows for a less biased estimation of true treatment effect.

Results: A patient responder analysis of PGI-C and OPB Score in the BSI subgroup showed a larger proportion of tradipitant treated patients improved versus placebo at start (Week 2) and end (Week 12) of the study. Similarly, at the same timepoints nausea was improved.

For the primary endpoint of change in nausea from baseline at week 12, tradipitant treated patients reported a greater reduction in nausea than placebo treated patients (-1.98 v. -1.28, $p=.028$). Improvement in tradipitant treated patients versus placebo was also seen at week 2 (-.99 v. -.50, $p=.013$). In the PGI-C scale more tradipitant treated patients demonstrated improvement as compared to placebo at week 2 (86% v. 53%, $p=.002$) and at week 12 (84% v. 65%, $p=0.056$). For the OPB scale, more tradipitant treated patients demonstrated benefit compared to placebo at week 2 (95% v. 68%, $p=.003$) and week 12 (92% v. 68%, $p=.009$).

Conclusion: Tradipitant treatment in the Baseline Severity Inflation Analysis subpopulation resulted in improvements in Nausea, PGI-C, and Overall Patient Benefit Score both the earliest (Week 2) and last (Week 12) timepoints.

Introduction: High-resolution impedance manometry (HRIM) allows evaluation of esophageal bolus retention in conjunction with assessment of esophageal motor phenomena.

Aims & Methods: The aim of this study was to evaluate the relationship between esophageal bolus retention metrics and peristaltic integrity using HRIM. We retrospectively reviewed HRIM studies performed between Dec 2015 to Jan 2021, using an Unisensor catheter with 36 pressure sensors and 18 impedance segments with dedicated software (Starlet, Star Medical).

After excluding patients with achalasia, esophagogastric junction outflow obstruction, distal esophageal spasm, and Jackhammer esophagus, 119 patients (age: 63.2±15.5, female 52%) were included in this study. HRIM data were analyzed to assess Chicago Classification (CC) metrics, the esophageal impedance integral (EII) ratio (estimated as the summated EII in post-swallow domain/EII in swallow domain), and impedance ratio (IR) (calculated as nadir impedance/peak pressure impedance).

Contractility of each swallow was evaluated according to CCv4.0, but the normal contraction was further divided into two categories with or without a small break: normal contraction, normal contraction with a small break (2-5cm break with DCI>450), fragmented swallow (>5cm break with DCI>450), weak contraction (100≤DCI≤450), and failed peristalsis

(DCI<100). Dysphagia symptom was graded using a 4-point graded Likert scale from no discomfort to very severe.

Results: A total of 1217 swallows in 119 patients were analyzed. A) Per-patient analysis. Esophageal motility diagnoses included normal (n=103), ineffective esophageal motility (n=11) and absent contractility (n=5) according to CCv4.0. There were significant correlations between the values of esophageal bolus retention metrics and the severity of esophageal motility diagnoses (Spearman's rho: EII ratio 0.44; IR 0.20).

The median values of these metrics were higher in dysphagia patients than in non-dysphagia patients (EII ratio: 0.16 vs. 0.09, $p=0.006$; IR: 0.69 vs. 0.64, $p=0.006$). The EII ratio and IR values significantly correlated with the dysphagia symptom severity (Spearman's rho: EII ratio 0.31; IR 0.30). B) Per-swallow analysis. Contractility in the esophageal body included normal (n=749), normal with a small break (n=179), fragmented (n=80), weak (n=125) and failed (n=84).

There were significant correlations between the values of esophageal bolus retention metrics and the severity of esophageal peristaltic dysfunction (Spearman's rho: EII ratio 0.58; IR 0.24). ROC curve analysis revealed that the EII ratio was a better marker for quantifying bolus retention associated with ineffective swallow than IR (AUC: EII ratio 0.849, IR 0.655), with a sensitivity of 60% and a specificity of 89% at a cut-off value of 0.25.

Conclusion: The EII ratio and IR showed a consistent trend of increased values with increasing degrees of peristaltic dysfunction. The EII ratio appears to be a useful metric for the quantitative assessment of esophageal bolus retention.

THE EFFECT OF BODY POSITION ON HIGH RESOLUTION ESOPHAGEAL MANOMETRY METRICS AND DIAGNOSIS IN ASIAN PATIENTS UNDERGOING ESOPHAGEAL MOTILITY TESTING

J. Kuang¹, K.B. Chuah¹, C. Chia¹

¹Tan Tock Seng Hospital, Gastroenterology & Hepatology, Singapore, Singapore

Contact E-Mail Address: ziyang_kuang@ttsh.com.sg

Introduction: The performance of upright wet swallows as a secondary position has been incorporated into the Chicago Classification (CC) 4.0 for the diagnosis of esophageal motility disorders. There is little data on the comparison of manometric diagnosis when comparing supine and upright swallows in Asian patients undergoing High Resolution Esophageal Manometry (HREM) testing.

Aims & Methods: This study aims to assess the effect of position on key HREM metrics and diagnosis based on CC 4.0, comparing testing performed in the conventional supine position with the upright position. The latter is generally favoured by patients as this represents the physiological posture during meals. A retrospective review of patients undergoing HREM at Tan Tock Seng Hospital, Singapore from January 2019 to January 2022 was carried out. HREM was performed using the Manoscan ESO high resolution manometry (Medtronic) software and solid-state catheter. Only patients who had at least 10 supine wet swallows and 5 upright wet swallows were included. Information on demographics, HREM metrics and manometric diagnosis was collected. SPSS version 15 was used to perform statistical analysis.

Results: A total of 104 patients were included in this study. The median age was 56 years old and 53.8% of patients were female. The median BMI was 24 kg/m². The indication for HREM in 64.4% of patients was for esophageal motility testing prior to 24-hour pH ambulatory testing. 31.7% of patients had dysphagia and 3.8% of patients had a dilated esophagus on computed tomography scans requiring HREM. Using 2-tailed paired sample T-test, comparison across all cases showed a consistently lower median Integrated Relaxation Pressure (IRP) [6.0 mmHg vs 8.7 mmHg; $p < 0.01$] and lower mean Distal Contractile Integral (DCI) [1463 mmHg/cm/sec vs 1864 mmHg/cm/sec; $p = 0.014$] in the upright position compared to supine position. The difference in the mean Distal Latency (DL) between these two positions was not significant [6.21 secs vs 6.27 secs; $p = 0.491$].

During upright position and supine position comparison respectively, subgroup analysis on subjects with normal HREM diagnosis showed an even lower median IRP [4.9 mmHg vs 7.5 mmHg; $p < 0.01$] and lower mean DCI [1436 mmHg/cm/sec vs 1695 mmHg/cm/sec; $p < 0.01$] with mean DL in this subgroup showing no significant difference [6.29 secs vs 6.38 secs; $p = 0.545$].

The final HREM diagnosis in the upright position is concordant with the conventional supine position in 81.7% of patients and showed an even higher concordance in terms of management similarity in 98.1% of patients. Only 2 patients had a significant discordance between supine and upright HREM diagnosis [normal HREM vs esophagogastric junction-outflow obstruction (EGJ-OO), and hypercontractile esophagus vs normal HREM]. Minor diagnostic discordance [normal HREM vs ineffective esophageal motility (IEM)] was noted in 16.3% of cases but this had no major clinical impact on patients and could be overcome by adopting a lower cut-off for mean DCI for the upright position group.

Conclusion: In conclusion, our study shows significantly lower median IRP and lower mean DCI values in the upright position as compared to the supine position. In addition, majority of patients had a final HREM diagnosis in the upright position that is concordant with that in the supine position. In patients who are unable to perform HREM in the supine position or in those who may be at high risk of aspiration when lying down, adopting the upright position shows a high clinical concordance and may be considered a more physiological approach in future HREM protocols.

Disclosure: Nothing to disclose.

Introduction: Ineffective esophageal motility (IEM) could be a manifestation of GERD. Recently, Chicago Classification (CC) v4.0 updated the criteria for IEM compared to CCv3.0, with CCv4.0 requiring $>70\%$ ineffective or $\geq 50\%$ failed swallows for a diagnosis of IEM, compared to $\geq 50\%$ ineffective swallows of CCv3.0.

Aims & Methods: The primary aim of this study was to investigate the prevalence of IEM according to CCv4.0 among those who had been diagnosed according to CCv3.0. The secondary aim was to compare acid exposure time (AET) and the other pH-impedance (MII-pH) parameters in patients with IEM as per CCv4.0 vs IEM as per CCv3.0. We extracted HRM tracings, endoscopy, and clinical data of patients diagnosed with IEM as per CCv3.0 between 2019-2020. We re-analyzed the tracings applying CCv4.0 criteria and grouped patients as follows: group A (IEM according to CCv4.0) and group B (No-IEM according to CCv4.0). Voluptuary habits, treatment with PPI, esophageal symptoms (heartburn, regurgitation, non-cardiac chest pain, dysphagia) were retrieved for all patients.

All patients had undergone upper endoscopy prior to HRM. During HRM, all patients underwent standard protocol and three multiple rapid swallows (MRS). After manometry, all patients underwent MII-pH. Vigor of contraction (DCI), prevalence of failed peristalsis and MRS/SS ratio were evaluated at HRM. Total and recumbent AET, number of reflux events and mean nocturnal baseline impedance (MNBI) and post-reflux swallowed induced peristaltic wave (PSPW)-index were calculated at MII-pH. The prevalence of GERD was calculated based on Lyon consensus criteria.

Results: Of 879 esophageal HRM performed, 134 (58F, mean age 51.9 $\pm$ 16.9 yrs) met the criteria for IEM as per CCv3.0 (15.2%). The prevalence changed to 86/879 (9.8%) applying CCv4.0 criteria. Group A, 86 patients (35F, mean age 51.5 $\pm$ 17.1 yrs), and Group B, 48 patients (23F, mean age 52.6 $\pm$ 16.2 yrs) did not show differences in epidemiological characteristics, voluptuary habits (alcohol, smoking, coffee) and clinical presentation (heartburn, regurgitation, dysphagia) ($p = \text{NS}$). Erosive esophagitis was more frequent in Group A (44/86 vs 15/48; $p = 0.03$). At HRM there were no differences in esophagogastric junction (EGJ) mean pressure, type III, integrated relaxation pressure, and distal latency ($p = \text{NS}$).

With regards to HRM results, DCI was lower, the number of failed swallows was higher, and MRS/SS ratio >1 was less frequent in group A compared to group B ($p < 0.001$). Reflux burden was higher in patients from group A: AET $>6\%$ was more frequent, number of total reflux events was higher, and PSPW index and MNBI were lower in group A compared to group B ($p < 0.001$). Table 1 reports the most relevant data.

	Group A (IEM CCv4.0)	Group B (No-IEM CCv4.0)	P value
Erosive Esophagitis	44/86 (51.2%)	15/48 (31.3%)	0.0303
AET $>6\%$	63/86	22/48	0.0026
AET tot	7.7 $\pm$ 2.7	6.3 $\pm$ 1.7	0.0015
Reflux numb	62.3 $\pm$ 31.8	51.5 $\pm$ 20.2	0.0355
PSPW-index	37.3 $\pm$ 11.4	41.6 $\pm$ 10.4	0.0327
MNBI	1367.3 $\pm$ 411	1524.7 $\pm$ 457.4	0.0433

Conclusion: Patients with IEM diagnosed with CCv4.0 criteria showed higher reflux burden in terms of erosive esophagitis, acid exposure, number of reflux events, and the novel MII-pH parameters (MNBI and PSPW-index) compared to those with IEM as per CCv3.0 who would be reclassified as no-IEM applying CCv4.0 criteria. These findings stress the tight relationship between GERD and IEM.

Disclosure: Nothing to disclose.

DOES BODY MASS INDEX INFLUENCE THE PARAMETERS OF HIGH-RESOLUTION ESOPHAGEAL MANOMETRY?

T. Surdea-Blaga¹, L.-E. David¹, C. Sabo¹, R.-L. Caragut¹, S. Grad¹, D.L. Dumitrascu¹

¹University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj-Napoca, 2nd Medical Department, Cluj-Napoca, Romania

Contact E-Mail Address: dora_bлага@yahoo.com

Introduction: In one of our previous studies (1), we reported that overweight patients with achalasia had the resting pressure of the lower esophageal sphincter (LES) lower compared to lean subjects. Integrated relaxation pressure (IRP) was also lower, while the length of the esophago-gastric junction was longer. The aim of this study was to see whether the body mass index influenced the manometric parameters of patients with normal esophageal high-resolution manometry (HRM).

Aims & Methods: This was a retrospective study, based on esophageal HRM recordings from our department, from November 2015 to November 2021. All the manometries were performed with the patients in the supine position, using the same system and solid-state catheter, with 36 sensors (Unisensor®). All patients, irrespective of their complaints, without major or minor esophageal motility disorder were included.

We compared the following parameters: esophago-gastric junction (EGJ) morphology, LES resting pressure, IRP, esophageal length, EGJ length and the vigour of contraction (distal contractile integral – DCI).

Results: We identified 52 patients with normal esophageal HRM, and 2 were excluded for incomplete data. In the end we analyzed 50 patients, 23 females. Twenty-seven patients were overweight (BMI ≥ 25kg/m²).

We compared the manometry parameters in lean vs. overweight subjects. The morphology of esophago-gastric junction did not differ between the two groups (chi-square test = 1.09, p=0.30). There was no difference between the resting LES pressure (36.8±12.0 mmHg, vs. 35.2±11.6 mmHg, p = 0.64), the mean IRP (18.1±6.5 mmHg vs. 16.7±4.4 mmHg, p=0.37), the esophageal length (22.9±2.4 cm vs. 22.0±2.9 cm, p=0.27) in lean patients compared to overweight patients.

We separated patients based on BMI in obese (n=10, 4 males, 58.6±10.5 years), lean (n=23, 12 males, 46.8±14.0 years), and slightly obese (BMI between 25-29.9 kg/m², n=17, 11 males, 55.2±11.0 years), and we compared the subgroups. The presenting symptoms were similar in the 3 subgroups, with almost half of the subjects with reflux symptoms and/or dysphagia. Obese subjects were significantly older compared to lean subjects (p=0.02). Eight out of 10 obese patients, had type II EGJ morphology, and one had type III morphology. Among the lean subjects, 12 (54.2%) had type II EGJ morphology, and the remaining had type I morphology. In overweight subjects, 50% had type I EGJ morphology, and none had type III. Consequently, a clear demarcation between LES and crural diaphragm was observed in 8/10 obese subjects, 7/23 lean subjects, and 5/17 overweight subjects. The morphology of esophago-gastric junction differed between obese and lean subgroups (chi-square test = 4.3, p=0.04).

Obese patients had higher EGJ length, but the difference was not significant (4.3±2.0 vs. 3.4±1.0, p=0.11). The resting pressure of the LES (34.1 ±6.5 mmHg vs. 35.8±12.5 mmHg, p=0.67), the mean IRP (16.8±3.0 mmHg vs. 17.6±6.6 mmHg, p=0.69), the esophageal length (21.3±3.8 cm vs. 22.9±2.4 cm, p=0.15), and the DCI (1225±513 vs. 1487±809, p=0.35) were lower in obese compared to lean subjects, but the differences were not significant.

Conclusion: Obese subjects were more likely to have a clear separation between LES and crural diaphragm, and a type II or III EGJ morphology. With the limitation induced by the small number of subjects, our study did not find significant changes in the manometry parameters in obese versus lean subjects.

ANXIETY, DEPRESSION AND QUALITY OF LIFE PATIENTS WITH FUNCTIONAL DYSPEPSIA: A CROSS-SECTIONAL STUDY

T. Kugler¹

¹Donetsk National Medical University named M.Gorky, Internal Medicine, Donetsk, Ukraine

Contact E-Mail Address: kugler2@mail.ru

Introduction: Functional gastrointestinal disorders are often associated with changes in the psycho-emotional sphere [1,2]. However, data on the contribution of anxiety and depression in the patient's quality of life (QOL) are insufficient. The urgency of the problem is determined by the fact that functional diseases mainly affect young people of working age. This makes the problem not only medical but also social.

Aims & Methods: The aim of this study was to evaluate the clinical characteristics of anxiety and depression in different subtypes of functional dyspepsia (FD) group in comparison with control group and to establish the presence of a possible correlation between anxiety/depression and QOL. 125 patients with FD (Rome criteria IV) and 70 healthy volunteers were included in cross-sectional study. All participants filled out a HADS scale to identify anxiety/depression, SF-8 questionnaire (standard 4-week form) to assessment of the quality of life, Leuven postprandial distress scale (LPDS) to rate the severity of epigastric pain (burning) or abdominal discomfort. Data were evaluated with MedStat and NCSS (PASS 11). Linear regression analysis was performed in the case of functional relationships between two groups of random variables. Results obtained with p<0.05 and 95% CI were considered statistically significant.

Results: Anxiety and depression were observed in 50.4% and 42.4% of FD patients, respectively, and in 13.3% and 6.66% of healthy volunteers (p<0.001). The average anxiety score in FD patients was higher than in control (7.93 vs. 4.17; p<0.001), with max 17. The average score of depression in FD patients was also higher (6.94 vs. 3.4; p<0.001), with a max of 15. All patients with FD had a low level of QOL, both due to physical health (PCS) and emotional and psychological components (MCS) compared to controls (p<0.001).

		FD group		Control group	
Factors		Anxiety	Depression	Anxiety	Depression
Sex	Male	6,54±3,55†	5,86±3,57*	4,96±2,76	3,17±2,79
	Female	8,54±3,70†	7,47±3,80*	3,56±2,13	4,20±3,31
Subtype	PDS	7,43±3,56*	6,90±3,71*		
	EPS	8,18±3,57*	6,45±3,80		
	Overlap	8,5±4,06*	7,16±3,96*		
Severity of symptoms	Moderate	7,92±3,74†	6,94±3,78†		
	Severe	7,96±3,80†	7,06±3,80†		
Duration	< 3 years	7,45±3,67*	6,54±3,76*		
	3-5 years	7,12±3,88*	6,96±3,89*		
	> 5 years	8,01±3,47*	7,34±3,23*		

Table 1. HADS indicators of FD and control groups (note: * - p < 0,05 in comparison with the control group, † - p < 0,05 in comparison with the control group and intragroup indicators).

A positive correlation was found between the level of anxiety, depression and the severity of clinical manifestations of the disease ($R = 0.353$ and $R = 0.291$ $p < 0.05$). A negative correlation was observed between the severity of dyspepsia and the QOL of patients ($R = -0.264$, $p < 0.05$). The linear correlation was found between the QOL (PCS) and depression ($R = -0.311$, $p = 0.004$). The linear regression equation is: $PCS = -0.6441 * HADS-D + 50.27$.

Conclusion: Mental disorders are associated with changes in visceral sensitivity in FD patients, who perceive pain impulses as aggravated. This includes the interaction and feedback mechanisms between changes in the gastrointestinal tract and psychological factors. The HADS assessment showed that anxiety outweighed depression.

The most significant factors influencing the level of anxiety and depressive disorders in FD group were the patient's gender and the severity of clinical symptoms. Self-reported symptom severity, anxiety and depression were clearly and independently associated with the QOL. This became an important tool for assessing the severity of the disease and the effectiveness of therapy.

P0043

DEFINING A THRESHOLD OF SEVERE FUNCTIONAL DYSPESIA FOR USE IN A CLINICAL SETTING

M.P. Jones¹, N.J. Talley², Y.A. Saito-Loftus³, F. Carbone⁴, J. Tack⁵
¹Macquarie University, School of Psychological Sciences, North Ryde, Australia, ²University of Newcastle, Faculty Of Health & Medicine, New Lambton Heights, Australia, ³Mayo Clinic, Gastroenterology & Hepatology, Rochester, United States, ⁴University of Leuven, TARGID, Leuven, Belgium, ⁵University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium

Contact E-Mail Address: mike.jones@mq.edu.au

Introduction: The Rome IV criteria for functional dyspepsia¹ are the generally accepted diagnostic criteria for this condition and can be used to funnel patients into therapy. However these criteria are based primarily on symptom frequency rather than severity and therefore a diagnosis according to these criteria does not automatically mean that a patient has a symptomatically severe condition. Symptom severity might affect the clinician's decision on whether to initiate treatment and what form of treatment to apply. Other equivalent conditions do have thresholds set for defining mild, moderate and severe symptoms including irritable bowel syndrome².

Aims & Methods: This study aimed to define a threshold for symptoms that define a severe condition.

Study data: Data from two completed clinical trials were employed in this study. The first was the Functional Dyspepsia Treatment Trial (FDTT, $n = 292$)³ which compared two antidepressants and a placebo while the second was a trial comparing the prokinetic Itopride with placebo⁴ ($n = 100$). Since only the baseline (pretreatment) time point was used in each study all patients from all study arms were included.

Symptom thresholds: The symptom severity was first evaluated from the symptom score from the Nepean Dyspepsia Index (NDI)⁵ was considered once including all symptoms (AllSx) and again considering only symptoms relevant to the Rome IV criteria (RomeSx). Generalizability was enhanced by replicating with the Leuven Postprandial Distress Scale (LPDS)⁶.

Analytic approach: The shape of the relationship between symptom severity measures and independent anchors was evaluated in the FDTT and a threshold for severe symptoms was established based on the upper tertile (1/3) of the distribution symptom scores. These results were replicated in the Itopride trial in which additional patient psychosocial anchors were available.

Finally, discrimination of high scores on the overall symptom score (OSS) measure by the defined severity thresholds were evaluated for the NDI symptom score and the LPDS.

Results: In the FDTT RomeSx correlated well with the gastrointestinal symptom rating scale (GSRS, $r = 0.56$), all dimensions of the NDI ($r = -0.43$ to -0.53) physical ($r = -0.46$) but not mental ($r = -0.20$) of the SF-36, nutrient drink test volume ($r = -0.35$) but not scintigraphy measured gastric emptying half-time ($r = -0.01$). Similar correlations were obtained for AllSx. The upper tertile for RomeSx was scores of 78 or greater while for RomeSx it was 29 or greater. Use of this threshold was associated with Cohen d effect sizes of 1.04 (> 0.8 indicates large effect) for the GSRS and between 0.87 and 1.26 for the NDI QoL domains.

In the Itopride trial, the AllSx and RomeSx correlations with the NDI QoL were replicated and additional correlations with the PAGI-Sym⁷ and OSS ($r = 0.44$ and 0.47) were demonstrated. Further, the LPDS correlated with the OSS ($r = 0.55$ for PDS and $r = 0.41$ for EPS). Use of the FDTT-defined thresholds yielded Cohen d values -0.80 for AllSx and -1.11 for RomeSx. The upper tertile of the PDS domain of the LPDS corresponded to values of 2.4 and above while for the EPS domain it was values 0.7 or above. Use of these thresholds yielded Cohen d values -1.27 for PDS and -0.82 for EPS for the OSS and based on the total PAGI-SYM score values of -0.98 for PDS and -1.53 for EPS.

Conclusion: Symptomatically severe functional dyspepsia can be defined by scores on either of two validated measures, the NDI and LPDS. Thresholds defined for both instruments have been demonstrated to correspond to symptomatically severe disease and with impact on other aspects of patient wellbeing.

DUAL ASSESSMENT OF GASTRIC FUNCTION WITH SIMULTANEOUS GASTRIC EMPTYING AND BODY-SURFACE GASTRIC MAPPING IN PATIENTS WITH GASTROPARESIS-LIKE SYMPTOM AND FUNCTIONAL DYSPESIA

I.-H. Huang^{1,2}, A.A. Gharibans^{3,4}, G. Schamberg³, S. Calder³, S. Pellens¹, L. Holvoet¹, C. Varghese⁴, K. Verbeke¹, G. O'Grady^{4,3}, J. Tack¹

¹Translational Research Center for Gastrointestinal Disorders, University of Leuven, Leuven, Belgium, ²Tri-Service General Hospital, National Defense Medical Center, Department of Gastroenterology and Hepatology, Taipei, Taiwan, ³Alimetry Ltd, Auckland, New Zealand, ⁴University of Auckland, Auckland, New Zealand

Contact E-Mail Address: albertstgsh@gmail.com

Introduction: The distinction between patients with gastroparesis (GP) from those with functional dyspepsia (FD) is a matter of ongoing debate. The current diagnostic armamentarium is limited to the endoscopy and gastric emptying tests (GET). The recent European consensus defined GP as a condition characterized by delayed gastric emptying in the absence of mechanical obstruction, with a symptom pattern of predominant nausea and/or vomiting and overlapping postprandial distress syndrome (PDS)¹. FD is defined by predominant PDS or epigastric pain syndrome (EPS) symptoms². Body surface gastric mapping (BSGM) has recently emerged as a new non-invasive diagnostic strategy.

Aims & Methods: Aim: To investigate myoelectrical abnormalities in patients with GPLS and FD using BSGM.

Methods: Consecutive patients with chronic gastric symptoms undergoing a GET (breath tests with a C13-octanoic acid labelled 250 kcal solid meal) were invited to participate. Exclusion criteria were organic gastrointestinal diseases and history of abdominal surgery. BSGM was performed simultaneously using a novel medical device (Gastric Alimetry, Alimetry, New Zealand), employing stretchable electronics attached to a wearable Reader over the epigastrium (8x8 electrodes; 225 cm²).

Symptoms of nausea, bloating, upper gut pain, heartburn, stomach burn, and excessive fullness were logged at 15 min intervals in a validated app (30min fasting, 4hr postprandially) and combined to form a "Total Symptom Burden" score. GPLS (nausea and/or vomiting ≥ 1 day/week and simultaneous PDS) and FD (PDS or EPS) were defined based on the Rome IV diagnostic questionnaires.

BSGM data included amplitude, dominant frequency, stability index (percentage of activity concentrated in a narrow frequency band across time), meal response (fed-fasting power ratio) and slow wave direction. Data are presented as median (interquartile range). Mann-Whitney U and Pearson's chi-square tests were performed, with comparisons to a reference range of >100 healthy controls.

Results: At interim analysis, 21 patients with GPLS and 16 with FD (14 PDS, 1 EPS, 1 overlap PDS-EPS) were analyzed. BSGM abnormalities were detected in 20 patients (54.1%). The prevalence of delayed gastric emptying (half gastric emptying time (T1/2) > 109 min) was 21.6% in GPLS and 12.5% in FD (p=0.24). Total Symptom Burden Score was not significantly different between GPLS and FD (14.3 (7.2-38.2) vs 9.8 (2.6-18.1), retrospectively, p=0.11).

There were no significant differences in dominant frequency, meal response and percent of retrograde propagation between the two groups. FD patients demonstrated lower average postprandial amplitudes (32.70 μ V (26.52-36.75) vs 42.04 μ V (33.70-50.74), p=0.04) and less stable myoelectrical activity evidenced by a lower stability index (27.6 (24.7-31.2) vs 33.0 (27.8-37.3), p=0.03).

Characteristics	GPLS (n=21)	FD (n=16)	P value	BSGM variables	GPLS (n=21)	FD (n=16)	P value
Female	17 (81.0%)	13 (81.3%)	1.00	Dominant frequency (CPM)	3.03 (2.95-3.16)	3.05 (2.87-3.26)	0.97
Age (years)	29.0 (26.0-41)	31.0 (22.8-58.5)	0.81	Amplitude (μ V)	42.04 (33.70-50.74)	32.70 (26.52-36.75)	0.04
BMI	22.5 (20.5-25.5)	23.4 (20.7-25.5)	0.74	Stability index	0.33 (0.28-0.37)	0.27 (0.25-0.31)	0.03
T1/2 (min)	87.0 (66.0-111.0)	87.5 (79.5-97.8)	0.77	Meal response	1.17 (1.05-1.80)	1.50 (1.24-1.89)	0.21
Delayed gastric emptying	6 (28.6%)	2 (12.5%)	0.24	Retrograde propagation (%)	0 (0-6.7)	0 (0-2.8)	0.72

Table.

Conclusion: Patients with GPLS and FD demonstrated a high rate of gastric myoelectrical abnormalities on BSGM. Attenuated amplitude and reduced stability index in FD indicates contributing underlying neuromuscular abnormalities. Adding BSGM to a diagnostic pathway is feasible in clinical settings and may increase identification of gastric dysfunction vs GET alone. Ongoing patient recruitment will further define relationships between BSGM and these two groups of patients.

CHRONOTYPES CORRELATES WITH PRESENCE AND SEVERITY OF UPPER GASTROINTESTINAL TRACT SYMPTOMS AND AFFECTS PATIENT'S QUALITY OF LIFE

S. Rurgo¹, M. Pesce¹, V. Vaino¹, M. Pagliaro¹, P. Senneca¹, G. Di Giorgio¹, B. Guida¹, G. Sarnelli¹

¹University of Naples "Federico II", Clinical Medicine and Surgery, Naples, Italy

Contact E-Mail Address: sararurgo91@hotmail.it

Introduction: Chronotype is the phenotype of behaviors controlled by the unique circadian rhythm possessed by individuals. Chronotype is under the control of finely regulated neuro-hormonal pathways and affects the sleep-wake cycle of a person. Circadian rhythms regulate multiple aspects of gastrointestinal physiology and recent evidence suggested their implication in symptoms' generation. Symptoms associated with disorder of gut-brain interaction negatively affect patients' quality of life and are associated with sleep disturbances. No structured studies have examined the chronotypes in patients with non-organic symptoms of the upper gastrointestinal tract.

Aims & Methods: To clarify the association between chronotypes, presence and severity of upper gastrointestinal tract diseases and their impact on quality of life. The subjects were 130 consecutive patients referring to the outpatients clinic for upper gastrointestinal symptoms (88 female, age 37 $\pm$ 13 years).

All subjects had a clinical and instrumental diagnosis of GERD or functional dyspepsia (FD). Subjects with underlying organic diseases were excluded. The standardized PAGI questionnaire was administered to all participants in order to assess the type, the severity and the impact on quality of life of specific symptoms.

Participants' chronotype, was assessed by the standardized Morningness-Eveningness Questionnaire (MEQ). The MEQ consists of 19 multiple-choice questions regarding sleep habits and daily performance, such as when feeling most productive in physical or mental activities, when feeling most tired, and when feeling most energetic. Patients were classified into morning, or evening chronotypes and GI symptoms analyzed, respectively.

Results: Thirty-four and 96 were classified as evening or morning chronotypes, respectively. Symptom's severity and relative impact on QoL significantly correlated with chronotype score ($r^2=0.1$ and 0.2 , respectively, all $p<0.05$). Patients with evening chronotype had significantly higher severity score than morning behavior (30 ± 17 vs. 15 ± 9 , $p<0.01$). A further analysis showed that dyspeptic (25 ± 14 vs. 11 ± 9 , $p<0.01$) but not Gerd-related symptoms (5 ± 3 vs. 3.8 ± 1.2 , $p=ns$) were significantly increased in evening chronotypes, with higher severity scores for postprandial fullness and epigastric bloating being observed (3.3 ± 0.8 vs. 1.8 ± 0.5 and 2.6 ± 0.6 vs. 1.3 ± 0.3 , $p<0.05$ and $p<0.01$, respectively). No significant differences were observed for the other symptoms.

Conclusion: We showed that chronotype correlates with upper gastrointestinal symptoms, with patients with an evening chronotype having more severe dyspeptic symptoms. Our findings suggest the involvement of disrupted circadian rhythms in the pathophysiology of dyspepsia and pave the way to alternative and personalized therapeutic approaches.

ASSESSING PREVALENCE AND CLINICAL FEATURES OF POSITIVE HYDROGEN BREATH TESTS IN PATIENTS REFERRED TO A TERTIARY UNIT, WITH SPECIAL ATTENTION TO FUNCTIONAL GASTROINTESTINAL CONDITIONS AND HEDS

H. Dervin¹, N. Zarate¹, R. Sweis¹, A. Mensah¹, K.C. Fragkos¹, C. Brugaletta¹, A. Raeburn¹, A. Emmanuel¹

Introduction: Hydrogen breath testing (HBT) is often used to diagnose small intestinal bacterial overgrowth (SIBO), however their specificity and sensitivity is poor and their role in the clinical management of patients with functional and motility disorders affecting the gut is controversial (Rezai et al. 2017).

It is known that patients with certain conditions are at higher risk of developing SIBO; however there is little evidence of its prevalence in congenital connective tissue disorders, particularly hypermobility type Ehlers Danlos Syndrome (hEDS).

Aims & Methods: We aimed to:

1. Assess the prevalence of positive HBT in patients referred to a tertiary unit with particular interest in the prevalence of patients with functional gut disorders and hEDS,
2. Evaluate the potential predictive value of GI symptoms on different cohorts of patients referred for SIBO test,
3. Evaluate the potential role of other factors such as PPIs on influencing a positive HBT diagnosis.

Consecutive patients referred to UCLH GI Physiology Unit for a HBT from January 2017 to January 2020 were included in the study. Patients typically presented with chronic (>3 months) lower GI symptoms. HBT was conducted as per published standard recommendations (Rezaie et al. 2017). Patients were classified in the following groups according to the most relevant diagnosis for referral: functional colorectal disorders; GI Maldigestion/malabsorption (i.e IBD, pancreatitis), Sensorimotor Disorders (i.e diabetes mellitus, radiation enteritis) and hEDS.

Descriptive statistics and median with interquartile ranges were used to describe the patient groups. A univariate analysis was used to compare the effect of the underlying disease on SIBO outcome using multiple predictors and chi-squared test.

Results: Over the 3-year period, a total of 1,062 HBT were performed. Seventy percent were female, with median age of patients being 47 (35- 60) years. Only, 7.5% (80/1062) patients were diagnosed as having a positive HBT. Prevalence of positive HBT was highest in patients with GI Maldigestion/Malabsorption (17.9%), Sensorimotor (15.9%), followed by functional disorders (1.6%). Interestingly, none of the hEDS patients tested positive for HBT (Table 1).

	N (Valid)	Gender [female (n, %)]	Age (years) [Median (IQR 25- 75 percentiles)]	Negative Test	Positive Test	Positive (%)
Functional	609	430 (70.6%)	43 (34.0-56.0)	599	10	1.6%
GI Maldigestion/ Malabsorption	273	183 (67.0%)	53.0 (37.0-68.5)	224	49	17.9%
Sensorimotor	132	86 (65.2%)	56.0 (43.0- 64.0)	111	21	15.9%
hEDS	48	45 (93.8%)	34.0 (28.0- 46.0)	48	0	0%
Total	1062	744 (70.0%)	47.0 (35.0-60.0)	982	80	7.5%

Table 1. Gender, age, percentage, frequency and total of each of the patient groups.

For the diagnostic accuracy of HBTs for all groups combined, the individual symptoms that had the highest diagnostic yield were diarrhoea, followed by fluctuating bowel habit. The remaining symptoms have no predictive value. A total of 531 patients had PPI usage recorded, with 137 of these patients (25.8%) fulfilling the criteria for long-term PPI use. Patients on PPIs were more likely to have a positive HBT than patients off PPI (16.1%vs6.9%; $p<0.0001$).

Conclusion: We have demonstrated that patients with a medical history of GI maldigestion/malabsorption disorders and sensorimotor disorders have greater prevalence and incidence of positive HBT, compared to patients with functional disorders and hEDS. Patients on PPIs are more likely to have a positive HBT compared to those that are not. Symptoms, along with the patient's medical history, can be a helpful triage tool in making appropriate therapeutic decisions and avoiding unnecessary hydrogen breath testing.

QUANTIFYING THE BURDEN OF FOOD RELATED ALLERGIC REACTIONS IN HYPERMOBILE EHLERS DANLOS SYNDROME

R. Topan¹, S. Pandya¹, S. Williams², J. K Ruffle¹, N. Zarate-Lopez³, Q. Aziz¹, A. Fikree¹

Introduction: Patients with Hypermobile Ehlers Danlos Syndrome (hEDS) – a connective tissue disorder with high prevalence of Gastrointestinal (GI) symptoms – commonly report allergic reactions. Mast Cell Activation Syndrome (MCAS) is often diagnosed, although the evidence for this association is unclear. Food is reported as a typical symptom trigger of these reactions, but there are no large scale studies to quantify this.

Aims & Methods: We aimed to investigate patient-reported reactions which are interpreted as allergic by hEDS patients, to determine the incidence and commonly associated triggers. We conducted a cross-sectional study from August '21 to January '22. hEDS patients from the charity organisation Ehlers-Danlos Support UK and tertiary Neurogastroenterology clinics completed questionnaires to identify reactions interpreted as allergic across four domains: gastrointestinal(GI), skin, cardiovascular and respiratory, and whether specific foods triggered symptoms.

Additional questionnaires assessed for the presence of Mast Cell Activation Syndrome(MCAS), Postural Orthostatic Tachycardia Syndrome(PoTS)), Anxiety and Depression(HADS-A/D),somatic symptoms(PHQ-15), autonomic symptoms(COMPASS 31) and Avoidant Restrictive Food Intake Disorder(ARFID). We used logistic regression with stepwise feature selection to ascertain which of the above factors were predictive of GI reactions interpreted as allergic.

Results: 681 participants responded (median: 39 years(range: 16-76), 95% female). 33.6% reported a diagnosis of MCAS; 49.0% reported a diagnosis of PoTS and 64.6% had an abnormal HADS-A score. Atopy was common – 42.8% asthma, 33.6% eczema and 50.2% hay fever. 64.7% reported allergic reactions, most commonly GI (abdominal pain(58.9%), bloat-

ing(58.4%) and diarrhoea(55.3%)) of which 85.4% were provoked by food. Food also provoked symptoms in skin(50.8%), cardiovascular(40.7%) and respiratory(35.6%) systems. 81% of patients reporting food-related allergies eliminated their food triggers; of these 90.1% reported subsequent symptom improvement. Specific foods associated with GI allergic type reactions included pickles(OR: 1.85, $p=0.03$), highly processed snacks(OR: 1.70, 95%, $p=0.03$) and wheat(OR: 1.70, $p=0.01$).

All other foods, including milk/dairy, nuts, eggs, fish, shellfish and alcohol were not significantly associated. After food, the most commonly reported triggers for GI reactions interpreted as allergic were stress(46.1%), medication(41.9%) and exercise(21.2%). Having a reported diagnosis of MCAS($p=0.04$) and a high HADS-A score ($p=0.04$) predicted having food related GI-symptoms, yet a reported diagnosis of PoTS or high COMPASS-31 score did not. 8.5% ($n=26$) of those reporting food related GI-symptoms were taking the supplement Quercetin of whom 96.2%($n=25/26$) found it helpful.

Although there was more use of antihistamines and mast cell stabilisers in those who reported GI symptoms compared to those who did not, these differences were not statistically significant.

Conclusion: The most frequent reactions interpreted as allergic in hEDS patients are abdominal pain, bloating and diarrhoea. Further work is needed to objectively determine whether these reactions are true allergies/intolerances. Food is the most common trigger whereby fermentable carbohydrates and highly processed foods are frequent culprits which can be considered for elimination. Quercetin is a potentially useful supplement which requires further study. Anxiety plays a role in the association between food and GI reactions interpreted as allergic, therefore addressing stress may be a crucial component of the management plan.

NO GENDER DIFFERENCES IN EOE DISEASE PRESENTATION, TREATMENT, AND COMPLICATIONS IN THE DANISH DANEEO COHORT – A POPULATION-BASED STUDY OF 236 PATIENTS

I. Kozon¹, L.T. Frandsen², B. Izgi¹, M.S. Trabjerg¹, L.E.M. Hansen³, D. Melgaard³, A.L. Krarup¹

Introduction: It is well known that there is a gender difference in the incidence eosinophilic oesophagitis (EoE) with more men affected. However, there is a lack of knowledge of gender difference in most other aspects of the disease.

Aims & Methods: This is a retrospective, registry-based, DanEoE cohort study of 236 adult EoE patients, (178 adult men and 58 adult women) diagnosed in 2007-2017 in the North Denmark Region. Medical registries were searched for patient files and pathology reports. We aimed to estimate the differences in phenotype, treatment, and complication rate between gender.

Results: There were no statistical or clinical significant differences in the phenotype regarding symptoms reported, macroscopic or histological findings at the diagnose (all $p>0.3$). However, a trend was observed towards 14% more men reporting allergy or asthma compared to women (61% men versus 47% women, $p=0.06$). A comparable number of men and

women were followed up symptomatically and histologically (all $p>0.3$). More men reported “no symptoms” on PPI (men 56% versus 39% women, $p=0.04$) although the histological response was not different between genders ($p=0.4$). The proportion of food bolus obstructions and dilations were comparable (all $p>0.4$).

Conclusion: In this study very few gender differences were found. Results suggests that men and women with EoE can be managed equally clinically. We did not find the expected gender differences as described in other gastrointestinal diseases.

Contact E-Mail Address: apslk@rn.dk

Introduction: Eosinophilic oesophagitis (EoE) is a chronic, immune-mediated, or antigen-mediated oesophageal disease characterized by symptoms related to oesophageal dysfunction and eosinophil-predominant inflammation.

Aims & Methods: To estimate the incidence and prevalence of EoE in Denmark during the period 2008-2018.

Based on data from nationwide registers we identified cases of EoE using two definitions: a broad definition based solely on oesophageal biopsies registered in the Danish Pathology Register and a narrow definition also including symptoms of oesophageal dysfunction registered in the Danish National Patient Registry.

The annual incidence and prevalence were standardized by sex and age in 5-year intervals to the 2013 study population.

Results: From 2008 to 2011, the standardized incidence of EoE (using the broad definition) was stable, but from 2011 to 2018 it increased from 3.9 (95% CI 3.3-4.4) to 11.7 (95% CI 10.8-12.6) per 100,000 person-years. Similar temporal trends were observed when using the narrow EoE definition.

The increase in incidence was most pronounced in men and in individuals above 40 years of age. In children, the EoE incidence was a fourth of the incidence in adults aged 40-64 years: 4.4 (95% CI 3.2-5.6) vs 17.6 (95% CI 15.7-19.5) per 100,000 person-years.

Overall, the biopsy rate as well as the proportion of oesophageal biopsies with detected eosinophilia increased during the study period.

Conclusion: This study of the entire population of Denmark during the period 2008 to 2018 shows that the incidence and prevalence of EoE is not yet plateauing and that EoE could be severely underdiagnosed in children.

Contact E-Mail Address: Christian.Otto.Mortensen@regionh.dk

Introduction: The population-based DanEoE cohort in the North Denmark Region is well described. Little is known of difference in EoE complications in the general population compared to patients at tertiary centres.

Aims & Methods: The aims of the study were to describe the EoE patient phenotypes and complications in a new cohort of adult EoE at an academic Hospital in the capital of Denmark. Secondly, to compare them to the population-based DanEoE cohort.

The EoE Copenhagen cohort included dysphagia patients with eosinophilia starting May 1st, 2013. Exclusion criteria were other causes of eosinophilia in oesophagus than EoE. From May 2013 to 20th of October 2017, strictly clinical data limited to the direct handling were recorded: Allergic disease, histological responses to treatment, pH and manometry results and complications. From 20th of October 2017 to 31st of December 2020 detailed information were entered in the same database as the population-based DanEoE cohort.

Two experienced gastroenterologists and EoE experts (IBA, CM) evaluated and entered all data. The index endoscopy was defined as the first endoscopy with biopsies showing oesophageal eosinophilia. In both cohorts the EoE diagnose followed the AGREE consensus.

Results: The 245 EoE patients in the Copenhagen cohort were 1) less likely to have comorbid GORD, 2) be of male gender, 3) younger both at symptom debut, and at the EoE diagnose (all $p < 0.05$). At the index endoscopy less endoscopists had suspected EoE as a diagnose (EoE Copenhagen: 11 % versus DanEoE: 78 %, $p < 0.001$). The findings at the endoscopy were very similar except for edema being described more often in the EoE Copenhagen cohort ($p = 0.01$).

Dilations were rarely necessary in both cohorts. However, dilations after the diagnose was more frequently done in patients from the Copenhagen cohort (EoE Copenhagen cohort 9.5 % versus DanEoE cohort 7.1 %, $p = 0.5$).

Conclusion: The results indicated that patients referred to the Danish academic centre had earlier symptom debut, were diagnosed earlier, had more fibrotic disease, and less comorbid GORD. This indicate that studies based on patients from Academic centres are not comparable to studies based on the general population.

DELAYED DIAGNOSIS OF EOSINOPHILIC OESOPHAGITIS IN THOSE PRESENTING TO THE EMERGENCY DEPARTMENT WITH FOOD BOLUS IMPACTION

D.A. Gyimah¹, H. Khan¹, B. Abdalla¹, H. Haboubi¹

¹University Hospital Llandough, Cardiff & Vale University Healthboard, Gastroenterology, Cardiff, United Kingdom

Contact E-Mail Address: dagymah1@gmail.com

Introduction: Food bolus impaction can be a manifestation of chronic untreated inflammation in those with underlying eosinophilic oesophagitis (EoE). The eosinophil predominant inflammation of the oesophagus is associated with a higher prevalence of fibrosis when it remains undetected and untreated. Non-malignant food bolus impaction is strongly associated with an underlying diagnosis of EoE, but outside of gastroenterology and other oesophageal interested specialists there remains poor understanding of how to diagnose and manage this condition.

Aims & Methods: We conducted a retrospective study of patients presenting to a tertiary emergency unit with oesophageal food bolus impaction between November 2018 and May 2021. Electronic attendance records and the endoscopy database were examined to determine the associations between demographics, comorbidities, endoscopic findings, biopsy findings and follow up. We also evaluated the effect of the pandemic on food bolus management with statistical analysis undertaken using IBM SPSS software.

Results: Of the 938 patients who presented to the emergency department with food bolus impaction, 83.6% were sent home with no follow up. Only 7.2% went on to have an endoscopy. In those with macroscopic evidence of inflammation, only 35.8% of patients had the correct number of biopsies taken to establish a histological cause for their symptoms. 1.6% of patients demonstrated histological evidence of EoE, of whom 80% were male and 20% female. The COVID-19 lockdown did not negatively impact access to endoscopy with mean wait time improving from 121-days prior to lockdown compared to 69-days during lockdown, $p < 0.01$.

Conclusion: Our findings highlight significant shortcomings in the management of those presenting emergently with food bolus impaction and possible undiagnosed EoE. There remains a need for clear management pathways to aid risk-stratification, discharge planning and endoscopic practices in the diagnosis of EoE. We therefore propose an algorithm for food bolus management to facilitate early endoscopy, effective diagnosis, and appropriate follow-up, ensuring optimal management for patients with non-malignant dysphagia requiring emergency admission for resolution of food impaction.

Introduction: Eosinophilic esophagitis (EoE) is a chronic immune-mediated condition characterized by eosinophilic infiltration of the esophageal mucosa. Endoscopic findings in EoE may be non-specific. The diagnosis is confirmed by histology with the finding of ≥ 15 eosinophilic granulocytes per high power field (HPF). The distribution of EoE may be patchy, hence, multiple biopsies from ≥ 2 segments are generally recommended to avoid false-negative diagnosis.

Aims & Methods: This study aims to evaluate whether chromoendoscopy with Iodine-Potassium iodine solution (IPIS) can improve the detection of EoE. Normal mucosa takes up IPIS and is stained dark brown, while mucosa with diminished uptake of IPIS becomes egg-yellow. Patients with dysphagia underwent gastroscopy with IPIS 1 % staining of the esophagus. A minimum of two biopsies were taken in ≥ 2 segments of the esophagus. In patients with heterogeneous staining after IPIS, selective biopsies were taken from areas with and without IPIS uptake, and forwarded separately for histological analysis.

Results: 52 patients were recruited prospectively. 31 (60%) of them had histologically proven EoE, of whom 11 (35 %) had normal endoscopic findings before installation of IPIS. All patients with EoE had diminished uptake of IPIS in whole or parts of the esophagus, giving a sensitivity of 100 % and a specificity of 78 %. The area under the receiver operating characteristic curve was 0.86. We identified three IPIS uptake patterns in EoE; 16 patients (53%) had diminished uptake in the whole esophagus, five (17%) had segmented and nine (30%) had a patchy pattern.

Of the 21 patients without EoE, seven (33 %) had diminished uptake of IPIS, of whom all had other identifiable diseases of the esophageal mucosa, including scleroderma, lymphocytic esophagitis, and squamous cell neoplasia. In patients with EoE and segmental or patchy IPIS patterns, the median number of eosinophils was significantly higher in areas with diminished uptake of IPIS, compared to areas with normal uptake (86 versus 7 eosinophils/HPF, $p=0.01$).

Conclusion: Our study suggests that around 35% of patients with EoE have normal endoscopic findings. Three IPIS uptake patterns can be seen in EoE. Biopsies taken from areas with diminished IPIS uptake show a significantly higher number of eosinophilic granulocytes, suggesting that the IPIS stain reflects the distribution of inflammation in the esophageal mucosa. Chromoendoscopy with IPIS may therefore be an useful in vivo technique for identifying EoE during endoscopy, allowing targeted biopsies, and thus increasing diagnostic sensitivity. IPIS staining is also useful for the identification of other mucosal conditions which cause dysphagia such as scleroderma, lymphocytic esophagitis, and squamous cell neoplasia.

Contact E-Mail Address: apslk@rn.dk

Introduction: The DanEoE is a previously described population- and register-based cohort of 236 adult patients with eosinophilic oesophagitis (EoE) in a well-defined Danish region with a population of 580.000 and free medical treatment.

Aims & Methods: To compare the phenotype and treatment response between EoE patients with complications to patients without complications at diagnosis.

Results: At the diagnostic endoscopy 61 % had never had a complication, and 39 % had had either FBO (n 77) or been dilated (n 15). The Complicated group had the same mean age at symptom debut (37 (16) versus 37 (17) years, $p = 1.0$), but were diagnosed significantly later (age: 49(15) versus 45(15) years, $p = 0.04$) with a resulting longer diagnostic delay (13(13) versus 7.9(11) years, $p = 0.01$). The complicated group were more often on a proton pump inhibitor at the time of diagnosis, complained more often of dysphagia, had rings or stenosis more frequent, but less often erosive oesophagitis (all $p < 0.05$).

Almost half of all patients were never treated to symptomatic remission (uncomplicated 40 %, complicated 49 %). The histological remission were not secured in the majority (uncomplicated 68 %, complicated 70 %). Despite this, less than 15 % of patients with previous FBO experienced this after the diagnose.

Conclusion: Results indicated that the complicated EoE phenotype at time of diagnosis was a patient with a five year longer diagnostic delay, and rings or stenosis already present. In the current study complication status did not determine treatment responses.

Introduction: Cow's milk protein is the main food trigger for eosinophilic esophagitis (EoE) in both children and adults, and should be continuously avoided from diet once identified as such.

Aims & Methods: This study evaluates tolerance of sterilized cow's milk (boiled instead of UHT processing) with regards to EoE remission maintenance, quality of life, nutritional intake and allergic sensitization in patients of all ages with milk-triggered EoE.

Eighteen patients in whom cow's milk was demonstrated to trigger EoE after empiric food elimination diet-based study, were prospectively recruited. They were given 200 mL of sterilized cow's milk twice daily for 8 weeks. Endoscopic assessment, intraepithelial peak eosinophil counts, esophageal-related symptoms, quality of life, blood eosinophils, eosinophil cationic protein, skin prick test and serum total and specific IgE to major milk proteins, were monitored before and after sterilized milk intake.

Results: Eighteen patients (mean±SD age 32±13.4 years, range 13 to 59 years; 13 male) with EoE triggered by milk who were in clinical and histologic remission underwent to a challenge with commercially available sterilized milk. After 8 weeks of daily intake, EoE remained in histological remission (<15 eos/hpf) in 12 out of the 18 EoE patients (66.7%), but EoE recurrence (≥15 eos/hpf) was documented in the remaining 6 patients.

Median±IQR baseline symptoms scored with DSS were 4±6 (range: 0-9) in the whole series, with no significant differences between patients who tolerated and not the sterilized milk. After sterilized milk challenge, tolerant patients maintained symptoms unchanged, but these tended to increase to 9±3.8 among milk-reactive subjects.

The esophagus was described as normal in all patients at baseline (ERFES score being 0), and remain unchanged in patients who maintained histological remission. In contrast, the median±IQR ERFES score increased up to 2.5±2.5 (range: 0-4) in patients who presented EoE recurrence after sterilized milk challenge. This increase was evidenced at the expense of inflammatory findings (edema, furrows and exudates), since no features of fibrosis were observed.

No differences in age, gender, symptoms score, endoscopic appearance, or personal/family allergic background were observed between those patients who tolerated the sterilized milk and those who did not.

Blood eosinophilia were in normal values at baseline, and tended to increase after sterilized milk challenge only in reactive patients who presented EoE recurrence. As for milk sensitization evaluation, total and milk specific IgE serum levels did not changed after sterilized milk consumption, with the exception of cow's milk specific IgE in reactive-EoE patients (median ± IQR increasing from 0.07±0.08 to 0.12±0.11, p=0.041 after sterilized milk challenge). Changes in eosinophilic cationic protein and tryptase were not significant from baseline in either tolerant and reactive patients. SPT to milk resulted negative in all the 18 but one participant at baseline. EoE-QoL-A score did not change significantly from baseline among patients who tolerated sterilized milk.

However, QoL significantly impaired among patient who did not tolerate sterilized milk, both in terms of the global score and the subscores corresponding to the dimensions Diet/eating Impact, Social Impact and Emotional Impact.

Conclusion: Most patients with EoE triggered by milk proteins are able to tolerate sterilized milk, with no signs of disease recurrence. This allows to improve patient's diets while maintaining an adequate disease control.

Disclosure: Nothing to disclose.

Introduction: Eosinophilic oesophagitis (EoE) is a chronic inflammatory disease characterised by a dense eosinophilic infiltration of the oesophagus.

gus and symptoms of oesophageal dysfunction. EoE represents a particular form of non-IgE-mediated food allergy that frequently associates to concomitant Th2 atopies. EoE often occur in families with several members affected. In addition, environmental factors and early life exposures have been involved in triggering EoE. However, limited information has been provided on the clinical differences between sporadic and familial EoE, and we do not know whether environmental risk factors to EoE influence differently on patients who have a family history of the EoE and those who do not.

Aims & Methods: To assess differences in demographic, clinical, endoscopic, pathological and environmental characteristics of familial EoE compared to sporadic cases. A cross-sectional analysis of the “European Registry of Clinical, Environmental and Genetic Determinants in Eosinophilic Oesophagitis” (EoE CONNECT) was performed to evaluate demographic, clinico-histological and early life factors in familial and sporadic cases of EoE. Statistical analyses (Mann-Whitney test and Kruskal-Wallis test for continuous variables and Chi-squared test for categorical variables) were performed using SPSS software.

Results: Data from 1,422 patients of EoE were analyzed (1,281 sporadic and 141 EoE patients with other relatives affected). Age at diagnosis was significantly lower in patients with familial EoE compared to sporadic disease (26.7±16.2 vs. 31.6±16.2; p=0.001). Patients with sporadic EoE tended to present greater diagnostic delay than familial cases (4.15±6.32 vs. 3.53±5.61 years; p=0.112), higher EREFS (Edema-Rings-Exudates-Furrows-Stricture) score (2.48±1.97 vs 2.71±1.73, p=0.13), peak eosinophil count (53.4±37.6 vs 50.2±29.8; p=0.79) and stricturing or mixed phenotypes, compared to familial cases.

However, none of this comparison achieved statistical significance. Regarding early-life exposures, antibiotic use during the first year of life, cesarean section delivery, preterm birth, contact with animals, place of residence (rural, urban or mixed), consumption of fast food in childhood and breast, formula-only or mixed (infant formula and breast milk) feeding did not present significant differences (p>0.05) between the group of patients with family history of EoE and those without.

	Overall (n=1422)	Esporadic cases (n=1281)	Familial cases (n=141)	p-value
Gender (n,%)				
Male	1084 (76,2)	981 (76,6)	103 (73)	0,35
Female	338 (23,8)	300 (23,4)	38 (27)	
Birth weight (Kg)	3,30±0,63	3,29 ±0,64	3,31±0,47	0,97
Age at diagnosis (years)	31,11±16,22	31,59 ± 16,16	26,73± 16,23	0,001
Diagnostic delay (years)	4,09±6,25	4,15 ± 6,32	3,53 ± 5,61	0,112
EoE Phenotype (n,%)				
Inflammatory	1035 (72,8)	923 (77,1)	112 (81,8)	0,40
Mixed	149 (10,5)	138 (11,5)	11 (8)	
Stenosing	150 (10,5)	136 (11,4)	14 (10,2)	
EREFS	2,64±1,68	2,73 ±1,69	2,61 ±1,86	0,32
DSS	8,16±3,36	7,79 ±3,58	7,95±3,32	0,73
peak eosinophils (eos/hpf)	53,19±35,61	53,42 ±37,57	50,20 ±29,78	0,79

Mean ± SD, Mann-Whitney test for continuous variables and Chi-squared test for categorical variables

Table 1. Demographic, clinical and histologic characteristics of familial EoE compared to sporadic cases.

Conclusion: This study suggests that patients with familial EoE are diagnosed at an earlier age than those presenting as sporadic cases, but neither the clinico-histological characteristics of the disease nor the early life exposures showed a differential influence over patients with or without familial EoE.

Disclosure: Nothing to disclose.

Introduction: Nitric oxide (NO) measurement is currently used in the setting of asthma patients' management as a marker of type 2 airway inflammation (1). NO is a crucial mediator also in the esophageal mucosa: luminal NO derives from exogenous (dietary) or endogenous sources, deriving from both constitutive and inducible isoforms of NO synthase (NOS): endothelial (eNOS) and neuronal (nNOS) NOS are physiological mediators of NO production at low concentrations, while inducible NO (iNOS) is an inflammation-induced enzyme, which can mediate production of high amounts of NO (2).

The esophageal luminal NO levels at fasting state might approximate iNOS activity and therefore mucosal inflammation. Non-invasively assessing esophageal inflammation might be important in the management of eosinophilic esophagitis (EoE). A non-invasive method for luminal esophageal gas sampling could consist in belch collection. The aim of this study was to assess the feasibility and standardize belch sample collection and NO analysis (Burp-Excreted++ Nitric Oxide – BuENO).

Aims & Methods: We consecutively enrolled 11 healthy subjects (6 females, mean age 41y±16; range 21-74). Belching samples were collected in the morning, after at least 8 hours of fasting to avoid exogenous NO formation. Subjects were instructed to close their nose with a clip and drink up to 500 ml of sparkling water to induce belching. When belching occurred, patients were instructed to keep the air in the closed mouth and expel it in an exhalation bag equipped with a unidirectional valve without blowing. The process had to be repeated until a sample of at least 200 ml was obtained. Samples were subsequently analyzed with a NO analyzer.

Results: Mean NO values were 734±889 ppb (Range 134-2585 ppb). No statistically significant difference was found between males and females. Values did not correlate with age or with the amount of sparkling water used. Two subjects showed values >1000 ppb, both referred typical gastroesophageal reflux symptoms during the night before the sample collection.

Conclusion: We set a protocol for belch collection and NO analysis. A first small sample of subjects showed values <1000 ppb with 2 exceptions, both referring gastroesophageal reflux disease, compatible with a situation of esophageal inflammation leading to activation of iNOS. The next phases of this study will enlarge sample size to obtain a normal range of values and to evaluate repeatability, and then assessing BuENO in patients with EoE. If validated, BuENO could represent a non-invasive method to detect esophago-gastric inflammation.

Introduction: Eosinophilic esophagitis (EoE) is an allergic inflammatory disease triggered by exposure to environmental or food allergens whose prevalence is increasing. It's clinical presentation is caused by altered motility resulting from permanent tissue swelling that causes subepithelial fibrosis.

Severe or long-standing cases develop fibrostenotic esophageal strictures that sometimes require endoscopic dilations, which carries the risk of complications. Therefore, treatment is necessary to achieve a clinical, endoscopic and histological response, either with proton pump inhibitors (PPI), topical corticosteroids or exclusion diets.

As of today, it is unknown whether there are characteristics to predict patients responding to PPI (PPI-REE) or non-PPI-REE, or if there is a correlation between non-PPI-REE and fibrostenotic development.

Aims & Methods: The aim is to determine whether patients with PPI-REE have personal history, environmental factors or clinical phenotype other than non-PPI-REE, to avoid using PPI in patients we know will not respond. A retrospective observational cohort study has been conducted. Patients diagnosed with EoE under the European and American Clinical Guide were included. Patients treated with exclusion diets and those with poor therapeutic adherence were excluded.

According to the clinical, endoscopic (EREFS score) and histologic response, patients were classified as complete, partial (clinical but not histologic) PPI-REE or non-PPI-REE. In addition, according to endoscopic findings, patients were classified as having an inflammatory or fibrostenotic phenotype.

The variables studied (Table 1) were obtained from the review of clinical, endoscopic and pathological reports. Statistical analysis was carried out by χ^2 of Pearson using the SPSS application.

Results: A group of 152 patients were analyzed in which the mean age of diagnosis was 40 years with a mean of 7 years of symptoms.

In 52.7% (80) complete PPI-REE was presented, 20.7% (32) presented partial PPI-REE and 26.6% (40) was non-PPI-REE. In the latter subgroup, 21.3% responded to corticosteroids and 5.3% did not respond to fluticasone/budesonide.

The analysis of variables (Table 1) did not show statistically significant differences between the PPI-REE and non-PPI-REE group, except for caesarian delivery, with a strong trend in favor of the non-PPI-REE group.

According to PPI response, 85.5% (94) of PPI-REE presented an inflammatory phenotype compared with 14.5% (16) of fibrostenotic. In non-PPI-REE patients, 75% (31) showed an inflammatory phenotype and 17.5% (7), a fibrostenotic phenotype. No association was observed between response type and phenotype (p 0.57).

Variables	Asthma	Rhinitis	Atopic dermatitis	Environmental allergy	Food allergy	Tobacco exposure	Pet exposure	Caesarean delivery
PPI-REE	35,5	50	31,8	68,5	31,2	46,4	22,7	10,1
NO PPI-REE	32,5	50	22,5	64,1	46,2	41,0	15,0	25,0
p valor	0,730	1	0,268	0,614	0,093	0,565	0,301	0,020

Table 1. Analysis of variables.

Conclusion: Given the exponential expansion in the incidence of EoE over the last two decades in the West, the possibility of knowing factors of non-PPI-REE patients would be a key tool for a therapeutic step-up strategy, which would reduce costs, endoscopies and active disease time.

This *ad hoc* study has not identified differentiating elements between the two cohorts, except for the caesarian delivery. It is clear that we still do not know about the response and the fibrous evolution of EoE, which prevents us today from predicting the natural history of the disease and the different clinical responses to the treatments available to us. Therefore, although it may be redundant, further research is needed.

EOSINOPHILIC ESOPHAGITIS: MOST NON-RESPONDERS TO FIRST COURSE OF PPIS ACHIEVE SUSTAINED HISTOLOGICAL REMISSION FOLLOWING SEQUENTIAL TREATMENT WITH TOPICAL STEROIDS AND SECOND COURSE OF PPIS MONOTHERAPY

P. Visaggi¹, A. Venturini¹, D. Stefani Donati¹, F. Baiano Svizzero¹, L. Mariani¹, M. Ghisa², B. Barberio², M. Bellini¹, E.V. Savarino², N. de Bortoli¹

Introduction: Proton pump inhibitors (PPIs) can be considered as first line treatment for eosinophilic esophagitis (EoE). When PPIs fail to achieve histological remission (i.e., eosinophils/high-power field - eos/HPF < 15), topical steroids (TS) can be used as second line. When patients report steroid-related side effects and decline treatment with elimination diets (ED), management becomes challenging. Little data regarding the efficacy of a second course of PPIs (scPPIs) in primary PPI non-responders is currently available.

Aims & Methods: We aimed at investigating if EoE patients who did not respond to a first course of PPIs and achieved histologic remission with subsequent TS treatment could be maintained in histologic remission with scPPIs monotherapy. We enrolled EoE patients who did not respond histologically (i.e., eos>15/HPF) to a 12-week course of high-dose PPIs who subsequently achieved histological remission following 12 weeks of second line therapy with topical steroids.

Among steroid responders (SR), those who complained of any steroid-related adverse event after a minimum of 12 weeks of treatment were offered a therapeutic switch to either ED or scPPIs. SR who had adverse events and opted for a therapeutic switch to scPPIs were evaluated histologically (minimum 4 esophageal biopsies) after 12 weeks of scPPIs.

Results: Among 68 primary PPIs non-responders who were SR, 18 patients (14M; 35.1±13yrs) reported adverse events after a minimum of 12 weeks of treatment (7 irritability, 6 edema, 4 oral candidiasis, 1 fatigue) and opted for scPPIs. Based on endoscopy with biopsies, 12 patients (10M, 34.3±13.8yrs) were scPPIs responders (scPPIs-R, i.e., eos/HPF<15), and 6 (4M, 36.8±13.4yrs) were scPPIs non-responders (scPPIs-NR, i.e., eos/HPF<15) at week 12. The two groups were comparable in terms of sex distribution, age at enrollment, age at diagnosis, smoking habits and coffee use, clinical presentation (dysphagia, chest pain, heartburn, regurgitation), history of asthma and food allergy. In contrast, scPPIs-NR more frequently drank >2 units of alcohol per day. Significantly more scPPIs-NR patients reported history of bolus impaction (scPPIs-NR=4 vs scPPIs-R=1, p=0.022) and had nasal polyposis (scPPIs-NR=5 vs scPPIs-R=1, p=0.004). Peak eosinophil count (PEC) was higher in scPPIs-NR at each histologic evaluation. scPPIs-R had higher although not significant prevalence of deep remission (i.e., eos<6/HPF) following steroid treatment (41.6% vs 0%, p=0.05). The EREFS score improved in scPPIs-R. Table 1 reports the most relevant clinical, endoscopy, and histology findings

	scPPIs responders (n=12)	scPPIs non-responders (n=6)	p value
EREFS score baseline (mean±sd)	3.5 ± 2.8	3.2 ± 2.6	0.82
EREFS score after first PPI course (mean±sd)	3 ± 1.9	3.2 ± 2.9	0.86
EREFS score after scPPIs (mean±sd)	1.3 ± 0.6	3.1 ± 2.4	0.02
PEC baseline (mean±sd)	31.5 ± 13.8	47.5 ± 16.4	0.04
PEC after first PPI course (mean±sd)	21.3 ± 3.2	32.9 ± 7.6	<0.001
PEC after scPPIs (mean±sd)	10.4 ± 4.1	27.9 ± 9.3	<0.0001
Previous bolus impaction (n/%)	1 (8.3%)	4 (66.7%)	0.02
Nasal polyposis (n/%)	1 (8.3%)	5 (83.3%)	<0.01
Alcohol >2 units/day (n/%)	1 (8.3%)	4 (66.7%)	0.02

Table 1.

Conclusion: scPPIs maintained histological remission for at least 12 weeks in 67% of primary PPI non-responder EoE patients who achieved histological remission with TS. History regarding bolus impaction, nasal polyposis, PEC, and deep remission following steroid treatment may identify patients more likely to achieve histological remission after scPPIs in case of primary PPI failure. Larger multicentric studies are needed to establish if this therapeutic strategy could be effective and widely applicable in the EoE setting.

Disclosure: Nothing to disclose.

CLINICAL HISTORY REPRESENTS A PERFECT SCREENING STRATEGY FOR EOSINOPHILIC ESOPHAGITIS IN PATIENTS REPORTING DYSPHAGIA: A CROSS-SECTIONAL CASE-CONTROL STUDY

P. Visaggi¹, D. Stefani Donati¹, F. Baiano Svizzero¹, A. Venturini¹, G. Del Corso², M. Ghisa³, B. Barberio³, R. Penagini⁴, M. Bellini¹, E.V. Savarino³, N. de Bortoli¹

Introduction: Eosinophilic esophagitis (EoE) is a chronic disease of the esophagus characterized by symptoms of esophageal dysfunction, including dysphagia and food impaction, which frequently presents in combination with atopy. The diagnosis requires at least 15 eosinophils per high-power field (eos/HPF) on at least one esophageal biopsy collected during an esophagogastroduodenoscopy (EGDS). Screening strategies to reduce the diagnostic delay of EoE are lacking.

Aims & Methods: We investigated if clinical characteristics could be used for the screening of EoE in patients with dysphagia. We included patients referred for dysphagia to the Esophageal Diseases Clinic of Pisa and Padua who had undergone an EGDS to rule out obstructive neoplasia within six months. All patients were screened for EoE with an EGDS (minimum 4 esophageal biopsies). Patients without EoE (eos/HPF<15) underwent esophageal high-resolution manometry (HRM) with reflux monitoring in case of gastroesophageal reflux disease (GERD) symptoms.

Consecutive patients with EoE complaining of dysphagia and controls with non-EoE dysphagia (NED) were enrolled in a 1:1 ratio. A detailed clinical history including age, sex, interval between symptoms onset and conclusive diagnosis (i.e., diagnostic delay), history of food impaction, allergic rhinitis, asthma, atopic dermatitis, and autoimmunity was recorded.

Differences in clinical characteristics between EoE and controls were assessed using the Student's *t*, Mann-Whitney *U*, or Chi-squared test when appropriate. Normality and heterogeneity of variances were investigated. A Monte-Carlo approach was used to find the optimal combination of clinical features providing a diagnosis of EoE. Significance threshold was *p* < 0.05.

Clinical characteristics	EoE patients (n = 20)	NED patients (n = 20)	p-value
Age (mean±sd)	40±14	54±18	0.005
Males/Females	16/4	10/10	0.047
Allergic Rhinitis (n/%)	15 (75%)	1 (5%)	<0.001
History of food impaction (n/%)	13 (65%)	4 (20%)	0.004
Asthma (n/%)	8 (40%)	3 (15%)	0.07
Atopic dermatitis (n/%)	2 (10%)	1 (5%)	0.08
Autoimmunity (n/%)	8 (40%)	3 (15%)	0.07

Table.

Results: Twenty patients with EoE (mean age 47±17 years, 16M) and 20 NED (mean age 54±18 years, 10M) were enrolled. The median diagnostic delay was 6 years (1.5-10.5) for EoE, and 3 years (1.3-6) for NED, *p*=0.4.

Among patients with NED, six had achalasia, five had a normal HRM (two GERD, one either myasthenia gravis, myotonic dystrophy, or no found cause), three had esophagogastric junction outflow obstruction, three hypercontractile esophagus, two absent peristalsis, and one distal esophageal spasm. Patients with EoE were significantly younger ($p < 0.01$), more frequently male ($p = 0.04$), more frequently reported a history of allergic rhinitis ($p < 0.001$) and food bolus impaction ($p = 0.004$) compared to NED. In contrast the two groups did not differ in terms of asthma, atopic dermatitis, and autoimmunity history.

Monte-Carlo analysis of the clinical characteristics that differed significantly between the two groups generated >50 predictive models for the screening of EoE. Among these, the model investigating male sex and/or the presence of allergic rhinitis performed best, with 100% sensitivity and 50% specificity for a diagnosis of EoE.

Conclusion: Performing an EGDS with multiple esophageal biopsies in a patient referred for non-neoplastic dysphagia, who is male or has allergic rhinitis, identifies 100% of EoE cases and avoids unnecessary biopsies in 50% of NED.

Despite this was a small cohort, the homogeneity of the two groups and the significance obtained strongly suggest that age, gender, history of rhinitis and bolus impaction segregate EoE from NED. Studies with larger cohorts of patients are needed to validate a clinical history-based screening for EoE.

Disclosure: Nothing to disclose.

P0060

EOSINOPHILIC ESOPHAGITIS, PREVALENCE, INCIDENCE AND PRESENTING FEATURES IN SOUTHWEST SWEDEN: A 20-YEAR POPULATION-BASED STUDY

J. Plate¹, T. Söderbergh¹, H. Larsson¹

¹NÄL County Hospital, Department of Otorhinolaryngology Head and Neck Surgery, Trollhättan, Sweden

Contact E-Mail Address: john.plate@vgregion.se

Introduction: Eosinophilic Esophagitis (EoE) is a chronic eosinophilic inflammatory condition of the esophagus and was first recognized in the 1990's as an own disease entity (1, 2) Symptoms in adults are mainly esophageal dysphagia but can also present as acute food bolus obstruction of the esophagus. Diagnosis requires symptoms of esophageal dysfunction and esophageal biopsy with ≥ 15 eosinophils/HPF. (3)

EoE seems to be rising in both prevalence and incidence (4).

The reported prevalence in USA and Europe is 45-55/100 000(6), though a Spanish study from 2018 reports a prevalence of 112/100 000.(5;6) Not until 2012 the disease could be registered via an own diagnostic code (K20.9A) in Sweden.

Aims & Methods: The aim of this study was to study prevalence, incidence and presenting symptoms among patients with EoE in the catchment area of NÄL county hospital, Sweden, 290 000 inhabitants. (7)

Patient records marked with the diagnostic code of EoE between 2012.01.01 - 2022.01.01 were studied. Incidence of acute food bolus obstruction and endoscopic findings were noted. Patients who did not meet the diagnostic criteria of EoE were excluded.

A search was made in the local data base for histological samples using the keywords Esophagus and Inflammation with a timeframe of 2000-01-01 - 2022-01-01. The patients with more than 15 eosinophils/HPF had their records studied. The patients who met the diagnostic criteria for EoE were included.

Results: 360 patients met the criteria for EoE diagnosis. 19 patients were diseased, leaving a total of 341 patients alive who had the diagnosis, giving a prevalence of 118/100 000.

Of the 341 patients the mean age at diagnosis was 40 years(1-79 years), 66% are men. 65 patients are under 18 years of age (16 girls and 49 boys) 42% had at least one acute bolus obstruction before diagnosis, 40% had endoscopic findings of fibrosis (trachealisation/stricture).

The mean yearly incidens was 8/100000 (2005-2021) and seems to be rising, mean incidence 5/100000 (2005-2010).

Conclusion: The prevalence of EoE January 2022 in the catchment area of NU-sjukvården is 118/100 000, which is significantly higher than generally reported.

42% had acute food bolus obstruction as presenting symptom possibly an effect of that patients was diagnosed late after symptom onset.

The incidence seems to be increasing, whether this is due to a real increase in diagnosed patients or increased awareness among practicing physicians remains unknown.

Introduction: Gastroesophageal reflux disease (GERD) is defined as weekly or more frequent gastroesophageal reflux symptoms (GERS) and/or visible mucosal changes, erosive esophagitis (EE), on an oesophago-gastroduodenoscopy (OEGD) (1). GERD is a chronic disease, but only a minority with GERS have EE (1). The role of histology in diagnosis of GERD is controversial (1, 2). A recent systematic review concluded poor mental health is a risk factor for GERD but community-based studies are very few (3). We investigated differences in histological markers and mental health in EE, non-erosive reflux disease (NERD) and subjects free from GERD from a random population sample who were endoscoped.

Aims & Methods: In a cross-sectional study investigating a random sample of individuals from the general population in a Swedish municipality, 384 subjects completed an upper endoscopy (OEGD). Biopsies were taken at three locations, at the Z-line, just above the Z-line and 2 cm above the Z-line. Participants reported gastrointestinal symptoms, including heartburn and acid regurgitation, on the Abdominal Symptom Questionnaire and mental health on the Hospital Anxiety and Depression Scale. Logistic regression was used to test differences in histological parameters and mental health between individuals with EE with or without GERS, NERD and individuals without any GERD. The models were adjusted for age, sex, body mass index (BMI) and proton pump inhibitor (PPI)/histamine (H₂) blocker treatment.

	Non GERD	NERD	EE without GERS			EE with GERS

*p<0.05; ***p<0.001

Table 1. Differences in histological parameters and mental health between individuals with and without erosive reflux disease and controls without reflux disease

Results: EE was found in 58 participants (15.1%: LA-A:9.4%, B:4.9%, C:0.8%). Compared to participants without GERD (n=242), participants with EE without GERS (n=33) showed changes at the Z-line: increased total

thickness and papilla length while participants with EE with GERS (n=25) displayed an increase in total thickness, basal layer thickness and papillary length just above the Z-line, see Table 1.

NERD (n=84) was associated with increased spongiosis 2 cm above the Z-line. No differences in anxiety and depression were observed.

Conclusion: Histological changes at the Z-line may provide useful information about GERD. There is no evidence in this study that mental health is linked to GERD in the community.

Introduction: Oesophageal dysmotility and gastroesophageal reflux (GER) are common in patients with respiratory disease and following lung transplantation (LTx). However, the effect of LTx and how oesophageal dysfunction prior to LTx influences outcome remains unclear. This leads to patients with abnormal pH-metry or significant dysmotility prior to LTx often been excluded from transplant waiting-lists, out of concern for adverse allograft outcomes.

Aims & Methods: Our aim is to further understand the effect of LTx on oesophageal motility and GER in patients with respiratory disease.

High Resolution Oesophageal Impedance Manometry (HRIM, CCv4.0) along with 24hr-pH/impedance was performed on 38 patients before and after LTx (mean age 60 yrs (range; 37-75 yrs), 25 males) between November 2017 and September 2021.

Results: Of 38 patients identified, 28 had restrictive lung disease, 6 obstructive disease, 3 combined restrictive/obstructive disease, and 1 pulmonary arterial hypertension.

HRIM: Pre-LTx, 17(45%) patients exhibited abnormal motility, of which 10(59%) had ineffective oesophageal motility (IEM), 6(35%) oesophago-gastric junction outflow obstruction (EGJOO) and 1(6%) absent contractility. Post-LTx, distal contractile integral increased from 793(414-1296) (median(IQR)) to 985(478-3136)(p=0.03). However, this was associated with a variety of changes in manometric diagnoses.

Of the 21 with normal motility pre-LTx, 11(52%) remained normal, 5(24%) changed to EGJOO, 2(10%) to IEM, 2(10%) to Jackhammer, and 1(4%) to distal oesophageal spasm post-LTx (Fig. 1). Of the 10 patients with IEM pre-LTx, 5(50%) remained IEM, 3(30%) changed to normal, and 2(20%) to EGJOO; and of the 6 patients with EGJOO pre-LTx, 3(50%) remained EGJOO, 2(33%) changed to normal, and 1(17%) to IEM.

The patient with aperistalsis pre-transplant changed to IEM.

24hr-pH/impedance: Pre-LTx 11(30%) patients had abnormal bolus exposure time (TBET) and 4(11%) abnormal number of reflux events reaching the proximal oesophagus. Post-LTx the number of patients with abnormal number of proximal events had doubled to 8(21%), although this did not reach significance($p=0.20$). The latter had no effect on TBET. Pre-LTx, patients with IEM (1.45(1.0-1.6) median(IQR)) had greater TBET than both patients with normal motility (0.5(0.4-1.1); $p=0.05$) and EGJOO (0.9(0.1-1.1); $p=0.05$).

Similarly, patients with IEM (12.5(5-17)) had more reflux events reaching the proximal oesophagus than those with normal motility (4(3-8); $p=0.07$) and EGJOO (3(0-7); $p=0.04$). Post-LTx these differences were lost (TBET: normal, 1.1(0.3-1.9); IEM, 0.9(0.6-2.1); EGJOO, 0.6(0-1.4); No. prox events: normal, 8.5(2-34); IEM, 7(2-26) and EGJOO, 4.5(1-11)).

Conclusion: Following LTx approximately half of motility diagnoses remained the same as pre-LTx, with the rest showing no consistent change. GER better associated with motility pre- than post-LTx. We conclude that pre-op testing remains valuable to allow optimal management of the patient till LTx, but post-op testing may be more important for the long-term outcome and allograft survival of patients.

Introduction: Hiatus hernia (HH) facilitates reflux by several pathophysiological mechanisms including abnormal reflux patterns, delayed acid clearance, and proximal displacement of a postprandial acid pocket, which could also contain bile. Esophageal reflux exposure contributes to abnormal esophageal mucosal integrity, which can be measured using mean nocturnal baseline impedance (MNBI) during impedance pH monitoring.

Aims & Methods: The aim of this study was to investigate the influence of HH on reflux patterns using impedance-pH monitoring and bile spectroscopy (Bilitec 2000), and compare distal esophageal mucosal integrity and bile exposure between non-erosive reflux disease (NERD) patients with similar acid burden with and without HH. We retrospectively analyzed data from PPI-refractory NERD patients referred to three tertiary referral centers who had undergone endoscopy, esophageal high-resolution manometry (HRM), and impedance-pH studies off PPI with or without Bilitec monitoring.

Inclusion criteria of the study consisted of patients who had distal acid exposure time (AET) of 6-12%, HH >2 cm (HH group) or no HH (non-HH group) on HRM. Prior to the reflux testing, endoscopy confirmed that none of the patients had reflux esophagitis or Barrett's esophagus. Patients who had obstructive motor disorders, pathological supragastric belching, ru-

mination or prior foregut surgery were excluded. HRM evaluated esophageal motility and the esophagogastric junction morphology. Impedance-pH monitoring measured AET, the number of reflux episodes, acid and bolus clearance, MNBI, (normal>1350 ohms) and post reflux swallow induced peristaltic wave index (PSPWI) whereas Bilitec 2000 measured esophageal bile reflux exposure time (normal $\leq 1.8\%$ bilirubin absorbance time).

These parameters were compared between the patients with and without HH. Univariate logistic regression, multivariable regression and correlational analyses were performed to identify factors influencing the distal esophageal MNBI.

Results: We identified 42 patients in the HH group and 40 patients in the non-HH group. Age, gender, BMI, esophageal motility, AET and esophageal clearance were similar between the two groups. The HH group had higher numbers of total reflux episodes ($p=0.015$) with similar proportion of acid/non-acid reflux compared to the non-HH group. Mean nocturnal baseline impedance (MNBI) in the distal esophagus was significantly lower in the HH group than the non-HH group at both 5cm ($p=0.002$) and 3cm ($p=0.015$) above the lower esophageal sphincter.

Multivariable regression analysis showed that HH, low number of non-acid reflux and PSPWI were independently associated with MNBI. Among 31 patients tested with bile spectrophotometry, the HH group had significantly longer bile exposure time than the non-HH group ($p=0.011$), and bile reflux inversely and significantly correlated with MNBI ($\rho=-0.75$, $p<0.001$).

Conclusion: In NERD patients with similar acid burden, the presence of HH, fewer non-acid reflux episodes and lower PSPWI were independently associated with impaired mucosal integrity. Correlational analysis suggested that HH damages mucosal integrity potentially through excessive bile reflux.

Introduction: Provocative manoeuvres are increasingly being performed during esophageal high-resolution manometry (HRM) in an attempt to increase the yield of the test. Recently, straight leg raise manoeuvre (SLR) (i.e., wet swallow with raised straight legs in supine position) has been proposed as novel provocative test to evaluate esophageal reflux barrier and contraction reserve (CR) (i.e., augmentation of the esophageal contractile vigor following multiple rapid swallow, MRS). The rationale is that SLR augments intra-abdominal pressure, which has been shown to augment the contractile vigor of the esophagus.

Aims & Methods: The aim of this study was to investigate the relationship between the CR after MRS and contractile vigor following SLR (i.e., obstructive stress reserve, OSR). Between Nov 2021-Jan 2022, consecutive patients reporting GERD symptoms who underwent high-resolution manometry (HRM) were enrolled. GERD symptoms, height and weight were

recorded for all patients. Distal contractile integral (DCI) was analyzed during single water swallows (SS) (10 × 5 mL), MRS (3 × 10 mL), and during SLR (2x5 mL). Preserved esophageal CR was defined as MRS/SS ratio was >1. Preserved OSR was defined as SLR/SS ratio >1. Data comparisons were performed using independent sample t test or the chi-square test, as appropriate. The Pearson's correlation coefficient was used to investigate the correlation between the DCI following MRS and DCI during SLR.

Results: 32 patients (17 female, mean age: 49.8±13.3 years) were enrolled. All patients reported heartburn as main symptom. Mean BMI was 23.8±2.2. Esophageal HRM was normal in 25/32 (78.1%) and ineffective esophageal motility (IEM) was detected in 7/32 (21.9%). Esophageal CR was observed during MRS in 21/32 (65.6%) and OSR was seen in 26/32 (81.3%) following SLR. The DCI response following MRS correlated with the DCI response following SLR (Table 1).

		Number of patients with MRS/SS ratio>1, n (%)		p value
		YES	NO	
Number of patients with SLR/SS ratio>1, n (%)	YES	21 (65.6%)	6 (18.8%)	<0.001
	NO	1 (3.1%)	4 (12.5%)	

Table 1.

The Pearson's correlation coefficient was 0.74 ($p < 0.001$). Mean±sd DCI was 1508.7±1074.9 mmHg-s-cm; mean DCI during MRS was 1672.1±1079.1 mmHg-s-cm and mean DCI during SLR was 2094.3±1521.8 mmHg-s-cm ($p=NS$).

Conclusion: Swallowing against the resistance of increased intra-abdominal pressure from SLR improves esophageal body peristaltic performance and correlates with esophageal body CR.

Disclosure: Nothing to disclose.

POST-REFLUX SWALLOW-INDUCED PERISTALTIC WAVE INDEX CORRELATES WITH BODY MASS INDEX AND IMPROVES WITH BARIATRIC SURGERY-INDUCED WEIGHT LOSS, REGARDLESS OF ESOPHAGEAL ACID EXPOSURE

M. Pesce¹, M. Pagliaro¹, P. Senneca¹, V. Vaino¹, G. Di Giorgio¹, M. Andreozzi¹, S. Rugo¹, E. Efficie¹, G. Sarnelli¹

¹University of Naples 'Federico II', Clinical Medicine and Surgery, Naples, Italy

Introduction: The Post-reflux swallow-induced peristaltic wave (PSPW) is an esophago-salivary reflex that allows the chemical clearance of the refluxate. As a result, when impaired, it progressively increases the risk of gastro-esophageal reflux disease (GERD) and its complications. Obesity is one of the major risk factors for GERD and progression to erosive esophagitis, Barrett esophagus and esophageal adenocarcinoma. Weight loss in severely obese subjects improves GERD by decreasing esophageal acid exposure time (AET) and reflux symptoms; but its impact on PSPW index (PSPWi), a novel pH-impedance (MII-pH) parameter, has never been systematically explored. However, achieving weight loss by means of bariatric surgical procedures has a still controversial effect on both esophageal motility and AET, which in turn could affect PSPWi.

Aims & Methods: Our aim was to verify how bariatric surgery, namely Mini-Gastric bypass (MGB) and Laparoscopic Sleeve Gastrectomy (LSG) affects MII-pH parameters and if weight loss is correlated to PSPWi. 57 morbidly obese subjects (37F, BMI 47.2±6.1) were enrolled in this prospective randomized, open-label, controlled trial to evaluate MII-pH parameters in the preoperative phase (T0) and at 6 (T1) and 12 months (T2) after MGB and

LSG, respectively. All subjects performed a preoperative upper gastrointestinal endoscopy, ruling out the presence of esophagitis or Hiatus Hernia, a high-resolution manometry (HRM) and an off-PPI 24h MII-pH. A standardized questionnaire assessing upper gastrointestinal symptoms severity (PAGI SYM) was administered at all time points. Data are expressed as mean±SD.

Results: 25 subjects underwent MGB (14F, BMI 47±7.3) while 32 patients were treated with LSG (23F, BMI 46±5.1). At baseline, no differences were found between the two groups in terms of BMI, PAGI-SYM scores and HRM or MII-pH data. At both time points, a significant weight loss from baseline (expressed as ΔBMI) was found in both groups with no differences between the two procedures (T0vsT1: -11 vs -11.2 kg/m² and T0vsT2: -14.5 vs -16.2 kg/m² in MGB and LSG group respectively, $p=ns$). At T2, AET was significantly increased in the LSG as compared to the MGB group (9.2±7.7 vs 1.4±2.4, $p < 0.01$), while the total number of reflux episodes did not differ between the two groups (61.5±36.9 vs 53.6±19.5, $p=ns$). At baseline, PSPWi values were equally reduced in both groups (42±11.2 and 42.6±15.2 in MGB and LSG, respectively).

Following bariatric surgery, a progressive increase in PSPWi was observed at both time points in MGB (T1 63.5±11.6; T2 72.4±8.8) and LSG groups (T1 62.9±16.1; T2 67.2±13.5; all $p < 0.001$). PSPWi improvement directly correlated with the reduction of BMI ($r^2=0.28$; $p < 0.0001$). When all variables were computed in a multivariate analysis, PSPWi was the only significant factor associated with BMI decrease ($r^2=0.058$; $p < 0.05$).

Conclusion: Severely obese subjects show a reduced PSPWi that improves in parallel with weight loss, independently from the bariatric surgical procedure. There was a strong inverse association between BMI decrease and PSPWi improvement, regardless of the acid exposure time. Our results suggest that a low PSPWi might be a marker of impaired visceral esophageal sensitivity influenced by obesity, which could contribute to the risk of GERD and its complications.

Disclosure: Nothing to disclose.

P0066

CENSORING REFLUX EPISODES BY THE WINGATE CONSENSUS REDUCES SUPPORTIVE EVIDENCE FOR GERD PROVIDED BY PH/IMPEDANCE MONITORING

S. Kindt¹, M. Surmont¹

¹UZ Brussels, Gastroenterology and Hepatology, Brussel, Belgium

Contact E-Mail Address: sebastien.kindt@telenet.be

Introduction: The Lyon consensus classifies the evidence of gastro-oesophageal reflux (GERD) based on endoscopic features and results of pH/impedance monitoring (pH-MII). Where only an acid exposure time > 6% represents conclusive evidence for GERD, presence of more than 80 impedance episodes, low post-reflux swallow-induced peristaltic wave (PSPW) index and low mean nocturnal baseline impedance (MNBI) on pH-MII provide adjunctive evidence. The Wingate consensus established criteria to reduce inter-reviewer variability when assessing reflux episodes and PSPW by impedance.

Aims & Methods: This study aims to assess the influence of the Wingate criteria on the different pH-MII parameters obtained by automated analysis. Forty consecutive pH-MII were reviewed manually according to Wingate criteria. Number of impedance episodes censored from automatic analysis were recorded. Reflux categorisation according to Lyon consensus between censored and uncensored data was compared by Chi square. Pearson correlations between impedance parameters and censored episodes were calculated.

Results: On average 27.6 (range 3-94) impedance episodes were censored. Reasons for censoring were: 1/ antrograde episode: 13 (range 1-70), 2/ impedance drop < 50%: 4,1 (0-60), 3/ duration < 4s: 1,5 (0 - 10), 4/ <2 distal

channels: 3.9 (0-20) and 5/ artefacts: 5.1 (0 – 19). Applying the Wingate criteria altered the categorisation of impedance episodes (<40 episodes, 7 vs 17 for resp. uncensored vs censored tracings, 40-80 episodes: 19 vs 19, and > 80 episodes: 14 vs 4, $p=.008$). MNBI and PSPW index were significantly correlated ($r=.47$, $p=.002$). The percentage of censored episodes was inversely correlated with the number of acidic impedance episodes ($r=-0.61$, $p=0.000$) and positively correlated with PSPW index ($r=.64$, $p=.000$).

Conclusion: Manual interpretation of impedance tracings based on the Wingate consensus reduces supportive evidence for GERD. The observed correlations indicate that acidic reflux episodes and reflux episodes followed by a PSPW are less likely to be censored, harbouring a potential at improving automatic pH-MII analysis.

Disclosure: Nothing to disclose.

VALIDATION OF THE LYON CONSENSUS CRITERIA FOR GERD DIAGNOSIS IN A GREEK POPULATION: A RETROSPECTIVE STUDY

T. Voulgaris¹, V. Lekakis¹, A. Orfanidou¹, J. Vlachogiannakos¹, D. Kamberoglou¹, G. Papatheodoridis¹, G. Karamanolis¹
¹National and Kapodistrian University, Laiko General Hospital, Department of Gastroenterology, Athens, Greece

Contact E-Mail Address: georgekaramanolis@yahoo.co.uk

Introduction: Gastroesophageal Reflux Disease (GERD) affects globally 8%–33% of worlds population, it is observed among all ages and does not differ among sex. The gold standard examination in diagnosing GERD is 24hrs pHmetry ± impedance. Recently new diagnostic criteria were introduced by the Lyon consensus for GERD diagnosis.

Aims & Methods: Our aim was to investigate the diagnostic yield of pHmetry ± impedance using the Lyon consensus criteria and to evaluate possible changes in the rate of GERD diagnosis with the adaptation of those new diagnostic criteria. Our study included 249 consecutive patients (M/F: 120/129, mean age 50±15 years (min 18 – max 86) who underwent 24-hour pH± impedance monitoring in the laboratory for esophageal disorders of our department during a five year period (6/2016-6/2021).

Acid exposure time (AET) was calculated as the percentage of time during which the pH was below 4 at the esophageal pH sensor, and AETs of 4.2% or 6% and greater were designated as abnormal thresholds. Number of reflux episodes (NRE), reflux-symptom association (symptom index-SI and symptom association probability –SAP) as well as mean nocturnal baseline impedance (MNBI) was also calculated. Epidemiological, endoscopic, clinical and 24-hour pH± impedance data were retrospectively collected.

Results: Typical GERD symptoms were reported by 140/249 (56.2%) patients, whereas 99/249 (39.6%) patients reported various extra-esophageal symptoms. The majority (137/249, 55%) of patients reported no amelioration of their symptoms when previously treated with Proton Pump inhibitors (PPis).

Endoscopic findings supportive of GERD by Lyon consensus (Esophagitis according to LA classification of grade A/B and/or hiatal hernia) were present in 42/185 (22.7%). An AET>6% was observed in 60/249 (24.1%), 22/249 between 4 and 6% and 147/249 <4%. The mean number of reflux episodes was 32±27 (min 0-max 198), 12/249 (4.8%) had over >80 reflux episodes and 62/249 (24.9%) >40, while 74 (29.7%) patients had a De Meester score over 14.7. Symptomatic Index was positive in 16/172 while Symptoms Associated Probability in 30/172.

Abnormal Mean Nocturnal Basal Impedance (MNBI) was observed in 38/249 patients. Hypersensitive esophagus was diagnosed in 26/249 patients (10.4%). GERD diagnosis according to the Lyon Consensus criteria was set in 63/249 (25.3%) patients; a rate significantly lower compared to

the rate observed by implementing the older criteria (32.1%), $p<0.001$. In the multivariate analysis the existence of endoscopic findings supportive to GERD diagnosis as defined by the Lyon consensus ($p=0.036$), a De Meester score over 14.7 and the presence of typical GERD symptoms were correlated to GERD diagnosis ($p<0.001$, respectively) by the criteria defined for pH- impedance monitoring. In the univariate analysis, response to PPis was closely correlated to GERD diagnosis by the Lyon consensus criteria (43/112, 38.4% among responders to PPis compared to 26/137, 19.0%, of non-responders, $p<0.001$), as also the existence of abnormal MNBI (16/63, 25.4% vs. 22/186, 11.8%, $p=0.027$), findings not observed in the multivariate analysis.

Conclusion: Changes in 24-hrs pH-impedance monitoring diagnostic criteria of GERD by the Lyon consensus led to a conclusive GERD diagnosis in approximately 25% of patients. This rate of GERD diagnosis is reduced in comparison to the one confirmed with the use of previous established criteria. Moreover, presence of typical symptoms, as well as existence of endoscopic supportive evidence of GERD was independently correlated with GERD diagnosis by pH-impedance-monitoring.

Disclosure: Nothing to disclose.

LCI IMPROVES THE VISIBILITY OF MINIMAL CHANGE ESOPHAGITIS - A LAB COLOR VALUE BASED QUANTITATIVE ANALYSIS

L. Wang¹, X. Lin¹, L. Zhang¹, X. Li¹, Y. Wang¹, PKUIH Upper-GI Disorder Study Group
¹Peking University International Hospital, Gastroenterology Department, Beijing, China

Contact E-Mail Address: wangli5@pkuih.edu.cn

Introduction: GERD (Gastroesophageal reflux disease) can be divided into NERD (non-erosive reflux disease) and RE (Reflux esophagitis. RE) according to endoscopic manifestation[1-3]. MCE (minimal change esophagitis) refers to the changes of mucosa above the dentate line including redness, edema and whitening but without mucosal damage[4-5].

Previous literatures found that traditional white light endoscopy had some difficulty in the diagnose of RE Grade-A and MCE, and the consistency with the golden standard 24-hour pH monitoring was also limited[6]. LCI (Linked color imaging) is a novel image enhanced technique. It can increase the contrast of mucosal color and highlight the red lesions. Therefore, we speculated that LCI has an advantage over white light in detecting the red lesions of GERD, especially MCE and Grade-A esophagitis as well.

Aims & Methods: We use quantitative analysis to explore whether LCI technology is helpful for the diagnosis of MCE and Grade-A esophagitis. The outpatients aged 18-75, regardless of gender, with typical acid reflux and heartburn in the past week, and had positive results of GERD-Q questionnaire (8 points or above) were selected for this research. Patients that had a history of gastrectomy or were highly suspicious of upper gastrointestinal tumors or achalasia were excluded. The termination criteria were esophagitis grade B or above, malignancies, Barrett esophagus, or whose cardia area could not be exposed sufficiently under endoscopy. We completed the gastroscopy in routine steps with Blue Laser Imaging Endoscope system and observed the area 5cm above the dentate line.

Then the pictures under both WLI (white light) and LCI were obtained respectively. These images were analyzed and scored by Adobe Photoshop software based on Lab color value in the CIELAB color space system[7]. L, a, and b color values were transformed into L* a* b* color values in CIELAB as follows[8]: $L^* = L/256 \times 100$, $a^* = a - 128$, $b^* = b - 128$. The color differences were calculated as follows: $\Delta L^* = L^*(red\ area) - L^*(normal\ mucosa)$, so as Δa^* and Δb^* . $\Delta E^* = [(\Delta L^*)^2 + (\Delta a^*)^2 + (\Delta b^*)^2]^{1/2}$. SPSS 24.0 software was used for data analysis.

Results: A total of 56 patients were obtained including 26 males and 30 females, aged 26 to 70. 112 qualified WLI and LCI images were selected. The L*, a*, b* values between red area and normal mucosa under both LCI and white light mode were compared respectively. The results showed that there were significant differences in L*, a*, b* between the red area and the normal mucosa in both mode (P<0.05). The scatter plot of a* and b* color values in CIELAB revealed that the spots separation of LCI mode is higher, suggesting that the color difference between red and normal mucosa in LCI mode is greater than that in white light mode. The color difference of ΔL^* , Δa^* , Δb^* and ΔE^* were calculated and compared between LCI and WLI mode, the results revealed that Δa^* , Δb^* and ΔE^* of LCI mode were all significantly higher than WLI (P<0.001), see Table-1.

L*, a* b* values	WLI	LCI	P
Δa^*	6.917±5.683	21.048±8.131	0.000
Δb^*	8.685±6.764	127.703±6.497	0.000
ΔE^*	13.589±6.969	130.011±6.514	0.000

Table-1. Color differences of Δa^* , Δb^* and ΔE^* between WLI and LCI.

Conclusion: LCI improved the color difference between the red area and surrounding mucosa in MCE and RE Grade-A and might therefore be helpful for the diagnosis.

P0069 LOW ESOPHAGEAL BASELINE IMPEDANCE AND NUMBER OF CHANNELS INVOLVED ARE ASSOCIATED WITH BARRETT'S ESOPHAGUS SEGMENT LENGTH

N. Bar¹, K. Staller², C. Velez², B. Kuo²
¹Tel Aviv Medical Center, Department of Gastroenterology and Hepatology, Tel Aviv, Israel, ²Massachusetts General Hospital, Center for Neurointestinal Health, Boston, United States

Contact E-Mail Address: nirb@tlvmc.gov.il
Introduction: Gastroesophageal reflux disease increases mucosal permeability, reducing the mucosal baseline impedance (BI) measured in multichannel intraluminal impedance pH studies (MII-pH). Low BI is reported in patients with increased acid exposure time (AET), erosive oesophagitis, and Barrett's oesophagus (BO).

Aims & Methods: As data about BI in BO are few, we aimed to examine the predictive capabilities of BI in BO.

We included all patients over a 10-year period undergoing 24h MII-pH and upper endoscopy with clinical suspicion for BO, knowing some patients will not have BO, and could serve as controls. The Medtronic software measures BI in the distal (Z6) channel only. To validate proximal channel BI measurements, MII-pHs were reanalyzed with blinded BI measurement at Z6: mean nocturnal BI (MNBI) in three 10-minute periods an hour apart during sleep (standard method) and point BI (PBI) measured BI during a stable (no swallow/reflux for ~20 minutes) supine period in all 6 channels. We tested the correlation between MNBI and PBI and compared the PBI in all patients with BO and without to validate the measurement methods. BO was diagnosed as >1 cm salmon-colored mucosa in tubular oesophagus with intestinal metaplasia; long segment was ≥3 cm. Abnormal MII-pH was defined as either distal acid exposure time (AET) >6% or >80 total reflux episodes. Those not meeting criteria were used as controls. P values were adjusted by Bonferroni correction as needed.

Results: The cohort included 110 patients. Patients with long BO had significantly lower distal channel MNBI, see table 1. To examine overall ability to diagnose BO, we excluded patients with increased acid exposure. The area under the ROC curve for MNBI detecting BO was excellent 0.91, (0.83-1.0). A cut-off of 0.6 kOhm had 100% sensitivity and 75% specificity. In multivariate logistic regression adjusting for age, sex, and race showed: MNBI was associated with BO or abnormal MII-pH with OR=0.52 (0.4-0.7, p<0.001) for every 1 kOhm, and having MNBI< 0.6 kOhm had an OR= 12.9 (1.6-102.3, p=0.016).

Studies with a normal MII-pH and a MNBI under 0.6, 1, 1.6 kOhm: the prevalence of BO was 2/3 (67%), 7/10 (70%), and 14/19 (74%), respectively. To validate the use of PBI in assessing BO extent, we found excellent correlation between PBI and MNBI in the distal channel MNBI (spearman's rho): 0.958 p<0.001. Patients with long BO had significantly more channels with low PBI compared to short BO and normal, see table 1.

	Total cohort (n=110)	Barrett's oesophagus (n=45)	Control (n=41)
Age [years, median (IQR)]	59 (25 - 85)	59.4 (53.3-70)	57.3 (48.8-65.2)
Female n (%)	63 (57)	21 (47)	26 (63)
Race - White n (%)	91 (83)	39 (87)	30 (73)
On PPI MII-pH n (%)	95 (86)	43 (96)	33 (81) *
	Long BO (n=13)	Short BO (n=32)	Abnormal MII-pH (n=24) Control (n=41)
Mean baseline impedance (kOhm) n=13	0.6 (0.5-0.97)	1.9 (0.8-3.2)*	1.3 (0.6-2.8) 3.6 (2.1-4.7)***
Patients with multiple low baseline impedance channels n (%)	11 (85)	8 (25)***	8 (33)** 1 (2)***

PPI- proton pump inhibitor; MII-pH – multichannel intraluminal impedance – pH study; BO- Barrett's oesophagus. *. p<0.05, **. p<0.01, *** - p<0.001. All p-values are Bonferroni corrected for multiple comparisons and compared to the long BO group as reference

Table 1.

Conclusion: We showed the extent of BO is associated with the extent of oesophageal mucosa with low BI and confirmed the association between BO and lower BI values. This supports the utility of BI in detecting reflux complications. Clinicians reading MII-pH studies should consider BO in the differential when encountering a MII-pH with low supine BI, especially when this spans across impedance channels.

BARIUM OESOPHAGRAM DOES NOT RELIABLY DETECT CLINICALLY RELEVANT REFLUX DEFINED BY 24-HOUR MULTICHANNEL INTRALUMINAL IMPEDANCE PH

N. Bar¹, K. Staller², C. Velez², B. Kuo²

¹Tel Aviv Medical Center, Department of gastroenterology and hepatology, Tel Aviv, United States, ²Massachusetts General Hospital, Center for Neurointestinal Health, Boston, United States

Contact E-Mail Address: nirb@tlvmc.gov.il

Introduction: Barium oesophagram is an important tool in the assessment of oesophageal disease, and its utility for identifying structural abnormalities or as a functional test of oesophageal emptying is well known. Spontaneous gastrooesophageal reflux (GOR) or GOR induced by different maneuvers are routinely reported, but scarce data exist about the relevance of these findings.

Aims & Methods: We aimed to examine the performance characteristics of oesophagram as a test for GOR disease (GORD)

Consecutive patients with both a multichannel intraluminal impedance-pH study (MII-pH), and a oesophagram reporting GOR degree were included. Patients were excluded if they had achalasia or reflux surgery between oesophagram and MII-pH. For oesophagram: We recorded presence and degree of oesophagram diagnosed reflux (oesophagram-R) and other parameters. For the MII-pH we recorded total oesophageal acid exposure time (AET), total reflux episodes, and whether the test was done on/off proton pump inhibitors (PPI). We also collected manometry parameters and diagnosis.

We calculated the Kappa coefficient for inter-test agreement, sensitivity (Se), specificity (Sp), and positive and negative predictive values (PPV, NPV) using MII-pH as the gold standard. We used different cut offs for off (1,2) and on (3) PPI studies to define abnormal GORD. As sensitivity analysis, we analyzed the utility of oesophagrams to detect GORD defined by reflux number only. All MII-pHs were analyzed on Reflux reader 6.1.1.11 (Medtronic Inc, Minneapolis, Minn)

Results: There were 113 patients included between Jul-Oct/2021. Median (IQR) age was 58.2 (47.8-65), with 70 (62%) females. Median (IQR) time between oesophagram and MII-pH studies was 2.6 (0.7-6.6) months. PPs were used in 64% of MII-pH studies. oesophagram-R was noted in 53% of oesophagrams, and 40% reported hiatal hernias (HH).

Sixty (53%) patients had some degree of oesophagram-R and were more likely to be female (69% vs. 51%), have a hiatal hernia (52% vs 29%), and had higher median (IQR) number of reflux episodes [81 (45-129) vs 50 (27-76)], $p < 0.05$ for all. Oesophagram-R was also associated with ineffective oesophageal motility (Chicago classification V4.0, 26% vs 9%, $p < 0.05$).

The AET, and the proportion of studies performed on PPIs were similar between groups.

To diagnose clinically significant GORD we used different cut offs (1-3) to define pathologic GOR, including specific cut offs for MII-pH done on PPI. We found fair agreement at best between the gold standard MII-pH and oesophagram by Kappa coefficients ($\kappa = 0.18-0.31$) and unsatisfactory test characteristics (universally poor Se/Sp/PPV/NPV) (Table 1). Performing the same analyses with only moderate or severe grade oesophagram-R showed similar results.

Reference -	Lyon (1)	Reflux only	Reflux only	Lyon (1) + Gyawali 2021 (3)	Zerbib 2013 (2)
Pathologic GORD definition	pH<6% or more than 80 refluxes	Total reflux (>80)	Total reflux (>40)	Off PPI see Lyon; On PPI AET>0.5% or >40 refluxes	Off: AET>5.8% reflux>53. ON: AET>0.4%, refluxes>57
Kappa	0.31	0.28	0.31	0.30	0.18
Se	55%	50%	85%	75%	71%
Sp	77%	79%	45%	54%	46%
PPV	74%	74%	65%	66%	62%
NPV	59%	58%	73%	65%	56%
†LR+	2.42	2.41	1.56	1.63	1.31
†LR-	0.58	0.63	0.32	0.46	0.63

Clinically relevant pathologic GORD was diagnosed by MII-pH. The different cut-offs in the top row were used. PPI- proton pump inhibitor; AET- Acid exposure time; Se – sensitivity; Sp – specificity; PPV – positive predictive value; NPV negative predictive value. LR – likelihood ratio. † LR+ is considered robust when > 10 , and LR- when < 0.1 .

Table 2. Barium oesophagram's test performance parameters.

Conclusion: While oesophagram has proven value in some aspects of the assessment of oesophageal structure and function, its ability to identify clinically-significant reflux is limited compared to a MII-pH gold standard. GORD diagnosis based on oesophagram may lead to unwarranted and uncomfortable work up.

HEALING WATER LEADS TO REDUCTION OF HEARTBURN: RANDOMISED, PLACEBO-CONTROLLED PHASE-III TRIAL (STOMACH STILL)

J. Labenz¹, M. Anschütz², J. Walstab³, F. Donath³, R.-S. Wedemeyer², H. Wolters⁴, B. Schug²

¹Diakonie Klinikum Jung-Stilling Hospital, Medizinische Klinik I, Siegen, Germany, ²Socra Tec R&D GmbH, Oberursel, Germany, ³Socra Tec R&D GmbH, Erfurt, Germany, ⁴Fachingen Heil- und Mineralbrunnen GmbH, Birlenbach, Germany

Contact E-Mail Address: j.labenz@t-online.de

Introduction: The healing water Staatl. Fachingen STILL has been used for decades for symptomatic treatment of gastrointestinal (GI) disturbances including heartburn. Its beneficial effect has not been systematically investigated in a placebo-controlled trial so far.

Aims & Methods: The primary objective of the multicentre, double-blind, randomised, placebo-controlled trial STOMACH STILL was to demonstrate superiority of the healing water (verum) over conventional mineral water (placebo) with respect to alleviation of heartburn. Efficacy in GI symptom reduction ("heartburn", "dyspepsia", "regurgitation") was assessed using the validated *Reflux Disease Questionnaire* (RDQ). Primary endpoint was the percentage of patients with a reduction of ≥ 5 points in the RDQ score for the dimension "heartburn" (responder rate). Secondary objectives included health-related quality of life (HRQOL) using the questionnaire *Quality of Life in Reflux and Dyspepsia* (QOLRAD), intake of rescue medication and safety/tolerability (adverse events, AEs). The trial population comprised adult patients with frequent heartburn episodes since ≥ 6 months (RDQ ≥ 8 within 7 days prior to screening, absence of reflux oesophagitis >Los Angeles Grade A) who drank 1.5L/day verum or placebo over the course of the day for 6 weeks.

Results: Overall, 148 patients with symptomatic heartburn were randomised (verum: n=73, placebo: n=75); 143 patients completed the trial. The responder rate was 84.72% in the verum group compared to 63.51% in the placebo group (p=0.0035, number needed to treat <5). Symptom improvement under verum compared to placebo was statistically significant for the dimension “heartburn” (p=0.0003) and the RDQ total score (p=0.0050) [exploratory analysis]: from baseline to treatment end, the RDQ score for “heartburn” decreased by (mean±standard deviation) 9.17±4.82 points in the verum group and by 6.33±5.07 points in the placebo group, and the RDQ overall score decreased by 20.65±14.04 and 14.31±12.83 points under verum and placebo, respectively. The RDQ dimension scores for “dyspepsia” and “regurgitation” numerically improved during treatment with verum compared to placebo. The absolute reductions of all three RDQ dimension scores in the verum group exceeded the previously determined minimal important changes for a beneficial treatment effect [1].

The reduction in symptom complaints was paralleled by an improved HRQOL: from baseline to treatment end, statistically significant improvements under verum compared to placebo were reported for QOLRAD domains “emotional distress” (p=0.0147), “food/drink problems” (p=0.0125) and “vitality” (p=0.0393) [exploratory analysis].

Consistent with the superior efficacy of verum over placebo, mean intake of rescue medication decreased from 0.73 tablets/day at baseline to 0.47 tablets/day in week 6 and thereafter in the verum group, whereas in the placebo group the intake of rescue medication remained constant during the course of the trial (baseline: 0.56 tablets/day, week 6 and thereafter: 0.60 tablets/day). Treatment-related AEs were only reported in 1 patient of the verum group and in 2 patients of the placebo group.

Conclusion: For the first time, superiority of the healing water Staatl. Fachingen STILL over placebo in the reduction of heartburn, accompanied by an improved quality of life, was demonstrated in a controlled clinical trial. Thus, STOMACH STILL provides the clinical evidence for a recommendation of Staatl. Fachingen STILL in the symptomatic treatment of GI disturbances including heartburn.

Contact E-Mail Address: shikokuri@yahoo.co.jp
Introduction: Proton pump inhibitor (PPI) refractory reflux esophagitis (RE) is often seen in patients with systemic sclerosis (SSc). We reported earlier that standard-dose PPI therapy could not control reflux esophagitis (RE) enough in SSc patients with absent contractility and weak esophago-gastric junction (EGJ) barrier function, and that vonoprazan (VPZ) maintenance therapy may be more effective than standard-dose PPI therapy in patients with SSc. The aims of this retrospective observational study were to clarify prevalence and risk factors for PPI or VPZ refractory RE in patients with SSc in a clinical setting.

Aims & Methods: A total of 188 consecutive patients with SSc who underwent both high-resolution esophageal manometry (HRM) and esophago-gastroduodenoscopy (EGD) between May 2009 and February 2021 at Gunma University Hospital were reviewed. Patients who underwent gastro-intestinal surgery were excluded. Esophageal motility was assessed retrospectively according to the Chicago classification v3.0. The second and subsequent EGDs were performed when patients had reflux symptoms. The presence of RE and grades of the gastroesophageal flap valve (GEFV) were assessed. Administration of acid secretion inhibitors and doses were decided based on patients’ reflux symptoms. The presence of RE or changes of medications were investigated. When RE was seen on any dose of PPI or VPZ, it was defined as medication-refractory RE. Observation periods were from the day of HRM to the final visit (median observation period: 4.36 years).

Variables	Number of patients	Univariate analysis		Multivariate analysis	
		Odds ratio (95%CI)	p value	Odds ratio (95%CI)	p value
≥ 65 years	73	0.625 (0.283-1.425)	0.271		
Male	36	1.451 (0.593-3.553)	0.415		
dcSSc	63	2.518 (1.172-5.409)	0.018	1.710 (0.729-4.012)	0.217
Observation periods ≥ 5 years	78	1.637 (0.770-3.483)	0.201	1.939 (0.823-4.564)	0.130
Gastric atrophy	77	0.480 (0.209-1.099)	0.083	0.517 (0.211-1.265)	0.148
GEFV Grade III or IV	47	2.724 (1.236-6.004)	0.013	1.908 (0.766-4.753)	0.165
Absent contractility	50	5.429 (2.452-12.017)	< 0.001	3.642 (1.519-8.734)	0.004

Table.

Backward stepwise regression analysis was used to select potential variables, and odds ratios and 95% confidence intervals were calculated for each potential variable using multiple logistic regression analyses.

Results: Ineffective esophageal motility (IEM) or absent contractility were seen in approximately 25% of SSc patients. Most of the patients (82%) received acid secretion inhibitor maintenance therapy to control their reflux symptoms. Medication-refractory RE was seen in 17.6% of patients. Most cases of the medication-refractory RE were seen on the standard-dose of PPI (11%), but was rarely seen on more than double-dose PPI (3%) or half-dose and standard-dose of VPZ (4% and 2%). GEV, absent contractility, and diffuse cutaneous SSc were significant factors in medication-refractory RE in a univariate analysis; however, only absent contractility was a significant factor in a multivariate analysis (Table).

Conclusion: Maintenance therapy of inhibition of acid secretion is required to control reflux symptoms in most patients with SSc. Medication-refractory RE is seen in a certain proportion of patients. Patients with absent contractility should receive more than double-dose PPI or VPZ maintenance therapy.

Disclosure: Authors did not have any Conflict of Interest regarding the abstract.

Introduction: Proton pump inhibitors (PPIs) are the most effective drugs for treating acid-related disorders. However, once-daily oral dosing with conventional PPIs does not completely control acid secretion over 24 hours. HIP1601, the newly developed esomeprazole formulation with dual delayed-release emission, has an extended duration of therapeutic plasma drug concentrations and is expected to improve the nocturnal symptoms of gastroesophageal reflux disease (GERD) by inhibiting nocturnal acid breakthrough.

This study aims to compare the clinical efficacy and safety of HIP1601 (dual delayed-release esomeprazole) 40mg and HGP1705 (delayed-release esomeprazole) 40mg in patients with erosive esophagitis (EE).

Aims & Methods: This study was designed as a multicenter, double-blind, randomized-controlled, non-inferiority trial of patients with EE. The patients with EE were randomized to receive either HIP1601 40mg (n = 107) or HGP1705 40mg (n = 106) for 4 or 8 weeks.

The primary endpoint was the complete healing rate of EE confirmed by endoscopy by week 8 in the per protocol set (PPS) population, including patients with healed EE at week 4. The secondary endpoints were:

1. The complete healing rate of EE confirmed by endoscopy at week 4,
2. The complete resolution rate of symptoms at week 4 or 8,
3. The proportion of symptoms-free days and nights after 1, 2, 4, 8 weeks of treatment,
4. The time to sustained resolution of symptoms, and 5) the number of rescue medication administered.

Results: Based on PPS analysis by week 8, estimated healing rates of EE were 97.8% in HIP1601 group and 96.8% in HGP1705 group with -4.7 to 7.2 of 95% confidence interval on the difference. This result was greater than the -10%, acceptable range for non-inferiority.

After 4 or 8 weeks of treatment, the healing rate of EE at week 4, the complete resolution rate of symptoms, the time to sustained resolution of symptoms, and the number of rescue medication use were similar in both

groups. The proportion of heartburn- and acid regurgitation-free nights by week 4 were higher in HIP1601 group compared to HGP1705 group, but the difference did not reach a clinical significance (87.7% vs 85.8%, $P = 0.514$, 87.5% vs 85.8%, $P = 0.774$). Adverse events were not significantly different between the two groups.

Conclusion: This study demonstrated that HIP1601 40mg is a highly effective and well-tolerated drug in healing EE and resolving GERD symptoms. And, the efficacy and safety of HIP1601 40mg is not inferior to HGP1705 40mg after both 4 and 8 weeks of treatment.

Introduction: Chronic PPI treatment in GERD is associated with high failure rate and concerns regarding PPI's side effects. In a previously published proof of concept study, a non-pharmacological, non-invasive transcutaneous, electrical stimulation system, reduced esophageal acid exposure in GERD patients unresponsive to standard dose PPI. However, in that study, a symptomatic response to electrical stimulation was not assessed.

Aims & Methods: To determine the effect of a transcutaneous electrical stimulation system (TESS) on symptoms (heartburn and regurgitation) and the percentage of esophageal acid exposure time in GERD patients. Patients suffering from heartburn and regurgitation were recruited into this multicenter study.

The first phase of this study was a one week, run-in period, off-PPI's, during which patients completed symptoms diaries and demographic questionnaires.

Thereafter, all patients underwent upper endoscopy with subsequently wireless esophageal pH capsule placement (off PPI). Based on pH analysis in the first 24-hours, (day 0) only those with increased acid exposure time (percent total time pH <4 above 6%) continued to the next phase. During phase two of the study, patients were treated for two weeks with TESS and documented their symptoms.

Primary end points included the reduction of baseline (pretreatment) number of heartburn and regurgitation episodes as well as 24-hour percent total time pH <4 and/or DeMeester score by at least 50%.

Results: 26 GERD patients (16 male, aged 47±15 years, mean BMI 25±3 kg/m²) completed the study. At baseline, mean number of daily heartburn and regurgitation events was 2.41±0.36 and 1.38±0.35, respectively. Following TESS, mean number of daily heartburn and regurgitation events dropped to 0.69±0.16 and 0.31±0.19, respectively ($p=0.01$). At baseline, mean percent total time pH <4 was 11.8±0.9. Following TESS, mean percent total time pH <4 dropped to 7.3±0.8, 7.8±1.0, 6.7±1.1 and 5.0±0.7

for day 1, 2, 3 and 4, respectively ($p=0.01$). At baseline, mean DeMeester score was 31.4 ± 2.1 . Following TESS, mean DeMeester score dropped to 20.1 ± 2.0 , 20.4 ± 2.5 , 17.3 ± 2.6 and 14.3 ± 2.0 for day 1, 2, 3 and 4, respectively ($p=0.01$).

Conclusion: TESS is effective in reducing both symptoms (heartburn and regurgitation) and esophageal acid exposure time in GERD patients.

MANAGEMENT OF RECURRENT GASTROESOPHAGEAL REFLUX DISEASE AFTER NISSEN OR TRANSORAL INCISIONLESS FUNDOPLICATION UTILIZING EITHER ANTIREFLUX MUCOSECTOMY OR RESECTION AND PLICATION: AN UPDATED MULTICENTER STUDY

N. Randhawa¹, A. Khalyfa², K. Ayub³

¹Pacific Northwest University of Health Sciences, Yakima, United States, ²Franciscan Health Olympia Fields, Olympia Fields, United States, ³Silvercross Hospital, New Lenox, United States

Contact E-Mail Address: randhnhk@gmail.com

Introduction: Gastroesophageal Reflux Disease is a common condition seen in approximately one out of every five Americans. This condition results from acid rising up to the esophagus, resulting in symptoms and further complications. PPIs are an effective first-line treatment for gastroesophageal Reflux Disease, however, the disease is not eradicated through this therapy. Some patients require continuous maintenance therapy for recurrent symptoms. Long-term PPI use can lead to adverse effects including, but not limited to osteoporosis, pneumonia, and hypomagnesemia; thus exploring anatomical treatments is imperative.

Aims & Methods:

Aims: To evaluate the safety and efficacy of Antireflux Mucosectomy or Resection and Plication in symptomatic patients with prior fundoplication.

Methods: This multicenter study was carried out at four hospitals on symptomatic patients with gastroesophageal Reflux Disease who had prior Nissen Fundoplication or TIF. Informed consent was obtained from all of the patients prior to the procedure. A standardized procedure for mucosectomy was performed and an approximately 210-degree area was resected.

Approximately, 1 cm of the distal esophagus and 2 cm of the cardia were resected along the lesser curve. Endoscopic submucosal dissection (ESD) was performed in 6 patients while Endoscopic mucosal resection (EMR) was performed in 12 patients. Suturing was used in 5 patients with Hill Grade 3 valve.

Results: Eighteen patients were enrolled in the study. Ten had prior TIF and 8 had prior Nissen Fundoplication. All patients underwent the ARMS or RAP procedure. Of these patients, 9 patients had a Hill Grade 3 Valve and 9 patients had a Hill Grade 2 valve. Follow-up endoscopy was performed at 4-12 weeks. At follow-up, 11 patients had a Hill Grade 1 valve and 7 patients had a Hill Grade 2 valve.

All patients had improvement in symptoms. Four patients developed dysphagia, 7 patients developed post-procedural pain, 1 patient had bleeding requiring 1 unit of transfusion, and 1 patient required dilation. In the remaining patients, dysphagia and pain resolved spontaneously.

The follow-up was 24 weeks to 32 months. A paired T-Test comparing each patient's pre-Hill compared to post-Hill revealed the procedure produced statistically significant data (difference in means = 1.111, $T=14.5774$, $p<0.001$)

Conclusion: This multicenter, pilot study revealed Antireflux Mucosectomy or Resection and Plication to be safe and effective treatments in symptomatic patients with prior fundoplication procedures.

Introduction: Previous studies have shown that patients with gastroesophageal reflux disease (GERD) have slower rates of gastric emptying than control subjects. However, the involvement of delayed gastric emptying (DGE) in the pathophysiology of gastro-esophageal reflux disease (GERD) remains debated.

Aims & Methods: The aim of this study was to investigate whether treatment with prokinetics in addition to PPI therapy would improve clinical symptoms in dyspeptic GERD patients with or without delayed gastric emptying.

Thirty consecutive patients refractory to PPI over six month period were included in the study.

DGE by Gastric Emptying Scintigraphy was defined when gastric emptying time ($T_{1/2}$) >70 min.

Patients were divided according to presence of dyspepsia into dyspeptic group ($n = 12$) and non-dyspeptic group ($n = 18$). Mosapride citrate in addition to esomeprazole 40 mg was administered for 4 weeks. Symptoms were evaluated using a standardized questionnaire before and after treatment.

Results: There was no statistical difference in age and gender between dyspeptic group and non-dyspeptic group ($P=0.92$ and $P=0.23$, respectively). Prevalence of esophagitis was similar between dyspeptic group and non-dyspeptic group (58% vs 39%, $P=0.31$). DEG was detected 75% in dyspeptic group and 28% in non-dyspeptic group ($P=0.01$). Symptom improvement was greater in dyspeptic group than non-dyspeptic group (75% vs 33%, $P=0.02$).

Conclusion: Gastric emptying in dyspeptic patients with GERD is significantly slower than in non-dyspeptic patients regardless of esophagitis. Combination therapy with prokinetics in addition to PPI improves typical GERD symptoms in dyspeptic patients with GERD.

Introduction: Patients with gastroesophageal reflux disease (GERD) frequently experience nighttime heartburn and sleep disturbance. Tegoprazan is a new potassium-competitive acid blocker which can rapidly block acid secretion.

Aims & Methods: Patients with erosive esophagitis and sleep disturbances were randomized 1: 1 in a double-blind fashion to receive tegoprazan 50 mg or esomeprazole 40 for two weeks.

The primary end point was time to first nighttime heartburn free interval. Percentage of nighttime heartburn-free days were also compared between the two groups.

Results: A total of 46 patients were enrolled in the study. Time to first nighttime heartburn-free interval was shorter for tegoprazan compared to esomeprazole but without statistical significance (1.5 d vs. 3 d). Percentage of nighttime heartburn-free days were higher for the tegoprazan group but without significance (57.8% vs. 43.1%). Adverse events occurred in two patients and were mild in severity.

Conclusion: Tegoprazan may induce faster symptom relief of nighttime heartburn symptoms and improve sleep disorders associated with nighttime heartburn. Further large-scale studies are required to validate our findings. (Clinical Trials NCT04309916).

Disclosure: This study was supported by HK inno.N Corporation.

Contact E-Mail Address: Annelies.Geeraerts@kuleuven.be

Introduction: Gastric acid is the main pathological factor in gastro-esophageal reflux disease (GERD) and the development of proton pump inhibitors (PPIs) was a major break-through in GERD treatment. However, PPIs are most suitable for continued intake and less for intermittent use in patients with intermittent or occasional reflux symptoms. GERDOFF® Plus is a novel chewable nonprescriptive 'medical device', for the relief of GERD symptoms, based on a bioadhesive mixture of hyaluronic acid, chondroitin sulfate and magnesium trisilicate (HA/CS/MT) which has the capability of attaching to the esophageal mucosa, promoting mucosal recovery and neutralizing acidity.

Aims & Methods: To investigate the efficacy and safety of oral HA/CS/MT for improving mucosal integrity and symptom severity in GERD patients with occasional symptoms, not treated with a PPI.

We performed a single-center, randomized, double-blind, placebo-controlled, cross-over pilot study in patients with typical GERD symptoms (heartburn and/or regurgitation), not treated with a PPI in the last 2 months. Patients received either HA/CS/MT (1100 mg) or placebo q.i.d. for 3 weeks followed by a wash-out period of 3 weeks after which patients crossed over to the other treatment arm for another 3 weeks.

At baseline and after each treatment period patients underwent a 24h pH-impedance measurement to assess mean baseline impedance values (primary endpoint) at 3cm, 5cm and 15cm above the esophago-gastric junction (EGJ) (1).

Symptom severity was assessed using the total ReQuest® questionnaire score at screening and before and after each treatment period. Safety was assessed through analysis of laboratory parameters, vital signs and physical examination.

Results: Twenty patients (10 females, mean age 39±15years) completed the study. No significant differences were observed for baseline impedance values at 3cm, 5cm and 15cm above the EGJ between HA/CS/MT and placebo ($p=0.3580$, $p=0.7674$ and $p=0.5987$, respectively).

However, a numerical increase in impedance values was observed at 3cm and 5cm post-treatment (+276.3Ω and +255.2Ω, respectively) with HA/CS/MT, and not in the placebo group (-5.7Ω and -13.3Ω, respectively). The median total ReQuest® questionnaire scores between the two groups were not significantly different both at baseline and post-treatment.

Post-hoc analysis revealed a significant difference in the percentage of patients with nocturnal heartburn after three weeks treatment between HA/CS/MT and placebo (45% vs. 0% and 42.1% vs. 26.3% respectively; p -value=0.014).

Furthermore, the mean changes between baseline and post-treatment were significantly more pronounced after HA/CS/MT treatment compared to placebo for upper abdominal complaints (-2.9±14.1 vs 3.3±8.4 respectively; $p=0.0470$). All the adverse events were classified as unrelated to the investigational product. Laboratory parameters, vital signs and physical examination did not show any safety issues.

Conclusion: HA/CS/MT had no significant effect on baseline impedance, the primary endpoint of this pilot study. However, we observed a numerical trend towards improved impedance values only after HA/CS/MT treatment and not after placebo.

The median total ReQuest® questionnaire scores were not significantly different, although a post-hoc between-group analysis suggests a statistically significant improvement of nocturnal heartburn and an improvement from baseline for upper abdominal symptoms post-treatment with HA/CS/MT.

Finally, the investigational product was safe and well tolerated.

Contact E-Mail Address: pierfrancesco.visaggi@gmail.com

Introduction: Gastro-oesophageal reflux disease (GORD) affects up to 50% of adults worldwide, with the most prevalent subtype being non-erosive reflux disease (NERD). However, the comparative efficacy and safety of medical therapies for gastro-oesophageal reflux symptoms in NERD is unclear.

Aims & Methods: We conducted a network meta-analysis to evaluate efficacy and safety of proton pump inhibitors (PPIs), histamine-2-receptor antagonists, potassium-competitive acid blockers (PCABs), and alginates compared with each other or with placebo in patients with NERD. We searched MEDLINE, EMBASE, EMBASE Classic, and the Cochrane central register of controlled trials from inception to 1st February 2022.

We included randomised controlled trials (RCTs) comparing the efficacy of all drugs versus each other, or versus a placebo, in adult patients with NERD. Results were reported as pooled relative risks (RRs) with 95% confidence intervals (CIs) to summarise effect of each comparison tested, with treatments ranked according to P-score.

Results: We identified 23 RCTs containing 10,735 subjects with NERD. In the short-term (≥ 2 to < 4 weeks), omeprazole 20mg o.d. (RR = 0.43; 95% CI 0.33-0.56, P-score 0.94) was ranked first in terms of failure to achieve complete relief of symptoms, with esomeprazole 20mg o.d. or 40mg o.d. second and third. Rabeprazole 10mg o.d. (RR = 0.73; 95% CI 0.60-0.90, P-score 0.95) ranked first for failure to achieve adequate relief.

In the longer term (≥ 4 weeks), dextansoprazole 30mg o.d. (RR = 0.48; 95% CI 0.35-0.65, P-score 0.95) ranked first for failure to achieve complete relief, with 30ml alginate q.i.d. combined with omeprazole 20mg o.d., and 30ml alginate t.i.d. second and third, although the latter two based on data from one relatively small RCT. Dextansoprazole 60mg o.d. was the most efficacious in terms of failure to achieve adequate relief (RR = 0.45; 95% CI 0.29-0.70, P-score 0.90) with dextansoprazole 30 mg o.d. and rabeprazole 20mg o.d. second and third. All drugs were safe and well-tolerated.

Conclusion: Our results confirm the superiority of PPIs, as a class, compared with other drugs in treating NERD. Future RCTs should aim to better classify patients with NERD, and to establish the role of alginates and PCABs in achieving adequate and complete symptom relief in NERD in both the short and long-term.

Introduction: Hiatus hernia (HH) is an everyday encounter in the daily endoscopic practice, but a comprehensive evaluation of its esophageal sequela is lacking.

Aims & Methods: We aimed to investigate HHs' prevalence and clinical presentation and provide a comprehensive evaluation of the esophageal sequela associated with HH. We conducted a retrospective, large cohort study by reviewing the electronic files of almost 75000 consecutive patients who underwent gastroscopy over a 12-year period (2008-2020). All patients with a documented endoscopic diagnosis of HH were included in the study group, while those without any endoscopic evidence of HH served as controls.

We derived comprehensive data concerned with the clinical presentation and a comprehensive assessment of benign and malignant esophageal pathologies, including esophageal diverticulum, Shatzki ring, Mallory Weiss, infectious and other non-reflux related esophagitis, benign esophageal strictures, food impaction, suspected motility disorders, and esophageal polyps' size, type and location. The clinical, procedural, endoscopic, and outcome measures were compared between the HH and control groups and further analyzed based on HH size and subtype. Multivariate analysis was performed to identify reflux esophagitis, Barret's esophagus, and esophageal cancer predictors.

Results: The overall diagnosis rate of HH in the entire cohort was (16.8%). The vast majority of HH patients (89.5%) had small HH, 8.7 % had large HH, while only 2% were considered to have para-esophageal or mixed HH. Female predominance was documented in HH patients (57.1% vs. 54%; $P < 0.001$), and they were significantly older compared to controls (61.1 ± 16.5 vs. 52.7 ± 20.0 ; $P < 0.001$). Indeed, the HH diagnosis rate was significantly higher in those 50 years or older when compared to younger adults below 50 years (21% vs. 10.46%; $P < 0.001$). Clinical indications associated with higher rate of HH detection compared to controls included reflux-related symptoms (20% vs. 7%; $P < 0.001$), nausea and vomiting (4% vs. 2.9%; $P < 0.01$), and dysphagia (5% vs. 3.4%; $P < 0.001$). A prominent and significant association was noted between anemia (18% and 17.4% vs. 8.7%; $P < 0.001$) as well as GI bleeding (15.7% and 17.4% vs. 6%; $P < 0.001$), and large and para-esophageal HHs, respectively. The outcome analysis of esophageal pathology revealed an independent and significant association between HH and erosive reflux esophagitis (25.7% vs. 6.2%; $OR = 3.8$ $P < 0.001$), severe distal esophagitis (4.4% vs. 0.7%; $OR = 4.4$, $P < 0.001$), and Barret's esophagus (3.8% vs. 0.7%; $OR = 4.7$, $P < 0.001$). These associations were more prominent for patients with large HH.

Moreover, Higher rates of benign esophageal strictures (3.8% vs. 0.5%; $P < 0.001$), Cameron's ulcers (5.6% vs. 0.6%; $P = 0.01$) Mallory Weiss tears (4.7 vs. 2.3%; $P = 0.01$), food impactions (0.7% vs. 0.2%; $P = 0.01$), and esophageal polyps (0.8% vs. 0.4%; $P < 0.001$) were documented in patients with large, but not small HH patients. Other esophageal pathology rates, including infectious and unspecified esophagitis, esophageal diverticulum, and suspected motility disorders, didn't differ significantly from controls.

Conclusion: HHs were associated with reflux esophagitis and Barret's esophagus. This association was more prominent for large HHs, which were also linked with higher rates of Cameron ulcers, benign esophageal strictures, food impactions, and esophageal polyps.

Disclosure: Nothing to disclose.

CONTRIBUTION OF ENZYMATIC ACTIVITY OF HEME OXYGENASE (HMOX) AND ITS BYPRODUCT, CARBON MONOXIDE (CO) IN BARRETT'S METAPLASIA DEVELOPMENT

K. Krukowska¹, E. Korbut¹, D. Wójcik-Grzybek¹, D. Bakalarz^{1,2}, K. Magierowska¹, M. Wierdak¹, U. Głowacka¹, A. Danielak¹, T. Brzozowski¹, G. Buszewicz³, **M. Magierowski¹**

Contact E-Mail Address: m.magierowski@uj.edu.pl

Introduction: Heme oxygenase (HMOX) is an enzyme involved in heme metabolism leading to the production of ferrous ion, biliverdin, and bioactive gaseous mediator, carbon monoxide (CO). Expressed under pathological conditions in gastrointestinal (GI) tract, inflammation-sensitive and inducible HMOX-1 isoform and CO released from pharmacological tools were shown in our previous studies to contribute in gastric ulcer healing and in esophagoprotection against acute esophagitis. Nevertheless, the role of HMOX-1 and CO in the prevention of Barrett's esophagus (BE) development and progression (BE) has not been elucidated so far.

Aims & Methods: Thus, we aimed to evaluate if the chronic treatment with pharmacological HMOX-1 inducer, hemin or its inhibitor, tin protoporphyrin IX (SnPP) as well as CO-releasing compound, tricarbonyldichlororuthenium(II) dimer(CORM-2) affects BE progression based on experimental in vitro and in vivo models. GEO2R tool and GSE34619, GSE1420, GSE13083 databases were used to assess the alterations in HMOX-1 mRNA expression in clinical BE samples. Human-derived esophageal keratinocytes (EPC2) were treated with bile mixture (BM, 100 µM) for 6 days to reflect clinical BE-specific molecular alterations.

Wistar rats with esophagogastrroduodenal anastomosis (EGDA) implemented to mimic clinical reflux disease (GERD) were treated i.g. for 8 weeks with vehicle or with hemin (0.2-5 mg/kg), SnPP (0.2- 5 mg/kg) or CORM-2 (0.2-5 mg/kg). Macroscopic esophageal lesions index (ELI) was assessed macroscopically and microscopically using standardized scale. Esophageal blood flow (EBF) was measured by laser flowmetry. Esophageal mRNA levels for HMOX-1, BE-specific KRT₇, interleukin 1 agonist (IL-1RA) and suppressor of cytokine signaling 3 (SOCS3) were determined by real-time PCR. COHb content in whole blood samples was evaluated by gas chromatography.

Results: HMOX-1 expression was decreased in BE clinical biopsies vs. normal squamous epithelium. In EPC2 cells treated chronically with BM mRNA expression of HMOX-1 was downregulated. In animal model, CORM-2 but not SnPP and hemin dose-dependently decreased ELI score and reversed BE-like molecular alterations as compared with vehicle by modulation of selected esophageal KRTs mRNA expression.

Enhanced esophageal expression for anti-inflammatory SOCS3 and IL-1RA in EGDA-rats administered with CORM-2 or hemin was observed. Our preliminary data showed that COHb concentration in blood samples was decreased in EGDA-rats.

Conclusion: We conclude based on clinical datasets, in vitro and in vivo animal models analysis that decreased expression of HMOX-1 and possible subsequent fall in CO bioavailability in esophageal mucosa and in systemic circulation contributes in the development of Barrett's metaplasia and its further progression.

Increased CO content due to selected pharmacological donor application may compensate the effect of this alteration leading to prevention of esophageal mucosa against GERD-related chronic and pre-cancerous

pathologies development. This beneficial effect of CO is accompanied by the upregulation of anti-inflammatory response pathways in esophageal mucosa. These observations could serve as a background for the further research targeting the implementation of novel and safe CO-prodrugs in GI pharmacology. [Funding source: National Science Centre, Poland (UMO-2019/33/B/NZ4/00616)]

Introduction: Barrett's esophagus (BE) is an entity with a well known histological progression to malignancy. Malignant transformation in patients with BE may arise from alterations of apoptotic regulatory proteins and the insulin-like growth factor (IGF) system is involved in the regulation of cell proliferation, differentiation and apoptosis. Dys-regulation of IGF-1 increases the risk of a number of malignancies and IGF binding protein-3 (IGFBP-3) is over-expressed in BE, dysplastic and tumour tissue of patients with adenocarcinoma.

The possibility of having a plasmatic biomarker of BE diagnosis or progression is very appealing. However, the role of IGF system in BE is not clear with controversial results regarding circulating levels of these proteins.

Aims & Methods: The objective of this study is to evaluate circulating levels of IGF-1 and IGFBP-3 in patients with BE at different histological stages and study its potential relationship with progression to neoplasm.

We performed a prospective study and determined baseline concentrations of IGF-1 and IGFBP-3 in all patients with BE who underwent an upper endoscopy from May 2012 to May 2015.

Endoscopy was performed under conscious sedation and biopsies were obtained following the Seattle protocol. Ten mL of blood were taken and determination of IGF-1 and IGFBP-3 was performed using the ELISA tech-

nique. The IGF-1/IGFBP-3 molar ratio was calculated. Patients without BE were included as a control group. The protocol was approved by the Ethics Committee and patients gave informed consent.

Results: A total of 116 patients with endoscopy and blood samples were included: 36 control and 80 with BE (46 with IM, 19 with LGD and 20 with ADK/HGD).

Mean levels of IGF-1 were higher in BE than in control group (138.43 ± 69.49 and 108.19 ± 46.69 ng/ml, respectively, $p=0.007$), but there not differences between IM, LGD and ADK/HGD groups. The IGF-1/IGFBP-3 molar ratio was also higher in BE than in control group (0.24 ± 0.98 and 0.19 ± 0.06 , $p=0.001$). 54 out of 65 patients with IM or LGD were followed for a median of 58.50 months (12-113) and 11 of them had progression to LGD ($n=8$) or ADK/HGD ($n=3$) with a median time of 30 months (12-112). Levels of IGF-1 and IGF-1/IGFBP-3 molar ratio were not different between the patients who progressed and not. Age, IMC, glucose and length of BE were similar in both groups.

Conclusion: In this small series of patients with BE with a considerable follow-up, circulating levels of IGF-1 and IGF-1/IGFBP-3 ratio were higher than in controls but were not associated with more advanced histology nor with progression, bringing into question its potential role as a biomarker of neoplastic progression in BE.

Disclosure: Nothing to disclose.

P0083

THE NATURAL COURSE OF UNTREATED NEOPLASIA IN BARRETT'S ESOPHAGUS - A CASE-SERIES

Introduction: Endoscopic eradication therapy (EET) is the preferred treatment for Barrett's Esophagus (BE) with high-grade dysplasia (HGD) to prevent progression to advanced esophageal adenocarcinoma (EAC). EET for early neoplasia is a minimally invasive organ-preserving therapy, in contrast, advanced EAC requires major surgery and is associated with a high mortality rate. The annual neoplastic progression risk is $\pm 7\%$ for HGD.

However, these studies originate from the early 2000's, when lower quality equipment may have missed prevalent cancer. Furthermore, these studies report combined rates of progression to early and advanced EAC. For rational use of EET in clinical practice, accurate risk estimates for progres-

sion to symptomatic EAC are also crucial. Therefore, we aimed to evaluate the time between diagnosis of HGD in BE and development of clinically evident EAC.

Aims & Methods: In the Netherlands, care for patients with BE is centralized in expert centers with a joint registry. We identified cases with HGD left untreated due to competing comorbidities or age and a FU period of at least 12 months. We retrospectively collected data from the electronic patient files and by consultation with the general practitioner to determine vital FU. Endoscopic FU was defined as the time between detection of HGD (i.e. baseline) and the last endoscopy. Vital FU was defined as the time between baseline and symptomatic EAC, death, or last data collection in those still alive. Primary outcome was time of progression to clinically evident EAC, defined as symptomatic EAC (i.e. symptoms of dysphagia) or EAC-related death.

Results: From our database, 11 cases were identified and met the inclusion criteria ($n=2091$, 0.5% of the entire database). The mean age was 78 years old, 64% was male and the median Charlson Comorbidity Index was 4 ($p25$ - $p75$ 4-5). At baseline, HGD was found in a visible lesion in 9 of the 11 cases (82%) and in random biopsies from flat BE in the remaining 2 patients (18%). Median endoscopic FU was 21 months ($p25$ - $p75$ 2-32) with median 2 ($p25$ - $p75$ 0-7) endoscopies per patient. Endoscopic FU had been stopped in 10/11 patients at moment of data collection. Median vital FU was 27 months ($p25$ - $p75$ 21-45). Overall, 4/11 patients (36%) progressed to clinically evident EAC. Three had clinical suspicion of cancer at baseline and 1 had flat HGD. All 4 patients presented as symptomatic EAC and died from EAC. Progression occurred median 52 months (range 17-78) after baseline. In all 4 patients, endoscopic FU was terminated median 30 months ($p25$ - $p75$ 16-44) prior to detection of the clinically evident EAC. Among the other patients (7/11), 3 had endoscopic suspicion of progression and underwent curative endoscopic resection for HGD ($n=1$) or T1-EAC ($n=2$) 19-21-26 months after baseline. The remaining 4 patients had median vital FU of 26 months ($p25$ - $p75$ 16-41) without progression and had unrelated death ($n=3$) or were alive without symptoms ($n=1$).

Conclusion: Even though HGD and early EAC are logical targets for minimal invasive EET, the actual progression to symptomatic disease had a significant duration in our case-series. This lag time in progression to symptomatic EAC may be relevant to consider in patients with a limited life expectancy with early neoplasia or during FU after successful EET.

CAN ENDOSCOPIC EVIDENCE OF BILE REFLUX PREDICT THE DEVELOPMENT OF BARRETT'S ESOPHAGUS?

Y. Iwaya¹, S. Kako², T. Miyazawa², D. Hara², K. Hashigami², A. Hirayama², T. Okamura², T. Nagaya³, T. Umemura²

Introduction: Numerous basic researches have shown that bile reflux plays an important role in the development of Barrett's esophagus (BE). However, the relationship between the endoscopic findings of bile reflux and BE remains unknown. We aimed to investigate whether endoscopic evidence of bile reflux is associated with the presence of BE.

Aims & Methods: We conducted a retrospective analysis of a prospectively maintained database comprised of consecutive Japanese patients who underwent screening gastroscopy. Endoscopic findings of BE, reflux esopha-

gitis, atrophic gastritis and sliding hernia were recorded. Evaluation of a BE was based on the Prague criteria. Endoscopic evidence of bile reflux was defined as the presence of bile-stained fluid in the gastric fundus. We performed univariate and multivariate analyses to determine factors that differed significantly between patients with and without BE.

Results: A total of 3,183 patients were enrolled; 715 (23%) had BE and 767 (24%) had endoscopic evidence of bile reflux. On multivariate analysis, endoscopic evidence of bile reflux was the strongest independent factor associated with the presence of BE (odds ratio (OR) 7.78, 95% confidence interval (CI) 6.33-9.56) compared with the presence of sliding hiatus hernia (OR 3.53, 95%CI 2.79-4.48) or male sex (OR 1.73, 95%CI 1.35-2.21).

Conclusion: Our study showed that endoscopic evidence of bile reflux was a strong independent factor associated with the presence of BE, suggesting that bile reflux may therefore predict which patients with gastroesophageal reflux disease are at risk of developing BE and which patients would benefit from gastroscopy surveillance.

Disclosure: Nothing to disclose.

CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION OF NEOPLASTIC BARRETT'S ESOPHAGUS

M. Omae¹, N. Wang², F. Baldaque-Silva¹

¹Karolinska University Hospital, Stockholm, Sweden, ²Karolinska University Hospital, Pathology, Stockholm, Sweden

Contact E-Mail Address: machami242000@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is a treatment option in neoplastic Barrett's esophagus (NBE) in cases with severe fibrosis and in which cancer cannot be resected *en bloc* by conventional mucosal resection. In cases of big or multifocal lesions, large ESD resections are performed. Large esophageal ESDs might be associated with high rate of adverse events, namely stricture. The advent of stricture prophylactic strategies, has reduced dramatically that risk. With this study we aimed to evaluate the safety and efficacy of large BE ESDs engaging all luminal circumference.

Aims & Methods: This study was approved by the Stockholm Regional Ethical Committee. All patients with NBE BE and macroscopic lesions were invited for ESD after discussion in a multidisciplinary conference. Procedures were performed under deep anesthesia. Stricture prophylaxis with steroids was performed in all patients. A stricture was defined as esophageal narrowing making it impossible for a 9.9 mm endoscope to pass through the esophagus regardless of dysphagia. Follow-up endoscopies were performed at 2 weeks and 2 months and then yearly, or when patients symptomatic.

The primary outcomes were the rates of adverse events such as bleeding, perforation and stricture. Secondary outcomes were the rates of *en bloc*, R0, curative resection, positive lateral and vertical margins.

Results: From of cohort of total 160 BE ESD, between 2011 to 2022, 6 corresponded to circumferential ESD in 5 patients. The mean age was 72.0 years, mean length of Barrett's mucosa C13 (0-24), 14 (0-25). Mean resection time was 345 minutes and the mean specimen size was 110 (85-170) mm.

Considering primary outcomes, there were strictures in 3/6 of cases, all treated successfully with balloon dilatation (1/3) or balloon dilation plus temporary metallic stent (2/3). No perforation and postoperative bleeding occurred.

Considering secondary outcomes, *en bloc* resection was present in 6/6, R0 resection in 4/6, and curative resection in 4/6 cases. The resected specimens corresponded to high-grade dysplasia in 2/6, intramucosal adenocarcinoma to submucosal adenocarcinoma (SM1) in 4/6 cases. Positive

lateral margins and positive vertical margins rates were 0/6 and 2/6 cases, respectively. The 30 days mortality was 0 and mean hospital stay was 3 days.

Two out of 3 non-curative cases were operated. Resected specimens corresponded to T1b and T2 cancers, both with no lymph node metastasis. One curative ESD in a patient with ultralong Barrett esophagus (ULSBE, C24M25) had recurrence lesion after 2 circumferential ESDs. In this patient, esophagectomy was performed due to esophageal recurrence. Esophagectomy specimen shown pT1b (SM3) cancer with no lymph node metastasis. Twenty months later, patient had a thoracic wall metastasis and received palliative treatment.

Conclusion: Circumferential ESD with steroid therapy shows a high safety profile in patients with HGD or mucosal cancer.

This is the first study evaluating the role of all circumferential ESD for NBE. This cohort shows that this strategy is associated with high rates of *en bloc* resection and of free lateral margins. The most common complication was stricture, however all those cases were managed endoscopically. R1 rate was 33% mainly due positive vertical margins.

Patients with NBE should be strictly selected for ESD and primary esophagectomy should be considered in patients with ultra long BE and suspected SM cancer. Circumferential ESD with steroid therapy shows a high safety profile in patients with HGD or mucosal cancer. Further comparative and larger studies are warranted.

Disclosure: None.

P0086

BARRETT'S ESOPHAGUS SURVEILLANCE – CAN WE DO BETTER?

M. Soliman¹, K. Kapur²

¹Medway Maritime Hospital, Medicine, Gillingham, United Kingdom, ²Barnsley Hospital NHSFT, Gastroenterology, Barnsley, United Kingdom

Contact E-Mail Address: Mina.soliman@nhs.net

Introduction: Barrett's esophagus (BO) has a pre-malignant potential. Several guidelines^{1,2,3} to optimise surveillance and early detection of dysplasia were produced.

A previous audit in our hospital revealed significant departure from the guidelines. Dedicated lists⁴ and educational intervention⁵, were suggested to improve the quality of surveillance.

Aims & Methods: We aim to evaluate the compliance of BO surveillance with the published guidelines in our centre between February 1st 2021 and March 31st 2022 after the introduction of dedicated lists with longer time slots of 30 minutes.

A retrospective database search was performed for the word "Barrett" using the built-in audit tool of Infoflex v.5 reporting system and cross referenced with the histopathology data base. Surveillance details were added to an excel spreadsheet against criteria extracted from both the British Society of Gastroenterology and the European Society guidelines. Results were compared to the previous audit.

Results: 204 BO reports were found during the study period. 112/204 (55%) patients were undergoing surveillance and 92/204 (45%) were newly diagnosed.

In the surveillance group; 80 were males (71%) and 32 females (29%). Age range was between 41-83 years, with a mean age of 62. Barrett's segment was described according to Prague criteria in 111 out of 112 (99 % compared to 89% in the previous audit). 31 were short segment (i.e. less than 3cm) and 81 were long segment (3cm or above).

Seattle protocol of biopsies was followed in 104/112 (93% compared to 70% previously) and Chromoendoscopy (Narrow Band Imaging and 2% acetic acid spray) was performed in 66/112 (59% compared to 33% in

previous audit). Inspection time was recorded in 7 out of 112 (6% vs 2.5% in previous audit). Correct surveillance interval from last examination occurred in 103 (92% as opposed to 88% in previous audit). Intestinal metaplasia (IM) was not confirmed in 6 patients. All were discharged from surveillance as this was second endoscopy with negative IM in compliance with the guidelines. Dysplasia was detected in 10 cases (9 low grade and one high grade). Seven LGD and one HGD were appropriately followed up and managed. A lesion within the Barrett's was seen in 2 cases, both had distance from incisors recorded and targeted biopsies taken but no Paris classification or position described according to the clock face. There was also a discrepancy in the length of the measured Barrett between the initial and follow up endoscopies in 40/112 cases (35%) but a significant difference that affects the surveillance interval was observed in 7 cases only (6%).

Conclusion: Despite significant improvements from previous audit, namely the use of Seattle protocol and chromoendoscopy, dedicated lists have not achieved >90% in all parameters that we intended. There is still more that needs to be done to optimise surveillance in relation to recording the BO inspection time, the accurate measurement of the BO length as well as lesion description. We introduced mandatory fields in the endoscopy reporting that would be triggered once BO surveillance has been chosen, to improve the above with further re-audit.

OPTICAL FLOW AS A METHOD FOR QUALITY ASSURANCE IN AI-AIDED EXAMINATION OF BARRETT'S ESOPHAGUS AND BARRETT'S ESOPHAGUS RELATED NEOPLASIA

M. Meinikheim¹, R. Mendel², A. Probst¹, M.W. Scheppach¹, H. Messmann¹, C. Palm², A. Ebigbo¹

¹University Hospital of Augsburg, Department of Gastroenterology, Augsburg, Germany, ²Ostbayerische Technische Hochschule Regensburg, Regensburg Medical Image Computing, Regensburg, Germany

Contact E-Mail Address: michael.meinikheim@uk-augsburg.de

Introduction: In order to offer the best possible performance, Artificial Intelligence (AI) based clinical decision support systems (CDSS) are dependent on high-quality input for real-time evaluation. Even though evaluation of lesions is perceived as real-time, modern AI systems still have to analyze the provided information frame by frame and sometimes pixel by pixel. The movement created by rapid alteration of the scope's position or flushing procedures can confound the AI algorithm and reduce its performance. Optical flow is a method of locating and quantifying motion between consecutive frames.

Aims & Methods: We aim to improve the human-computer interaction (HCI) by establishing a real-time feedback mechanism of the provided data quality for endoscopists using our AI algorithm "Barrett-Ampel" for the evaluation of Barrett's esophagus (BE) and Barrett's esophagus related neoplasia (BERN).

Therefore, unaltered videos in White Light (WL), Narrow Band Imaging (NBI) and Texture and Color Enhancement Imaging (TXI) of eight endoscopic examinations of histologically confirmed BE and BERN were analyzed by our AI algorithm. The motion between consecutive input frames was calculated using Farneback's dense optical flow algorithm and split into per-pixel magnitudes and angles.

The features used to rate the image quality were the mean magnitude and the entropy of the histogram of angles. Frames were automatically extracted, if predefined threshold values of 3.0 for mean magnitude and 9.0 for the entropy of the histogram of angles were surpassed. Experts first reviewed unaltered videos without AI support and evaluated them regarding the imaging quality, subjective perception of distractions like movement or water flushing, and, if applicable, whether they felt those factors would influence their diagnostic accuracy. Secondly, they reviewed the extracted frames.

Results: During steady movement in one direction, like during pushing and pulling of the endoscope, entropy was low, while there was still significant magnitude. Chaotic visual movement observable for example during flushing led to a high entropy as the water spreads in many directions. Increased optical flow appeared when examination videos were not steady, when abundant fluids disturbed the scope's vision or due to esophageal motility, and correlated with the experts' opinion on the quality of the videos.

Directly proportional to the mean optical flow, experts agreed that the imaging quality and distracting motion influenced their performance. When the optical flow's threshold values of 3.0 for magnitude and 9.0 for entropy of the histogram of angles were surpassed, the associated image quality was insufficient for interpretation in 94% of the cases, even for expert endoscopists.

Conclusion: Optical flow as a quality indicator offered real-time feedback on the quality of the provided input data. Optical flow has the potential to improve human-computer interaction and ultimately help to not only unveil the full potential of AI algorithms but also help endoscopists interpret the provided information.

Disclosure: Nothing to disclose.

DOES BARRETT'S ESOPHAGUS START TOO EARLY IN LIFE? ANALYSIS OF ENDOSCOPIC FINDINGS IN A PEDIATRIC COHORT

P.R. Tripathi¹

¹Ankura Hospital for Women and Children, Pediatric Gastroenterology, Hyderabad, India

Contact E-Mail Address: parijattripathi1986@gmail.com

Introduction: Barrett's esophagus (BE) is a premalignant condition found usually in adults. Long term acid exposure of esophageal mucosa is an important predisposing factor of BE. When do endoscopic changes start appearing and do the children with dyspeptic symptoms develop BE in adulthood, is not clear. We aimed to analyze endoscopic changes in esophagus in children presenting with clinic features of chronic acid reflux and dyspepsia.

Aims & Methods: We have retrospectively analyzed endoscopic findings of the esophagus in children presenting with symptoms suggestive of chronic gastroesophageal reflux disease (GERD) and dyspepsia over two years duration (March 2020 to February 2022). Children who had recurrence or

persistence of symptoms after ≥ 4 weeks of proton pump inhibitor therapy were included in the study. Children with associated neurological diseases were excluded.

Results: 119 (52% male) children with ages ranging from 3-204 months were included. The duration of symptoms ranged from 2 to 60 months (Table 1). One-third of all the patients had endoscopic changes in the lower esophagus (LE). 85% of them had an extension of gastric mucosa in the lower esophagus up to variable length. 4 patients had isolated islands of gastric mucosa in LE, maximum up to 3 cm above GE junction. Majority of patients (71%, $n=25$) had extension <1 cm above GE junction while in 5.7% ($n=2$) it was more than 2 cm. Biopsy in these two patients suggested gastric columnar epithelium without any dysplasia. Repeat endoscopy was performed after one year in both the patients which did not show any changes in endoscopic findings.

Total number of patients, n	119
Age, months $\pm$ SD	74.4 $\pm$ 45.4
Sex, male(%)	62 (52)
Indications	
Predominant pain abdomen, n (%)	43 (36.1)
Predominant vomiting, n (%)	59 (49.6)
Other dyspepsia related complaints, n (%)	17 (14.3)
Duration of symptoms, months $\pm$ SD	13.4 $\pm$ 12.8
Endoscopic findings of acid reflux in the lower esophagus, n (%)	41 (34.5)
Extension of gastric mucosa, n (%)	35 (85.4)
Islands of gastric mucosa, n (%)	10 (24.4)
Nodules in the lower esophagus, n (%)	3 (7.3)
Erosions in the lower esophagus, n (%)	4 (9.8)
Length of gastric mucosa in the esophagus, n	35
<0.5 cm, n (%)	14 (40)
0.5 cm- ≤ 1 cm, n (%)	11 (31.4)
1 - ≤ 2 cm, n (%)	8 (22.9)
≥ 2 cm, n (%)	2 (5.7)
Histopathology of the lower esophagus biopsy	10
Gastric metaplasia	6
Intestinal metaplasia	0
Dysplasia	0
Leiomyoma	1

Table 1: Endoscopic and histological changes in children with chronic gastroesophageal reflux disease and dyspepsia

Conclusion: Endoscopic changes in mucosa develop early in children with chronic dyspepsia and GERD although intestinal metaplasia and dysplasia are rare. Children with endoscopic changes in LE mucosa should be closely monitored for long-term outcomes.

Disclosure: Nothing to disclose.

P0089

EARLY DETECTION OF BARRETT'S ESOPHAGUS AND ESOPHAGEAL CANCER IN PRIMARY CARE USING TRANSNASAL ENDOSCOPY: A PROSPECTIVE COHORT STUDY

L. Huibertse¹, Y. Peters¹, P.D. Siersema¹

¹Radboud University Medical Center, Gastroenterology & Hepatology, Nijmegen, Netherlands

Contact E-Mail Address: y.peters@radboudumc.nl

Introduction: The ongoing increasing incidence of esophageal adenocarcinoma (EAC) during the last few decades and its dismal prognosis have stimulated interest in screening for EAC and its precursor Barrett's esophagus (BE). Screening programs to detect BE followed by endoscopic surveillance and treatment of dysplasia or early neoplasia seem able to reduce EAC incidence and improve survival. Although unsedated transnasal endoscopy (uTNE) is an accurate endoscopic procedure for the detection

of esophageal columnar epithelium only the American College of Gastroenterology considers uTNE to be an alternative to conventional esophago-gastroduodenoscopy (cEGD) for BE screening.

Aims & Methods: The primary aim of this prospective screening study was to assess the feasibility, diagnostic yield, and acceptability of BE/EAC screening using uTNE.

Patients aged 50-75 years who were diagnosed with reflux symptoms in primary care were eligible for participation. Patients underwent uTNE by an experienced endoscopist. BE was diagnosed by the presence of columnar epithelium of any length above the gastroesophageal junction during uTNE. All patients in whom BE was suspected during uTNE underwent cEGD to confirm the diagnosis and obtain biopsies according to the Seattle protocol (standard care). Confirmed BE was defined as the endoscopic presence of >1 cm of columnar epithelium combined with the presence of intestinal metaplasia in biopsies. Before and after uTNE, patients filled out questionnaires for tolerability.

Results: Between April 2021 and April 2022, 370 patients were invited to undergo screening using uTNE, of whom 166 patients were included in four different general practices (participation rate 44.9%; 95% CI 39.9-50.0). During uTNE, fourteen cases of BE were detected (8.4%) of which eleven were confirmed during cEGD. Two were not confirmed during cEGD because no intestinal metaplasia was detected in the obtained biopsies and one patient is scheduled for cEGD. Of the BE cases detected during uTNE, 85.7% were male (12/14), aged 53-74 years, and BE-length ranged from C0M1-C5M6. Other relevant endoscopic findings were reflux esophagitis grade A ($N = 18$, 10.8%), reflux esophagitis grade B ($N = 17$, 10.2%), reflux esophagitis grade C ($N = 3$, 1.8%), and hiatal hernia ($N = 37$, 22.4%). No dysplasia was detected in any of the biopsies. In 77 participants (46.4%), no abnormalities were found. No (severe) adverse events were seen. Mean patient tolerability measured using a validated 10-point visual analogue scale (VAS-scale) was 6.3 (0 being worst and 10 being best experience).

Conclusion: The diagnostic yield of detecting BE using uTNE followed by cEGD was 6.6% (95% CI 3.7-11.5) in patients with reflux symptoms in primary care. uTNE is a safe and well-tolerated alternative to cEGD as a screening tool for BE and EAC that can potentially be used in an office-based setting. As further evidence is needed on the yield of uTNE-guided biopsies to detect neoplasia, uTNE should only be used as a triage test, after which confirmatory cEGD is indicated when BE is suspected.

MICROBIAL BIOMARKERS OF ESOPHAGEAL SQUAMOUS CELL CARCINOMA AND PRECANCEROUS LESIONS BY METAGENOMICS

M. Li¹

¹National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, National Central Cancer Registry, Beijing, China

Contact E-Mail Address: liminjuan9@163.com

Introduction: Esophageal cancer is a kind of gastrointestinal cancer with heavy disease burden worldwide, in which esophageal squamous cell carcinoma (ESCC) is a main subtype. Early detection and early diagnosis are effective methods to decrease the mortality and morbidity of ESCC, and microbiota is associated with the progression of ESCC and precancerous lesions.

With the development of high-throughput sequencing, there is a high possibility and feasibility to early detect and early diagnose the high-risk population of ESCC and precancerous lesions from the view of microbial biomarkers.

Aims & Methods: Based on the national screening project of ESCC in China, we enrolled forty-five participants and collected esophageal swabs and epidemiological information from each participant. Specifically, there were nine in normal, nine in esophagitis, nine in low-grade intraepithelial neoplasia (LGIN), nine in high-grade intraepithelial neoplasia (HGIN), nine in ESCC. Metagenomic sequencing was performed on the Illumina Nova-Seq platform. The microbial diversity and microbial composition at species were analyzed based reads.

Results: There was no statistical difference of alpha diversity among normal, esophagitis, LGIN, HGIN, and ESCC. However, the beta diversity was significant, especially ESCC. Combined the results of LefSe, pairwise comparison in STAMP, and random forest, *Fusobacterium nucleatum* [3183], *Dialister pneumostintes* [2391], *Peptostreptococcus stomatis* [8192], *Streptococcus australis* [6321], *Porphyromonas gingivalis* [3008], and unknown *Neisseria* [3964] were associated with the progression of ESCC. Then, combine normal and esophagitis into one group, LGIN, HGIN, and ESCC into one group.

The decision tree showed only *Porphyromonas gingivalis* [3008], *Fusobacterium nucleatum* [3183], and *Streptococcus australis* [6321] were actually included, of which the accuracy was 82.22%.

Conclusion: Microbial biomarkers can be used for the early detection and early diagnosis of ESCC and its precancerous lesion, which can help concentrate the high-risk population of ESCC then save the resources of endoscopy screening.

Disclosure: Nothing to disclose.

CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION FOR THE TREATMENT OF ESOPHAGEAL GASTROINTESTINAL STROMAL TUMORS: A TEN-YEAR EXPERIENCE FROM A LARGE TERTIARY CENTER IN CHINA

J.-X. Xu¹, T.-Y. Chen¹, Y.-B. Liu¹, Y.-Q. Zhang¹, P.-H. Zhou¹

¹Endoscopy Centre and Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, China

Contact E-Mail Address: xu.jiaxin1@zs-hospital.sh.cn

Introduction: Esophageal gastrointestinal stromal tumors (E-GISTs) are extremely rare and surgical resection is the recommended approach. However, surgical resection has large trauma that may cause significant postoperative morbidity. Endoscopic resection (ER) has developed rapidly recent years, and been widely used in gastrointestinal lesions. However, the feasibility and efficacy of ER in management of E-GISTs are unknown.

Aims & Methods: A total of 28 patients with E-GIST treated by ER were retrospectively collected from January 2011 to December 2020 in a large tertiary center of China.

Results: Of the 28 patients, there were 21 males and 7 females, with a median age of 55 years (40-70 years). The median tumor size was 15 mm (5-80mm). Complete resection rate was 100% (28/28), while en bloc resection rate was 96.4% (27/28). The median operation time was 35 minutes (10-410 minutes). Sixteen (57.2%) tumors were very low risk, six (21.4%) were low risk, six (21.4%) were high risk. The median hospital stay was 2 days (1-8 days). One patient suffered from hydrothorax and required drainage, leading to a major adverse event rate of 3.6% (1/28). There was no conversion to surgery, and no death during 30 days after the procedure. Imatinib was given to two patients after ER under the multidisciplinary team surveillance. During the median follow-up time of 54 months (9-122 months), no recurrences and metastasis were observed.

Conclusion: ER is safe and effective for E-GISTs, and become a promising choice in the future. Multicenter, prospective, large sample with long-term follow-up studies are still needed.

Disclosure: Nothing to disclose.

COMPREHENSIVE GENETIC ANALYSES IN CHRONIC ESOPHAGITIS AND ESOPHAGEAL SQUAMOUS CELL CARCINOMA CLASSIFIED BY THE SEVERITY OF LUGOL-VOIDING LESIONS

N. Akizue¹, K. Okimoto¹, T. Matsumura¹, T. Kaneko¹, Y. Ohta¹, T. Taida¹, K. Saito¹, J. Kato¹, N. Kato¹

¹Chiba University Hospital, Department of Gastroenterology, Chiba, Japan

Contact E-Mail Address: n.akizue@gmail.com

Introduction: It has been reported that the risk of carcinogenesis of chronic esophagitis varies according to the grade classification by Lugol-voiding lesions (LVLs). However, according to this classification, the differences in genetic characteristics in chronic esophagitis and esophageal squamous cell carcinoma (SCC) are still not apparent. The present study elucidated the details of genetic mutations in chronic esophagitis and esophageal SCC classified by grade of LVLs.

Aims & Methods: We extracted DNA from the background mucosa (Lugol's stained area) and SCC of 23 esophageal SCC cases, respectively. Next-generation sequencing analysis was performed using a system that targets all exon regions of 69 esophageal cancer-related genes to identify somatic mutations with leukocytes as controls. We also checked whether each mutation was oncogenic or not concerning OncoKB. All cases were classified according to the number of LVLs in one field of view (Grade A: 0, Grade B: 1-9, Grade C: 10-).

Results: Of the 23 cases, 5/11/7 were Grade A/B/C.

Patient age was 72(31-72)/73(54-77)/72(49-77) (p=0.272), and the proportion of women was 40%/10%/14% (p=0.308). The proportion of no smoking was 60%/18%/0% (p=0.042) and no drinking was 60%/0%/14% (p=0.013).

In the background mucosa (Grade A/B/C), 3.6/5.9/6 somatic mutations per case (p=0.117) were found. Oncogenic mutations per case (0.2/0.5/1.3) (p=0.038) were significantly more common in the grade C than in the grade A (p=0.013). (p=0.047, after Bonferroni correction).

Only one case in grade A had no mutation at all in the background mucosa. The other cases had at least one somatic mutation.

In SCC, 5.4/6.5/3.4 somatic mutations per case (p=0.450), and 1.0/1.5/0.8 oncogenic mutations per case (p=0.252) were detected.

Conclusion: Patients in grade A were significantly more likely to be non-drinkers and nonsmokers.

The background mucosa of SCC patients contained many genetic mutations, regardless of the grade of LVLs. However, chronic esophagitis caused by exposure to stronger carcinogens, such as drinking and smoking, may have more LVLs and obtain oncogenic mutations.

The results suggest that the risk of carcinogenesis may differ genetically depending on the grade classification of chronic esophagitis.

Introduction: The number of elderly patients with superficial esophageal cancer (SEC) is increasing.

Aims & Methods: We aimed to evaluate the clinical outcomes and prognostic factors of overall survival (OS) in elderly patients undergoing endoscopic submucosal dissection (ESD) or surgical resection for SEC. Between January 2001 and May 2020, 290 patients aged ≥ 65 years who underwent ESD or surgical resection for SEC were evaluated. Their clinical outcomes and prognosis were assessed, and independent risk factors for OS were identified.

Results: The mean patient age (269 men and 21 women) was 70.9 years (range 65-90 years). En bloc, R0, and curative resections were achieved in 94.5%, 90.0%, and 73.4% of the patients, respectively. During the follow-up (mean: 54.6 months [range: 1-210 months]), 79 patients died. The 3-, 5-, and 10-year OS rates were 82.5%, 73.1%, and 59.7%, respectively.

In multivariate analysis, cancer history of the other organs, American Society of Anesthesiologists performance status, and presence of lympho-vascular involvement (hazard ratio=1.852, 1.656, and 1.943, respectively; all $P < 0.05$) were independent risk factors for poor OS. The high-risk group (≥ 2 risk factors) showed a significantly lower OS than the low-risk group (≤ 1 risk factor) ($P < 0.001$).

Conclusion: The three risk factors could be useful in predicting the long-term prognosis of elderly patients with SEC.

Disclosure: Nothing to disclose.

Introduction: Patients with head and neck squamous cell carcinoma (HNSCC) frequently develop second primary tumors (SPTs) in the esophagus or stomach. Metachronous screening could lead to timely detection of SPTs in early stages and therefore improves the survival in these patients.

Aims & Methods: We conducted a metachronous screening study in patients with HNSCC in a Western country. Patients with HNSCC in the oropharynx, hypopharynx or other sub-locations with alcohol abuses diagnosed between January 2017 and August 2020 were included. Included patients received curative treatment and routine follow-up for HNSCC. A metachronous screening esophagogastrroduodenoscopy (EGD) was performed more than 6 months after HNSCC diagnosis.

Primary outcome was the incidence of SPTs, defined as presence of high grade dysplasia (HGD), esophageal squamous cell carcinoma (ESCC) or any other cancer in the upper gastrointestinal tract.

Results: 120 patients (78% male, median age 65 years) were included. HNSCC was located in the oropharynx (32%), larynx (27%), hypopharynx (24%), or oral cavity (17%).

In total, 9 SPTs were detected in 7 patients (6%). 53 (44%) of the included patients had undergone previous synchronous screening, leading to the detection of 3 early-stage SPTs (2 HGD, 1 ESCC). Metachronous screening was performed within 2 years (54%), 2-3 years (15%), or 3-5 years (31%) after HNSCC diagnosis.

SPTs were detected in 6 (5%) patients (2 HGD, 3 ESCC, 1 esophageal adenocarcinoma). Most SPTs (5/6) were detected in early stages and could be curatively treated with endoscopic resection. No SPTs were detected with routine follow-up imaging for HNSCC prior to metachronous screening.

Conclusion: Metachronous SPTs in the esophagus or stomach were detected in 5% of patients with HNSCC. Metachronous screening for SPTs should be considered in a selection of HNSCC patients.

Disclosure: Nothing to disclose.

ESOPHAGEAL STENTING FOR ESOPHAGOGASTRIC CANCER PALLIATION: HOW TO PROSPECTIVELY EVALUATE QUALITY OF LIFE?

C. Pinto¹, R. Ortigão², I. Pita¹, C. Costa¹, P. Pedrosa¹, C. Taveira¹, P. Medeiros³, P. Redondo³, R.P. Bastos¹, P. Pimentel-Nunes¹, R. Silva¹, M. Dinis-Ribeiro¹

Introduction: Esophageal stents have a well-established role in the palliation of esophageal and esophagogastric cancers. However, there is little prospective data on the impact of esophageal stenting in patients' quality of life (QoL).

Aims & Methods: Our aim was to evaluate the feasibility of a web-based app to assess the impact of esophageal stenting in the QoL of patients with esophageal malignancy.

Prospective study from August 2017 to October 2019. Three validated questionnaires (EORTC-QLQ-C30, QLQ-OES18 and QLQ-OG25) were incorporated in a smartphone app.

Questionnaires were applied to esophagogastric cancer patients before stent placement (baseline) and at three moments after stenting (30, 90 and 180 days), directly through a smartphone app or during a nursing phone consultation. Answers were wirelessly transmitted to the statistics department for analysis.

Results: Eighty esophageal or esophagogastric stents were placed in 72 patients, with an immediate success rate of 100% and no immediate complications.

Ten patients died at 30 days. Sixty-eight patients (94%) answered the baseline QoL questionnaire, 23 at 30 days, 12 at 90 days and 4 at 180 days. We included 23 patients for QoL analysis at 30 days post-stenting: 23 for global health status (QLQ-30) and 15 for esophageal symptoms (QLQ-OES18).

There was a significant improvement in swallowing saliva (mean score 44vs73, $p=0.017$) and constipation (mean score 55vs86, $p=0.015$) and a tendency for dysphagia improvement (37vs61, $p=0.05$) There was a mean score improvement ≥ 10 points in global health status, although not statistically significant.

Conclusion: QoL assessment is paramount to evaluate the effectiveness of endoscopic palliative techniques. In this study, prospective QoL evaluation of stent palliation for esophageal malignancy was feasible and consistent with an improvement in QoL. The main constraint was to abstain from involving health professionals during the follow-up.

Disclosure: Nothing to disclose.

Contact E-Mail Address: gmaps177@gmail.com

Introduction: For curative treatment of esophageal squamous cell carcinoma (ESCC), detection of ESCC at early stage is mandatory. The effectiveness of image-enhanced endoscopy (IEE) for early detection of gastrointestinal neoplasms has been reported. A randomized trial demonstrated that narrow band imaging (NBI), which enables narrow light observation similar to blue light imaging (BLI), had higher detection of ESCC than white light imaging (WLI) had. In another randomized trial, linked color imaging (LCI), which is one of the IEE to emphasize color contrast, was more effective than WLI for detecting neoplastic lesions in the pharynx, esophagus, and stomach. However, it remains to be elucidated which of BLI/NBI or LCI is optimal as a screening mode for ESCC.

Aims & Methods: The aim of this study was to compare the diagnostic performance of BLI with that of LCI in ESCC screening. This is a prospective, multicenter randomized controlled trial (the trial number: JRCT1022190018). Patients with high-risk for ESCC (defined as follows: previous ESCCs or HNSCCs treated with endoscopic resection or radiation therapy, and present HNSCCs) were enrolled and randomly assigned to either primary BLI group (BLI during insertion, followed by LCI during withdrawal) or primary LCI group (LCI during insertion, followed by BLI during withdrawal). Pathological diagnosis of ESCC in biopsy following Lugol chromoendoscopy was regarded as gold standard. The primary endpoint was the detection rate of ESCC in the primary mode. The secondary endpoints included (1) the miss rate of ESCC in the primary mode and (2) the diagnostic parameters, including sensitivity, in the primary mode.

Results: Between January 2020 and April 2021, 351 patients were assigned to the BLI group and 348 to the LCI group. The detection rate of ESCC in the primary mode was 4.0% (14/351) in the BLI group and 4.9% (17/348) in the LCI group, with no significant difference (risk ratio, 0.82; $p = 0.587$) (Table). However, the number of patients with ESCC in the BLI group (19 patients with 20 lesions) tended to be lower than that in the LCI group (30 patients with 42 lesions) ($p = 0.097$). The miss rate of ESCC in the BLI group was significantly lower than that in the LCI group (26.3% [5/19] vs. 63.3% [19/30]; risk ratio, 0.42; $p = 0.012$); in particular, no cases (0/5)

with ESCCs missed by BLI was detected by LCI. In per-lesion analysis, the sensitivity of BLI was significantly higher than that of LCI (75.0% vs 47.6%; $p = 0.042$). On the other hand, the positive predictive value of BLI tended to be lower than that of LCI (28.8% vs 46.5%; $p = 0.076$).

	BLI group	LCI group	RR (95% CI)	pvalue
Patients with ESCC, n/N (%)	19/351 (5.4)	30/348 (8.6)		0.097
Detected by primary mode	14/351 (4.0)	17/348 (4.9) [†]	0.82 (0.41–1.63)	0.565
Missed by primary mode	5/19 (26.3)	19/30 (63.3) [†]	0.42 (0.19–0.92)	0.012
Detected by secondary mode	0/19 (0.0)	15/30 (50.0)		
Detected by Lugol chromoendoscopy	5/19 (26.3)	4/30 (13.3)		

[†] Six patients in the LCI group had both lesions detected and missed by primary mode.

Table. Detection and miss rates of ESCC in each group.

Conclusion: BLI had better diagnostic performance for ESCC than LCI except the detection which would have been affected by the imbalanced prevalence of ESCCs. BLI has the potential to be the standard screening mode for ESCC in high-risk patients.

CAN CONCOMITANT USE OF H2RA PLAY AN IMPORTANT ROLE IN PREVENTING THE GASTRIC MUCOSAL INJURIES LIKE P-CAB OR PPI IN PATIENTS TAKING ASPIRIN?

Y. Shimada¹, R. Om¹, Y. Aonuma¹, S. Arii¹, Y. Kita², Y. Ikeda¹, K. Nomura¹, S. Sato¹, A. Murata¹, S. Sato¹, A. Nagahara², T. Genda¹

Introduction: The mechanism of aspirin-induced gastric mucosal injury is thought to be mediated by multiple processes involving either topical or systemic effects. Recently, it has been found that topical effects play a pivotal role in causing gastric mucosal injury ⁽¹⁾.

In addition, it is revealed that almost all aspirin-induced gastric mucosal injuries were observed in low intragastric pH condition (pH<4) ⁽²⁾.

Therefore, concomitant use of antacids is the standard strategy in preventing aspirin-induced gastric mucosal injury. However, it is not well known how differences in antacids affect the severity of gastric mucosal injuries in patients taking aspirin.

Aims & Methods: The aim of this study is to reveal the differences in preventing ability from aspirin-induced mucosal injuries between histamine-2 receptor antagonist (H2RA) users and proton pump inhibitor (PPI) or potassium competitive acid blocker (P-CAB) users.

This is a case-controlled study conducted at our department. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and March 2020. We focused on the subjects taking only aspirin as an anti-thrombotic agent. We divided into three groups; concomitant use of P-CAB or PPI group (P group), concomitant use of H2RA group (H group) and NO concomitant use of antacids group (N group). In each group, we compared the severity of

gastric mucosal injury, individually. Severity of gastric mucosal injury was evaluated endoscopically according to the modified LANZA score (MLS)^(3,4). Statistical analyses were performed by using Fisher's exact test.

Results: 310 subjects out of 6,031 were taking aspirin. In P group (134 men, 54 women; mean age 72.8 years), average MLS was 0.54±1.32. In H group (11 men, 4 women; mean age 70.1 years), average MLS was 0.67±1.50. In N group (61 men, 46 women; mean age 74.4 years), average MLS was 0.93±1.60. Average MLS in P group was statistically significantly lower than that in N group (p=0.024), but average MLS in H group was not lower than that in N group (p=0.542).

Conclusion: It is suggested that the concomitant use of H2RA is not sufficient in preventing aspirin-induced gastric mucosal injuries. We strongly recommend P-CAB or PPI as antacids for patients taking aspirin to prevent gastric mucosal injuries.

Introduction: Fexuprazan is a novel potassium-competitive acid blocker that could benefit patients with gastric mucosal injury.

Aims & Methods: We aimed to assess the efficacy and safety of fexuprazan for 2 weeks in patients with acute or chronic gastritis. In this study, 327 patients with acute or chronic gastritis who had one or more gastric

erosions on endoscopy and subjective symptoms were randomised into three groups receiving fexuprazan 20 mg q.d., fexuprazan 10 mg b.i.d., or a placebo for 2 weeks. The post-treatment assessments were the primary endpoint (erosion improvement rate), secondary endpoints (cure rates of erosion and oedema and improvement rates of redness, haemorrhage, and subjective symptoms) and drug-related adverse events.

Results: Among the patients, 57.8% (59/102), 65.7% (67/102), and 40.6% (39/96) showed erosion improvement 2 weeks after receiving fexuprazan 20 mg q.d., fexuprazan 10 mg b.i.d., and the placebo, respectively. Both fexuprazan 20 mg q.d. and 10 mg b.i.d. showed an efficacy superior to that of the placebo. Likewise, both fexuprazan 20 mg q.d. and 10 mg b.i.d. also showed erosion healing rates higher than that of the placebo.

No difference was noted in the oedema healing rate and the improvement rates of redness, haemorrhage, and subjective symptoms between the fexuprazan and placebo groups. No significant difference was noted in the incidence of adverse drug reactions.

Full analysis set	Fexuprazan 20 mg q. d.	Fexuprazan 10 mg b.i.d.	Placebo
No. of patients	102	102	96
Erosion improvement rate (%)	59 (57.8)	67 (65.7)	39 (40.6)
Common risk difference (95% CI)	17.0 (3.3–30.6)	25.1 (11.7–38.6)	
P-value (compared with the placebo group)	0.0167	0.0004	

Table

Conclusion: Using fexuprazan 20 mg q.d. and 10 mg b.i.d. for 2 weeks showed therapeutic efficacy superior to that of the placebo and a favourable safety profile in patients with acute or chronic gastritis.

Introduction: Keverprazan is a novel potassium-competitive acid blocker for the treatment of acid-related disorders.

Aims & Methods: This study aimed to establish the non-inferiority of keverprazan to lansoprazole in patients with duodenal ulcer (DU).

In this phase III, double-blind, multicentered study, 360 Chinese patients with endoscopically confirmed active DU were randomized 1:1 to either keverprazan (20 mg) or lansoprazole (30 mg) treatment groups for up to 6 weeks.

The primary endpoint was DU healing rate at 6 weeks. The secondary endpoints were DU healing rate at 4 weeks and symptom improvement. Safety was also assessed.

Results: Full analysis set showed the cumulative healing rates at week 6 were 94.44% (170/180) and 93.26% (166/178) for keverprazan and lansoprazole, respectively (difference: 1.19%; 95% CI: -4.03% to 6.54%). At week 4, the respective healing rates were 83.89% (151/180) and 80.34% (143/178).

Per-protocol set showed the 6-week healing rates with keverprazan and LPZ were 98.19% (163/166) and 97.60% (163/167), respectively (difference: 0.59%; 95% CI: -3.08% to 4.42%); the 4-week healing rates were respectively 86.75% (144/166) and 85.63% (143/167).

Keverprazan was non-inferior to lansoprazole in DU healing at 4 and 6 weeks. The incidence of treatment-emergent adverse events was comparable among groups.

	Keverprazan (n=180)	Lansoprazole (n=178)	Pvalue
TEAEs, patients (%)	104 (57.78)	105 (58.99)	0.8309
Mild	92(51.11)	101(56.74)	
Moderate	11(6.11)	4(2.25)	
Severe	1(0.56)	0(0.00)	1.0000
Study drug related	46 (25.56)	58 (32.58)	0.1627
Leading to study drug discontinuation	3 (1.67)	2 (1.12)	1.0000
Leading to study drug discontinuation (study drug-related)	1 (0.56)	1 (0.56)	1.0000
Serious adverse events	3 (1.67)	1 (0.56)	0.6229
Serious adverse events (study drug-related)	1 (0.56)	0	1.0000
TEAEs, treatment-emergent adverse events.			

Table 1. Treatment-emergent adverse events and serious adverse events (safety analysis set).

Conclusion: Keverprazan 20 mg was not inferior to lansoprazole 30 mg once daily for healing of DU with a good safety profile.

Disclosure: Nothing to disclose.

Introduction: Increasingly extranodal marginal B-cell lymphoma of mucosa-associated lymphoid tissue, known as MALT lymphoma, is a type of non-Hodgkin's lymphoma. Approximately one-third of cases of MALT lymphoma and 85% of gastrointestinal MALT lymphomas present in the stomach as the affected site¹. Primary MALT lymphoma (GML) has a rare incidence and only accounts for approximately 5% of all primary gastric neoplasms².

This disease demands high attention. Researchers have observed that GML patients had significant risk of atrophic gastritis, intestinal metaplasia and secondary tumors³. Compared to the healthy population, the incidence of gastric adenocarcinoma in GML patients was 6 times higher in the GML population⁴.

The prognosis of primary GML patients can be affected by many factors. Clinical risk factors, including age, type of therapy, sex, stage and family hematologic malignancy history, also have significant effects on the development of the disease⁵. Meanwhile, previous studies demonstrated a good prognosis of the disease, with 5-year survival rates of up to 99%. However, more than 95% of studies were only based on stage I/II patients with a small sample size, and few of them even used different staging standards^{6,7}.

Matysiak-Budnik, T *et al.*⁸ conducted a multicenter study in France, and 416 GML patients were retrospectively enrolled. They surprisingly found that 25% of subjects diagnosed at stage III/IV and 11% of patients obtained missed or false diagnoses, which was similar to other studies.

Furthermore, the available data are mainly focused on epidemiology; in contrast, few studies have investigated the prognostic variables for overall survival (OS) in patients with primary GML. Based on the realities above, we searched a large amount of data on patients diagnosed with primary GML in the SEER database. The aim was to develop and verify a survival nomogram model that can predict the OS prognosis of primary GML by combining prognostic and determinant variables.

Aims & Methods: Aim: To create an effective survival nomogram for patients with primary gastric mucosa-associated lymphoid tissue (MALT) lymphoma (GML).

Methods: All data of patients with primary GML from 2004 to 2015 were collected from the Surveillance, Epidemiology, and End Results (SEER) database. The primary endpoint was overall survival (OS). Based on the LASSO and COX regression, we created and further verified the accuracy and effectiveness of the survival nomogram model by the concordance index (C-index), and time-dependent receiver operating characteristic (td-ROC) curves.

Results: A total of 2604 patients diagnosed with primary GML were selected for this study. A total of 1823 and 781 people were randomly distributed into the training and testing sets at a ratio of 7:3. The median follow-up of all patients was 71 months, and the 3- and 5-year OS rates were 87.2% and 79.8%, respectively. Age, sex, race, Ann Arbor stage and radiation were independent risk factors for OS of primary GML (all $p < 0.05$). The C-index values of the nomogram were 0.751 (95% CI: 0.729-0.773) and 0.718 (95% CI: 0.680-0.757) in the training and testing cohorts, respectively, showing the good discrimination ability of the nomogram model. Td-ROC curves and calibration plots also indicated satisfactory predictive power and good agreement of the model. Overall, the nomogram shows favorable performance in discriminating and predicting the OS of patients with primary GML.

Conclusion: Nomograms are a low-cost and convenient clinical tool in assessing individualized prognosis and treatment for patients with primary GML.

Introduction: Endoscopic submucosal dissection (ESD) is considered the treatment of choice for early gastric cancer (EGC) with a negligible risk of lymph node metastasis. However, locally recurrent lesions on artificial ulcer scars are difficult to manage.

Therefore, predicting the risk of local recurrence after ESD is important to manage and prevent the event. This study aimed to elucidate risk factors associated with local recurrence after ESD of EGC.

Aims & Methods: Between November 2008 and February 2016, consecutive patients (n=641; mean age, 69.3±9.5 years; men, 77.2%) with EGC who underwent ESD at a single tertiary referral hospital were retrospectively analyzed to evaluate the incidence and factors associated with local recurrence. Local recurrence was defined as the development of neoplastic lesions at or adjacent to the site of the post-ESD scar.

Results: En bloc and complete resection rates were 97.8% and 93.6%, respectively. The local recurrence rate after ESD was 3.1%. The mean follow-up period after ESD was 50.7±32.5 months. One case of gastric cancer-related death (0.15%) was noted, wherein the patient had refused additive surgical resection after ESD for EGC with lymphatic and deep submucosal invasion. Lesion size ≥15 mm, incomplete histologic resection, undifferentiated adenocarcinoma, scar, and absence of erythema of the surface were associated with a high risk of local recurrence.

Conclusion: Predicting local recurrence during regular endoscopic surveillance after ESD is important, especially in patients with a larger lesion size (≥15 mm), incomplete histologic resection, surface changes of scars, and no erythema of the surface.

Disclosure: We have no conflicts of interest or financial ties to disclose.

Introduction: Iron deficiency anaemia (IDA) can be a sign of serious underlying disease but is often overlooked. Recently updated guidelines of the British Society of Gastroenterology (BSG) recommend male and post-menopausal female patients with IDA should be screened for coeliac disease and undergo dual endoscopy (or CT).

Aims & Methods: This project looked to assess current adherence to these guidelines at the Queen Elizabeth Hospital in Birmingham, England.

A retrospective audit was performed using health informatics for patients who attended AMU/CDU from April 2018 to March 2021. The number of patients with IDA in this time frame was identified.

A further analysis of this group was made to determine the proportion of patients with IDA who had IgA TTG measured as well as those who had OGD and colonoscopy/CT colonoscopy requested.

Results: There were 67797 patients in this study period. 32422 (47.8%) were anaemic (Hb < 120g/dl for women, <130g/dl for men as per WHO guidelines) of which 6357 (19.6%; 9.38% of total) had a microcytic anaemia (MCV <83 as per University Hospitals Birmingham laboratory reference range). Ferritin was tested in 3337 (52.5%) of this group, and of those, 1041 (31.2%) were found to have overt IDA (ferritin <30 µg/mL).

Rate of investigation.

The patient cohort with confirmed IDA comprised 334 males (32.0%), 556 post-menopausal females (53.4%, defined as age ≥45) and 151 pre-menopausal females (14.5%). A further analysis was made to explore how male and post-menopausal female cases were investigated, and if the rate of investigation was affected by the COVID-19 pandemic from 1st March 2020 onwards in this subgroup.

Results are shown in the table below. In general, only a minority of patients underwent further investigation with males more likely to undergo OGD than females. Surprisingly, apart from increased TTG check latterly, little difference was seen after onset of the COVID-19 pandemic.

	Total patients in study		Effect of COVID-19 pandemic	
Patients with confirmed IDA	Male	Post-menopausal females	1 st April 2018 – February 28 th 2020 (pre-pandemic) ¹	1 st March 2020 – 31 st March 2021 (during pandemic) ¹
Number	334	556	488	432
TTG screened	23 (6.89%)	34 (6.12%)	12 (2.46%)	45 (10.4%)
OGD	144 (43.1%)	150 (27.0%)	167 (34.2%)	130 (30.1%)
Colonoscopy/CT colon	61 (18.3%)	77 (13.8%)	73 (15.0%)	65 (11.9%)

¹ = 30 patients had admissions during both time periods so counted in both columns

Table.

Conclusion: This large-scale study found that only a small minority of patients with IDA underwent further investigation. Whilst the study period includes the pandemic era, our results don't suggest this made a significant impact on practice. Nevertheless, these findings indicate a strong need for increased awareness and quality improvement about optimising IDA investigation according to BSG guidelines.

GASTRIC XANTHOMA: YELLOW TRAFFIC LIGHT ALSO IN THE WESTERN WORLD

S. Molina Tejedor¹, V. Roales Gómez¹, E. Velasco Martínez¹, I. Blanco Nodal¹, M. Machín Delgado¹, I. Cacho Soblecherro¹, C. López Martínez¹, E. Rey Díaz-Rubio¹

Introduction: Gastric xanthomas (GX) are benign lesions with a whitish and granular appearance, characterized by the accumulation of lipids in foamy macrophages. Its presence is usually an incidental finding during upper endoscopies and its prevalence varies between 0.23-7%. It is most common in the antral and prepyloric areas.

In recent years, gastric xanthomas have been associated with atrophy, intestinal metaplasia (IM) and early gastric cancer located in the perixanthomatous region. This suggests that GX could be a useful marker to predict advanced gastric lesions.

Previous studies mostly have focused on Asian populations, and evidence in Western populations is very limited.

Aims & Methods: The aim of this study is to evaluate in a sample of western subjects whether gastric xanthoma is associated with a higher prevalence of IM, dysplasia, atrophy or adenocarcinoma relative to the general dyspeptic population.

It is a retrospective, observational and descriptive study.

The sample includes 116 cases of patients in whom a gastric xanthoma was clearly identified during an endoscopy. We also include 116 controls, defined as dyspeptic patients who went through a gastroscopy, with no identification of GX.

The following variables were analyzed: age, sex, diabetes mellitus, Helicobacter Pylori (Hp) and the presence of advanced lesions (AL) like atrophy, IM, dysplasia or adenocarcinoma.

Controls were randomly matched by age and sex in a 1:1 proportion with cases using a random number generator based on the "Mersenne twister" algorithm.

To evaluate variables associated with the presence of xanthomas, we ran a conditional logistic regression model in which statistically significant or trend variables in univariate analysis were included in multivariate analysis. Data were analyzed using STATA v. 14.

Results: We identified AL in 85 patients, of which gastric xanthoma was present in 76.5% (65), while 23.5% (20) belonged to the control group. This difference was statistically significant ($p < 0.001$), finding a positive correlation between the presence of gastric xanthoma and the probability of having AL (OR 6.7 [3.2-14.1], $p < 0.001$).

When we reviewed the lesions one-by-one, we found that there is a significantly higher percentage of patients with intestinal metaplasia and atrophy in the case group (OR 5.9 [2.8-12.4], $p < 0.001$ and OR 6 [1.3-26.8], $p = 0.019$ respectively). Due to the low incidence of gastric dysplasia and

adenocarcinoma in our sample, we found no significant differences between the case and the control group. No significant differences were found regarding DM or Hp.

Table 1 summarizes these results.

		Univariable analysis		Multivariable analysis		
		Xantoma (N=116)	Control (n=116)	p	mAOR (95% CI)*	p
Sex	Male, n (%)	41/82 (50.0%)	41/82 (50.0%)	>0.999		
	Female, n (%)	75/150 (50.0%)	75/150 (50.0%)			
Age, mean (SD)		63.3 (13.5)	63.1 (13.2)	0.202	1.1 (0.9-1.4)	0.232
H.Pylori, n (%)		29/59 (49.2%)	30/59 (50.8%)	0.873		
Diabetes, n (%)		23/47 (48.9%)	24/47 (51.1%)	0.873		
Lesion**, n (%)		65/85 (76.5%)	20/85 (23.5%)	<0.001	6.7 (3.2-14.1)	<0.001
Metaplasia, n (%)		63/83 (75.9%)	20/83 (24.1%)	<0.001	5.9 (2.8-12.4)	
Atrophy, n (%)		12/14 (85.7%)	2/14 (14.3%)	0.019	6 (1.3-26.8)	

*Matched adjusted Odds Ratio (95% Confidence Interval)

**Presence of metaplasia, atrophy, dysplasia and/or adenocarcinoma

Table 1. Univariable and multivariable analysis of factors associated with the finding of xanthomas.

Conclusion: We concluded that the presence of GX strongly recommends performing biopsy mapping, because we find a strong association between GX and AL (almost 7 times higher than in the dyspeptic population) independent of the endoscopy indication. In populations with a low incidence of gastric cancer, such Spanish and European Caucasian populations, we believe that being aware of indirect signs of AL is particularly relevant. GX are easy to detect even for unexpert endoscopists without needing any advanced equipment.

Introduction: Gastric cancer (GC) is the second most common gastrointestinal neoplasm and the sixth highest incident and fatality rates in Spain (less than 30% of 5-year survival). In 2019, one Spanish study investigated the missed rate of GC for the first time and reported a 9.1% (similar that data from Western countries).

Aims & Methods: To determine the frequency and characteristics of missed gastric cancer (MGC) in a determined population in Spain. To compare MGC and non-MGC tumors.

Retrospective observational study of all patients diagnosed with gastric adenocarcinoma between January-2012 and December-2021 in a defined geographic area (Burgos, Spain). Missed GC was defined as a case diagnosed with a negative esophagogastroduodenoscopy (EGD) in the previous 3 years.

Results: From 767 cases of GC, 29 cases were excluded (non-data). The overall rate of MGC was 6.8% (50/738). Mean total age was 73.8 ± 12.08. 62.5% (461/738) was male (68% MGC). The most frequent symptom was anaemia (23.3%), except in the group of MGC that was the acute gastrointestinal haemorrhage (24%). One third of all patients were in stage I and II, nevertheless this rate was higher in patients with MGC (54%). Stage III patients were found in 25.9% (16% MGC) and stage IV in 34.6% (28% MGC). Survival rate was not significantly different between both groups of patients. However, it seems that the survival of patients with previous EGD was some higher.

MALT LYMPHOMA A LONG-TERM FOLLOW-UP FROM A SINGLE CENTER EXPERIENCE

L. Correia Gomes¹, M. Rajão Saraiva¹, J. Moleiro¹, I. Claro¹

¹Instituto Portugues de Oncologia de Lisboa, Gastroenterology, Lisboa, Portugal

Contact E-Mail Address: luisfilipe.gomes@outlook.com

Introduction: Gastric mucosa-associated lymphoid tissue B-cell lymphoma (GML) is the most frequent site of extranodal marginal-zone B-cell lymphoma. Synchronous or metachronous malignancies have been reported in patients with GML with inconsistent results. We aimed to characterize the prevalence and development of gastric premalignant and malignant conditions during follow-up of these patients.

Aims & Methods: We retrospectively analysed 156 GML patients (1993 – 2020) with a mean follow-up time of 95 months (8 years) and a mean of 10 endoscopies per patient.

Results: Of 156 patients, 79 (51%) were male, mean age at diagnosis of 56-years-old. At diagnosis, endoscopic appearance was, predominantly, ulcer (26.4%), erosions (25%) or erythema (20.8%). The histology at diagnosis revealed gastric atrophy in 31 (21.5%) and intestinal metaplasia in 19 (13.2%), mainly in the antrum.

Most of the patients (88.16%) performed only eradication of *H. pylori* infection; others also needed chemotherapy (3.29%) or radiotherapy (1.97%). Patients' follow-up revealed that 54 patients (39.71%) developed intestinal metaplasia between 4 and 192 months of follow-up.

From the total of 73 patients with intestinal metaplasia, 1 evolved to high grade dysplasia and 1, exposed to radiotherapy, to gastric adenocarcinoma at 24 and 46 months of follow-up, respectively, both in the antrum. Besides, 2 patients developed large B cell Lymphoma, one 8 months after the diagnosis and the other after 108 months.

Conclusion: Despite some limitations, our data showed frequent progression to precancerous lesions of gastric mucosa in GML patients. However, only two patients developed dysplasia and adenocarcinoma, diagnosed within 5 years of follow-up and from the 2 identified diffuse large B-cell lymphoma, only 1 was developed after the 5 years period.

So, despite most literature report increased risk of secondary primary malignancies in these patients, more information is needed to stratify the patients according to risk factors and personalise long-term follow-up.

Introduction: Gastroscopy is the standard procedure for gastric cancer (GC) diagnosis and its use for GC screening in some countries has demonstrated a 30% reduction in GC mortality. Early GC diagnosis improves clinical outcomes and may be cured by endoscopic resection. In Italy, with an intermediate risk for GC incidence, mass gastroscopy screening is not feasible due to costs and invasiveness.

Currently, the available pepsinogen (PG) test (PG-test) based on the combination of serum PG-I level and PG-I/PG-II ratio is considered a good predictor for GC in populations with high GC incidences. In our experience as well as in other studies reported in regions at high/intermediate risk of GC, with a widely accepted cut-off point of PGI <70ng/ml and PGI/PGII <3.0, the sensitivity for GC is satisfactory (≥80%), but the specificity (< 75%) needs to be improved.

We previously developed a model based on coefficient for PG-test combining with patient's age, sex, anti-*Helicobacter pylori* (*H. Pylori*) immunoglobulin level (IgG), and serum gastrin G17 level to discriminate patients at high risk for gastric adenocarcinoma and neuroendocrine tumors, DSC test (1,2).

Aims & Methods: This is the first report of prediction of high-risk gastric lesions using this model and with an acceptable ability to find participants at risk for high gastric lesions.

88 consecutive Caucasian individuals who presented to the Oncological Gastroenterology Unit of the Centro di Riferimento Oncologico in Aviano, Italy, for dyspepsia and/or suspected GC were involved in a prospective

monocenter study. Data of patients' age and sex were collected; expression profiles of serum PG, Gastrin G17, and *H. Pylori* IgG were performed and analyzed to group patients in risk classes for low, medium, and high gastric lesions, respectively. The accuracy of the model was established with gastroscopy and histological diagnosis of the gastric biopsies performed in the near time.

Results: Since June 2020, we enrolled 88 participants for DSC risk classification. Individuals with $y1 > 0.385$ and $y2 > 0.294$ were classified as DSC-high risk (21.6%), those with only $y1$ or $y2$ positive criteria as DSC-medium risk (6.8%), the remaining individuals as DSC-low risk (71.6%). 5 were found to have a high-grade lesion histologically confirmed (68%), 13 (14.77%) showed moderate atrophy and 57 (71.6%) did not show evident lesion or gastric atrophy and were excluded from secondary endoscopic follow-up.

The percentage of correctly diagnosed individuals with high-grade lesions was 4 (80%) and those correctly diagnosed as low/negative risk was 57 (81.4%). Of the 13 patients with a moderate lesion at the endoscopic examination, 6 (46.2%) were classified in the high-risk, 2 (15.4%) in the medium, and 5 (38.5%) in the low-risk DSC-risk group.

In total, the global DSC-test reaches 80.0% sensitivity, 86.36% of specificity, and an accuracy of 86.0% (100% in younger, 80.45% in older patients). PG-II level, but no PG-I, increased in patients with *H. pylori* infection, but proportionally increase with aging independently of *H. pylori* infection. Accordingly in *H. pylori*-negative individuals the range of PGI/PGII ratio shows the highest variability in the elderly.

Conclusion: We demonstrated the accuracy of the DSC-test in a prospective study including 88 participants with confirmed endoscopic and histological diagnoses. Whether DSC-test is effective in the follow-up remains to be seen, since high gastric lesions may be developed later.

Introduction: Image-enhanced endoscopy (IEE) has advanced to become a mandatory modality in clinical practice, especially for surveillance of neoplastic lesions^{1,2}. Linked color imaging (LCI) (Fujifilm Medicals, Japan) is a unique IEE and it provides images similar to those provided by white light imaging (WLI).

A multicenter randomized study showed that LCI was superior to WLI for surveillance of neoplasia in the upper gastrointestinal (GI) tract. However, the doctors and lesions for which IEE is clinically useful have not been clarified.

Aims & Methods: The aim of this study was to determine the clinical advantage of LCI in endoscopic diagnosis of epithelial neoplasia using eye tracking. Nine doctors (3 experts, 3 trainees and 3 novices) who did not have information on the prepared endoscopic images participated in this study. Sixty cases including 30 epithelial tumors (8 cases of esophageal cancer and 22 cases of gastric cancer) and 30 normal cases or cases with no tumors were selected. A total of 120 images including 60 images of WLI and 60 images of LCI taken at the same position were randomly and anonymously set. The opt-out method to obtain consent for participants in this study was applied and this study was performed in accordance with the ethical standards detailed in the Declaration of Helsinki.

The authors' institutional ethics committee approved this study on October 27, 2021 (021-0081). EMRACTUS (nac Image Technology Inc., Japan) was used for eye tracking, and endoscopic images were displayed for 10 seconds followed by a black screen for 2 seconds. 'Correct answer' was defined as gazing at the lesion and pressing the button within 5 seconds from the start of display of images. Entry time was defined as time to the first gaze of the lesions from the display of images.

The primary endpoint was sensitivity for diagnosis of epithelial neoplasia in WLI and LCI, and secondary endpoints were specificity, positive predictive value (PPV), negative predictive value (NPV) and entry time.

Results: Sensitivities were 68.1% (95%CI: 64.8-70.8) in LCI and 51.9% (48.3-54.9) in WLI, and sensitivity in LCI was significantly higher than that in WLI ($P=0.002$). Also, NPV in LCI was significantly higher than that in WLI (73.9% vs 64.3%, $P=0.007$), but there was no significant difference in specificity or PPV between LCI and WLI.

Sub-analysis is showed that sensitivity in LCI was significantly higher than that in WLI in trainees (70.0% vs 54.4%, $P=0.045$), novices (65.6% vs 42.2%, $P=0.003$) and esophageal cancer (73.6% vs 45.8%, $P=0.007$). Entry times were 0.74 ± 0.6 in LCI and 0.74 ± 0.73 in WLI ($n.s.$)

Conclusion: LCI is an effective modality for diagnosis of epithelial tumors in the upper GI tract, especially for trainees and novices. It is necessary to consider effective use of IEE according to endoscopists and target patients and lesions.

Introduction: Linitis plastica (LP) is a very aggressive and rare carcinoma with a scirrhous stroma that affects the submucosal and muscular layers of the stomach even without mucosal alterations. Lack of timely diagnosis is a crucial problem related to its prognosis and treatment.

The probe-based Confocal Laser Endomicroscopy (pCLE) enables *in vivo* analysis of tissue microarchitecture and precise identification of areas suitable for biopsy sampling by enhancing contrast and magnification of the diseased tissues at the cellular level. This technique has also been used in a few studies to objectively assess microvessel density at different neoplastic stages and angiogenic status of gastrointestinal cancers. pCLE has been shown not only to be a useful tool but also a valid technique for the evaluation of vascular changes in gastric cancer [1-2].

Aims & Methods: With the aim of developing new approaches to improve LP diagnosis, in this study we used the pCLE technique for the first time to determine whether these lesions, with negative histological samples, are also characterized by aberrant vasculature similar to gastric cancer.

During standard endoscopy, mucosal architecture, tortuosity and enlargement of vessels, as well as the presence of vascular leakage and efficiency of the blood flow were assessed in six LP consecutive patients using probe-based Confocal Laser Endomicroscopy (pCLE).

Results: In all LP patients, we detected abnormal changes in vasculature. The aberrant features of the vascular network were common to all LP patients examined and consisted of vessel enlargement, tortuosity, and leakage associated with the affected submucosal layer.

Conclusion: This is the first study to highlight the presence of marked vascularization associated with LP, characterized by the presence of abnormal and non-functional vessels, similar to what is observed in neoplastic tissues. Therefore, the analysis of LP by pCLE may provide a new endoscopic approach and strategy to better define these patients.

Introduction: As the incidence of duodenal neuroendocrine tumors (DNETs) is steadily increasing, the role of endoscopic treatment for small and low-grade lesions is also raised. We aimed to investigate the efficacy and safety of endoscopic treatment for DNETs.

Aims & Methods: Patients who underwent endoscopic treatment for DNETs between 2000 and 2019 were included. The clinical features, treatment modalities, recurrence rate, and endoscopic outcomes according to tumor size were analyzed retrospectively.

Results: Overall, 125 patients underwent endoscopic treatment including forceps biopsy (n=18), endoscopic mucosal resection (EMR, n=98), endoscopic submucosal dissection (ESD, n=6), and argon plasma coagulation (n=3). Of patients who underwent EMR or ESD, En bloc resection rates were 98.1% (n=102), and complete resection rates were 64.4% (n=67). Complete resection rates were significantly higher in <1 cm small-sized lesions than in 1-2 cm large-sized lesions (69.8% vs. 38.9%, $p=0.013$). The rates of lateral and vertical margin involvements were 7.7% (n=8) and 34.0% (n=35), respectively. The 4 cases of perforation required surgical intervention, and no procedure-related mortality occurred. The tumor recurrence rates were 5.6% (n=7), and no tumor-related mortality occurred during median follow-up period of 50 months (interquartile range 18-79).

Conclusion: Based on our favorable long-term outcome, endoscopic treatment for DNETs less than 1 cm in diameter and confined to mucosal and submucosal layers could be an effective and safe treatment strategy.

Introduction: Autoimmune atrophic gastritis (AAG) is a chronic inflammatory disorder affecting the oxyntic mucosa, leading to mucosal atrophy, intestinal metaplasia (IM), up to possible development of type I neuroendocrine tumors (T1gNET), dysplasia, and intestinal-type gastric cancer (GC). The occurrence of epithelial and neuroendocrine lesions in AAG patients at long-term follow-up was not assessed so far.

Aims & Methods: The aim of this study was to assess the occurrence of gastric neoplastic lesions (GNL) at long-term follow-up (FU), in a prospective cohort of AAG patients (diagnosed 1996-2020) adhering to endoscopic-histological surveillance. FU gastroscopies were scheduled at 4 years before 2011 and then every 3 years, according to MAPS guidelines. In case of new symptoms not reported during baseline evaluation, worsening of known symptoms, or onset of anemia, gastroscopy was anticipated. The

main features of patients with and without GNL were compared at univariate and multivariate analyses to assess for eventual predictive features. Kaplan-Meier survival curves were obtained.

Results: A total of 275 AAG patients [72.0% female, median age 61 (23-84) years] were included with a median FU of 5 (1-17) years. Overall, 58 gastric neoplastic lesions were detected (crude incidence 21.1%). At FU, GC/high grade dysplasia (HGD) was diagnosed in 7 patients (crude incidence 2.5%), low grade dysplasia (LGD) in 9 patients (crude incidence 3.3%), and 42 T1gNET in 28 patients (13 patients with recurrent T1gNET) (crude incidence 15.3%). The annual incidence rate person-year was 3.9% for all GNL (0.5%, 0.6%, and 2.8% for GC/HGD, LGD, and T1gNET, respectively). All GNL showed at baseline endoscopic-histological evaluation OLGA score 2, except 2 patients with LGD and 1 patient with T1gNET that presented OLGA 1 at baseline evaluation. At logistic regression, considering as dependent variable the presence of epithelial GNL (GC, HGD, LGD) at FU, a positive association was found for age ≥ 60 years (OR 6.6, 95%CI 1.45-31.5) and the presence of baseline IM without PPM (OR 5.4, 95%CI 1.4-21.0); considering as dependent variable the presence of T1gNET at long term FU, a positive association was found for the presence of baseline severe corpus atrophy (OR 3.3, 95%CI 1.1-9.9).

In AAG patients presenting IM without PPM at baseline, a shorter mean overall survival time (95%CI for the mean) free of epithelial GNL was observed [15.4 (14.4-16.4) years vs 13.3 (11.0-15.7) years ($p=0.02$). In AAG patients with severe corpus atrophy at baseline, a shorter mean overall survival time free of T1gNET [15.9 (15.0-16.8) years vs 13.0 (11.8-14.3) years ($p=0.04$)] was shown.

Conclusion: The current study provides data to confirm the higher risk of developing GNL in AAG patients, despite the low-risk OLGA scores, quantified by an annual incidence rate of 3.9%-person year. Regular endoscopic-histological surveillance should be proposed in AAG patients for early diagnosis of GNL, in particular in those over 60 years of age, presenting with IM without PPM and/or with severe corpus atrophy at diagnosis, possibly optimizing surveillance strategies.

USEFULNESS OF LINKED COLOR IMAGING FOR DETECTION AND CHARACTERIZATION OF EARLY UNDIFFERENTIATED-TYPE GASTRIC CANCER

W. Lee¹

¹Chonnam University Hwasun Hospital, Internal Medicine, Gastroenterology, Jeollanam-do, Korea (Republic of)

Contact E-Mail Address: jadelook@hanmail.net

Introduction: Linked color imaging (LCI) is based on the bioluminescent imaging technique, which enhances slight differences in mucosal color allowing for the reddish mucosa to appear redder. Small number of studies have reported the usefulness of LCI for assessing differences in early gastric cancer (EGC) cases, however, the results were mostly about differentiated EGC.

This study aimed to analyze the color difference between cancerous and non-cancerous areas to compare LCI with conventional white light image (WLI) in a cohort of undifferentiated-type EGC patients.

Aims & Methods: We prospectively enrolled 46 patients with undifferentiated-type EGC from three national based hospitals between September 2020 and October 2021. All lesions were observed first by WLI, followed by LCI. Additional biopsy was taken from surrounding mucosa to check for intestinal metaplasia, and test for *Helicobacter pylori* were performed. Color difference was measured in accordance with the International Commission on Illumination (CIE) details.

Results: Color difference value with LCI was significantly higher and approximately twice that of WLI, while this difference did not appear to be higher in the cases of accompanying *H. pylori* infection or intestinal metaplasia. In subgroup analysis, color difference of poorly-differentiated EGC was marked in LCI compare to WLI, but in signet ring cell type or mixed type EGC, the difference was not statistically significant.

Conclusion: LCI appears to be effective for detection of undifferentiated type EGC than WLI in endoscopic screening. Moreover, LCI may discriminate pathologic subgroup of undifferentiated type EGC possibly due to characteristic cellular growth pattern.

Disclosure: Nothing to disclose.

CLINICOPATHOLOGICAL AND ENDOSCOPIC FEATURES OF GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE

J. Cao¹, D. Zhuang², Y. Yang¹, L. Zhang³, Q. Xu¹, M. Xu¹

¹Shanghai East Hospital, Tongji University School of Medicine, Endoscopy Center, Department of Gastroenterology, Shanghai, China, ²Zhejiang Zhoushan Hospital, Department of Gastroenterology, Zhoushan, China, ³Shanghai East Hospital, Tongji University School of Medicine, Department of Pathology, Shanghai, China

Contact E-Mail Address: jia_cao@yeah.net

Introduction: Gastric adenocarcinoma of the fundic gland type (GA-FG) is a new type of gastric cancer discovered in recent years, and its histopathological features are similar to fundic gland cells. It can be accompanied with other epithelial tumors with or without *H. pylori* infection. Besides, GA-FG can sometimes occurred among younger patients. Most GA-FG cases turn out to have good prognosis.

However, it can also be combined with other well differentiated or even poorly-differentiated epithelial tumors, so that its ability to invade or metastasize needs further research.

Aims & Methods: To retrospectively observe and compare the clinicopathological features of gastric adenocarcinoma of the fundic gland type (GA-FG).

The clinicopathological features of 19 cases of GA-FG diagnosed in our center from April 2019 to March 2022 were retrospectively analyzed, including age, sex, tumor location, shape, diameter, surrounding mucosa and the status of *Helicobacter pylori* infection. The depth of tumor invasion and immunohistochemical results were analyzed in 15 cases treated with EMR/ESD.

Results: Most of the patients were middle-aged or elderly, among whom the youngest was 37 years, and the average age was 55.5±11.6 years, the sex ratio was 8 male: 11 female. Most of the lesions were type 0-IIa with irregular microsurface pattern (IMSP) and irregular microvascular pattern (IMVP) (14/19), which originated from the non-atrophic mucosa in the upper or middle part of the stomach. The average diameter of the tumors was ≤1.0 cm (0.7±0.2cm), and the their phenotypes were chief cell predominant type. In 15 cases (15/19) treated with EMR/ESD, the lesions invaded into submucosa, but no lymphovascular invasion was found. The Ki-67 index of all lesions was ≤10%.

Conclusion: GA-FG is a rare and low-malignant tumor. It occurs on the non-atrophic mucosa of the upper or middle third of the stomach, most of GA-FGs are superficial elevated lesions. GA-FG can occur in younger patients, and it can also be accompanied with other epithelial tumors. Pathology and immunohistochemistry are helpful with the diagnosis.

Introduction: Type I Gastric Neuroendocrine Tumors (GNETs) have an increasing incidence, but data on the most appropriate management is scarce.

Aims & Methods: The aim of the study was to evaluate the outcomes of different therapeutic strategies (polypectomy/surgery, mucosectomy [EMR], endoscopic submucosal dissection [ESD], surgery and somatostatin analogues) in patients with type I GNET.

Retrospective study including consecutive patients admitted for type I GNETs between January 2010 and December 2019 was performed.

Results: 113 patients with type I GNET were included, 62% were women, with a mean age of 60 years. At diagnosis, 18% of patients had anemia and 16% vitamin B12 deficiency. Anti-parietal cell and intrinsic factor antibodies were present in 76% and 4% of patients with autoimmune gastritis, respectively.

At diagnosis, the surveillance/polypectomy strategy was adopted in 77 patients. Twenty-four patients underwent EMR, 6 underwent ESD, 3 underwent surgery (2 for evidence of lymph node metastases) and 3 started somatostatin analogues.

Patients undergoing EMR and ESD had no statistically significant differences in maximum lesion diameter (16 vs 13mm, p=0.515), Ki67 index (p=0.745) and grade (p=0.855). The rate of complete histological resection (78 vs 60%, p=0.255) and the presence of negative horizontal and vertical margins (89 vs 100%, p=0.597; 77 vs 60%, p=0.470, respectively) were similar in both groups. Lesions removed by ESD had more frequently lymphovascular invasion (40 vs 6%, p=0.120).

The development of metachronous lesions was similar in the group undergoing EMR, ESD and surgery (38 vs 40% vs 33%, p=0.876). Overall survival was 100%.

Conclusion: Regardless of disease stage, the overall survival of patients with type I GNET is excellent. ESD and EMR achieved similar short- and long-term results in this group of patients.

Disclosure: Nothing to disclose.

CLINICAL COMPARISON OF ENDOSCOPIC RESECTION VERSUS SURGICAL TREATMENT AMONG PRIMARY DUODENAL GASTROINTESTINAL STROMAL TUMORS (D-GISTS)

X.-Q. Li¹, Z.-Q. Liu¹, Q.-L. Li¹, P.-H. Zhou¹

¹Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Shanghai, China

Contact E-Mail Address: li.quanlin@zs-hospital.sh.cn

Introduction: Duodenal gastrointestinal stromal tumors (D-GISTs) are relatively rare. Due to small numbers in reported cohorts, the prognostic characteristics and therapeutic efficacy of duodenal GISTs remain uncertain. There are few studies focused on the safety and efficacy of endoscopic resection (ER) compared with surgical resection (SR).

Aims & Methods: We aimed to compare the safety and efficacy of endoscopic resection (ER) with surgical resection (SR) of D-GISTs in Zhongshan hospital. The study included 88 patients with D-GISTs between January 2014 and December 2021, among them 28 patients undergoing ER and 60 patients undergoing SR. Clinicopathological characteristics, intraoperative and postoperative complications, and long-term follow-up were compared between the 2 groups. Disease-free survival (DFS) was calculated using Kaplan-Meier analysis.

Results: The mean age (56.0±8.9years vs. 57.7±11.3years, $p = 0.214$) and man ratio (19/28, 67.9% vs. 33/60, 55%, $p = 0.253$) between the two groups were not significantly different. The most common location of D-GISTs was the descending portion (16/28, 57.1% vs. 41/60, 68.3%). Patients undergoing ER had significantly smaller tumor size (1.83 vs. 4.72 cm, $p < 0.001$), shorter procedure time (73.58 vs. 168.80 min, $p < 0.001$), and shorter hospital stay (2.64 vs. 14.83 days, $p < 0.001$) compared with those undergoing SR. The en bloc resection rate was achieved in 96.4% ($n = 27/28$) of patients in the ER group, whereas 100% ($n = 60/60$) in surgical group ($p = 0.318$). However, during long-term follow-up (50.34±27.7 months), recurrence occurred in one patient in the ER group (occurring at 12 months postoperatively) and one in the SR group (occurring at 30 months postoperatively). the three-year recurrence rate (3.5% vs. 1.7%, $p = 0.5$) was not significantly different between the two groups. One patient in the SR group died two years after surgery.

Conclusion: Endoscopic resection might be an alternative therapeutic method for GISTs in the duodenum in selective cases.

Disclosure: Nothing to disclose.

P0114

PREVALENCE AND PREDICTORS OF MALNUTRITION IN PATIENTS WITH GASTRIC CANCER – A SINGLE CENTRE PROSPECTIVE STUDY

P. Patil¹, A.K. Jain¹, S. Mehta¹, S. Sundaram¹, O. Salvi², S. Khan¹, A.M. Khan¹

¹Tata Memorial Hospital, Homi Bhabha National Institute (HBNI), Department of Digestive Diseases and Clinical Nutrition, Mumbai, India, ²Tata Memorial Hospital, Homi Bhabha National Institute (HBNI), Mumbai, India

Contact E-Mail Address: prachipatil@gmail.com

Introduction: Malnutrition is seen in 60-90% of patients with gastric cancer (GC). Both the malignancy and adverse effects of multimodality treatments can lead to malnutrition. Malnutrition can result in increased treatment toxicity, decreased response rates, and increased length of stay in patients with Gastric cancer (GC) and may also impact outcomes. Various nutrition assessment tools such as Subjective Global Assessment (SGA), Malnutrition Universal Screening Tool (MUST), Mini Nutritional Assessment (MNA), and the Nutrition Risk Screening (NRS) 2002 are used in practice to assess for malnutrition in addition to the standard anthropometric measurements.

Aims & Methods: We conducted a prospective IRB-approved observational study with the primary aim of studying the prevalence of malnutrition in GC and secondary aims of studying the concordance between SGA and other screening tools and assessing the predictors of malnutrition in GC. 1000 consecutive untreated patients with biopsy-proven GC (adenocarcinoma) registered at Tata Memorial Hospital, a referral cancer center were recruited over 3 years. Demographic details and baseline disease status were noted. Nutritional assessments were done by a trained dietician at baseline and at predefined intervals. We present the baseline data here.

Results: The mean age was 53.4 years (range 18-86 years) and 71.5% were males. 15.2% were ≤ 40 years of age (young GC). 770 (77%) patients had an ECOG-Performance Status of 0/1 at baseline. 2.5% of patients were from

Upper socioeconomic status (SES), 38.6% from middle SES and 58.9% were from lower SES. 9% each had a previous history of gastric surgery and a family history of malignancy. Features suggestive of gastric outlet obstruction (GOO) were present in 36.5% of patients with GC (42.9% amongst malnourished and 15.7% amongst well-nourished).

The prevalence of malnutrition using the SGA was 76.5%. 524 (52.4%) were SGA B (moderately malnourished) and 241 (24.1%) patients were SGA C (severely malnourished). Using MUST, MNA, and NRS 2002, 82.3%, 91.2%, and 58.3 % of the patients respectively were malnourished or at risk.

The kappa coefficient analysis to study concordance between the MUST, MNA, NRS 2002, and the gold standard SGA showed the best agreement between the SGA and MUST (0.617). There was moderate agreement between the SGA and MNA (0.450) and SGA with NRS 2002 (0.425). Sensitivity with MUST, MNA, and NRS 2002 was 95.56%, 99.48%, and 70.98% respectively in detecting malnourishment, but the specificity was lower (60.85%, 35.74%, and 82.98%, respectively).

Body mass index <18.5 Kg/m², low calf circumference, and low mid-upper arm circumference suggestive of malnutrition were seen in 34.7%, 86.1%, and 28.5% patients respectively.

On multivariate logistical regression analysis, symptoms of nausea/vomiting, weight loss, anorexia, pain, and the presence of gastric outlet obstruction increased the likelihood of malnutrition with an Odds ratio of 3.8, 9.9, 2.5, 1.35, and 2.5 respectively as compared to those who did not have those symptoms.

Conclusion: Malnutrition was seen in 76.5% of Gastric Cancer patients at diagnosis. MUST had a better concordance with SGA as compared to MNA or NRS 2002. BMI and anthropometry underestimated the prevalence of malnutrition hence standard validated screening tools should be preferred. Symptoms of weight loss, nausea or vomiting, anorexia, and pain predicted malnutrition in patients with GC. Nutritional assessment and appropriate intervention should be an integral part of GC care pathways.

Disclosure: Nothing to disclose.

P0115

PIECEMEAL COLD SNARE POLYPECTOMY FOR THE REMOVAL OF LARGE DUODENAL ADENOMAS

H. Wang¹, M. Sidhu¹, S. Gupta¹, P. Kumar^{1,2}, O. Cronin¹, A. Whitfield¹, T. O'Sullivan¹, S. Williams¹, E. Lee¹, N.G. Burgess¹, M.J. Bourke¹

Contact E-Mail Address: olivergcronin@gmail.com

Introduction: Large (≥15mm) duodenal adenomas (DA) are premalignant and require removal. Existing endoscopic resection techniques are compromised by adverse events, most notably post procedural bleeding (PPB) or recurrence. To ameliorate these problems we sought to evaluate the novel technique of piecemeal cold snare polypectomy (P-CSP) against the emerging standard of conventional EMR with thermal ablation of the post resection margin (EMR-T) for the safe and effective removal of DA.

Aims & Methods: Consecutive patients were enrolled in a single expert Western endoscopy centre for P-CSP and prospectively analysed against a previously reported cohort of EMR-T from the same centre. The primary outcome was rate of adverse events. Patient and lesion characteristics, technical success and recurrence at the first surveillance endoscopy (SE1) were collected.

Results: Between July 2017 until April 2022, 48 DA were removed via P-CSP (median size 30mm, range 10mm – 100mm, mean age 68 years old) compared with 54 DA EMR-T (median size 30mm, range 10mm – 70mm,

mean age 67 years old). P-CSP had a significantly lower rate of intra-procedural bleeding (4.1% vs 31%, $P < 0.00006$) and PPB (4.1% vs 16.7%, $P = 0.04$). 3 cases (6.3%) of immediate perforation occurred in P-CSP. In all 3 cases, perforation occurred due to amputation of ensnared tissue against the tip of the endoscope in the second part of the duodenum. These were recognised intraprocedurally and closed with clips without sequelae. Overall serious adverse events (15% vs 16.7%, $P = 0.77$), hospital admission rate (32.7% vs 42.6%, $P = 0.46$), technical success (98% vs 100% $P = 0.47$), and procedural time (33mins vs 30mins, $P = 0.95$) were similar. Recurrence at SE1 was significantly lower in EMR-T (2.3% vs 15.8%, $P = 0.048$).

	P-CSP (n = 48)	EMR-T (n = 54)	P-value
Duration (minutes), median (IQR)	33 (20 – 50)	30 (20-60)	0.95
Technical success	47 (98)	54 (100)	0.47
En bloc resection	0 (0)	9 (16.7)	0.003
Hospital admission	17 (32.7)	23 (42.6)	0.46
IPB	2 (4.1)	20 (37)	0.00006
SAE*	7 (15)	9 (16.7)	0.77
Immediate perforation	3 (6.1)	0 (0.0)	0.10
PPB	2 (4.1)	9 (16.7)	0.04
Recurrence at SE1	6 (15.8)	1 (2.3)	0.048

Values are number (%) except where indicated otherwise.
 *other SAE included pancreatitis (1 patient), duodenal stenosis requiring dilation (1 patient) in P-CSP group
 P-CSP, piecemeal cold snare polypectomy; EMR-T, thermal ablation of the post resection margin after endoscopic mucosal resection; IQR, Interquartile range; IPB, intraprocedural bleeding; SAE, serious adverse events; PPB, post procedural bleeding; SE1, first surveillance endoscopy

Table 1. Procedural outcomes

Conclusion: P-CSP reduces IPB and PPB however it may increase the risk of immediate perforation and is associated with significantly higher rate of recurrence at SE1. Further technical refinements are required to optimise endoscopic resection techniques for DA.

Disclosure: Nothing to disclose.

Introduction: Gastric cancer is the second leading cause of cancer-related death worldwide and one of the most common cancers in East Asia. Improving the detection rate of early gastric cancer (EGC) can greatly improve the survival rate of gastric cancer patients. It has been demonstrated that magnifying narrow-band imaging (ME-NBI) and magnifying blue laser imaging (ME-BLI) diagnosis accuracy of early gastric cancer is higher than white light endoscopy, and both techniques have been widely applied in clinical practice.

With the rapid development of artificial intelligence (AI), deep learning technologies have been widely researched in the field of digestive endoscopy. In clinical practice, we can use different brands or types of equipment to do a same examination for patients. Different devices have some different characteristics, such as color, imaging resolution, shape and so

on. Although these differences in details rarely affect doctor's diagnosis, they may interfere with the performance of AI models. Should we extensively collect highly heterogeneous images for training, or should we train different deep learning models for different patterns of images? There is no satisfactory answer to this question.

Aims & Methods: To explore the effect of training set diversity on the performance of deep learning models for predicting early gastric cancer (EGC) under endoscopy.

Images of EGC and non-cancerous lesions under narrow-band imaging (ME-NBI) and magnifying blue laser imaging (ME-BLI) were retrospectively collected. Training set 1 was composed of 1505 noncancerous and 309 EGC ME-NBI images, training set 2 was composed of 1505 non-cancerous and 309 EGC ME-BLI images, and training set 3 was the combination of training set 1 and 2. Test set 1 was composed of 376 non-cancerous and 1052 EGC ME-NBI images, test set 2 was composed of 529 non-cancerous and 71 EGC ME-BLI images, and test set 3 was the combination of test set 1 and test set 2.

Three deep learning models were constructed, which were respectively CNN1, CNN2 and CNN3 (CNN1, CNN2 and CNN3 were independently trained using training set 1, training set 2 and training set 3 respectively), and their performance on each test set was respectively evaluated. 138 ME-NB videos and 17 ME-BLI videos were further collected to evaluate and compare the performance of each model in real time.

Results: The performance of CNN3 was the best in the three test sets. The accuracy, specificity and sensitivity of test set 1 in CNN3 were 87.89% (1255/1428), 90.96% (342/376) and 86.79% (913/1052) respectively. The accuracy, specificity and sensitivity of test set 2 in CNN3 were 95% (570/600), 97.92% (518/529) and 73.24% (52/71) respectively.

The accuracy, specificity and sensitivity of test set 3 in CNN3 were 89.99% (1825/2028), 95.03% (860/905) and 85.93% (965/1123) respectively. The performance of CNN3 was also the best in videos test set.

The accuracy, specificity and sensitivity of videos test set in CNN3 were 91.03% (142/156), 90.58% (125/138) and 94.44% (17/18) respectively. In clinical practice, we can use different brands or types of equipment to do a same examination for patients.

Different devices have some different characteristics, such as color, imaging resolution, shape and so on. Although these differences in details rarely affect doctor's diagnosis, they may interfere with the performance of AI models.

Conclusion: The deep learning model with the most diverse training data has the best diagnostic effect.

Disclosure: Nothing to disclose.

Introduction: Artificial intelligence assisted devices (AIAD) have been widely applied in endoscopy in recent years [1-3], some of which have been utilized in clinical environment. We have developed an AIAD for gastroscopy which could monitor the blind spot and detect the early gastric cancer (EGC) in real time [3].

The AIAD was applied in several health centers for some time and we retrospectively collected the data of gastroscopy cases before and after the utilization of AIAD to explore the efficacy of AIAD in clinical practice.

Aims & Methods: This is a historical multicenter controlled trial and conducted in 7 hospitals in China to explore the difference between the AIAD group and the control group to evaluate the AIAD in clinical environment, which are closer to the real clinical treatment procedures and related with less intervention like the prospective controlled study. The AIAD was designed and aimed to adopted in daily endoscopy process. So, except the clinical trials, the historical without the supervision of researcher may truly presented the efficacy of artificial intelligence assisted device.

A total of 220,498 patients who underwent the gastroscopy were included from January 1 2017 to February 28 2022 and divided into the AIAD group (after the use of AIAD) and control group (before the use of AIAD). The EGC detection rates were compared using a two tailed Chi-squared test. And the EGC detection rate was defined as the number of EGC divided by the sum number of EGC and gastric developed cancer.

Results: The control group and AIAD group were included 101696 and 118802 patients respectively. 144 EGC and 1007 gastric developed cancer were found in the control group as well as 431 EGC and 825 gastric developed cancer were found in the AIAD group. The AIAD group presented a higher EGC detection rate (11.61% vs. 34.42%, $P < 0.0001$).

Conclusion: The use of the AIAD during upper gastrointestinal endoscopy significantly increased the EGC detection rate in clinical practice without intervention. AIAD-assisted gastroscopy has the potential to improve the detection of EGC.

Introduction: The role of *Helicobacter Pylori* (HP) infection has been well demonstrated in the genesis of gastric MALT lymphoma. Its involvement in Gastric Diffuse Large B Cell Lymphoma (GDBCL) is less clear. However, improved prognosis and even complete regression of the tumour have been reported after HP eradication therapy.

Aims & Methods: The aim was to study the frequency of HP infection during GDBCL and evaluate the response to HP eradication therapy.

This is a retrospective study investigating patients with GDBCL managed in our gastroenterology department between January 2009 and December 2020.

Patients were divided into 2 groups:

G1 : patients diagnosed with GDBCL and HP infection

G2 : patients diagnosed with GDBCL without HP infection

Results: Forty-five patients were included with a mean age at diagnosis of 59 years old and a M/F sex ratio of 2. HP infection was found in 32 patients (71.1%). GDBCL was mainly de novo in both groups (G1: 68.8%, G2: 28.1%), whereas transformation from a MALT lymphoma was only observed in 28.1% in G1 and 30.8% in G2.

The presence of atrophy (G1: 9.4% vs G2: 7.7%) and intestinal metaplasia (G1: 28.1% vs G2: 15.4%) were more frequent in G1 with no statistically significant difference ($p = 0.86$ and 0.37 respectively).

The NGC (Non-Germinal Center) subtype was the most frequent in both groups (G1: 40.6% vs G2: 46.2%).

Advanced GDBCL (stage III or VI) was more frequent in G2 (G1: 25%, G2: 38.5%) with no statistically significant difference ($p = 0.37$).

More complications such as bleeding, perforation and tumour lysis syndrome were observed in G1 with no statistically significant difference ($p = 0.48$).

In G1, 20 patients (62.5%) received HP eradication therapy and this eradication was controlled in only 9 patients with 2 patients failing.

The evolution was more negative in G2 with tumour progression in 35.8% of patients, while it was only 6.3% in G1 with no statistically significant difference ($p = 0.6$).

Conclusion: A negative HP status appears to be associated with a more advanced GDBCL with a worse outcome and prognosis.

Disclosure: Nothing to disclose.

Introduction: Sufficiently clear mucosa during upper endoscopy is essential for proper diagnosis in the upper gastrointestinal tract. Still discussed, especially in terms of effect and effective dose, is the use of simethicone and N acetylcysteine, substances with antifoam and mucolytic effects, to increase the clarity of the mucosa in the upper gastrointestinal tract.

Aims & Methods: The primary objective was to demonstrate that a higher, maximum dose of mucolytic administered 20-30 minutes before gastroscopy increased the upper gastrointestinal visibility score compared to D arm, without mucolytic solution and water.

The secondary objective was to demonstrate that the visibility score after administration of the maximum dose of mucolytic administered to arm A is higher than the visibility score in the upper gastrointestinal tract after administration of the lower mucolytic dose in arm B.

The primary endpoint was the visibility score evaluated by the examining blinded endoscopist, given by the sum of 5 scores 0-5 in the esophagus, fundus, body and antrum of the stomach and in the duodenum, for a total of 0-25.

The secondary endpoint was the visibility score evaluated according to 10 photos taken according to ESGE recommendations and blinded endoscopists, given again by the sum of 5 scores 0-5.

The study was double-blind, randomized and conducted from May to September 2021, at the Digestive Diseases Center, Vitkovice Hospital, Ostrava, Czech Republic. The study protocol was approved by the local ethics committee, the State Institute for Drug Control of the Czech Republic and was registered in the Clinical Studies Registry at ClinicalTrials.gov (NCT04641455).

Patients were randomized into four arms, with administration of the maximum dose of mucolytic solution (arm A, 100 ml water + 600 mg N-acetylcysteine + 400 mg simethicone), with administration of a lower dose of mucolytic solution (100 ml water + 400 mg N-acetylcysteine + 20 mg simethicone), with administration of 100 ml water (arm C), and without administration of water and mucolytic solution (arm D). During the examination, a total of 10 photographs were taken in the defined areas.

The overall visibility score was given by the sum of the 0-5 scores of the five areas and was assessed by the endoscopist performing the procedure and then by two blinded endoscopists who assessed this from the photodocumentation taken. Other parameters monitored were the time of the examination and the amount of residual fluid in the stomach.

Results: A total of 129 patients who met the inclusion criteria were enrolled in the study. 9 patients were subsequently excluded. Patients did not differ significantly in age or gender distribution between arms.

Overall visibility score as assessed by the performing endoscopist, was similar between arms A, B and C (18.9±2.9 vs. 18.6±3.0, p=1.000); however, when comparing the total visibility scores of arms A, B, and C with arm D, only arm A demonstrated significantly higher visibility scores compared with arm D (18.9±2.9 vs. 16.6±3.3, p=0.023).

The secondary endpoint was different between the two blinded endoscopists. The total amount of residual fluid in the stomach and the time of examination were comparable between the different arms.

Conclusion: Administration of mucolytic solution with maximum dose of N-acetylcysteine and simethicone before gastroscopy improves mucosal clarity in the upper gastrointestinal tract during the examination compared without fluid or mucolytic solution when evaluated by the performing endoscopist.

Disclosure: No Conflict of Interest.

Contact E-Mail Address: krzysztof.budzyn96@gmail.com

Introduction: The prognosis of survival in gastric and esophageal cancers is related to the disease stage. Screening esophagogastroduodenoscopy (EGD) has proven beneficial in populations at high risk of gastric cancer. Esophageal (EA) and gastric adenocarcinoma (GA) develop in multistep processes from atrophic gastritis (AG) and Barrett's esophagus (BE), respectively. Surveillance of the conditions mentioned above is a recognized method in diagnosing early lesions that can be treated endoscopically.

Aims & Methods: The main aim of the study was to assess if population-based one-time screening EGD would be suitable for a population at low to moderate risk of upper gastrointestinal cancer. Two databases were analyzed – 23864 patients with esophageal and gastric malignant neoplasm in the national cancer registry (KRN) diagnosed between 2014 and 2017 and another 5984 patients who underwent diagnostic EGD in three endoscopic units (retrospective cohort) from 03.2018 to 10.2019.

A retrospective cohort was analyzed to assess the age of patients diagnosed with precancerous conditions (AG and BE), esophageal and gastric dysplasia (ED and GD, respectively), cancers (EA and GA) and healthy individuals. Also, a retrospective cohort was analyzed to estimate particular histologic types of malignant esophageal and gastric tumors. An Internet questionnaire was provided to 304 individuals to estimate the acceptable ratio of potential benefits and harms of screening EGD.

Variable	Age groups					
	40-44	45-49	50-54	55-59	60-64	65-69
Number of potential cancers to avoid	10480	10074	9386	8164	6488	4697
Number of procedures needed to avoid one cancer	236	235	290	360	394	344
Ratio of potential benefits and harms	47	47	38	31	28	32

Number of potential cancers to avoid – number of esophageal adenocarcinomas and gastric non-cardia adenocarcinomas diagnosed in consecutive age groups (based on national cancer registry - KRN);

Number of procedures needed to avoid one cancer – the proportion of the number of procedures (population in each age group) and number of potential cancers to avoid;

The ratio of potential benefits and harms – the proportion of the 1/ number of procedures needed to avoid one cancer and risk of complications (9/100 000) [1].

Results: In the retrospective cohort, 131 patients were diagnosed with BE, 707 with AG, 26 ED, 102 GD, 5 EA, and 23 non-cardia GA. The mean age was significantly higher in patients with AG and BE (group 1; 62.9 SD 13.9), ED and GD (group 2; 67.2 SD 12.6), EA and GA (group 3; 64.6 SD 12.5) than in healthy controls (54.9 SD 16.6, all of the comparisons p<0.0001) and between group 1 and 2 (p=0.004). The risk of precancerous BE and AG, ED and GD, EA and GA diagnosis has been rising from age groups 40-

44 (OR 1.6; 95%CI 1.04-2.4), 55-59 (OR 3.6; 95%CI 1.3-9.7), and 60-64 (OR 12.1; 95%CI 1.5-98.6) respectively in comparison with patients at age <40 years. 10 480 cases in KRN were identified as EA and non-cardia GA aged 45 years or older. Based on questionnaire acceptable median ratio of potential benefits and harms was 100 for the 40-44 years group and 10 for the other 45-64 years groups. The estimated ratio of potential harms and benefits was higher than expected in screening groups aged 45-69 years and highest in the group 45-49 years.

Conclusion: The implementation of one-time screening EGD could be potentially beneficial and acceptable in groups aged 45 to 69 years, even in a population at low to moderate risk of esophageal and gastric cancer.

CYSTIC FIBROSIS-RELATED GI DISEASE: A GROWING BURDEN FOR BOTH SERVICES

C. Mc Closkey¹, T. Nicholson¹, E. McKone¹, S.M. O'Reilly¹

¹St. Vincent's University Hospital, Centre for Colorectal Disease, Dublin, Ireland

Contact E-Mail Address: 10ciaran@gmail.com

Introduction: Ireland has one of the highest incidences of Cystic Fibrosis (CF) in the world, with approximately 1 in 19 Irish people carrying the gene. Much of the morbidity in patients with CF has traditionally related to their respiratory disease. Over time, this patient cohort has seen an increase in GI symptoms due to a number of factors including chronic PPI and laxative use, and increasing life expectancy. Whether CFTR modulators play a role or not has yet to be determined.

Data in recent years has also demonstrated significantly increased risk of GI tract malignancies in this cohort. While there is well established guidance regarding colorectal cancer screening in patients with CF, the link with many other GI tract pathologies remains unclear.

Aims & Methods: To explore the burden of GI disease in the CF population at a National Specialist Centre, on both hospital admissions and the endoscopy department, and to determine the prevalence of GI tract dysplasia in this patient cohort.

Results: From 2015 to 2020, there were 485 patients admitted a total of 11483 times, to the day or inpatient ward. 132 patients (27.2%) had at least one admission with a gastrointestinal issue as either a primary or secondary diagnosis over 6 years. The number of GI related admissions has increased almost threefold over the past 5 years, from 2.9% (55) to 8.4% (165).

The prevalence of diagnoses among this cohort were as follows; GORD (42.4%), CFRLD (40.2%) of which 4.5% had OLT, DIOS (19.7%), PEG/RIG insertion (11.4%), Chronic constipation (7.6%), Pancreatitis (3%) and Barrett's oesophagus (2.3%).

184 of 485 patients (37.9%) had at least one GI endoscopic procedure in our centre. 123 patients (25.3%) had an OGD with a median age of 39. 12 patients (9.8%) had endoscopic evidence of Barrett's oesophagus, 3.3% had histologic metaplasia and 1% had high grade dysplasia. Prevalence of Barrett's in the non-CF population at a comparable age is estimated at between 2 and 8%. Other diagnoses included; 7.3% benign polyps, 23.6% hiatal hernia (5.7% undergoing fundoplication), 8.1% Varices. 54 patients had a colonoscopy with a median age of 35, 20.4% had tubular adenomas with low grade dysplasia, 5.6% had tubulovillous adenomas and 1.9% had adenocarcinoma.

Conclusion: There is a rising prevalence of GI disease among the CF patient cohort, which is likely attributable at least in part to the introduction of CFTR modulators. Our study found significantly higher rates of GI tract dysplasia in this population, both upper and lower GI. It is possible that the increase in Barrett's is due to chronic oesophagitis and gastritis as opposed to being attributable to the genetic mutation.

Despite established colonoscopy screening guidelines, there are no upper endoscopy guidelines for this cohort, with more work needed to be done in this area. As life expectancy continues to improve, it is likely we will see an increasing burden on endoscopy services in years to come. Use of non-invasive methods for screening should be evaluated in this population.

Disclosure: Nothing to disclose.

Contact E-Mail Address: nikmez@gmail.com

Introduction: *Helicobacter pylori* (Hp) infection still represents an important public health issue worldwide. The most recent large meta-analysis reported an estimated prevalence of Hp infection in Europe of 47% (56% in Italy)¹.

With regard to morbidly obese patients, the prevalence and role of Hp infection is still controversial, with limited data available, especially from western countries. Routine upper gastrointestinal endoscopy before bariatric surgery is generally recommended, to rule out pathological abnormalities, including Hp infection.

Aims & Methods: Data from all consecutive patients undergoing preoperative endoscopic evaluation for bariatric surgery at our institution (Fatebenefratelli Hospital, Milan, Italy) between January 2019 and December 2021 were retrospectively analyzed. Hp infection was evaluated with histology from biopsy samples, which are part of the preoperative evaluation protocol.

Results: 123 patients (96 females, median age 44 years) were included (Table 1). The median BMI was 40.5, with most patients suffering from grade III obesity (58.5%). Half of patients (n=59) were non-smokers.

Diabetes was present in 11% of patients, hypertension in 35%, OSAS 11%, and hypothyroidism in 13%. Hp infection was present in 29% of patients. There was no statistically significant association between Hp status and demographic or clinical characteristics; interestingly, Hp positive patients were less frequently affected by diabetes compared to Hp negative patients, although this trend was not statistically significant (3% vs 14%, p=0.1).

Regarding endoscopic findings, overall, 24% of patients presented no abnormalities; 11% had esophagitis, 73% hiatal hernia, 44% hyperemic gastritis, 15% erosive gastritis, 13% duodenitis: these endoscopic findings did not differ between Hp positive and negative patients.

Regarding histologic findings, acute and/or chronic gastritis was significantly more common among Hp positive patients (100% vs 73%, p<0.001), while atrophy didn't depend on Hp status.

Surprisingly, there was a trend toward a higher frequency of intestinal metaplasia in Hp negative patients, although not statistically significant (8% vs 0% in Hp positive, p=0.1).

Conclusion: In our cohort of morbidly obese patients, the prevalence of Hp infection – diagnosed by histology – was 29%, which resulted slightly lower compared to what has been reported in the literature in the overall population. Hp positive patients didn't appear to have worse endoscopic

findings compared with Hp negative patients, but histologically proven gastritis was significantly more frequent among Hp positive patients. Finally, diabetes was more frequent in Hp negative patients, but this latter evidence, as well as the others, must be interpreted with caution, and are needed to be confirmed in a larger cohort.

REFRACTORY *H. PYLORI* INFECTION AND GASTRIC MICROBIOTA

J. Wang¹, Y. Xie¹

¹The First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China

Contact E-Mail Address: dnk63006@163.com

Introduction: Since Marshall and Warren discovered *Helicobacter pylori* in 1983(1), the international digestive community has made a breakthrough progress in the etiology research and treatment of chronic gastritis, peptic ulcer disease and gastric cancer. Over 50% of people were infected with *H.pylori*(2).

At present, the World Health Organization (WHO) has regarded *H.pylori* as the class I carcinogen of gastric cancer(3). However, In recent years, with the application of high-throughput sequencing technology, people have

made great progress in the cognition of gastric flora. Many previous studies mainly focused on the role of changes in gastric flora in the occurrence and development of gastric diseases(4-7). However, the diversity, composition and function of gastric flora after *H.pylori* colonization and eradication treatment are not clear. There are many subjects who fail to eradicate *H.pylori* for many times in clinic, and the eradication is still unsuccessful after multiple replacements of antibiotics. Therefore, the related gastric microecology research is particularly important. At present, there is no research on the influence of multiple *H.pylori* eradication history on gastric flora.

Aims & Methods: To investigate the effect of refractory *Helicobacter pylori* infection on the diversity, composition and function of gastric flora. We designed a clinical study involved with 32 subjects who were divided into three groups: 1. nAGHp. a group: *H.pylori* positive was first found in non-atrophic gastritis; 2. nAGHp. b group: *H.pylori* negative in non-atrophic gastritis; 3. EFHp. a group: Refractory *H.pylori* infection. Gastric mucosa samples were collected for 16S rRNA sequencing analysis.

Results: There are significant differences between *H.pylori* positive group and *H.pylori* negative group in species diversity, gastric flora structure and bacterial function. The results of LEfSe analysis suggested that the beneficial *Lactobacillus* in *H.pylori* positive group was significantly enriched than that in refractory *H.pylori* infection group. The bacterial interaction network diagram suggested that the interaction between bacteria in refractory *H.pylori* infection group decreased. We found that the refractory *H.pylori* infection group gastric microbiota was enriched in energy metabolism, bacteria secretion system, glutathione metabolism, protein folding and associated processing, surficial metabolism, membrane and intracellular structural molecules, lipopolysaccharide biosynthesis, ubiquinone and other terpenoid-quinone biosynthesis, inorganic ion transport and metabolism as well as metabolism of cofactors and vitamins compared with *H.pylori* positive group by PICRUST2 analysis.

Conclusion: *H.pylori* infection is an important factor affecting the diversity, composition and function of normal gastric flora. Multiple *H.pylori* eradication history can lead to imbalance of gastric mucosal flora to a certain extent, which is mainly reflected in inhibiting the growth of beneficial *Lactobacillus* in the stomach, and multiple *H.pylori* eradication history can change some functions of gastric flora.

P0123

EFFECT OF HELICOBACTER PYLORI VIRULENCE FACTORS ON THE MORPHOLOGICAL CHANGES OF GASTRIC MUCOSA IN PATIENTS WITH CHRONIC GASTRITIS AND THEIR ROLE IN CLARITHROMYCIN PRIMARY RESISTANCE

L. Nikulina¹, G. Solovyova^{1,2}

¹Bogomolets National Medical University, Kyiv, Ukraine, ²Gastro Center of the Clinic «Oberig», Kyiv, Ukraine

Contact E-Mail Address: Lilinika95@gmail.com

Introduction: Helicobacter pylori is recognized as the main etiological factor in the development of gastric cancer. The virulence factors of CagA and VacA have demonstrated their genetic differences among other HP strains, making them of clinical interest as possible predictors of gastric cancer. Some studies also have found an association between virulent strains of *H. pylori* and the presence of antibiotic resistance, however these data are controversial.

Aims & Methods: The aim of this study was to evaluate the effect of HP virulence factors (CagA + VacA +) on morphological changes of the gastric mucosa and to determine their relationship with clarithromycin resistance. This study was conducted as a cross-sectional study in adult subjects with HP chronic gastritis. EGD with chromoscopy and NBI and biopsy with gastritis evaluation by OLGA and OLGIM was used for the detection of chronic gastritis.

We compare the degree of inflammation, activity of gastritis, presence and degree of atrophy, metaplasia and dysplasia in patients with HP virulence factors and without virulence factors (control group). Genotyping for virulence factors and Hp gene mutations in the V 23S rRNA domain associated with clarithromycin resistance were determined by PCR. The 23S rRNA gene was analyzed with three-point mutations (A2142G/C, A2143G, T2182C) for clarithromycin. Patients who had received macrolides antibiotics within the last 6 months were excluded from the study.

Results: The study included 64 patients with chronic HP-associated gastritis, aged 25-70 years (mean age 46.0 ± 11.8 years). Among the patients, 38 (59,4%) were men and 26 (40,6%) women. Highly pathogenic CagA + VacA + Hp strains were detected in 38 patients (59,4%).

The level of both gastric and antral body inflammation was higher in patients with CagA+VacA+ strains. The level of antral inflammation was I-st degree in 13,1%; II-nd in 71,1%; III-d in 15,8% in examined patients and I-st degree in 61,5%; II-nd in 38,5%; III-d in 0% in control group ($\chi^2 = 17.9$, $p < 0.0001$).

The level of body inflammation was I-st degree in 31,6%; II-nd in 15,8%; III-d in 52,6% in examined patients and I-st degree in 100% of the control group ($\chi^2 = 29.9$, $p < 0.0001$). The grade of antral atrophy was significantly higher in patients with CagA+VacA+ strains (63,1% vs 42,3%; $\chi^2 = 2.7$, $p < 0.05$). An inflammatory activity degree and metaplasia were observed at the same frequency in both groups ($p > 0.05$).

The level of primary resistance to clarithromycin was 31.2%. Clarithromycin resistance was significantly lower in CagA+VacA+ than CagA-VacA- strains (13,1% vs 57,7%; $\chi^2 = 14.25$, $p < 0.0001$). The most observed resistance mutation was A2143G (75%).

Conclusion: Our study shows that patients infected with highly pathogenic strains of Hp (CagA+VacA+) tended to have more pronounced morphological changes of the gastric mucous, namely inflammation and atrophy. Nevertheless, primary clarithromycin resistance is more common in patients infected with non-pathogenic CagA-VacA- strains of Helicobacter pylori.

Disclosure: All authors have declared no conflict of interest.

EVALUATION OF IL-17F A7488G POLYMORPHISM IN *HELICOBACTER PYLORI*-INFECTED PATIENTS IN QOM-IRAN

F.S. Mirtalebi Roknabadi¹, A. Hormati², S. Shams³, M. Aghaali⁴

¹Islamic Azad University Qom Branch, Department of Genetics, Qom, Iran (Islamic Republic of), ²Qom University of Medical Sciences, Gastroenterology and Hepatology Disease Research Center, Qom, Iran (Islamic Republic of), ³Qom University of Medical Sciences, Cellular and Molecular Research Center, Qom, Iran (Islamic Republic of), ⁴Qom University of Medical Sciences, Department of Epidemiology, School of Medicine, Qom, Iran (Islamic Republic of)

Contact E-Mail Address: sshamsmed@gmail.com

Introduction: *Helicobacter pylori* is a gram-negative gram, microaerophilic, and spiral bacteria. The prevalence of infection varies from country to country and from population to population and is closely related to the socioeconomic status of the people. There are no specific symptoms in most colonized patients, but clinical complications can range from gastritis and duodenal ulcer to cancer and mucosa-associated lymphoid tissue (MALT) lymphoma. *H. pylori* infection and its progression are influenced by the heterogeneity of virulence factors, environmental factors, host genetic predisposition, and gene regulation. Among the virulence factors, the CagA (cytotoxin-associated gene A) is a known oncoprotein, encoded by the *cagA* gene localized in the *H. pylori* pathogenicity island. IL-17, as an inflammatory cytokine, plays an important role in the severity of gastric mucosal inflammation and gastric cancer development.

Aims & Methods: Our aim was to evaluate the IL-17 A7488G polymorphism in *H. pylori*-infected patients and its association with the *cagA* virulence gene in Qom, Iran, for the first time. In this case-control study, 86 samples of the gastric biopsy were collected from patients with gastrointestinal problems referred to the endoscopy ward of Shahid-Beheshti hospital. Rapid urease test (for initial screening) and PCR of 16S rRNA gene (to confirm infection) were performed to identify positive and negative cases of *H. pylori*. The *cagA* gene was also evaluated as a pathogenic bacterial factor. PCR-RFLP was performed to investigate the IL-17 polymorphism using the *NotI* enzyme.

Results: Among 86 participants, 49 (57.0%) patients were male, and 37 (43.0%) cases were female, with a mean±SD age of 47.13±16.72 years. *H. pylori*-positive ratio in males (30/43, 69.8%) was significantly higher than in females (13/43, 30.2%). The mean±SD of age in the case and control groups was 45.14±14.90 and 49.12±18.54, respectively ($p=0.276$). In the *H. pylori*-positive group, abdominal pain (32 cases-74.4%) and duodenal ulcer (12 cases-27.9%) were the most clinical symptom and endoscopic finding, respectively. Except for abdominal pain ($p=0.015$), no significant relationship was observed between other clinical symptoms and endoscopic features in both groups of patients. There was also no significant difference between the two groups in terms of age, height, weight, BMI, smoking, and education. In addition, in case group, 13 patients (30.2%) were positive for the *cagA* gene. Regarding IL-17 genotypes distribution, the wild genotype (AA) frequency was 96.5% in patients in both groups (40/43, 93.0% in the case group vs. 43/43, 100.0% in the control group). Only three patients had polymorphisms in the IL-17 gene (AG in one patient and GG in two patients), all belonged to the case group. There was no association between infection and even the presence of *cagA* and the IL-17 polymorphism. Interestingly, three patients with GG and AG variants were positive for the *cagA* gene.

Conclusion: This study provides the first data on IL-17F A7488G gene polymorphism among individuals with *H. pylori* infection in Qom. Our results showed no association between polymorphism and infection among patients under study. According to the results of the *cagA* gene, it seems that

the strains evaluated in this study were less pathogenic. Also, no correlation was observed between *cagA*-positive strains and cytokine polymorphism. However, three patients with mutant patterns were positive for the *cagA* gene, which might be an association between pathogenic strains and this polymorphism. However, this finding needs further investigation.

PERNICIOUS ANEMIA AND *HELICOBACTER PYLORI* INFECTION : AN INTRICATE ASSOCIATION

M. Mtir¹, M. Ayari¹, A. Chehaider¹, Y. Ben Hamadi¹, W. Khemiri¹, I. Abdelaali¹, T. Jomni¹, M.H. Douggui¹

¹Internal Security Forces Hospital of Tunis, Gastroenterology Department, Tunis, Tunisia

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Pernicious anemia, also known as Biermer's disease, is an autoimmune atrophic gastritis caused by autoantibodies targeting intrinsic factor and/or gastric parietal cells, leading to impaired absorption of vitamin B12. Its association with a colonization by *Helicobacter pylori* (Hp), itself incriminated in the occurrence of atrophic gastritis and vitamin B12 deficiency, may suggest the possibility of an unfavorable outcome of this disease, including a potentiation of the carcinogenic risk.

Aims & Methods: The aim of our study was to determine the prevalence and the impact of Hp in patients diagnosed with Pernicious anemia.

We conducted a retrospective single-center study, including all patients followed for pernicious anemia over a 7-year period [2014 - 2021]. Clinicobiological, endoscopic, histological data and outcomes were collected. Anatomopathological examination was used to assess the severity of gastritis according to the Sydney system as well as the presence of Hp and the patients were classified into two groups:

- G1 (N=17): pernicious anemia Hp +
- G2 (N=50): pernicious anemia Hp -

A descriptive and analytical statistical study using SPSS software was performed to compare the two groups.

Results: In total, we included 67 patients with a mean age of 63 years [38-89] and a sex ratio M/F of 1.68. The prevalence of Hp in patients followed for pernicious anemia was 25.4%. In Hp+ group, severe atrophy was observed in 88.2% of cases versus 64% in Hp- ($p=0.05$). Similarly, the degree of activity was severe in 11.8% of cases in Hp + group versus 2% in the absence of Hp.

However, there was no significant difference in severe intestinal metaplasia lesions in both groups, which were respectively 17.6% in G1 and 26% in G2. All patients received vitamin B12 therapy for a mean duration of 41 months. A significantly better response was observed in the group of patients without Hp infection.

	Group 1			Group 2		
	Before treatment	After treatment	p-value	Before treatment	After treatment	p-value
Mean Hb (g/dl)	11.2	12.6	0.02	9.3	15.2	0.02
Mean MCV(μm3)	84.2	79.3	0.041	92.5	84.1	0.0001
Mean VB12 (pg/ml)	172.5	260.6	0.171	102	565.7	<0.0001

During the follow-up, we observed the occurrence of stomach cancer in 7 patients: 4 cases of gastric carcinoid tumor, 2 cases of gastric adenocarcinoma and one case of gastric MALT lymphoma, which were respectively 11.7% for G1 and 10% for G2 with $p\text{-value}=0.837$, suggesting the absence of an over-risk of carcinogenesis in the presence of Hp.

In univariate study and using the chi-square test, the factors associated with Hp in Biermer's disease were: gender ($p=0.035$), anemia ($p=0.009$) and vitamin B12 deficiency ($p=0.009$).

Conclusion: According to our study, one in four patients with pernicious anemia have Hp infection. Although this association may not present an over-risk of carcinogenesis, it is most likely to cause more severe gastric atrophy, anemia, vitamin B12 deficiency and lower response to treatment. Early systematic screening and eradication of Hp in this context is recommended to improve the course of the disease.

HELICOBACTER PYLORI INFECTION PROMOTES CARCINOGENESIS BY UP-REGULATING ACE2 EXPRESSION

H. Wang¹, J. Rong¹, Y. Xie¹

¹The First Affiliated Hospital of Nanchang University, Gastroenterology, Nanchang, China

Contact E-Mail Address: 1099163722@qq.com

Introduction: As a SARS-CoV-2 receptor, ACE2 has attracted much attention in recent years, and studies have shown that ACE2 is widely expressed in human digestive tract. A clinical study showed that *Helicobacter pylori* (*H. pylori*)-positive patients infected with SARS-CoV-2 showed more severe gastrointestinal symptoms. However, the relationship between ACE2 and *H. pylori* infection and its role in the pathogenesis of *H. pylori* infection are unknown.

Aims & Methods: An in vitro coculture system and an in vivo C57BL/6 mouse model of *H. pylori*-infected gastric epithelial cells were established. The effect of *H. pylori* infection in vitro and in vivo on ACE2 expression was detected by western blot, and the changes of ACE2 expression in gastric mucosa tissues of *H. pylori*-infected mice were also detected by IHC. At the same time, 28 pairs of gastric cancer and paracancer tissue specimens were collected in this study, and the expression differences of ACE2 in gastric cancer and paracancer tissues were detected. Finally, overexpression and knockdown ACE2 cell lines were constructed, and the effects of ACE2 on cell biological functions were detected by CCK8, EdU, plate clone formation, cell scratch repair assay and Transwell cell migration and invasion assay.

Results: *H. pylori* infection in vitro and in vivo can significantly up-regulate the expression of ACE2, and the expression of ACE2 in gastric cancer tissues is significantly higher than that in paracancer tissues. Cell biological function experiments showed that ACE2 overexpression significantly promoted the proliferation, migration and invasion of gastric epithelial cells, while knockdown ACE2 expression significantly reduced the proliferation, migration and invasion of gastric epithelial cells.

Conclusion: *H. pylori* infection significantly up-regulated the expression of the oncogene ACE2, suggesting that ACE2 may be involved in the pathogenesis of *H. pylori* infection.

Introduction: Detection of *Helicobacter pylori* by a stool antigen test (SAT) is an attractive non-invasive alternative.

Aims & Methods: The aim of this study was to assess the accuracy of a new SAT, the automated LIAISON® Meridian *H. pylori* SA chemiluminescent immunoassay (CLIA) based on monoclonal antibodies, as compared to the ¹³C-Urea Breath Test (UBT) gold standard. This prospective multicentre study (9 Spanish centres) enrolled patients over 18 years of age with clinical indication to perform UBT, both for initial diagnosis and confirmation of eradication of *H. pylori*.

Patients taking PPIs, antibiotics or prior gastric surgery were excluded. Two UBT methods were used, as available: mass spectrometer (MS), including citric acid in its protocol; and infrared spectrophotometer (IRS), without citric acid.

Results: Three-hundred and seven patients (145 naïve and 162 confirmation of eradication) were included: 67% female, mean age 47 years (range 19-81). When using recommended cut-off values (negative SAT <0.90, positive ≥1.10), the sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 67%, 97%, 86%, 92% and 91% respectively; obtaining an area under the ROC curve (AUC) of 0.85. In total, 28/307 patients, including 7 false positives and 21 false negatives, presented a discordant result between SAT and UBT.

Among the 21 false negatives, 4/6 tested with MS and 11/15 tested with IRS had a borderline UBT delta value (values between 5.2 and 5.8, being the cut-off point of 5‰ with MS, and close to the cut-off point of 2.5‰ with IRS). In 25/28 discordant samples, PCR targeting *H. pylori* DNA was

performed and SAT accuracy was re-analysed: sensitivity, specificity, positive predictive value, negative predictive value, accuracy and AUC were 94%, 97%, 86%, 99%, 97% and 0.96 respectively. Diagnostic accuracy was calculated separately for the naïve and post-treatment groups (Table 1).

Comparison SAT vs UBT	Sensitivity 95% CI	Specificity 95% CI	PPV 95% CI	NPV 95% CI	LR+ 95% CI	LR- 95% CI	Global accuracy 95% CI	AUC 95% CI

Introduction: *Helicobacter pylori* (Hp) infection is an etiologic agent of autoimmune gastritis (AIG). However, AIG incidence in Japan is low despite high rates of Hp infection and atrophic gastritis. Therefore, AIG pathogenesis in Japan may differ from that in the West.

Aims & Methods: This study aimed to investigate the effects of Hp infection on endoscopic, serological, and histological findings and to clarify its involvement AIG pathogenesis in Japan. A total of 99 Japanese patients (mean age ± standard error [SE], 64.7 ± 1.2 years; 57 women) were diagnosed with AIG at ten institutes in Japan between January 2010 and November 2020.

We evaluated the serum gastrin, anti-parietal cell antibody (APCA), anti-intrinsic factor antibody (AIFA), pepsinogen (PG), clinical findings (pernicious anemia), and endoscopic findings by Hp infection status.

AIG was defined as follows:

1. Predominantly atrophic corpus on endoscopy;
2. APCA elevation by 20 times or more, AIFA, endocrine cell micronest (ECM), and enterochromaffin-like (ECL) cell hyperplasia; and,
3. Hypergastrinemia (serum gastrin > 500 pg/mL).

Hp infection status was defined by the presence of serum Hp-IgG antibody. In addition, the group with a history of Hp eradication confirmed on the questionnaire was defined as the Hp eradication group. Data among the three groups classified by Hp status were analyzed using the Kruskal-Wallis and χ -square tests. Statistical significance was set at $P < 0.05$.

Results: There were 69, 19, and 11 cases in the Hp-negative, Hp eradication, and Hp-positive groups, respectively. Serum gastrin (mean ± SE) was significantly lower in the Hp-positive (1477.6 ± 266.8 pg/mL) and Hp eradication groups (1734.4 ± 264.6 pg/mL) than that in the Hp-negative group (3035.9 ± 243.6 pg/mL). PGII was significantly higher in the Hp-positive group (16.0 ± 2.5 ng/mL) than that in the negative (10.4 ± 0.6 ng/mL) and eradication groups (9.9 ± 0.9 ng/mL). Serum PGI, PGI/II, APCA positive rate, ECM positive rate, and pernicious anemia rate were not significant among the three groups.

Endoscopic findings showed that atrophy in the antrum was significantly higher in the Hp-positive (90.9%) and eradication groups (73.7%) than that in the negative group (31.9%). Diffuse redness in the corpus was significantly higher in the Hp-positive group than that in the negative group (63.6% vs. 13.0%).

Conclusion: Hp infection affected serum gastrin, PGII, and endoscopic findings in AIG.

Furthermore, there were AIG cases not associated with Hp infection. In cases of extensive atrophy of the antrum and corpus, it is necessary to consider AIG cases caused by Hp infection.

PCR IMPROVES DETECTION OF *HELICOBACTER PYLORI* IN UNSELECTED ADULT PATIENTS UNDERGOING ROUTINE GASTROSCOPY

T. Butler¹, F. Fitzgibbon², D. McNamara³, S. Smith¹

¹Trinity College Dublin/Tallaght University Hospital, Clinical Medicine (Trinity College Dublin) & Gastroenterology (Tallaght University Hospital), Dublin, Ireland, ²Technological University Dublin, Biological & Health Sciences, Dublin, Ireland, ³Tallaght University Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: thbutler@tcd.ie

Introduction: Accurate detection of *H. pylori* is essential for effective patient management. Reduced prevalence and wide usage of PPI's can negatively impact commonly employed tests, including rapid urease tests (CLO), culture and standard histological examinations. Additional tests in at risk patients could improve detection.

Aims & Methods: Aims: To compare the performance of a PCR-based assay for the detection of *H. pylori* versus routine histological testing in an Irish context.

Methods: Following ethical approval and informed consent, adults were prospectively recruited. During routine gastroscopy subjects had 2 additional antrum and corpus biopsies taken for DNA extraction and PCR using custom-designed primers for the urease gene. CLO tests and antral and corpus histology (H&E and IHC, where indicated in the hospital laboratory) were performed as standard.

Results: In all, 118 patients with available histology and PCR results were included in the analysis. 27 had chronic active gastritis (CAG), of which 21 (78%), 20 (74%) and 13 (48%) had positive histology, PCR and CLO tests respectively. Of interest, in 44 subjects with chronic inactive gastritis (CIG), 11 (25%) had a positive PCR and only 1 (2%) positive histology. PCR detected the urease gene in 31 (26%) patients indicative of infection; 20 and 11 with CAG and CIG respectively. Based on PCR the sensitivity, specificity, PPV and NPV for histology were 67%, 98%, 89% and 89% respectively.

Conclusion: PCR-based testing should be included in cases where no *Helicobacter*-like organisms are detected on routine histology, particularly if the patient has a presentation of chronic gastritis irrespective of activity.

Disclosure: Nothing to disclose.

P0129

ALCOHOL INCREASES TREATMENT FAILURE FOR *HELICOBACTER PYLORI* ERADICATION IN ASIAN POPULATIONS

X. Wang¹, J. Yu¹

¹Changzhou No.2 People's Hospital, Gastroenterology, Changzhou, China

Contact E-Mail Address: wxy20009@126.com

Introduction: Although the underlying link between alcohol consumption and the risk of *Helicobacter pylori* (*H. pylori*) eradication failure has been revealed in previous studies, there are some conflicting reports in this regard. Based on the published research, this study aims to address these conflicts.

Aims & Methods: Eligible studies were screened and retrieved through January 2022 using PubMed, Web of Science, and a manual review of references. Results were expressed as odds ratios (ORs) and 95% confidence intervals (CIs). Subgroup, publication bias, and sensitivity analyses were also conducted.

Results: A total of 40 studies were included in the meta-analysis. No significant association was found between alcohol consumption and the risk of *H. pylori* eradication failure (OR = 1.09, 95% CI, 0.94–1.26). However, in subgroup analyses stratified by region, alcohol consumption was associated with increased treatment failure for *H. pylori* eradication in Asian patients (OR = 1.23, 95% CI, 1.03–1.47).

Moreover, in Asian patients, when the duration of therapy was >7 days (OR = 1.17, 95% CI, 1.10–1.25) or when the treatment regimen included nitroimidazoles (OR = 1.16, 95% CI, 1.09–1.24), alcohol consumption was associated with an increased risk of *H. pylori* eradication failure. Increased alcohol intake (>40 g/day) was also associated with a higher risk of *H. pylori* eradication failure (OR = 3.17, 95% CI, 1.56–6.41).

Alcohol consumption reduced the *H. pylori* eradication rate in Asian patients in whom bismuth-containing quadruple therapy (OR = 1.17, 95% CI, 1.10–1.25) was used to treat *H. pylori* infection; however, alcohol consumption had no effect on *H. pylori* eradication rate in Asian patients who were administered a vonoprazan (VPZ)-based therapy regimen (OR = 1.73, 95% CI, 0.98–3.05).

Conclusion: Alcohol consumption dose-dependently increases the risk of *H. pylori* eradication failure in Asian populations. However, a VPZ-based treatment regimen can prevent this effect.

Disclosure: Nothing to disclose.

THE EFFECT OF LACTOBACILLUS REUTERI-CONTAINING QUADRUPLE THERAPY IN FIRST-LINE ERADICATION THERAPY FOR *HELICOBACTER PYLORI* INFECTION: A SINGLE-CENTER OPEN-LABEL RANDOMIZED CONTROLLED STUDY

C. Li¹, B. Suo¹, X. Tian¹, Y. Zhang¹, X. Ren¹, Z. Song¹

¹Peking University Third Hospital, Department of Gastroenterology, Beijing, China

Contact E-Mail Address: 17865190329@163.com

Introduction: With the increasing resistance rate of *Helicobacter pylori* to levofloxacin, clarithromycin, metronidazole and other antibiotics, the efficacy of commonly used eradication regimens recommended by guidelines gradually declines, and may lead to increased antibiotic resistance rates, gut microbiota disruption and various adverse reactions.

Studies have shown that probiotics can reduce *Helicobacter pylori* infection and improve the adverse reactions of eradication therapy by producing antibacterial substances, inhibiting bacterial colonization, and enhancing mucosal barrier, etc.

Aims & Methods: This study aims to determine whether Lactobacillus Reuteri-containing quadruple therapy is inferior to bismuth-containing quadruple therapy with respect to the efficacy, safety and compliance in Helicobacter pylori eradication. A total of 240 treatment-naïve Helicobacter pylori-positive patients were randomly divided into a Lactobacillus Reuteri-containing quadruple therapy group (Group A) and a bismuth-containing quadruple therapy group (Group B), with 120 cases in each group, receiving the two eradication regimens for 14 days respectively. Group A consisted of Lactobacillus Reuteri (2g, twice a day), esomeprazole (20mg, twice a day), amoxicillin (1g, twice a day), and levofloxacin (0.5g, once a day).

Group B consisted of bismuth potassium citrate (220mg, twice a day), esomeprazole (20mg, twice a day), amoxicillin (1g, twice a day), and levofloxacin (0.5g, once a day). The safety and compliance of patients were evaluated 1-3 days after the end of eradication therapy, and whether the Helicobacter pylori was successfully eradicated was determined by urea breath test about 8 weeks after the end of eradication therapy. Data were collected to analyze whether there were significant differences in eradication efficacy, incidence of adverse reactions and compliance between the two groups.

Results: Lactobacillus Reuteri-containing quadruple therapy and bismuth-containing quadruple therapy have comparable eradication rates in first-line Helicobacter pylori therapy (ITT analysis: 80.0% vs 81.7%, $p=0.743$, PP analysis: 88.7% vs 89.6%, $p=0.825$), and there was no significant difference in the incidence of overall adverse reactions (13.9% vs 20.5%, $p=0.183$) and compliance (93.9% vs 93.2%, $p=0.816$). Diarrhea occurred less frequently in the Lactobacillus Reuteri-containing quadruple therapy (3.5% vs 10.3%, $p=0.042$), while the incidence of other adverse reactions was similar between the two groups.

Conclusion: The efficacy, safety and patient compliance of Lactobacillus Reuteri-containing quadruple therapy in the first-line eradication treatment of Helicobacter pylori are similar to bismuth-containing quadruple therapy, and Lactobacillus Reuteri can reduce diarrhea in patients.

Disclosure: The authors declare no potential conflicts of interest.

Introduction: *Helicobacter pylori* (*Hp*) infection is associated with numerous intragastric and extra gastric diseases, and *Hp* eradication is extremely important for the treatment and prevention of *Hp*-related diseases.

Under the background of increasing resistance rate of *Hp* to clarithromycin, metronidazole and levofloxacin, the eradication rate of *Hp* decreased largely. At present, *Hp* strains resistant to amoxicillin and furazolidone are rare.

Aims & Methods: We aimed to evaluate the effectiveness and safety of bismuth quadruple regimen containing amoxicillin and furazolidone for *Hp* infection, based on real-world data, so as to provide a theoretical basis for formulating an efficient and safe treatment scheme for *Hp* eradication.

This was a prospective observational study of bismuth quadruple regimen containing amoxicillin and furazolidone for *Hp* infection in real-world practice. From December 2019 to February 2022, patients who were con-

firmed to infected *Hp* by ¹³C-UBT DOB value > 6‰ or of ¹⁴C-UBT DPM value > critical value + 50% critical value or rapid urease test ≥ (++) (to rule out near the critical value of false positives) or histopathology or bacterial culture or stool antigen test received eradication treatment (acid suppressant, bismuth, amoxicillin and furazolidone) in *Hp* specialist clinics or partial general clinics at the First Affiliated Hospital of Nanchang University. Within ±2 days after *Hp* eradication, adverse events and compliance during treatment were obtained via clinic or telephone return visit. At least 4 weeks after completion of therapy, *Hp* eradication was assessed by ¹³C-UBT or ¹⁴C-UBT or histopathology.

Results: A total of 625 patients completed this study, the overall eradication rate was 87.4% (546/625) by intention-to-treat (ITT) analysis and 89.5% (537/600) by per-protocol (PP) analysis. The ITT eradication rates for 10-day and 14-day regimen were 86.3% vs 89.0%, respectively ($P=0.328$). The ITT eradication rates for initial treatment and rescue treatment were 88.7% vs 79.8%, respectively ($P=0.017$). 89 patients (14.2%) experienced at least one adverse event, the majority of adverse events were mild and overall compliance rate was 96.0%. The incidence of adverse reactions for 10-day regimen were higher than 14-day regimen (16.8% vs 10.2%, $P=0.020$). The incidence of adverse reactions for initial treatment and rescue treatment were 14.7% vs 11.7%, respectively ($P=0.445$). Nausea/vomiting (3.7%), headache/dizziness (3.1%), abdominal pain/bloating (2.4%), skin rash (2.1%), anorexia (1.4%) and asthenia (1.1%) were common adverse events.

Conclusion: Bismuth quadruple regimen containing amoxicillin and furazolidone proved safe and provided fair initial eradication in real-world practice.

Disclosure: Nothing to disclose.

P0132

EFFECTIVENESS AND SAFETY OF BISMUTH QUADRUPLE REGIMEN CONTAINING FURAZOLIDONE AND TETRACYCLINE FOR *HELICOBACTER PYLORI* INFECTION: A STUDY BASED ON REAL-WORLD DATA

Introduction: *Helicobacter pylori* (*Hp*) infection is associated with numerous intragastric and extra gastric diseases, and *Hp* eradication is extremely important for the treatment and prevention of *Hp*-related diseases. Under the background of increasing resistance rate of *Hp* to clarithromycin, metronidazole and levofloxacin, the eradication rate of *Hp* decreased largely. At present, *Hp* strains resistant to furazolidone and tetracycline are rare.

Aims & Methods: We aimed to evaluate the effectiveness and safety of bismuth quadruple regimen containing furazolidone and tetracycline for *Hp* infection, based on real-world data, so as to provide a theoretical basis for formulating an efficient and safe treatment scheme for *Hp* eradication.

This was a prospective observational study of bismuth quadruple regimen containing furazolidone and tetracycline for *Hp* infection in real-world practice. From December 2019 to February 2022, patients who were confirmed to infected *Hp* by ¹³C-UBT DOB value > 6‰ or of ¹⁴C-UBT DPM value > critical value + 50% critical value or rapid urease test ≥ (++) (to rule out near the critical value of false positives) or histopathology or bacterial culture or stool antigen test received eradication treatment (acid suppressant, bismuth potassium citrate, furazolidone and tetracycline) in *Hp* specialist clinics or partial general clinics at the First Affiliated Hospital of Nanchang University. Within ±2 days after *Hp* eradication, adverse events

and compliance during treatment were obtained via clinic or telephone return visit. At least 4 weeks after completion of therapy, *Hp* eradication was assessed by ¹³C-UBT or ¹⁴C-UBT or histopathology.

Results: A total of 495 patients completed this study, the overall eradication rate was 96.2% (476/495) by intention-to-treat (ITT) analysis and 98.3% (465/473) by per-protocol (PP) analysis. The ITT eradication rates for 10-day and 14-day regimen were 96.1% vs 96.5%, respectively ($P=0.819$). The ITT eradication rates for initial treatment and rescue treatment were 96.2% vs 96.1%, respectively ($P=1.000$). 100 patients (20.2%) experienced at least one adverse event, the majority of adverse events were mild and overall compliance rate was 95.6%. The incidence of adverse reactions for 10-day regimen were lower than 14-day regimen (18.2% vs 27.0%, $P=0.039$). The incidence of adverse reactions for initial treatment and rescue treatment were 18.6% vs 24.8%, respectively ($P=0.130$). Nausea/vomiting (6.3%), abdominal pain/bloating (3.2%), headache/dizziness (3.0%), diarrhea (2.8%), dry/bitter taste (1.6%), asthenia (1.6%) and anorexia (1.2%) were common adverse events.

Conclusion: Bismuth quadruple regimen containing furazolidone and tetracycline proved both highly effective and safe in real-world practice, both for initial treatment and rescue treatment.

Disclosure: Nothing to disclose.

OPTIMIZATION OF VONOPRAZAN-AMOXICILLIN DUAL THERAPY FOR ERADICATING *HELICOBACTER PYLORI* INFECTION IN CHINA: A PROSPECTIVE, RANDOMIZED CLINICAL PILOT STUDY

Y. Hu¹, X. Xu¹, Y. Ouyang¹, C. He¹, N. Li¹, C. Xie¹, C. Peng¹, Z. Zhu¹, Y. Xie¹, X. Shu¹, N. Lu¹, Y. Zhu¹

¹The First Affiliated Hospital of Nanchang University, Nan Chang, China

Contact E-Mail Address: 360041934@qq.com

Introduction: Vonoprazan-amoxicillin (VA) dual therapy has been shown to achieve acceptable cure rates for treatment of *Helicobacter pylori* (*H. pylori*) in Japan. Its effectiveness in other regions is unknown. We aimed to explore the efficacy of VA dual therapy as first-line treatment for *H. pylori* infection in China.

Aims & Methods: This was a single center, prospective, randomized clinical pilot study conducted in China. Treatment naïve *H. pylori* infected patients were randomized to receive either low or high dose amoxicillin-vonoprazan consisting of amoxicillin 1 g either b.i.d. or t.i.d. plus VPZ 20 mg b.i.d. for 7 or 10 days. ¹³C-urea breath tests were used to assess the cure rate at least 4 weeks after treatment.

Results: 323 patients were assessed and 119 subjects were randomized. The eradication rates of b.i.d. amoxicillin for 7 days and 10 days, t.i.d. amoxicillin for 7 days and 10 days were 66.7% (16/24), 89.2% (33/37), 81.0% (17/21) and 81.1% (30/37) ($P=0.191$) by intention-to-treat analysis, respectively, and 72.7% (16/22), 89.2% (33/37), 81.0% (17/21) and 81.1% (30/37) ($P=0.454$) by per-protocol analysis, respectively.

Conclusion: Neither 7- or 10-day VA dual therapy with b.i.d. or t.i.d. amoxicillin provides satisfied efficacy as the first-line treatment for *H. pylori* infection in China. Further optimization is needed.

Disclosure: The authors declare that there are no conflicts of interest.

ALTERED GUT MICROBIOTA AND SHORT-CHAIN FATTY ACIDS AFTER VONOPRAZAN-AMOXICILLIN DUAL THERAPY FOR *HELICOBACTER PYLORI* ERADICATION

Y. Hu¹, X. Xu¹, Y. Ouyang¹, C. He¹, N. Li¹, C. Xie¹, C. Peng¹, Z. Zhu¹, X. Shu¹, Y. Xie¹, N. Lu¹, Y. Zhu¹

¹The First Affiliated Hospital of Nanchang University, Nan Chang, China

Contact E-Mail Address: 360041934@qq.com

Introduction: The combination of Vonoprazan (VPZ) with amoxicillin (VA therapy) has been shown to achieve acceptable eradication rates for *Helicobacter pylori* (*H. pylori*). Our aim was to explore the short-term effect of VA therapy on the gut microbiota and short-chain fatty acids (SCFAs).

Aims & Methods: 119 *H. pylori*-positive patients were randomized into low or high dose VA therapy (i.e., amoxicillin 1 g b.i.d. or t.i.d.) and VPZ 20 mg b.i.d. for 7 or 10 days. 13 *H. pylori*-negative patients served as normal controls. Fecal samples were collected from *H. pylori*-positive and negative patients. The gut microbiota and SAFCs were analyzed by 16S rRNA gene sequencing and Gas Chromatography-Mass Spectrometry, respectively.

Results: The gut microbiota of *H. pylori*-positive patients had higher richness, diversity and better evenness of gut microbiota and a slightly increased abundance of SCFAs compared to matched patients.

The integrated analysis of gut microbiota and SCFAs identified that *Prevotellaw* was associated with SCFAs alterations. 53 patients were studied before and after *H. pylori* eradication divided into low (L-VA) and high amoxicillin dosage (H-VA). The diversity and composition of gut microbiota among L-VA patient showed no differences at the three time points.

However, among H-VA patients, the diversity was decreased and the microbial composition was altered immediately after H-VA eradication but restored by the confirmation time point. The decreased abundance of *Ruminococcus* and *Eubacterium* were associated with the alteration of SCFAs level.

Conclusion: Vonoprazan-amoxicillin dual therapy for *H. pylori* eradication has minimal negative effects on gut microbiota and SCFAs.

Disclosure: The authors declare that there are no conflicts of interest.

Introduction: The overall prevalence of *H. pylori* infection in Europe is declining; however, it still remains high in the elderly population. Therefore, it is important to assess the treatment efficacy and possible differences in the elderly and non-elderly populations.

Aims & Methods: To evaluate and compare the efficacy of first- and second-line *H. pylori* eradication regimens between the non-elderly and elderly European populations.

The "European Registry on *H. pylori* Management" (Hp-EuReg) is a European multicenter prospective non-interventional registry recording information of *H. pylori* infection management. Data from the year 2013 to 2022 were recorded at AEG-REDCap e-CRF. Data were subject to quality review. The subjects were divided into non-elderly (18-59 years) and elderly (≥60 years) groups. Per-Protocol (PP) and modified Intention-To-Treat (mITT) analyses were performed to evaluate effectiveness of the six most frequently used regimens in each group. In the multivariate analysis, the effect was evaluated by calculating OR and 95% CI. Statistical significance was considered at $p < 0.05$.

Results: Overall 49,461 patients were included in the Hp-EuReg. There were 34,994 (71%) non-elderly and 14,467 (29%) elderly patients. In first-line treatment, quadruple therapies were prescribed in 45% of the cases, and triple therapies in 44%. In second-line treatment, quadruple therapies were prescribed in 51% of the cases, and triple therapies in 44%. The treatment schemes prescribed are detailed in Table 1. The overall first-line treatment effectiveness was 89% by PP and 88% by mITT in the non-elderly, and 90% by PP and 89% by mITT in the elderly ($p < 0.05$). The overall second-line treatment effectiveness was 84% both by PP and mITT analyses in the non-elderly and elderly groups ($p > 0.05$). In the multivariate analysis, the elderly group was associated with significantly higher overall mITT eradication rate in the first-line treatment as compared to the non-elderly (OR=1.13; 95% CI 1.05-1.12; $p < 0.005$); however, there were no significant differences in the overall second-line treatment mITT effectiveness. The effectiveness by treatment scheme and line is reported in Table 1, with statistically significant differences in the first-line treatment mITT cure rates reported between age groups when either quadruple PPI-clarithromycin-amoxicillin-metronidazole therapy was prescribed or when sequential PPI-clarithromycin-amoxicillin-tinidazole was used. In second-line, no statistically significant differences were reported in the mITT effectiveness in any of the treatment schemes evaluated.

Comparison of First-line Treatment Regimens Between the Non-elderly and Elderly Populations						
Treatment	Non-Elderly (18-59 years)			Elderly (≥60 years)		
	Use, N	PP % (95% CI)	mITT % (95% CI)	Use, N	PP % (95% CI)	mITT % (95% CI)
Triple PPI+C+A	10,540	87 (86-87)	86 (85-87)*	4,065	88 (87-89)	87 (86-89)*
Triple PPI+C+M	1,150	86 (84-88)	86 (83-88)	491	83 (79-86)	83 (79-86)

PP – per protocol; mITT – modified Intention-To-Treat; 95% CI – 95% confidence interval; PPI – proton pump inhibitor; C – clarithromycin; A – amoxicillin; M – metronidazole; B – bismuth; T – tinidazole; L – levofloxacin; Tc – tetracycline; ¹Pylera®: three-in-one single-capsule containing metronidazole, tetracycline and bismuth. * statistically significant differences between the age groups, p<0.05.

Table 1. Most frequent first- and second-line *H. pylori* eradication prescriptions and their efficacies in the non-elderly and elderly populations

Conclusion: The overall effectiveness of both first- and second-line *H. pylori* eradication regimens in Europe is suboptimal (<90%). The effectiveness of the most frequent first- and second-line triple therapies in the non-elderly and elderly populations is also suboptimal (<90%). Optimal effectiveness (>90%) was mostly achieved by using quadruple therapies. Although statistically significant, no clinically relevant differences in the effectiveness between elderly and non-elderly patients was observed in the most frequently prescribed first-line treatments. No differences were observed either in second-line prescriptions.

Disclosure: Nothing to disclose.

Introduction: *Helicobacter pylori* (Hp) eradication can reduce the recurrence of gastric and duodenal ulcers and the risk of gastric cancer¹. Chinese guidelines for Hp eradication recommend bismuth-containing quadruple therapy comprising two antibiotics and a proton pump inhibitor (PPI)². Vonoprazan, a potassium-competitive acid blocker, demonstrated potent and sustained acid-inhibitory effects, making it a candidate for PPI replacement in quadruple therapy³. This study evaluated bismuth exposure in vonoprazan- or esomeprazole-based quadruple therapy in a Hp-positive healthy Chinese population.

Aims & Methods: This phase 1, double-blind, parallel-group study was implemented at a single study site in China (April–November 2021). Eligible, Hp-positive healthy subjects aged 18–60 years were randomised 1:1 to receive quadruple therapy comprising vonoprazan (20 mg) or esomeprazole (20 mg), bismuth potassium citrate (600 mg [equivalent to 220 mg of bismuth]), clarithromycin (500 mg), and amoxicillin (1000 mg) twice daily for 2 weeks.

The primary endpoint was to evaluate plasma and urine pharmacokinetic (PK) parameters of bismuth with vonoprazan- or esomeprazole-based quadruple therapy on Day 14, summarised by descriptive statistics. Similarity of plasma PK parameters was inferred for the treatment groups if the 90% CIs of geometric mean ratio for bismuth AUC₀₋₁₂ and C_{max} were within 0.5–2.0 confidence limits. Secondary endpoints were the percentage of subjects who experienced ≥1 TEAEs and those who discontinued treatment due to an AE. Hp eradication was determined by carbon-13 urea breath test (¹³C-UBT) at a follow-up visit 4 weeks after treatment.

Results: Of 44 enrolled subjects (vonoprazan, n=22; esomeprazole, n=22), mean age was 34.5 and 31.6 years with 63.6% and 59.1% being male, respectively. The mean duration of exposure to treatment was 13.5 and 13.0 days for vonoprazan and esomeprazole, respectively. The key plasma and urine PK parameters of bismuth were similar between the two groups (Table 1).

On Day 42, ¹³C-UBT for Hp infection was negative in 100% and 94.4% of subjects receiving vonoprazan and esomeprazole, respectively. The incidence of TEAEs was similar between the treatment groups; most were mild, and no serious AEs occurred. Dysgeusia was most frequently reported in 68.2% and 81.8% of subjects receiving vonoprazan and esomeprazole, respectively. Two and five subjects receiving vonoprazan and esomeprazole, respectively, discontinued the study due to TEAEs. All study subjects had normal results of neurological examinations throughout the study. No new safety concerns related to potential drug-drug interactions were identified.

PK parameter	Geometric LS mean (95% CI)	Ratio (vonoprazan vs esomeprazole)	90% CI of geometric mean ratio	95% CI of geometric mean ratio
AUC ₀₋₁₂ (h*ng/mL)				
Vonoprazan (n=20)	146 (117, 183)	1.07	(0.82, 1.40)	(0.78, 1.48)
Esomeprazole (n=18)	137 (108, 173)			
C _{max} (ng/mL)				
Vonoprazan (n=20)	42.8 (32.6, 56.2)	1.30	(0.94, 1.81)	(0.88, 1.93)
Esomeprazole (n=18)	32.9 (24.7, 43.8)			
Ae ₀₋₁₂ (μg)	Mean (SD)			
Vonoprazan (n=20)	1026 (546.0)	--	--	--
Esomeprazole (n=18)	1037 (562.5)			

Ae₀₋₁₂, amount of drug excreted in urine during a dose interval; AUC₀₋₁₂, area under the plasma drug concentration-time curve; C_{max}, maximum plasma drug concentration; CI, confidence interval; LS, least squares; PK, pharmacokinetic; SD, standard deviation; τ, length of dosing interval ¹PK analysis set comprised subjects who received study treatment, completed minimum protocol-specified procedures with no significant protocol deviations and were evaluable for PK

Table 1: Comparison of key bismuth PK parameters (PK analysis set¹)

Conclusion: Vonoprazan did not differentially affect PK parameters of bismuth in comparison with esomeprazole. The results suggest that vonoprazan may be an option of bismuth-containing quadruple therapy for Hp eradication in China.

REINFORCED MEDICATION ADHERENCE IMPROVES *H. PYLORI* ERADICATION RATE IN DEVELOPING COUNTRIES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

R. Zeng¹, Y. Xie¹

¹The First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China

Contact E-Mail Address: 3402871273@qq.com

Introduction: The eradication rate of *H. pylori* (*Helicobacter pylori*) remains variable for the same eradication regime even in the identical region, eradication regimen even in the identical region, especially in developing countries. There are many well-known factors involved, such as strains, drugs, and genetic polymorphisms.

However, the factor of compliance during medication is often ignored. In recent years, a number of randomized controlled trials (RCTs) have investigated the effect of enhanced medication adherence on eradication rates. The patients with poor compliance may be more prominent in developing countries owing to the complicated regimens, adverse reactions and low levels of education.

To address this dilemma, reinforced medication adherence maybe a promising strategy to improve *H. pylori* eradication rate. Herein, we conducted a systematic review and meta-analysis of RCTs to assess the effect of medication adherence on *H. pylori* eradication rates in developing countries.

Aims & Methods: A systematic review was conducted in international databases (Web of Science, Cochrane Library, PubMed, and EMBASE) and national databases (CBM, WanFang Data, CNKI, and VIP Database) to identify relevant RCTs from inception to April 2022. The Cochrane Collaboration's tool for assessing the risk of bias in RCTs was used to assess the quality and risk of bias of the included studies. The core indicator was the changes in eradication rates after enhanced adherence. Meta-analysis was performed to estimate the pooled relative risk (RR) with 95% confidence intervals (CI) using R4.1.2.

Results: A total of 3286 patients with confirmed *HP* infection were included in 19 RCTs, including 1632 patients in the intervention group and 1652 patients in the control group. Interventions include telephone, message, WeChat, and combined regime.

The results of meta-analysis showed that the eradication rate of the intervention group was significantly different from that of the control group in the intentional analysis (ITT) [RR=1.25, 95%CI(1.12, 1.31), $P<0.0001$] and compliance protocol analysis (PP) [RR=1.16, 95%CI(1.08, 1.24), $P<0.0001$].

The compliance of the intervention group was high [RR=1.27, 95%CI(1.16, 1.40), $P<0.0001$], the incidence of adverse reactions was lower than the control group [RR=0.72, 95%CI(0.52, 0.99), $P=0.04$], gastrointestinal symptom relief was better than control group [RR=1.23, 95%CI(1.06, 1.43), $P=0.005$], the patient satisfaction [RR=1.26, 95%CI(1.19, 1.35), $P<0.0001$] and disease knowledge rate [SMD=1.82, 95%CI(0.77, 2.86), $P=0.0007$] were better than the control group. Egger funnel plot suggested that there was no potential publication bias among included studies ($P=0.718$).

Conclusion: Guided therapy improved patients' treatment compliance and *HP* eradication rate, reduced adverse reactions, improved disease-related symptoms, improved patients' satisfaction with medical services, and effectively improved residents' *HP* related knowledge literacy, which has the value of promotion and application.

Introduction: The adherence to *Helicobacter pylori* eradication treatment is a cornerstone for achieving an adequate treatment efficacy.

Aims & Methods: Objective: To determine which factors could influence on the compliance of eradication treatments employed in Europe. Methods: Systematic prospective non-interventional registry (Hp-EuReg) of the clinical practice of European gastroenterologists. Treatment compliance was defined as adequate with >90% drug intake. The data was collected from 2013 until September 2021 at AEG-REDCap e-CRFand was subject to quality control. Modified intention-to-treat (mITT) analyses were performed. The multivariate analysis evaluated the factors associated with the effectiveness of the treatments and the compliance.

Results: Of the 38,698 available records, 646 (1.7%) did not have adequate compliance. There was a higher rate of non-compliance in patients with dyspepsia than in those treated for peptic ulcer (1.7% vs. 1.4%; $p < 0.05$). 7-day treatments showed greater compliance than 10- or 14-day pre-

scriptions (0.8% vs. 1.8 and 1.6%, respectively; $p < 0.001$). Non-adherence was lower in first-line as compared to rescue treatment (1.5% vs 2.2%; $p < 0.001$). Non-adherence in the three most frequent first-line treatments was: 1.1% with PPI-Clarithromycin-Amoxicillin; 2.3% with PPI-Clarithromycin-Amoxicillin-Metronidazole; and 1.8% with bismuth quadruple therapy (single capsule Pylera®); $p < 0.001$. Compliant patients achieved greater eradication rates in those treatment schemes as compared to those with poor compliance: 86% vs. 44%; 90% vs. 71% and 93% vs. 64% respectively; $p < 0.001$.

In the multivariate analysis, the variable which was most significantly associated with eradication success was the correct compliance with the treatment (OR: 6.3; 95%CI: 5.2-7.7; $p < 0.001$). Non-compliance was greater in the presence of adverse events as compared to the cases without (5% vs 0.6%; $p < 0.001$).

Conclusion: Compliance with *H. pylori* eradication treatment is very high. Factors associated with poor compliance include treatment for uninvestigated/functional dyspepsia, rescue-treatment, prolonged treatment regimens and the presence of adverse effects, as well as the use of sequential and concomitant treatments. Adequate treatment compliance was the variable most closely associated with eradication success.

Emergency and Organ Transplantation, Bari, Italy, ²Section of Gastroenterology, DETO, University of Bari, Dr., Bari, Italy, ³National Institute of Gastroenterology “S. de Bellis” Research Hospital, Laboratory of Nutritional Pathophysiology, Castellana Grotte, Italy

Contact E-Mail Address: giuseppelos@alice.it

Introduction: The eradication of *Helicobacter pylori* (*H. pylori*) may be difficult due to antibiotic resistance. Indeed, after one failure, a second-line therapy is needed, a Bismuth containing quadruple therapy (BQT) with the three in one capsule formulation is becoming very popular. Therefore, we aimed to evaluate effectiveness and safety of BQT in second line.

Aims & Methods: We recruited consecutive patients with one therapy failure. Patients received for ten days the three-in-one BQT Pylera® therapy, in combination with a proton-pump inhibitor (PPI), decided at the choice of the investigator, at full dose bid. Eradication rate was calculated as intention-to-treat (ITT) and per-protocol (PP) and 95% confidence intervals (CI) were calculated.

Results: Seventy-three patients were recruited, 41 females and 32 males (mean age 53.0±13.1 years) Fifty-five patients had previously failed triple therapy with amoxicillin and clarithromycin and the remaining 18 sequential therapy.

Seventy-two patients assumed at least 90% capsules, while only one did not complete therapy due to adverse events (nausea and diarrhea). BQT was successful at ITT in 62 subjects (eradication rate 84.9%, 95%CI 76.7-93.1%). At PP analysis, the eradication rate was 86.1% (95%CI 78.1%-94.1%).

Failure was not influenced by the type of PPI ($p=0.08$) or previously failed regimen ($p=0.27$); in detail, BQT was effective in 81.8% of those who failed triple and in 94.4% of patients failing sequential therapy. Adverse events were observed in 14 subjects (20.5%), the most common ones were diarrhea (6 patients) and weakness (6 patients).

Conclusion: In conclusion, our report confirmed that BQT is effective as an empiric second-line regimen.

Disclosure: Nothing to disclose.

P0140

EFFECT OF METRONIDAZOLE RESISTANCE ON *HELICOBACTER PYLORI* ERADICATION REGIMENS

Introduction: According to guidelines, in our geographic area, characterized by a clarithromycin resistance rate >15%, bismuth containing quadruple therapy (BQT) or concomitant therapy (CT) should be used in first line. Both regimens contain metronidazole, however the effect of metronidazole resistance on CT and BQT has not been fully elucidated yet. We aimed to investigate whether metronidazole resistance may impact on eradication rates of CT/BQT in *H. pylori* naïve patients.

Aims & Methods: We prospectively recruited patients with *H. pylori* infection in the period January 2020–December 2021. Recruited patients received either CT or BQT, both lasting 10 days. Before therapy, patients collected a fecal sample using the THD fecal test device. *H. pylori* DNA was extracted and, by means of real time polymerase chain reaction (RT-PCR), mutations in *rdxA/frxA* gene were investigated for metronidazole resistance.

Moreover, we investigated the A2143G point mutation in the bacterium gene encoding for 23S rRNA subunit for clarithromycin resistance. Treatment was blindly prescribed regardless of molecular investigation result (post-hoc analysis).

Results: Ninety-six patients were recruited; 29 patients received BQT and 67 CT. No drop outs were observed. The overall eradication rate was 91 out of 96 (94.8%, 95% CI 90.4–99.2%) and, in detail, it was 29/29 (100%) for BQT and 62/67 (92.5%, 95% CI 86.2–98.8) for CT. Metronidazole resistance was detected in 18 patients (18.8%, 95% CI 11–26.6%), while clarithromycin resistance in 19 (19.8%, 95% CI 11.9–27.7%). All 18 patients with metronidazole resistance underwent eradication. Five had assumed BQT and 13 CT. Conversely, eradication rate in metronidazole sensitive strains was 73/78 (93.6%, 95% CI 88.2–99%). Of these, 24 received BQT, with a 100% success, and 54 assumed CT with 5 failures. In detail, 2 failing patients were resistant to clarithromycin and the remaining 3 were surprisingly susceptible to both clarithromycin and metronidazole. We did not find any statistical significance in eradication rate between metronidazole resistant and sensitive strains ($p = 0.58$).

Conclusion: In our series, metronidazole resistance does not seem to affect eradication rate of BQT and CT regimens.

Disclosure: Nothing to disclose.

Introduction: *Helicobacter pylori* (*H. pylori*) is causally associated with chronic gastritis, peptic ulcer and gastric cancer, with a reported prevalence of 19–35%. Due to increasing antibiotic resistance, the worldwide efficacy of *H. pylori* eradication treatment has decreased.

Aims & Methods: This study aimed to determine eradication success of *H. pylori* in primary care in the Netherlands, as a proxy measure for antibiotic resistance development. Real-world routine health care data from Electronic Medical Records from general practices in the region Leiden/The Hague was used. Data was provided by ELAN (Extramural LUMC Academic Network). Patients with an ICDPC-code for gastric symptoms or an ATC code for acid inhibition in the period 2010–2020 were selected. Patients with *H. Pylori* infection were detected based on having received eradication treatment.

We investigated antibiotic resistance, defined as the prescription of a second eradication treatment within 12 months. The types of antibiotics prescribed as first eradication treatment were evaluated for resistance rates. If no second treatment was prescribed within 12 months, patients were suspected to have been successfully eradicated.

Results: We identified 138,455 patients with gastric symptoms or acid inhibition from 80 general practices. Mean age was 57 years (SD 18.2) of whom 43% were male. A total of 5,224 (4%) patients received a first eradication treatment and were considered *H. pylori* positive. The antibiotic treatment combinations amoxicillin-clarithromycin, amoxicillin-metronidazole and clarithromycin-metronidazole were used in 4,847 (93%), 154 (3%) and 111 (2%) of first eradication treatments, respectively.

A second eradication treatment was prescribed within one year to 416 (8%) patients. Thereof, 380 (8%) patients received amoxicillin-clarithromycin, 16 (10%) amoxicillin-metronidazole and 11 (10%) clarithromycin-metronidazole as first eradication treatment and were considered antibiotic resistant.

Conclusion: Almost one-tenth of *H. pylori* infections in primary care are not successfully treated after a first treatment with clarithromycin and/or metronidazole and require a second eradication treatment. Therefore, antibiotic resistance should be kept in mind when treating patients with *H. pylori*.

Disclosure: Supported by a grant from the Antibiotic Resistance Care Network Holland West

Introduction: Introduction: Randomized clinical trials and meta-analyses, primarily from Asian countries, have reported good effectiveness with high-dose dual therapy (HDDT, i.e., PPIs plus high amoxicillin doses) when prescribed for *H. pylori* first-line or rescue treatment. However, combining amoxicillin with PPIs in the 1990s in several European countries yielded suboptimal results. The objective was to analyse the effectiveness, compliance and safety of HDDT in the European real clinical practice.

Aims & Methods: Methods: International, multicenter, prospective non-interventional Registry aimed at evaluating the decisions and outcomes of *H. pylori* management by European gastroenterologists. All infected adult cases treated with HDDT were registered at AEG-REDCap e-CRF up to June 2021. Patients receiving HDDT (amoxicillin 1,000 mg three times a day plus a PPI), with or without bismuth, in any treatment line and for at least 10 days, were selected for inclusion.

Results: Sixty patients received HDDT (98% compliance), 19 of them as first-line and 41 as rescue treatment (2nd–6th line). Overall HDDT effectiveness was 52% (per-protocol) and 51% (modified intention-to-treat, mITT). First-line and rescue treatment lines were similarly effective. Cure rates were lower when patients had previously received metronidazole (mITT 32% vs. 70%, p<0.05), tetracycline (mITT 26% vs. 69%, p<0.05) or rifabutin (mITT 25% vs. 65%, p<0.005). Adding bismuth to HDDT in rescue treatment did not yield better results. Adverse event incidence was 30%, diarrhoea being the most common (20% of patients); no serious adverse events were reported.

HDDT	ITT n/N (%)	p	PP n/N (%)	p	mITT n/N (%)	p
Overall	28/32 (46.7%)		28/54 (51.9%)		28/55 (50.9%)	
1st line	11/19 (57.9%)	0.235	11/17 (64.7%)	0.200	11/17 (64.7%)	0.171
2 nd -6 th line	17/41 (41.5%)		17/37 (45.9%)		17/38 (44.7%)	
2nd line	2/4 (50%)	0.187	2/3 (66.7%)	0.102	2/3 (66.7%)	0.110
3rd line	2/5 (40%)		2/4 (50%)		2/4 (50%)	
4th line	1/2 (50%)		1/2 (50%)		1/2 (50%)	
5th line	12/23 (52.2%)		12/21 (57.1%)		12/22 (54.5%)	
6th line	0/7 (0%)		0/7 (0%)		0/7 (0%)	

Conclusion: Although safe and with proven good compliance, HDDT does not represent an effective option in European first-line or rescue *H. pylori* treatment, even when bismuth is added.

Introduction: The prevalence of *H. pylori* infection in the elderly population still remains quite high and this group is usually characterized by multimorbidity, polypharmacy and age-related physiological changes. Therefore, there might be some peculiarities in the diagnostics and treatment of *H. pylori* in such population.

Aims & Methods: **Aims:** To compare the diagnostics and treatments of *H. pylori* infection in the elderly and non-elderly populations.

Methods: The "European Registry on *H. pylori* Management" (Hp-EuReg) is an international European multicenter prospective non-interventional registry recording information of *H. pylori* infection management. Data from the year 2013 to 2022 were analysed.

The subjects were divided into non-elderly (18-59 years) and elderly (≥60 years) groups. Basic demographic information, previous eradication attempts, diagnostic methods, prescribed treatment and its outcome, and adverse events were analysed.

Results: The detailed statistical results are presented in Table 1. 14,467 elderly (29%) and 34,994 non-elderly (71%) patients were included in the Hp-EuReg. Differences of the main indications for *H. pylori* testing (functional dyspepsia and peptic ulcer disease) and the main symptoms before the treatment (dyspepsia and heartburn) were reported between both age groups.

Compared to non-elderly group, more patients in the elderly group were taking concurrent medications (27% vs. 55%, $p<0.05$) and more patients had drug allergies (4% vs. 6%, $p<0.05$). There were significant differences in most of the main *H. pylori* diagnostic tests prescribed before treatment between both age groups, the main being histological examination (47% vs. 38%, $p<0.05$), rapid urease test (RUT) (both groups 38%) and urea breath test (UBT) (25% vs. 31%, $p<0.05$). The main diagnostic tests post-treatment in both groups were UBT (66% and 62%, $p<0.05$), stool antigen

test (14% and 15%, $p<0.05$) and histological examination (5% and 4%, $p<0.05$). In both groups, 81% of the cases were treatment-naïve. For the first-line treatment, quadruple therapies were prescribed in 45% of the elderly and 46% of the non-elderly cases; and triple therapies in 42% and 45%, respectively ($p<0.05$).

For the second-line treatment, quadruple therapies were prescribed in 52% of the elderly and 51% of the non-elderly cases; and triple therapies in 43% and 45%, respectively ($p<0.05$). The duration of first-line treatment in the elderly and non-elderly was: 7 days in 14% and 12%, 10 days in 50% and 49%, and 14 days in 36% and 40% ($p<0.05$ in all groups).

	Elderly (≥60 years)	Non-elderly (18-59 years)	p-value
Gender, N (%)			
- Total	14,467 (29%)	34,994 (71%)	<0.05
- Male	5,365 (37%)	14,244 (41%)	<0.05
- Female	9,093 (63%)	20,730 (59%)	<0.05
Average age ± standard deviation	68.1±6.3	42.8±10.7	>0.05
Main treatment indications, N (%)			
- Functional dyspepsia	5,111 (36%)	13,248 (38%)	<0.05
- Peptic ulcer disease	2,893 (20%)	5,094 (15%)	<0.05
Main symptoms, N (%)			
- Dyspepsia	10,571 (73%)	27,070 (77%)	<0.05
- Heartburn	3,831 (26.3%)	9,183 (26.5%)	>0.05
Concurrent medications, N (%)	7,364 (55%)	8,834 (27%)	<0.05
Drug allergies, N (%)	796 (6%)	1,306 (4%)	<0.05
Main diagnostic methodspre-treatment, N (%)			
- Histology	6,840 (47%)	13,191 (38%)	<0.05
- Rapid urease test	5,463 (38%)	13,138 (38%)	>0.05
- Urea breath test	3,550 (25%)	10,702 (31%)	<0.05
Main diagnostic testspost-treatment, N (%)			
- Urea breath test	9,544 (66%)	21,755 (62%)	<0.05
- Stool antigen test	1,968 (13.6%)	5,401 (15.4%)	<0.05
- Histology	715 (5%)	1,529 (4%)	<0.05
Treatment compliance, N (%)	12,938 (97%)	31,270 (97%)	>0.05
PPI potency in first-line treatment, N (%)			
Low	5,275 (46%)	12,312 (45%)	>0.05
Standard	2,726 (24%)	6,831 (25%)	>0.05
High	3,516 (31%)	8,539 (31%)	>0.05
PPI potency in second-line treatment, N (%)			
Low	750 (40%)	1,691 (36%)	<0.05
Standard	423 (23%)	1,059 (23%)	>0.05
High	705 (38%)	1,983 (42%)	<0.05
First-line treatment duration, N (%)			
- 7 days	1,583 (14%)	3,170 (12%)	<0.05
- 10 days	5,700 (50%)	13,351 (49%)	<0.05
- 14 days	4,185 (37%)	11,019 (40%)	<0.05
Second-line treatment duration, N (%)			
- 7 days	75 (4%)	197 (4%)	>0.05
- 10 days	1,023 (56%)	2,618 (56%)	>0.05
- 14 days	744 (40%)	1,881 (40%)	>0.05
Adverse events (AEs)			
- Overall, N (%)	3,062 (23%)	8,144 (25%)	<0.05
- Treatment cessation due to AEs, %	1.5%	1.2%	>0.05

Table 1. The main differences in the demographics, diagnostics and treatment of *H. pylori* between the elderly and non-elderly populations

The overall duration of second-line treatment was 7 days in 4%, 10 days in 56% and 14 days in 40% of the cases in both groups. No significant differences in the prescribed PPI doses between the elderly and non-elderly were found in the first-line treatment, the most frequent being low-dose (46% vs. 45%, $p>0.05$), high-dose (both groups 31%, $p>0.05$) and standard-dose (24% vs. 25%, $p>0.05$). In the second-line, low PPI doses were more frequently prescribed in the elderly (40% vs. 36%, $p<0.05$), while high PPI

doses were more frequently prescribed in the non-elderly (38% vs. 42%, $p<0.05$). There were no differences in the frequency of standard doses of PPI (both groups 23%).

No differences were found in terms of the treatment compliance in both groups. Statistically significantly less adverse events (AEs) were reported in the elderly group compared to non-elderly (22.8% vs. 25.1%, $p<0.05$); however, there were no differences in the rate of treatment withdrawal due to AEs (1.5% vs. 1.2%, $p>0.05$). The AEs were usually mild to moderate in intensity and lasted up to 14 days.

Conclusion: The diagnostics and treatment of *H. pylori* infection does not generally differ between the elderly and non-elderly groups. The main differences were reported in the concurrent medications, drug allergies, adverse events and the type of prescribed regimen (triple vs. quadruple) both in first- and second-line treatment. However, treatment compliance was similar between groups and the treatment was generally well-tolerated.

Disclosure: Nothing to disclose.

Introduction: Failure of eradication therapy based on macrolides, quinolones or metronidazole is associated with increased *H. pylori* antibiotic resistance; and so, prescribing the same antibiotic as in previous eradication treatment should be avoided. In addition, quinolones are not recommended in first-line therapy given the higher incidence of adverse events reported.

Aims & Methods: Objectives: To describe the frequency of use of quinolones in first-line therapy and the frequency of use of clarithromycin, levofloxacin or metronidazole in second-line, after failure of a first-line therapy based on these same antibiotics.

International, multicenter, prospective, non-interventional registry of the clinical practice of European gastroenterologists. All infected adult patients were systematically registered at AEG-REDCap e-CRF from 2013 to December 2021. *Variables included:* Patient's demographics, previous eradication attempts, prescribed treatment, adverse events, and outcomes. A modified intention-to-treat (mITT) analysis was performed. Data were quality reviewed.

Results: In total, 45,778 patients from 29 countries were included in analysis, being the most frequent: Spain (40%), Russia (16%), Italy (10%), Slovenia (8.1%), and Lithuania (4.8%). First-line therapy was prescribed in 36,699 (80%) cases, second-line in 6,435 (14%), and third- to sixth-line in 2,644 (5.7%). Among those first-line therapies, 952 (2.6%) included levofloxacin, with a decrease in the consumption over the years (from 15% in 2013 to 5.9% in 2021) and differing between countries (Italy 3.4%, Lithuania 2.3%, Russia 2.0%, Slovenia 0.5%, Spain 1.9%; $p < 0.001$). In second line, 2,878 cases used levofloxacin, 1,295 clarithromycin and 1,086 metronidazole. After a first-line eradication failure, clarithromycin was repeated in second-line therapy in 788 patients (16%), metronidazole in 312 (18%) and levofloxacin in 43 (28%) cases. A detailed analysis by country is presented in Table 1.

Antibiotic	Total n (%)	Italy n (%)	Lithuania n (%)	Russia n (%)	Slovenia n (%)	Spain n (%)	Other n (%)	p value
Clarithromycin	788 (16.0)	83 (13.8)	27 (10.7)	272 (46.8)	19 (5.6)	263 (10.3)	124 (21.1)	<0.001
Amoxicillin	3,403 (70.7)	410 (64.4)	243 (97.2)	435 (69.2)	191 (92.3)	1,695 (68.2)	429 (71.1)	<0.001
Metronidazole	312 (17.6)	3 (2.8)	1 (4.5)	21 (28.0)	11 (7.6)	198 (17.2)	78 (28.8)	<0.001
Levofloxacin	43 (28.1)	3 (11.1)	0 (0.0)	15 (71.4)	-	19 (22.9)	43 (28.1)	<0.001

Table 1. Antibiotic prescriptions in second-line therapy, after first-line failure with the same antibiotic, by country.

Conclusion: The erroneous administration of quinolones in first-line therapy has decreased in recent years in Europe. After a first line-therapy failure with either clarithromycin, levofloxacin or metronidazole, the same antibiotic is frequently (and incorrectly) prescribed in second-line therapy.

Disclosure: Nothing to disclose.

Introduction: *Helicobacter pylori* (HP) eradication is recommended for prevention of gastric complications such as peptic ulcer disease or adenocarcinoma.

Currently, bismuth quadruple therapy (BQT) is indicated as first-line treatment in areas with a high incidence of dual metronidazole and clarithromycin resistance, with its use being limited by its tolerability and financial costs. A novel regimen with high-dose amoxicillin (HDA) dual therapy has emerged as an alternative. The aim of this study was to compare the results of these two treatments on HP eradication.

Aims & Methods: Prospective randomized study including 100 consecutive patients undergoing HP eradication. Each patient was randomized to one branch of treatment: BQT (bismuth 140mg + metronidazole 125mg + tetracycline 125mg, 4 times a day, for 10 days) or HDA (amoxicillin 1000mg alternating with amoxicillin 500mg, 4 times a day, for 14 days), both associated with esomeprazole 40mg twice a day. Four weeks after treatment, efficacy (stool HP antigen test and symptom persistence) and tolerability (side effects and treatment interruption) were assessed in each branch.

Results: A total of 100 patients were included, 54% women, with a mean age of 55±14 years. From these, 14 lost follow-up. Effective eradication proven by negative stool antigen test was significantly higher in patients randomized to HDA when compared to BQT (96% vs 83%; $p=0.047$). This difference was even higher considering only those patients refractory to previous therapies for HP eradication (100% vs 72%; $p=0.030$).

Furthermore, the percentage of patients with dyspeptic symptoms after treatment was also lower with HDA treatment (4% vs 19%; $p=0.021$).

The incidence of side effects (2% vs 9%; $p=0.133$) and treatment interruption (2% vs 4%; $p=0.460$) did not significantly differ between both treatments.

Conclusion: When compared to BQT, treatment with HDA presented higher efficacy in eradicating HP infection, without differences in reported side effects or therapeutic adherence. This treatment represents an interesting alternative for populations with increasing incidences of resistance to the currently recommended antibiotic regimens.

Disclosure: Nothing to disclose.

Introduction: Management of *Helicobacter pylori* infection (*H. pylori*) requires co-treatment with proton pump inhibitors (PPIs) and the use of antibiotics to achieve successful eradication

Aims & Methods: To evaluate the role of PPIs in the eradication of *H. pylori*, based on the "European Registry on *Helicobacter pylori* Management" (Hp-EuReg).

The Hp-EuReg is a multicentre, prospective, non-interventional, registry assessing decisions and outcomes of *H. pylori* management by European gastroenterologists in routine clinical practice. Countries recruiting more than 1,000 patients were included. Effectiveness was assessed by modified intention-to-treat (mITT). Data were quality reviewed.

Results:

	Eradication rate n/N (%) mITT	Low Dose	Standard Dose	High Dose	p-value
10 days N: 12214 (55.3%)	Triple PPI+CM/ A	1277/1634 (78.2)	1088/1261 (86.3)	417/466 (89.5)	0.0001
	Quadruple sequential PPI+C+AT/M	981/1112 (88.2)	48/51 (94.1)	603/647 (93.2)	0.002
	Quadruple Concomitant PPI+C+A+T/M	1262/1437 (87.8)	507/580 (87.4)	440/476 (92.4)	0.013
	Quadruple with bismuth PPI+C+A+B	200/233 (85.8)	213/235 (90.6)	93/101 (93.0)	0.137
	Pylera®/ Quadruple with bismuth PPI+B+M+Tc	1533/1683 (91.1)	865/917 (94.3)	1300/1371 (94.8)	0.0001
14 days N: 7782 (35.2%)	Triple PPI+C+M/ A	426/528 (80.7)	758/850 (89.2)	1273/1391 (91.5)	0.0001
	Quadruple Concomitant PPI+C+AT/M	597/702 (85.0)	385/429 (89.7)	1573/1685 (93.4)	0.0001
	Quadruple with bismuth PPI+C+A+B	165/180 (91.6)	797/859 (92.8)	969/1067 (90.8)	0.299
	Pylera®/ Quadruple with bismuth PPI+B+M+Tc	18/20 (90.0)	55/59 (93.2)	11/12 (91.6)	0.893

A: amoxicillin; B: bismuth; C: clarithromycin; M: metronidazole; Tc: tetracycline; T: tinidazole; mITT: modified intention to treat; PPI: proton pump inhibitor; N= Total treated; n=Success; *Low dose PPI - 4.5 to 27 mg omeprazole equivalent; standard dose PPI - 32 to 40 mg omeprazole equivalent; high dose PPI - 54 to 128 mg omeprazole equivalent, b.i.d

Table 1.

Overall, 22,078 patients from 5 countries were analysed. Optimal (>90%) first-line mITT effectiveness was achieved with the following treatments: 14-day clarithromycin-amoxicillin-bismuth quadruple therapy, and 14-

day metronidazole-tetracycline-bismuth quadruple therapy, both independently of the PPI dose prescribed; in all 10- or 14-day therapies with high-dose PPIs (except with standard 10-day triple therapy); in 10-day sequential and 10-day quadruple clarithromycin-amoxicillin-bismuth, and 10-day quadruple metronidazole-tetracycline-bismuth with standard-dose PPIs. None of the 7-day therapies achieved optimal cure rates regardless of the PPI dose used. The PPI dose was significantly associated with the effectiveness of: 10- or 14-day standard triple and quadruple concomitant therapies, and 10-day quadruple sequential and metronidazole-tetracycline-bismuth therapies. Table 1 details the mITT effectiveness by duration and PPI dose used.

Conclusion: In first-line *H. pylori* treatment, ≥90% effectiveness is obtained with standard-dose PPIs in 10-day sequential and 10- or 14-day bismuth quadruple therapies and with high-dose PPIs in all 10- or 14-day therapies except with standard 10-day triple therapy.

EFFECTIVENESS AND SAFETY OF NOVEL VONOPRAZAN-BASED REGIMEN FOR *H. PYLORI* ERADICATION: A SINGLE CENTER, PROSPECTIVE, RANDOMIZED TRIAL

X. Wang¹, J. Yu¹, L. Tang¹

¹The Affiliated Changzhou No. 2 People's Hospital of Nanjing Medical University, Gastroenterology, Changzhou, China

Contact E-Mail Address: wxy20009@126.com

Introduction: To date, vonoprazan-based regimens for *H. pylori* infection in Japan have been shown to achieve acceptable eradication rates. However, its effectiveness and safety is unclear in Chinese.

Aims & Methods: This study aimed to evaluate the efficacy and safety of the novel Vonoprazan-based regimen as first-line treatment for *H. pylori* and to compare with bismuth-based quadruple regimen. This prospective, randomized clinical trial was performed in China. Patients with *H. pylori* and naive to treatment were randomly assigned to either VAS group (vonoprazan 20 mg twice/day, amoxicillin 750 mg three times/day and *S. boulardii* 250 mg twice/day) for 10 days or PCAB group (Esomeprazole 20 mg, amoxicillin 1000 mg, clarithromycin 500 mg and bismuth 220 mg twice/day) for 14 days. Eradication success was evaluated by ¹³C-urea breath test at least 4 weeks after treatment and adverse events were recorded. Factors associated with eradication success and cost-effectiveness analyses were also performed.

Results: 135 subjects were screened and 126 were randomized. The eradication rates of VAS and PCAB groups were 87.3% and 88.9% ($p=1.000$) by intention-to-treat analysis, and 87.3% and 91.8% ($p=0.560$) by per-protocol analysis, respectively. The incidence of adverse events in PCAB group was significantly higher than that in VAS group (17.5% VS 4.8% $P=0.044$). In the VAS group, successful *H. pylori* eradication was associated with small body surface area (BSA) (eradication rate: 92.2% in patients with BSA <1.831 vs. 66.7% in those with BSA ≥1.831, $p=0.037$) and non-smokers (eradication rate: 92.9% in non-smokers vs. 42.9% in smokers, $p=0.003$). Cost-effectiveness ratio of VAS group was less than that of PCAB group (4.64 vs. 4.79, Chinese Yuan, per percent).

Conclusion: This novel Vonoprazan-based regimen is as effective as bismuth-based quadruple regimen, with less adverse events and more cost-effective. This regimen is more suitable for small BSA and non-smoking patients.

Disclosure: Nothing to disclose.

AN EVOLVING RESISTANT PANDEMIC. RISING COMMUNITY *H. PYLORI* TREATMENT FAILURE TO CLARITHROMYCIN-BASED TRIPLE THERAPY: AN OBSERVATIONAL STUDY

T. Butler^{1,2}, P. Armstrong², M.T. Gregg², S. Smith¹, D. McNamara^{1,2}
¹Trinity College Dublin, Clinical Medicine, Dublin, Ireland, ²Tallaght University Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: thbutler@tcd.ie

Introduction: Clarithromycin-based triple therapy is commonly prescribed as a first-line treatment for *H. pylori* in Ireland. Worldwide, increased clarithromycin resistance has been reported. It is unclear whether this is due to personalised antibiotic exposure inducing resistance over time, or endemic community prevalence of a resistant strain of *H. pylori*, acquired from youth.

We hypothesise that older age cohorts would have had more exposure to antibiotics and that increased resistance rates, leading to treatment failure with age, would support a developed resistance model.

Aims & Methods: To identify treatment failure rates to first-line clarithromycin-based triple therapy and to compare rates according to age and gender.

All patients referred for their post-eradication 13C-urea breath test (UBT), having received clarithromycin-based triple therapy (40 mg esomeprazole b.i.d., 500 mg clarithromycin b.i.d., amoxicillin 1 g b.i.d. for 14 days) between 2019 and 2022 were identified and included in the analysis. Following clarithromycin triple therapy a positive UBT, delta-over-baseline >4, was considered a surrogate marker of clinical resistance.

Results: In all 482 patients were identified (mean age = 50.6 ± 16.8 ; 45.6% (n=220) male, 54.4 (n=262) . The overall clarithromycin resistance rate was found to be 25.5 % (n=123). We found no statistical difference in resistance rates across ages or between age groups, divided into decades analysed via two-way ANOVA.

Dividing the cohort into those aged less than 45 and greater than 45, the resistance rates were also statistically similar (26.6% (n=49) versus 24.8% (n=74), respectively; Fisher's exact test, p=0.69).

It was also found that failure rates were comparable for both male and female patients (21.8% (n=48) versus 28.6% (n=75), respectively, Fisher's exact test, p = 0.094).

Conclusion: Across adult age groups, clarithromycin resistance has reached alarmingly high levels with 1 in 4 patients failing first-line therapy. In addition, it suggests a high community prevalence of clarithromycin-resistant *H. pylori*. The authors propose that clarithromycin-based triple therapy should no longer be used without sensitivity testing as a treatment for *H. pylori* in Ireland.

HELICOBACTER PYLORI INFECTION MEDIATES P53 REGULATION OF MITF-INDUCED MITOPHAGY

J. Rong¹, H. Wang¹, Y. Xie¹
¹The First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China

Contact E-Mail Address: 915939113@qq.com

Introduction: Mitophagy is a type of selective autophagy that is essential for maintaining cellular homeostasis. Helicobacter pylori (*H. pylori*) infection is closely related to the development of gastric cancer (GC), however, the mechanism by which *H. pylori* infection regulates mitophagy in GC remains unclear.

Aims & Methods: In vivo and in vitro models of *H. pylori* infection were constructed to study the relationship between *H. pylori* infection and mitophagy. The interaction between p53 and MITF was verified by immunoprecipitation (CO-IP). Overexpression of p53 and ROS inhibitor NAC treatment were used to study the relationship between p53, mitoSOX and MITF in GC, and the role of MITF in mitophagy induced by *H. pylori* infection.

Results: *H. pylori* infection can upregulate mitoSOX production and induce mitochondrial membrane depolarization, mitochondrial fission and mitophagy in GC. NAC treatment can reduce mitoSOX production and reduce mitophagy induced by *H. pylori* infection. *H. pylori* infection can up-regulate the expression of MITF, and knocking down MITF can inhibit the mitophagy induced by *H. pylori* infection. NAC treatment could attenuate the up-regulation of MITF expression induced by *H. pylori* infection. *H. pylori* infection can down-regulate the expression of p53. MITF protein interacts with p53 protein in GC cell. Overexpression of p53 weakens the expression of MITF by inhibiting the production of mitoSOX, thus weakening the mitophagy induced by *H. pylori* infection.

Conclusion: *H. pylori* infection regulates mitochondrial oxidative stress through p53, thus mediating MITF to regulate mitophagy in GC.

P1032

HELICOBACTER PYLORI INFECTION INHIBITS P53 REGULATION OF PGK1-MEDIATED GLYCOLYSIS

J. Rong¹, H. Wang¹, Y. Xie¹
¹The First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China

Contact E-Mail Address: 915939113@qq.com

Introduction: Phosphoglycerate kinase 1(PGK1) is a key enzyme in the glycolysis pathway and is closely related to the development of various cancers. However, the mechanism of PGK1 in gastric cancer (GC) and its relationship with helicobacter pylori (*H. pylori*) infection remain unclear.

Aims & Methods: *H. pylori* positive and negative gastric tissue samples were collected to detect the expression of PGK1. In vitro and in vivo *H. pylori* infection model, the relationship between PGK1 and *H. pylori* was studied. The effects of PGK1 on cell proliferation, invasion, migration and glycolysis were verified by CCK-8 and EdU cell proliferation, colony formation, Transwell and lactic acid detection. The interaction between PGK1 and p53 was determined by immunoprecipitation.

Results: We found that PGK1 was highly expressed in GC tissues compared to adjacent noncancerous tissues. During the progression from mild chronic non-atrophic gastritis to GC, the expression of PGK1 gradually increased in human gastric tissue and was associated with *H. pylori* infection. PGK1 overexpression promotes GC cell proliferation, invasion and migration, whereas PGK1 knockdown inhibits GC cell proliferation, invasion and migration. *H. pylori* infection promotes the entry of PGK1 into mitochondria, up-regulates lactate, ECAR, and down-regulates OCR in GC. PGK1 protein interacts with p53 protein in GC cell. Overexpression of p53 suppressed *H. pylori* infection-induced lactate elevation by reducing PGK1 expression.

Conclusion: This study showed that *H. pylori* infection plays a key role in the development of GC by regulating the expression of PGK1 through p53.

APRAGLUTIDE DOES NOT IMPACT ANTI-TUMOR AND IMMUNOSUPPRESSIVE EFFICACY OF CONDITIONING CHEMOTHERAPY IN MICE

V. Dimitriadou¹, B. Biemans¹, N.N. Youssef², M. Minden³

¹VectivBio, Preclinical Development, Basel, Switzerland, ²VectivBio, Basel, Switzerland, ³University of Toronto, Department of Medical Biophysics, Toronto, Canada

Contact E-Mail Address: nader.youssef@vectivbio.com

Introduction: Conditioning chemotherapy reduces tumor burden and provides immunoablation to prevent graft rejection with hematopoietic cell transplantation, but often induces mucosal barrier breakdown and mucositis.

Apraglutide is a novel, long-acting synthetic glucagon-like peptide-2 (GLP-2) analog that has been shown to protect the gastrointestinal (GI) epithelium from chemotherapy-induced injury, improves survival, and allows better weight maintenance in mice undergoing chemotherapy.

Aims & Methods: Preclinical studies aim to evaluate the impact of apraglutide on the efficacy of chemotherapy in reducing tumor load and inducing immunosuppression.

Study 1 assessed cytarabine's antitumor effects in leukemic NOD/SCID mice. Apraglutide or vehicle was administered on Days -4 to 4. Cytarabine or vehicle was administered on Days 0 to 4. Bone marrow and spleen samples were collected on Day 7 for determination of the percentage of hCD45+ cells.

Study 2 assessed the effect of apraglutide on cytarabine-induced immunosuppression and included three groups of BALB/c mice: (A) vehicle-only; (B) cytarabine-only on Days 0 to 4; (C) cytarabine on Days 0 to 4 plus apraglutide pre-treatment on Days -4, -2, and continued as concomitant treatment on Days 0, 3, 6, 9, and 12. Red blood cells, platelets, white blood cells (WBC), neutrophils (NEU), and lymphocytes (LYMPH), were assessed. A cohort was allowed to survive for four weeks to evaluate the effect of apraglutide on immunosuppression recovery.

Study 3 assessed the effect of apraglutide on melphalan-induced immunosuppression. Three groups of BALB/c mice were included: (A) vehicle-only; (B) melphalan-only on Day 0; (C) melphalan on Day 0 plus apraglutide pre-treatment on Days -8, -6, -4, -2, and continued as concomitant treatment on Days 0, 2, 4, and 6. WBC, NEU, and LYMPH were assessed.

Results: Study 1 showed that human leukemia cells reduction did not differ significantly between cytarabine-only and apraglutide-treated groups but were significantly greater when compared to the vehicle-only group. The percentage of hCD45 in bone marrow after chemotherapy was 35.5±4% with cytarabine-only and 33.9±4.2% with apraglutide-treated mice.

A dramatic decrease in leukocytes at the end of the treatment period in Study 2 indicated that cytarabine-induced immunosuppression was not impaired by apraglutide treatment (91% reduction in lymphocytes with both cytarabine-only and apraglutide-treated mice). Apraglutide did not impact the recovery of hematological parameters four weeks after the end of treatment.

Study 3 showed that melphalan elicited immunosuppression as evidenced by leukocyte decrease. Mice treated with melphalan, with or without apraglutide, had severe reductions in WBC and LYMPH vs. vehicle-only.

Conclusion: The addition of apraglutide treatment did not impair the anti-tumor efficacy of cytarabine *in vivo*. Moreover, combination with apraglutide had no negative impact on cytarabine- or melphalan-induced immunosuppression. Apraglutide did not negatively impact the anti-tumor or immunosuppressive effects of chemotherapy.

Disclosure: The study was sponsored by VectivBio and conducted in collaboration with the University of Toronto. V. Dimitriadou and B. Biemans received fee for service as a consultant. N.N. Youssef is an employee of VectivBio.

QUANTITATIVE MAGNETIC RESONANCE ENTEROGRAPHY SHOWS EVIDENCE OF TREATMENT RESPONSE IN PEDIATRIC SMALL BOWEL CROHN'S DISEASE: A PROSPECTIVE STUDY

J. Dillman¹, A. Menys^{2,3}, J. Tkach¹, L. Denson⁴

¹Cincinnati Children's Hospital Medical Center, Department of Radiology, Cincinnati, United States, ²Motilent, London, United Kingdom, ³University College London, Centre for Medical Imaging, London, United Kingdom, ⁴Cincinnati Children's Hospital Medical Center, Department of Pediatrics, Cincinnati, United States

Contact E-Mail Address: alex.menys@motilent.co.uk

Introduction: There is a diverse and effective range of approaches to the management of Crohn's Disease but matching the patient with the best treatment is dependent on using the appropriate test. This is particularly important in a pediatric population.

Cross sectional imaging is important not just in establishing the location and behavior of the disease but also in grading inflammatory activity. GI-Quant is a recently FDA/CE cleared tool that quantifies bowel wall motion as a biomarker of disease activity based on MR enterography (MRE). It is hypothesized that a positive change in bowel wall motion is an early indicator of mucosal healing (1).

The MRE exam can be routinely performed in the clinic without the need for gadolinium contrast material administration or a spasmolytic (2).

Aims & Methods: The aim of this study was to investigate whether the now commercially available software GIQuant (Motilent, London, UK) could detect therapeutic response in a pediatric population after the initiation of anti-TNFalpha therapy at:

- i. 6-week and,
- ii. 6 month time points.

Secondly, we aimed to explore the inter-reader agreement of the GIQuant score.

20 children and young adults (mean age 14.6) with newly diagnosed ileal Crohn disease underwent research MRI examinations of the small bowel, including dynamic cine imaging (2-images/s 60s scan duration). Patients with Crohn's disease underwent imaging before as well as six weeks and six months after anti-TNF alpha therapy initiation.

Terminal ileal intestinal motility scores (from GIQuant) were generated from cine imaging (2D steady-state free precession) by two blinded operators, with higher GIQuant scores indicating greater intestinal motility.

Linear mixed models were used to assess if intestinal motility scores changed (increased) over time in response to treatment.

Inter-operator absolute agreement was assessed using intra-class correlation (ICC).

Results:

1. Intestinal motility scores changed over time in response to biologic therapy for both operators (operator 1, $p=0.036$; operator 2, $p=0.034$). Intestinal motility scores increased significantly between the baseline and six month visits for both operators (operator 1, $p=0.0065$; operator 2, $p=0.0078$);
2. There was no difference in peristalsis between the six week and six month visits ($p>0.95$ for both operators).
3. There was excellent absolute agreement in intestinal motility scores between operators ($ICC=0.89$).

Conclusion: GIQuant could detect treatment response as early as six weeks post initiation in this pediatric cohort. Interestingly, the six week and six month observation was non-significantly different (although both were from baseline), however there was a large amount of variation in the group.

The next question is, what do we do with this information?

Recent observations from the STARDUST (3) study suggested that endoscopy performed earlier (16 weeks) with corresponding therapeutic adjustment did not improve outcomes over standard practice and it may prove to be the same with transmural measures of small bowel disease.

Regardless, the change at 6 months suggests the importance of earlier follow-up than one year given the breadth of therapeutic options. Strong inter-reader agreement is reassuring and GIQuant needs neither nor gadolinium or spasmolytic potentially improving patient compliance.

Contact E-Mail Address: tomo1993baske@gmail.com

Introduction: Chronic Idiopathic Intestinal-pseudo Obstruction (CIIP) is a severe, rare gastrointestinal intractable disease. Hyperendotoxemia has been reported to be associated with infections, fatigue, and depression, but the association between CIIP patients and endotoxin remains unclear. The purpose of this study was to investigate and fecal intestinal microbiota with a focus on endotoxin in CIIP patients.

Aims & Methods: Fecal and blood samples were collected from 10 CIIP patients who were not taking antibiotics, had not undergone surgery, and whose diagnosis was confirmed by cine MRI, as well as from 15 healthy

subjects (HC). Intestinal flora analysis was performed at the phylum and genus level using next generation sequencing. Diversity analysis was performed using the Shannon index. Endotoxin-producing bacteria were defined as the genera *Gemmiger*, *Bacteroides*, *Escherichia/Shigella*, *Akkermansia*, and *Klebsiella*. Peripheral blood endotoxin was measured using endotoxin activity assay.

Results: At the phylum level, Firmicutes (83% vs. 62%, $p<0.05$ CIIP vs HC), Proteobacteria (7.3 vs. 2.9%, $p<0.05$), Verrucomicrobia (10.1% vs. 0.4%, $p<0.05$) and Fusobacteria (3.1% vs. 0%, $p<0.05$) were significantly increased in CIIP patients compared to HC.

At the genus level, *Lactobacillus* (28.8% vs 0.1%, $p<0.01$) and *Akkermansia* (9.2% vs 0.4%, $p<0.05$) were significantly increased; *Blautia* (8% vs 26%, $p<0.001$), *Lachnospiraceae_incertae_sedis* (4% vs 13%, $p<0.001$), *Faecalibacterium* (2% vs 11%, $p<0.001$), *Rosebria* (1% vs 7%, $p<0.01$) and *Collinsella* (0.1% vs 1.7%, $p<0.001$) were significantly decreased in CIIP patients compared to HC.

In addition, endotoxin-producing bacteria in stool were significantly increased in CIIP patients, and blood endotoxin levels were significantly elevated in CIIP patients (0.26 vs 0.08, $p<0.001$).

Conclusion: The present study suggests that increased of endotoxin-producing bacteria may be the cause of the abnormal endotoxemia, and that treatment of CIIP patients with a focus on endotoxin may provide a new approach to reduce infectious deaths and alleviate symptoms.

Disclosure: Nothing to disclose.

P0154

THE DIAGNOSTIC CAPABILITIES OF NON-INVASIVE FECAL BIOMARKERS OF NSAID-INDUCED INTESTINAL LESIONS IN PATIENTS WITH OSTEOARTHRITIS

O. Gubska¹, A. Kuzminets¹

¹Bogomolets National Medical University, Therapy, Infectious Diseases and Dermatology Postgraduate Education, Kyiv, Ukraine

Contact E-Mail Address: andrewkuzminets@gmail.com

Introduction: Osteoarthritis (OA) is a common disease among the population, especially the elderly, requiring frequent nonsteroidal anti-inflammatory drugs (NSAIDs), which are harmful to the upper and lower parts of the gastrointestinal tract.

Aims & Methods: To analyze the diagnostic possibilities of non-invasive fecal biomarkers of NSAID-induced intestinal lesions in patients with OA and to check the possibility of predicting the presence of such lesions based on fecal biomarkers.

We investigated 91 patients with OA of different localizations and degrees (then divided into three subgroups depending on NSAIDs use and their selectivity) and 30 people without OA as a control group (CG). We studied the following fecal biomarkers: calprotectin (FC), secretory immunoglobulin A (sIgA), and hemoglobin/haptoglobin (Hb/Hp) complex (ELISA method).

Results: The FC content in OA patients was significantly higher than in CG (147.19 (IQR 132.76-161.8) mg/kg vs 20.91 (IQR 19.5-32.53) mg/kg ($p<0.001$). It was 68.78 (IQR 61.48-90.3) mg/kg in those not taking NSAIDs, 259.65 (IQR 234.67-294.99) mg/kg in those taking non-selective and 111.93 (IQR 105.31- 149.63) mg/kg in those taking selective NSAIDs.

We found a significant difference between all 3 subgroups from the CG ($p<0.01$). NSAIDs subgroups differed from the "non-NSAIDs" ($p<0.01$). In "non-NSAIDs" subgroup patients, the moderately elevated (50-200 mg/kg) level of FC was significantly more common than in CG (OR = 4.92; 95% CI 1.273-23.965; $p=0.0012$); non-selective NSAIDs subgroup had a significantly higher prevalence of elevated (>200 mg/kg) FC than in "non-NSAIDs" subgroup.

Hb/Hp complex content in CG was 0.73 (IQR 0.65-0.79) mg/kg vs 4.77 (IQR 3.41-6.81) mg/kg in the OA group. In OA-“non-NSAIDs” - 1.88 (IQR 1.23-2.6) mg/kg, non-selective-NSAIDs - 9.38 (IQR 7.47-13.29) mg/kg and in selective NSAIDs - 2.98 (1.34-4.62) mg/kg. OA-non-selective-NSAIDs differed significantly from CG and “non-NSAIDs”. The OA-selective-NSAIDs differed from the non-selective and CG ($p < 0.05$). OA patients had elevated Hb/Hp complex while in the CG it was not elevated in all cases. OA-non-selective-NSAIDs had elevated levels of Hb/Hp complex significantly more frequent than CG ($p < 0.001$) and “non-NSAIDs” (OR=4.229; 95% CI 1.288-15.289; $p < 0.001$).

SIgA content differed in OA patients from the CG (1088.83 (IQR 986.0-1.291.25) mg/kg vs 593.57 (IQR 549.0-761.91) mg/kg, $p < 0.01$), but not in subgroups ($p > 0.05$).

The developed logistic model allows to predict the risk of NSAID-induced intestinal lesions. It looks like $\ln(P/(1-P)) = -2.168 + 0.2986 \cdot (\text{Hb/Hp}) + 0.0083 \cdot \text{FC}$. AUC of the model is 0.872 (95% CI 0.773 - 0.97), $p < 0.05$; the optimal threshold = 0.987.

At the chosen threshold, the sensitivity of the model is 65% (95% CI 40.8% - 84.6%), specificity 90% (95% CI 73.5% - 97.9%), Positive Predictive Value - 81.2% (95% CI 54.4 - 96), Negative Predictive Value - 79.4% (95% CI 62.1 - 91.3).

Conclusion: The NSAID enteropathy manifests in increased FC and Hb/Hp complex content. Our model can predict such lesions. These markers are slightly increased in OA patients even if they do not take NSAIDs. SIgA content is not affected by NSAIDs intake.

Disclosure: This study was partly funded by R-Biopharm AG, Darmstadt, Germany, by supplying the reagent kits for FC and SIgA determination.

A PHASE 1, OPEN-LABEL EVALUATION OF THE PHARMACOKINETICS AND SAFETY OF A SINGLE DOSE OF APRAGLUTIDE IN SUBJECTS WITH NORMAL AND IMPAIRED RENAL FUNCTION

G. Greig¹, D. Cong², N. Hurley¹, E. Michel¹, N.N. Youssef¹

¹VectivBio, Basel, Switzerland, ²ICON PRA Health Sciences, Biostatistics, Dublin, Ireland

Contact E-Mail Address: nader.youssef@vectivbio.com

Introduction: Patients with intestinal failure associated with short bowel syndrome (SBS-IF) have an increased risk of complications, including renal dysfunction. With currently available glucagon-like peptide 2 (GLP-2) therapy, dosage adjustments are recommended for patients with moderate and severe renal impairment and end-stage renal disease. Apraglutide has unique pharmacokinetic (PK) and pharmacodynamic (PD) properties, with preclinical studies indicating low clearance, slow absorption, and high protein binding resulting in a longer half-life than subcutaneously injected native GLP-2 and other GLP-2 analogs. Apraglutide is degraded into small peptides and amino acids via catabolic pathways, similar to endogenous GLP-2.

Previous preclinical PK and metabolism trials showed no intact parent compound (apraglutide) was found in urine, suggesting renal elimination does not play a significant role in apraglutide removal.

Aims & Methods: This Phase 1, non-randomized, open-label, parallel-group trial evaluated the PK and tolerability of a single dose of subcutaneous apraglutide 5 mg in subjects with renal impairment and healthy volunteers matched for age and body weight.

Part 1 assessed subjects with severe renal impairment (eGFR < 30 mL/min/1.73 m² not on hemodialysis) and subjects with normal renal function (eGFR ≥ 90). According to plan, the study was stopped after completion of Part 1 because exposure of subjects with severe renal impairment was not greater than that of healthy subjects.

Results: Eight subjects with severe renal impairment and eight healthy matched subjects were enrolled and completed the study. There was no apraglutide overexposure in subjects with severe renal impairment compared to the healthy subjects. The geometric mean renal/healthy ratio was AUC_{inf} (0.693) and C_{max} (0.620). Three out of eight (37.5%) subjects with severe renal impairment reported 7 AEs, and 2/8 (25%) subjects with normal renal function reported 3 AEs. All AEs had resolved at the end of the study. The investigators considered 5 AEs related to apraglutide; all were reported by the subjects with severe renal impairment (1 increased alanine transaminase; 2 nausea and emesis; 1 erythematous papule; 1 ecchymosis at the injection site). The treatment-related AEs do not differ from those reported to date in other apraglutide clinical studies. No serious AE or death was reported. No clinically relevant changes within groups or differences between groups were observed over time in clinical chemistry, hematology, urine, or other safety parameters. No relevant changes in vital signs (blood pressure, heart rate, and body temperature) or ECGs occurred from screening to follow-up.

Conclusion: Exposure to apraglutide in subjects with severe renal impairment is not increased compared to healthy subjects. A single dose of 5-mg apraglutide in subjects with severe renal disease and healthy matched subjects was well-tolerated, and no unexpected safety issues were raised. The study results are clinically significant as 28% of patients with SBS-IF have renal impairment (Wang P et al. 2021) and may not be candidates for treatment with currently available GLP-2, which requires dose adjustment. By contrast, apraglutide dose adjustments are not necessary for subjects with renal impairment.

Introduction: The natural history of chronic intestinal pseudo-obstruction (CIPO), a rare disease characterized by episodes of non-mechanical obstruction, is unclear in adults.

Aims & Methods: This study evaluated the clinical course of CIPO and palliative care needs. From April 2011 to March 2021, 74 patients who underwent cine magnetic resonance imaging, and had a definitive diag-

nosis were prospectively included. We investigated the disease etiology and outcomes, age of onset, nutritional status at consultation (body mass index [BMI], serum albumin), hydrogen breath test (HBT) results, and total parenteral nutrition (TPN) during the disease course.

Results: Forty-seven patients (64%) were women, with mean ages of 44 and 49 years at onset and diagnosis, respectively. Primary CIPO was observed in 48 patients (65%). Secondary CIPO was observed in 26 cases (35%); among them, 18 (69%) had scleroderma. The mean BMI, serum albumin, and HBT positivity rate were 17 kg/m², 3.8 mg/dL, and 60%, respectively. TPN management and invasive decompression therapy were performed in 23 (31%) and 18 (24%) patients, respectively. Intestinal sterilization was performed in 51 (69%) patients and was effective in 33 (65%); of these, 28 (85%) were taking metronidazole. Seven (9%) patients used opioids. There were nine deaths (12%), including five (56%) from infection and two (22%) from suicide. Of the deaths, six (67%) and four (44%) underwent TPN management and decompression therapy, respectively. Fifty-one patients (69%) needed palliative care.

Conclusion: CIPO is a rare, severe, and unrecognized disease. Standardization of treatment strategies, including palliative care and psychiatric interventions, is warranted.

Disclosure: Nothing to disclose.

Contact E-Mail Address: takaomi0027@gmail.com

Introduction: Chronic intestinal pseudo-obstruction (CIPO) is a rare intractable gastrointestinal disease which decreases quality of life. CIPO is caused by the stagnation of intestinal contents and small intestinal bacterial overgrowth (SIBO); this occurs mainly in the small intestine, due to decreased gastrointestinal peristalsis. If this condition worsens, it becomes a serious intractable disease that leads to nutritional disorders caused by small intestinal insufficiency, and bloodstream infections (sometimes fatal) due to the breakdown of barrier function (1).

SIBO is recognized in CIPO regardless of the origin (idiopathic or secondary). SIBO has been reported as a complication in 43% of systemic sclerosis patients, (2) regardless of the presence of CIPO. Rifaximin-a (RFX) is a rifamycin antibacterial agent that exhibits antibacterial activity against gram-positive, gram-negative, aerobic, and anaerobic bacteria by inhibiting bacterial RNA synthesis.

In addition, it is absorbed minimally even when administered orally, and acts mainly in the gastrointestinal tract. Therefore, this drug is localized in the gastrointestinal tract, and is expected to be an effective drug for treating SIBO.

Aims & Methods: The aim of this study to evaluate the efficacy and safety of RFX in patients with CIPO. This randomized, double-blind, placebo-controlled, phase 2a study (ClinicalTrials.gov; NCT04118699) recruited adult patients with CIPO (idiopathic CIPO and CIPO secondary to systemic sclerosis), and those with ≥ 2 abdominal bloating as per the Global Symptom Score (GSS). GSS is defined on a scale of 0-3, with 0 being no symptoms and 3 being severe. Eligible patients were randomly assigned (2:1) to receive oral RFX (400 mg thrice daily) or placebo (PBO) for four weeks.

The primary endpoint was percent improvement in the GSS-abdominal distension score (score 0 or 1); an objective index, the volume in the small intestine was measured using CT. Small intestinal bacterial overgrowth (SIBO) was diagnosed with a glucose hydrogen breath test. Blood endotoxin was measured by endotoxin activity assay. Gut microbiota measurements were performed by illumina Miseq. Efficacy analysis was performed by full set analysis. This trial was registered with ClinicalTrials.gov; NCT04118699.

Results: Between November 26, 2019 and May 24, 2021, 15 patients were screened; 12 eligible patients were assigned to the RFX group (n=8) or the placebo group (n=4). The rate of improvement in abdominal distension score (GSS) was 75% (3/4 patients, 95% CI: 19-99) in the PBO group and 25% (2/8, 95% CI: 3-65) in the RFX group (p=0.2).

There was no significant difference in the absolute change in small intestinal volume and the SIBO disappearance rate, between groups. There were no significant changes in intestinal bacteria before and after medication between the two groups. In CIPO with SIBO alone, the SIBO disappearance rate decreased in the RFX group (RFX: 3/4 (75%), PBO: 1/4 (25%), p=0.15). The absolute change in the hydrogen concentration from the baseline to the maximum value in the HBT was significantly lower in the RFX group than that in the PBO group (PBO vs. RFX, 131 vs. -108, p=0.03). The CT gas volume and blood endotoxin level also tended to decrease in the RFX group (CT gas volume: PBO vs. RFX, 79 vs. -7, p=0.08; endotoxin activity: PBO vs. RFX, 0.02 vs. -0.12, p=0.08). No life-threatening events, severe adverse events, or treatment-related deaths occurred during the study.

Conclusion: RFX is safe for CIPO and may potentially reduce small intestinal gas volume and hydrogen gas concentration in CIPO patients.

Introduction: The human intestinal tract reacts to extensive resection with spontaneous intestinal adaption. Therapy with GLP-2 analogues (GLP-2-A) enhances intestinal adaption by promoting mucosal growth and intestinal absorption. Clinical response to GLP-2-A treatment is characterized by a

significant reduction in parenteral volume or calorie demands but varies widely. Currently there are no biomarkers available to predict either spontaneous intestinal adaption or response to GLP-2-A therapy nor to assist with clinical management of GLP-2-A.

In addition, the mechanisms in intestinal barrier regulation of intestinal permeability (IP) during adaptive response or therapy are not well understood. We analyzed whether measurement of IP is a useful biomarker to describe the regulation mechanisms in the intestinal barrier in patients with Short Bowel Syndrome (SBS) with or without GLP-2-A.

Aims & Methods: IP was assessed using a sugar drink test containing lactulose (Lac), mannitol (Man) and sucrose (Sac). Urinary recovery rate of each sugar was analyzed by HPLC analysis. Clinical data were collected for remaining small bowel length, PN requirements, and therapy with GLP2-A.

Results: SBS patients showed increased Lac/Man ratio compared to controls, (n= 24/14, p=0.0004). Man recovery was decreased in SBS (mean SBS 4.3% vs. controls 10.7%, p= 0.00011), whereas LAC recovery was similar to controls (mean SBS 0.18% vs. controls 0.22%, p= 0.32). Gastroduodenal permeability (Sac recovery) was similar to controls (mean SBS 0.14 % vs controls 0.11 %, p=0.73).

For Man recovery, a positive correlation with the remaining small bowel length was found ($r^2 = 0.408$, p=0.004 (SBS wo GLP-2) while Lac recovery showed less correlation ($r^2=0.24$, p=0.041). No correlation was found for Sac recovery ($r^2=0.023$, p=0.55).

Man recovery was elevated in patients treated with GLP-2-A compared to therapy naïve patients (wo GLP-2 4.28% vs. with GLP-2 therapy 6.68%; Δ Man recovery 56%). Lac recovery showed only minor changes (wo GLP-2 0,175 % vs. with GLP-2 therapy 0,197%; Δ Lac recovery 12%). Sac recovery showed no changes (0.138% vs 0.135%)

An inverse correlation were found for Man recovery and parenteral nutrition requirements [kcal per week] ($r^2= 0.273$, p=0.01). No relation was found for Lac recovery ($r^2=0.09$, p=0.16) or Sac recovery ($r^2=0.003$, p=0.81).

Conclusion: Intestinal permeability testing based on sugar recovery in urine samples is applicable in SBS patients, but results have to be interpreted with caution as the mere use of the widely accepted marker "Lac/ Man ratio" leads to misleading results. In SBS patients, mannitol recovery correlates with remaining small bowel length and caloric i.v. needs and recovery rate in patients with GLP-2 treatment is higher compared to therapy naïve patients.

Therefore, we suggest that mannitol may serve as biomarker in order to gain additional information about absorptive processes or changes during GLP-2 therapy.

Contact E-Mail Address: brune.de-dreuille@inserm.fr

Introduction: Teduglutide (TED), a GLP-2 agonist, is effective to reduce Parenteral Nutrition (PN) dependence in patients with Short Bowel Syndrome (SBS), with some heterogeneity of response between patients. PN reduction at 6 months of TED treatment is significantly associated with patients' oral intake at baseline (1).

Aims & Methods: We aimed to study the impact of food intake on TED efficacy in the longer term and the evolution of food intake during treatment. This work was a monocentric retrospective study conducted in an expert center of PN. We enrolled 49 SBS patients treated with TED for at least one year. Information regarding oral food intake and PN prescription at the time of initiation and during treatment were collected in medical charts. Food intake is expressed using a ratio: FIR = Daily caloric intake (kcal) / Resting Energy Expenditure (REE) (kcal). REE is calculated using Harris and Benedict formula.

Results: Baseline food intake at treatment initiation was collected for 49 patients, and at least two values of food intake during treatment were available for 44 of these patients. The mean follow-up duration of the patients is 27 months (± 2.8).

There is a positive correlation between food intake at treatment initiation and reduction of PN volume during treatment ($r=0.38$, p=0.007). Moreover, patients who reached PN weaning with TED (n=19) had a much higher food intake before TED than those who remained dependent to PN (n=30), p<0.001 (FIR=2.3 vs 1.6). These 19 weaned patients were all hyperphagic (FIR>1.5) before TED initiation.

In addition, patients who had the lowest food intake before TED initiation (non-hyperphagic, FIR<1.5, n=13) significantly increased their oral intake during treatment (p=0.001, FIR=1.0 vs 1.6).

Those who presented hyperphagia before TED maintained their oral intake.

Conclusion: This study confirms the positive impact of basal oral dietary intake on the efficacy of TED in the long term, which supports the idea of promoting food intake in SBS patients before TED initiation. Furthermore, treatment with TED seems to have a beneficial effect on patients' food intake when it was low before TED initiation, which could be linked with the better physical and/or psychological condition of the patients.

Introduction: Proton Pump Inhibitors (PPI) are clinically used to treat gastroesophageal reflux disease and peptic ulcers. 4-8 weeks usage of PPI can be defined as PPI-long term use. Patients with PPI-long term use show hypochlorhydria and small intestine bacterial overgrowth (SIBO), reporting bloating as the main symptom.

Aims & Methods: The aim was to characterize the gut microbiota of patients under long-term PPI treatment and to assess if there was a signature of SIBO. The gut microbiota of 152 patients referred to Gastroenterology outpatient clinic was stratified based on PPI treatment [n=43 PPI-on, n=109 PPI-off]. A sub-analysis was performed considering only patients without probiotics-intake at the time or 3 months before stool sample [n=31 PPI-on, n=82 PPI-off]. Phyla and taxa were analyzed using 16S ribosomal RNA (rRNA) sequencing.

Comparisons between two groups were made using the normal approximation for the Wilcoxon two-sample test and statistical significance was defined as a p -value < 0.05 .

Results: Compared to PPI-off patients, PPI users demonstrated a lower richness ($p < 0.05$, 95% CI) and significant increased abundances for some taxa either frequently observed in oral microbiota or belonging to Proteobacteria like *Lactobacillus* ($p < 0.005$), *Lactococcus* ($p < 0.05$), *Streptococcus* ($p < 0.005$), *U. m. of Coriobacteriaceae* ($p < 0.005$) *Hafnia* ($p < 0.05$) and *Butyrivimonas* ($p < 0.005$). Other taxa demonstrated significant lower values (Table 1). Out of 43 patients treated with PPI, 29 reported bloating as the main symptom. Moving to the analysis on probiotic-free patients, a statistically significant increase of the same taxa was confirmed.

<i>Turicibacter</i>	0,0006922 +/- 0,0023865	0,0003446 +/- 0,0009684	0,0471

Table 1. Specific mean score for each taxa analyzed with Wilcoxon/Kruskal-Wallis two-sample test decreased in PPI on patients.

[SD: standard deviation.]

Conclusion: Long-term PPI treatment has an important impact on patients' gut microbiota and might worsen bloating symptoms. As already reported, PPI users show an increase in oral bacteria especially Lactobacillales. Due to the possible link existing between bloating, dysbiosis, and PPI use, intercepting subjects with this signature can lead to a PPI reduction, if possible, and/or the administration of antibiotics to reduce SIBO related symptoms.

Disclosure: Nothing to disclose.

SMALL INTESTINAL BACTERIAL OVERGROWTH (SIBO) IS ASSOCIATED WITH LIVER FIBROSIS AND INFLAMMATION

J. Keller¹, A. Bornhorst¹, S. Rose¹, V. Andresen¹, P. Layer¹

¹Israelitisches Krankenhaus Hamburg, Department of Medicine, Hamburg, Germany

Contact E-Mail Address: j.keller@ik-h.de

Introduction: In patients with non-alcoholic steatohepatitis (NASH), bacterial translocation from the gut lumen contributes to progression of liver steatosis, inflammation and fibrosis (Schnabl&Brenner 2014, Ghoshal et al. 2020). Studies indicate that bacterial translocation may occur predominantly in the small bowel, so that small intestinal bacterial overgrowth (SIBO) may be of particular pathophysiological relevance (Bruns et al. 2016).

Indeed, patients with NASH and patients with significant fibrosis were shown to have a significantly increased incidence of SIBO (Mikolasevic et al. 2021). It is unclear, however, whether patients with SIBO are generally at an increased risk of developing liver injury.

Aims & Methods: We aimed to investigate whether SIBO is associated with increased liver fibrosis or other signs of liver injury. Therefore, patients with unclear gastrointestinal symptoms compatible with SIBO (abdominal pain, bloating, diarrhea) underwent a standardized glucose-H₂-breath test (Keller et al. 2005, Hammer et al. 2021) as part of their diagnostic work-up. An increase in H₂-exhalation by ≥ 20 ppm was regarded as diagnostic of

SIBO (SIBO++), an increase between 10 and 19 ppm as suggestive (SIBO+). Patients with < 10 ppm increase in H₂-exhalation served as controls (SIBO-). Patients additionally underwent shear wave elastography for quantification of liver fibrosis (SWE), investigation of liver fat content (attenuation imaging, ATI) and of a parameter of liver inflammation (shearwave dispersion, DISP) using the Liver Analysis Tool (LAT, Canon). Demographic data and clinical data on preexisting liver injury and predisposing diseases (e.g. diabetes mellitus, hyperlipoproteinemia) were collected.

Results: 131 patients (95 females) were included. Their mean age was 43.5 $\pm$ 16.5 years, median BMI was 21.3[19.5-25.0]kg/m². 51 subjects were SIBO positive (SIBO++), 31 probably had SIBO (SIBO+, increase in H₂ ≥ 10 ppm), 49 were SIBO negative (SIBO-). Sex distribution, BMI and proportion of patients with preexisting liver injury or predisposing diseases were similar in all groups, however, SIBO++ were about 10 years older than SIBO+ and SIBO- patients ($p = 0.003$).

Data obtained by LAT showed significant differences between groups for SWE ($p = 0.043$). SIBO++ had significantly higher values than SIBO-; for SIBO+ we observed a trend towards higher values in comparison with SIBO- (tab.). For DISP and ATI, respectively, there was a trend towards higher values compared with SIBO-, if SIBO++ and SIBO+ were combined ($p < 0.067$).

According to multiple linear regression analysis, SIBO is a significant predictor of SWE ($R = 0.35$, $p < 0.001$) and DISP ($R = 0.31$, $p = 0.004$), independent of age, sex, BMI and preexisting liver injury or predisposing diseases.

	SWE, kPa	DISP, (m/s)/kHz	ATI, dB/cm/MHz
SIBO- (N=49)	4.2 [3.7-5.1]	11.8 [10.3-12.5]	0.54 [0.50-0.6]
SIBO+ (N=31)	4.9 [4.3-5.6] [§]	12.4 [11.0-13.4]	0.56 [0.53-0.59]
SIBO++ (N=51)	4.8 [4.1-5.8] [*]	11.9 [10.6-13.8]	0.57 [0.53-0.62]

^{*} $p = 0.015$ vs SIBO-, [§] $p = 0.092$ vs SIBO-

Table.

Conclusion: Patients with SIBO had increased liver fibrosis compared with controls, independent of known risk factors for liver fibrosis. This could be due to inflammatory processes induced by increased hepatic delivery of toxic bacterial metabolites and/or components, the more so as SIBO was also associated with increased shear wave dispersion, which is assumed to be a marker of liver inflammation. However, the exact clinical role of this parameter still remains to be elucidated.

Disclosure: This study was supported by a grant from Canon Medical Systems GmbH.

Introduction:

Small intestine bacterial overgrowth (SIBO) symptoms frequently overlap with the digestive symptoms seen in functional digestive disorders, especially irritable bowel syndrome. The most widely diagnostic method used to diagnose SIBO is breath test (BT) with hydrogen (H₂) and methane (CH₄) exhaled evaluation.

Aims & Methods:

Aims: To describe the clinical characteristics of patients referred for evaluation of suspected SIBO and to determine if there are clinical differences between SIBO positive vs SIBO negative and the different subtypes of SIBO (SIBO-H2 and SIBO-CH4).

Methods: Consecutive patients referred for glucose BT for suspected SIBO from september 2021 to february 2022 were invited to participate; all the participants completed validated questionnaires for digestive symptoms and the IBS severity score. Demographic and clinical data was obtained from the electronic records.

Results:

	SIBO-H2 n=9	SIBO-CH4 n= 12	p Value
Age in years (range)	60.92 ± 14.65 (50)	49.93 ± 15.85 (55)	
Sex - n (%)			
Male	4 (44.4)	3 (25.0)	0.31
Female	5 (55.6)	9 (75.0)	0.37
Current smoking - n (%)	8 (88.9)	10 (83.3)	0.61
Abdominal surgery history - n (%)	6 (66.7)	2 (11.8)	0.006
Systemic disease associated with SIBO - n (%)			
Systemic sclerosis	0 (0)	4 (23.5)	0.003
Diabetes mellitus	2 (22.2)	1 (8.3)	
Multiple sclerosis	0 (0)	0 (0)	
Postprandial symptoms - n (%)	3 (33.3)	10 (83.3)	0.03
Usual stool pattern (Bristol Stool Chart) - n (%)			
Type 1	2 (22.2)	6 (50.0)	0.20
Type 2	1 (11.1)	3 (25.0)	0.41
Type 3	0 (0)	6 (50.0)	0.02
Type 4	3 (33.3)	3 (25.0)	0.52
Type 5	2 (22.2)	5 (41.7)	0.32
Type 6	6 (66.7)	3 (25.0)	0.07
Type 7	5 (55.6)	1 (8.3)	0.03

Table. Demographic and Clinical Characteristics of patients with a breath test compatible with SIBO (n=21)

123 patients participated in the study (78.9% were female, 52.5± 16.1 years). A total of 26 (21.1%) patients had a BT compatible with SIBO (SIBO-H2 11.4%, SIBO-CH4 13.8% and SIBO-Mixed 4.1%). There were no clinical differences between patients with a positive test and patients with a negative test.

Comparing the clinical characteristics between the different subtypes of SIBO (table 1), patients with SIBO-CH4 had a higher prevalence of systemic sclerosis (23.5% vs 0% p=0.003) and presented more postprandial symptoms (83.3% vs 33.3% p =0.03). SIBO-H2 patients had a higher prevalence of past gastrointestinal surgery (66.7% vs 11.8% p= 0.006) and more frequent loose stools pattern (Bristol 6 - 7) (66.7% vs 25.0% p=0.07).

Conclusion: In our study, symptoms of patients with SIBO diagnosed by a positive BT and patients with a negative test are non specific. Comparing SIBO subtypes, The SIBO-CH4 subtype is associated with postprandial symptoms and SIBO-H2 is associated with loose stools.

Introduction: Gluten-free diet is the only therapy that provides clinical and histological remission of celiac disease. The detection of gluten immunogenic peptides (GIP) in fecal samples, only present if gluten ingestion, may constitute a useful tool to evaluate dietary adherence.

Aims & Methods: Observational, retrospective, longitudinal, between-groups design study. We collected clinical data from patients who had GIP measurement during follow-up from January 2017 to June 2021.

A descriptive and comparative analysis was performed using SPSS software.

The primary objective was to evaluate the clinical effectiveness of GIP measurement during follow-up of celiac patients. The secondary objective was to analyze the relation between GIP levels and demographic data (gender, age), laboratory results and histopathology.

Results: 103 patients were included, from whom 182 fecal samples were obtained. The characteristics are summarized in Table 1. 29 patients had positive levels of GIP; 12 of them normalized during follow-up (41.38%).

Age (years)	18.32 (SD=17.55)
Children / adults	58 (57%) / 43 (43%)
Gender (Female/male)	73 (71%) / 30 (29%)
Disease duration (months)	65.14 (SD=59.86)
GIP-positive	29 (28%)
Anti- tissue transglutaminase IgA (UI IgA/ml)	9.37 (SD=24.45)
Anti-gliadin IgA (mg/l)	11.87 (SD=33.44)
Anti-gliadin IgG (mg/l)	7.91 (SD=22.16)
Hemoglobin (g/dl)	14.08 (SD=1.23)
Mean corpuscular level (fL)	85.01 (SD=8.65)
Ferritin (ng/ml)	51.79 (SD=42.34)

Table 1. Characteristics of patients included (N=103). Quantitative variables are expressed as means and standard deviation (SD); qualitative variables are presented as total number of events and percentage.

No differences were found between hemoglobin, ferritin, mean corpuscular volume or antibodies levels and the result (positive/negative) of GIP in the total of samples nor analyzing samples of adults and children separately. Only anti-gliadin IgG antibodies were higher in GIP-positive patients (p=0.028). No differences were found between the result (positive/negative) of GIP and histology at diagnosis, gender or age (adults/children). It is important to mention that 77 patients had negative anti-tissue transglutaminase levels and 21 of them (27.27%) had GIP in feces. We didn't find differences in the result of GIP depending on age or disease duration. However, when pediatric patients were selected, positivity for GIPs increased with age (p=0.032).

Conclusion: - GIP are a useful tool in the follow-up of celiac patients to monitor dietary compliance, and may detect dietary transgression in subjects with negative antibodies.

- Antibody levels, age and disease duration are not associated with positivity rates of GIP.

- Only adolescents in the children group had more dietary transgressions according to detection of GIP.

Disclosure: Nothing to disclose.

Introduction: The use of flow cytometry to analyze the epithelial lymphogram has proven efficacy in assessing celiac disease (CeD) in patients with discordant results between serology, genetics and histology. In addition, it is the only method able to accurately diagnose CeD with non-atrophic enteropathy and when gluten has been excluded from the diet (1). Duodenal mucosa of CeD patients is characterized by increased densities of lymphocytes (CD45+) and TCRγδ+ sub-population, while CD3+CD103- are decreased. The institution of a gluten free diet (GFD) induces the reversion of these changes but the increase in TCRγδ+ lymphocytes, which remains elevated in 80-85% of CeD patients (2,3). In the last years, non-celiac gluten/wheat sensitivity (NCGS) has emerged as an entity with higher prevalence than CeD (6% vs 1%) (4).

It appears in patients in whom CeD and wheat allergy have been excluded, but their symptoms improve after GFD. The lack of additional methods to evaluate CeD in the past led many patients without villous atrophy and/or a positive serology to be diagnosed of CeD when they presented a genetic predisposition and a favorable response to GFD.

This study aims to evaluate the impact of using flow cytometry on duodenal mucosa samples of patients with an inconclusive previous diagnosis of CeD.

Aims & Methods: This study aims to evaluate the impact of using flow cytometry on duodenal mucosa samples of patients with an inconclusive previous diagnosis of CeD. Endoscopic biopsies obtained from two duodenal locations (second portion and bulb) were processed and marked with four antibodies (CD3, CD45, CD103 and TCRγδ), and analyzed using a Cytek Northern Lights (two lasers) flow cytometer.

The following cut-off values were used for TCRγδ+ lymphocytes (2): CeD confirmed with TCRγδ+≥8.5% in both locations; suggestive of NCGS with TCRγδ+<5% in both locations; and no conclusive, TCRγδ+>5% in one location. Demographic and clinical characteristic were compared between CeD-confirmed and NCGS-suspicious patient groups. Statistical significance was established for p-values<0.05.

Results: Biopsies from 25 patients (92% women) were analyzed. Mean age was 45±15 years and median GFD length was 8.3 years (range 2.1-11.9 years). Histology when CeD diagnosis was established was: Marsh 0 (n=1), Marsh 1 (n=19), Marsh 2 (n=4) and Marsh 3 (n=1). After flow cytometry evaluation and according to TCRγδ+ results, 6 patients had their

CeD confirmed (24%, all with Marsh 1 at diagnosis), 17 were classified as NCGS-suspicious (68%) and 2 showed no conclusive results (8%, including the patient with a Marsh 3 grade). Regarding increasing densities in CD45+ lymphocytes, 3 CeD-confirmed (50%) and 7 NCGS-suspicious (41%) patients showed lymphocytosis in at least one duodenal location.

For CeD serology, no patients had values above the upper normal limit currently. No statistical differences were observed between groups for time length under a GFD, anti-tissue transglutaminase IgA values in the latter serum analysis and CeD familiar background.

Finally, genetic HLA variants for high or moderate risk of CeD (DQ2.5, DQ2.2 and DQ8) were present in most CeD-confirmed and NCGS-suspicious patient groups. However, the low-risk DQ7.5 genotype was found in 2 CeD-confirmed patients (33%) but only in 1 patient of the NCGS group (6%).

Conclusion: The performance of epithelial lymphogram by flow cytometry in patients with GFD but diagnosed of CeD without villous atrophy and/or positive serology showed that 68% of them had no increase in TCRγδ+ lymphocytes. Therefore, they could present a NCGS instead of CeD and could eat small quantities of gluten according to their tolerance profile.

COMPARISON OF OUTCOMES BETWEEN DIRECT OR STRUCTURED PEDIATRIC-TO-ADULT HEALTHCARE TRANSITION IN COELIAC DISEASE

C. Ciacchi¹, S. De Vivo¹, E. Di Feo¹, F. Zingone²

¹University of Salerno, Medicine Surgery Dentistry, Scuola Medica Salernitana, Salerno, Italy, ²University of Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy

Contact E-Mail Address: fabiana.zingone@unipd.it

Introduction: In celiac disease (CeD), the transition from paediatric to adult care should be a collaborative process involving patients, relatives, and physicians, to have the adolescent gradually take full responsibility for the disease.

Aims & Methods: Our study aims to compare the structured transfer of care outcomes with a direct transfer from the pediatrician to adult care, in particular awareness and knowledge of CeD, adherence to the gluten-free diet, autonomy, and quality of life. In 2017, we guided the transition of a group of teenagers/young adults (YA) through a structured process with parents and the pediatrician.

In January 2021, we interviewed a subgroup of them again and compared them with a similar group of CeD patients diagnosed at pediatric age who did not receive any transition of care.

We evaluated the progress in knowledge of the disease, gluten-free diet (GFD) compliance, relationship with healthcare givers, autonomy in managing the disease's needs and quality of life, using standardized questionnaires in patients who underwent a transition and between this latter and those who did not perform a transition.

Results: Of 58 YA included in 2017, 38 were eligible for follow-up in 2021. Of them, we obtained complete answers in 20 (14 females, mean age 20.05±2.6 years). The remaining patients were not available or did not accept to participate. Twenty-five patients who did not receive any transition was also included (18 females, mean age 20.7±5.2 years).

Those who underwent a transition, at follow-up in 2021 showed improvement only in the knowledge of the disease compared to findings in 2017. Patients who underwent a structured transition were more informed than those without transition. At the same time, as per adherence to the GFD, autonomy, and quality of life measured by the CDDUX questionnaire, the groups did not show any significant score difference.

Conclusion: To our knowledge, the present study is the first to measure the outcomes of the structured vs. non-structured transition of care, showing that a structured transition improves the knowledge of the CeD but does not improve adherence, autonomy, or QoL of the young adults.

Disclosure: Nothing to disclose.

Introduction: In the last decades the public debate around vaccinations has achieved increasing attention.

Vaccines hesitancy (defined as a delay in acceptance or refusal of vaccination despite availability) and skepticism towards vaccinations in the general population have been investigated.^{1,2}

COVID-19 pandemic and the resulting new global vaccination campaign has contributed in exhuming again this issue.

Patients with chronic diseases, such as those affected by Coeliac Disease (CD), should be generally encouraged to receive common vaccines against preventable diseases (VPDs) particularly for that pathogens which could be specifically harmful for their condition.

In particular, previous studies have demonstrated an association between CD and hyposplenism or splenic hypofunction,³ with a possible increase in some infections (encapsulated bacteria);⁴ hence UEG guidelines suggest to vaccine hyposplenic CD patients against pneumococcus, and to consider additional vaccination against *Haemophilus*, meningococcus and influenza.⁵

However, patients with CD may be more fearful about vaccinations compared to general population, possibly because of their immune-mediated disorder.⁶

For this reason the identification of CD patients' vaccination status and attitudes toward vaccines is of great importance.

Aims & Methods: The aims of this study were to investigate coverage against VPDs, attitude towards vaccinations and its positive and negative determinants among CD patients.

An anonymous web-based adapted version of a validated questionnaire⁷ was sent to the mailing list of *Ioelglutine*, a nonprofit organization of CD adult patients followed at our tertiary referral Center in Milan, Italy.

Patients were asked to self-report their previous vaccinations; attitude towards vaccinations was defined as positive, negative, partially positive/negative. We investigated the influencing factors towards vaccinations calculating crude and adjusted odds ratios (AdjORs) with 95% confidence intervals (CIs).

Results: The questionnaire was sent to 412 patients with a response rate of 31.6% (130 patients, 25 men, median age 40, interquartile range 36–51). Patients self-reported to be vaccinated against the following diseases: 96 tetanus, 55 flu, 26 MMR, 25 meningitis, 21 pneumococcus. Thirty-two did not remember every previous vaccination.

One hundred and four (80%) had a positive attitude towards vaccines, 25 (19.2%) a partially positive/negative, one (0.8%) negative.

The determinants positively influencing attitude towards vaccinations were graduation (AdjOR 7.49, 95% CI 1.74–32.1) and the belief of possible return of VPDs with decline of vaccination coverage rates (AdjOR 7.42, 95% CI 1.32–41.6), while use of complementary and alternative medicines and past negative experience were negative associated (AdjOR 0.11, 95% CI 0.01–0.71, AdjOR 0.16, 95% CI 0.04–0.62, respectively).

Conclusion: Albeit 4 every 5 CD patients showed a strong positive attitude towards vaccinations, yet 1 every 5 had a partially negative position. Moreover, only a minority (~20%) reported to be vaccinated against some VPDs potentially harmful for their chronic illness.

Since CD patients should be encouraged to receive all common vaccines, the identification of the determinants influencing patients' attitude toward vaccinations may be helpful to optimize patient–doctor communication and to develop specific vaccination campaigns by patients' associations.

Introduction: Liver involvement in celiac disease (CeD) is known but its various etiologies and the effect of gluten free diet (GFD) on it is understudied.

Aims & Methods: We planned to study the spectrum of liver involvement in patients of CeD and the response of GFD on elevated transaminase levels. We searched PubMed & Embase databases from date of inception to 3rd September, 2020 to look for studies reporting on CeD and liver abnormalities. We searched for additional studies till March 7, 2022. Pooled proportion of patients of CeD with deranged transaminases, etiologies of various other liver diseases with CeD and the response to GFD in form of normalization of transaminases were estimated. Subgroup analysis based on the age group, geographic distribution and duration of GFD was also done.

Results: Total 42 studies (8976 patients) reported hypertransaminasemia in patients with celiac disease. The pooled proportion of patients elevated transaminases was 21.42% (95% CI: 17.02-26.59, I²=94%) overall with similar prevalence noted among adults (21.20%) and children (21.51%). The commonest etiology for the liver abnormalities was reported as celiac hepatitis at 49.23% (95% CI: 30.09-68.59, I²=87%) followed by other liver diseases. Compliance with GFD was noted in 87.83% of adults and 94.57% of children (overall 90.27%).

The proportion of CeD patients with liver abnormalities who showed response to GFD was 87.55% (95% CI: 82.80-91.13, I²=66%) overall with similar response among adults (86.03%) and pediatric population (90.48%). Western studies reported a similar response to GFD at 88.05% compared to the east (85.18%). (Table 1)

Patients of celiac disease with following parameter	Pooled proportion
Elevated transaminases	Overall: 21.42% (95%CI, 17.02-26.59%, I ² =94%), Adults: 21.2% (95%CI, 15.14-28.85%, I ² =93%), Children: 21.51% (95%CI, 15.49-29.06%, I ² =95%)
Compliance to gluten free diet (GFD) with elevated transaminases	Overall: 90.27% (95%CI, 85.91-93.38%, I ² =75%), Adults: 87.83% (95%CI, 82.01-91.94%, I ² =79%), Children: 94.57% (95%CI, 89.07-97.39%, I ² =12%)
Response to GFD with elevated transaminases	Overall: 87.55% (95%CI, 82.8-91.13%, I ² =66%), Adults: 86.03% (95%CI, 80.58-90.14%, I ² =68%), Children: 90.48%(95%CI, 80.44-95.65%, I ² =63%)
Response to GFD with elevated transaminases	West: 88.05% (95%CI, 83.05-91.72%, I ² =71%) East: 85.18% (95%CI, 66.41-94.35%, I ² =42%)
(based on hemisphere)	
Response to GFD with elevated transaminases (based on duration of GFD)	Less than 6 months: 87.57% (95%CI, 73.59-94.69%, I ² =69%), More than 12 months: 82.46% (95%CI, 72.12-89.52%, I ² =93%)

Table 1.

Conclusion: Liver involvement was noted in 21.42 % of CeD patients. Celiac hepatitis was reported in less than half of them. Good compliance and response were noted with GFD.

THE HEPATOBILIARY DISORDERS IN COELIAC DISEASE

R. Limam¹, S. Ben Azouz², N. Ben Douissa², H. Hassine², H. Kchir², N. Maamouri³

¹Rabta B, Tunis, Tunisia, ²Rabta B, Gastroenterology, Tunis, Tunisia, ³La Rabta Hospital, Tunis, Tunisia

Contact E-Mail Address: limamrihab33@gmail.com

Introduction: Different hepatic and biliary tract disorders may occur in coeliac disease. Some have been hypothesized to share genetic or immunopathogenetic factors, such as primary biliary cirrhosis, primary sclerosing cholangitis, and autoimmune hepatitis. Other hepatic changes in celiac disease may occur with malnutrition resulting from impaired nutrient absorption, including hepatic steatosis.

The aim of this study is to assess the prevalence, the different forms as well as the evolution of hepatobiliary manifestations in patients with coeliac disease (CD).

Aims & Methods: We conducted a retrospective descriptive study from 1999 till 2021, including all patients with CD followed in a gastroenterology department. Epidemiological and clinico-biological data were collected as well as the evolution on gluten-free diet (GFD).

Results: During the period of the study, 110 cases of CD were included. The average age was 34,5 years [15 - 69 years]. The sex ratio (F/H) was 4.7. Hepatobiliary disorders were noted in 18 cases (16%): 17 women and one man with a mean age of 42.7 years. Liver disease was revealed during the course of CD in 72% of cases, at the diagnostic of CD in 22% of cases and before the diagnosis of CD in 6% of cases.

The different liver disorders associated with CD were: autoimmune hepatitis (AIH) (n=2), primary biliary cholangitis (PBC) (n=1), overlap syndrome (AIH - PBC) (n=2), portal cavernoma due to combined deficiency of protein C and antithrombin III (n=1), nodular regenerative hyperplasia (n=1), hepatic steatosis (n=4) and cryptogenic liver disease (n=7), one of which was at the stage of cirrhosis.

All patients were put on GFD in addition to the specific treatment of the associated liver disease. Liver function tests got back to normal in all cases within an average of 6 months from the start of the treatment.

Conclusion: In our study, 38% of cases of idiopathic liver dysfunction were caused by CD and liver function tests got back to normal after GFD. Consequently, newly onset celiac disease should be rigorously checked for asymptomatic hepatic damage and conversely, any cryptogenic liver disorder, including end-stage liver disease, should be investigated for celiac disease.

Disclosure: Nothing to disclose.

Introduction: Celiac disease (CD) is a chronic autoimmune enteropathy triggered by gluten, occurs in susceptible individuals and is associated with dietary restriction and subsequent nutritional deficiencies.

Aims & Methods: This study investigates the diet quality, the nutrition imbalances and the nutrition status among young children, adolescents and adults with CD who had referred to many hospitals in Lebanon. A cross-sectional study in 50 individuals (31.74 ± 15.64 years) with CD was conducted, using dietary, anthropometric, biochemical parameters, and assessing physical activity.

Results: Out of 50 participants, 38% and 16% were presenting low serum levels of iron and vitamin B12, respectively. The majority of participants were physically inactive and around 40% of them had low muscle mass. A weight loss of 10% to 30% indicating mild to moderate malnutrition were shown in 14% of individuals. The assessment of food related behaviors shows that 80% of participants were reading nutrition labels and 96% of them were following gluten free diet (GFD). Some barriers of which: family ignorance (6%), language on the nutrition labels (20%) and expensive GF products (78%) were limiting the adherence to GFD. Adequacy of the daily energy intake was low and insufficient intakes of calcium and vitamin D were remarked among individuals with CD.

However, protein and iron intake were exceeding the recommendations among all age groups, except in males aged 4-8 years and 19-30 years. Half the study participants were using dietary supplements where 38%, 10%, 46%, 18%, 16% and 4% used vitamin D, vitamin B12, Iron, calcium, folate and probiotics, respectively.

Conclusion: The GFD is the cornerstone of treatment for CD. However, it is not without inadequacies and may result in certain deficiencies such as calcium and vitamin D leading to low bone density as long-term consequence. Dietitians specializing in CD play a critical role in the education and maintenance of the GFD for patients with CD.

Introduction: Coeliac disease (CD) is an immune-mediated systemic disorder elicited by the ingestion of gluten in genetically predisposed individuals. Gluten restriction in CD sufferers leads to numerous limitations in various aspects of daily life and can significantly impact quality of life (QoL). The specific and widely used Coeliac Disease Questionnaire (CDQ) is an excellent tool to evaluate QoL in patients with CD, assessing physical, psychological and social domains.

This questionnaire is unavailable in Spain. Therefore, our study is the first to translate, culturally adapt, validate, and apply the Spanish version of CDQ to a representative sample of Spanish teenagers and adults with CD.

Aims & Methods: A total of 153 CD participants with biopsy-proven and self-reported gluten-free adherence were included in the cross-sectional study, which included four stages:

1. translation and retranslation of the French CDQ version into Spanish;
2. cultural adaptation and semantic evaluation;
3. CDQ validation through the internal consistency determination and reproducibility of the QoL; and,
4. application of the questionnaire to Spanish teenagers and adults with CD and estimation of QoL using EQ-5D.

Results: The internal consistency and test-retest reliability of the Spanish CDQ were satisfactory and no ceiling or floor effects were detected. Significant correlations were identified between the CDQ scales and the instrument for validation covering similar dimensions of the QoL were identified. The mean CDQ total score was 131.03±24.1, and the social domain had the highest rating.

There was no correlation between the time spent on a gluten-free diet and QoL. A significantly higher QoL score was reported among males and adolescents in the 15-17 age groups.

Conclusion: The newly Spanish CDQ is an appropriate tool to assess the QoL of teenager and adult patients with CD. This study highlights the importance of identifying the affected scales to address actions to reduce the impact of the gluten-free diet burden of coeliac patients and maintain public health regulations that support patients with chronic diseases such as CD.

Introduction: Celiac disease (CD) is associated with an increased risk of small bowel adenocarcinoma (SBA). However, little is known about their clinical features, characteristics and outcome due to the rare cases of SBA.

Aims & Methods: We reviewed all SBA diagnoses in CD patients in our tertiary CD referral center from 2000 to 2022. Data on demographics, clinical features, treatments and outcome were recorded.

Results: Among 1024 CD patients, 8 (0.78%) had SBA. Median age was 64.5 (IQR:57.7-68.5). SBA diagnosis was simultaneous to CD diagnosis in 2 patients and preceded the CD diagnosis in 1. For the 5 other patients, median time between diagnoses was 65 months (IQR:41-101). One patient had a type II refractory CD, and 2 patients had persistent villous atrophy. Localizations of SBA were jejunal (n=6) and duodenal (n=2). Iron deficiency anemia (IDA) (n=4), sub-occlusion (n=1) and ileus (n=2) lead to SBA diagnosis.

All patients had surgical treatment and 3 had an adjuvant chemotherapy for a positive lymph node (N1), a metastatic stage (M1) and a T4N0M0 stage. Molecular biology data are available in 5 patients, showing microsatellite instability (n=3) and KRAS mutation (n=1).

During a median follow-up of 34 months (IQR:15-89.2), only the patient with the metastatic stage died 2 years after the SBA diagnosis and no recurrence occurred in others.

Conclusion: We report one of the largest series of SBA in CD patients and the first SBA in a refractory CD. Frequent microsatellite instability could bring some elements to its pathogenesis.

Introduction: Refractory celiac disease type II (RCD II) is a rare complication of celiac disease (CD) with an increased risk of enteropathy-associated T cell lymphoma (EATL).

Aims & Methods: The aim of this study is to investigate the role of capsule endoscopy (CE) and enteroscopy in the diagnosis of EATL in RCD II patients compared to cross-sectional imaging.

A retrospective review of all RCD II patients was made between 2000 and 2021 including clinical, endoscopic, and imaging data.

Results: 75 patients with RCD II were identified among 1024 celiac patients. 20 CE and 35 upper enteroscopy procedures were performed in these patients. 15 patients (75%) had ulcerative jejunitis (UJ) on CE. The most common location was the proximal jejunum (60%) followed by the distal jejunum (20%) and ileum (20%). Ulcerated stenoses were observed in 13% of patients without capsule retention, and one patient had deep ulcerations.

68% of patients (n=24) had UJ on enteroscopy, five of whom had stenosis. Biopsies performed during enteroscopy confirmed an EATL diagnosis in 31.4% (n=11/35) of patients. Among 14 magnetic resonance enterography (MRE) performed, only 3 pathological aspects were identified (one stenosis, one jejunal thickening, and one mesenteric lymphadenopathy). Only 3 patients showed similarities between the imaging and the endoscopic aspect.

Conclusion: CE and enteroscopy are useful tools to diagnose EATL in RCD II patients and are more relevant than MRE.

Disclosure: Nothing to disclose.

Contact E-Mail Address: matilde.topa@unimi.it

Introduction: Celiac disease (CeD) is a risk factor for osteopenia and osteoporosis, although the pathogenesis of bone impairment associated with CeD is still unknown. The main etiologies are malabsorption and chronic inflammation; however, the role of intestinal atrophy and its extension is unclear.

Aims & Methods: Our aim was to evaluate the correlation between villous atrophy extension and dual-energy X-ray absorptiometry (DXA) parameters.

We have retrospectively gathered data on 47 celiac patients (36 women and 11 men), aged between 31 and 86 years, treated at Fondazione IRCCS Ca' Granda Ospedale Maggiore in Milan, who underwent videocapsule endoscopy (VCE) and DXA scans from 2004 to 2019. Quantitative and qualitative DXA parameters were derived only from the most recent DXA measurements (since 2015). Different bone parameters were collected, namely quantitative (BMD, T-score and Z-score), qualitative (TBS and BSI) and geometric (BR, CSA, CSMI, Z, HAL and NSA) findings.

Results: Patients were divided into three categories depending on the type of small bowel finding and any extension detected during VCE examination. The first group included those with no lesions (23 patients), the second those with typical lesions (mucosal atrophy, mosaicism and scalloping) in less than one-third of the small bowel (16 patients) and, the third those with typical lesions in more than one-third of the small bowel (7 patients).

One patient was excluded because of missing data. In those patients in whom typical lesions were found in two-thirds or more of the small bowel, bone mineral density seems to be lower in both the lumbar spine and the hip ($p=0.026$ and $p=0.011$, respectively). The deterioration of bone structure in individuals with severe and extended small bowel disease due to CeD seems to be statistically significant ($p=0.032$).

Interestingly, we found that bone density, structure and geometry do not correlate with the duration of a gluten-free diet. Furthermore, autoimmune comorbidities do not affect DXA results.

Conclusion: The main result is that neither endoscopic nor histological atrophy itself can explain the deterioration in bone mineralization and structure, while atrophy extension is mostly responsible for bone impairment. In fact, as villous atrophy becomes more severe and widespread, lumbar and femoral bone density deteriorates. In severe CeD, microarchitectural and textural injury (TBS) increases.

Disclosure: Nothing to disclose.

P0174

COELIAC DIAGNOSIS IN OLDER ADULTS: DOES AGE REALLY MATTER?

O. Fagan¹, G. Madders¹, E. Shannon¹, C. Deane¹, V. Byrnes¹

¹University Hospital Galway, Gastroenterology, Galway, Ireland

Contact E-Mail Address: olgafagan@gmail.com

Introduction: Coeliac disease is being increasingly diagnosed in later life.

Aims & Methods: To assess if the presentation and outcomes of coeliac disease (CD) diagnosed after the age of 65-years differs from that of younger adults.

Chart review of all patients with newly diagnosed CD between January-2012 and December-2021. Variables such as demographics, mode of presentation, TTG-titre and mucosal healing in patients aged > 65 and ≤ 65-years at diagnosis were recorded.

Results: 305 newly diagnosed coeliacs were included, comprising 59 patients >65-years (median age 71 [65-89 years], F:M ratio 2:1), and 247 patients <65-years (median age 36 [16-64 years], F:M ratio 2:1). Abdominal pain/bloating (33% vs 27%, $p=0.22$) and diarrhoea (27% vs 29%, $p=0.4$) were the commonest mode of presentations seen in both older and younger patients.

Weight loss at presentation was numerically more prevalent in the older cohort compared to that of the younger cohort (20% v 12%, $p=0.05$). Anaemia was more prevalent at the time of diagnosis in older patients (36% vs 14%, $p<0.05$). Vitamin-D deficiency at presentation were comparable in older and younger cohort (43% vs 50%, $p=0.25$).

Older patients had lower TTG-titres at diagnosis [33 (range 5-160) v 49 (range 5-840) $p=0.58$] and a higher prevalence of seronegative disease, (12% v 4%, $p<0.05$). The existence of thyroid disease (7% vs 10%, $p=0.3$) and other autoimmune diseases (19% vs 25%, $p=0.16$) were comparable in both groups.

While mucosal recovery was similar in the two groups, (48% v 49%, $p=0.53$), anaemia failed to resolve following 12-months of a GFD (25% v 5%, $p<0.05$) in the older cohort when compared to their younger counterparts. Interestingly, there was an inverse correlation between TTG-titre at diagnosis and poor mucosal healing in both cohorts ($p<0.05$).

Conclusion: Age is just a number. Older patients with CD present similarly to their younger counterparts. The higher rates of anaemia at time of diagnosis in older adults suggests a lower index of suspicion for coeliac disease with advancing age, which may be complicated by the higher rates of seronegative disease in this cohort.

Contrary to prior studies, older adults have equivalent rates of mucosal recovery, which is suggestive of the *de novo* loss of gluten tolerance in this age group as opposed to decades of delayed diagnosis.

Disclosure: Nothing to disclose.

P0175

COELIAC DISEASE (CD) AND CHRONIC INFLAMMATORY BOWEL DISEASE (IBD) ASSOCIATION

D. Azzouzi¹, M. Borahma¹, N. Iagdari¹, M. kadi¹, F.Z. Chabib¹, I. Benelbarhdadi¹, F.Z. Ajana¹

¹Mohamed V University, Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: azzouzidriass.ad@gmail.com

Introduction: The association of coeliac disease (CD) and chronic inflammatory bowel disease (IBD) is rare and has been little studied. CD and IBD are chronic gastrointestinal disorders of inflammatory origin that develop in response to environmental triggers in genetically predisposed individuals.

Aims & Methods: This study aimed to clarify the frequency, anatomical-clinical and evolutionary characteristics, and outcomes of this association. This is a retrospective, descriptive and analytical study of 13 patients between 2005 and 2022. The diagnosis of CD was established based on clinical, serological and histological data. The diagnosis of IBD was based on a combination of clinical, endoscopic, histological and radiological evidence.

Results: 13 cases of CD and IBD association were analysed in a cohort of 341 CD and 1020 Crohn's and 570 ulcerative colitis (UC). The frequency of association was 3.81% in the CD cohort and 0.81% in the IBD cohort. The sex ratio was 5F/M, a predominantly female ratio of 84.6%. The diagnosis of CD preceded that of Crohn's disease in 76.9% ($n=10$), with a mean delay of 32 months (12-72 months).

All patients were put on a gluten-free diet (GFD). Despite good compliance for at least 18 months, the evolution was marked by the persistence of anaemic syndrome and dysenteric syndrome in six cases (60%), diarrhea and abdominal pain of the colonic type in five cases (50%) and by the occurrence of rectal bleeding, anaemic syndrome and dysenteric syndrome in two cases (20%). Given the persistence of symptoms, we first ruled out resistance to GFD. Upper and lower gastrointestinal endoscopy, radiological and histological examination concluded that Crohn's disease was present: isolated colonic in five patients (50%); gastric and colonic in three patients; gastric and oesophageal in one patient; oesophageal in one patient. In 7 cases, the involvement was luminal inflammatory, stenosing in two patients and fistulising in one patient.

The diagnosis of IBD preceded that of coeliac disease in 23% of cases ($n=3$), 2 patients had luminal colonic Crohn's disease and the third had left UC. The diagnosis of CD was clinically retained by the appearance of an anaemic

mic syndrome associated with atypical abdominal pain in 2 cases and a dysenteric syndrome in the other case. Serologically, 2 patients had positive IgA antibodies to transglutaminase and the other was seronegative. Histologically, all three patients had intraepithelial lymphocytosis greater than 30% with subtotal atrophy. The evolution was favourable after the GFD which was always associated with the treatment of IBD, with a good clinical, biological and endoscopic improvement.

Conclusion: Our work shows that the association of CD and IBD is often rare but not exceptional with a strong predominance of CD and Crohn's disease. It should be suspected in the presence of any resistance to GFD or an unusual evolution during the course of IBD despite good therapeutic compliance.

Disclosure: Nothing to disclose.

Contact E-Mail Address: dr.ibtissamkhalif@gmail.com

Introduction: Celiac disease (CD) is a chronic autoimmune enteropathy, triggered by ingestion of gluten and other related prolamins in genetically predisposed individuals.

Several liver disorders have been described, and isolated hypertransaminasemia remains the most common hepatic presentation of the CD. The association with portal hypertension (PH) is rare.

The objective of our work was to describe this association, and study the impact of the gluten-free diet on the evolution of portal hypertension signs.

Aims & Methods: It was a retrospective and descriptive study conducted over 26 years, from 1995 to december 2021, collecting twenty patients with the association celiac disease and portal hypertension from a total of 340 celiac patients.

The diagnosis of CD was retained on clinical, serological and histological criteria.

Results: Twenty patients were collected, which represented a prevalence of 5,8%.

The mean age was 34,2 years with extremes ranging from 19 to 60 years. The sex ratio F/M was 3 with a female predominance in 75%.

On the functional level, 2 main symptoms, the abdominal pain and the weight loss were present in 45% of the cases, followed by oedemato-ascitic syndrome in 35% of the cases, chronic diarrhea of the malabsorption type in 30% of the cases, atypical diarrhea in 20% of the cases, vomiting in 15% of the cases, and only one case of upper gastrointestinal hemorrhage made of hematemesis and melena.

Clinical examination revealed an enlarged spleen in 70% of patients and collateral venous circulation in 30% of patients. Liver examination revealed a cirrhotic-looking liver in 20%, and a clinically normal liver in 80% of cases.

Abdominal ultrasound coupled with Doppler showed a homogeneous liver with regular contours in 65% of cases, a heterogeneous liver with spiculated contours in 35% of cases, portal cavernoma in 25% of cases, and one patient only had focal thrombosis of the inferior vena cava. Common causes of chronic liver disease were excluded in all patients.

Liver biopsy was performed in all our patients and the etiological profile was as follows, PH on porto-sinusoidal vascular disease in 40%, PH on celiac cirrhosis in 20%, PH on granulomatous hepatitis associated with celiac disease in 15%, and normal liver histology in 25% of the cases. The PH on portal thrombosis was secondary to hyperhomocysteinemia.

The upper endoscopy found esophageal varices (EV) in 55% of cases.

PH revealed celiac disease in 4 patients and was discovered on average 7.5 years after the diagnosis of PH.

A gluten-free diet (GFD) as well as prophylactic and therapeutic treatment of EV rupture with monitoring were instituted.

The evolution of the patients was marked by the aggravation of EV and the appearance of their complications in 20% of the cases over an average period of 5 years with non-adherence to the GFD. Histologically, 2 patients developed cirrhosis after an initially normal histology, after respectively 4 and 5 years with non-adherence to the GFD.

Conclusion: The association of celiac disease and portal hypertension is rarely reported in the literature, in our series it represented a prevalence of 5.8%.

Celiac disease is responsible for PH by various mechanisms not yet fully elucidated, so its search is systematic during PH. Adherence to a gluten-free diet has a beneficial effect on the evolution and severity of PH.

Disclosure: Nothing to disclose.

Introduction: European Society for Paediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN) guidelines for diagnosing coeliac disease (CD) in children and adolescents published in 2012 were the first to include the possibility of diagnosing CD without duodenal biopsy.

It has been shown in the following years that paediatric gastroenterologists are often reluctant to use a no-biopsy approach, despite their patients being eligible based on the established criteria (symptoms or signs

suggestive of CD and TGA IgA $\geq 10 \times \text{ULN}$). ESPGHAN guidelines updated in 2020 extended the possibility to use a no-biopsy approach to asymptomatic children belonging to known risk groups.

Aims & Methods: The aim of our study was to assess how often a no-biopsy approach is used in children and adolescents, diagnosed with coeliac disease in 2021 in the Danube region.

A prospective anonymised multi-centre study was conducted in the scope of CD SKILLS project including paediatric gastroenterologists from 8 European countries (Austria, Croatia, Czech Republic, Hungary, Moldova, Romania, Serbia, Slovenia), providing medical data of patients with CD aged ≥ 19 years diagnosed in 2021.

We focused on the presence of symptoms and level of TGA at the time of diagnosis and the used diagnostic approach. The data was compared with the results of the similar study conducted in Central Europe during the Focus IN CD project in 2016.

Results: Data from 284 newly diagnosed CD patients (64.8% female; median age 6.5 years) from 8 European countries were included in the study. 247 children (87%) were symptomatic at the confirmation of the diagnosis. No-biopsy approach was used in 63.7% ($N=181$) of included children (in 70.3% of asymptomatic and in 62.7% of symptomatic children).

Out of 103 children, who were diagnosed using duodenal biopsy, further 19 (18.4%) have also been eligible for the no-biopsy approach based on the very high levels of TGA antibodies. Comparing the data with the similar study conducted in Central Europe in 2016, we found the significant rise in the use of no-biopsy approach (Table 1).

	DANUBE REGION 2021			CENTRAL EUROPE 2016			p-values
	TOTAL	BIOPSY	NO-BIOPSY	TOTAL	BIOPSY	NO-BIOPSY	
CROATIA	61	25 (41%)	36 (59%)	58	54 (93.1%)	4 (6.9%)	<0.001
HUNGARY	85	23 (27.1%)	62 (72.9%)	302	238 (78.8%)	64 (21.2%)	<0.001
SLOVENIA	44	16 (36.4%)	28 (63.6%)	45	28 (62.2%)	17 (37.8%)	0.013
TOTAL	284	103 (36.3%)	181 (63.7%)	653	546 (83.6%)	107 (16.3%)	<0.001

Table 1. The use of no-biopsy approach in countries of Danube region and Central Europe.

Conclusion: In this prospective study it has been shown that the use of no-biopsy approach to diagnose CD in children and adolescents has risen significantly in the recent years. Paediatric gastroenterologists are probably becoming more comfortable with this possibility proposed by both ESPGHAN 2012 and 2020 guidelines for diagnosing CD. Compared to ESPGHAN 2012 guidelines, new 2020 guidelines also allow the use of no-biopsy approach in asymptomatic children.

In our study, the no-biopsy approach was used in 70.3% of asymptomatic children, further indicating that the awareness about possibilities included in ESPGHAN 2020 guidelines and their use among paediatric gastroenterologists in participating countries is high.

Disclosure: Nothing to disclose.

Introduction: Coeliac disease (CeD) is an immune-mediated systemic disorder triggered by the ingestion of gluten in genetically susceptible individuals, which, if untreated, can lead to chronic malabsorption. The mainstay treatment for CeD currently is a gluten free diet (GFD), which some studies have linked to an increased risk of weight gain and the development of metabolic disorders. Most of these studies are focused on the effect of the GFD on the Body Mass Index (BMI).

Aims & Methods: We aimed to evaluate the nutritional status, using different nutritional parameters, in two cohorts of CeD patients at diagnosis and on a GFD compared with healthy controls.

We consecutively recruited CeD patients at diagnosis and on a GFD from June 2020 to April 2022 at our outpatient clinic of the Azienda Ospedale - Università di Padova. Healthy subjects were recruited among family and friends of hospital staff. We collected demographic and clinical data at the time of the recruitment and recorded weight, height, BMI, Hand Grip Strength and bioelectrical impedance. Student t-test and Mann-Whitney test were used to compare parametric and non-parametric variables, respectively. Stata 11 software was used for statistical analysis.

Results: The study population was composed by 28 CeD patients at diagnosis [61% females, mean age 34 (Standard Deviation, SD 12)], 28 CeD patients on a GFD for at least one year [61% females, mean age 33 (SD 14)] and 28 healthy controls [61% females, mean age 34 (SD 11)].

CeD patients at diagnosis had a poorer nutritional status compared with healthy controls; in particular, lower phase angle (PA) ($p<0.001$), body cell mass index (BCMI) ($p=0.006$), fat free mass index (FFMI) ($p=0.007$), and appendicular skeletal muscle index (ASMI) ($p=0.007$). Finally, CeD patients had also a higher percentage of extracellular water (ECW) compared with controls ($p<0.001$).

Considering CeD patients on a GFD, they had only a lower FFMI ($p=0.02$) and ASMI ($p=0.02$) compared with healthy subjects. CeD patients on a GFD had a higher phase angle than CeD patients at diagnosis ($p=0.02$) and lower percentage of ECW ($p=0.02$). Finally, BMI resulted similar among the three groups.

	CeD at diagnosis	CeD on GFD	Controls	CeD diagnosis vs Controls	CeD on GFD vs Controls	CeD diagnosis vs CeD on GFD
BCMI	8.4 (7.8-9.6)	9.3 (8.4-10.4)	9.5 (8.6-10.7)	$p=0.006^{**}$	$p=0.31$	$p=0.06$
FFMI	3 (2-3)	3 (3-3)	4 (3-5)	$p=0.007^{**}$	$p=0.02^{**}$	$p=0.63$
ASMI	2.5 (2-3)	3 (2-3)	3 (3-3)	$p=0.007^{**}$	$p=0.02^{**}$	$p=0.63$
PA	5.7 $\pm$ 0.6	6 $\pm$ 0.6	6.3 $\pm$ 0.6	$p<0.001^{*}$	$p=0.15$	$p=0.02^{*}$
ECW (%)	47.4 $\pm$ 2.8	45.6 $\pm$ 2.7	44.7 $\pm$ 2.5	$p<0.001^{*}$	$p=0.19$	$p=0.02^{*}$

*=Student t-test; **=Mann-Whitney test

Table.

Conclusion: CeD patients at diagnosis have a poorer nutritional status compared with healthy controls, which improves on a GFD, except for FFMI and appendicular skeletal muscle index, which still result statistically significant different between CeD on GFD and controls. Therefore, our study describes a compromised nutritional status at CeD diagnosis

but also a positive effect of a GFD on it for most of the parameters analyzed, underlining the inefficacy to evaluate this aspect only through the BMI evaluation.

Introduction: Celiac disease (CD) is considered to have a high heritability. Several studies have indicated that a strong HLA-DQ ‘gene dose’ effect exists with apparent implications on CD development and disease phenotype.

Aims & Methods: A retrospective analysis of medical records was performed using the adult CD patient cohort attending a single tertiary referral centre. The study was carried out between January 2015– December 2019 and included 81 patients. Complete HLA-DQ typing alleles were isolated using genomic DNA extracted from EDTA-anticoagulant peripheral blood according to the manufacturer instructions.

Results: HLA-DQA1*02/DQA1*05 was identified in 49.3%, DQA1*05/DQA1*05 in 21.3% of cases, and HLA-DQB1*02/DQB1*02 in 41.3 % of cases. 8% of patients are DQ2.5 homozygous, 64% are DQ2.5 heterozygous, 24 cases DQ2.5 / DQ2.2, 24 (32%) have the DQ2 genotype 2.5/DQX, 2.67% inherited DQ2.5/DQ7, respectively 1 isolated HLA-DQ2.2 homozygous case. DQX/DQX were identified at 10 (13.33%).

Low frequency was identified for HLA-DQ8. When assessing disease phenotype, the carriage of 2 HLA-DQB1*02 copies was associated with the presence of anaemia ($P=0.024$), but not with the presence of recurrent or chronic diarrhea, loss of weight, infertility or dyspepsia. No differences were detected between the presence of one versus two DQB1*02 copies

and the different Marsh classifications, $P=0.725$. However, the CD patients expressing 2 copies were more likely to have increased IgA-tTG and IgA AGA levels compared to those expressing only one copy.

Conclusion: The number of copies inherited by CD patients influences disease phenotype, but does not interfere with histological involvement. The lack of dosage effect on histological changes suggests that the presence of HLA-DQ heterodimers confers risk of disease, but there are additional factors that determine severity.

Introduction: Celiac disease (CD) is a systemic immune-mediated disease triggered by gluten ingestion in genetically susceptible individuals, characterized by the presence of a variable combination of clinical manifestations, CD-specific antibodies and enteropathy. The phenotypic expression of the disease has changed over time with a decrease of classical CD and increase of atypical and subclinical phenotype. Moreover, the presence of symptoms is not always related to intestinal injury since CD-patients with a normal mucosa can complain symptoms. This condition is known as potential CD (P-CD) and it is related to people with a normal intestinal mucosa, but presence of serum CD-antibodies.

Recent cohort studies in children at risk of CD showed that P-CD have an increased risk to progress to classical CD. In pediatric patients the presence of CD-antibodies at intestinal level predicts the development of intestinal atrophy and is used to support diagnosis of P-CD. In adult patients intestinal CD-antibodies showed 100% sensitivity in classical CD, while no data are available in adult P-CD and in other gastrointestinal (GI) diseases.

Aims & Methods: We conducted a prospective and multicentric study which involved five-different gastroenterological units in North Italy. The aim of this study was to investigate the sensitivity and the specificity of intestinal CD-antibodies in patients suspected for CD and for other GI disorders in adulthood.

Adult subjects (> 19 years) who performed biopsy for suspected CD or other GI diseases have been prospectively enrolled.

Intestinal CD-antibodies have been investigated by measuring anti-endomysium antibodies (AEA) in the supernatant of intestinal biopsy culture.

Results: Ninety-eight patients were enrolled (63F-35M, median age 33±18y) and divided in 3 groups.

Group A: 18 patients, with CD suspicion and tested positive for HLA DQ2/8 and for serum CD abs. Histological analysis showed villous atrophy in all of them, intestinal AEA were tested positive in biopsy supernatant of 18/18. All these patients were diagnosed as CD patients and put in GFD.

Group B: 5 symptomatic patients, with CD suspicion and tested positive for HLA DQ2/8 and for serum CD abs. The intestinal mucosa was normal in all of them, intestinal AEA were tested positive in biopsy supernatant of 5/5. All these patients were diagnosed as P-CD patients and put in GFD.

Group C: 75 patients underwent GI endoscopy because suffering from other gastrointestinal disorders and 23/75 tested positive for HLA DQ2/8. Intestinal AEA were not detectable in biopsy supernatant of these patients. All controls were negative for serum CD-antibodies.

Sensitivity and specificity of intestinal AEA are absolute (100%).

Conclusion: Intestinal CD-antibodies have shown absolute sensitivity and specificity to detect both CD and P-CD patients. In particular, the detection of these auto-antibodies at intestinal level make prompt diagnosis in symptomatic P-CD patients who may benefit of a well-founded diagnosis reducing both unnecessary medical investigations and delay in diagnosis and treatment.

Introduction: Several studies have shown that the knowledge about coeliac disease (CD) is not satisfactory among healthcare professionals (HCP).

Aims & Methods: The aim of our study was to assess the knowledge of HCPs about CD in the Danube region.

HCPs from 8 countries in the Danube region were asked to complete the web-based questionnaire about CD. The questions were divided into subsections on epidemiology with clinical presentation, diagnostics, and treatment with follow-up. Achieved scores between participating countries and among different specialists managing patients with CD were compared. The scores of HCPs were compared with the results of a similar study conducted in Central Europe within the Focus IN CD project in 2016.

Results: Questionnaire was completed by 799 HCPs from Austria, Croatia, Czech Republic, Hungary, Moldova, Romania, Serbia and Slovenia. Most participants were paediatricians (68.6%), followed by internal medicine specialists (9.5%), general practitioners (6.5%) and other HCPs.

Significant differences ($p < 0.001$) were found between different specialists with paediatricians (mean score: 56.9%) and internal medicine specialists (51.7%) scoring higher than general practitioners (40.4%) and other specialists (37.7%). Comparing paediatricians from different countries, those from Croatia scored the highest, followed by Czech and Slovenian paediatricians.

When comparing gastroenterologists (GE) (paediatric GE (N=72) and internal medicine-GE (N=48)) with primary care physicians (primary care paediatricians (N=362) and general practitioners (N=52)) we found that paediatric GE scored significantly higher than internal medicine-GE, primary care paediatricians (and general practitioners (mean score: 75.3% vs 55.1% vs 53.9% vs 40.4%; $p < 0.001$). Among countries, Slovenian paediatric GE scored the highest, followed by Croatian and Austrian paediatric GE. Comparing the data with the similar study conducted in Central Europe in 2016, we found a significant rise ($p < 0.001$) in the knowledge of paediatric GE (Table 1). Also, overall knowledge of HCPs is slightly higher in the Danube region in 2021 compared to Central Europe in 2016 (52.2% vs 50.9%; NS). We also found that HCPs who previously took part in the Focus IN CD project (N=69), achieved higher score (61.1% vs 50.8%; $p < 0.001$).

CENTRAL EUROPE 2016	GENERAL PRACTITIONERS (N=424)	PRIMARY CARE PAEDIATRICIANS (N=405)	PAEDIATRIC GE* (N=49)	INTERNAL MEDICINE GE (N=20)
Overall mean score	53.4% (SD ±16.5)	53.4%(±15.5)	69.4% (±10.7)	54.2% (±9.4)
Epidemiology and clinical presentation	46.2% (SD±17.5)	46.3% (±17.1)	60.8% (±13.8)	51.7% (±13.6)
Diagnostic procedure	40.4%(SD±26.2)	39.7% (±27.8)	63.3% (±23.3)	34.2% (±14.8)
Treatment and follow-up	67.8%(SD±17.9)	68.1% (±16.2)	80.8% (±15.1)	68.5% (±14.2)
DANUBE REGION 2021	GENERAL PRACTITIONERS (N=52)	PRIMARY CARE PAEDIATRICIANS (N=362)	PAEDIATRIC GE* (N=72)	INTERNAL MEDICINE GE (N=48)
Overall mean score	40.4% (SD ±14.2)	53.9% (±15.9)	75.3% (±13.9)	55.1% (±12.5)
Epidemiology and clinical presentation	32.7% (SD±16.5)	47.8% (±17.6)	69.9% (±18.1)	50.7% (±14.6)
Diagnostic procedure	36.2% (SD±18.6)	49.1% (±22.8)	76.2% (±15.4)	55.4% (±22.3)
Treatment and follow-up	51.7% (SD±19.3)	65.5% (±19.1)	80.6% (±16.5)	59.9% (±14.8)

* p<0,001

Table 1. Results achieved by primary care physicians and gastroenterologists (GE) according to different subsections of the questionnaire in Central Europe and Danube region.

Conclusion: The knowledge about CD among HCPs in Danube region is not satisfactory. However, paediatric GE achieved highest scores, which might be related to a higher awareness about the burden of CD in this group. Also, compared to previous study in Central Europe, there has been a significant rise in the knowledge of paediatric GE, showing the benefit of various awareness raising activities that were carried out, also in the scope of the Focus IN CD project. It has been shown that various learning activities can improve the knowledge of HCPs and reduce the number of unrecognized patients and unnecessary diagnostic delays.

Disclosure: Nothing to disclose.

IMMUNE RESPONSES TO COVID-19 VACCINES IN CELIAC DISEASE

K.E.A. Lundin¹, J.H. Ibsen², F. Lund-Johansen³

¹K. G. Jebsen Coeliac Disease Research Centre, University of Oslo and Oslo University Hospital, Gastroenterology, Oslo, Norway,

²University of Oslo, Oslo, Norway, ³University of Oslo, Institute of Immunology, Oslo, Norway

Contact E-Mail Address: jostein.ibsen@gmail.com

Introduction: SARS-CoV-2 infection and development of the disease Covid-19 is a serious threat to our society. Effective vaccines have now entered the market, but most patient populations were not included in the registration clinical trials. There is evidence that patients with celiac disease (CeD) have reduced effect of vaccines such as the hepatitis B vaccine. Hence, we investigated the humoral response to COVID-19 vaccines (Chadox1, Corminaty and Spikevax) in CeD patients and healthy controls.

Aims & Methods: Patients with biopsy confirmed CeD diagnosis from patient biobank at Oslo University Hospital (OUH) were invited to donate serum samples before and after vaccination. We sent out 1537 invitations, and received adequate samples from 85 individuals, these were compared with similar samples from 238 healthy controls. Sera were analyzed for

content of antibodies to the Spike protein from SARS-CoV2 and the receptor-binding domain (RBD). The results were then converted into BAU/ml to compare.

Results: Post vaccination analysis showed overlap of antibody levels between CeD and healthy controls. On average, the CeD patient group had 5555.0 binding antibody units per milliliter (330.1 SD) while the average in healthy controls was 5419 (184,7 SD).

Conclusion: The humoral response to SARS-CoV-2 vaccines in CeD patients is similar to that observed in healthy controls.

IS THE GLUTEN-FREE DIET A RISK FACTOR FOR FATTY LIVER DISEASE IN CELIAC DISEASE?

A. Ben Mohamed¹, M. Yakoubi¹, M. Medhioub¹, A. Khsiba¹, M. Moufida¹, M.L. Hamzaoui¹, M.M. Azzouz¹

¹Mohame Taher Maamouri Hospital, Gastroenterology, Nabeul, Tunisia

Contact E-Mail Address: asmabenmed2014@gmail.com

Introduction: Fatty liver disease (NAFLD) is a common condition in the general population, and its prevalence during diagnosis of celiac disease (CD) appears to be similar to that of the general population. The contribution of the gluten-free diet (GFD) in its genesis is still a subject of controversy.

Aims & Methods: The aim of our study was to determine the prevalence of NAFLD during CD and to study the role of the GFD in the onset of advanced fibrosis. We conducted a retrospective study including patients with CD among a period of 6 years. Two groups were identified according to the observance of the GFD;

Group 1: Good compliance,

Group 2: Poor compliance.

Compliance was evidenced by clinical, biological and endoscopic remission. Fibrosis was studied by the Fibrosis 4 (FIB 4) score in both groups. Patients with diabetes mellitus, dyslipidemia, excessive alcohol consumption, body mass index > 30, chronic liver disease and those with follow-up less than 12 months were excluded.

Results: The study involved 70 patients middle-aged of the 35-year-old [15- 65] and with a sex ratio M / F of 0.28. The body mass index was less than 20 in 30% of the cases, between 20 and 25 in 54% of the cases and between 25 and 30 in 6% of the cases.

Group 1 contained 72% of the cases and group 2 contained 28% of the cases. The evaluation of Fibrosis by the FIB score 4 in group 1 showed; Absence of fibrosis (FIB 4 <1.30) in 80% of patients, F3 / F4 Fibrosis (FIB 4> 2.67) in 18% of patients, indeterminate fibrosis or gray area in 2% of patients.

In group 2; all patients had an F0 fibrosis score. In analytical study; adherence to the GFD was not correlated with F 3 / F 4 Fibrosis (p = 0.22).

Conclusion: In our series, the prevalence of NAFLD was 18% in patients complying with the GFD. In the analytical study, the GFD was not associated with an increased risk of developing NAFLD, which joins some studies.

Disclosure: Nothing to disclose.

Introduction: To evaluate the prevalence, incidence, and characteristics of people avoiding gluten without celiac disease in 2000 and 2011 in a large population-based cohort.

Aims & Methods: Comprehensive health- and diet-related data were collected in nationwide Health 2000 and 2011 surveys comprising 5,978 and 4,268 individuals, forming representative samples for 2,946,057 and 2,079,438 Finnish adults. Samples for transglutaminase antibody (TGA) testing were available from 96.6% and 90.6%, respectively. Altogether 3,424 patients participating in both surveys comprised a prospective follow-up cohort. Non-celiac subjects who were on a gluten-free diet and had no positive TGA formed the study cohort.

Results: The prevalence of non-celiac gluten-avoiding individuals was 0.2% in 2000 and 0.8% in 2011 ($p < 0.001$), with an annual incidence rate of 51 per 100,000 persons in the prospective cohort. These subjects had more frequent visits to the doctor annually (mean 6.2 vs. 3.7, $p = 0.010$), had more often irritable bowel syndrome (6.5% vs. 1.7%, $p = 0.040$) and lactose intolerance (22.6% vs. 7.5%, $p = 0.002$), and maintained lactose-free diet (41.9% vs. 12.0%, $p < 0.001$) and a specific food restriction for allergy (9.7% vs. 2.9%, $p = 0.025$) more often than the gluten-using survey participants. No difference between the groups was seen in demographic data, body mass index or presence of autoimmune diseases.

Conclusion: The number of gluten-avoiding individuals without celiac disease quadrupled within a decade, comprising almost one percent of the population in the end of the study. These subjects had higher use of health-care services and increased prevalence of also other dietary restrictions.

SMALL INTESTINAL NEUROENDOCRINE NEOPLASMS WITH PANCREATIC METASTASES

A.C. Milanetto¹, A.-L. Gais Zurcher¹, C. Pasquali¹

¹Università degli Studi di Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy

Contact E-Mail Address: acmilanetto@unipd.it

Introduction: Small intestinal neuroendocrine neoplasms (NENs) present in advanced stage with liver or peritoneal metastases. The occurrence of pancreatic metastases has been rarely reported. We reviewed our experience in small intestinal NENs observed from 2006 to 2020 in our Unit to detect a pancreatic involvement in these patients.

Aims & Methods: The objective is to evaluate the results of pancreatic surgery and survival in patients with pancreatic metastases from small intestinal NENs. Among 47 patients with small intestinal NENs (including duodenum) observed, five patients showed a pancreatic involvement. Follow-up to December 2021.

Results: Patients enrolled in the study were 3 F/2 M, averaging 60 years. All the patients but one had a synchronous pancreatic involvement at surgery. The mean primary tumor size was 2.9 (range 1.4-5.5) cm. All patients presented with lymph-node metastases. Only two patients had liver metastases and one had lung metastases.

One patient had a MEN4 syndrome with acromegaly. In one patient the pancreatic lesion was found 8 years after surgery in progressive disease. In one patient the lesion had progression 3 months after surgery and she died shortly after with jaundice and liver failure.

Four patients underwent surgery for the pancreatic metastases: one enucleation, one duodenum-preserving pancreatic head resection, one distal pancreatectomy, and one pancreatico-duodenectomy. Post-operative complications occurred in two patients: a pancreatic fistula (grade B) and an infected abdominal fluid collection which needed reoperation.

Three patients died 3, 34 and 92 months after surgery, respectively. Two patients are still alive with disease 10 and 15 years after surgery, respectively.

Conclusion: Secondary pancreatic lesions in small intestinal NENs are an uncommon finding, but they occurred in up to 11% of cases in our experience. Single pancreatic metastases may be resected with a long-term survival.

Disclosure: Nothing to disclose.

Introduction: Primary small-bowel follicular lymphoma (FL) is mainly diagnosed as a duodenal lesion in esophagogastroduodenoscopy. Recently with the widespread use of small-bowel endoscopy, FL in the jejunum and ileum can be detected. Most patients with small-bowel FL are diagnosed at the localized stage with the watch and wait policy. However, the predictive factors for the progression of small-bowel FL have not been clarified.

Aims & Methods: This study aims to examine the predictive factors for the progression of primary localized stage small-bowel FL based on the clinicopathologic and endoscopic findings. We enrolled 60 consecutive patients with primary small-bowel FL diagnosed at two tertiary hospitals between January 2005 and December 2020, who have localized stage (clinical stage I-II1 of Lugano classification), low grade (WHO grade 1-2), and low tumor burden (LTB) according to the criteria of *Groupe d'Etude des Lymphomes Folliculaires* (GELF) with the watch and wait policy.

We examined the predictive factors for progression according to the clinicopathologic and endoscopic findings. Endoscopic findings were focused on the color tone (white or similar to the peripheral mucosa), horizontal location of follicular lesions (circumference $\geq 1/2$ or $< 1/2$), fusion of follicular

lesions (fusion [+]) or [-]), and protruded lesion ≥ 6 mm. Progressive disease (PD) was defined as either progression of clinical stage, extension of intestinal lesions, or transformation to diffuse large B-cell lymphoma.

Results: PD was observed in 12 patients (20%), including progression of clinical stage in six patients (10%), extension of intestinal lesions in five patients (8%), and transformation to diffuse large B-cell lymphoma in one patient (2%) (mean observation period 76.9 ± 56.6 months).

In the multivariate analysis, “circumference $\geq 1/2$ ” (OR 8.12, 95% CI 1.34–49.0, $P < 0.05$) and “fusion (+)” (OR 12.46, 95% CI 1.51–102.7, $P < 0.05$) were significant predictive factors for progression. Kaplan–Meier analysis of “circumference $\geq 1/2$ ” and/or “fusion (+)” versus “circumference $< 1/2$ ” and “fusion (-)” showed that progression-free survival was significantly shorter in the “circumference $\geq 1/2$ ” and/or “fusion (+)” groups.

Three out of the 12 patients with exacerbations continued with the watch and wait policy because they met the criteria of GELF for LTB (mean observation period, 82.1 months). The other nine patients received rituximab alone or combined with rituximab chemotherapy. Patients who received rituximab alone or combined with rituximab chemotherapy achieved complete response and had no relapse (mean observation period, 63.5 months).

Conclusion: In the watch and wait policy of patients with primary localized stage small-bowel FL, endoscopic findings of “circumference $\geq 1/2$ ” and “fusion (+)” were the significant predictive factors for progression.

Introduction: Small bowel angioectasias often present as overt or occult obscure gastrointestinal bleeding.

Aims & Methods: The aim of this study was to evaluate the characteristics of the angioectasias found in small bowel capsule endoscopy (SBCE) and correlation with patients' haemoglobin value. A retrospective and unicentric study examining SBCE performed during a 3-year period was conducted, selecting those in which angioectasias were reported. Patients' demographic and biochemical data were recorded, as well as the number, size and location of angioectasias. Patients with red spots, erythematous patch or active bleeding without the identification of any lesion were not included.

Results: A total of 62 SBCE reported angioectasias, with half of the patients having angioectasias exclusively in the first tertile. In patients with small bowel angioectasias, as age increases, the mean haemoglobin value decreases ($r = -0.482$, $p < 0.001$). Additionally, as the number of angioectasias in the first tertile increases, the patient's haemoglobin value decreases ($rs = -0.317$, $p = 0.025$), which did not occur in patients with angioectasias in the second or third tertile.

Overall, patients with well filled angioectasias had a lower mean haemoglobin value (8.2 ± 2.5 g/dL) the year before undergoing SBCE, with a mean difference of 1.9 g/dL ($p = 0.016$). This was also observed in patients with angioectasias in the first tertile, who had lower mean haemoglobin value

(7.7 ± 2.0 g/dL) the year before undergoing SBCE, with a mean difference of 2.3 g/dL ($p = 0.003$). However, this was not observed in patients with angioectasias in the second or third tertile. Patients who presented with overt obscure gastrointestinal bleeding (Mdn=4,6) experienced a higher drop in haemoglobin value, $U = 105.50$, $z = -2.41$, $p = 0.016$.

Conclusion: Small bowel angioectasias were more common within the first tertile. A higher number of angioectasias and well filled angioectasias found within the first tertile were associated with lower mean haemoglobin values at presentation. Patients with overt obscure gastrointestinal bleeding had a higher drop in haemoglobin value.

Disclosure: Nothing to disclose.

Introduction: Cryptogenic multifocal ulcerous stenosing enteritis (CMUSE) is a rare disease that mimics various chronic inflammatory and ischemic strictures with considerable dilemmas in management.¹ Although it is increasingly reported in adults, literature in children is scarce.¹⁻² We aimed to distinguish characteristics of CMUSE that could differentiate from small bowel Crohn's disease (SBCD) and intestinal tuberculosis (ITB) in children.

Aims & Methods: Confirmed cases of CMUSE presenting to a pediatric gastroenterology referral center with the following criteria were analysed³: (1) unexplained superficial multiple small bowel strictures with or without ulceration; (2) no signs of systemic inflammation (3) not satisfying diagnostic criteria for SBCD and ITB. The clinical details and investigative profile (imaging, small bowel or capsule endoscopy, laparotomy and histopathology) and response to treatment were noted. Poor outcome was defined as progression of diseases despite surgery and or immunosuppression.

Results: CMUSE was diagnosed in 12 of 47 (25%) of isolated small bowel and ileocecal strictures referrals (table 1).

Presentations were obscure gastrointestinal bleeding (83%), protein losing enteropathy (41%), subacute obstruction (75%) and/or short stature (75%). Four children were diagnosed on capsule endoscopy, rest on imaging and laparotomy. Capsule retention occurred in two. Upfront immunosuppression [steroids and azathioprine, median duration 6 months, interquartile range (IQR) 4-17 months] failed in all 6 patients requiring surgery (intestinal resection). Upfront surgery followed by immunosuppression [median duration 24 months, IQR 18-36 months] was required in 6 patients. Two patients each from the above groups ($n = 4$) had ulcer-stricture recurrence requiring repeat intestinal resection.

None of the recurrence patients had change in the phenotypic presentation. Poor outcome was seen in all 4 patients with recurrence. In the total follow-up period of 33 months (IQR 5-216) months, 8 (67%) showed improvement in growth parameters.

Conclusion: CMUSE is an important entity underdiagnosed in children. Characteristic features on enteroscopy, laparotomy and histopathology differentiate this disease from small bowel crohn's disease and intestinal TB. Two-third patients have favorable outcome with combination of surgery and immunosuppression.

Characteristics	CMUSE, n=12	Small bowel crohn's disease, n=6	Intestinal TB, n=21
Age (months), median (IQR)	15 (14-17)	14 (12-16)	14 (12-17)
Disease duration (months), median (IQR)	45 (29-63)	12 (6-17)	9 (4-14)
Disease distribution	Jejunum (67%) Jejunum + proximal ileum (33%)	Jejunum 33%, Mid Ileum 33% Jejunum + mid ileum 34%	Ileo-caecal (66.7%)
Lesion description (enteroscopy or laparotomy)	Multiple, short (1-2 mm) regularly-spaced, mostly superficial, (semi) circumferential ulcers with variable degrees of narrowing.	Deep, linear ulcers, long narrowed segment (15-25 mm), cobblestoning and skip areas	Deep, circumferential or linear ulcers (100%)with ileocecal valve deformity (67%)
Necrotic lymph nodes, n (%)	0	0	11(52%)
Peritoneal involvement and loculated ascites, n(%)	0	0	4(19%)
Upstream dilatation, n (%)	4(33%)	3(50%)	12 (63%)
Comb sign on imaging, n(%)	0	6(100%)	0
Histopathological features on intestinal specimen	Mild mixed inflammatory cell infiltrates in mucosa and submucosa. No granulomatous,transmural or vasculitic changes. No fat creeping.	Transmural inflammation with fat creeping (100%), Non-caseating granuloma(17%)	Caseating granuloma(48%) with Ziel-Neelson stain positivity (42%)

Table 1: Salient features of patients with CMUSE, small bowel crohn's disease and intestinal TB:

Contact E-Mail Address: drnamesl@gmail.com

Introduction: Aspirin is among the most commonly prescribed oral pills for therapeutic or prophylactic purposes and is often long-term prescribed in clinical settings. Clinical expansion of capsule endoscopy (CE) has revealed that low dose aspirin frequently cause small bowel (SB) injury by disrupting mucosal barrier. Small-sized randomized controlled or cross-over studies have shown that mucoprotective agent (MPA) has a protective effect on SB mucosa in aspirin or NSAID users. However, the relevant evidence is still lacking other than misoprostol, and there are no large-scale studies.

Aims & Methods: We evaluated the protective effect of MPA on SB bleeding in aspirin users using the claim data from the National Health Insurance Service (NHIS).

An aspirin-SB cohort were constructed using the NHIS claim data since CE has been insured. Follow up period was limited to a maximum of 24 months. Suspected SB bleeding was defined as anemia, melena or hematochezia occurred within 4 weeks before and after CE performed. Cox proportional hazard model included sex, age, Charlson comorbidity index (CCI), duration of aspirin use, concurrent use of anticoagulants, MPAs, and acid suppressants such as proton pump inhibitor (PPI) and histamine-2 receptor antagonist (H2RA). Subgroup analyses according to the use of acid suppressants were performed and cumulative hazards were compared among the various categories of gastrointestinal (GI) drugs.

Results: A total of 15,542 aspirin users were included. Multivariate cox model showed that anticoagulant use (HR=3.22), high CCI score (HR=2.10 and HR=3.54, respectively, in score 1 and ≥2), and concurrent use of PPI (HR=2.85) were significantly associated with increased occurrence of SB bleeding. SB bleeding was more frequently occurred in cases with concurrent use of acid suppressants vs. non-use (1.3%, vs. 0.5%).

Whereas, it was inversely associated with eupatilin use (HR=0.35, p=0.013). In subgroup analysis, only eupatilin significantly reduced the risk of SB bleeding among various MPAs in aspirin users with concomitant use of acid suppressant (HR=0.23 vs 1.96 and 2.55).

Conclusion: Eupatilin was associated with reducing the risk of SB bleeding in aspirin users with concomitant use of acid suppressant. Eupatilin use should be considered in aspirin users and especially concomittent users of acid suppressant in patient with high-risk of GI bleeding.

Disclosure: Nothing to disclose.

Contact E-Mail Address: dora.matis@icloud.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) has emerged as one of the most common causes of chronic liver disease worldwide and represents a global public health problem. The most effective treatment for NAFLD is weight loss, however, it has been shown that body composition has a crucial effect on NAFLD resolution. Anyhow, most studies on this topic were cross-sectional and therefore could not demonstrate a causal relationship between certain parameters and NAFLD resolution.

Aims & Methods: In this systematic review and meta-analysis, we aim to evaluate the correlation between different body composition parameter changes and the resolution of NAFLD in longitudinal studies.

This study was registered on PROSPERO under registration number CRD42021278584. A systematic search was performed in Embase, MEDLINE (via PubMed), and Cochrane Central Register of Controlled Trials (CENTRAL) up to September 26, 2021. Studies were eligible if they reported on the correlation between the change of hepatic steatosis state and the change of various body composition parameters in adults with NAFLD. We calculated pooled correlation coefficients (R) with 95% confidence intervals (CIs) using a random-effect model. We separated Spearman's and Pearson's correlation analyses.

Results: Out of 21612 studies after search, altogether we included 14 studies in our quantitative and qualitative synthesis. Based on three studies containing 175 patients we found a moderate correlation between visceral adipose tissue (VAT) decrease and liver fat content reduction (Pearson's R=0.33, CI: 0.19-0.46).

Similarly, in two studies with 85 patients, VAT change showed a moderate correlation with steatosis decrease in Spearman's correlation analysis (R=0.49, CI: 0.22-0.69). On the other hand, subcutaneous adipose tissue (SAT) change showed a moderate correlation with steatosis reduction in two studies (n=163, Pearson's R=0.42, CI: 0.29-0.54).

We also analyzed the correlation between body fat mass, visceral fat rating, skeletal muscle area, and muscle bodyweight ratio change and steatosis reduction, however, we included only one study in each analysis.

Conclusion: We found a moderate correlation between the VAT and SAT content change and liver fat reduction. Body composition parameter measurement should be introduced in the management of NAFLD.

Disclosure: Nothing to disclose.

Introduction: The mini gastric bypass surgery (MGB) is a relatively simple surgical procedure which is gaining popularity in recent years. Recent studies reported symptomatic biliary reflux gastritis and esophagitis as predominant complications. Hepatobiliary scintigraphy (HIDA) is the test for diagnosis of bile reflux, but there are very few published studies regarding its use for detecting bile reflux after bariatric surgery.

Aims & Methods: The aim of this study was to define an optimized HIDA scintigraphy protocol for demonstrating bile reflux in post MGB patients and demonstrate the prevalence of bile reflux in symptomatic patients with reflux symptoms.

The study was conducted prospectively. Patients after MGB with complaints suggestive of bile reflux, were included. All patients underwent HIDA scintigraphy with a dedicated protocol for demonstrating bile reflux in the Nuclear Medicine Department in the Galilee Medical Center. The presence of the isotope in the stomach or esophagus was reported for each patient as well as the prevalence and severity of bile reflux.

HIDA scan protocol: The patients were instructed to fast for at least 4 hours prior to the scan. mCi eHIDA (commercial details) were injected intravenously. Planar dynamic and static images of the upper abdomen and chest were acquired with the patient in a prone position immediately following the HIDA injection for up to 30 minutes. At this time, the patient was given a small piece of chocolate to eat. If no obvious reflux was seen to the stomach pouch or esophagus, the patient was given a standard meal of a cheese or omelet sandwich (according to patient's preference).

Immediately following the meal, dynamic and static planar images were acquired for up to 30 minutes. If no reflux was seen, reflux encouraging maneuvers were conducted. Immediately following the maneuvers, dynamic and static planar images were acquired for up to 15 minutes. If at any time the isotope was noted in the esophagus on the planar images, SPECT/CT of the upper abdomen and chest was acquired immediately. If no obvious reflux was seen until the end of the scan protocol, SPECT/CT was acquired at the end of the protocol, up to 120 minutes after injection.

Results: Nineteen patients were included. The mean time from surgery to the scan of 22.4 months. Bile reflux into the gastric pouch was documented in 11 patients (53%). In 3 patients the reflux to the stomach pouch was severe (27%), in 2 patients moderate (18%) and in six patients mild (55%). Bile reflux into the esophagus was documented in 4 patients (21%). In 1 patient the reflux was severe (25%) and in the rest mild (75%).

Comparison was conducted between the 11 patients who had bile reflux (group A) as compared to the 8 patients who didn't have (group B). Group A had a significantly higher rate of vomiting and heartburn and regurgitation (63.6% and 100%, P=0.02) as compared to group B (12.5% and 62.5%, P=0.04), respectively.

Moreover, group A had a higher rate of esophagitis (40%), as compared to group B (0), $P=0.02$. On regression analysis to elucidate whether hiatal hernia or resected gallbladder were risk factors for bile acid reflux showed no association with either hiatal hernia (OR 1.28, 95% CI 0.16-10.45, $P=0.81$) and resected gallbladder (OR 0.57, 95% CI 0.09-3.64, $P=0.55$).

Conclusion: The tailored HIDA scan protocol used for this study detected bile reflux in more than half of the post MGB patients included in the study. We believe that the changes introduced to the protocol increase the scans sensitivity while being technically easy to reproduce with good patient tolerability.

Disclosure: Nothing to disclose.

EVALUATION OF THE EFFICACY AND SAFETY OF ENDOSCOPIC SLEEVE GASTROPLASTY (ESG) IN THE MANAGEMENT OF PATIENTS WITH OBESITY IN A FOLLOW-UP FROM 12 TO 48 MONTHS

B. Queiroz Sander¹, D.T.H. de Moura², L.R. Alberti³

¹Sander Medical Center, Bariatric Endoscopy, Belo Horizonte, Brazil, ²Faculdade de Medicina da Universidade de São Paulo, Gastroenterology Department, São Paulo, Brazil, ³Universidade Federal de Minas Gerais, Surgery Department, Belo Horizonte, Brazil

Contact E-Mail Address: brunosander@hotmail.com

Introduction: According to the World Health Organization (WHO), in 2019, 2.3 billion people were overweight. In Brazil, overweight already affects 52.5% of the adults and this rate only increases every year.

Endoscopic Sleeve Gastroplasty (ESG) is a promising less-invasive technique that allows the suture of the stomach through endoscopy. Its use is increasing, but just short-term follow-up studies are available in the literature.

Aims & Methods: To evaluate the safety and efficacy of ESG, in the short and medium-term follow-up in patients with obesity.

This is a single center retrospective cohort study of prospectively collected data including participants whom underwent ESG between July 2017 and August 2020.

A total of 189 patients were included in the analysis and were divided into different groups, with follow-up times ranging from 12 to 48 months, depending on the interval between procedure and data collection.

All patients were at least 18 years old, had a minimum body mass index (BMI) of 30 kg/m² (grade I obesity) and had not previously undergone bariatric surgery.

Variables that could influence the effectiveness and durability of ESG (Suture patterns, Oversuture, Resuture, Number of threads, Number of bytes, Weight Lost, AWL%, EWL%, Safety, Efficacy, Durability, Argon Plasma Coagulation use and Follow-up with Nutritionist and Psychologist), intra-procedural adverse events (AEs), post-procedure AEs, and follow-up data for up to four years after the procedure, at 12-month intervals, were analyzed.

Results: Regarding safety, there was no intra-procedural AEs. Post-procedural AEs were observed in 7.9% of patients. All AEs were mild and occurred in the first 15 days after the procedure including 33% self-limited gastric bleeding and 67% vomiting.

Regarding efficacy, 87.8% of the patients achieved more than 10% absolute weight loss (%AWL) and more than 25% excess weight loss (%EWL). Mean %AWL was 21.09% with a %EWL of 70.83%. The %AWL values at each time interval were: 16.54% (12M), 20.15% (24M), 19.77% (36M) and 21.09% (48M), and the %EWL were: 56.04% (12M), 69.7% (24M), 70.5% (36M) and 70.8% (48M).

		Weight (Kg)	Weight Lost	% AWL	% EWL	BMI
	Number of Patients	Average	Average	Average	Average	Average
Initial Time	189	99.37 [97.3; 101.44]	...	...	...	36.08 [35.66; 36.5]
12 months	189	82.8 [81.1 ; 84.5]	-16.82 [-17.78 ; -15.87]	-16.54% [-17.78 ; -15.87]	56.04% [53.30% ; 58.78%]	30.13 [29.73 ; 30.52]
24 months	149	78.52 [76.51 ; 80.53]	-20.26 [-21.60 ; -18.92]	-20.15% [-21.60 ; -18.92]	69.69% [65.81% ; 73.58%]	28.67 [28.17 ; 29.16]
36 months	51	78.76 [74.79 ; 82.72]	-20.11 [-22.73 ; -17.49]	-19.77% [-22.73 ; -17.49]	70.54% [64.20% ; 76.89%]	28.41 [27.63 ; 29.19]
48 months	16	76.92 [68.17 ; 85.66]	-21.26 [-26.27 ; -16.24]	-21.09% [-26.27 ; -16.24]	70.83% [61.25% ; 80.42%]	28.66 [27.21 ; 30.10]

Table: Evolution of patients' weight by treatment time

Mean average absolute weight was 99.37 kilos, ending with an average absolute weight of 76.92 kilos, in the 48 months of follow-up group. The BMI presented a reduction from 36.08 kg/m² to 28.66 kg/m². Regarding the 12-month durability, the procedure was effective in 85% of the patients evaluated, with consolidation of fibrosis between the gastric folds, promoting the tubulization of the stomach (a format that mimics the surgical sleeve, with a reduction of more than 40% of the distensibility and gastric diameter, under endoscopic visualization).

Conclusion: ESG is safe and effective in the short and medium-term follow-up, with satisfactory durability of the gastric restriction (Tubulized Stomach). Follow-up with a nutritionist and psychologist has a positive effect on weight loss.

In addition, the use of five or more threads, more than 98 bytes, and the performance of the oversuture as reinforcement, increases the durability of the ESG, in the medium term, by maintaining the tubulized stomach. So, the oversuture U-pattern is more durable and more effective than the U-pattern.

Introduction: Obesity is a major global health problem associated with comorbidities such as diabetes, cardiovascular disease and cancer. Bariatric surgery is recognised to be the most effective weight loss intervention, but it is highly invasive, costly and can have serious side effects. Intra-gastric balloon (IGB) placement by endoscopy has been shown to be comparatively well tolerated and effective in patients with obesity. The more recently introduced duodenojejunal bypass liner (DJBL) has also been found to induce significant weight loss and dramatically ameliorate type 2 diabetes mellitus (T2DM) by causing nutrients to bypass the duodenum.

Aims & Methods: We aimed to compare the efficacy of DJBL and IGB for induction of weight loss in patients with obesity. In this retrospective, propensity score-weighted observational cohort comparison, participants with a body mass index (BMI) of 30-55 kg/m², aged 18-70 years, were randomized to DJBL or IGB for 12 months. Patients were matched for age, gender and BMI.

Study outcomes were summarised as the changes in percentage excess body weight lost (%EBWL), total body weight lost (TBWL), and percentage total body weight lost (%TBWL).

Results: A total of 140 (70 DJBL, 70 IGB) of the 321 patients screened were matched by propensity score. Mean age was 44.1 ± 10.4 years, and the patients were predominantly female (61.4%). Baseline BMI was 42.0 ± 8.1 kg/m². At month 6, %TBWL in the DJBL group was 11.0 ± 6.5% versus 15.1 ± 9.5% for IGB (*p* < 0.05). After 12 months, %TBWL for the two groups was 12.7 ± 7.5% (DJBL) versus 13.6 ± 9.7% (IGB) (*p* = 0.996). The IGB cohort experienced significantly more adverse events than the DJBL group.

Conclusion: Both IGB placement and DJBL induce clinically meaningful weight loss. Although IGB seems to induce clinically superior weight loss in the first 6 months, after 12 months, the final weight loss was found to be similar. However, DJBL was associated with lower rates of complications and adverse events.

P0192

COMPARATIVE EFFICACY AND SAFETY OF DIFFERENT INTRAGASTRIC BALLOONS IN A REAL-WORLD POPULATION – A PROPENSITY SCORE MATCHING ANALYSIS

N. Hein¹, S. Theodoridou², A. Aksan³, H. Krammer⁴, O. Schröder⁵, P. Staikov¹, J. Stein⁵

Contact E-Mail Address: nhein@khs-ffm.de

Introduction: The liquid-filled intragastric balloon is an established alternative in the treatment of obesity and has been shown to be well tolerated and effective. However, comparative data on the efficacy and safety of commonly used balloon systems are scarce.

Aims & Methods: The aim of this study was to compare the efficacy and safety of the most commonly used balloon systems in Europe under everyday conditions. In a retrospective, multicentre, observational study (conducted May 2016 to Jun 2021), 202 participants with a BMI of 30-55 kg/m², aged 18-65 years, were followed up for 6 months.

The study outcomes were percentage excess body weight lost (%EBWL), and percentage total body weight lost (%TBWL), the primary endpoint being TBWL% at 6 months; primary and secondary safety endpoints were rates of early balloon removal (within 3 weeks after implantation) and detection of periprocedural complications.

Results: Of 202 patients in total, 68 (57/68 female, 39.1 ± 11.1 years) received a MedSil® balloon (BSB Medical GmbH, Lingen, Germany) and 134 (99/134 female, 41.8 ± 10.5 years) an Orbera® balloon (Apollo Endosurgery, Austin, TX, USA). Mean body mass index (BMI) was similar in each of the two groups at baseline, at 34.2 ± 5.5 kg/m² vs. 36.3 ± 7.2 kg/m², respectively. At month 6, %TBWL was 13.3 ± 9.1% in the MedSil group and 11.7 ± 8.2% in the Orbera group (*p* > 0.05).

When patients were classified according to balloon fill volume (<500 mL, 500-600 mL or >600 mL), no significant volume-related differences in weight loss outcome were observed. However, in those with a greater balloon volume, the rate of adverse events was significantly higher (21.8% vs 36.4%). Early balloon removal occurred in 17.6% of patients with MedSil and 15.8% with Orbera (*p* = 0.483).

Conclusion: Both balloon systems, MedSil and Orbera, induce clinically significant weight loss and have similar outcomes. However, independent of balloon type, the patients with a greater balloon fill volume experienced significantly more adverse effects. Since weight loss outcomes did not differ significantly according to balloon volume, it would appear prudent to decide on fill volumes cautiously in order to minimise complications of balloon therapy.

P0193

THE IMPACT OF THE DUODENOJEJUNAL BYPASS LINER ON IRON HOMEOSTASIS

S. Hess¹, A. Aksan¹, O. Schröder², L. Tessmer², S. Ulrich-Rückert², J. Stein^{2,3}

¹Justus-Liebig University, Institute of Nutritional Science, Giessen, Germany, ²DGD Clinics Sachsenhausen, Department of Gastroenterology and Clinical Nutrition, Frankfurt am Main, Germany, ³Institute of Pharmaceutical Chemistry, Goethe University, Frankfurt am Main, Germany

Contact E-Mail Address: o.schroeder@em.uni-frankfurt.de

Introduction: Since obesity represents an increasing global concern and is associated with co-morbidities such as type 2 diabetes, hypertension and dyslipidaemia, it also increases the burden on health systems. In patients with severe obesity, bariatric surgery is being increasingly used to achieve both sustainable weight loss and metabolic improvement.

An alternative is the endoscopically inserted Endobarrier® duodenojejunal bypass liner (DJBL), which consists of an impermeable tube that excludes the duodenum and proximal jejunum from digestion. By allowing less fully digested food pulp to make contact with the mucosa only mid-jejunum, weight loss and improved diabetes control can be achieved. However, the question arises as to how this affects absorption of vitamins or essential trace elements such as iron, which is mainly absorbed in the anterior small intestine.

Aims & Methods: We aimed to measure iron parameters over the course of DJBL therapy to assess the impact of DJBL implantation on iron status in patients with obesity. The present study was conducted as a retrospective observational study in patients who underwent DJBL implantation at a specialist obesity centre in Frankfurt, Germany.

Following implantation, the DJBL remained in situ for 12 months. Laboratory parameters were assessed at baseline and after 1, 3, 6, 9 and 12 months, and BMI at baseline, 6 and 12 months. Blood samples were analysed for HbA_{1c}, CBC, blood lipids (LDL, HDL, triglyceride, cholesterol), iron status (serum ferritin, SF; transferrin; transferrin saturation, TSAT) and high-sensitivity CRP (hsCRP) using standard methodology. Inflammation was defined as hsCRP ≥5mg/dL.

Results: 17 patients with obesity (10f,7m; 52,4±10,6y), mean BMI 38.2±8.5 kg/m², were included in the study. Of these, 15 (88%) had been diagnosed with diabetes, 9 (53%) with hypertension and 14 (82%) with dyslipidaemia. DJBL implantation had a significant positive effect on BMI [(40.2 (32.4-65.2) at baseline; 33.1 (28.4-58.1) at month 6; 33.6 (26.7-7.8) at month 12 (p<0.001)] and HbA_{1c} [(8.3 (5.8-12.7) at baseline; 7.5 (5.1-10.5) at month 6; 6.8 (5.3-56.5) at month 12; p<0.001)] over the course of 12 months. During this period, no major changes were observed in levels of Hb, Hct, MCV, MCHC or transferrin. Only MCH showed a slight increase at 12 months (p<0.038).

However, during the implantation period, SF levels decreased consistently (p<0.047). TSAT showed no significant changes, remaining <20% at all time points. Similarly, hsCRP levels remained at ≥5 mg/dL. The observed decrease of ferritin levels <100 µg/L in the absence of changes in CRP concentrations may reflect increasing functional deficiency due to DJBL placement.

Conclusion: Implantation of the DJBL induced a sustained reduction in body weight. However, functional iron deficiency was observed at follow-up 6 months after implantation, with serum ferritin levels showing a constant decrease until the time of device removal.

These results need confirming in larger studies, but indicate a necessity for regular screening of iron parameters in patients undergoing DJBL therapy and consideration of intravenous iron replacement in patients diagnosed with functional iron deficiency.

GHEE BUTTER FROM BOVINE COLOSTRUM ALLEVIATES INTESTINAL INFLAMMATION IN DEXTRAN SULFATE SODIUM-INDUCED COLITIS IN MICE

A. Tarasiuk¹, M. Talar¹, J.B. Krajewska¹, A. Binienda¹, A. Bartoszek¹, A. Fabisiak², P. Mosinska¹, K. Dziedziczak¹, K. Niewinna¹, M. Salaga¹, J. Fichna¹

Introduction: Nutrition is closely linked to inflammatory bowel disease (IBD). The most recent research indicates that diet and nutrition play an important role in the disease's etiopathogenesis, though their specific role throughout the disease's clinical course is still unknown. Ghee butter from bovine colostrum (GBBC) is a clarified butter produced by heating milk fat to 40°C and separating the precipitating protein. Free fatty acid receptors (FFARs), which are expressed on intestinal epithelial cells, are members of the luminal-facing receptor family that respond to nutrients. As colostrum mainly contains fatty acids (FAs), immunoglobulins, maternal immune cells, we hypothesized that it may exert anti-inflammatory effects through FFARs.

Aims & Methods: Therapeutic activity and mechanism of action of GBBC was investigated in dextran sulfate sodium (DSS) mouse model of colitis, which recapitulates ulcerative colitis in humans. Quantitative biochemical examinations were performed to assess inflammation progress. qPCR was used to determine tight junctions (TJs) mRNA in distal colon samples collected from control, DSS-treated, DDS+GBBC-treated mice, and mice-treated DSS with the combination of GBBC+FFAR 1 or 4 antagonists. Enzyme-linked immunosorbent assays (ELISA) were performed to measure the level of inflammatory cytokines in colon tissue homogenates.

Results: GBBC (*per os*, 100µL/mouse) significantly reduced colon damage score, (myeloperoxidase) MPO activity, stool score, and concentration of fluorescein isothiocyanate (FITC) dextran in serum in comparison with DSS mice. GBBC notably reduced the level of TNFα, IL17, and IL23 while compared to the DSS mice group.

Moreover, administration of the FFAR4 antagonist followed by treatment with GBBC remarkably increased the anti-inflammatory effect of GBBC by reducing the production of IL17 and 23 and the IL6 level in comparison with DSS. Administration of GBBC alone restored the expression of OCLD1 and CLDN1 to the level of control as well as notably increased expression of these TJs mRNA above the basal level. FFAR1 antagonist combined with GBBC significantly potentiated this effect.

Importantly, attenuation of FFAR4 expression reversed the effect of GBBC, thus indicating that FFAR4 receptor may affect the expression of OCLD1 and CLDN 1 in the colon.

Conclusion: Our results suggest that GBBC displays anti-inflammatory effects in the mouse model of DSS-colitis, with the potential involvement of FFARs. This is the first study to show the anti-inflammatory potential of a nutritional supplement derived from GBBC in the colitis animal model.

SIGNIFICANT IMPROVEMENTS IN STRESS AND COGNITIVE OUTCOMES WITH BIFIDOBACTERIUM LONGUM 1714 SUPPLEMENTATION – A REAL-WORLD EXPERIENCE PROGRAMME IN ATHLETES

K. Sorensen¹, J. Kupuseravic², J. Jackman²

¹Novozymes, Medical Affairs, Cork, Ireland, ²ART Health Solutions, Science Team, Gateshead, United Kingdom

Contact E-Mail Address: kass@novozymes.com

Introduction: The physical and psychological demands of intense training have been associated with gut dysbiosis in athletes. The implications of this may extend beyond gastrointestinal health, affecting mental wellbeing and cognitive function via the microbiome-gut-brain axis¹. Clinical studies have demonstrated that probiotic supplementation with *Bifidobacterium longum* 1714 may improve perceived stress, energy/vitality and cognitive function^{2,3}. However, real-world data is limited.

Aims & Methods: This experience programme evaluated wellbeing and cognitive outcomes in athletes before and after 8 weeks of probiotic supplementation. Athletes volunteered or were referred to the experience programme by their nutritionist and/or coach, to receive a daily probiotic supplement containing *Bifidobacterium longum* 1714 (1x10⁹ colony-forming units) and B vitamins, for 8 weeks. Perceived sleep quality and energy levels were measured via an online survey prior to starting the programme, and at week 9 (post supplementation).

Perceived stress (Likert scale) and cognitive function including reaction time (Simple Reaction Time test), decision-making (adapted Stroop task), and distractibility (adapted Flanker task) were measured via the Omics™ app at weeks 1, 3, 4, 6 and 8. Data analysis compared the Loading period (weeks 1-4) vs the Observation period (weeks 6-8), including paired samples T-test for perceived stress and cognitive function data. Data are presented as the percentage of athletes who improved, and the average percentage change over time.

Results: 35 athletes completed the programme (75% aged 18-34 years, 25% aged 35-54 years; 81% male, 19% female; 61% team sports, 39% individual sports). During the observation period, 66% of athletes reported improvements in perceived stress (6% average improvement, p=0.015). Improvements in sleep quality and energy levels were reported in 58% and 54% of athletes respectively. Significant improvements in cognitive function were observed for reaction time (63% of athletes; 4% average improvement, p=0.008) and decision-making (72% of athletes; 5% average improvement, p=0.006). Distractibility improved in 43% of athletes (3% average improvement, p=0.196 ns). 87% would recommend the probiotic supplement to others.

Conclusion: These real-world data suggest that supplementation with *Bifidobacterium longum* 1714 may be associated with improvements in wellbeing and cognitive function in athletes, through modulation of the gut-brain axis. This supports the findings of cognitive benefits observed in clinical trials which investigated the bacterial strain without B vitamins in a general, healthy population^{2,3}, suggesting a strain-specific probiotic effect with broader applicability. Further research into the potential mode of action of this strain is warranted.

Contact E-Mail Address: cecilia.weznaver@vgregion.se

Introduction: Diet plays an important role in both triggering and alleviating gastrointestinal (GI) symptoms in irritable bowel syndrome (IBS). While research has focused on the effects of reducing poorly digested carbohydrates, i.e., the low fermentable oligo-, di-, monosaccharides, and polyols (FODMAP) diet, there are no studies investigating patients' experiences concerning the implementation of required dietary changes.

Aims & Methods: In this study, we aim to highlight the patients' perspectives on undergoing a dietary intervention with the aim to alleviate GI symptoms in IBS.

Within a qualitative design using inductive content analysis, semi-structured interviews were conducted in 19 patients (14 women, 20-68 years) with IBS undergoing dietary interventions. The patients were recruited from two dietary intervention groups in a randomized controlled trial, comparing three treatment options for 4 weeks; a diet low in total carbohydrates, a low FODMAP diet combined with traditional IBS dietary advice, and optimized medical treatment. The interviews were conducted at follow-up visits, 3 and 6 months after the end of the intervention.

Results: The structured dietary intervention was experienced as supportive, motivating, and educational. The IBS patients found the intervention necessary for both initiating and completing the dietary changes.

THEMES	SUBORDINATED CATEGORIES
Supportive, educational, and motivating	- Structured diet support - Support from others - Learnings by eating - For me and others
Multidimensional challenging	- Dominant dietary preferences - Limits in time and energy - Struggles within social contexts
Reflective and developing	- Self-awareness - Individual adjustments and developments

Table. Themes and subordinated categories of patients' experiences of dietary changes during structured dietary interventions in patients with IBS.

Even if the dietary changes could be challenging to implement, competing with many other dimensions of life like dominant dietary preferences, time, and social life, the experiences led to self-awareness and individual dietary adjustments. Reflections made during and after the intervention period helped the participants to develop various new ways to manage and implement the new diet in daily life. (Table)

Conclusion: Patients living with IBS experienced structured dietary support as being effective for implementing the dietary changes. Furthermore, the achieved self-awareness contributed to individual dietary adjustments that were not only related to alleviating GI symptoms but also functional solutions in everyday life. This study supports previous knowledge about the importance of providing support and education in health-care for patients living with IBS.

Introduction: Erythritol and xylitol are naturally occurring bulk sweeteners. Erythritol is absorbed at high rates in the intestine and excreted unchanged in the urine. Recently, a conversion of erythritol into erythronate in human cells has been proposed [1]. Xylitol is absorbed at about 50% in the small intestine and fermented at about 50% in the colon.

Aims & Methods: The aim of this study was to determine the absorption and metabolism of different concentrations of erythritol and xylitol. Seventeen healthy normal weight participants (10 women, BMI mean±SD: 21.6±1.3, range: 19.4-24.0 kg/m², age: 26±6, range: 18-41 years) received intragastric (i.g.) solutions of 10, 25 or 50g erythritol (arm 1) or 7, 17 or 35g xylitol (arm 2) on three study days in this parallel trial. Within each arm, the trial was randomized, double-blind and crossover for the doses administered. Plasma samples were collected at fixed time intervals to assess the concentrations of erythritol, xylitol and erythronate with gas chromatography-mass spectrometry. Data were analyzed using linear mixed model.

Results: A dose-ranging absorption of erythritol was found. The erythritol plasma concentrations increased in response to the three i.g. loads (AUC₁₈₀: 10g vs. 25g, p<0.001; 10g vs. 50g, p=0.006; 25g vs. 50g, p=0.034). We found also a dose-ranging metabolism of erythritol into erythronate (AUC₁₈₀: 10g vs. 25g, p<0.001; 10g vs. 50g, p=0.001; 25g vs. 50g, p=0.024). The metabolic ratio AUC_{erythritol}/AUC_{erythronate} was highest with 10g erythritol and decreased with higher doses. Absorption of xylitol was low and could not be detected in any of the subjects after the low dose, but

in some subjects after the medium dose and in all subjects after the high dose. No erythronate levels could be detected in any of the subjects after any dose of xylitol.

Conclusion: In this study we showed that:

- Erythritol is absorbed in a dose-ranging manner;
- Erythritol is metabolized into erythronate in a dose-ranging manner, confirming previous reports;
- The decreasing metabolic ratio with higher doses of erythritol indicates that an increasing fraction of erythritol is metabolized into erythronate;
- There is no evidence that xylitol is metabolized into erythronate.

Introduction: Dietary fibers are indigestible by the human host, but fermented by the gut microbiota. Emerging evidence supports the importance of dietary fibers in maintaining gut health and a beneficial gut microbial composition and function.

However, if and how cooking methods affect dietary fiber content has been greatly overlooked, but may represent an important confounder in dietary studies and gut microbial research.

Aims & Methods: We aimed to study the effect of cooking methods on dietary fiber content and composition in commonly used food products using standard cooking methods and contemporary analytical methods. Potato, onion, oats, and broccoli were selected, and processed using standard cooking techniques (raw, cooking, steaming, baking, and frying). Aliquots of 250 g to 500 g were stored at -20°C. We combined the ISO 17025 validated AOAC 2011.25 and AOAC 2017.17 method to estimate dietary fiber content and composition, using enzymatic gravimetric liquid chromatography (Eurofins, the Netherlands).

Since samples may have taken up fat and water content might change after exposure to the different cooking methods, additional tests and calculations in dried and defatted material were performed to account for this. Only the oats samples did not undergo defatting as the fat content was not expected to exceed 10%.

Results: After food processing, the total dietary fiber (DF) and fractions of insoluble high molecular weight DF, soluble high molecular weight DF and low molecular weight DF remained fairly constant (table 1).

The main difference within a product type was for the onion samples where insoluble high molecular weight DF was lower and soluble high molecular weight DF higher after both cooking methods.

Furthermore, when overlaying the chromatograms, a decrease of fructose was seen in the pan-fried samples, possibly due to the involvement of these sugars in Maillard or caramelization reactions. A higher variation was also noted in the potato samples, possibly related to changes in resistant starch (RS2) and the formation of resistant starch (RS3).

Sample type	Oats - Raw	Oats - Cooked	Oats - Oven baked	Broccoli - Oven baked	Broccoli - Steamed	Onion - Raw	Onion - Steamed	Onion - Pan-fried	Potato - Pan-fried	Potato - Oven baked	Potato - Steamed
Insoluble High Molecular Weight DF	8.4	9.7	9.4	43.5	40.9	16.5	12.2	10.4	8.0	10.4	8.3
Soluble High Molecular Weight DF	4.3	4.4	2.7	16.1	15.6	4.1	10.2	9.6	5.5	5.9	4.7
Low Molecular Weight DF	0.8	0.8	0.8	1.4	2.0	20.9	20.3	29.5	2.2	2.6	1.8
Total DF	13.5	14.9	12.9	61.1	58.4	41.6	42.8	49.5	15.7	18.9	14.8

Table 1: Dietary fiber (DF) results reported on % w/w in the total carbohydrate content of the dried and/or defatted samples.

Conclusion: Cooking methods only negligibly affect dietary fiber content and composition, and should therefore not be taken into account as a major confounder in dietary and gut microbial studies.

Disclosure: Nothing to disclose.

Introduction: Obesity has a negative impact on many health outcomes. We aimed to identify the prevalence of gastrointestinal symptoms compatible with one or more of the specified disorders of gut-brain interaction (DGBI) among patients with obesity, and to study the effect of three obesity treatments on Quality of life (QoL).

Aims & Methods: We used baseline and two-year follow-up data from a prospective non-randomized cohort study including 1121 patients with BMI ≥ 35 kg/m² referred for treatment of obesity in Region Västra Götaland, Sweden, between May 2015 and November 2017, the BARIatic surgery SUBstitution and Nutrition (BASUN) study. Patients completed the Rome III diagnostic questionnaire before being treated with Roux-en-Y gastric bypass (RYGB), sleeve gastrectomy (SG), or medical treatment (MT) including a period with very low energy diet according to clinical guidelines and the patient's preference.

Additional measures used to characterize the cohort included validated questionnaires assessing anxiety (BAI), depression (PHQ-9), and quality of life (QoL) (EQ-5D VAS scale). The effect of treatment on QoL in patient

with vs. without DGBI diagnoses at baseline was assessed using Two-way repeated measures ANOVA. Data are presented as mean $\pm$ SD, percentage (95%CI), or mean difference (95% CI for difference).

Results: In total, 911 patients (75% female, 44 $\pm$ 13 years, 42 $\pm$ 5 kg/m², 40% RYGB, 21% SG 39%, MT) completed the Rome III questionnaire at baseline and 660 patients (32 $\pm$ 6 kg/m²) at follow-up. The proportion of obese patients fulfilling diagnostic criteria for one or more DGBI at baseline and at follow-up was 61.8% (58.7%, 64.8%) and 55.3% (51.5%, 59.1%), respectively. Details about the prevalence of the different DGBI diagnoses per GI region at baseline and follow-up are given in the table.

In both patients with and without a DGBI at baseline, the QoL significantly improved over time across all treatment groups (Within-Subjects treatment*time effect: F(2, 387)=14.7, p<0.001 (with DGBI) and F(2, 237)=9.2, p<0.001 (without DGBI)).

However, only in patients with a DGBI at baseline, the main effect of treatment on average QoL scores across time was statistically significant (Between-Subject treatment effect: F(2, 387)=8.5, p<0.001 (with DGBI) and F(2, 237)=1.3, p=0.27 (without DGBI)). Bonferroni adjusted pairwise comparisons showed that patient with a DGBI at baseline had significantly more improvement of QoL when receiving RYGB compared to MT (Mean difference of EQ-5D vas scale of 7.7 (3.2, 12.1)).

Disorder of gut-brain interaction	Baseline			2-year follow-up		
	Roux-en-Y gastric bypass	Sleeve gastrectomy	Medical treatment	Roux-en-Y gastric bypass	Sleeve gastrectomy	Medical treatment
Esophageal disorders	29.2 (24.5, 34.3)	22.4 (16.5, 29.3)	18.5 (14.5, 23.1)	12.9 (8.9, 17.8)	21.7 (14.6, 30.4)	13.6 (9.3, 18.9)
Gastroduodenal disorders	27.2 (22.6, 32.2)	19.0 (13.4, 25.6)	27.1 (22.4, 32.1)	29.0 (23.4, 35.2)	22.4 (15.2, 31.1)	20.2 (15.1, 26.1)
Bowel disorders	39.0 (33.8, 44.3)	39.1 (31.8, 46.8)	36.0 (30.9, 41.3)	38.0 (31.9, 44.5)	35.3 (26.7, 44.8)	28.6 (22.9, 34.9)
Anorectal disorders	10.7 (7.6, 14.4)	11.6 (7.2, 17.2)	7.7 (5.1, 11.1)	9.1 (5.8, 13.5)	9.6 (4.9, 16.5)	6.0 (3.2, 10.1)

Data are presented as percentages (95%CI).

Conclusion: The majority of patients suffering from obesity fulfil criteria for one or more DGBI. After treatment to reduce weight, the proportion of patients having a DGBI has mostly decreased, but in some treatment arms, the proportion of patients having a gastroduodenal disorder has increased. In patients with a DGBI before treatment, the QoL of patients receiving RYGB improved significantly better compared to MT.

Introduction: Achalasia cardia is characterized by absence of normal peristalsis and relaxation of lower esophageal sphincter leading to dysphagia and variable degree of weight loss. As a consequence, cases with achalasia are at significant risk of malnourishment.

Aims & Methods: In this study, we aimed to perform a comprehensive nutritional assessment of untreated cases with achalasia and compare them with cases with functional bowel diseases.

This is a prospective study including consecutive cases diagnosed with achalasia at a tertiary care centre (December 2021 to April 2022). The diagnosis of achalasia was established using standard protocol. Nutritional assessment was performed using biochemical parameters (hemoglobin, serum albumin, serum pre-albumin, serum iron, serum calcium, serum vitamin D and B12), triceps fold thickness (TSF), mid-arm circumference (MAC), mid-arm muscle circumference (MAMC), hand grip strength.

Subjective global assessment (SGA) was used to characterize these patients into well nourished, moderately malnourished and severely malnourished groups. Cases diagnosed as functional bowel diseases (functional dyspepsia, irritable bowel syndrome, functional constipation) and matched for age and gender served as controls. Multivariate analysis was performed to assess for the risk factors formalnourishment in cases with achalasia.

Results: 118 cases (41.2±13.9 years, 61% males) were diagnosed with achalasia during the study period and compared with 200 matched controls (43.4±11.9 years, 69% males). The subtypes of achalasia included type I in 20 (16.9%), II in 90 (76.3%) and III in 8 (6.8%).

Overall, 53 (44.9%) cases with achalasia were moderately (38.1%) or severely (6.8%) malnourished. The mean symptom duration was non-significantly higher in the malnourished cohort (26.8±26.4 vs 24.5±20.9 months; $p=0.604$). Mean Eckardt score was significantly higher in the malnourished cases with achalasia (6.8±1.8 vs 5.9±1.8; $p=0.014$). The proportion of malnourished patients (SGA) were significantly higher in type I achalasia as compared to type III (60% vs 14.3%; $p=0.038$).

As compared to controls, the mean values were significantly lower in cases with achalasia for serum albumin (4.3 vs 4.7; $p=0.024$), pre-albumin (19.4 vs 25.2; $p=0.001$), serum calcium (8.6 vs 9.7; $p=0.012$), vitamin D (17.6 vs 25.2; $p=0.001$), serum iron (58.2 vs 78.4; $p=0.001$), triceps fold thickness (9.2 vs 10.2; $p=0.002$) and hand grip strength (21.5 vs 27.4; $p=0.001$). On multivariate analysis, symptom severity (Eckardt score) was a significant predictor of malnourishment in cases with achalasia.

Conclusion: Cases with achalasia are at significant risk of malnourishment as compared to those with functional bowel diseases. Increased symptom severity is an independent risk factor for malnourishment in these cases. (NCT05161923)

ORTHOREXIA NERVOSA IS MORE PREVALENT IN PATIENTS WITH IRRITABLE BOWEL SYNDROME COMPARED TO HEALTHY CONTROLS

C. Tuck¹, M. Foyster¹, N. Sultan¹, M. Tonkovic¹, A. Govus¹, J. Biesiekierski^{1,2}

Contact E-Mail Address: C.Tuck@latrobe.edu.au

Introduction: Concern has been raised that use of restrictive dietary interventions, such as the low fermentable carbohydrate diet in irritable bowel syndrome (IBS), or nutrition for peak sport performance may increase the risk of disordered eating. Orthorexia nervosa is a form of disordered eating where people restrict their diet based on its quality rather than quantity, becoming so obsessed with eating healthily that it leads to malnutrition or impaired daily functioning. Little is known about the prevalence and risk factors of orthorexia in these proposed at-risk groups.

Aims & Methods: The aim of this cross-sectional survey was to measure the prevalence of orthorexia in participants with IBS, athletes, people with eating disorders (ED), and healthy controls (HC). Participants with IBS (Rome IV), athletes (minimum 5 hours training per week), ED partici-

pants (assessed via DSM-5 with mild-moderate symptoms in past 5 years), and healthy controls were recruited via online advertisement. Orthorexia was assessed utilising the 'Sick, Control, One-stone, Fat, Food' (SCOFF, ≥ 2 indicating disordered eating) and eating habits questionnaire (EHQ). Additional questionnaires assessed gastrointestinal symptoms (IBS-severity symptom score), and the eating motivations survey (TEMS). Data was analysed using one-way ANOVA as appropriate.

Results: Two hundred and four IBS, 54 athletes, 34 ED participants, and 112 healthy controls completed the study. Significantly more orthorexic traits were exhibited in the IBS and ED cohorts compared to athletes and healthy controls when measured by the SCOFF (IBS, ED, athletes, and HC respectively, 54% vs 71% vs 41% vs 31%, $p<0.01$) and in all 3 groups compared to the healthy controls when measured by the EHQ (IBS, ED, athletes and HC respectively, mean±SD, 75±20 vs 73±22 vs 76±17 vs 60±19, $p<0.01$). There were no significant differences between IBS and ED for either the SCOFF or EHQ. Participants with one or more food intolerance rated higher on the EHQ compared to those with none (95% CI: [6, 14], $t(245)=-4.62$, $p<0.01$). Using the TEMS, 'health' ($r=0.32$ (95% CI [0.21, 0.42])), 'natural concern' ($r=0.42$ (95% CI [0.31, 0.51])) and 'weight control' ($r=0.44$ (95% CI [0.34, 0.52])) were motivations positively associated with orthorexia.

Conclusion: These findings suggest that orthorexia is a significant concern, especially in IBS where more than half of patients are displaying orthorexic traits, with similar prevalence to those with a known eating disorder. Presence of food intolerances, and motivations of healthfulness and weight control may be predictors of higher tendency towards orthorexia.

Clinicians should be aware of orthorexia and consider if a restrictive diet is appropriate in individuals with IBS. Future prospective studies should further evaluate orthorexia traits within this patient group, particularly those using restrictive dietary therapies.

Disclosure: No conflict of interest to declare.

THE EFFECT OF RIBOFLAVIN SUPPLEMENTATION ON THE SYSTEMIC REDOX STATUS IN HEALTHY VOLUNTEERS: A POST-HOC ANALYSIS OF THE RIBOGUT TRIAL

A.T. Otten¹, A.R. Bourgonje¹, M. Sadaghian Sadabad², J.Z.H. von Martels¹, M.L.C. Bulthuis³, K.N. Faber¹, H. van Goor³, G. Dijkstra¹, H.J.M. Harmsen²

Introduction: Riboflavin (vitamin B₂) is a redox-active vitamin that plays a pivotal role in human energy metabolism. Riboflavin may have beneficial health effects by increasing extracellular antioxidant capacity, thereby alleviating oxidative stress. Reduced levels of free thiols in blood reflect systemic oxidative stress, since they are readily oxidized by reactive species. In this study, we aimed to investigate the potential of riboflavin supplementation to improve the systemic redox status in healthy volunteers.

Aims & Methods: This study was a post-hoc analysis of the Ribogut study, a randomized, double-blind, placebo-controlled human intervention trial that investigated the effect of riboflavin supplements on the gut microbiota composition of healthy individuals. Serum free thiols were quantified before and after intervention and adjusted to serum albumin levels. Changes in albumin-adjusted free thiols were analyzed, as well as potential associations with routine laboratory parameters and fecal bacterial quantification by fluorescence in-situ hybridization (FISH).

Results: A total of 99 participants were randomized for a two weeks intervention of either placebo ($n=34$), riboflavin 50 mg daily ($n=32$), or riboflavin 100 mg daily ($n=33$). At baseline, no significant differences in albumin-adjusted serum free thiols were observed.

After intervention with either placebo or riboflavin, albumin-adjusted serum free thiols did not significantly change ($P>0.05$), however, observed changes were inversely associated with changes in C-reactive protein (CRP) levels ($r=-0.22$, $P<0.05$). At baseline, albumin-adjusted serum free thiols were positively associated with fecal relative abundances of *Faecalibacterium prausnitzii* ($P<0.01$).

Conclusion: Riboflavin did not change the systemic redox status in healthy individuals. Observed changes in albumin-adjusted free thiol levels were negatively associated with changes in CRP levels, confirming that inflammation and oxidative stress are two highly associated processes. Strikingly, albumin-adjusted free thiols were independently associated with relative abundances of fecal *F. prausnitzii*, which may suggest a potential host redox-microbiota interaction.

GUT MICROBIOTA AND ITS ASSOCIATION WITH SMALL INTESTINAL BACTERIAL OVERGROWTH IN PATIENTS WITH HYPERLIPIDEMIA

K. Kvit¹, N. Kharchenko²

¹Danylo Halytsky Lviv National Medical University, Therapy №1 and Medical Diagnostics, Lviv, Ukraine, ²Shupyk National Healthcare University of Ukraine, Gastroenterology, Dietology and Endoscopy, Kyiv, Ukraine

Contact E-Mail Address: akskris88@gmail.com

Introduction: The variety of microbes colonizing the human gut is almost 10 times more than the total cells in a human. Current evidence suggests that the intestinal microbiota is involved in cardiovascular disease occurrence with the host-microbe interaction regulating metabolic pathways. Recent studies suggest that the characteristics of the gut microbiota are altered in hyperlipidemia patients, and also, that small intestinal bacterial overgrowth (SIBO) contributes to the pathogenesis of this condition. However, such associations remain poorly investigated and characterized. The LPS from intestinal flora bacteria can induce a chronic subclinical inflammatory process with further atherosclerosis development. Additionally, microbiota injuries through activation of TLR4 pathway could impact on lipid metabolism in the liver.

Aims & Methods: The aim of this study was to examine the composition of gut microbiota and its correlation relationship with SIBO in patients with hyperlipidemia. TLR4 serum level was examined as one of the proinflammatory factors that could play a substantial role in gut-liver-cholesterol axis.

105 patients with hyperlipidemia (average age 42.52 ± 2.6) with an average BMI of 26.08 ± 0.81 were examined in Danylo Halytsky Lviv National Medical University (Lviv, Ukraine). 52 control subjects (average age 37.38 ± 2.6), an average BMI of 24.01 ± 0.75 . All control subjects had normal lipid range and no history of coronary disease. Determination of microbial composition at the level of major microbial phyla was carried out by identification of Bacteroidetes, Firmicutes, and Actinobacteria DNA with quantitative real-time PCR (qRT-PCR), using gene-targeted primers. The examination of lactulose breath test was proved to patients of both groups. Quantitative detection of TLR4 in the serum was realized by using the Cusabio Elisa kit.

Results: The composition of microbiota was significantly different in separate groups of species between patients with and without hyperlipidemia. Bacteroidetes in main group amounted to $40.70\pm25.43\%$, Firmicutes –

$39.43\pm23.77\%$, Actinobacteria – $8.95\pm9.41\%$, while in the control group - Bacteroidetes $52.98\pm13.62\%$, Firmicutes $33.85\pm12.47\%$, Actinobacteria – $5.36\pm1.76\%$. Firmicutes/Bacteroidetes index in the main group averaged 2.98 ± 1.61 , in control – 0.75 ± 0.54 . Negative correlation between Bacteroidetes and Firmicutes ($r=-0.84$), Bacteroidetes and Actinobacteria ($r=-0.52$), and Bacteroidetes and Firmicutes/Bacteroidetes index ($r=-0.74$) was marked in patients of the main group. Additionally, there was a positive correlation between triglycerides, cholesterol and Actinobacteria ($r=0.48$). SIBO prevalence was 58,5% in main group, while in control - 31%. TLR4 serum level was 2.67 ± 1.05 ng/mL in hyperlipidemia group, 1.23 ± 0.99 ng/mL in controls (normal range 1,25-2,5 ng/mL).

Conclusion: There is an essential role of microbiota in lipid metabolism due to the fact of SIBO prevalence in patients with hyperlipidemia in comparison with the control group (58,5% vs. 31%). Moreover, the TLR4 serum level that is usually activated by LPS as the result of SIBO was higher more than the normal range in patients with hyperlipidemia (2.67 ± 1.05 ng/mL).

Additionally, the composition of the microbiota was different between both groups - Actinobacteria and F/B index were significantly higher in patients with hyperlipidemia. Actinobacteria was in correlational relationship with triglycerides and cholesterol level.

Disclosure: Nothing to disclose.

IDENTIFYING ARFIDS IN SEVERE DGBIS WHO PRESENT TO TERTIARY CARE GI PSYCHOLOGY AND DIETETICS

L.D. Martin^{1,2}, K. MartinKova³, C. Perrin², C. Brugaletta², A. Emmanuel², N. Zarate-Lopez²

¹University College London Hospital, Nutrition & Dietetics, London, United Kingdom, ²University College London Hospital, GI Physiology Unit, London, United Kingdom, ³University College London, London, United Kingdom

Contact E-Mail Address: lee.martin1@nhs.net

Introduction: Avoidant Restrictive Food Intake Disorder (ARFID) is an eating disorder associated with anxiety and food avoidant/restrictive behaviours which are also commonly observed in Disorders of Gut Brain Interaction (DGBI). ARFID diagnostic criteria defined in the Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) is open to clinical interpretation, making identification difficult.

We therefore aimed to identify patients with a severe DGBI who presented with DSM-5 ARFID and examine their psychological and nutritional characteristics compared to Non-ARFID presentations.

Aims & Methods: The cohort under investigation included all patients with a Rome IV diagnosed DGBI ($n=33$, 88% female, mean age 39 ± 15 years, 42% Irritable Bowel Syndrome, 39% Functional Dyspepsia). Severity was defined as requiring both GI Psychology and Neurogastroenterology Dietitian input in tertiary care over an 18 month period (May 2018 to October 2019). Medical notes were retrospectively reviewed and a diagnosis of ARFIDs was applied if the DSM-5 Criteria was met along with severity cut offs chosen by our unit for Criteria A as follows:

- A1. Weight loss (severely or very severely underweight (BMI $\leq 17\text{kg/m}^2$) and/or experienced $>10\%$ weight loss),
- A2. Nutritional Deficiency (defined as eating ≤ 5 foods and/or laboratory assay),
- A3. Dependence on enteral tube feeding (ETF) or oral nutrition supplements (ONS) (defined as $\geq 50\%$ of daily caloric intake from ONS or any ETF not required by a concurrent medical condition),
- A4. Psychosocial impairment (defined as symptoms that impact on usual daily activities).

ARFID sub type was also ascribed. Characteristics measured included dietary restrictions (if specific diets were followed or specific foods were avoided), medical conditions, severe anxiety (≥ 15 on GAD-7), severe depression (≥ 15 on PHQ-9) and high somatic burden (≥ 13 on PHQ-12).

Results: 11 patients (33%) met DSM-5 ARFID diagnostic criteria. 100% had the concern of aversive consequences subtype. Applied severity Criteria A was met as follows; A1(weight loss)=82% (n=9), A2(Nutritional Deficiency)=9% (n=1), A3(ONS/ETF Dependence)=54% (n=6), A4(Psychosocial)=100% (n=11).

When comparing ARFID vs Non-ARFID a non-significant higher percentage of severe anxiety (83% vs 45%), severe depression (57% vs 50%) and high somatic symptoms (50% vs 30%) were observed in ARFID.

ARFIDs were more likely to have a chronic pain disorder (0=0.016), and ≥ 3 medical conditions ($p=0.026$). In non-dependent ONS/ETF ARFID (n=5/11) 60% had BMI $\leq 17\text{kg/m}^2$ and 20% BMI $\leq 18\text{kg/m}^2$, however there were no differences in dietary restrictions compared to Non-ARFID (n=22), none of whom were underweight (BMI $\leq 18.5\text{kg/m}^2$).

Conclusion: ARFIDs is present in one third of severe DGBIs who require both dietetic and psychological tertiary care support, and awareness of DSM-5 criteria is essential. In particular suspicion of ARFID should be raised in those who present with aversive consequences of eating associated with significant weight loss ($\geq 10\%$), BMI ≤ 17 and/or dependence on ONS or ETF.

Psychosocial impairment is perhaps of less relevance in identifying ARFID as it is already recognised as part of diagnostic criteria in DGBIs. Despite no differences in dietary restrictions between Non-ARFID and non-dependent ONS/ETF ARFID, 80% were underweight indicating restriction of volume rather than variety is an important dietary factor to consider.

The findings of significant chronic pain conditions in ARFIDs, which shares similar fear avoidance behaviours, plus the high prevalence of severe anxiety indicate factors to explore further.

Disclosure: Nothing to disclose.

P0205

RISK STRATIFICATION, PREVENTION AND OCCURRENCE OF REFEEDING SYNDROME IN ADULTS USING A COMPUTER-BASED TOOL: A PROSPECTIVE COHORT STUDY

Introduction: Refeeding syndrome (RS) is defined as severe fluid and electrolyte shift during oral, enteral (EN) or parenteral nutrition (PN). Incidence can reach 30%, according to the risk prevalence (1). Prevention includes identification of individuals at risk, controlled nutritional intake, and vitamin/electrolyte replacement. (2) The aim of this prospective cohort study is to assess the occurrence of RS based on computer-based risk stratification and application of a systematic nutrition protocol.

Aims & Methods: All consecutive, adult patients requiring medical nutrition therapy with EN or PN outside the ICU were considered. Exclusion criteria included other reasons for electrolyte shifts (ex renal failure), indications for EN or PN apart malnutrition (ex stroke with swallowing disorders, acute abdominal surgery) and an estimated length of stay (LOS) < 5 days. Patients were classified according to a computer-based risk stratification application in low, moderate and high RS risk and medical nutrition modalities were applied accordingly regarding initial protein-caloric intake and progressive increase in administration rate.

All patients received electrolyte supplementation (phosphate and magnesium) or correction of preexisting electrolyte disturbance (hypokalemia), as well as intravenous thiamine administration prior to initiating EN or PN. Imminent RS (electrolyte shift such as hypophosphatemia, hypokalemia and/or hypomagnesemia) and manifest RS (electrolyte shift AND clinical criteria such as oedema/tachycardia/tachypnea) was recorded according to predefined criteria. Descriptive statistics were expressed in median (min-max) and %.

Results: : From 1/02/21 to 1/02/22, 213 patients were screened and 172 were included; 91 men (53%), age: 62,5 (17-92), body mass index: 20,3 kg/m² (11,4-42) and serum prealbumin: 0,12 gr/L (0,05-0,38). Eighty-four (48,8 %) patients had cancer, 56 (32,6%) benign digestive disorders and 10 (5,8%) psychiatric disease (eating disorders).

Computer-based risk stratification for RS identified a high or moderate risk in 166 (96,5%) and 6 (3,5%) patients, respectively. Seventy-seven (44,8 %) patients received EN, 89 (51,7 %) PN and 6 (3,5 %) had both. Imminent RS was identified in 38/172 (22,1%) patients and managed by electrolyte supplementation and adapting nutrition intake.

One patient (0,6%) presented manifest RS, requiring interruption of PN and administration of diuretics. LOS was 19 days (5-58) and 43 (25%) patients were still hospitalized 30 days after admission. Medical nutrition could be stopped in 72 (41,8 %) patients because of sufficient oral intake. Twenty-one (12,2%) patients died during the 30-day period following admission.

Conclusion: Computer-based risk stratification combined with application of a systematic nutrition protocol including thiamine and electrolyte supplementation and/or correction prior to medical nutrition, as well as adapting medical nutrition administration, may help in mitigating RS.

COMPLICATIONS OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) TUBE PLACEMENT BY PROVIDER TRAINING: A RETROSPECTIVE ANALYSIS

P. Ziegler¹, B. Schwartz¹, A. DeMeo², J.-M. Hermes¹, G. Swanson³

Introduction: Percutaneous endoscopic gastrostomy (PEG) is well established as a minimally invasive method of supplementing nutrition in patients with a variety of clinical presentations and nutrition requirements. In recent years, this endoscopic technique has been widely adopted in a multidisciplinary fashion and enteral nutrition is often preferable to starting parenteral nutrition due to complications and expense. Although PEG tube insertion is usually considered a safe procedure, complications can occur at a variable rate based on the study population.¹

One of the challenging aspects of evaluating the existing literature might be due to the variability of studies as each study defines complications differently. PEG tubes are placed by both gastroenterologists and surgeons alike and there have been no studies, to our knowledge, that have examined differences in outcomes, nor have they commented on the benefit of extended formal endoscopic training.

This study aims at assessing the overall complications of PEG tube placement according to endoscopic training in both surgical and gastroenterology sub-specialties.

Aims & Methods: This was a single-center retrospective chart review study examining PEG tube placement by provider specialty with gastroenterology or general surgery over two years. Peri-procedural complication rates were compared within 30 days of endoscopy.

Disease severity was compared using the American Society of Anesthesiology (ASA) classification. A total of 330 patients were included in the study; 70 of these patients underwent PEG tube placement by gastroenterology and 260 patients underwent placement with general surgery.

Results: At baseline, ASA class scores (gastroenterology mean 3.14, standard deviation 0.601 (n=69, one absent ASA class documentation event) vs surgery (n=260) mean 3.138, standard deviation 0.485) were not statistically significantly different between the gastroenterology and surgery groups by Mann-Whitney U-test (p=0.8186). Gastroenterology PEG tubes were associated with statistically significantly lower rates of overall complications (12.86% vs 28.85%, p=0.005) as well as major bleeding events (0% vs 6.92%, p=0.017) and peri-stomal leakage or exudate (0% vs 5.77%, p=0.047).

There were no statistical differences in rates of necrotizing fasciitis, internal organ injury, aspiration pneumonia, buried bumper syndrome, sepsis, peri-stomal infection, or gastric outlet obstruction between gastroenterology and surgery.

Conclusion: These results suggest that there may be differences in rates of PEG tube placement complications between gastroenterology and general surgery based on the endoscopic training of the operating physician.

This study could provide insight into the importance of more extensive endoscopic training, post gastrostomy follow-up, and management of PEG procedures.

Given this was a single-center retrospective study, further review of larger populations will provide a better understanding of the differences in complication rates between different provider specialties to continue to improve outcomes and deliver quality care.

MALNUTRITION WITH LOW MUSCLE MASS IS COMMON AFTER WEANING OFF HOME-PARENTERAL NUTRITION FOR CHRONIC INTESTINAL FAILURE

L. Wauters^{1,2}, S. Dermine², B. de Dreuille², J. Bettolo², C. Hutinet², E. Lecoq², L. Billiauw², A. Nuzzo², C. Stefanescu², X. Treton², O. Corcos², Y. Bouhnik², F. Joly²

Introduction: Although a formal definition and classification of intestinal failure (IF) was proposed [1], the differences in nutritional outcomes are still unclear. Weaning off home-parenteral nutrition (HPN) is more likely in short bowel syndrome (SBS) patients with a colon-in-continuity and/or use of GLP2-analogues, but the impact has not been compared to other subgroups.

Aims & Methods: Differences in outcomes were studied between subgroups of adult IF patients who were followed and weaned off HPN at a single tertiary care center (2019-2022). IF was classified as temporary (small bowel >2m after continuity surgery) or definite SBS (enterostomy or small bowel <2m with colon-in-continuity), dysmotility, mucosal disease and fistulas. Nutritional markers included BMI, body composition using bioimpedance analysis (fat free mass index or FFMI) and serum albumin levels. Functional markers included handgrip strength (HGS). Changes during HPN and follow-up (FU) after weaning were compared between groups and proportions of malnutrition defined using the Global Leadership Initiative on Malnutrition (GLIM)-criteria [2].

Results: In total, 87 patients (46 female, median (IQR) age 58 (47;70) years) were included, with similar demographics between groups. Duration of HPN significantly differed and temporary (n=23) or definite SBS (enterostomy (SBS-I, n=8), jejuno-colonic (SBS-JC, n=23) or jejuno-ileo-colonic (SBS-JIC, n=14) anastomosis) and dysmotility (n=11) were most common (table), followed by mucosal disease (n=5) and fistulas (n=3) which were excluded from subgroup analyses. Changes in BMI during HPN differed between groups (table), with no change in temporary SBS but significant increases in definite SBS and dysmotility (all p<0.01) patients.

In contrast, albumin levels increased in both temporary (p<0.0001) and definite SBS or dysmotility (all p<0.01) patients with no between-group differences (table).

Period/ changes	Temporary SBS (n=23)	SBS-JC (n=18)	SBS-JIC (n=14)	SBS-I (n=8)	Dysmotility (n=11)	p-value
HPN (weeks)	11 (8;23)	42 (28;66)	29 (15;79)	79 (35;134)	47 (16;109)	<0.0001
BMI (kg/m ²)	0.2 (-1.8;1.4)	1.9 (1.2;9)****	1.4 (0.1;2.9)**	4.5 (2.4;6.4)**	1.7 (0.8;4.7)**	0.005
albumin (g/L)	12.9 (3.7;20.9)****	10.6 (2.7;17.3)**	11.9 (5.3;18.6)**	11.5 (4.5;12.4)**	8.4 (4.8;13.9)**	0.73
FU (weeks)	31 (15;45)	34 (11;76)	27 (13;83)	41 (10;55)	45 (18;79)	0.25
BMI (kg/m ²)	1.5 (-0.4;2.8)	-1.6 (-2.9;-0.6)*	-0.4 (-1.6;1)	-0.3 (-1.4;0.3)	2.5 (0.3;6)*	<0.001
albumin (g/L)	2.3 (-1.3;6.9)	2.7 (0.7;4.9)	3.6 (2.1;9.7)	-0.7 (-2.1;0.7)	1.2 (-3.6;4.8)	0.3

Legend: p-values given for between-group analysis, within-group: *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001

Table.

Duration of FU was similar between groups and differences in BMI were explained by a significant decrease in SBS-JC ($p=0.01$) but increase in dysmotility ($p=0.02$) patients with stable albumin levels (table). Malnutrition (GLIM) was present in 41.7% of all patients, of which 86.7% with reduced muscle mass (FFMI). Of note, BMI remained stable in SBS-JC patients on GLP2-analogues ($n=5$), of which none were malnourished.

Finally, HGS significantly increased (median 4 (0.1;8.4) kg, $p<0.0001$) during FU in all patients, including SBS-JC (median 7.1 (2.9;9.4) kg, $p=0.03$).

Conclusion: Malnutrition is common after weaning off HPN for chronic IF, with alterations in body composition including low muscle mass. Despite significant weight loss in SBS-JC patients after weaning, the nutritional and physical implications are rather limited considering the increased muscle strength. Compared to the beneficial outcomes with GLP2-analogues, close follow-up is needed in SBS patients after weaning off HPN.

Introduction: Percutaneous endoscopic gastrostomy (PEG) related complications usually occur shortly after hospital discharge and sometimes motivate readmission for inpatient treatment. Mild local infections at the tube insertion site have been reported in approximately 11% of cases and require only local treatment. Recent studies have reported severe complications (acute and during feeding) in 3.8%–10% of PEG patients (1).

A prospective study has shown that in the absence of adequate gastrostomy aftercare, 6-month hospital readmission rates are as high as 23% (2).

Aims & Methods: The aim of this study was to assess the rate of complications and hospital readmissions in PEG patients. Demographic data, early and unscheduled PEG replacements and gastrostomy complications and readmission rates were retrospectively collected from a cohort of discharged gastrostomy patients regularly observed in an outpatient nurse clinic over a 4-year period, from January 2018 until December 2021.

Major complications were defined as those who required intravenous or oral drug treatment, tube dysfunction and endoscopic intervention or hospital readmission.

Results: One-hundred and twelve patients (32.1% women), age range [23-91] generated 968 consultations. The main indications for PEG were neurodegenerative (63.4%) and oncological diseases (26.8%).

There were 226 PEG replacements: 18.1% unscheduled; 35.8% early replacements. We detected 167 complications: 75 (44.9%) stoma-related and 92(55.1%) tube-related. Forty three (25.7%) major complications were observed: 7 (4.2%) stoma related and 36 (21.5%) tube-related.

All tube-related major complications and six (85.7%) of the major stoma ones were solved in a single clinical visit. There were no hospital readmissions.

Conclusion: This study demonstrates that a dedicated nurse-led outpatient clinic for PEG patients may, in a single visit, treat most PEG-related complications and therefore avoid hospital readmissions. Nevertheless, the persisting high rate of major complications leaves room for improvement of gastrostomy aftercare.

Introduction: Currently, endoscopy is the gold standard for the evaluation of disease activity and inflammation in clinical practice. However, it is an invasive procedure for the patient, costly and time-consuming. Therefore, there is an urgent need to identify non-invasive biomarkers with the potential clinical utility to diagnose inflammatory bowel disease (IBD) patients, improve the patient's quality of life and increase efficiency in the Health Systems.

Aims & Methods: The identification of non-invasive biomarkers in blood and urine through a proteomic approach for early and differential diagnosis of Crohn's disease and ulcerative colitis. Integration of proteomic and clinical results to clarify the molecular mechanisms involved in the development of these diseases.

A label-free quantitative proteomics method was used to profile the urinary and serum proteomes of 100 patients with newly diagnosed IBD, before starting any treatment [50 patients with Crohn's disease (CD) and 50 patients with ulcerative colitis (UC)] and 50 healthy controls (HC). The

resulting peptides were separated by NanoLC (EVOSEP ONE) and coupled online by electrospray to Trapped Ion Mobility Spectrometry (TIMS) TOF Pro for tandem mass spectrometry analysis. Mass spectrometry data were processed and analyzed with MaxQuant and Perseus software.

Proteins with $p \leq 0.05$ and ratio > 1.5 in any sense, were considered as significantly dysregulated. Bioinformatic analysis of differentially expressed proteins was performed to characterize involved biological processes, molecular functions, cell locations and proteins pathways (PANTHER and STRING v11.5).

Results: A total of 2,500 proteins were identified in the urine, and 468 proteins were identified in the serum with at least two different peptides at FDR $< 1\%$. Of the urine proteins, 110 were significantly changed in UC versus HC, 50 proteins were differentially expressed between CD and HC, and a total of 31 proteins were significantly changed in CD compared with UC patients. In serum samples, a total of 45 differentially expressed proteins were identified in the comparison between UC and HC groups, 32 proteins significantly expressed in CD versus HC, and 12 proteins in CD compared with UC.

Finally, biological information analysis was performed according to these differential proteins. The molecular functions, biological processes, and pathways enriched mainly involved the neutrophil degranulation, complement and coagulation cascades and immune system responses.

Conclusion: Proteome profiling revealed significant differences in newly diagnosed patients with CD or UC. Both serum and urine seem to be appropriate biological matrices for this approach. Next steps of our research will be to understand the role of candidate proteins as well as to validate those with potential as biomarkers in independent cohort.

Introduction: Inflammatory Bowel Disease (IBD) is a chronic inflammatory autoimmune disease which affects the gastrointestinal tract. Among other alterations, microbiota dysbiosis and altered metabolomic profiles have been reported in IBD patients. Recently, G-protein coupled receptors (GPCRs) have been identified as promising pharmacological targets.

Aims & Methods: We aim to characterize the tissular metabolite-sensing GPCRs expression, metabolomic patterns and microbiota composition of IBD patients.

Intestinal resections from Ulcerative colitis (UC) (n=18), Crohn's Disease (CD) (n=21) and non-IBD (n=32) were obtained. Metabolomic analysis was performed by Nuclear Magnetic Resonance and UPLC Q-ToF Mass Spectrometry. Results are expressed as μg metabolite/g tissue. Gene

expression was analyzed by qPCR and data expressed as fold induction (mean±SEM). Microbiota characterization was performed by 16S rRNA gene Illumina Miseq sequencing. Bioinformatic analysis of sequencing data was performed using constrained correspondence analysis and non-parametric Wilcoxon test to compare species proportions. Bacterial load was estimated by qPCR.

Results: Differential expression of metabolite-sensing GPCRs were found in both UC and CD patients, as summarized in the table.

	GPR 35	TAAR1	CaSR	GPR 91	GPR 81	GPR 109a	GPR 109b	GPR 43	GPR 41	GPR 84	GPR 40	GPR 120	GPR 119	TGR 5

CD	1.74 ±0.28	814.2 ±283.5	123.7 ±34.47	63.29 ±22.71	77± 21.24	400.6 ±130.6	295.7 ±53.41	118.7 ±35.88	269.5 ±90.24	11.64 ±5.17	40.43 ±9.50	0.23 ±0.10	82.52 ±29.8	10.47 ±2.48

Table.

Next, the following results were obtained in the metabolomic analysis of intestinal resections from non-IBD (colon), UC, non-IBD (ileum), CD: aspartic acid (20.3±1.88;33.93±3.08;54.82±6.49;66.08±5.98), phenylalanine (5.16±0.54;8.77±1.55;12.09±1.59;25.09±3.21), glutamic acid (98.42±9.44;13 6.30±10.82;150.20±23.05;185.20±17.95) succinic acid (7.29±0.94;7.97±0.8 8;7.17±0.83;14.06±1.70), b-hydroxybutyric acid (6.18±0.47;8.28±0.85;9.0 5±0.88;13.13±1.07), lactic acid (204.70±27.77;297.50±34.66;125.70±30.22 ;303.20±35.78), propionic acid (4.71±0.74;7.71±1.13;4.09±0.44;7.82±0.97) , acetic acid (7.72±0.88;7.47±0.80;10.81±1.33;16.01±1.82), butyric acid (1. 21±0.20;1.77±0.49;3.54±0.26;4.28±0.42), undecanoic acid (0.24±0.01;0.32 ±0.02;0.41±0.01;0.42±0.01), decanoic acid (1.01±0.24;4.47±0.90;0.27±0.07 ;0.79±0.33), eicosapentaenoic (2.59±0.38;3.73±0.54;0.49±0.08;0.86±0.20) , docosahexaenoic (17.73±3.50;25.90±3.15;7.99±2.60;10.43±2.02), α-linoleic acid (11.73±2.74;23.12±4.02;3.66±1.15;4.11±1.44), oleic acid (927.60±209.5 0;1208.00±204.70;186.50±42.82;164.80±25.93), N-oleylethanolamide (0.07 ±0.01;0.06±0.01;0.08±0.01;0.08±0.01) and myristic acid (25.52±5.72;64.53± 8.73;13.7±4.68;19.62±8.03).

Finally, microbiota characterization revealed a reduction in bacterial diversity and load in UC, whereas no differences were found in CD. Next, significant differences at genus and species level between UC, CD and its respective non-IBD controls were also detected. For instance, *Cellulosimicrobium NA* was increased in UC patients while *Escherichia NA* was decreased. Regarding CD, *Ruminococcus bromii* and *Faecalibacterium prausnitzii* were decreased in CD patients.

Conclusion: Altered levels of several metabolites, metabolite-sensing GPCRs expression and microbial dysbiosis is detected in intestinal resections from IBD patients pointing new promising protagonists which need to be further studied.

Introduction: As a member of short-chain fatty acids, propionate has been proved to be able to regulate host metabolism and immunity and also exert anti-inflammatory effects in many diseases, but its role and mechanism on intestinal inflammation remain largely unknown.

Aims & Methods: In this study, the dextran sulfate sodium (DSS) -induced colitis model was used to explore the protective effect of propionate in vivo. Bone marrow-derived macrophages (BMDM) and RAW264.7 cell line were used to explore the effect and mechanism of propionate on the polarization of macrophages in vitro. Real-time polymerase chain reaction (RT-PCR) was performed to detect the expression of macrophage markers and cytokines in colon tissue and cells.

Enzyme-linked immunosorbent assay (ELISA) was used to detect the level of interleukin-6, interleukin-10, and tumour necrosis factor (TNF)-α. Immunofluorescent Staining and flow cytometry were used to evaluate the ratio of macrophage polarization. Western bolt was used to detect histone deacetylase protein levels. ChIP assay was used to determine the mechanism of IL-10 transcription.

Results: The in vivo results showed that the propionate group had less barrier damage and less inflammatory infiltration than the control indicating it could ameliorate DSS-induced colitis. Propionate promoted the production of anti-inflammatory cytokine IL-10 and reduced the production of IL-6 and TNF-α in DSS-induced mice and cells.

To explore the mechanism of IL-10 production, we found that propionate promoted the polarization of M2 macrophages by upregulating the expression of M2 marker ARG1 and CD206.

Further investigation revealed increased cell surface markers CD301 and IL-1R, which are expressed by the M2a macrophage subtype. Flow cytometry analysis showed increased proportion of M2a macrophages in colon tissue and bone marrow of mice.

Moreover, propionate inhibited histone deacetylase 2 (HDAC2) expression, and HDAC inhibitor trichostatin A (TSA) played a similar role to propionate in promoting IL-10 production and surface markers expression.

Furthermore, we analyzed the mechanism of propionate regulating IL-10 production at the gene level and showed that propionate promoted histone H3K9 acetylation and drove transcription of IL-10, thus increasing the production of IL-10.

Conclusion: Propionate ameliorated DSS-induced colitis by promoting the polarization of M2a macrophages and produced robust amounts of interleukin (IL)-10, thus regulating the intestinal immune homeostasis, and could be a promising immunological intervention for ulcerative colitis.

Introduction: A critical goal for the treatment of inflammatory bowel diseases (IBD) is to identify biomarkers which allow optimization of therapeutic dose and response. Indeed, molecular characterization from diseased tissues coupled with clinical measures of IBD therapeutic responders and non-responders has identified patient pathotypes enabling future tailoring of treatments to disease-driving mechanisms.

As such, our ability to identify biomarkers tied to patient subtypes and pathways is critical in understanding how best to treat patients. Most existing clinical datasets do not pair gut and peripheral samples and focus on well-defined IBD populations.

Therefore, the generation of content-rich datasets from heterogeneous IBD populations is an outstanding effort worth pursuing. A high-content dataset containing matched gut and peripheral samples with extensive multi-omics data dimensions associated with clinical metadata would help address this unmet need.

Aims & Methods: Endoscopic biopsies were obtained from 39 Crohn's disease (CD) patients, 59 Ulcerative colitis (UC) patients, and 15 non-IBD donors from multiple matched colon and ileum sites. RNA and protein were co-extracted from the biopsies for RNAseq and mass spectrometry-based proteomics (LC-MS). Peripheral whole blood was used for generating donor genotype, RNA, and protein followed by RNAseq, LC-MS proteomics along with untargeted SOMAscan plasma proteomics.

Differential expression analysis was done on transcriptome and proteome from gut and peripheral samples, using linear regression model (LIMMA package in R). Genotyping (Illumina Infinium Human Omni2.5-8 v1.3 array) was completed; eQTL and pQTL analysis is ongoing.

Results: This IBD cohort had patients in remission or with mild, moderate, or severe disease activity as defined by Mayo UC endoscopic scores or SES CD scores. Principal component analysis showed distinct tissue-based clustering for colon and ileum and for lesional (L) vs. non-lesional (NL) biopsies. No separation in CD vs. UC donors was observed in biopsy and blood data. The colon and ileum biopsies revealed significantly up-regulated metabolic and immune pathways in both L vs. NL disease, and in IBD vs. non-IBD controls for both gene and protein expression. Differentially expressed changes from biopsies overlapped when comparing both proteomics and genomics data, while in the periphery the changes were less pronounced and concentrated on neutrophil and immune markers.

We identified biomarkers in tissue and blood that tracked with disease severity, allowing for development of a panel to predict IBD severity. Correlation with other disease-related biomarkers and clinical metadata is ongoing, along with analyses to identify key drivers of IBD using co-expression network approaches to address patient heterogeneity in the cohort.

Conclusion: Here, we focused on paired gut to peripheral samples and on IBD patients with a range of disease pathotypes. Data analyses did not distinguish between UC and CD; rather, we identified tissue location and involvement changes related to metabolic and immune pathways and a panel predicting IBD severity.

Therefore, the generation of content-rich datasets from these IBD populations will further the molecular classification of IBD patients, as well as the correspondence of diseased tissues to blood in addition to clinical measures. These findings will help characterize patient pathotypes enabling future tailoring of therapies to disease-driving mechanisms.

EFFECTS OF ANTI-TNFA AND ANTI-A4B7 DRUGS ON CIRCULATING DENDRITIC CELLS MIGRATORY CAPACITY IN INFLAMMATORY BOWEL DISEASE

I. Soletó^{1,2}, S. Fernández-Tomé³, I. Mora-Gutierrez⁴, M. Baldan-Martin^{1,2}, C. Ramirez^{1,2}, C. Santander^{1,2}, J.A. Moreno-Monteagudo^{1,2}, M.J. Casanova^{1,2}, F. Casals^{1,2}, S. Casabona^{1,2}, I. Becerro^{1,2}, M. Chaparro Sanchez^{1,2}, D. Bernardo⁵, J. Gisbert^{1,2}

Contact E-Mail Address: irenesoletof@gmail.com

Introduction: Inflammatory bowel disease (IBD) is an idiopathic and chronic disorder that includes ulcerative colitis (UC) and Crohn's disease (CD). Both diseases are different but show an uncontrolled intestinal immune response that generate tissue inflammation. Dendritic cells (DC) are antigen presenting cells that play a key role in the tolerogenic maintenance of the gastrointestinal mucosa.

It has been reported that DC are recruited by intestinal mucosa in a CCR2 dependent manner and in IBD patients, this recruitment is more prominent than in healthy controls (HC), but the specific migration mechanism is still unknown. Taking in account this, we decide to study if anti-TNFA and anti-α4β7 drugs modify the GI mucosa recruitment capacity of DC in the same manner.

Aims & Methods: This is a cross-sectional observational post-marketing study where the modulatory effect of different biologic treatments on samples from patients with endoscopic diagnosis of IBD and HC was studied *ex vivo*.

Peripheral blood mononuclear cells were obtained from 15 patients per group (HC, UC active and quiescent, CD active and quiescent). After that, the expression of homing markers and the migratory capacity of circulating DC toward CCL2, CCL25 and MadCam1 from the different study groups were determined.

Then, cells were cultured in presence of anti-TNF α or anti- α 4 β 7, following culture, surface markers expression was determined hence assessing the differential effect of biological drugs (if any) over the DC subset in the different groups.

Finally, we evaluated the DC migratory capacities in presence of biological drugs or with culture media alone.

Results: Our data reveal that cDC2 (CD11c⁺ CD1c⁺) express more surface markers than other DC subsets, in addition, the expression of CCR9 within this subset was expanded in both quiescent groups (UC and CD).

According to the treatment with biologic drugs only integrin β 7 was modulated by anti- α 4 β 7 but not by anti-TNF. Focus on DC migratory capacities CCL2 showed a clear chemoattract but it was not modulated by biological drugs. In this sense, surprisingly, anti-TNF increased the migratory capacities in almost all groups.

Conclusion: We described for the first time a cDC2 subset as a potential diagnostic marker in IBD. Circulating DC from IBD patients express a different migration pattern than HC, being the expression of these molecules modulated by anti- α 4 β 7 in a different manner in UC and CD. CCR9 seem to elicit a protective function over IBD. The migratory capacity of circulating DC to migrate towards CCL2 is higher than towards culture media not being diminish by any biological drug.

THE OVERLAP BETWEEN CANNABINOID AND NOCICEPTIN SIGNALING AND ITS ROLE IN INTESTINAL INFLAMMATION – A PILOT STUDY

M. Wołyniak¹, K. Owczarek¹, M. Zielinska¹, A. Mokrowiecka², E. Małeczka-Wojcieszko², A. Fabisiak²

Introduction: Due to the loss of efficiency and adverse events of the current drugs in colitis, novel therapeutical options are needed. Both, the endogenous cannabinoid system (ECS) and nociceptin receptor (NOP) have been implicated in the pathogenesis of the inflammatory bowel diseases (IBD). Based on functional similarities between the ECS and NOP systems and anti-inflammatory effects exerted by their ligands, we hypothesize that there is an interaction between cannabinoid receptors 1 and 2 (CB1 and CB2) and NOP during colitis.

Aims & Methods: Our aim was to investigate the potential cross-talk between the cannabinoid receptors and NOP in chemically-induced model of colitis in mice. Colitis was induced by dextran sodium sulfate (DSS). NOP agonist (SCH 221510, 3 mg/kg), CB1 antagonist (AM 6545, 3mg/kg) or CB2 antagonist (AM 630, 5mg/kg) were given intracolonicallly, twice daily, alone or in combination.

On day 8 the mice were sacrificed, macroscopic scoring was performed and colonic samples were taken for further studies. The protein level of extracellular signal-regulated kinase (ERK) 1/2 was measured using Western blot. The expression of genes encoding CB1 and CB2 receptors was determined in the mouse colon using real time RT-PCR. One-way ANOVA followed by the Newman-Keuls post-hoc test was used for analyses of multiple treatment means. Data are showed as mean $\pm$ SEM.

Results: We observed an initial increase in total colon damage score in DSS-treated mice as compared to control group (6.40 $\pm$ 1.52 vs. 1.20 $\pm$ 0.46, respectively), which decreased after treatment with SCH 221510 (4.10 $\pm$ 0.50). Interestingly, addition of AM 6545, AM 630 or combination of both drugs significantly increased a total damage score as compared to mice treated with SCH 221510 alone (11.83 $\pm$ 0.44 vs. 4.10 $\pm$ 0.50, (P<0.01) for AM 6545,

9.12 $\pm$ 1.54 vs. 4.10 $\pm$ 0.50 (P<0.05) for AM 630 and 8.57 $\pm$ 0.86 vs. 4.10 $\pm$ 0.50 (P<0.05) for combination of both antagonists). Similar trend was found in comparison of myeloperoxidase activity in tissues of these groups (14.69 $\pm$ 5.84 vs. 13.96 $\pm$ 3.67, 18.97 $\pm$ 2.40 vs. 13.96 $\pm$ 3.67, and 17.60 $\pm$ 3.31 vs. 13.96 $\pm$ 3.67, respectively).

We found a significant reduction in protein level of ERK 1/2 in the colon collected from mice treated with NOP agonist and CB2 antagonist as compared to mice treated with SCH 221510 alone (1.30 $\pm$ 0.16 vs. 1.89 $\pm$ 0.31, P<0.01). Real time RT-PCR analyses showed that SCH 221510 increased the relative expression of cannabinoid receptors as compared to mice treated only with AM 630 (23091 $\pm$ 3050 vs. 5021 $\pm$ 1794, respectively for CB1 expression and 24488 $\pm$ 8316 vs. 2800 $\pm$ 1050, respectively for CB2 expression).

Conclusion: We obtained promising results suggesting the existence of cross-talk between the CB and NOP receptors. Fully elucidating this phenomenon could aid in developing novel treatment options for patients with IBD based on the modulation of activity of ECS or NOP receptors.

Disclosure: Nothing to disclose.

Introduction: Fibrosis is a common complication of Crohn's disease (CD) in which macrophages play a central role. Epithelial mesenchymal transition (EMT) and the WNT pathway have been associated with fibrosis.

Aims & Methods: We aimed to analyze the relevance of the tissue microenvironment in macrophage phenotype and the EMT process. Intestinal surgical resections were obtained from control and CD patients with stenotic or penetrating behavior. Cytokines expression, macrophages phenotypes, EMT markers and WNT signalling pathway were determined by WB, RT-PCR, ELISA or Cytometry. U937 cells were treated with IFN γ , TNF α , IL1 β , IL4 or IL10 and co-cultured with HT29 cells, and were treated, in some cases, with XAV939 or miFzd4. The expression of macrophage, EMT and WNT pathway markers in U937 or HT29 cells was analyzed by WB or RT-PCR.

Results: IFN γ , WNT6, CD16 and CD86 were increased in intestinal tissue from CD patients. U937 cells treated with IFN γ increased significantly the protein expression of WNT2b (1,3 $\pm$ 0,07 N=13* vs vehicle), CD86 (1,425 $\pm$ 0,1194 N=19* vs vehicle) and CD16 (1,459 $\pm$ 0,1355 N=12* vs vehicle). IFN γ -U937 co-cultured with HT29 increased significantly the protein expression of EMT markers, β CATENIN, WNT2b and WNT6 in HT29 cells (VIMENTIN: 2,7 $\pm$ 0,3 N=6* vs vehicle-HT29; SNAIL1: 1,5 $\pm$ 0,1 N=5* vs vehicle-HT29; β CATENIN: 1,4 $\pm$ 0,09 N=5* vs vehicle-HT29; WNT2b: 2,0 $\pm$ 0,3 N=8* vs vehicle-HT29; WNT6: 1,742 $\pm$ 0,2503 N=4* vs vehicle). Treatment HT29 cells with XAV939 (VIMENTIN: 1,4 $\pm$ 0,4 N=6 vs vehicle-HT29 XAV; SNAIL1: 1,0 $\pm$ 0,1 N=5 vs vehicle-HT29 XAV; β CATENIN: 0,8 $\pm$ 0,1 N=5 vs vehicle-HT29 XAV) or with miFzd4 (VIMENTIN: 0,3 $\pm$ 0,07 N=12* vs IFN γ -HT29 mock; SNAIL1: 0,5 $\pm$ 0,06 N=12* vs IFN γ -HT29 mock; β CATENIN: 0,6 $\pm$ 0,04 N=12* vs IFN γ -HT29 mock; FZD4: 0,5 $\pm$ 0,04 N=12* vs IFN γ -HT29 mock) partially reversed the increases produced by IFN γ -U937 in HT29 cells.

Conclusion: IFN γ -treated macrophages may stimulate the expression of WNT ligands in an autocrine and paracrine manner. The expression of WNT ligands at the epithelial level could favor mesenchymal epithelial transition through WNT2b and WNT6 ligand and FZD4 receptor.

Introduction: Inflammatory bowel disease (IBD) is a collective term used for describing two main conditions, Crohn's Disease (CD) and ulcerative colitis (UC), characterized by chronic inflammation of the gastrointestinal tract (GI), and associated with genetic susceptibility and alterations in the intestinal microbiome of the host. Standard approaches linking host-microbiome relationship with disease activity and progression mostly focus on metagenomic data.

However, the changes in the host-associated proteome in response to IBD are crucial for disease diagnostics and have led to the investigation of new disease biomarkers, such as calprotectin. Meta-proteomics analyses would allow simultaneous elucidation of microbiome- and host-associated translational profiles.

Thus, a multi-omics data integration approach may provide insights on both host and microbiome functional profiles, which is essential to guide therapeutic care and develop personalized treatment for IBD.

Aims & Methods: We aimed to identify novel protein, gene, and lipid biomarker signatures in fecal samples from IBD patients, using a comprehensive multi-omics analytical and data integration approach, involving metagenomics, metaproteomics, and lipidomics analyses.

We mapped the reads derived from the metagenomics analyses to those from the Integrated Gene Catalog (IGC) and the Unified Human Gastrointestinal Protein (UHGP-95) catalogs. We used gene abundance and coverage profiles to determine differentially abundant genes and build an in-house spectral gene library.

Metaproteomics data-independent acquisition was carried out by high-resolution mass spectrometry (MS); we processed the obtained raw data and spectral libraries against the in-house gene library using Spectronaut. Lipid profiling of the fecal samples was performed using high-resolution MS direct infusion analysis; targeted MS assays were applied on a broad panel of 196 lipid mediators and 47 bile acids.

Results: We performed multi-omics analysis of human fecal samples from 14 and 11 patients with UC and CD, respectively, and 12 healthy donors. All the samples were purchased from The Biocollective (Colorado, USA). As a result of metagenomics analysis over 20,000 genes were found to be differentially abundant in IBD cases compared to that in healthy groups, for both gene catalogs.

We generated in-house IGC and UHGP-95 databases (2.4 M and 3.1 M protein sequences, respectively) from the metagenomics reads and found 17 differentially abundant host proteins, including calprotectin, in IBD patients. Moreover, we identified 36 lipid mediators, 370 structural lipids, 4 ceramides, and 29 bile acids host specific. To investigate any potential

disease-associated switch for translational regulation, we compared abundance gene profiles (metagenomics) with their metaprotein product intensities. Through Multi-Omics Factor Analysis (MOFA), we were able to highlight common disease effects and particular trends in disease subgroups, which provided an integrative perspective.

Conclusion: We developed a multi-omics approach and applied it for the analysis of genes, proteins, and lipids in fecal samples from IBD patients, highlighting specific disease-related signatures.

Introduction: Human intestinal conventional dendritic cells (cDC) maintain the balance between immunity and tolerance. However, their specific function in patients with Crohn's disease (CD) is scarce. Hence, we hereby decided to assess their phenotype in the inflamed and non-inflamed tissue from patients with CD referred to non-inflamed controls.

Aims & Methods: Tissue resections from patients with ileocolonic CD and controls (healthy tissue from patients with proximal colonic cancer) were obtained, being subsequently enzymatically digested. Total intestinal cDC were identified within singlet viable leukocytes as CD14-CD64-HLA-DR+CD11c+.

Three cDC subsets were sorted based on the expression of CD103 and SIRPα+ (CD103-SIRPα+, CD103+SIRPα+, CD103+SIRPα-) while total macrophages were sorted as CD14+CD64+HLA-DR+. cDC subsets and macrophages were further cultured with allogeneic CD4+ naïve T-cells to assess their Th1, Th17 and Treg phenotype.

Results: All 3 intestinal cDC subsets from controls stimulated naïve T-cells as opposed to intestinal macrophages. Indeed, cDC stimulated T-cells produced IL-10 and co-expressed FoxP3, being this capacity increased in both CD103+ subsets (CD103+SIRPα- and CD103+SIRPα+).

Moreover, all three ileal cDC subsets stimulated T-cells more efficiently than their paired colonic counterparts, although the acquired T-cell profile did not differ among tissues. None of the cDC subsets, on the contrary, induced the expression of IFN γ or IL-17 on the stimulated T-cells. Referred to CD patients, all three colonic cDC subsets were more stimulatory than their counterparts from the control tissue, while CD103+SIRPα+ cDC from the inflamed ileum primed the generation of IL-17+ responding T-cells.

Conclusion: We have demonstrated that all human intestinal cDC prime the generation of Tregs, being this capacity increased in CD103+ cDC. Indeed, ileal cDC were more stimulatory than their paired colonic coun-

terparts, suggesting an increased capacity of the ileum to generate Tregs. Nevertheless, this process was dysregulated in the inflamed tissue from patients with CD where CD103+SIRPα+ cDC seem to have been reprogrammed by the tissue microenvironment to prime the generation of Th17 T-cells hence driving disease progression.

Introduction: Exclusive enteral nutrition (EEN) is a first-line induction therapy for pediatric Crohn's disease (CD). Although the protective mechanisms remain unclear, previous studies showed substantial changes in microbiome composition in response to EEN.

Aims & Methods: The aim of the study is to assess the protective function of EEN and its impact on gut microbiome signatures in pediatric CD. We prospectively followed 20 newly diagnosed paediatric CD patients who received EEN. Patients were treated according to international guidelines including EEN therapy for 6-8 weeks, followed by a gradual re-introduction of solid food and concomitant start of maintenance treatment.

Disease activity and inflammatory biomarkers were monitored during 12-months follow-up. 16S rRNA gene sequencing and targeted/untargeted metabolomics was performed on stool samples collected weekly during EEN and monthly thereafter (n = 289).

Dietary modulation and clinical activity of patient-derived stool microbiota were studied by *ex vivo* continuous faecal culturing and after faecal microbiota transplantation (FMT) and subsequent dietary intervention in germ free (GF) IL10-deficient (*Il10^{-/-}*) mice.

Results: All patients achieved remission with EEN therapy but 7/20 had recurrent CD activity within 6 months. Microbiota profiling of patient-derived fecal microbiota before and after EEN confirmed the heterogeneity of gut microbiome composition and identified two bacterial community clusters dominated either by the two phyla Firmicutes and Bacteroidetes or the two phyla Firmicutes and Proteobacteria.

Longitudinal microbial profiling showed highly individualized responses to EEN without a coherent EEN-specific signature. Despite the individual variations, integrated microbiota and metabolite profiles resulted in better separation and the selection of bacterial taxa associated with certain metabolites (mostly long-chain fatty acids) improved the diagnostic classification of CD patients based on the diet (EEN vs. post-EEN).

FMT into GF mice showed that humanized mice recapitulated the phenotypic and the dysbiotic features of their respective human donors. FMT using patient-derived baseline fecal microbiota after exposure to *ex vivo* continuous culturing with EEN media showed no colonic inflammation. In contrast, mice colonized with fermented baseline microbiota following

the exposure to fiber rich (FR) media developed inflammation associated with substantial changes in gut microbiota composition, confirming that *ex vivo* fermentation can simulate EEN-induced remission by driving microbial shifts.

Interestingly, EEN-like diet maintained the disease inactive behaviour of EEN remission-associated microbiota but induced inflammation in the *Il10^{-/-}* mice when fermented under FR media. In contrast, EEN-like diet failed to mitigate the aggressive behaviour of relapse microbiota in both *ex vivo* culture and FMT experiments. Transfer of the same microbiota in the mouse model together with pre-treatment with an EEN-like purified diet reduced inflammation severity, suggesting that fiber might play a role in provoking inflammation after EEN cessation.

Conclusion: Our data show that clinical efficacy of EEN in pediatric CD is accompanied by temporal and individual gut microbial and metabolite changes but regardless of individual variations, integrated multi-omics data analysis identified diet-related microbiome signatures.

Findings from continuous culture and gnotobiotic mouse models point towards a direct impact of diet on the composition and metabolic activity of patient-derived microbiota and on regulating intestinal inflammation.

Introduction: Metabolomics can advance the understanding of inflammatory bowel disease (IBD) pathophysiology, and children with new-onset IBD without concomitant disease or medication are in many ways an ideal study population for metabolomic research. However, most studies have examined adult populations and few have addressed the intestinal mucosa where the primary inflammation occurs.

Aims & Methods: To explore the metabolomic profiles of children with IBD, we compared the mucosal and plasma metabolomes in new-onset paediatric IBD patients and symptomatic non-IBD paediatric controls, and correlated plasma inflammation markers and disease characteristics with the altered metabolites.

Paired colonic and ileal biopsies and plasma from 67 treatment-naïve children with incident Crohn's disease (CD; n=47), ulcerative colitis (UC; n=9), and non-IBD controls (n=11) were analysed using ultra-performance liquid chromatography-mass spectrometry (UPLC-MS/MS). Inflammatory plasma proteins (n=92) were assessed.

Results: The metabolomes in inflamed mucosal biopsies differed between IBD patients and controls. In CD, mucosal levels of several lysophospholipids (lysophosphatidylcholines, lysophosphatidyletanolamines, lysophosphatidylinositols, and lysophosphatidylserines) were decreased, correlating with various plasma metabolites, including amino acid analogues and *N*-acetylated compounds. In both CD and UC, mucosal sphingolipids, including ceramide (d18:2/24:1, d18:1/24:2), lactosyl-*N*-palmitoyl-sphingosine (d18:1/16:0), behenoyl sphingomyelin (d18:1/22:0), lig-

noceroyl sphingomyelin (d18:1/24:0), and/or sphingomyelin (d18:1/24:1, d18:2/24:0) were increased, correlating with sphingolipids, bile acids, and/or *N*-acetylated metabolites in plasma. Among proteins associated with CD, interleukin-24 correlated with plasma metabolites, including lactosyl-*N*-palmitoyl sphingosine (d18:1/16:0) and phosphatidylethanolamine (18:1/18:1), haemoglobin, and faecal-calprotectin. In UC, interleukin-24, interleukin-17A, and C-C motif chemokine 11 correlated with several plasma metabolites, including *N*-acetyltryptophan, tryptophan, glycerate, and threonate, and with the paediatric ulcerative colitis activity index, C-reactive protein, and faecal-calprotectin.

Conclusion: In this study we demonstrate specific patterns of metabolomic alterations in the inflamed mucosa of children with new-onset IBD compared with symptomatic non-IBD controls. Perturbations of lysophospholipids and sphingolipids characterized the mucosal metabolome in IBD and correlated with plasma metabolites.

By integrating plasma metabolomics data with inflammatory proteins and clinical data, we identified clinical and inflammatory markers associated with metabolomic signatures for IBD. Further studies are warranted for confirmation and to determine the role for these bioactive lipid classes in IBD.

Finally, this study demonstrates that exploration of mucosal metabolomes provides a foundation for improving the understanding of IBD pathogenesis and for future diagnostic biomarker discoveries in paediatric IBD.

Introduction: The efficacy of Anti-TNF therapy is hampered by anti-drug antibodies (ADA) formation. Complexes formed between the bivalent Infliximab (IFX) and the trimeric TNF molecule were shown to drive ADA formation in a mouse model and to activate human innate blood cells. However, the relation between drug/TNF ratios and immunogenicity is still not clear.

Aims & Methods: We aimed to assess the effect of drug/TNF ratio on complex size and consequential immune activation and immunogenicity. Whole blood was incubated with IFX/TNF complexes formed at a range of molar ratios (0.25-32 IFX/TNF) keeping TNF at a constant concentration.

Cellular response was evaluated by TNF mRNA expression.

Size exclusion chromatography (SEC) was used to assess IFX/TNF complex size distribution and to collect high molecular weight fractions for cellular induction.

C57B6 mice were injected with complexes prepared with constant TNF and increasing IFX concentrations, or with excess of an IgG isotype control. Human-TNF transgenic mice were injected with IFX in different dosages. Serum ADA were quantified by ELISA.

Fcg receptors activation was assessed using Jurkat cells expressing FcgR with a downstream NFAT-driven luciferase reporter. Cells were incubated with IFX/TNF complexes and luciferase activity was measured.

Results: Whole blood incubation with complexes formed at different IFX/TNF ratios led to the induction of TNF mRNA expression. Gradual addition of IFX increased TNF expression to a maximal value, beyond which further IFX addition caused a dose-dependent reduction of TNF mRNA expression. A similar phenomenon was observed in the mouse model. Lower ADA levels were observed upon increasing the IFX/TNF ratio of injected complexes beyond an optimal ADA inducing ratio. In human-TNF transgenic mice, increasing IFX dosage also led to reduction in ADA formation. SEC analysis demonstrated that similar high molecular weight complexes were formed regardless of IFX/TNF ratio and that addition of IFX led to the accumulation of free IFX.

Pre-incubation of whole blood with IFX, or addition of an IgG isotype control instead of excess IFX, reduced complex-induced TNF mRNA expression, suggesting competition between the complexes and free drug/IgG.

Mice were injected with IFX/TNF complexes at a 4:1 and 16:1 molar ratio, or with the 4:1 complex supplemented with an IgG control. ADA levels exhibited a similar reduction with IgG and excess IFX.

A reporter cell-based assay demonstrated that Fcg receptor activation by the complexes was reduced when increasing the IFX/TNF ratio. Induction by high molecular weight fractions alone demonstrated that at the high IFX/TNF ratios, free IFX antagonized the complex inducing effect.

Conclusion: IFX/TNF complexes induce immunogenicity by innate cell activation via receptor binding. High molecular weight drug/target complexes form regardless of drug concentrations. Free IFX and IgG compete with drug/target complex binding to Fcg receptors, thereby reducing immune activation both *in vitro* and *in vivo*. The finding suggests that low anti-TNF levels are immunogenic secondary to lack of competition of receptor complex binding by free IFX. Therefore, high dose anti-TNF therapy may serve as a strategy for the reduction of immunogenicity.

Introduction: The putative Ergothioneine Transporter, SLC22A4/OCTN1, is expressed in the intestine and in monocytes/macrophages, and its widely represented missense variant L503F (0.4 Minor Allele Frequency in Caucasians) has been found to be associated with Crohn's disease, sporadic colorectal cancer in early age and ulcerative colitis (UC) patients.

The leucine-to-phenylalanine substitution at amino acid 503 affects OCTN1 capacity to transport ergothioneine, acetylcholine and likely other substrates of endogenous or microbial origin; however, whether this defect contributes to inflammatory bowel disease (IBD) pathogenesis, and the mechanistic underpinnings, remain elusive.

Aims & Methods: In order to gain mechanistic insight on the role of SLC22A4 in IBD, we first analyzed primary monocytes from healthy donors and UC patients of varying OCTN1 genotypes. Then we stably knocked-down or overexpressed OCTN1 and its disease-associated variant in the monocytic cell line THP-1. Finally, we compared wild type and OCTN1 knockout C57BL/6 mice in a chemical colitis paradigm in vivo.

Results: Primary adherent monocytes from healthy donors homozygous for the IBD-associated allele (TT) displayed a significant enhancement of interleukin 1 beta (IL-1β) response to peptidoglycan (PGN) compared to the other genotypes. Likewise, cells from UC patients bearing the 503F variant released more IL-1β in response to live bacteria and displayed reduced expression of autophagy markers (e.g. p62, LC3), compared to patients negative for the variant.

In agreement with these findings, OCTN1-deficient THP-1 macrophages secreted reduced amounts of IL-1β when challenged in vitro with PGN or live bacteria. Most relevant, THP1 cells engineered to overexpress the 503F variant of OCTN1 displayed a much stronger IL-1β response to muramyl dipeptide and PGN challenge, compared to cells transduced with the "wild type" transporter.

Also consistent with a role for OCTN1 variants in inflammatory cascades relevant to IBD, *in vivo* studies revealed a milder DSS-induced colitis in OCTN1 knockout mice compared to wild type animals, both at the peak of disease severity and at the end of the recovery period.

Conclusion: Collectively our initial evidence supports the view that OCTN1 may have a causative role in IBD via deranged bacterial sensing and cytokine production, with 503F likely behaving as a gain-of-function variant. Thus, targeting OCTN1 variant may provide unprecedented opportunities for the personalized treatment of IBD patients and a better understanding of disease pathogenesis.

Introduction: Host intestinal immune gene signatures and microbial dysregulations expose potential mechanisms in the pathogenesis of inflammatory bowel diseases (IBD). Profiling of mucosa-attached microbiota allows the understanding of locally present microbial communities and their immediate impact on the host. This study evaluated interactions between host mucosal gene expression and intestinal mucosa-attached microbiota in IBD.

Aims & Methods: Intestinal mucosal bulk RNA-sequencing data was combined with mucosal 16S rRNA gene sequencing data from 696 intestinal biopsies derived from 337 patients with IBD (181 with Crohn's disease [CD] and 156 with ulcerative colitis [UC]) and 16 non-IBD controls. Hierarchical all-against-all associations testing (HALLA) was used to assess factors affecting host gene expressions and microbiota. Sparse canonical correlation analysis (sparse-CCA) was used to identify inflammation-related gene-microbe components. Intestinal cell type enrichments were predicted by RNA-seq deconvolution. Linear mixed interaction models were used to investigate host-microbiota interactions, while adjusting for age, sex, BMI, disease location, tissue inflammation, medication use and batch effects.

Results: In total, 15,934 intestinal genes and 113 microbial taxa were identified and included in subsequent analyses. Host intestinal gene expressions were characterized by tissue- and inflammation-specificity, whereas intraindividual variability of the mucosal microbiota dominated over disease location and inflammation effects. Using sparse-CCA, six distinct inflammation-related pathways were modulated by the intestinal microbiota (FDR < 0.05), covering 94% of individual gene-bacteria associations.

Notably, higher expression of host fatty acid metabolism pathway genes was associated with increases of *Bifidobacterium*, while metallothionein signaling pathway genes were affected by the presence of *Bacteroides*. Mucosal abundance of *Erysipelotrichaceae* was inversely associated with genes involved in collagen biosynthesis.

Further, we observed a loss of a *Lachnospirillum*-dominated gene-bacteria networks in non-stenotic intestinal tissue of patients with fibrostenotic CD. Patients using TNF-α-antagonists demonstrated *Ruminococcaceae*-associated gene interactions related to fatty acid metabolism.

In addition, gene-bacteria associations were dependent on the degree of mucosal dysbiosis. Furthermore, the identified gene-bacteria associations showed high concordance in an independent replication cohort from the integrative Human Microbiome Project (HMP2).

Finally, deconvolution of bulk RNA-seq data revealed that mucosal microbiota significantly contributed to the variation (up to ~10%) in intestinal epithelial cells, macrophages and NK-cells.

Conclusion: Our results demonstrate a complex and heterogeneous interplay between the mucosal microbiota and gene expressions in context of IBD phenotypes. Multiple novel mucosal host-microbe interactions were exposed, which could aid in guiding drug development and foster precision medicine in IBD.

Introduction: Intact mucus layer is crucial for intestinal mucosal barrier function. Mucins, mucus layer building blocks, are secreted by goblet cells and composed of glycans that are essential for resisting bacterial interactions. Mucins composition alterations may contribute to intestinal inflammation such as that in inflammatory bowel diseases (IBD).

Aims & Methods: Our aim is to assess intestinal mucus expression and composition in IBD, and inflammation-induced alterations.

Patients with IBD and non-IBD controls were recruited prospectively and mucosal samples were obtained by endoscopy and from surgical specimens, respectively. Hierarchical clustering of MUCs gene expression was assessed in intestinal biopsies from 52 subjects; 32 patients with IBD (Crohn's disease [CD], ulcerative colitis [UC] and pouchitis) and 20 non-IBD controls, using gene expression data to generate a heatmap.

To study mucus composition, Carnoy's-fixed and paraffin embedded mucosal biopsies from patients with CD, were stained with PNA (Galactose-binding lectin), using immunofluorescence. Human intestinal organoids (HIOs) obtained from surgically resected intestines of non-IBD controls were differentiated to enrich goblet cells and increase mucus secretion. Following treatment with pro-inflammatory cytokines glycan-binding lectins, and MUCs mRNA levels were assessed by flow cytometry, and RT-PCR, respectively.

Results: Hierarchical clustering analysis revealed significant increase in MUC1, MUC4, MUC6 expression and slight increase in MUC2 expression in patients with IBD with active inflammation compared to non-IBD controls. Galactose expression was lower in inflamed compared to the non-inflamed mucosal explants of patients with CD (n=4). Also, galactose expression was reduced in HIOs treated with cytokines mix (IFN- γ , TNF- α and IL-2). MUC1 RNA levels were upregulated following treatment with IL-22, or IL-6 in HIOs (p<0.001, and p<0.05, respectively, n=3). MUC4 RNA levels were upregulated in HIOs treated with IFN- γ , IL-22, or IL-6 (p<0.0001, p<0.0001, and p<0.05, respectively, n=3). Additionally, MUC6 RNA expression levels were upregulated in HIOs treated with IL-13 or IL-4 (p<0.001, n=3).

Conclusion: Upregulated MUC1, MUC2, MUC4 and MUC6 expression in the inflamed mucosa suggest mucins potential importance in the pathophysiology of IBD. Reduced galactose expression in inflamed mucosal explants,

and HIOs treated with cytokines mix, stresses the effect of inflammation on mucins composition. Moreover, inflammation-induced alterations in MUC genes expression, indicates that mucus layer modifications may be immune-mediated. HIOs may serve as a platform for studying alterations in mucus layer characteristics.

Introduction: Inflammatory bowel diseases (IBD) are chronic inflammatory disorders of the gastrointestinal tract. IBD is associated with hyperactivation of immune cells and imbalanced pro- and anti-inflammatory cytokines. Anti-TNF- α treatment is widely used, but 10-30% of the patients are primarily not responding to the treatment or lose response over time.

In vitro organoid cultures (OCs) generated from tissue specific adult stem cells can mimic cellular diversity and function of the organ of origin and may be utilized as a predictive model. However, the lack of knowledge of the OC's cytokine pattern and characteristics limit the possible use of the OCs as an *ex vivo* model.

Aims & Methods: Our aims were to characterize the cytokine profiles of the IBD colon organoids and compared them to the colon biopsies they were originated from and to control colon organoids.

In this study 20 IBD and 8 non-IBD patient sample were used. The biopsies were taken during colonoscopy from inflamed part of the colon of IBD patients. To establish colon organoid cultures crypts were isolated from the biopsy samples. Cytokine Array was used to determine cytokine expression patterns in our samples.

After first passage the gene expressions of control and IBD OCs were determined by qPCR. TNF- α concentrations was determined by ELISA and immunostainings, respectively in control and IBD organoids. To determine therapeutic response OCs were treated with anti-TNF- α therapy.

Results: We didn't observe any significant difference between the biopsies and the organoid's cytokine pattern until the first passage. Major pro-inflammatory cytokines such as IL-6 and IL-8 were detected both in biopsies and organoids. After the second passage the cytokine expression decreased or disappeared in OCs. ELISA showed that TNF- α was expressed in the organoid cultures, however a similar decrease was observed, which was also confirmed by immunofluorescence staining.

Increased gene expression of TNF- α , IL-1 β and IL-6 were detected in IBD organoids compared to controls. ELISA also showed higher TNF- α concentration in organoids from inflamed origin compared to healthy controls. After anti-TNF- α treatment we detected a decrease in the IL-6 gene expression in treated OCs.

Conclusion: Our results suggest that colon OCs maintain the cytokine expression *ex vivo* until the 2nd passage. Furthermore, *in vitro* treatment induces detectable changes in the cytokine expression. Based on these results patient-derived organoids may be utilized as an *ex vivo* model to predict therapeutic response of IBD patients.

Disclosure: Nothing to disclose.

Introduction: In inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), inflammatory CD4⁺ T cell responses to microbial antigens drive chronic intestinal inflammation in a genetically susceptible host. The phenotype, function and specificity of these inflammatory CD4⁺ T cells remains unknown. Previously, IgG antibodies to commensal *Lachnospiraceae* bacteria-derived flagellins were detected in a subgroup of adult CD patients with complicated disease.

However, whether these IgG responses already occur in therapy-naïve pediatric patients and whether they relate to insufficient or hyperactive anti-microbial innate immunity is unknown.

Moreover, as IgG antibody responses require CD4⁺ T cell help, IgG specificity may serve as a proxy for T-cell specificity, providing a way to study the specificity and phenotype of anti-microbial T-cell responses.

Therefore, we hypothesize that a subgroup of pediatric CD patients has IgG responses to *Lachnospiraceae* flagellins and concomitant flagellin-reactive T-cell responses that are inflammatory and detectable at the therapy-naïve stage.

Aims & Methods: Plasma IgG reactivity to 20 flagellins from *Lachnospiraceae* bacteria that colonize mouse and human gut was measured in therapy-naïve pediatric IBD patients (CD: n=49; UC: n=16), non-IBD controls (n=12) and age-matched healthy controls (HC: n=17). CD patients were divided into two groups: 'flagellin-high' (elevated IgG responses to 11-20 flagellins) and 'flagellin-low' (elevated IgG responses to 0-10 flagellins), whose immunological and clinical profiles were compared.

Results: The proportion of flagellin-high patients was higher in CD patients (41%) compared to UC (6%), non-IBD (8%) and HC (6%). Flagellin-high CD patients more often had ileocolonic disease, while flagellin-low CD patients more often had isolated ileal disease. Clinical disease activity score, CRP and ESR did not relate to flagellin-high or -low reactivity. In the blood, flagellin-high patients had significantly increased frequencies of CD38⁺ (CD62L^{neg}CD4⁺) effector T cells, which are enriched for gut-homing properties, compared to flagellin-low patients. These gut-homing T cells had similarly increased frequencies of proliferative Ki67⁺ and decreased frequencies of regulatory TIGIT⁺ cells in flagellin-high and -low patients

compared to HC. After antigen-specific peripheral blood re-stimulation with recombinant flagellins, flagellin-high patients had higher frequencies of flagellin-reactive CD4⁺ T cells than flagellin-low patients.

Surprisingly, the increase in flagellin-reactive and inflammatory gut-homing T cells in flagellin-high patients associated with less histological disease activity, i.e. reduced neutrophilic and mononuclear infiltration and epithelial damage, and less phosphorylated NFκB in colonic biopsies compared to flagellin-low patients. In addition, the plasma concentration of EN-RAGE, a protein produced by neutrophils, was decreased in flagellin-high compared to flagellin-low patients.

Conclusion: In conclusion, a subgroup of pediatric therapy-naïve CD patients has high IgG reactivity to *Lachnospiraceae* flagellins at diagnosis. Although these flagellin-high patients have increased frequencies of circulating gut-homing and flagellin-specific CD4⁺ T cells, they have lower colonic histological disease activity and reduced NFκB activation, suggesting less innate immune cell activation and/or infiltration.

Together, our data raise the question whether elevated anti-*Lachnospiraceae* adaptive immune responses are related to insufficient anti-microbial innate immune responses in the colon.

Disclosure: Nothing to disclose.

Introduction: Crohn's disease (CD) is often complicated by the appearance of intestinal stenosis (B2 behaviour) or fistulas (B3 behaviour), and the factors determining the pattern of disease and the etiology of these lesions, both associated with fibrosis and requiring surgery, are poorly defined.

Aims & Methods: Our aim has been to detect transcriptomic alterations in intestinal tissues affected by stenosis or fistulas, and have centred our attention in genes affecting vessel formation and function as potential contributors to these lesions. We conducted a small RNA sequencing profiling on ileal surgical resections from CD patients with B2 (n=10) or B3 (n=10) behaviour. We obtained a sample from affected tissue and the paired non-affected ileum from each patient.

Results: Tissues affected by stenotic or penetrating lesions present a differential expression of two pro-angiogenic miRNAs (miR-378c and miR-424-5p), and an increased expression of genes associated with vascular regulation, and both alterations are more pronounced in penetrating lesions. The expression of this set of genes shows a generalized and significant correlation with that of the pro-angiogenic miRNAs (negative with the down-regulated miR-378c, positive with the up-regulated miR-424-5p), especially in the affected tissue.

Conclusion: Ileal tissues from CD patients affected by stenosis or penetrating injuries present a local alteration in the expression of miRNAs with pro-angiogenic functions that probably contributes to the up-regulation of genes associated with vessel formation and to the modification of the vascular compartment in these lesions.

Disclosure: Nothing to disclose.

Introduction: Crohn's disease (CD) is a chronic immune mediated disorder of the gastrointestinal tract. Wide screening-based studies revealed that immune cell subsets with unique plasticity and immune-regulatory properties accumulate in CD patients.

Aims & Methods: To investigate the presence of unique T cells in the intestinal mucosa phenotype and functional studies were performed on inflamed and not-inflamed biopsies from patients with CD and healthy controls. We established an anti-CD45 mAbs-based barcoding approach to simultaneously analyze hundreds of surface-molecules expressed on cells isolated from intestinal tissue of CD patients.

Using 31 color flow-cytometry and phenograph clustering analysis, unique T cell populations were detected in inflamed tissue. Functional capacity was studied by intracellular staining with anti-cytokine mAbs after *in vitro* T cell activation.

Results: In intestinal tissue we found mutually exclusive expression of CD39 and CD73 ectonucleotidases on CD4⁺T cells and CD39 and CD45RA on TCR V δ 1⁺ T cells, defining phenotypically and functionally distinct populations.

In inflamed tissue of patients with CD, we observed:

- Augmented proportion of effector memory CD4⁺T cells;
- Accumulation of activated CD4⁺CD39⁺T cells producing IL-17 and IL-21;
- Increased frequency of terminally differentiated TCR V δ 1⁺ T cells producing TNF- α and IFN- γ and;
- Decreased frequency of T-effector memory TCR V δ 1⁺CD39⁺ T cells producing IL-9 and IL-6. No major alterations in CD8⁺T cells and MAIT cells were found.

Conclusion: The inflamed areas of intestinal tissue in CD patients showed significant changes of CD4⁺ and TCR V δ 1⁺ T cell populations, each secreting different types of pro-inflammatory cytokines, thus indicating their non-overlapping contribution to inflammation. The abnormal accumulation of TCR V δ 1⁺ T cells with phenotype of terminally differentiated T cells implicates continuous activation in inflamed tissue.

Disclosure: Nothing to disclose.

Contact E-Mail Address: laetitia.pele@bioresource.nihr.ac.uk

Introduction: Inflammatory Bowel Disease (IBD), comprising Crohn's disease (CD) and ulcerative colitis (UC), affects ~500,000 people in the UK, causing relapsing intestinal inflammation. Long-term management often requires costly drug treatments and major surgery. While recent advances in 'omics' technologies have improved our understanding in IBD pathogenesis and outcomes, their full potential will only be realised if allied to routinely collected clinical data.

For this purpose, the Health Data Research (HDR) Hub for IBD - Gut Reaction was launched in 2019 after a successful bid to HDR UK. Gut Reaction is led by Cambridge University Hospitals NHS Foundation Trust and Eastern AHSN in partnership with the NIHR BioResource, UK IBD Registry, Crohn's & Colitis UK, thirteen NHS Trusts and three technology partners.

Aims & Methods: Building a multidimensional data resource: We are developing methodologies to link data assets from ~36,000 NIHR IBD BioResource participants to centrally-held data at NHS Digital and electronic healthcare record data for a subset of ~11,000 patients recruited from thirteen participating NHS Trusts. In particular, we are working toward integrating genomic data with structured phenotypic data and routinely collected longitudinal healthcare data including laboratory test results; histopathology, endoscopy and radiology results, digitised radiology and histopathology images (where applicable), prescribing data, clinic letters and commissioning data sets.

Accessing the multidimensional data resource: Since NIHR IBD BioResource participants have consented to their medical records being accessed for research purposes, the resulting built-in Gut Reaction data 'panel' is open to any investigators, from science or industry, to facilitate studies requiring access to integrated real world IBD patient data. Working in partnership the Gut Reaction Patient Advisory Committee, the NIHR BioResource Data Access Committee and the Scientific Advisory Board review research applications based on scientific merits and projected benefit to patients and, upon approval, provide integrated data using secure cloud research environments.

Results: Almost 3 years on, Gut reaction has received > 20,000 standard files, and > 11 million 'records' from participating Trust including >6 million test results, >28,000 radiology images and >98,000 radiology reports and ~3 million correspondence, to name a few.

The aspirations of Gut Reaction have generated a lot of interest from industry and academia alike, and to date the HDR Hub for IBD has been able to facilitate two commercial and two academic use cases:

- Exploring association differences across multiple sub-phenotypes of CD and UC.
- Turning samples into data by providing access to de-identified health data and gut biopsy samples from clinically phenotyped UC and CD patients.
- Developing a tool to predict clot risk in IBD.
- Assessing whether immunosuppressant / biologic therapies do or do not increase Covid risks, and whether vaccines are or are not effective in patients on these medications.

Conclusion: Gut Reaction is on course to deliver a world-class multidimensional integrated data resource for research and innovation. Its success may be recapitulated across other disease areas to benefit other patient communities.

Disclosure: Nothing to disclose.

Contact E-Mail Address: jaynedoherty@hotmail.com

Introduction: Accelerated vaccine development and mass vaccination campaigns have been conducted to induce protective immunity against SARS-CoV-2. Although data is conflicting, certain agents with the ability to regulate the immune response, such as vitamin D have been shown to prevent and improve outcomes in respiratory illnesses including COVID-19 infection [1].

Aims & Methods: Determine the impact of vitamin D deficiency in patients with inflammatory bowel disease (IBD) on Spike Protein (SP) immunoglobulin (Ig) G levels post-vaccination against COVID-19 and the impact on rates of COVID-19 infection.

IBD patients and healthy controls (HC) were recruited prospectively from five hospitals and quantitative antibody responses and vitamin D levels assessed following COVID-19 vaccination. Infection with COVID-19 was defined by a positive polymerase-chain-reaction or antigen test.

Results: 485 participants had vitamin D samples analysed (331 patients, 154 controls). 319 had SP IgG levels analysed post two doses of COVID-19 vaccine. 231 (47.3%) participants were male. Median age was 39.5 years. A significant diurnal variation was found in median vitamin D levels between the winter and summer period ($p < 0.001$). Vitamin D levels were significantly higher in IBD patients compared to HCs (27.8 ng/ml versus 18.1 ng/ml, $p < 0.001$) with 56.9% of IBD patients being vitamin D deficient compared to 74.7% of HCs ($p < 0.001$). Vitamin D levels did not correlate with SP IgG levels post-vaccination against COVID-19 (Correlation coefficient -0.41, $p = 0.47$). Median vitamin D levels were significantly lower in participants who were previously infected with COVID-19 compared to those who were not infected (16.4 ng/ml versus 27.0 ng/ml, $p < 0.001$).

	Healthy controls (n=154)	IBD cohort (n=331)	p - value
Median age (IQR)	40.6 (30.0 - 49.4)	34.8 (28.3 - 49.6)	0.1
Male gender (%)	27 (17.5%)	204 (61.6%)	<0.001
Previous COVID-19 infection (%)	48 (31.2%)	25 (7.5%)	<0.001
Median Vitamin D levels	18.1	27.8	<0.001

Table.

Conclusion: Vitamin D deficiency has no impact on response rates to COVID-19 vaccination. However vitamin D deficiency was more prevalent in participants who had experienced COVID-19 infection. Vitamin D deficiency was common and replacement may not alter vaccine response but along with vaccination may modify risk of COVID-19 disease in the population.

Introduction: Crohn's disease (CD) is characterized by an increase in the relative abundance of Escherichia coli and a disturbance of the mucosal immune system, accompanied by an increase in the level of IgA in the intestinal lumen. IgA antibodies are secreted by the mucosa to block bacteria from penetrating the epithelium.

Aims & Methods: The aim of the study was to evaluate the effect of IgA on a commensal strain of E. coli 1_39_1 isolated from the feces of a healthy donor and closely related to probiotic E. coli Nissle1917 [1].

Commensal E. coli isolate 1_39_1 from a healthy individual was incubated with IgA (600 µg) as well as 2% BSA and PBS (negative controls) for 2 hours at room temperature (in triplicate).

Total RNA from samples was isolated with standard phenol-chloroform extraction method and then treated with DNase I (NEB). rRNA was depleted with NEBNext rRNA Depletion kit for bacteria (NEB). mRNA library was made using NEBNext Ultra II RNA library Prep kit (NEB).

Next-generation sequencing was performed on the NextSeq 500 Illumina platform. Sequence reads were mapped on reference genome E. coli strain 1_39_1 (GCA_008041535.1) using Bowtie2, counted with featureCounts. Differently expression of genes was made by Deseq2 in R.

Results: In this study treatment of the clinical E. coli strain from healthy individual with IgA leads to differential expression of 218 genes. Of particular interest was the significantly increased expression of genes encoding serum survival lipoprotein Iss (iss), proteins involved in adhesion (type 1 fimbrial protein), invasion and vesicle formation (bamB, nlpA), motility-associated proteins (fliC/fljB, flgK, motA) and O6-antigen synthesis (wzx, wzy). IgA treatment stimulates bacterial cell division by increasing the expression of genes ftsQ, zapC, zipA and decreasing the expression of division inhibitor sulA.

At the same time, the expression of pks-island genes encoding the colibactin production system (clbJ, clbI, clbE, clbC) decreased. The functional role of colibactin is controversial, but it is necessary for probiotic E. coli to realize its anti-inflammatory effects.

Conclusion: Testing a commensal strain of E. coli from a healthy donor for IgA treatment revealed an increase in the expression of virulent factors such as adhesion, invasion, motility and immune stimulation that help bacteria survive and colonize the intestine.

Thus, in addition to imbalance in bacterial community, CD is accompanied by a change in the interaction of commensal bacteria with human immune system leading to an increase in bacterial virulence.

Introduction: Crohn's Disease (CD)-associated adherent-invasive *E. coli* (AIEC) are, by definition, able to adhere to and invade intestinal epithelial cells (IECs), and to survive and replicate within macrophages inducing inflammatory response. Besides, macrophages from CD patients are specifically defective to control AIEC replication.

It has been recently shown that anti-TNF agents limit AIEC replication within macrophages by modulating Chitinase 3-Like 1 (CHI3L1) expression. AIEC bacteria adhere to IECs through the interaction between the AIEC protein ChiA and CHI3L1. Whether CHI3L1-ChiA interaction could play a role in promoting AIEC entry into macrophages is unknown.

Aims & Methods: We aimed to assess whether the CHI3L1-ChiA interaction is implicated to promote AIEC entry and survival within macrophages and to decipher the involved mechanisms.

The physical interaction between these two proteins have been assessed by Western blot. Human cultured macrophages (THP-1) and human macrophages-derived monocytes (hMDM) were infected with the reference AIEC LF82 strain (LF82 AIEC WT), the corresponding *chiA*-negative mutant (LF82- Δ *chiA*) and its transcomplemented for *chiA* (LF82- Δ *chiA*:: Δ *chiA*), and with a commensal strain of *Escherichia coli*(K12C600). Other AIEC strains, isolated from CD patients were also used.

Fluorescent protein (green and red) genes have been added in bacteria's genomes in order to visualise them during co-infection observed by cell-live or confocal imagery. Anti-CHI3L1 antibodies and recombinant CHI3L1 have been used to block ChiA-CHI3L1 interaction.

Results: After incubation with AIEC, recombinant CHI3L1 protein binds AIEC LF82 bacteria with a 2.5-fold higher intensity than the *chiA*-invalidated mutant ($p < 0.05$) confirming ChiA-CHI3L1 interaction. LF82- Δ *chiA* bacteria uptake (at 1h post-infection) within human macrophages was reduced of 40 % and 45 % in THP-1 and hMDM, respectively, compared to wild type LF82 ($p < 0.05$). In contrast, we did not show any impact on AIEC survival at 10h and 24h post-infection.

Live imaging recording macrophages infection with a mixture (1:1 ratio) of LF82 AIEC WT (labelled in red) and the LF82- Δ *chiA* mutant (labelled in green), showed that LF82- Δ *chiA* mutant had a two-fold reduced entry into hMDM ($p < 0.05$) than LF82 AIEC WT.

Incubation with recombinant CHI3L1 to inhibit ChiA-CHI3L1 interaction, led to a two-fold decrease of AIEC uptake within macrophages at 1h post-infection ($p < 0.05$). Blockage of ChiA-CHI3L1 interaction using anti-CHI3L1

antibodies significantly decreased the survival ability within macrophages of several AIEC bacteria strains isolated from CD patients including LF82 ($p < 0.05$), demonstrating that this mechanism may be common to different AIEC strains.

Conclusion: ChiA-CHI3L1 interaction plays a key role in the CD-associated AIEC ability to enter within macrophages. Blocking this interaction may be promising to target AIEC in patients with CD.

Disclosure: Nothing to disclose.

Introduction: Colon mucosa of Ulcerative colitis (UC) and Crohn's disease (CD) display variations in the number and distribution of immune cells that are difficult to assess by eye. Digital pathology enables deep learning-based analysis on whole slide images (WSI) to extract complex quantitative data. This may uncover differences in inflammatory patterns and help identify histological features with prognostic or predictive value. T cell disturbances in IBD mucosa create a pro-inflammatory environment. The epithelial area has a large population of tissue resident $\gamma\delta$ T cells that play key roles in gut immunity, but their role in IBD is not clear ¹.

Aims & Methods: In this study, we use deep learning-based segmentation and cell detection on 57 WSIs from 37 CD patients, 83 WSIs from 58 UC patients, and 41 WSIs from 33 healthy controls, to quantify CD3 and $\gamma\delta$ T cells in the epithelial, subepithelial and lamina propria compartments of proximal and distal colon mucosa, defined by Nancy histological index.²

We assessed the impact of oral corticosteroids, age, and gender on mucosal numbers of CD3 and $\gamma\delta$ T cells, and used flow cytometry to assess correlation between relative amounts of $\gamma\delta$ T cells in blood and colon mucosa.

Results: We found significantly lower numbers of intraepithelial $\gamma\delta$ T cells in inactive CD compared to inactive UC (Fold change (FC): 0.5, 95% CI 0.3-0.8, $p = 0.007$). HC had more intraepithelial $\gamma\delta$ T cells than inactive CD, but less than inactive UC, although the differences were not significant. However, oral corticosteroids were found to impact the intraepithelial numbers of $\gamma\delta$ T cells. Adjusting for this, the difference between inactive UC and HC became significant (FC 1.7, 95% CI 1.0-2.8, $p = 0.049$).

Further, histological disease activity was not associated with change in $\gamma\delta$ T cells in the epithelium in CD, in contrast to a significant loss of $\gamma\delta$ T cells from the epithelium in active UC (FC 0.3, 95% CI 0.2–0.5, $p < 0.001$). Interestingly, the total number of intraepithelial CD3 cells was not significantly affected by disease activity in CD or UC, which implies a role for other T cell subsets in the active UC epithelium. Another interesting finding was the generally higher numbers of CD3 cells in colon mucosa in CD compared to UC and HC.

By delineating a narrow subepithelial zone we found significantly higher numbers of CD3 cells in inactive CD than in inactive UC (FC 1.4, 95% CI 1.0–1.9, $p = 0.024$) and HC (FC 1.6, 95% CI 1.2–2.2, $p = 0.01$). The numbers of CD3 cells were also higher in lamina propria (FC 1.6, 95% CI 1.1–2.1, $p = 0.016$) and in the epithelium (FC 1.4, 95% CI 1.0–1.9, $p = 0.06$) in inactive CD than in HC. The numbers of $\gamma\delta$ T cells beneath the epithelium or in lamina propria did not differ significantly between CD, UC, and HC, and was not affected by disease activity. Proximal colon had significantly higher numbers of CD3 and $\gamma\delta$ T cells than distal colon. We found no effect of age or gender, and no significant correlation between the relative abundance of $\gamma\delta$ T cells in blood and mucosa.

Conclusion: The study uncovers significant differences in number and distribution of CD3 and $\gamma\delta$ T cells in particularly the epithelial microenvironment between inactive and active CD, UC, and HC. We hypothesize that fewer intraepithelial $\gamma\delta$ T cells in CD may represent a deficiency state of mucosal innate immunity³ leading to impaired acute responses and higher strain on other immune cells deeper down in the gut wall.

The study demonstrates the utility of deep learning techniques in tissue segmentation and cell quantification to describe the complex features of chronic inflammation more precisely in IBD.

Introduction: Claudins are transmembrane proteins of tight junctions (TJs). Alterations in the expression of many claudins along the gastrointestinal tract may lead to loss of the epithelial barrier function and contribute to the pathogenesis of inflammatory bowel diseases (IBD). In addition, tight junction proteins can contribute to the control of cell proliferation required for intestinal tissue repair. A better understanding of the role of claudins in cell proliferation during intestinal inflammation is needed.

Aims & Methods: The aim of this study was to investigate the connection between stem cell zone proliferation and epithelial tight junction protein claudin-2 expression on intestinal tissue repair in a mouse model of dextran sodium sulphate (DSS) induced acute colitis with the recovery phase. The expression of claudin-2 and Ki-67 as a marker of cell proliferation was evaluated on colon tissue sections by immunohistochemistry and correlated with colitis-associated parameters such as colon shortening, endoscopy score and intestinal permeability.

Results: DSS (1,5%) challenge given for 6 days followed by 6 days of recovery phase elicited increased colitis associated parameters such as disease activity index score (DAI), colon shortening and intestinal permeability in challenged group, which were all decreased in cyclosporine A treated animals. Colonoscopy examination showed the presence of oedema, mucosal thickening and vascular pattern changes in colon, while histopathology analysis revealed chronic inflammation and mucosal damage with beginning the of re-epithelization in the disease control group.

Significantly upregulated expression of claudin-2 and Ki-67 marker was detected in the disease control group in comparison with the water control and cyclosporine A treated group. A strong correlation between claudin-2 protein expression and cell proliferation marker Ki-67 in the colon can be seen in all groups, as well as the correlation between claudin-2 and clinical read-out of intestinal permeability (Spearman's Rank-Order Correlation, $p < 0.001$).

Conclusion: Our findings reveal significant upregulation of colonocyte proliferation and claudin-2 expression at the tight junctions along the basolateral membrane in the stem cell niche during DSS induced colitis model suggesting a greater role of tight junction proteins in the development of new epithelial cells in crypt base (Díaz-Coránguez, 2019). Results of present study further highlighted the role of claudin 2 in intestinal epithelial renewal.

In summary, results of our study indicate a role of claudin 2 expressing epithelial cells situated within stem cell niche in crypt proliferation and their contribution to increased permeability of mucosal barrier.

The strong correlation between colonic claudin-2 overexpression and increased intestinal permeability makes claudin-2 protein a good histopathological marker and therapeutic target for the leaky intestinal barrier in IBD.

Introduction: Crohn's disease (CD) is thought to result, in part, from a dys-regulated mucosal immune response towards the commensal gut microbiota. Perianal fistulas are a severe complication of CD, but also occur in patients without CD (cryptoglandular fistulas). The gut microbiota of CD patients with active inflammation is known to be different from healthy controls.

However, the existence of a fistula-specific microbiota in CD-associated perianal fistulizing disease has not been unraveled yet. In this pilot study, we aimed to identify the microbiota in the feces and fistula tract in both patients with CD-associated and cryptoglandular fistulas.

Aims & Methods: We analyzed fecal (n=16) and fistula swab (n=16) samples from 24 patients with perianal fistulas (CD: n=14; cryptoglandular: n=10) using 16S rRNA sequencing. From eight patients we obtained both fecal and fistula swab samples. No patients, apart from one CD patient, used antibiotics. Twelve out of fourteen CD patients used biologics, including infliximab, adalimumab, and/or vedolizumab, during sample collection. Microbiota analyses and visualizations were performed in R (v4.0.4).

Differential abundance analysis was performed at genus level using DE-Seq2 with the Wald test. P-values were adjusted using Benjamini-Hochberg correction and adjusted p-values < 0.05 were considered significant. In addition, RNA in situ hybridization (RNAscope®) was applied on formalin-fixed, paraffin-embedded specimens for the detection of bacterial RNA using a 16S RNA probe for eubacteria.

Results: Analyses of the fecal and fistula microbiota revealed a different microbial composition between the two locations, including more skin bacteria (e.g. *Lawsonella*, *Cutibacterium*, *Staphylococcus*), bacteria belonging to the Peptostreptococcus family, and especially a high relative abundance of the phylum Fusobacteriota in the fistula tracts. Fusobacteriota was especially abundant in CD-associated fistula tracts.

Comparison of CD and cryptoglandular fistula microbiota showed a significantly higher level of oral disease-associated bacteria (*Sneathia* - belonging to phylum Fusobacteriota, and *Eikenella*) in CD fistulas compared to cryptoglandular fistulas, next to enrichment of *Sutterella*. In cryptoglandular fistulas high levels of some so-called 'colitis protective bacteria' (*Coprostanoligenes*, *Holdemanella*, *Parasutterella*, *Christensenellaceae*, *Subdoligranulum*) were found compared to CD fistulas. Besides this, we were able to detect bacteria infiltrating the tissue around the fistula tract in CD fistulas.

Conclusion: In this study we revealed the existence of microbiota specific for CD-associated perianal fistulas with increased relative abundance of oral disease-associated bacteria and *Sutterella*, the latter known for its degradation of IgA¹. Observed differences in the fistula microbiota between CD and non-CD patients could lead to identification of new biomarkers to distinguish both diseases.

Introduction: Crohn's disease (CD) is a chronic inflammation of the gastrointestinal tract leading to progressive, often irreversible bowel damage, such as strictures, fistulae and/or functional impairment. The complexity and heterogenous presentation highlight the need for individualized therapeutic approach.

Many studies have identified CD biomarkers using proteomic tools; however, clinical and disease signature markers indicative of the molecular progression of the disease are yet to be developed.

Aims & Methods: We aimed to analyse the serum proteome of CD patients with different phenotypes by employing mass-spectrometry (MS) techniques, in order to identify novel candidate biomarkers for disease progression.

We prospectively included in this study 30 CD patients and 15 healthy controls (HC). CD patients who had confirmed strictures or penetrating disease at the time of inclusion in this study (n=15), and a group of patients with persistent inflammation but no strictures or fistulae (n=15) were selected. Baseline demographic data, disease characteristics and phenotype, as well as the type and duration of IBD treatment were recorded. Serum samples were collected and subjected to depletion of highly abundant proteins and to label-free nano-LC coupled with Q-TOF mass spectrometry analysis (nano-LC HDMS).

For the analysis of two groups we used Welch's t-test or Mann-Whitney-Wilcoxon rank sum test; for correlation analysis we used Spearman's rho test. Significant proteins were chosen when p<0.05, fold change >1.5, and rho >0.8. The mean decrease in Gini from a random forest model with 2000 trees was used to determine the importance of selected proteins and clinical biomarkers in differentiating between CD and healthy individuals and between CD phenotypes, where B1= inflammatory and B2/B3 = stricturing/penetrating (B1 and B2/B3). Bioinformatic tool Metascape was used towards identification of pathways and protein interactions of proteins with changed abundance.

Results: The serum proteome was characterized and over 300 non-redundant proteins were identified in each sample group with good coefficient of variation (CV<15%) and peptide coverage. A total of 21 proteins, including haptoglobin, plexin, serum amyloid 1 distinguished between CD and HC groups. A statistically significant panel of 28 proteins was identified between the B1 versus B2/B3 phenotypes.

Twenty-four proteins were significantly abundant in the B1 phenotype group compared to the B2/B3 group, including: Interleukin-18 (IL-18), Cilia- and flagella-associated protein 36 (CFAP36), Plexin-A2 (PLXNA2), Protein S100-Z, Immunoglobulin heavy variable 1-58 (IGHV1-58), Plasma

serine protease inhibitor (SERPINA5). In the B2/B3 group, there was a significant elevation of 4 proteins in comparison to the inflammatory group: WD repeat-containing protein 31, Leucine-rich alpha-2-glycoprotein (LRG), Serum amyloid A-1 protein (SAA1), Plexin-A1 (PLXNA1).

Conclusion: Proteomic analysis by MS is able to differentiate among inflammatory and complex CD. Some of the proteins that differentiate stricturing/penetrating phenotype were found to be implicated in acute inflammatory response (SAA1, LRG) Th1 and natural killer cell immune responses (IL-18), innate and adaptative immune responses (haptoglobin, IGHV1-58), coagulation, cellular proliferation, adhesion and migration (PLXN A1/A2, SERPINA5). Unique biomarker panels based on protein sets were identified and could provide significant insight into CD progression.

SALIVARY EXOSOMES AGGRAVATE COLITIS BY REGULATING THE GUT IMMUNITY

C. Yang¹, J. Chen¹, Y. Xu¹, P. You¹, T. Peng¹, N. Chen¹

¹Peking University People's Hospital, Beijing, China

Contact E-Mail Address: yangcongyi@yeah.net

Introduction: Inflammatory bowel disease (IBD) is a chronic intestinal immune-dysfunctional disease involving the ileum, rectum, colon and even the entire digestive tract. More and more reports recognized the close correlation between the oral cavity and IBD incidence. Human saliva, as a readily available body fluid, may be a powerful indicator for evaluation of both local and systemic diseases. Numerous studies have shown that exosomes are important for information exchange, especially in the communication between distant organs.

However, the role of salivary exosomes in the colitis remains unknown. This study aimed at exploring the effect and mechanism of salivary exosomes on colitis.

Aims & Methods: Salivary exosomes were obtained from IBD patients using ultracentrifugation. In vivo, we used C57BL/6 mice to illustrate exosomes can travel from the oral cavity to the colorectum. Human myeloid leukemia mononuclear (THP-1) cells and Caco-2 cells were stimulated with lipopolysaccharides (LPS), which simulated an inflammation environment in vitro.

Results: Co-culture of THP-1 cells and Caco-2 cells with salivary exosomes from IBD patients were shown to raise inflammation in macrophages, which leads to increased release of inflammatory factors including TNF- α , IL-6, IL-1 β and promotes the polarization of M1 phenotype of macrophages.

Conclusion: In conclusion, the membrane structure of exosomes can resist the action of gastric acid and safely transport their contents to the intestine, where they can be taken up by macrophages to play a role. Salivary exosomes from IBD patients were found to promote intestinal inflammation via activating macrophages. Abnormal elevation of inflammatory factors was positively correlated with disease activity in IBD patients.

Introduction: The interplay between neuromodulators and serotonergic signaling might have an important role in the pathophysiology of inflammatory bowel diseases (IBD).

Interactions between mentioned signaling pathway and neurotrophins, such as brain-derived neurotrophic factor (BDNF) have been widely studied in the central nervous system (CNS), however, there is little data regarding this subject outside of this area.

Serotonergic transmission is heavily dependent on the serotonin reuptake transporter (SERT). It regulates the amount of serotonin in synapses by retrieving released serotonin back to the vesicles, thus changing the intensity of signal transmission. The direct interplay between BDNF and SERT in the CNS is quite evident, but interactions within the gastrointestinal tract remain elusive.

Aims & Methods: The aim of the study was to compare the expression of SERT mRNA and BDNF mRNA in IBD and healthy controls as well as assess their interactions and influence on the disease course.

The study group consisted of 68 patients with IBD (27 UC - ulcerative colitis, 41 CD - Crohn's disease) and 27 healthy controls (HC). Disease activity was assessed using the Harvey-Bradshaw index or partial Mayo score for CD and UC respectively. Venous blood samples were collected. RNA isolation from peripheral blood mononuclear cells was performed using the Trizol method. Synthesis of cDNA was conducted with a reverse transcription kit. The level of expression of chosen genes was determined by qRT-PCR. Amplification of the studied genes was compared to the reference gene β -actin. Relative expression was calculated using $\Delta\Delta C_t$ method. The study has been financed by National Science Centre, Poland-2018/31/N/NZ5/03715.

Results: IBD group showed an increased expression of SERT mRNA ($p=0.023$) and BDNF mRNA ($p=0.015$) compared to HC. SERT mRNA expression positively correlated with BDNF mRNA ($r=0.24$, $p=0.044$). In IBD patients, women have higher SERT mRNA expression than men ($p=0.019$), but not BDNF. There was no difference in genes expressions between the UC and CD group or between subjects with exacerbation and remission. The expression of SERT mRNA and BDNF mRNA was not affected by chronic diseases such as rheumatoid arthritis, asthma, diabetes, or surgical history ($p<0.05$).

Conclusion: Both SERT and BDNF may be important factors contributing to the pathophysiology of IBD, independently of the subjects' clinical status, IBD type, and other concomitant chronic conditions. Our results show that further research on the subject of interactions between SERT and BDNF in IBD might contribute to the state of knowledge on this condition and potentially improve current clinical practice.

Disclosure: Nothing to disclose.

Introduction: The immune pathogenesis of ulcerative colitis (UC) is linked to imbalanced CD4+ T-cell responses. In contrast, the contribution of CD8+ T cells to disease pathogenesis, their spatial localization within the intestine as well as their functions in UC are not well characterized. CD8+ T cells may become dysfunctional and acquire an exhausted phenotype during chronic viral infection or cancer. Recently, exhausted T cell (Tex) signatures have been proposed as a potential prognostic marker in autoimmune diseases.

Aims & Methods: We therefore set out to perform a comprehensive analysis of CD8+ T cells with regard to their spatial distribution as well as functions in UC patients. Immune phenotyping in formalin-fixed and paraffin-embedded sigma biopsies from patients with ulcerative colitis (n = 21) was performed using Imaging Mass Cytometry (IMC) and subsequent Phenograph cluster analysis. In addition, lymphocytes were isolated from sigmoid biopsies of UC patients in remission (n = 9) and active disease (n = 20) and analyzed *ex vivo* by flow cytometry. Results were correlated with disease activity (Mayo score) and mucosal inflammation (assessed endoscopically and histologically [Nancy score]).

Results: IMC analysis and subsequent whole tissue cluster analysis revealed two clusters of CD8+ T cells localized within epithelia and the submucosa, respectively. Further analysis defined 13 distinct CD8+ T cell clusters in which markers of activation as well as T cell exhaustion (Tex) were predominantly induced during active disease.

Unbiased spatial analysis as well as a cell-based neighborhood approach revealed that intraepithelial CD8+ T cells had an activated phenotype during flaring disease, but their abundance was rather limited as compared to subepithelial CD8+ T cells. CD8+ T cells expressing markers reminiscent of Tex also expressed effector cell markers. They were mainly localized in the submucosa and their spatial location correlated with the presence of CD20+ B cells. *Ex vivo* FACS analysis of intestinal CD8+ T cells confirmed that expression of exhaustion markers was significantly increased during active disease as compared to remission.

These cells also displayed dysfunctional cytokine profile patterns, as assessed by an established functional exhaustion score. This phenotype also closely correlated with clinical, endoscopic and histological markers of UC disease activity.

Conclusion: Our findings define clusters of CD8+ T cells correlating with disease activity in UC and displaying a specific spatial localization within the intestine. Interestingly, inflammation in the intestines of UC patients is associated with the induction of CD8+ T-cell responses that phenotypically and functionally resemble Tex.

Our data support a model in which pathogenic activated effector CD8+ T cells expand in active disease and develop exhaustion features that limit their immunopathogenicity. The functional relevance, prognostic value and therapeutic relevance of these exhausted CD8+ T cell signatures in UC need to be analyzed in future studies.

Introduction: Emerging evidence suggests that food additives lead to intestinal inflammation via modulating gut microbiota in animal models. In this study, we aim to determine food additives consumption and their interactions with gut microbiota in patients with Crohn's disease (CD).

Aims & Methods: Previous and current consumption of nine main food additives intake (polysorbate-80, carboxymethylcellulose, carrageenan, aspartame, sucralose, saccharin, titanium dioxide, aluminosilicate, and sulfites) was quantified in 156 subjects including 92 Crohn's disease patients (CD), 21 first-degree relatives of CD (FDR), 21 non-related healthy household members of CD patients (HHM) and 22 healthy controls (HC), using a validated 26-item food additive questionnaire.

Fecal shotgun metagenomic sequencing was performed to analyze bacterial profiles. The stool dissimilarity score for each subject was defined as the median Bray-Curtis dissimilarity to the reference NC group. The bacterial species which differentially abundant among different groups were determined by MaAsLin2 with age, gender and smoking status adjusted.

Results: No significant differences of food additive consumption were observed among the CD, FDR, HHM, and HC groups. Nevertheless, nanoparticles are still the predominant factor in separating the bacteria community in CD and HC. Besides, nanoparticles are independent element among all types of food additives.

The Principal Coordinates Analysis (PCoA) showed that the CD and HC groups separated completely, with the FDR and HHM intermediate between these two groups. In line with it, a large proportion of the FDR and HHM subjects were also found to possess dissimilarity scores of a similar magnitude to the CD group. The consumption of the food additive nanoparticles (Aluminosilicate (AlSiO) and Titanium dioxide (TiO2)) was positively correlated with the stool dissimilarity scores in CD subjects ($P < 0.05$).

Using only the CD datasets from CD-HHM pairs in comparison to HC, a total of 33 CD-depleted species and 25 CD-enriched species were identified. Of these, 3 of the CD-depleted species and 10 of the CD-enriched species showed concordant changes in the HHM. *Fusobacterium ulcerans*, which was not detectable in the HC group, was positively correlated with both AlSiO and TiO2 intakes in the CD and HHM groups ($R^2 = 0.27$, $P < 0.01$ and $R^2 = 0.43$, $P < 0.001$, respectively).

Additionally, among all pathways which *F. ulcerans* read counts assigned to, both ALSiO and TiO2 positively correlated with L-histidine degradation pathway ($R=0.28$, $P<0.001$; $R=0.34$, $P<0.001$) and negatively correlated with starch degradation pathway ($R=-0.18$, $P<0.05$; $R=-0.24$, $P<0.01$).

Conclusion: Long-term exposure to food additive nanoparticles is associated with gut microbiome derangements in CD and HHM via modulating the relative abundances of specific members of the stool microbiota. These food additive-associated microbial changes may play a critical role in the pathogenesis of Crohn's disease.

EMERGING ROLE OF IL-33/ST2 AND GUT MICROBIOTA AXIS IN THE INFLAMMATORY PROCESS OF ULCERATIVE COLITIS PATIENTS WITH ILEAL POUCH-ANAL ANASTOMOSIS

L.R. Lopetuso¹, L.M. Vetrone¹, V. Petito¹, D. Pugliese¹, L. Parisio¹, L. Laterza¹, M. Neri², F. Scaldaferrì¹, A. Gasbarrini¹, A. Papa¹

Contact E-Mail Address: lopetusoloris@libero.it

Introduction: It is now well-established that IL-33/ST2 axis and gut microbiota are important factors in the pathogenesis of IBD with a potential reciprocal influence. Recent evidence has shown that IL-33/ST2 axis controls the mucosal healing process during intestinal inflammation. Restorative proctocolectomy with ileal pouch-anal anastomosis is a surgical procedure in patients with ulcerative colitis (UC) refractory to medical therapies. Pouchitis, the most common complication, is the inflammation of the pouch with a controversial etiology.

Aims & Methods: We aimed to explore the potential combined involvement of the IL-33/ST2 axis and gut microbiota in the inflammatory process of pouchitis.

23 ulcerative colitis patients with ileal pouch-anal anastomosis were enrolled. After clinical, endoscopic and histological assessment (based respectively on Pouchitis Disease Activity Index and Pouchitis Histological Score) 13 showed pouchitis and 10 a normal pouch. Mucosal samples were collected from the afferent ileal loop and from the pouch and processed for cytokines assessment, IHC and histological evaluation, and gut microbiota analyses (16S ribosomal RNA gene amplicon pyrosequencing). Multivariate analyses were run to generate transcriptional interaction networks and identify biomarkers for patients with inflamed pouches.

Results: Between the two categories of patients, at Multiplex analysis, IL-1Ra, IL-6, IL-8, IL-17, IP-10, MCP-1, MIP-1a, MIP-1b resulted increased in samples obtained from the inflamed pouch vs. those obtained from the normal pouch. In patients with pouchitis, IL-7 resulted reduced in the inflamed pouch vs. samples obtained from the afferent ileal loop. In patients with the normal pouch, no differences were recorded between the pouch and the afferent ileal loop. In patients with pouchitis, at ELISA, IL-33 and ST2 protein levels were significantly reduced in the pouch vs. the afferent

ileal loop and resulted overall decreased vs. samples obtained from patients with normal pouch indicating a potential IL-33/ST2-mediated defective healing process. At western blot, full-length, bioactive IL33, ST2L and sST2 were expressed in all experimental groups; the cleaved, less active form of IL33 was increased in only patients with pouchitis. IHC confirmed these observations. IL-33 and ST2 staining were less intense within the inflamed and ulcerated mucosa of pouchitis patients compared to the normal pouch, and in close proximity to areas of re-epithelialization.

Microbiota analysis showed an overall decreased biodiversity in patients with pouchitis vs. patients with normal pouch (both at pouch and afferent ileal loop level). Lower levels of Verrucomicrobia and increased abundance of Actinobacteria were recorded in inflamed pouch vs normal pouch. In patients with pouchitis, the afferent ileal loop and the pouch showed significantly decreased levels of Akkermansia muciniphila and augmented abundance of Collinsella vs. samples obtained from patients with normal pouch. In patients with pouchitis, multivariate analyses evidenced a significant inverse correlation between Collinsella e Collinsella aereofaciens abundance and ST2 levels.

Conclusion: In patients with pouchitis vs patients with normal pouch, divergent inflammatory molecular pathways and microbial populations distinctly characterize the pouch and the afferent ileal loop.

Overall, our results suggest a potential role for IL-33/ST2 and gut microbiota axis in driving the gut mucosal wound healing in patients with ileal pouch-anal anastomosis. Further studies are underway to determine mechanisms of action that support these findings.

Introduction: The microbiome of patients with inflammatory bowel disease (IBD) is characterized by specific dysbiosis, including a decrease in the relative abundance of *Faecalibacterium prausnitzii* species, one of the prevailing representatives of the human intestinal bacterial community. Currently, *F. prausnitzii* is proposed to be used as a new generation probiotic in various diseases. However, there are only limited data on the genetic diversity of the bacteria in patients with IBD and healthy individuals.

Aims & Methods: The aim of the study was to reveal the genetic diversity of the *F. prausnitzii* from microbiota of IBD patients.

Total DNA was isolated from fecal samples of 72 IBD patients (35 with Crohn's disease (CD) and 37 with ulcerative colitis (UC)) and 42 healthy volunteers, followed by shotgun sequencing on the Illumina NextSeq 500 platform [1].

Strain-level profiling of metagenomic samples was performed with Pan-PhlAn 3 using *F. prausnitzii* reference genomes database. Clusters based on the presence of *F. prausnitzii* genes were identified using k-means method.

Results: *F. prausnitzii* genomes were found in the microbiota of 40 healthy individuals, 28 CD patients and 26 UC patients. By the presence of genes in each strain, we revealed two clusters, which characterize the genetic

diversity of *F. prausnitzii*. It was found that the frequency of occurrence of the strains from CD and UC patients in the first cluster is significantly higher (82.1% and 80.8% of all patients' strains, respectively) than from control group – 50% ($p < 0.05$ assessed by Exact Fisher test with BH adjustment). The second cluster is predominantly represented by the strains from healthy controls (50% of all controls' strains, 17.9% of the CD patients' and 19.2% of the UC patients' strains).

The genomes of *F. prausnitzii* from the first cluster (IBD cluster) differ significantly by a reduced frequency of occurrence of 1739 genes and an increased frequency of occurrence of 375 genes ($p < 0.05$ assessed by Exact Fisher test). It was found that the gene for γ -glutamyl- γ -aminobutyrate hydrolase involved in the synthesis of 4-aminobutyrate is significantly less frequently detected in the strains from the IBD cluster. 4-aminobutyrate is a substrate for the production of butyrate, which has anti-inflammatory properties and serves as the main energy source for colonocytes.

In addition, it was found that the genes involved in the synthesis of the bacterial cell wall also have a reduced frequency of occurrence in the IBD cluster, while the genes participating in peptidoglycan breakdown have an increased frequency of occurrence.

Thus, these alterations may lead to cell wall disintegration and to its barrier dysfunction. It was also found that the frequency of occurrence of genes coding iron binding proteins was significantly reduced in *F. prausnitzii* from the IBD cluster, which may lead to a decrease in the competition ability of the strains in the intestinal microbiota.

Conclusion: The strain-level metagenomic profiling revealed that *F. prausnitzii* from CD and UC patients are likely to produce less amounts of butyrate, have an impaired cell wall and less competitive ability than strains from healthy volunteers. Thus, the *F. prausnitzii* from healthy donors could potentially be used as a next-generation probiotics to alleviate symptoms of IBD.

Contact E-Mail Address: th_greuter@bluewin.ch

Introduction: It is unknown how high altitude exposure causes inflammatory bowel disease (IBD) flares. We assessed disease activity in healthy controls, IBD patients after 3h exposure in a hypobaric pressure chamber (imitating an altitude of 4000m above sea level).

Aims & Methods: In a prospective study, 11 Crohn's disease (CD, 6 males, 35.6y±13.7), 9 ulcerative colitis (UC, 3 males, 31.4y±10.8) patients and 10 healthy controls (7 males, 27.7y±4.9) underwent rectosigmoidoscopy in

our outpatient clinic (490m, baseline T1) and after 3h exposure in a hypobaric pressure chamber (follow-up day 1 T2 and day 7 T3). Symptoms were assessed using the Harvey Bradshaw Index and the partial Mayo Score before and after hypobaric pressure chamber exposure (baseline T1, day 1 T2, day 7 T3 and day 30 T4).

Disease activity was further assessed using CRP levels and fecal calprotectin. Intestinal mucosa-associated microbial composition was analyzed using high-throughput sequencing.

Results: The 3h exposure in a hypobaric pressure chamber was well tolerated in all subjects. Mean oxygen saturation decreased from 97.5%±1.3 to 80.9%±4.1, and increased back to normal levels (98.8%±1.2%) after the hypobaric intervention ($p < 0.0001$). Clinical and endoscopic disease activity were not significantly changed before vs. after intervention.

However, mild flare was seen in 2 UC patients and another UC patient was lost to follow-up due to a disease flare. New endoscopic lesions were detected in one healthy subject and one UC patient. Fecal calprotectin levels significantly increased in CD patients during the follow-up period ($p = 0.031$), but not in UC and healthy controls.

No changes in CRP levels were observed. Percentage of calprotectin-based disease remission (fecal calprotectin <100ug/g) decreased in all groups after hypobaric pressure chamber exposure, and increased thereafter with a significant decrease in the control group (100% at baseline vs. 50% at day 1, $p = 0.029$) and all patients combined (73.3% at baseline vs. 36.7% at day 7, $p = 0.013$). No differences in alpha and beta diversity of stool microbiota composition before vs. after hypobaric pressure chamber exposure were observed.

Conclusion: In this prospective study involving IBD patients and healthy controls, a 3h exposure in a hypobaric pressure chamber (corresponding to an altitude of 4000m) did not result in higher disease activity.

However, mild flares and development of endoscopic lesions were seen in a subset of patients. Calprotectin-based remission rates significantly decreased between baseline and day 7 suggesting a subclinical effect of short-term hypoxia, not explained by changes in the microbiome. (Clinicaltrials.gov number, [NCT02849821](https://clinicaltrials.gov/ct2/show/study?term=NCT02849821))

Disclosure: Nothing to disclose.

Introduction: The epidemiological data pointed out that exposure to ambient air pollution may increase the risk of irritable bowel syndrome and ulcerative colitis both in children and adults (Opstelten et al. 2016; Elten et al. 2020). Air pollutants affect the intestines through mucociliary clearance of particulate matter (PM) from the lungs, by food or water intake (Beamish et al. 2011).

Aims & Methods: In the present study, we tested the hypothesis that water-suspended smoke preparations (SPs) derived from the combustion of poplar wood might affect the integrity of the intestinal mucosa, induce an inflammatory response, and increase the susceptibility to chemically-induced colonic inflammation after the introduction of SP intravenously or through a gastric tube. Smoke from poplar wood was collected under laboratory conditions during the entire flaming and mixed combustion phase, as well as the smoldering phase. Male Wistar rats (180-200 g) were

injected with SP in two ways: 1) into the tail vein at a dose of 500 µg/100 g (n = 28); 2) by gavage at a dose of 180 µg/100 g (n=20). In 1 hour after SP injection, the experimental colitis was induced by a single rectal injection of 0.1 ml 6% iodoacetamide (7 cm from the anus) or vehicle 1% methylcellulose. Rats were euthanized in 2 h after colitis induction.

We examined colonic vascular permeability by Evans blue extravasation (mg/g wet colon), MPO level, total glycoprotein level at surface mucus by PAS-staining, intestinal permeability by the translocation of bacteria into the blood of the portal vein.

Results: Intravenous administration of the SP did not increase the negative effect of iodoacetamide-induced colitis on changes in the state of the endothelial barrier, myeloperoxidase activity, and the total glycoprotein level at surface colonic mucus in the rat colon. But, intravenous administration of SP led to the appearance of blood in the, which may be due to the damage to the fenestrated capillaries of the glomerulus.

However, intravenous administration of the drug did not increase the negative effect of iodoacetamide-induced colitis on changes in the state of the endothelial barrier, myeloperoxidase activity, and the amount of superficial mucus in the colon. At the same time, oral administration of SP increased the translocation of bacteria into the blood of the portal vein which represents the increased gut permeability of rats.

These changes were accompanied by the Oral administration of SP to simulated colitis rats likely reduced the amount level of total glycoprotein at surfaceperforal colonic mucus compared to the placebo group with colitis. However, oral administration of SP did not have a significant effect on colonic vascular permeability and the activity of myeloperoxidase vs. the placebo group with colitis.

Conclusion: The airborne particulate matter PM, obtained from the combustion of natural precursors such as poplar wood, can cause primary pro-inflammatory changes in the intestines in a very short time after penetration into the organism both through the blood and mucociliary clearance by food ingestion. Moreover, they can contribute to the violation of the integrity of the intestinal barrier in the conditions of simulated experimental colitis.

MYCOBACTERIUM AVIUM PARATUBERCULOSIS INCIDENCE IN PATIENTS WITH CROHN'S DISEASE AND CONTROLS: A SINGLE CENTRE STUDY

T. Nugent¹, N. O'Sullivan¹, E. Low¹, E. Herlihy¹, K. Hazel¹, I. Grant², C. O'Morain¹

¹Beacon Hospital, Department of Gastroenterology, Dublin, Ireland, ²Queens University, Institute for Global Food Security, School of Biological Sciences, Belfast, United Kingdom

Contact E-Mail Address: nugentti@tcd.ie

Introduction: Mycobacterium avium subspecies paratuberculosis (MAP) has been postulated to play a role in the pathogenesis of Crohn's Disease (CD)(1). Present in food such as pasteurised dairy and potable water, MAP was first identified in 1895 as the cause of a chronic enteritis in cattle known as Johne's disease, which shares a number of clinical and histopathological similarities to CD (2)(3).

MAP was first cultured from patients with CD in the 1980s and subsequent trials have demonstrated an association between MAP and CD, although this relationship is not fully understood (1)(4-7).

Aims & Methods: This study aimed to measure and compare serum samples of patients with CD and healthy controls for the presence of MAP.

CD patients and asymptomatic healthy controls were recruited at a single centre (Beacon Hospital). Whole blood samples were drawn, processed and then transported to a specialist facility for testing within a 24 hour period (Queens University Belfast). Each sample was blind tested for the presence of MAP using both an adapted culture method and a phage assay previously used to test human serum for the presence of MAP (7)(8).

Results: 45 participants, 22 CD patients and 23 controls were enrolled. Participant characteristics and results are described in Table 1.

Pozzato culture method was positive in 81.8% of CD patients and 95.7% of controls. Phage assay results were positive in 77.2% of CD patients and 78.3% of controls. Mean phage plaque numbers were 166.7 for CD patients compared with 198.9 for controls. Estimated MAP/ml for CD was 381.0 and 516.7 for controls.

	Crohn's Disease (CD)		Control	Crohn's Disease			Control	Crohn's Disease			Control	
Age (range)	49 (27-79)	34 (24-74)		Treatment ¹				- mean plaque no.			166.7	198.9
Gender			- No treatment	3		-		- Est. mean MAP/ml ²			381.0	516.7
- Male	13	12	- Amino-salicylates	1		-						
- Female	9	11	- Immuno-suppressant	2		-						
Harvey Bradshaw Index			- Biological agent	17		-						
- Remission (<5)	13	-	'More than one category possible									
- Mild Dis. (5-7)	8	-	Results	CD (+)	CD (-)	Control (+)	Control (-)					
- Moderate Dis. (8-16)	1	-	- Phage plaque assay	17 (77.2%)	5 (22.7%)	18 (78.3%)	5 (21.7%)					
- Severe Dis. (>16)	0	-	- Pozzato Culture	18 (81.8%)	4 (18.2%)	22 (95.7%)	1 (4.3%)					

Table 1.

Conclusion: This study showed significantly elevated levels of MAP in blood samples taken from both CD patients and asymptomatic healthy controls. This may be as a result of persistent MAP infection in human populations or secondary to consistent and regular exposure to viable MAP in dietary intake. The increased MAP levels shown in this study, relative

to previous human studies, may be explained by a reduced transit time and thus quicker time to sample testing. Lower levels of MAP detection in CD patients relative to controls is also noted, one explanation for which is the potential effect of CD therapies on MAP, restricting its replication or encouraging dormancy. Viable MAP is consistently present in the blood of both Crohn's patients and controls however further research is required to determine what role, if any, this zoonotic bacterium plays in disease pathogenesis.

Introduction: Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), is a T-cell driven intestinal inflammation. Current T-cell suppressive therapeutic regimens are moderately successful due to a large clinical heterogeneity amongst patients. Detailed understanding of aberrant inflammatory and inhibitory T-cell responses in individual patients is lacking.

Previously, we have shown that, in healthy individuals, 40% of peripheral blood CD38⁺(CD62L^{neg}CD4⁺) effector T cells, which are enriched for intestinal antigen specificity, express the inhibitory molecule T-cell immunoglobulin and ITIM domain (TIGIT). TIGIT⁺CD38⁺ effector T cells have

a regulatory function, produce IL-10 and express multiple co-inhibitory receptors. Conversely, TIGIT^{neg}CD38⁺ effector T cells are enriched in inflammatory IFN- γ producing cells. In a small cohort of pediatric-onset IBD patients, low frequencies of TIGIT⁺CD38⁺ effector T cells were associated with a reduced duration of clinical remission.

We hypothesize that a subgroup of IBD patients has reduced frequencies of circulating inhibitory TIGIT⁺CD38⁺ effector T cells, reflecting a distinct pathogenesis associated with a more severe disease course.

Aims & Methods: In the Rotterdam PIBD-SETQuality cohort were included newly diagnosed pediatric IBD patients (CD: n=37; UC: n=16), IBD-negative controls (n=12) and age-matched healthy controls (n=22). We monitored TIGIT⁺ and TIGIT^{neg}CD38⁺ effector T cells in peripheral blood by flow cytometry and collected plasma to measure plasma protein concentration at diagnosis and during immunosuppressive therapy.

Results: At diagnosis, 50% of CD patients had strongly reduced frequencies of inhibitory TIGIT⁺CD38⁺ effector T cells (TIGIT^{low} patients) compared to UC patients and age-matched healthy controls. TIGIT^{low} CD patients needed earlier anti-TNF treatment with 60% of patients receiving anti-TNF within 1 year versus 36% for CD patients with normal frequencies of TIGIT⁺CD38⁺ effector T cells (TIGIT^{norm} patients).

Moreover, 53% of TIGIT^{low} patients experienced a disease relapse by 1 year versus 25% of TIGIT^{norm} patients, suggesting a more severe disease course. Reduced frequencies of TIGIT⁺CD38⁺ effector T cells associated with active inflammation as frequencies were restored to the level of TIGIT⁺ cell frequencies in HC after 3 months of induction therapy.

Phenotypic characterization of TIGIT^{neg}CD38⁺ effector T cells in CD patients at diagnosis showed an inflammatory profile enriched in Ki67, reflecting recent proliferation, and high expression of chemokine receptors associated with inflammatory non-classical T helper-1 IFN- γ ^{high}IL-17^{low} producing (Th1*) cells. In agreement, high frequencies of TIGIT^{neg}CD38⁺ effector T cells correlated with high plasma IFN- γ concentrations.

Conclusion: These results demonstrate that reduced frequencies of circulating inhibitory TIGIT⁺CD38⁺ effector T cells discriminate a subgroup of pediatric CD patients with high frequencies of inflammatory Th1* cells and high plasma IFN- γ concentrations.

TIGIT^{low} CD patients have a more severe disease course and a higher chance of receiving anti-TNF within 1 year, altogether suggesting a distinct disease pathogenesis.

Disclosure: Nothing to disclose.

P0246

PREVALENCE AND RISK FACTOR OF PERIODONTITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A CASE-CONTROL, PROSPECTIVE STUDY

G. Baima¹, M. Muwalla¹, G. Testa², M. Vernero³, M. Aimetti¹, D.G. Ribaldone²

Contact E-Mail Address: davrib_1998@yahoo.com

Introduction: A plausible bidirectional association between periodontitis and IBD is receiving growing scientific interest. However, most of the available literature presented arbitrary case definitions for periodontitis, inaccurate assessment of the outcomes, uneven samples of IBD and non-IBD patients, and the risk of residual confounders in the analyses.

The aim of this study was to evaluate the association between periodontitis and inflammatory bowel disease (IBD) respect to an age and gender-matched control group of healthy controls.

Aims & Methods: Patients affected by IBD and healthy controls were consecutively recruited and compared for the diagnosis of periodontitis assessed according to CDC/AAP periodontitis case definitions via a full-mouth periodontal examination, including plaque index (FMPS), probing depth, clinical attachment level and bleeding on probing. The association of risk variables with both IBD and periodontitis was tested through univariate analysis and multivariate logistic models.

Results: One hundred eighty patients with IBD (117 Crohn's disease, CD and 63 ulcerative colitis, UC) and 180 healthy controls were compared. Significantly more patients with IBD had periodontitis and severe periodontitis (85.6% and 36.7%, respectively) than controls (65.6% and 25.6%, respectively). Differences remained significant when UC (85.0% in cases and 38.3% in controls) and CD (85.4% in case and 35.0% in controls) were considered separately, and they were higher in the 35-50 and 51-65 age groups. Individuals with IBD presented a chance ~3 and ~4.5 higher of having moderate (OR = 3.21; 95% CI 1.80-5.72; $p < 0.001$) and severe periodontitis (OR = 4.48; 95% CI 2.30-8.73; $p < 0.001$), respectively.

Significant variables associated with periodontitis in the whole sample (360 individuals) were: older age, presence of IBD, and higher FMPS. When focusing on the IBD sample, gender (male), IBD-associated surgery, IBD duration, and localization (pancolitis) were factors significantly associated with the co-occurrence of periodontitis.

Conclusion: Within the investigated sample, CD and UC patients had a significantly higher prevalence of periodontitis than controls without IBD. The risk association with disease-associated characteristics suggests a bi-directional relationship.

Disclosure: I disclose this.

Introduction: Ulcerative proctitis may have a mild and less aggressive course, although evidence is scarce because these patients are excluded from participation in randomized controlled clinical trials.

Aims & Methods: The aim is to identify clinical characteristics and complications associated with ulcerative proctitis refractory to conventional therapy. Patients included in the prospectively maintained ENEIDA registry from GETECCU (IBD Spanish Group) with ulcerative proctitis were included. Socio-demographic data and complications associated with immunosuppression (hospitalizations, surgeries, tumors) were evaluated.

We defined ulcerative proctitis based on ECCO guidelines and immunosuppression as the use of immunomodulators and/or biologics. Logistic regression was used to identify the independent factors associated with immunosuppressive therapy. The differences between the probability of persistence of biological therapy were analysed with Kaplan Meier.

Results: From a total of 34.716 patients with ulcerative colitis (ENEIDA registry, November 2021), 6281 (18%) patients with ulcerative proctitis were identified. Mean age was 53±15 years and mean duration of illness was 12±9 years.

Surgery was necessary only in 1.7% of patients, 31 (0.5%) panproctocolectomy or subtotal colectomy. 134 (2%) patients were hospitalized, 316 (5%) needed surgeries, 13 (0.2%) developed colorectal tumor and 316 (5%) other different tumors. 636 (10%) patients were refractory to 5-ASA and corticosteroids, necessitating immunosuppression: 487 thiopurines (7.4%), 49 with methotrexate (0.8%), 191 with infliximab (9%), 125 with adalimumab (2%), 50 with golimumab (0.8%), 57 with vedolizumab (0.9%), 6 with ustekinumab (0.1%) and 3 with tofacitinib. 316 (5%) patients needed one biologic therapy, 95 (1.5%) needed 2 biologics and 40 (0.6%) at least three different biologics. Polyarthritis [OR=3.58, CI 1.87-6.71; $p < 0.001$] and

thrombosis [OR=5.57, IC 0.98-28.75; p=0.039] were associated with higher risk of immunosuppression; no smoking [OR=0.58, IC 0.35-0.98; p=0.039] was associated with low risk. Immunosuppression was related to higher risk of hospitalization (mean 0.36 ±0.86 vs 0.06 ±0.30; p<0.001).

Conclusion: 10% of patients with ulcerative proctitis need immunosuppression therapy. Non-smokers have a lower immunosuppression requirement, however, polyarthritis or a history of thrombosis confers higher risk. Immunosuppression is associated with higher risk of hospitalization.

Introduction: Recent studies have brought to light the important economic impact in healthcare costs and resources utilization of IBD. The annual cost of IBD-patients in US is over 3-fold higher costs than their matched non-IBD patients (1).

Aims & Methods: The aim of this study is to evaluate the current healthcare expenditures of IBD in Catalonia.

All patients with IBD included in the Catalan Health Surveillance System (CHSS) including data on more than 7 million individuals in 2020.

Data on prevalence, incidence, comorbidities, stratification of risk, use of healthcare resources and economic impact were also extracted from the CHSS according to ICD-10-CM codes. Health expenditure was calculated according to the standard costs of each service provided by the Department of Health (Generalitat de Catalunya) (2).

The utilization of healthcare services and associated expenditure of IBD were compared with the population of patients not identified as IBD adjusted by age, sex, and income level (hereinafter referred to as "non-IBD").

Results: The prevalence and incidence of IBD in 2020 per 100,000 inhabitants was 405.61 and 27.2 respectively. Total number of IBD patients in 2020 was 37,381. Prevalence of comorbidities (neoplasia, arthritis, chronic obstructive pulmonary disease, asthma, cardiac disease, ictus and mental disease) was higher in IBD patients' when compared to non-IBD population. The risk of hospitalization in IBD was twice those of the non-IBD. The global healthcare expenditures of patient with IBD was 164,085,799€. The average annual expenditure for an IBD patient was 4,212.3€ versus 1,257.6€ for non-IBD population; being more than 3.4-fold higher (table 1).

Sanitary resource	IBD population			Non-IBD population			Relation
	Total annual cost (€)	cost per patient (€)	% cost	Total annual cost (€)	cost per patient (€)	% cost	
Primary Healthcare	9,750,778	230.3	5.9%	6,375,231	163.7	13%	x1.5
Pharmacy	100,888,316	2,589.9	61.5%	18,122,860	466.1	37.1%	x5.6
Hospitalization	24,157,004	620.1	14.7%	12,030,129	308.8	24.6%	x2
Emergency room	6,092,252	156.4	3.7%	3,778,156	97	7.7%	x1.6
Outpatient clinic	16,014,048	411.1	9.8%	4,314,309	110.8	8.8%	x3.7
Socio-sanitary	2,351,141	60.4	1.4%	1,458,510	37.4	3.0%	x1.6
Others	4,832,260	93	3%	2,065,575	73.9	5.9%	x2.3
Total	164,085,799	4,212.3	100%	48,987,769	1,257.6	100%	x3.4

Table 1. Comparison of the cost of the population with IBD and the matched population for each health resources

Conclusion: Patients with IBD presented a higher risk of comorbidities (1.5-2 fold) and healthcare resources utilization. Healthcare expenditure per patient were approximately 3.4 times higher than the non-IBD population.

SEROLOGIC RESPONSE WITH ANTIMICROBIAL ANTIBODIES DURING THE PRECLINICAL PHASE OF INFLAMMATORY BOWEL DISEASE

I. Rodríguez-Lago¹, J.L. Cabriada¹, M. Barreiro-de Acosta²

¹Hospital Universitario de Galdakao, Gastroenterology, Galdakao, Spain, ²Hospital Clínico Universitario de Santiago de Compostela, Gastroenterology, Santiago de Compostela, Spain

Contact E-Mail Address: iago.r.lago@gmail.com

Introduction: Previous data have shown that the inflammatory process underlying ulcerative colitis (UC) and Crohn's disease (CD) can start years before the diagnosis. Serum proteomic and serologic markers have been identified during this period, providing the opportunity for early detection of the initial immune disturbances.

Aims & Methods: Our aim was to determine if patients with an incidental diagnosis of UC or CD can demonstrate a serologic response based on antimicrobial antibodies in the years preceding the symptomatic onset of the disease. We performed a single-center prospective study including all asymptomatic subjects with a diagnosis of UC or CD during the colorectal

cancer screening program between October 2013 and February 2022 were included. The diagnosis of IBD was established by a combination of clinical data, including the presence of endoscopic findings suggestive of UC or CD and after histologic confirmation. ASCA IgA, ASCA IgG (EliA ASCA IgA/IgG, ThermoFisher) and ANCA (EUROPattern, PerkinElmer; EliA IgG, ThermoFisher) antibodies were determined. Positive results were considered above 10 U/mL for ASCA, 3.5 for ANCA-MPO and 2.00 for ANCA-PR3. Descriptive statistics were used.

Results: A total of 26 patients were included, 19 with UC (21% left-sided, 32% extensive; 53% former smokers), and 7 with CD (57% ileal, 29% colonic; 14% active smokers), with a median age of 51 years (IQR, 51-57). Two patients showed at least one positive test (7.7%). One patient (5%) with extensive UC showed positive ANCA results, and he developed symptoms 2 months after diagnosis. One patient (14%) with stricturing ileocolonic disease CD at diagnosis showed positivity to ASCA IgA/IgG, and he has remained asymptomatic after a median of 42 months. After a median follow-up of the whole cohort of 53.5 months (IQR, 26-67), 12 patients (46%) developed symptomatic disease.

Conclusion: A lower than expected proportion of patients with an incidental diagnosis of IBD demonstrate a serological response based on antimicrobial antibodies, suggesting that this situation corresponds to the initial phases of IBD when systemic immune disturbances might not be detectable yet.

Disclosure: Nothing to disclose.

THE BI-DIRECTIONAL RISK OF INFLAMMATORY BOWEL DISEASE AND ANXIETY OR DEPRESSION: A SYSTEMATIC REVIEW AND META-ANALYSIS

T. Bisgaard¹, K. Allin^{1,2}, R. Elmahdi¹, T. Jess^{1,2}

¹Aalborg University, Center for Molecular Prediction of Inflammatory Bowel Disease, PREDICT, Department of Clinical Medicine, Copenhagen, Denmark, ²Aalborg University, Department of Gastroenterology and Hepatology, Aalborg, Denmark

Contact E-Mail Address: taniabisgaard@gmail.com

Introduction: There is increasing awareness of the gut-brain axis and the interplay between psychiatric and gastrointestinal diseases. An association between inflammatory bowel disease (IBD), and anxiety and depression has been suggested, but the magnitude and directionality of risk remains uncertain.

Aims & Methods: This systematic review and meta-analysis of unselected population-based cohort studies examines the risk of depression or anxiety in IBD patients and the risk of IBD in patients with depression or anxiety. The objective is to quantify the bi-directional risk of anxiety or depression following a diagnosis of IBD, and the risk of IBD in individuals with depression or anxiety using population representative data.

We performed a systematic literature search using MEDLINE and Embase for studies published from 1991 through 2021. We undertook Random Effect Model meta-analysis for relative rate estimates of eligible studies to calculate a pooled hazard ratio (HR) for the risk of anxiety and depression in IBD and undertook subgroup meta-analysis to calculate risk by IBD subtype (Crohn's disease (CD), ulcerative colitis (UC)), sex and for pediatric-onset IBD.

Results: Out of 6,391 screened articles, 8 studies fulfilled all inclusion criteria. Five studies examining anxiety and depression among >100,000 individuals with IBD were included in meta-analyses, which showed an increased risk of both anxiety (HR 1.52, 95% CI 1.29-1.79) and depression (HR 1.62, 95% CI 1.41-1.86) following an IBD diagnosis. The risk of anxiety was increased following both CD (HR 1.73, 95% CI 1.43-2.09) and UC (HR 1.39 (95% CI 1.21-1.61).

The risk of depression was also elevated both following CD (HR 1.69, 95% CI 1.52-1.89), and UC (HR 1.52, 95% CI 1.31-1.77). Pediatric-onset CD patients had a particularly elevated risk of anxiety (HR 2.21, 95% CI 1.98-2.47). There were no significant differences in risk between males and females. Two studies investigating more than 400,000 individuals with depression showed a 2-fold increased risk of IBD following depression. The overall quality of included studies was good, and risk of publication bias was low.

Conclusion: This meta-analysis of population-based studies shows a 1.6-fold increased risk of depression and a 1.5-fold increased risk of anxiety following IBD, with pediatric-onset IBD patients having a particularly elevated risk of anxiety. Population-representative evidence for IBD risk after depression or anxiety diagnosis is sparse but points to a 2-fold increased risk of IBD following depression. This bidirectional association is clinically relevant and could indicate shared or mutually dependent disease mechanisms.

Disclosure: Nothing to disclose.

P0251

RISK OF POLYPS AND COLORECTAL CANCER IN PATIENTS WITH MICROSCOPIC COLITIS: CASE-CONTROL STUDY WITH LONG-TERM FOLLOW-UP

I. Fajardo¹, Y. Zabana^{1,2}, A. Salas³, M. Aceituno^{1,2}, L. Ruiz^{1,2}, M. Esteve^{1,2}, F. Fernández-Bañares^{1,2}

¹Hospital Universitari Mútua Terrassa, Department of Gastroenterology, Terrassa, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain, ³Hospital Universitari Mútua Terrassa, Department of Pathology, Terrassa, Spain

Contact E-Mail Address: ingridfajan@gmail.com

Introduction: A previous study (Fernandez-Bañares et al, UEGJ 2016;4s: A434) showed that in microscopic colitis (MC) there is a low frequency of polyps and colorectal cancer (CRC) compared to the general population at medium risk, without observing differences with a group of chronic diarrhoea and normal colonic histology.

Aims & Methods: The aim of the present study is to assess whether this low incidence of adenomas in patients with MC and chronic diarrhoea persists in the long term. Patients with follow-up colonoscopies for control of colonic polyps or for diarrhoea recurrence after index colonoscopy were included in two groups: patients in the MC group (32/100 patients, Group A) and in the chronic diarrhoea group (68/200 patients, Group B). Colonic polyps were recorded, collecting adenomas, advanced adenomas (AA; high-grade dysplasia -HGD-, villous component and size > 1cm) and CRC. A conditional logistic regression analysis was performed (COXREG: 1 case-2 controls, matched by age and sex).

Results: With a median follow-up of 9 years (IQR =7-12 years), 2 CRC were diagnosed in Group B (2/200). A total of 44 colonoscopies were performed in Group A and 105 in Group B, with no significant differences between groups (p=0.35). Recurrent diarrhoea was present in 25% of Group A and 38% of Group B (p=0.19). In these endoscopies, the total frequency of adenomas was: Group A 28% and Group B 56% (p=0.009). The frequency of AA was: Group A 12.5% and Group B 14.7% (p=1). The frequency of HGD/CRC was 0% in Group A and 5.8% in Group B (p=0.30). For adenomas, the COXREG OR was 0.2 (CI=0.05-0.75; p=0.017) and for AA (with CRC included) 0.8 (CI 0.26-2.9; p=0.8).

Conclusion: After long-term follow-up, patients with MC have a decreased frequency of adenomas and a trend to have less HGD/CRC compared with patients with chronic diarrhoea and normal colonic histology. These differences, therefore, are probably due to the MC itself and not to a protec-

tive effect of diarrhoea, as had been previously suggested. These results support the recommendation of not doing specific screening for CRC prevention in patients with MC.

P0252

EVOLUTION OF DISEASE PHENOTYPE, TIME TO BIOLOGICAL THERAPY AND MEDIUM-, LONG-TERM SURGERY RATES IN CROHN'S DISEASE PATIENTS IN WESTERN HUNGARY – A POPULATION-BASED STUDY BETWEEN 2007–2018, DATA FROM THE VESZPREM COUNTY COHORT

L. Gonczi¹, L. Lakatos², P.A. Golovics³, Z. Kürti¹, T. Pandur⁴,

G. Dávid², Z. Erdelyi², I. Szita², P.L. Lakatos⁵

¹Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary, ²Ferenc Csolnoky County Hospital, Department of Gastroenterology, Veszprem, Hungary, ³Hungarian Defence Forces Medical Centre, Department of Gastroenterology, Budapest, Hungary, ⁴Grof Eszterhazy Hospital, Department of Gastroenterology, Papa, Hungary, ⁵McGill University Health Center, Division of Gastroenterology, Montreal, Canada

Contact E-Mail Address: lorantgonczi@gmail.com

Introduction: The number of prospective population-based studies evaluating the natural disease course and surgical outcomes of Crohn's disease (CD) are still limited from Eastern Europe. The present study is a continuation of the Veszprem IBD population-based cohort with a follow-up of the incidence and disease course of IBD since 1977.

Aims & Methods: Our aim was to evaluate disease course by examining progression in disease phenotype, time to biological therapy and surgery rates in a prospective population-based database from Veszprem Province, including incident CD patients diagnosed between January 1, 2007 and December 31, 2018.

Data of 421 incident CD patients were analyzed (male/female: 237/184; median age at diagnosis: 29 years(y) [IQR: 21–42]). Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up. The mean length of follow-up was 8.53y (SD: 3.3). Disease phenotype was evaluated based on the Montreal classification. Probability of medium-, long-term change in disease course and surgical outcomes were analyzed using Kaplan–Meier survival analysis.

Results: Disease location was ileal (L1), colonic (L2) in and ileo-colonic (L3) in 29.7%/ 24.5%/ 45.8% of patients at diagnosis. At the end of follow-up (8.53y), disease location was 27.1%/ 22.8%/ 50.1% (L1/L2/L3). The proportion of patients with upper gastrointestinal manifestation remained stable (7.6% and 8.1%), while perianal disease increased from 13.5% to 19% by the end of follow-up. Disease behavior at diagnosis was luminal (B1) in 62.5% of the patients. The probability of disease behavior progression from luminal into stenosing or penetrating phenotype was 11.9% (SE:1.7) at 3 years, 13.2% (SE:1.7) at 5 years and 17.6% (SE:1.7) at 10 years. The Probability of receiving biological therapy after diagnosis was 20.9% (SE:2.0) at 5 years and 28.8% (SE:2.0) at 10 years in this cohort.

Overall resective surgery rate was 29.5% in the total population, while perianal surgery rate was 31.3% in patients with perianal disease at the end of follow-up. The probability of resective surgery was 20.7% (SE:2.0) at 1 year, 26.1% (SE:2.2) at 5 years and 30.7% (SE:2.4) at 10 years. For the probability of first perianal surgery among patients with perianal disease.

Conclusion: The probability of progression in disease behavior was lower compared to data from previous decades and similar to results from recent pan-European population-based data. (Burisch 2018, JCC). One-year surgery rates after diagnosis were considerably higher compared to previous data from our cohort or compared to Western and Northern Euro-

pean centers. (Lakatos 2011, IBD). Medium-term (5y) surgery rates were similar (~20%) compared to recent Hungarian and European data, while long-term (10y) rates decreased compared to data from previous decades. (Lakatos 2011, IBD; Lakatos 2012, AJG).

Disclosure: Nothing to disclose.

P0253

INCIDENCE, PREVALENCE, DISEASE PHENOTYPE AND MAXIMAL THERAPEUTIC STEP IN ULCERATIVE COLITIS PATIENTS IN WESTERN HUNGARY – A POPULATION-BASED STUDY BETWEEN 2007–2018, DATA FROM THE VESZPREM COUNTY COHORT

Introduction: Recent trends indicate a change in the epidemiology of inflammatory bowel disease (IBD) with previously low incidence areas now reporting progressive rise. The number of epidemiological population-based studies are still limited from Eastern Europe.

The present study is a continuation of the Veszprem IBD population-based cohort with a follow-up of the incidence and disease course of IBD since 1977.

Aims & Methods: Our aim was to analyze the incidence and disease phenotype at diagnosis, and the maximal therapeutic step distributions during follow-up in a prospective population-based database from Veszprem Province, including incident ulcerative colitis (UC) patients diagnosed between January 1, 2007 and December 31, 2018.

Data of 467 incident UC patients were analyzed (male/female: 236/231; median age at diagnosis: 36 years(y) [IQR: 25–54]). Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up. The source of age- and gender-specific demographic data for statistical analysis was derived from the results of a national population census in 2011 (Hungarian Central Statistical Office). Disease extension was evaluated based on the Montreal classification.

Results: Adjusted mean incidence rate was 11.02 (CI95%: 10.1–12.1) /10⁵ person-years in this 12 year period [males: 11.53 (CI95%: 10.2–13.1) /10⁵; females: 10.54 (CI95%: 9.3–12.0) /10⁵]. Prevalence rate was 283.51 (CI95%: 265.7–300.7) /10⁵ persons in 2011 and 317.79 (CI95%: 298.8–335.8) in 2015. For detailed annual incidence rates and age-specific mean incidence rates. Peak onset age in UC was 20–29 years of age. Diagnostic delay from symptom onset was ≥1year in 19.1%, and ≥3 years in 4.1% of the patients. Disease extension was proctitis (E1) in 22.3%, left sided colitis (E2) in 43.9%, and extensive colitis (E3) in 33.8% of the patients at diagnosis. Patients with extensive colitis were younger (32.9y, SD:16.6) at diagnosis compared to patients with proctitis (40.1y, SD:15.9; p<0.001) or left sided colitis (44.0y; SD:19.1; p<0.001). Extraintestinal manifestations were as follows: hepatic 5.4% (PSC 2.1%), arthritis 10.7%, ocular 0.9%, skin 3.6%. Active smokers at diagnosis were 12.6%, while past-smokers 18.2%. Distribution of maximal therapeutic steps during the course of follow-up (8.34y, SD: 3.5) were 5-ASA in 46.9%, systemic corticosteroids in 16.3%, immunosuppressive therapy in 19.3%; anti-TNF biologic therapy in 12.2% and other biologic therapy in 4.3%.

Conclusion: The incidence of UC in this 12 year period was high, comparable to high-incidence areas in Western European countries, and comparable to previous data from the Veszprem cohort, while prevalence rates continue to rise compared to our previous data. (Lakatos 2011, IBD). Disease extension at diagnosis and distribution of highest treatment step was comparable to European population-based data. (Burisch 2019, JCC).

Introduction: The number of prospective population-based studies evaluating the natural disease course and surgical outcomes of ulcerative colitis (UC) are still limited from Eastern Europe. The present study is a continuation of the Veszprem IBD population-based cohort with a follow-up of the incidence and disease course of IBD since 1977.

Aims & Methods: Our aim was to evaluate disease course by examining progression in disease phenotype, time to biological therapy and colectomy rates in a prospective population-based database from Veszprem Province, including incident UC patients diagnosed between January 1, 2007 and December 31, 2018.

Data of 467 incident UC patients were analyzed (male/female: 236/1231; median age at diagnosis: 36 years(y) [IQR: 25-54]). Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up. The mean length of follow-up was 8.34y (SD: 3.5). Disease phenotype was evaluated based on the Montreal classification. Probability of medium-, long-term change in disease course and surgical outcomes were analyzed using Kaplan–Meier survival analysis.

Results: Disease extension was proctitis (E1), left sided colitis (E2), and extensive colitis (E3) in 22.3%/ 43.9%/ 33.8% of patients at diagnosis. The probability of disease progression into more extensive phenotype was 6.9% (SE:1.2) at 3 years, 8.3% (SE:1.3) at 5 years and 11.3% (SE:1.6) at 10 years. The Probability of receiving biological therapy after diagnosis was 9.9% (SE:1.4) at 3 years, 13.9% (SE:1.6) at 5 years and 17.8% (SE:2.0) at 10 years in this cohort.

Overall colectomy rate was 4.1% in the total population at the end of follow-up. The probability of colectomy was 1.5% (SE:0.6) at 1 year, 3.6% (SE:0.9) at 5 years and 4.4% (SE:1.0) at 10 years in Kaplan–Meier analysis.

Conclusion: The probability of progression in disease extent was low overall, similar to results from recent pan-European population-based data. (Burisch 2019, JCC). Medium- and long-term colectomy rates were lower compared to Western European centers, but somewhat higher compared to our previous data from the Veszprem cohort (2002–2006). (Lakatos 2011, IBD).

Disclosure: Nothing to disclose.

Introduction: Limited data are available on the incidence and predictors of colorectal cancer (CRC) in ulcerative colitis (UC) derived from population based studies, especially from the Eastern European region. The present study is a continuation of the Veszprem IBD population based cohort with a follow-up of the incidence and disease course for over 40 years.

Aims & Methods: Our aim was to analyze the incidence and risk factors of CRC in a prospective population-based database from Veszprem Province, including incident UC patients diagnosed between January 1, 1977 and December 31, 2018.

Data of 1,370 incident UC patients were analyzed (male/female: 702/668; median age at diagnosis: 37 years(y) [IQR: 26-51]), with a median of 17y (IQR 9-24) follow-up. Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up. Disease extension was evaluated based on the Montreal classification. The risk of CRC was estimated using standardized incidence ratios (SIR). Age- and sex-specific CRC rates of the background population were derived from the National Cancer Registry (NCR) and Hungarian Central Statistical Office (KSH).

Results: CRC was diagnosed in 41/1,370 patients (2.99%), equaling an incidence rate of 41/23,240 person-year-duration. Median age at diagnosis of CRC was 59y (IQR: 50-67.5). The overall standardized incidence ratio of CRC in UC patients was 2.02 (CI95%: 10.1-12.1), compared to the background population. Marked elevation in SIRs were showed with more extensive disease (SIR_{proctitis}: 0.19, CI95%: 0.03-1.37; SIR_{left-sided}: 2.09, CI95%: 1.36-3.21; SIR_{extensive}: 3.77, CI95%: 2.41-5.91). The number of CRCs diagnosed during the complete follow-up increased by disease duration (0-10y: 4/395, 1.01%; 11-20y: 16/498, 3.21%; 20+y: 21/477, 4.40%). The cumulative risk of developing CRC after a disease duration of 10 years was 0.9% (SE: 0.3), 3.5% (SE: 0.7) after 20 years, and 6.5% (SE: 1.1) after 30 years. Patients with extensive disease and chronic continuous disease activity had higher probability of developing CRC compared to left sided disease extension and remitting disease activity (pLogRank=0.015 and 0.003). Longer disease duration, extensive colitis, chronic continuous disease activity, primary sclerosing cholangitis (PSC), anaemia and dysplasia were identified as risk factors for developing CRC in univariate analysis. In a multivariate logistic regression model, longer disease duration (p=0.018), PSC (p=0.001), anaemia (p=0.036) and dysplasia (p=0.029) remained significant predictors of CRC.

Conclusion: The cumulative risk of CRC was somewhat lower compared to previous results from this cohort; and also lower compared to previously reported results from Western European and North American studies. Longer disease duration, extensive colitis, chronic continuous disease activity, dysplasia, and PSC were identified as important risk factors for developing CRC.

Disclosure: Nothing to disclose.

P0256

EVOLUTION OF DISEASE PHENOTYPE, TIME TO BIOLOGICAL THERAPY AND MEDIUM-, LONG-TERM SURGERY RATES IN IBD-U PATIENTS IN WESTERN HUNGARY – A POPULATION-BASED STUDY BETWEEN 1977–2018, DATA FROM THE VESZPREM COUNTY COHORT

L. Gonczi¹, L. Lakatos², P.A. Golovics³, T. Pandur⁴, G. Dávid², Z. Erdelyi², I. Szita², P.L. Lakatos⁵

Introduction: The number of epidemiological population-based studies on unclassified inflammatory bowel disease (IBD-U) patients are very limited. The present study is a continuation of the Veszprem IBD population based cohort with a follow-up of the incidence and disease course of IBDU since 1977.

Aims & Methods: Our aim was to evaluate disease course by examining progression in disease phenotype, time to biological therapy and surgery rates in a prospective population-based database from Veszprem Province, including incident IBD-U patients diagnosed between January 1, 2007 and December 31, 2018.

Data of 119 incident IBD-U patients were analyzed (male/female: 55/64; median age at diagnosis: 34 years(y) [IQR: 24-47]). Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up. The mean length of follow-up was 18.0y, (SD: 8.9). Probability of medium-, long-term change in disease course and surgical outcomes were analyzed using Kaplan–Meier survival analysis.

Results: Disease extension at diagnosis was proctitis in 7.6%, one-sided colitis (left-sided colitis, or isolated right-sided colitis) in 36.1%, and extensive (pancolitis) in 56.3%. The probability of progression in colonic disease extent over the course of follow-up was 6.7% (SE:2.3) at 3 years, 10.3% (SE:2.8) at 5 years and 15.3% (SE:3.4) at 10 years. In originally IBD U patients, new disease activity in the terminal ileum developed in 6.7% (n=8) patients over the total follow-up. The cumulative probability of developing terminal ileitis was 2.6% (SE:1.5) at 5 years and 3.5% (SE:1.7) at 10 years. Perianal disease developed in 5% (n=6) of all patients during the total follow-up. The probability of biological therapy initiation was 8.7% (SE:2.6) at 5 years, 11.4% (SE:3.0) at 10 years after diagnosis. In a sub-analysis of patients diagnosed after the year 2000 (n=62), the probability of receiving biological therapy was 15.5% (SE:4.8) after 5 years, and 19.4% (SE:5.3) after 10 years of follow-up. The overall surgery rate was 16.8% at the end of follow-up. Segment resection was performed in 5.0% of the patients, and 11.8% underwent subtotal- or total colectomy. The cumulative probability of resective surgery was 7.6% (SE:2.4) at 1 year, 9.3% (SE:2.7) at 5 years, 13.5% (SE:3.3) at 10 years, and 18.5% (SE:3.9) at 20 years. Colorectal cancer was detected in n=5 cases (4.2%) during the total follow-up.

Conclusion: Initial disease phenotype was severe in most cases of IBD-U, and colonic progression is substantial over time. However development of terminal ileitis or perianal disease was relatively low in this cohort. Therapeutic strategy was aggressive with high proportions of biological therapy, similar to the therapeutic strategies of Crohn's disease. Surgery rates were high, comprising mainly colectomies, which is also suggestive of the severe disease course of IBD-U.

Disclosure: Nothing to disclose.

Introduction: Ulcerative colitis (UC) and Crohn's disease (CD) are two chronic conditions of the gastrointestinal tract. Previous data have shown that the inflammatory process starts years before the initial symptoms and the diagnosis.

Our aim was to determine if patients with an incidental diagnosis of UC or CD have an increase in healthcare utilization in the years preceding the symptomatic onset of the disease.

Aims & Methods: We performed a multicenter retrospective case-control study. Asymptomatic patients with a diagnosis of UC or CD during the colorectal cancer screening program at 9 hospitals between October 2010-January 2021 were included. Cases were matched 1:3 with controls adjusted by sex, age and date, excluding subjects with any visit to Gastroenterology, and with a cohort of patients with a symptomatic debut of IBD.

The main outcomes were the number of outpatient or Emergency Room visits, hospital admissions, radiological examinations (ultrasound, CT, MRI), sick-leaves, and prescriptions of antibiotics or systemic steroids up to 5 years before the diagnosis. Descriptive statistics were used, followed by chi-square tests and a multivariable hurdle or negative binomial regression model, adjusted by gender, age at diagnosis, smoking habits and Charlson index, in order to perform a per year and grouped (3 and 5 years) analysis.

Results: A total of 124 cases were included (87 UC, 30 CD, 7 IBD unclassified; median 56 years (IQR, 53-62); 44% female) and compared with 372 controls. Baseline characteristics including comorbidities were comparable between both cohorts. Patients demonstrated an increase in the number of visits to Primary Care during the combined periods including 3 and 5 years before the diagnosis (aIRR 1.59, 95% confidence interval [CI] [1.37-1.86], p=0.001; aIRR 1.43, 95% CI [1.24-1.67], p=0.01; respectively). This difference was also observed in the comparison of visits to specialized care physicians (aOR 62.74, 95% CI [26.10-151.41], p<0.0001; aOR 66.90, 95% CI [28.16-158.97], p<0.001; 3 and 5 years before, respectively). Systemic steroids were more frequently prescribed to patients also (aOR 2.84, 95% CI [1.21-6.69], p=0.03; aOR 2.25, 95% CI [1.06-4.79], p=0.04; 3 and 5 years before, respectively). Patients with symptomatic IBD had an increased number of visits to specialist care, Emergency Room, CT/US ex-

aminations, and prescriptions of both antibiotics and systemic steroids during the whole study period, while they showed a lower number of visits to Primary Care, compared to those with preclinical disease.

Conclusion: Patients with IBD show an increased need for medical assistance in the years prior to the diagnosis, even during the presymptomatic phase of the disease. Tools focused on early identification of IBD may start on Primary Care facilities, but certain factors as steroids may alter the development of symptoms and the full spectrum of the disease.

Disclosure: Nothing to disclose.

Introduction: Little evidence exists on possible phenotypic differences in inflammatory bowel disease (IBD) between men and women. In published studies, gender is one more variable, whose possible effects may be masked by interference with other variables, or not appear due to a small sample size.

Aims & Methods: AIM: To assess whether there are differences in the clinical patterns of IBD between women and men.

METHODS: Multicenter observational study that included all patients diagnosed with Crohn's disease (CD) or ulcerative colitis (UC) from the ENEIDA registry (GETECCU).

Results: A total of 51,595 patients from 86 centers were included, 25,947 with CD (13,238 men, 12,709 women) and 25,648 with UC (13,596 men and 12,052 women). Women in our IBD cohort more often had a family history of IBD than men (14.5% vs 12.8%, $p < 0.001$)

Significant differences were observed in the age of onset of both CD and UC between men and women. The age at onset of CD was lower in men [mean age: 34.7(15) vs. 35.7(16) years, $p < 0.001$], while in UC it was lower in women [mean age: 41.2 (16) vs. 38.4(15) years, $p < 0.001$].

In CD, males more often had a penetrating behavior (20% vs 16%, $p < 0.001$), more frequently developing intra-abdominal fistulas (14.7% vs 11.7%, $p < 0.001$) and related complications such as intra-abdominal abscess (8.2% vs 6.4%, $p < 0.001$) and perforation (3.6% vs 3%, $p = 0.005$). Men also had a higher prevalence of perianal disease (27.4% vs. 23.1%, $p < 0.001$). Women more often had an inflammatory behaviour (65.8% vs 62.9%, $p < 0.001$).

In UC, women more often had involvement limited to the rectum (26.3% vs. 19.3%, $p < 0.001$), while extensive UC was more frequent in men (40.7% vs. 34.3%, $p < 0.001$). Toxic megacolon (1.07% vs. 0.71%, $p = 0.003$) and perforation (0.43 vs. 0.25%, $p = 0.018$) were also more prevalent in men.

Extraintestinal manifestations were more frequent in women. 27.3% of women with CD (3475) vs. 20.4% of men with CD (2703) had extraintestinal manifestations, $p < 0.001$. In UC, 16% of women (1937) vs. 12.4% of men (691) had extraintestinal manifestations, $p < 0.001$. See Table 1.

Surgical treatment was more frequent in men in both CD (40.9% vs. 38.5%, $p < 0.001$) and UC (9.2% vs 6.8%, $p < 0.0001$)

	Men with CD n=13238	Women with CD n=12709	p-value	Men with UC n=13596	Women with UC n=12052	p-value
Peripheral spondyloar- thropathy	999 (7.55%)	1582 (12.45%)	<0.001	603 (4.44%)	819 (6.80%)	<0.001
Ankylopoietic spondylitis	556 (4.20%)	373 (2.93%)	<0.001	226 (1.66%)	137 (1.14%)	<0.001
Sacroiliitis	413 (3.12%)	384 (3.02%)	0.672	173 (1.27%)	187 (1.55%)	0.065
Erythema nodosum	233 (1.76%)	805 (6.33%)	<0.001	77 (0.57%)	252 (2.09%)	<0.001
Pyoderma gangrenosum	81 (0.61%)	125 (0.98%)	0.001	66 (0.49%)	90 (0.75%)	0.009
Uveitis	137 (1.03%)	224 (1.76%)	<0.001	71 (0.52%)	100 (0.83%)	0.003
Episcleritis	84 (0.63%)	151 (1.19%)	<0.001	46 (0.34%)	58 (0.48%)	0.089
Venous Thrombosis	155 (1.17%)	111 (0.87%)	0.021	150 (1.10%)	82 (0.68%)	<0.001
Primary sclerosing cholangitis	63 (0.48%)	46 (0.36%)	0.186	175 (1.29%)	85 (0.71%)	<0.001

CD: Crohn's disease, UC: ulcerative colitis

Table 1. Extraintestinal manifestations

Conclusion: Men seem to develop a more complex inflammatory bowel disease than women. In CD, men more often have a penetrating pattern and in UC, they have more extensive disease. Complications and the need for surgery are also more frequent in men than in women in both CD and UC. However, extraintestinal manifestations are more prevalent in women than in men, with the exception of venous thrombosis and primary sclerosing cholangitis.

Disclosure: Nothing to disclose.

DE NOVO INFLAMMATORY BOWEL DISEASE PICKED UP VIA NATIONAL BOWEL CANCER SCREENING PROGRAMME: 10 YEAR EXPERIENCE AT A LARGE ENGLISH SCREENING CENTRE

K. Georgas¹, S. Mahdibeiraghdar¹, K. Kaur¹, M. Gismond¹, C. Banks¹, D. Murugiah¹, J. Stebbing¹, M. Gallagher¹, C. Alexakis¹

¹Royal Surrey NHS Foundation Trust, Guildford, United Kingdom

Contact E-Mail Address: k.georgas@nhs.net

Introduction: In England, all adults from the age of 60 years are offered two yearly faecal occult blood testing, as part of the national bowel cancer screening (BCS) programme. Those with positive stool tests are offered colonoscopy. The finding of incidental cases of inflammatory bowel disease (IBD) amongst individuals undertaking BCS has previously been reported¹, but this cohort of patients has never been characterised in depth.

Aims & Methods: We aimed to describe and characterise all new cases of IBD picked up in patients undertaking BCS at a single large screening centre in South East England covering 1.6 million people, over a 10 year period. Using endoscopy reporting software, we retrospectively identified all BCS colonoscopy reports for the period January 2012 until December 2021.

All reports were reviewed for endoscopic evidence of mucosal inflammation. Patients with pre-existing IBD were excluded from analysis, as were those with radiation proctitis. For patients with reports describing new endoscopic colonic or terminal ileal (TI) inflammation, two independent

experts in IBD reviewed the colonoscopy reports, the endoscopic images and the corresponding histology to validate true cases of de novo IBD. In instances where the opinions of the two experts differed, a third IBD expert reviewed such cases, to conclude on the final diagnosis. For all confirmed cases of de novo IBD, data was collected including patient demographics, disease subtype (ulcerative colitis (UC), Crohn's disease (CD), indeterminate colitis (IC)), severity of mucosal inflammation, other endoscopic data, and IBD treatments/management offered at time of index BCS colonoscopy.

Results: 5200 screening colonoscopies were performed in 4059 patients over the study period. After excluding existing IBD patients, 103 patients had endoscopic evidence of new mucosal inflammation. Following the validation exercise by the three IBD experts, we identified 73 (1.4%) incident cases of IBD. Mean age at diagnosis was 66.3 years. 63.0% of cases were male. 97.3% of patients had confirmatory biopsies taken at procedure. 52.1% of cases included inspection of the terminal ileum.

Other non-IBD pathology was identified in 64.4% of patients (malignancy 3.0%, polyps 43.9%, diverticulosis 45.5%, other pathology 7.6%). IBD subtypes were as follows: UC 50.7% (proctitis E1 - 37.8%, left sided disease E2 - 35.1%, pancolitis E3 27.0%), CD 20.5% (TI disease only 13.3%, colonic disease 86.7%) and indeterminate colitis 28.8%. 80.1% of patients had mild mucosal disease.

No patients had evidence of severe mucosal inflammation. IBD specific treatment was started post colonoscopy in 16.4% of cases. This included 8 patients started on oral mesalazine, and 4 patients on topical mesalazine agents. In 17.8% of cases, the endoscopist either referred or suggested referral to specialist gastroenterology services at the time of colonoscopy.

Conclusion: Uncovering incident cases of IBD through national BCS is not uncommon. Fortunately, the disease severity appears to be mild in most cases. With numbers of older-onset IBD rising worldwide, colorectal cancer screening programmes potentially offer a juncture to identify, stage and initiate treatment in this cohort of patients.

Introduction: Data on the disease activity patterns of patients with inflammatory bowel disease (IBD) in the biological era is scarce, and little is known about the influence on long-term outcomes.

Aims & Methods: We aimed to describe the median and long-term disease activity patterns of IBD patients. We included all incident patients diag-

nosed with IBD as well as all prevalent individuals alive and diagnosed with IBD in Denmark between 1995 and 2018 in a nationwide registry study. We used information regarding IBD-related hospitalizations, IBD-related surgeries excluding perianal surgery, redeemed prescriptions of IBD-treatments to identify episodes of active disease and to grade these as mild-moderate or severe flares during each year of follow-up.

Mild-moderate: a course of topical corticosteroids, oral budesonide, or topical 5-aminosalicylic acid.

Severe: hospitalization, surgery, oral corticosteroids or biological therapy. The disease activity patterns for 5 and 10-year periods were assessed. Patients with UC having had colectomy were considered to have no subsequent events. Patients with rheumatological or dermatological disease which shares treatment regimens were excluded.

Results: A total of 17,820 Crohn's disease (CD) and 32,516 ulcerative colitis (UC) were included in this study. In incident patients with CD, severe disease activity occurred in 80% (N=11,330/14,169) in the year of diagnosis while 5.4% (N=764/14,169) had mild-moderate disease. The following years, the proportion of CD patients in remission during a year increased steadily to 89% (N=1,522/1,713) after 20 years of disease. In incident patients with UC, severe disease activity occurred in 75% (N=20,507/27,396) in the year of diagnosis, 3.4% (N=945/27,396) underwent colectomy and 13% (N=3,521/27,396) had mild-moderate disease. The proportion of UC patients in remission each year increased to 72% (N=2,316/3,228) being in remission after 20 years. After 10- and 20 years, 9.5% and 14% of UC patients had in total undergone colectomy.

When assessing all prevalent patients in Denmark, during each year approximately 75% and 60% of the CD and UC patients, respectively, were in remission while 22% and 15% had an episode of severe disease. This pattern remained stable throughout the study period. 5- and 10-year disease activity patterns are found in Table 1.

In Cox models adjusted for sex, age at IBD diagnosis and primary sclerosing cholangitis (PSC), the quiescent disease pattern in CD patients had a significantly higher risk of intestinal cancer (HR: 2.38, 95%CI: 1.11-5.11). No other association between the 10-year disease activity patterns and intestinal cancer was found among CD or UC patients.

Disease activity pattern	Patients with Crohn's disease (5-year pattern: N=9,162, 10-year pattern: N=5,788)	Patients with ulcerative colitis (5-year pattern: N=18,662, 10-year pattern: N=11,663)	
No year with disease activity	8.3% (N=756/9,162)	3.7% (N=684/18,662)	
1-2 years with disease activity	60% (N=5,511/9,162)	55% (N=10,197/18,662)	
3-4 years with disease activity	26% (N=2,393/9,162)	32% (N=5,960/18,662)	
5 years with disease activity	5.5% (N=502/9,162)	9.8% (N=1,821/18,662)	
Chronic continuous	6.0% (N=346/5,788)	11% (N=1,252/11,663)	First 10 years with at least 8 years with activity
Chronic intermittent	16% (N=904/5,788)	16% (N=1,887/11,663)	First 10 years with activity pattern that does not meet any of the other criteria
Decreasing	45% (N=2,583/5,788)	45% (N=5,272/11,663)	First 5 years with 2 or more years with activity. Following 5 years 2 or less years with activity
Increasing	4.2% (N=242/5,788)	5.0% (N=578/11,663)	First 5 years with less than 2 years with activity. Following 5 years 2 or more years with activity
Quiescent	30% (N=1,713/5,788)	23% (N=2,674/11,663)	First 10 years with 1 or less years with activity

Table 1.

Conclusion: In this nationwide cohort study, we reported the distribution of patients within temporal disease activity patterns. The share of patients in remission each year after diagnosis was increasing.

However, the prevalent cohort revealed, that the proportion of patients in remission each calendar year was stable. No clear relation was found regarding the 10-year disease activity patterns and risk of intestinal cancers or mortality.

Introduction: Inflammatory Bowel Diseases (IBD) (i.e., Crohn's Disease (CD) and Ulcerative Colitis (UC) may have extraintestinal manifestations, including disorders of the urinary tract. The prevalence of urinary symptoms (US) in CD or UC patients is still unclear.

Aims & Methods: This study aims to assess the prevalence of US in patients with CD or UC; to evaluate the variables implicated in any difference in US prevalence between CD or UC; to assess any relationship between disease activity and the US.

Type of study: cross-sectional, observational. Patients: 301 IBD patients, 161 males, and 140 females, 99 with CD, and 202 with UC, median age 45 years. The US assessed through standardized questionnaires i.e., the Bristol Female Lower Urinary Tract Symptoms (BFLUTS) for women and the NIH-Chronic Prostatitis Symptom Index (NIH-CPSI) together with the International Prostate Symptom Score (IPSS) for men. CD disease activity

was determined through the Crohn's Disease Activity Index (CDAI) whereas UC disease activity through the Partial Mayo Score (PMS) and/or the Total Mayo Score (TMS).

Results: The median BFLUTS total score for IBD female patients was 6 (3–11). Patients with a higher age at diagnosis (A3, according to Montreal classification) had worse filling (BFLUTS-F) symptoms ($p=0.049$) and a worse quality of life (BFLUTS-QoL, $p=0.005$). The IPSS questionnaire showed that in male IBD patients, 67.1% had mild, 28.5% moderate, and 4.4% severe symptom levels.

Following the NIH-CPSI, the overall prevalence of chronic prostatitis-like symptoms was 26.8% (in detail, 21.3% in CD and 29.2% in UC, $p < 0.01$). There were no significant differences in US scores levels between CD and UC patients in terms of BFLUTS, NIH-CPSI, and IPSS ($p > 0.05$). UC patients with proctitis (E1 according to Montreal classification) presented worse levels of NIH-CPSI and IPSS ($p < 0.05$).

In male patients with UC (according to NIH-CPSI) an S Montreal parameter of remission (S0) was associated with a higher percentage of patients with mild US compared to patients with worse levels of US ($p < 0.05$). The NIH-CPSI total score showed a good correlation with PMS ($p=0.003$) and TMS ($p=0.014$).

Conclusion: CD and UC patients often complain of US as assessed through the administration of standardized questionnaires. Age is associated with worse filling symptoms and QoL in female IBD patients. The US in male IBD patients are prevalently mild, and are more frequent in those with proctitis. Male UC patients in remission experience mild US more frequently than severe US. UC patients had a higher prevalence of chronic prostatitis-like symptoms than those with CD. In male UC patients, US correlated with disease activity. Evaluation of US through the use of validated questionnaires should be considered in IBD patients for prompt diagnosis and early treatment.

HIDRADENITIS SUPPURATIVA AND INFLAMMATORY BOWEL DISEASE IN A CASE-CONTROL STUDY

B. Neri¹, M. Mossa¹, V. Appolloni¹, C. Pensa², S. Lambiase², E. Calabrese¹, S. Salvatori¹, I. Marafini¹, G. Monteleone¹, E. Campione², L. Biancone¹

¹Università degli Studi di Roma Tor Vergata, Medicina dei Sistemi, Rome, Italy, ²Università degli Studi di Roma Tor Vergata, Dermatology Unit, Rome, Italy

Contact E-Mail Address: benedettoneri@gmail.com

Introduction: Hidradenitis Suppurativa (HS) is a chronic inflammatory skin disease characterized by recurrent nodules and abscesses in intertriginous areas association with Inflammatory Bowel Disease (IBD) has been suggested in few heterogeneous studies.

Aims & Methods: In a retrospective, single-center, case-control study, we aimed to assess characteristics of HS in patients (pts) with or without concomitant IBD.

In a case-control study, each IBD pt with concomitant HS (Case) was matched with 4 pts with HS but no IBD (Controls) for: gender and age (± 5 yrs). In a multidisciplinary approach, all Cases and Controls were assessed by the same dedicated gastroenterologists and dermatologists at the University "Tor Vergata" of Rome, Italy.

Inclusion criteria for Cases: age ≥ 15 and ≤ 85 yrs; well-defined diagnosis of IBD; well-defined diagnosis of HS. Inclusion criteria for Controls: age ≥ 15 and ≤ 85 yrs; well-defined diagnosis of HS; no diagnosis of IBD. Exclusion criteria for Cases and Controls: low compliance; incomplete data. HS was classified according to the Hurley score.

Data were expressed as median [range]. Clinical characteristics IBD and HS were reported and comparisons between groups assessed by the Student-t Test and χ^2 test.

Results: The study population included 120 pts with HS: 24 with IBD and 96 matched pts with no IBD (4 M [16.6%] vs 16 [16.6%]; $p=1$). In IBD, pts were: 18 (75%) Crohn's disease (CD), 5 (20.8%) Ulcerative Colitis (UC), 1 (4.2%) Unclassified Colitis. The median IBD duration was 15 [3–37] yrs. Extra-intestinal manifestations were recorded in 10 (41.7%) IBD pts. CD ($n=18$) involved: ileum (6 [33.3%]), colon (3 [16.7%]), ileum-colon (5 [27.8%]), upper GI (4 [22.2%]). CD behavior was non stricturing-non penetrating in 7 (38.9%), structuring in 7 (38.9%), penetrating in 4 (22.2%) pts. In CD pts with HS, perianal disease was observed in 10 (55.6%) and surgery in 8 (44.4%) pts. UC extent included proctitis in 1 (20%), left-sided in 1 (20%) and pancolitis in 3 (60%) pts.

No difference was observed in terms of median age in Cases vs Controls (40 [20–59] vs 37 [15–63] yrs; $p=0.68$). However, HS duration was significantly shorter in Cases vs Controls (5.8 [1–32] vs 11 [1–40] yrs; $p=0.0003$), although most IBD pts referred a long history of lesions compatible with undiagnosed HS.

The frequency of HS localizations was comparable between Cases and Controls (pts): axillary (5 [20.8%] vs 23 [23.9%]; $p=0.95$); inguinal (8 [33.3%] vs 27 [28.1%]; $p=0.8$), concomitant inguinal and axillary (8 [33.3%] vs 39 [40.9%]; $p=0.67$). Uncommon HS localizations (trunk, gluteal areas) did not significantly differ between Cases and Controls (8 [33.3%] vs 52 [54.1%]; $p=0.11$). Median Hurley stage of HS was comparable between groups (2 [1–3] vs 2 [1–3]; $p=0.34$). Active/ex smokers were 13 (54.2%) in Cases vs 69 (71.9%) in Controls ($p=0.15$). A history of previous or current treatment with TNF-antagonists was significantly more frequent in Cases vs Controls (13 [54.2%] vs 22 [22.9%]; $p=0.005$).

Conclusion: Perianal disease may be observed in a high proportion of CD patients with HS. HS may be underestimated in patients with IBD.

A SYSTEMATIC REVIEW AND META-ANALYSIS OF SLEEP QUALITY IN INACTIVE INFLAMMATORY BOWEL DISEASE

A. Barnes¹, S. Madigan¹, R. Mountfield¹, J. Baker¹, P. Spizzo¹, P. Bampton², S. Mukherjee³

¹Flinders Medical Centre, Gastroenterology, Bedford Park, Australia, ²Flinders University, College of Medicine and Public Health, Bedford Park, Australia, ³Flinders Medical Centre, Respiratory and Sleep medicine, Bedford Park, Australia

Contact E-Mail Address: shaunamadigan@gmail.com

Introduction: Poor sleep in people with inflammatory bowel disease (IBD) has been demonstrated to be prevalent and has been associated with disease activity.

Aims & Methods: This meta-analysis aimed to assess the prevalence of poor sleep in inactive inflammatory bowel disease and in controls by considering cohort and cross-sectional studies. Electronic databases were searched for publications from inception to November 1st, 2021. Meta-analysis was performed according to the preferred reporting item for systematic reviews and meta-analyses (PRISMA) guidelines. Quality of studies was assessed using the modified Newcastle-Ottawa Scale or Newcastle-Ottawa Scale as appropriate. Poor sleep and IBD activity were defined according to self-reported subjective sleep measures. A random effects model was used to determine the standardised mean difference between poor sleep in inactive IBD and healthy controls. Publication bias was assessed by funnel plot and Egger's test.

Results: 519 studies were screened with 9 studies included in the meta-analysis incorporating a total of 729 people with IBD and 508 controls. Publication date ranged from 2006 to 2020. A random effects model showed a standardised mean difference with poor sleep being more frequent in those with inactive IBD than controls with moderate effect size (Hedge's g 0.41, CI (0.22-0.59) and no significant heterogeneity. Funnel plot was symmetric and Egger's negative ($p=0.37$).

Conclusion: Poor sleep is more common in individuals with inactive IBD than healthy controls. This finding suggests that IBD activity may not be the sole driver of the observed poor sleep in this population. Further studies should consider potential mechanisms to explain this result including the role of subclinical inflammation and psychosocial factors that may influence sleep quality in people with IBD.

RISK OF CERVICAL CANCER IN INCIDENT ULCERATIVE COLITIS: A NATIONWIDE POPULATION-BASED STUDY SPANNING 10 YEARS

H.-S. Kim¹, J.K. Lee¹

¹Yonsei Univ. Wonju College of Medicine, Internal Medicine, Wonju, Korea (Republic of)

Contact E-Mail Address: hyskim@yonsei.ac.kr

Introduction: The association between ulcerative colitis (UC) and increased risk of cervical cancer in women remains controversial.

Aims & Methods: We investigated the risk of cervical cancer in patients with UC using the nationwide population-based claims data in South Korea. We analyzed the claims data of the Korean National Health Insurance (NHI). UC was defined using both ICD-10 codes and UC-specific prescription.

We analyzed incident cases of UC diagnosed between 2006 and 2015. Age-matched women without UC (control group) were randomly selected from the general population in a ratio of 1:3. Hazard ratios (HRs), adjusted for different covariates, were calculated using multivariate Cox proportional hazard regression.

Results: In total, 12,632 and 36,797 women with UC and without UC, respectively, were enrolled. Cervical cancer developed in 0.21% (68 person-years) among UC patients, and 0.14% (172 person-years) among control group, respectively. The HR (95% CI) of cervical cancer in UC group, with reference to control group, was 1.56 (0.97-2.50). When stratified according to age, the HR was significantly high in elderly UC patients (≥ 60 years) at 3.65 (1.54-8.66), compared those in control group. In UC patients, old age (≥ 40 years), and low socioeconomic status were associated with increased risk of cervical cancer.

Conclusion: The elderly UC patients had a higher incidence of cervical cancer than age-matched controls in Korea. In UC patients, old age These findings suggest that newly diagnosed UC patients in old age should be screened for cervical cancer.

Disclosure: Nothing to disclose.

A SYSTEMATIC REVIEW ON CLINICAL OUTCOMES IN PAEDIATRIC INFLAMMATORY BOWEL DISEASE PATIENTS

J. Van Hecke¹, L. Wauters², G. Veereman³

¹Free University Brussels, Medicine and Pharmacy, Brussels, Belgium, ²University Hospitals Leuven, Gastroenterology and Hepatology, Leuven, Belgium, ³UZ Brussels, Dept. of Paediatric Gastroenterology, Brussels, Belgium

Contact E-Mail Address: vanheckejonathan01@gmail.com

Introduction: Research on paediatric inflammatory bowel disease (PIBD) has grown over the past few years. Several IBD cohorts and registries in the world led to reports on disease progression in paediatric patients.

Aims & Methods: We aim to report on response and remission rates in PIBD by reviewing prospective cohorts and registries and comparing outcomes. One reviewer (JVH) performed a systematic worldwide literature search in MEDLINE and EMBASE from inception until March 17, 2022.

In addition, all publications of the ImproveCareNow registry were reviewed. Inclusion criteria were: prospective cohort studies with patients <18 years at diagnosis and minimum follow-up of 1 year mentioning disease phenotype and disease activity.

Exclusion criteria were:

- Reporting disease activity only at diagnosis,
- Retrospective cohort studies,
- Full-text unavailable,
- Outcome limited to steroid-free remission.

The Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA) checklist guidelines and Newcastle-Ottawa scale for prospective cohort studies were applied.

Results: The search yielded 395 records and 7 inclusions with sample sizes ranging from 33 to 390 patients (total population: 888). The median follow-up ranged from 1 to 5 years. Proportions between groups were compared using a chi-square test with significance level of 5%.

Disease location is consistent with cohorts for Crohn's disease (CD) ($p=.004$) but not for ulcerative colitis (UC) ($p=.69$). L4 was more frequent in the Belgian cohort ($\chi^2=4$).

Primary outcome: proportions of disease activity differed at M0 and M12 ($p<.00001$) with more inactive ($\chi^2=5.5$) and less moderate-to-severe disease ($\chi^2=23$).

Secondary outcome: proportions of disease activity, limited to BELCRO (Belgium), did not differ between 1, 2, 3 and 5 years ($p=.94$). After 5 years these proportions did differ significantly from baseline (M0) ($p<.0001$ for evolution).

Country	Belgium [1]	Switzerland [2]	Hungary [3]	Hungary [3]	Scotland [4]	Turkey [5]
Population, n	CD, 84	UC, 56 CD, 90 IBD-U, 7	UC, 124	CD, 266	UC, 4 CD, 26 IBD-U, 3	UC, 22 CD, 12 IBD-U, 2
M0, n (%)	A, 4 (5) B, 16 (19) C, 64 (76)	A, 80 (52,3) B, 39 (25,5) C, 18 (11,8)	A, 2 (1,7) B, 49 (40,8) C, 69 (57,5)	A, 20 (7,8) B, 112 (43,8) C, 124 (48,4)	A, 25 (76) B, 5 (15) C, 3 (9)	A, 23 (67,6) B, 8 (23,5) C, 3 (8,3)

A: inactive disease; B: mild disease; C: moderate-to-severe disease. IBD-U: IBD type unclassified; NA: not available.

Table 1: disease activity at start of the study (M0) and 1 year follow-up (M12).

Conclusion: Prospective reports on evolution of disease severity in PIBD are scarce. The European cohorts report a significant decrease in disease activity after 1 year with more inactive and less moderate-to-severe dis-

ease. Proportions of disease activity did not differ between 1 to 5 year follow-up in the Belgian cohort but did differ significantly from baseline (M0) after 5 years.

Introduction: Iron deficiency (ID) and anaemia in Inflammatory Bowel Disease (IBD) are associated with reduced quality of life, worse disease outcomes, and an increase in healthcare costs. In the European guidelines, anaemia is listed as one of the treatment goals, but data on the prevalence of anaemia and ID are inconsistent. Therefore, we evaluated the prevalence of ID, anaemia, and potential risk factors in a large Dutch outpatient population.

Aims & Methods: Between January and November 2021, consecutive adult outpatients with IBD, who did not have significant comorbidities associated with anaemia, were included in this study across 16 general, teaching, and academic hospitals within the Netherlands.

Besides demographic and clinical data, relevant biochemical parameters such as haemoglobin (Hb), Mean Corpuscular Volume (MCV), iron indices, and inflammatory markers (e.g., C-reactive protein (CRP) and faecal calprotectin (FCP)) were extracted from medical records. Active IBD was defined by either CRP >5 mg/L and/or FCP >150 mg/kg. ID was defined by ferritin <100 µg/L in case of biochemical inflammation and <30 µg/L in inactive IBD; if ferritin values were unavailable, transferrin saturation <20% was defined as ID despite biochemical inflammation.

The Dutch national reference range was used to define anaemia: Hb <7.5 mmol/L or <8.5 mmol/L for females and males, respectively. The data were analysed by stratifying patients into the Crohn's Disease (CD) and Ulcerative Colitis (UC) groups, with the latter also including patients with IBD-unclassified (IBDU).

Results: In total, 2197 patients (1271 CD, 849 UC, and 77 IBDU) were included in the study. Iron parameters were available in 59.3% of cases. The overall prevalence of anaemia, iron-deficiency anaemia (IDA), and ID was: 18.0%, 12.2%, and 43.4%, respectively. The prevalence of all three conditions did not differ between the CD and UC groups ($P > 0.05$ for all). Severe anaemia (Hb <6.2 mmol/L) was only observed in 28 patients. ID(A) was more frequently observed in biochemically active IBD compared with quiescent IBD (ID: 70.8% versus 23.9%; $P < 0.001$).

Female gender, younger age, low MCV, and an increase in biochemical inflammation were associated with ID in multivariable analysis: Log₂FCP [OR 1.39; 95% CI: 1.29–1.50; $P < 0.001$] and Log₂platelets [OR 1.85; 95% CI: 1.16–2.95; $P < 0.01$]. In multivariable analysis, low ferritin and MCV, inflammation, older age, and male gender were associated with a higher prevalence of anaemia; however, disease location or behaviour was not associated with the prevalence of anaemia or ID.

Conclusion: One in five outpatients with IBD suffers from anaemia that – despite infrequently measured iron parameters – is primarily caused by ID. Biochemical inflammation is the major risk factor associated with ID and anaemia prevalence regardless of IBD type or disease location.

High prevalence of ID and anaemia, even after the publication of the European treatment guidelines, suggests the need for screening and treatment optimisation.

P0268

THE IMPACT OF SMOKING ON ULCERATIVE COLITIS AND INTERACTION WITH FAMILY HISTORY: A KOREAN POPULATION-BASED COHORT STUDY

H.S. Ahn¹, H.J. Kim¹

¹Korea University Medical College, Department of Preventive Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: iebm.ku@gmail.com

Introduction: The impact of smoking on ulcerative colitis (UC) among Asian populations is controversial. Although a few studies on gene-smoking interactions in IBD pathogenesis have been performed, they yielded inconsistent results, and the direction of interactions between current/former smoking and genetic factors are not well-studied.

Aims & Methods: Our aim was to evaluate the association between smoking and UC and assess interactions between smoking and family history in UC development. We used the National Health Insurance database to acquire information on all insured individuals and their dependents. A total of 5.5 million individuals were identified from 2002-2019 with information on familial relationships and smoking history. To examine the association between UC and current/former smoking, Cox proportional hazard regression was used and familial risk was estimated by comparing the incidence of individuals with and without a family history.

The amount of interaction and its statistical significance as a departure from additivity between family history and smoking were assessed using the relative excess risk due to interaction (RERI).

Results: Current smoking was associated with a decreased risk of disease (HR 0.53, 95% CI 0.49-0.56), while former smoking was associated with an increased risk (HR 1.62, 95% CI 1.53-1.71), compared to non-smokers. Through our family relationship analysis, we identified the familial group that consisted of 25,332 individuals with UC-affected FDR and 5,499,071 individuals with unaffected FDR, which made up the non-familial group. Among the familial group, 288 individuals developed UC, with the familial risk being 7.51 (95% CI 6.68-8.45). We observed an interaction between the familial risk of UC and both current and former smoking, but in opposing directions. The protective effect of current smoking was more pronounced among those with a family history, as their combined effect was lower than the sum of their individual risks (HR 4.37 vs 7.55), while the harmful effect of former smoking was more prominent among this group and their combined effect was higher than the sum of their individual effects (HR 10.20 vs 8.57), indicating statistically significant interactions (RERI current: -3.18 95% CI -4.89 - -1.47; former: 1.63 95% CI 1.00-4.25). Both effects were more pronounced in heavy smokers compared to moderate smokers, suggesting a dose-dependent relationship.

		No Smoking and No Family History	Smoking	Family History	Both Smoking and Family History	RERI (95% CI)
Current Smoking	Total	1.00	0.56	7.99	4.37	3.18 (4.89 - 1.47)
	Moderate	1.00	0.60	7.99	4.41	3.19 (5.07 - 1.31)
	Heavy	1.00	0.47	7.99	4.22	3.24 (5.58 - 0.90)
Former Smoking	Total	1.00	1.57	8.00	10.20	1.63 (1.00 - 4.25)
	Moderate	1.00	1.42	7.99	9.06	0.65 (2.30 - 3.60)
	Heavy	1.00	2.07	7.98	14.02	4.96 (0.10 - 10.02)

Table 1: Combined Effect of Family History and Smoking on the Risk of Ulcerative Colitis among First-Degree Relatives

Conclusion: Our nationwide population-based study found that current smoking was associated with a decreased risk, while former smoking increased the risk of developing UC, suggest that the effect of smoking on IBD does not differ between Asian and Western populations. An interac-

tion was observed between the family history of UC and smoking, in which the effect of current/former smoking were both more pronounced among those with a family history. Our results indicate the importance of familial factors and smoking in the etiology of UC and point towards a significant interaction.

Introduction: Pediatric inflammatory bowel disease (pIBD) impacts the physical, psychological, and socioeconomic functioning of patients and caregivers. However, work productivity and activity impairment are often poorly evaluated in this population.

Aims & Methods: The aim was to assess the effects on work productivity in caregivers of patients with pIBD.

We performed a multicenter, observational, cross-sectional and descriptive study from February 2021 to February 2022. The Work Productivity and Activity Impairment Questionnaires for Crohn's disease and Ulcerative Colitis (WPAI-CD-Caregiver and WPAI-UC-Caregiver), with 6 items each, were translated and adapted for the Spanish population and subsequently completed by the participants.

These questionnaires explore 4 aspects: absenteeism (failure to attend work by an employee who was thought to attend, excluding vacation periods, strikes and sick leave), presenteeism (understood as a phenomenon

that revolves around the worker's anxiety about losing their job and is influenced by a high level of stress that forces the individual to report to work when they are not able to do so), loss of productivity labor and impairment of daily activity due to pIBD. Demographic and clinical data and results of the questionnaires were collected using the REDCap® platform and analyzed with SPSS®.

Results: A total of 207 patients from 28 hospitals were included, 117 were male (56.5%), 138 with Crohn's disease, 65 with ulcerative colitis and 4 with IBD unclassified. The mean age at the time of completing the questionnaire was 14.2±2.4 years and the time of evolution of the disease was 2.4 years (IQR 1.2-4.9). Amongst the 207 patients, 115 (55.5%) were in remission (PUCAI < 10 or WPCDAI < 12.5).

Data from 310 parents (186 mothers and 124 fathers) were obtained. Up to 75.8% of the fathers and 67.2% of the mothers had a remunerated job at the time of completing the questionnaire. 62.8% of parents experienced absenteeism from work in the previous week with a median of 12.7% of lost hours (IQR 5-10); 69.1% recognized deterioration or impairment of productivity during the working day, with a decrease in productivity that week of 40% (IQR 20-60%).

The percentage of affectation/global deterioration of the working life of the parent secondary to the illness of the child was 38% (IQR 20-67). The deterioration of the parent's ability to carry out daily tasks was 54.3%.

Conclusion: pIBD negatively impacts the work and daily sphere of their parents. Having 50% more forms from mothers may be related to the fact that they are the main caregivers of the patients.

However, the employment rate of our sample corresponds to that of the population aged 20-64 published by the INE (The Spanish National Statistics Institute).

Disclosure: Nothing to disclose.

EXPOSURE TO SYSTEMIC ANTIBIOTICS INCREASES THE RISK OF INFLAMMATORY BOWEL DISEASE IN A DOSE-DEPENDENT MANNER: A POPULATION-BASED CASE-CONTROL STUDY IN KOREA

S.J. Oh¹, C.K. Lee¹, H.J. Kim¹

¹Kyung Hee University College of Medicine, Center for Crohn's and Colitis, Department of Gastroenterology, Seoul, Korea (Republic of)

Contact E-Mail Address: linus204@naver.com

Introduction: Environmental factors that alter the gut microbiome are thought to be involved in the epidemiological evolution of inflammatory bowel disease (IBD) globally. This study aimed to assess whether the increased use of antibiotics was associated with the development of IBD in Korea where the incidence and prevalence of IBD has been rapidly increasing in recent years.

Aims & Methods: A population-based case-control study was conducted using the National Health Insurance Service database from 2004 to 2018. Each case diagnosed with IBD was matched to five controls based on age, sex, and residence. Conditional logistic regression was used to estimate associations between antibiotic exposure and subsequent development of IBD. Systemic (oral, intravenous or intramuscular) antibiotic exposure 2-5 years prior to diagnosis was stratified by frequency and duration of prescription, and the class of antibiotic. We also separately analyzed the risk of childhood-onset (age <16) IBD according to antibiotic exposure in the first year of life.

Results: We identified 68,633 cases of IBD (ulcerative colitis [UC], 52,756; Crohn's disease [CD], 7,898) and 343,165 controls. Ever use of antibiotics was significantly associated with an increased risk of IBD (adjusted odds ratio [AOR], 1.35; 95% CI, 1.30-1.40). The risk of IBD and its subtypes increased with the cumulative frequency and duration of antibiotics.

Among the classes of antibiotics, metronidazole, and sulfonamides were associated with a higher risk, and metronidazole particularly increased the risk of CD by more than twice (OR, 2.37; 95% CI, 2.18–2.59). Antibiotic exposure in the first year of life was significantly associated with an increased risk of childhood-onset IBD (OR, 1.50; 95% CI, 1.24–1.81).

Any antibiotic use	Case	Control	Crude OR	Adjusted OR
IBD				
Never	7,900	47,921	ref	ref
Ever	60,733	295,244	1.25 (1.22 - 1.28)	1.35 (1.30 - 1.40)
UC				
Never	6,038	37,597	ref	ref
Ever	46,718	226,183	1.29 (1.25 - 1.32)	1.35 (1.29 - 1.40)
CD				
Never	1,777	9,905	ref	ref
Ever	13,426	66,110	1.32 (1.20 - 1.45)	1.41 (1.28 - 1.55)

Table.

Conclusion: Exposure to systemic antibiotics significantly increases the future development of IBD in a dose-dependent manner, suggesting that the perturbation of gut microbiome by antibiotics use may be one of several key environmental factors to influence development of IBD in newly industrialized countries.

Disclosure: This work was supported by the Big Data Research Group of the Korean Society of Gastroenterology and data analysis was supported by Data Science Team, Hanmi Pharm. Co., Ltd.

Introduction: Data on mortality in patients with elderly-onset inflammatory bowel disease (IBD) is conflicting. Our objective is to explore the overall mortality rates and causes in patients with elderly-onset IBD compared to elderly non-IBD patients.

Aims & Methods: As part of the validated epidemiological cohort of the Israeli IBD Research Nucleus (epi-IIRN), we included all elderly-onset IBD

patients (age at diagnosis>65 years) from the four Israeli health funds diagnosed from 1.1.2005 until 30.06.2020, covering 98% of the population. Each IBD case was matched to 3 non-IBD individuals by year of birth, sex, geographic district, and health fund. Time to mortality was compared using the Kaplan-Meier survival analysis, stratified by IBD subtype and sex. Cox proportional hazards models were sought to explore mortality risk adjusted by comorbidities (ischemic heart disease, heart failure, chronic obstructive pulmonary disease, cumulative number of other chronic diseases) as possible confounders. Main causes of death as reported to the Israeli Mortality Register were compared using the chi-square test.

Results: A total of 2,162 elderly-onset IBD patients were identified (46% males; median (IQR) age at inclusion 71 [68, 76]) and compared to 6,486 matched non-IBD controls. During median (IQR) follow up of 74 (40, 118) months, 632 of patients with IBD (29.2%, mortality rates 292.32/1000 PY, 95% CI 273.53-311.85/1000 PY) and 1,889 of controls (29.1%, mortality rate 291.24/1000 PY, 95% CI=280.31-302.42/1000 PY) died.

Time to mortality was similar in IBD and controls (p=0.79) as well as in IBD subgroups (CD (p=0.62) and UC (p=0.45)). Survival analysis remained similar when stratified by sex (females (p=0.96) and males (p=0.64)). Using the co-morbidity adjusted Cox model, the overall hazard of mortality (HR) was 1.07 (95% CI=0.98-1.17) for all IBD (HR=1.13 (95% CI=0.98-1.3) for CD and HR=1.03 (95% CI=0.91-1.15) for UC). No significant differences in the proportions of the different causes of death were observed (table).

	Elderly onset IBD n=2162	Matched non-IBD controls n=6486	P value
Malignancy	139 (6.4%)	390 (6%)	0.52
Heart disease	84 (3.9%)	274 (4.2%)	0.53
Septicemia	30 (1.4%)	80 (1.2%)	0.66
Cerebrovascular disease	23 (1.1%)	91 (1.4%)	0.28
Diabetes mellitus	19 (0.9%)	80 (1.2%)	0.22
Nephritis and nephrosis/nephrotic syndrome	14 (0.6%)	51 (0.8%)	0.62
Pneumonia and influenza	10 (0.5%)	50 (0.8%)	0.18
Dementia (non-Alzheimer)	11 (0.5%)	49 (0.8%)	0.3

Table. Most frequent defined causes of death among elderly-onset IBD patients and matched non-IBD controls.

Conclusion: Elderly-onset IBD was not associated with increased mortality risk compared with matched non-IBD elderly individuals. Causes of death were similar to individuals without IBD, with malignancy and heart diseases as the leading causes.

Disclosure: Nothing to disclose.

P0272

FACTORS ASSOCIATED WITH TREATMENT PERSISTENCE OF ANTI-TNF AGENTS AS FIRST LINE BIOLOGIC TREATMENT IN GREEK PATIENTS WITH INFLAMMATORY BOWEL DISEASES

E. Orfanoudaki¹, E. Theodoraki¹, K. Foteinogiannopoulou¹, I. Drygiannakis¹, G. Chlorakis¹, M. Tsafaridou¹, I. Koutroubakis¹
¹University Hospital of Heraklion, Medical School, University of Crete, Gastroenterology, Heraklion, Greece

Contact E-Mail Address: elina_or@yahoo.gr

Introduction: A remarkable proportion of inflammatory bowel disease (IBD) patients on long term anti-TNF therapy eventually discontinue their treatment due to either loss of response or adverse events.

Aims & Methods: We aimed to record the treatment persistence of anti-TNF agents as first line biologic therapy in IBD patients and possible factors associated with it. Consecutive IBD patients with no prior exposure to biologics who were initiated with either infliximab (IFX), adalimumab (ADA) or golimumab (GOL) between 2002-2022 having at least 36 months of follow up were studied retrospectively.

Demographic and clinical patient characteristics were recorded based on an updated prospective, longitudinal IBD registry. Treatment persistence was assessed using Kaplan Meier analysis for a 36month period and Mann Whitney test was used to identify predictors of drug persistence.

Results: Out of 268 naïve IBD patients commenced on anti-TNF during the study period, 220 who met the inclusion criteria were included [Males 126 (57%), median age (IQR) 47(35.5-58) years, Crohn's disease (CD) 158 (72%), median time of follow up after anti-TNF initiation (IQR) 51 (20-89) months, under IFX 130 (59%), under ADA 74 (34%), under GOL 16 (7%), concomitant immunomodulators 106 (48%)].

Thirty six months after anti-TNF treatment initiation, the persistence rates for IFX, ADA, GOL were 67%, 66% and 38% respectively. Concomitant immunomodulator use significantly prolonged drug survival (58 vs 46 months; p=0.045), as well as treatment intensification (66 vs 43 months; p=0.0002) and IFX use vs ADA (58 vs 45 months; p=0.034). No other factors including gender, disease type, BMI, disease duration at anti-TNF initiation were found to be associated with anti-TNF persistence.

Conclusion: Longer drug survival was observed for IFX and ADA (67% and 66%) compared with GOL (38%). Concomitant immunomodulator use, treatment intensification and IFX use play an important role in treatment persistence.

Disclosure: No conflicts of interest.

Introduction: There is no data on the epidemiology of pediatric inflammatory bowel disease (PIBD) in Catalonia neither on the trends of pharmacologic treatment over time. The present study aims to evaluate the incidence, prevalence, associated morbidity and pharmacological treatment of PIBD between 2011-2020 in Catalonia.

Aims & Methods: Population-based retrospective cohort study. Children with diagnosis of PIBD (less than 18 years old) included in the Catalan Health Surveillance System database were identified using the ICD-9-CM and ICD-10-CM codes. Data on prevalence, incidence, associated morbidity and pharmacological treatment were extracted from the same database and analyzed for the study period.

Results: The pediatric population during the study period ranged from 1,369,079 in 2011 to 1,408,685 in 2020. The prevalence of PIBD rose from 27 per 100,000 inhabitants (aged <18 years old) in 2011 to 66.2 in 2020 but seems to plateau over the last 2 years of the study period. This trend was observed for ulcerative colitis (UC) (11.1 to 28.1 per 100,000 inhabitants) and Crohn's disease (CD) (15.9 to 38 per 100,000 inhabitants).

The incidence of PIBD was steadily increasing during the study period, especially for CD, and ranged from 6.8 per 100,000 inhabitants in 2011 (93 cases: 50 CD and 43 UC) to a maximum of 13.8 per 100,000 inhabitants in 2018 (193 cases: 114 CD and 79 UC). In 2019-2020 the incident cases decreased for CD and UC.

	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
IBD cases	371	426	514	593	653	696	780	882	933	932
CD prevalent cases	218	254	323	348	377	402	456	513	546	536
UC prevalent cases	153	172	191	245	276	294	324	369	387	396
IBD incident cases	93	103	151	144	146	135	171	193	155	122
CD incident cases	50	71	99	68	87	77	101	114	91	65
UC incident cases	43	32	52	76	59	58	70	79	64	57
Pediatric Population	1.369.079	1.385.127	1.389.929	1.389.796	1.390.956	1.393.928	1.399.850	1.402.825	1.404.978	1.408.685

Table.

The rate of IBD related hospital admissions decreased over the study period from 244.3 per 1,000 people/year in 2011 to 112.8 per 1,000 (despite of this trend there was a peak of admissions of 257.9 per 1,100 in 2016); while the number of outpatient clinic visits increased over the study period, from 1825 visits in 2011 to 4901 in 2020.

The percentage of patients with UC treated with systemic steroids decreased from 39.9% in 2011 to 17.9% in 2020 while the use of immunosuppressant treatment remained stable (38.6 to 30.1%). The use of biological treatment rose every year from 9.2% in 2011 to 19.9 % in 2020.

Regarding CD patients, the percentage of patients treated with systemic steroids and immune modulators decreased from 34.9% and 53% in 2011 to 12.7% and 30.2% respectively in 2020. The use of biological treatment remained stable over the study period (around 30-35%).

Conclusion: The prevalence of PIBD increased over the study period but seems to remain stable over the last 2 years, as the incident cases decreased in 2019-2020. It's important to elucidate if these change of trends in PIBD has been influenced by the SARSCOV2 pandemic or reflects a stabilization of PIBD as described in other countries. The admission rates of PIDB patients, use of systemic steroids and immunosuppressant treatment decreased (specially in UC), while the use of biologics rose.

P0274

POOR SLEEP IN IBD IS ASSOCIATED WITH ACTIVE DISEASE, ANXIETY AND DEPRESSION, AND OUTCOMES SUCH AS INCREASED FATIGUE, INCREASED DISABILITY, AND POOR QUALITY OF LIFE

A. Barnes¹, S. Madigan¹, P. Spizzo¹, R. Mountfield¹

¹Flinders Medical Centre, Gastroenterology, Bedford Park, Australia

Contact E-Mail Address: shaunamadigan@gmail.com

Introduction: Sleep has become of increasing interest in inflammatory bowel disease (IBD) as a patient reported outcome, and as a possible exacerbating factor or extra-intestinal manifestation.

Aims & Methods: This study aimed to document the associations with poor sleep in IBD, and its relationship with other important patient report outcomes such as Disability and Quality of Life. As part of the IBD-SLEEP study a questionnaire was distributed to tertiary hospital IBD mailing lists and advertised through social media and Crohn's Colitis Australia.

The questionnaire included validated instruments assessing IBD activity (HBI and SCCAI), sleep quality (Pittsburgh Sleep Quality Index (PSQI)), physical activity (international physical activity questionnaire), depression (PHQ9), anxiety (GAD7), fatigue (FACIT-F), disability (IBD-DI reduced form), and quality of life (EQ-5D-5L). Disease and treatment characteristics were also sought including medications, complications, and other comorbidities.

Results: There was 544 participants who completed the entire questionnaire. Mean age was 42 years (SD 13), 61% had Crohn's disease, and median disease duration was 10 years (IQR 3-17). Poor sleep quality as assessed by PSQI > 5 was associated with (odds ratio (OR), 95% CI, p value) patient reported active IBD (HBI > 5, SCCAI > 5, OR 3.26 (2.06-5.14) p<0.001), clinically significant depression (PHQ9 > 15, OR 4.28 (2.22-8.24) p < 0.0001), and clinically significant anxiety (GAD7 > 10, OR 4.44 (2.52-7.81) p < 0.001), but not physical activity in the form of total sitting time, vigorous activity, and total activity (METs). People with IBD who had poor sleep quality were more disabled (IBD-DI reduced form, p < 0.0001), had worse quality of life (EQVAS, p < 0.0001), and reported higher levels of fatigue (FACIT-F, p < 0.0001).

Conclusion: IBD patient reported sleep quality was associated with patient reported active disease as well as Anxiety and Depression. Poor sleep quality was associated with worse patient reported outcomes such as fatigue, disability, and quality of life. Consideration should be given in IBD clinic to assessing and addressing sleep quality.

NEW-ONSET INFLAMMATORY BOWEL DISEASE DURING TREATMENT WITH THE ANTI-INTERLEUKIN-17A MONOCLONAL ANTIBODY SECUKINUMAB. A CASE SERIES PRESENTATION

G. Gerasimatos¹, M.-T. Koutroumpi¹, G. Andrianakou¹, E. Karamintziou¹, E. Ionas¹, E. Strathgagos¹, G. Michalopoulos¹, A. Braimakis¹, E. Kotzagiannidou¹, L. Theodoropoulos¹, I. Karoumpalis¹, A. Konstantinidis¹, V. Ntelis¹

¹GHA G. Gennimatas, Department of Gastroenterology, Athens, Greece

Contact E-Mail Address: gerasimatos.ger@gmail.com

Introduction: IL-17 is a cytokine with strong proinflammatory action. Research studies has revealed high expression of IL-17 in the inflamed mucosa of patients with active Crohn disease(CD) or Ulcerative colitis(UC) in contrast with people with normal mucosa. In particular, patients with active CD have higher levels of IL-17 than those with UC. Anti-interleukin-17a monoclonal antibody is currently used against psoriasis, psoriatis arthritis and ankylosing spondylitis. Anti-IL-17a monoclonal antibody's role in IBD is still unclear although new findings suggest new-onset or flare of bowel disease. The aim of this study is to present 4 cases of new-onset patients treated in our hospital.

Aims & Methods: A retrospective study was performed by evaluation of 4 patients' clinical history under secukinumab for rheumatologic disease who developed IBD.

Results: Characteristics of patients and their IBD are summarized in Table 1.

Basal characteristics of patients and their IBD	Patient 1	Patient 2	Patient 3	Patient 4
Age(years)	42	30	51	41
Smoking history	Yes	Yes	Yes	Yes
Familiarity of IBD	No	No	No	No
Time of secukinumab treatment(months)	14	1	2	7
Indication of treatment	AS	AS	AS	AS
Location of IBD	B1,L3	B1p,L3,4	B1p,L3	B1,L3
Severity of IBD	Severe	Severe	Moderate	Moderate
IBD therapy	Adalimumab	Adalimumab	Infliximab	Corticosteroids/ASA
Response to treatment(RMN)	Yes	Yes	Yes	Yes

Table 1.

Conclusion: All patients were men with new-onset CD without family history of IBD. Three of them had smoking history and presented with IBD symptoms after one to 14 months under treatment with secukinumab. The 4th patient presented with symptoms of IBD after 14 months but he was under combination treatment with methotrexate for the first 11 months of secukinumab treatment and developed IBD 2 months after stopping methotrexate. The severity of IBD was moderate to severe with total (100%) response to treatment.

Despite the low incidence of IBD in patients treated with secukinumab, it seems that deteriorates their quality of life. According to our findings, an exhaustive search for patients with subclinical bowel disease is suggested. Patients who appear with GI symptoms after treatment with secukinumab should be referred for gastroenterological evaluation.

Disclosure: Nothing to disclose.

P0276

IMPACT OF INFLAMMATORY BOWEL DISEASE ON THE QUALITY OF LIFE OF PATIENT'S HOUSEHOLD MEMBERS

M. López-Vico¹, A.D. Sánchez-Capilla¹, E. Redondo-Cerezo¹
¹"Virgen de las Nieves" University Hospital, Gastroenterology, Granada, Spain

Contact E-Mail Address: leunamlv@gmail.com

Introduction: Inflammatory bowel disease is a chronic disease of unknown etiology characterized mainly by digestive symptoms with an increasing incidence and prevalence and with a rise in the direct and indirect costs. It is well established its impact on the quality of life of patients and their main caregivers.

Nonetheless, no study has yet considered the consequences of IBD on cohabitants with no direct involvement in patient's care. Due to the chronic and relapsing nature of IBD, our aims were to analyze quality of life in cohabitants of people with IBD and identify potential related factors.

Aims & Methods: We conducted a cross-sectional study that included patients with IBD and their house-hold members. Participants were recruited from a period of two months from patients attending the IBD unit of our hospital. Inclusion criteria were a definite diagnosis of IBD at any stage and household members living in the same house for a period of 1 year or more. Exclusion criteria were an age <18, refusal to participate or subjects unable to fulfill the questionnaires. Patients and household members that met all the inclusion criteria and none of the exclusion criteria and agreed to participate were included in the study.

Demographic data was obtained for patients and household members, including age, sex occupation, educational level, marital status, and the relationship with the patient in the case of household members.

IBD activity was assessed by using the Partial Mayo Score and the Harvey-Bradshaw score. Information was collected about prior surgeries, extraintestinal manifestations, past and current treatments, number of hospitalizations, number of relapses, and laboratory data such as CRP and calprotectin and others.

Quality of life was assessed in the case of the patients with the Inflammatory Bowel Disease Questionnaire (IBDQ-32) and for the household members we used the Household Members Quality of Life-Inflammatory Bowel Disease (HHMQoL-IBD) questionnaire.

Results: Fifty-six patients and 82 household members were included. Both groups had similar sociodemographic characteristics. We included 22 patients with UC, 32 patients with CD and 2 patients with indeterminate colitis.

The univariate analysis of the quality of life of cohabitants showed a significant association of HHMQoL-IBD and IBDQ-32 score in their relatives ($p<0.0001$), last CRP ($p=0.043$), number of disease flares in the last year ($p=0.04$), extraintestinal diseases ($p=0.01$) and particularly articular disease ($p=0.04$).

Cohabitants of patients with CD had significantly lower HHMQoL-IBD than UC ones (53 ± 18 vs. 62 ± 23 ; $p=0.049$).

Among cohabitants of patients with UC, patient's CRP in the last control was related to HHMQoL-IBD score ($p=0.043$) and the cohabitants's score was related with IBDQ-32 in patients ($p=0.019$). Among cohabitants of patients with CD, patient's CRP in the last control was related to HHMQoL-IBD score ($p=0.04$).

In a linear multiple regression analysis, IBDQ-32 score ($p<0.0001$) in patients and the presence of extraintestinal disease ($p=0.048$) were independent predictors of cohabitant's quality of life, and particularly articular disease.

Conclusion: Quality of life in household members of patients with IBD is related to patient's quality of life and extraintestinal conditions related to the disease.

Our study shows how important is to analyze and act in the patient's whole environment, taking into consideration not only clinical variables, which are the main ones, but also the relational conditions and impact of the disease.

Disclosure: Nothing to disclose.

P0277

EFFECTIVENESS OF SARS-COV2 BOOSTER VACCINATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD): PRELIMINARY REPORT FROM A SINGLE REFERRAL CENTER IN SOUTHERN ITALY

D. Brinch^{1,2}, S. Muscarella¹, C. Cunsolo¹, M. Saladino¹, L.M. Amato¹, P. Melatti¹, L. Carrozza¹, F.M. Di Giorgio¹, P.L. Almasio³, M. Cappello¹

¹University of Palermo, PROMISE, Gastroenterology and Hepatology Section, Palermo, Italy, ²University of Palermo, Palermo, Italy, ³University of Palermo, PROMISE, Palermo, Italy

Contact E-Mail Address: danielebrinch@gmail.com

Introduction: Observational studies and metanalyses have reported comparable risk to contract the SARS-CoV-2 infection between the general population and patients with IBD. However, a matter of concern remains the effectiveness of Sars-Cov2 vaccine in patients with immune mediated disease and concomitant biological and/or immunosuppressive treatments.

Aims & Methods: Our aim was to evaluate the rate of new infections, symptomatic or asymptomatic, after full mRNA SARS-CoV2 vaccination, including a third dose, in a homogeneous cohort of patients with IBD followed up in a tertiary referral center from southern Italy. The relationships with disease characteristics and concomitant therapies were also assessed. Data were collected between 03/2021 and 03/2022.

Most patients received the third dose of SARS-CoV2 vaccine between 11/2021 and 01/2022. IBD type, disease features (location, behaviour, extra intestinal manifestations), biologic therapy, immunosuppressive treatment, previous surgery, smoking habit, comorbidities and vaccination protocol were analysed.

Results: Our cohort is composed of 108 patients with IBD, 52 CD and 56 UC, mean age 53,67 years, 58 pts were on biological therapy. 25/108 patients developed COVID-19 infection (23 %), 7/25 patients (28%) didn't receive the third dose because contracted the infection before the booster dose. There was a significant difference in the rate of infection between those who received the third dose and those who did not ($p<0,001$).

The COVID-19 population was younger ($48,6 \pm 16,5$) than the non COVID-19 population ($55,2 \pm 15,9$, $p=0,07$) and female sex was more frequent (56% vs 36%, $p=0,1$). 19/25 (76 %) had symptomatic infection (flu-like symptoms) but none of them experienced pneumonia or severe disease.

Symptomatic infection was more frequent in patients who didn't complete the vaccination protocol (68,42% VS 83,33%), though the difference was not significant. Biological therapy was not associated with the development of infection either symptomatic or asymptomatic. Smoking habit, comorbidity, type of IBD, were not significantly related to COVID-19.

Conclusion: Our results confirm the effectiveness of mRNA SARS-CoV2 vaccination in patients with IBD independently from concomitant immunosuppressive therapy since only 23% of them developed the infection, most with mild symptoms. The protective effect was statistically significant in those who received the booster dose. The need of additional doses in IBD patients on biologics will be a matter of debate.

Disclosure: Nothing to disclose.

Contact E-Mail Address: samuelmartinez94@hotmail.com

Introduction: The prevalence of Non-Alcoholic Fatty Liver Disease (NAFLD) is increasing rapidly around the world, becoming one of the main comorbidities in patients with Inflammatory Bowel Disease (IBD).

Aims & Methods: Consecutive outpatients ≥ 18 years with IBD were recruited in a reference center and patients ≥ 18 years without IBD were recruited in 2 Primary Care centers from the same health area. The presence of NAFLD and liver fibrosis was assessed by ultrasound and Transient Elastography (TE) considering NAFLD in case of ultrasound steatosis and/or CAP > 245 dB/m and risk of advanced liver fibrosis if TE was ≥ 8 kPa. Patients with risky alcohol consumption or chronic liver disease were excluded. A comparative analysis of cases and controls (univariate and multivariate) and risk factors associated with NAFLD and liver fibrosis was performed. A p value < 0.05 was considered statistically significant. The study was approved by local ethic committee.

Results: 702 patients with IBD and 189 controls without IBD were included (sample characteristics in Table 1).

CU		53.9%			

BMI: Body Mass Index, CD: Crohn's Disease, CKD: Chronic Kidney Disease, IBD: Inflammatory Bowel Disease, UC: Ulcerative Colitis. N (%). * Median and interquartile range

Table 1. Characteristics of the sample

No statistically significant differences were found between the prevalence of NAFLD or liver fibrosis in cases and controls (44.2% vs 44.9%, $p=0.856$; 9.1% vs 2.7%, $p=0.061$, respectively).

In the multivariate analysis in patients with IBD, NAFLD was significantly associated with older age (OR (95% CI) 1.04 (1.02-1.06), $p < 0.001$), overweight/obesity (OR (95% CI) 0.26 (0.17-0.39), $p < 0.001$), increased waist-hip ratio (OR (CI 95%) 0.32 (0.21-0.48), $p < 0.001$) and absence of active lifestyle (OR (CI 95%) 2.41 (1.44-4.05, $p < 0.001$) whereas liver fibrosis was associated with hypertension (OR (CI 95%) 0.07 (0.10-0.45), $p = 0.006$). No association was found between NAFLD and/or liver fibrosis and type of IBD, location, extension, pattern or treatment of the disease.

Conclusion: NAFLD is highly prevalent both in the general population and in patients with IBD, and in both cases it is associated with the same risk factors.

Disclosure: This Project has been partially financed by Diputación General de Aragón (DGA).

EFFECTIVENESS OF SMOKING CESSATION INTERVENTIONS IN PATIENTS WITH CROHN'S DISEASE: A SYSTEMATIC REVIEW

S. Nasr¹, I. Nsiri², F. Nabl²

¹Faculté de Médecine de Tunis and Mohamed Taher Maamouri Hospital, Gastroenterology Department, Nabeul, Tunisia, ²Monastir University, Monastir, Tunisia

Contact E-Mail Address: sahar.nasr2508@gmail.com

Introduction: Smoking cessation (SC) in Crohn's disease (CD) is extensively studied and widely accepted to be the most important modifiable factor to improve outcomes in these patients CD (14). Several studies have shown that SC can reverse the negative disease course with quitters having comparable outcomes and prognosis to non-smokers.

In spite of these findings, the percentage of smokers among patients with CD remains high. These observations highlight the critical need for effective and appropriate SC interventions in patients with Crohn's disease.

Aims & Methods: Therefore, we aimed in this review to provide a summary of the evidence base regarding the effectiveness of smoking cessation interventions in patients with Crohn's disease. This systematic review was designed and conducted in accordance with PRISMA guidelines.

The following databases were systematically searched from inception to February 2022 for relevant articles published either in English or French: PubMed, Embase, Google Scholar and Cochrane Library. Eligible studies were randomized control trials, non-randomized controlled trials, quasi-experimental studies, and cohort studies. We included interventions that primarily aimed to help Crohn disease patients, who are actively smoking or who present smoking relapses, to quit. All studies included were systematically reviewed by two different authors.

Results: Overall, five articles met the research criteria and were included. The designs of the interventions were highly heterogeneous. Studies sample size ranged from 17 to 474 patients. Nicotine dependence was assessed in two studies with The Heaviness Smoking Index and the Fagerström Test. The motivation to quit was assessed with the Richmond test or the motivation to quit score. Motivational interviewing and behavioral counseling were used in four studies. At the outcome level, The SC rates ranged from 14.8% to 42% and was $\leq 25\%$ in four studies.

Surprisingly, the highest rate was observed in a study where all patients included initially refused referral to a SC unit and where the intervention was limited to motivational interviewing. The three studies with control groups did not report statistically higher SC rates in the intervention groups. No predictors of success of SC interventions were identified in this review.

Conclusion: The findings of this review suggest that additional efforts are needed to design smoking cessation interventions in patients with CD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: dragasevicsanja@gmail.com

Introduction: Stress is a significant environmental factor that contributes to the pathogenesis of inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC). The onset of IBD is associated with the changes in the patient's mental status, occurrence of depression and anxiety.

Aims & Methods: The aim of the study was to determinate the level of stress, depression and anxiety for newly diagnosed IBD patients and its association with the mucosal expression of *IL17A*, *IL17F*, and *IL23* genes compared with the control group. Study involved 50 active CD (median age = 35.0, male % = 66.0), 54 active UC patients (median age = 43.5, male % = 44.4) and 100 non-IBD control subjects (median age = 50.0, male % = 43.0). All subject were tested on Perceived Stress Scale (PSS), Patient Health Questionnaire (PHQ-9), and Hospital Anxiety and Depression Scale (HADS).

Endoscopic biopsies were taken from inflamed IBD mucosa and analyzed for the expression of *IL17A*, *IL17F*, and *IL23* genes. For IBD group, laboratory and endoscopic examination were also conducted at the same time-point. *IL17A*, *IL17F* and *IL23* gene expression was analysed using real-time PCR Taq-Man method.

Results: PSS score was significantly higher in CD and UC compared to control group (median 18.5, 22.0 and 6.5, respectively, $p < 0.0001$). In CD and UC groups, increased frequency of mild (PHQ-9 = 5-9), moderate (10-14) and moderately severe (15-19) depression has been detected (CD: 56%, 40%, 4%; UC: 57.4%, 35.2%, 7.4%, respectively), compared to control group where most of the subjects were not (PHQ-9 = 0-4) or have been mildly depressed (5-9) (82%, 18%, respectively).

Frequency of abnormal HADS score (11-21) was significantly higher in CD (58%) and UC (53.7%) than in the control group (15%) ($p < 0.0001$). PSS score correlated with the expression of *IL17F* mRNA level in inflamed ileal CD mucosa ($r = 0.62$, $p = 0.0008$). Level of *IL23* mRNA was significantly higher in inflamed ileal mucosa of CD subjects with abnormal level of HADS (11-21) compared to subjects with normal (0-7) and borderline abnormal (8-10) HADS scores ($P = 0.007$).

Conclusion: Significantly higher degree of stress, depression and anxiety was identified in patients with CD and UC. Patients with increased expression of *IL17F* mRNA and *IL23* mRNA level in inflamed ileal CD mucosa had higher PSS and abnormal levels of HADS, indicating the association between psychological abnormalities, immune dysregulation and inflammation in IBD patients.

Disclosure: Nothing to disclose.

THE UK INFLAMMATORY BOWEL DISEASE BIORESOURCE: PROGRESSING FROM GENETICS TO FUNCTION AND CLINICAL TRANSLATION IN CROHN'S DISEASE & ULCERATIVE COLITIS IN ADULTS, YOUNG PEOPLE AND CHILDREN

L. Pele^{1,2}, R. Simpkins^{1,2}, C. Thorbinson^{1,2}, R. Shawky^{1,2}, S. Hearn³, H. Uhlig³, M. Parkes^{1,2,4}, UK IBD Genetics Consortium ¹NIHR IBD BioResource, Cambridge, United Kingdom, ²University of Cambridge, Department of Medicine, Cambridge, United Kingdom, ³University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom, ⁴NIHR Cambridge Biomedical Research Centre, Cambridge, United Kingdom

Contact E-Mail Address: laetitia.pele@bioresource.nihr.ac.uk

Introduction: Inflammatory Bowel Disease (IBD), comprising Crohn's disease (CD) and (UC), affects ~500,000 people in the UK causing relapsing intestinal inflammation, with 25% of patients presenting before the age of 18 years. Accelerating research into the causes CD and UC across all ages is essential for clinical translation but requires access to large and well-characterised cohort of patients.

For that purpose, the UK IBD Genetics Consortium and the NIHR BioResource launched IBD BioResource in 2016 and the Paediatric IBD BioResource (PIBD) in 2022.

The aim is to build a large national platform of 50,000 adults with CD or UC and 5,000 paediatric onset IBD patients with rich genetic and phenotypic data to facilitate downstream translational research.

Aims & Methods: Building the IBD BioResource panel: Following patient enrolment at UK participating hospitals, phenotype data are collected through a clinical data sheet based on the Montreal classification, medication response and surgical history while health and lifestyle information are obtained via a patient questionnaire. Plasma, serum and DNA samples are collected – the latter for genetic analysis (GWAS), including whole genome / exome sequencing (WGS / WES).

Recently diagnosed patients provide further biological sampling including stool, biopsy tissue and whole blood for RNA and longitudinal follow-up of their medical course through clinical records and from the subjects / parents themselves.

Accessing the IBD BioResource panel: The panel of patients and their data is open to any investigators from science or industry. Submitted research proposals or data access applications are reviewed by the NIHR BioResource Scientific Advisory Board or the Data Access Committee, respectively, and approvals granted on scientific merits and projected benefit to patients. These studies may involve access to data only, access to data and existing samples or patient recall studies.

Results: Recruitment: IBD BioResource is open in > 90 participating hospitals across the UK and has recruited ~36,000 patients with established IBD and > 400 patients who are new to their diagnosis. To date ~21,000 samples have been sent for GWAS analyses and ~32,000 for WGS/WES.

The opening of PIBD was approved in January 2022, with Oxford Children's Hospital being the first site opening in March and recruiting their very first paediatric IBD patient in April. A further eight tertiary hospitals across the UK will open in the coming months.

Research translation: Since the launch of the IBD BioResource, 60 research applications have been received. These studies cover a full range of research activity including:

1. Analysis of existing genetics and clinical data
2. Access to existing banked serum samples from patients on biologics
3. Assessing the contribution of infection to IBD pathogenesis
4. Running surveys of the impact of certain aspects of IBD on quality of life
5. Recall studies of patients selected by genotype for functional genomics

6. Recall studies to develop early diagnostic tests
7. Aiding recruitment to observational studies and intervention studies
8. Aiding recruitment to commercial drugs trials

Conclusion: The IBD BioResource and its network are on course to facilitate IBD Research through access to their panel and furthering knowledge / understanding of IBD for the benefit of all Crohn's and colitis patients.

Disclosure: Nothing to disclose.

Contact E-Mail Address: i.j.hidding@umcg.nl

Introduction: Genome wide association studies have identified over 200 risk loci for Inflammatory Bowel Disease (IBD)^{1,2}. Additional studies have shown an inflammation dependent effect on gene expression³ and it has been shown that inflammation increases the rate of which somatic variants are introduced in the gut of patients diagnosed with IBD⁴. The effect of these somatic variants on IBD pathogenesis is poorly understood.

We hypothesise that these somatic variants can affect the inflammation and thereby can explain at least some of the difference in disease heterogeneity and therapy response between patients.

Aims & Methods: Here we investigated the impact of these somatic variants on IBD by analysing the variants on a variant, gene and pathway level. Biopsies (n=547, UC=232, CD=315) have been taken from patients diagnosed with IBD (n=272, UC=122, CD=150). We sequenced bulk RNA data from the biopsies and whole-exome data from the blood of these same patients. GATK Mutect2 was used to call somatic variants from the comparisons. As healthy controls were not available, comparisons were performed on an inflammation, disease and location basis by linear regression model and multiple testing correction.

Additionally, the data was corrected for gene expression as the detecting of somatic variants is dependent on a high enough level of gene expression. Genes enriched with somatic mutations were grouped for pathway analysis.

Results: Biopsies consisted of 50+ different cell types and the number of somatic variants per biopsy ranged from 9 475 to 53 551 (mean=27 137, std=6 540).

Within sample enrichment was performed to analyse genes enriched with somatic mutations regardless of phenotype. XIAP is the gene with most somatic variants found across all biopsies (mean=80, std=35.7), this gene is linked to very early onset IBD as a monogenic cause for disease.

Comparing the number of somatic variants per gene in biopsies from inflamed tissue with biopsies from non-inflamed tissue resulted in 104 significant genes after correcting for age, sex, BMI and gene expression, one of which DUOX2 (adj. p-value = 0.004) is a gene associated with IBD and has a significantly higher number of somatic variants in inflamed biopsies compared to non-inflamed biopsies.

Additionally, 440 genes showed a significant difference in the number of somatic variants when comparing ileum versus colon biopsies. CD36 (nominal p-value = 1.8e-05) was the most significant gene when compar-

ing CD to UC. This gene is associated with inflammation and the difference in variants could show a difference in the inflammation mechanism between UC and CD.

Additionally, variant annotation showed a number of pathogenic and likely pathogenic variants from the Clinvar database ranging from 0 to 21 per sample (mean=7, std=5.8), showing that variants with a confirmed pathogenic effect can remain undetected from standard genetic screening. However, Clinvar annotation is based on germline variants and not somatic, which means any pathogenic effect on genomic level might not have the same impact on a local level.

Conclusion: Overall, our study has shown that somatic mutations can have a large impact on the genes in cells in the gut of patients with IBD, through pathogenic mutations and accumulation of mutations in genes related to IBD. Although, it is not expected that every mutation has an effect, overall trends in increased mutations can be interpreted as a biological effect and should be investigated further.

Introduction: Ulcerative colitis is a chronic invalidating disease, whose therapeutic strategies include amino-salicylates, steroids, probiotics, immune-modulators, biologics, fecal microbiota transplantation and surgery. Though, in clinical practice, there are no evidence available about

elements that could predict response to each of the above-mentioned therapies. Our group thinks that OCTN1, an organic cation transporter directly involved in innate immunity, with its variants (C503L homozygous, heterozygous or T503F), could have a role in predicting individual response to biologic therapies (antiTNFa and vedolizumab).

Aims & Methods: In this prospective and retrospective study, we enrolled a cohort of 90 patients with active ulcerative colitis (50 in treatment with antiTNF agents and 40 with vedolizumab), determining their OCTN1 genotype and evaluating their clinical response to therapy, calculated with clinical Mayo score, after six weeks (T1) and six months (T2).

Results: Left colitis at diagnosis was more frequent in C503L patients (61.7% left colitis vs 38.3% pancolitis) than patients than in patients with T503F (32.5% left colitis vs 62.5% pancolitis). At the same way, the average age at diagnosis was sensibly lower in patients with T503F genotype (35.5 years C503L vs 33.3 years heterozygous vs 28.9 years T503F).

We used clinical response at T2 (6 months) as a primary outcome of our study. Among patients under antiTNFa therapy, patients with C503L genotype were divided into 8 no responders and 6 responders (43% responders vs 57% no responders), whilst patients with T503F genotype were divided into 10 responders and 2 no responder (80% responders vs 20% no responders). On the contrary, patients under vedolizumab therapy showed different trend: patients with C503L genotype were divided into 15 responders and 4 no responders (78.9% responders vs 21.1% no responders), whilst patients with T503F genotype were 3 responder and 1 no responder.

Conclusion: Patients with T503F genotype present an overall worse course of disease, with higher rate of pancolitis and younger age at diagnosis. Furthermore, the presence of the mutation (allele T) could have a role in increasing the response rate to antiTNFa.

Introduction: Food additives, including artificial sweeteners, have been epidemiologically and experimentally linked to an increased risk of developing Crohn's disease (CD). This is thought to be mediated by sweeteners altering the microbiota to be more pro-inflammatory.

However, the physiological fate of these sweeteners has not been fully evaluated. We aimed to determine the level of commonly consumed artificial sweeteners in urine, stool and serum samples of patients with CD compared with controls.

Aims & Methods: We included a total of 317 subjects [(184 CD patients), 40 first-degree relatives of CD (FDR), 52 non-related healthy household members of CD patients (HHM) and 41 healthy controls (HC)] from Australia and Hong Kong. Consumption of common artificial sweeteners (aspartame, sucralose and saccharin) was quantified using a validated 26-item food additive questionnaire, and their concentration in stool, urine and serum samples quantified using mass spectrometry based on a newly developed and validated standard operating procedures.

Results: Aspartame, sucralose and saccharin concentrations in urine, stool and serum samples were consistent with their known metabolism. Only saccharin was detectable in serum, and no significant differences were observed between groups.

However, the CD group had a greater saccharin concentration in urine than HC ($P<0.001$) and the sucralose and aspartame concentrations in stool were also significantly greater in CD than HC ($P=0.007$ and $P=0.041$, respectively). There was a positive correlation between sucralose stool concentration (the main exposure pathway for sucralose) and sucralose intake assessed by validated questionnaire that captured past 12 months intake ($R^2=0.4431$, $P<0.001$).

Conclusion: In the first human study that quantifies artificial sweetener levels concentrations of artificial sweeteners in urine and stool were increased in Crohn's disease compared with healthy controls. Sucralose and aspartame in stool may play a role in the pathogenesis of Crohn's disease inflammation.

Introduction: COVID-19 outbreak and consequential restrictive measures have strongly influenced clinical management of several chronic diseases, causing lengthening of waiting times for visits, follow-up and procedures, particularly conditioning the clinical presentation.

In this short case series study, we aim to demonstrate how COVID-19 pandemic has influenced Crohn's disease (CD) clinical course by increasing the number of patients with more severe symptoms at presentation.

Aims & Methods: In our study we observed the clinical presentation of all previously diagnosed, or subsequently confirmed, CD patients who accessed the emergency department and first time visited in our operative gastrointestinal unit from January 2020 to December 2021. The absolute percentage of all symptoms was reported and compared to a CD population admitted to emergency department during a previous two-years period (January 2018 to December 2019).

All data were collected from years-related databases based on information contained in medical records. Student T test was used to compare the difference in clinical presentation among the two groups. P values <0.05 were considered statistically significant.

Results: A total of 91 CD patients were first time visited in the two-year period 2020-2021. The median age of patients was 31.7 years (23-35) and 57.8 % (63 out of 109) were female. The most frequent clinical presentations

at first medical examination were abdominal pain in 82 patients (90.1%), tiredness/fatigue in 80 patients (87.9%), diarrhoea in 54 patients (59.3%) and abdominal bloating/distension in 61 patients (67.0%). A severe clinical presentation with intestinal obstruction or perforation occurred in 10 (10.9%) and 5 (5.4%) patients, respectively. In the two-year period 2018-2019, a total of 145 CD patients were first time visited; the median age was 32.8 years (25-36) and 61.5% (83 out of 135) were female.

At the first medical examination abdominal pain reported in 128 (88.3%) and tiredness/fatigue in 125 patients (86.2%) appeared to be the most common symptoms followed by diarrhoea in 85 patients (58.6%) and abdominal bloating/distension in 87 patients (60.0%). No severe presentation symptoms were recorded in 2018-2019 two-years period.

Hence, abdominal pain ($p=0.035$) and tiredness/fatigue ($p=0.049$) were statistically higher in patients observed during two-year period 2020-2021, moreover diarrhoea, abdominal bloating/distension, obstruction and perforation clinical pattern were more frequent although not reaching the statistical significance.

Conclusion: Our data suggest a change in clinical presentation of CD patients with an increase of all symptoms including severe presentation, such as intestinal obstruction and/or perforation in 2020/2021 two-year period, likely as direct or indirect consequence of COVID19 outbreak. Further clinical investigation is needed to confirm this observation.

Introduction: Patients with immune-mediated inflammatory diseases (IMIDs) are at higher risk for infectious diseases, especially when receiving immunosuppressive treatments. In 2018, we set up the prospective COL-OSSeUM registry in order to track and optimize their vaccination coverage for influenza, pneumococci and hepatitis B. Once COVID19 vaccines became available, national authorities provided IMID patients priority access, but data on actual COVID19 vaccination coverage in this population are missing.

Aims & Methods: We evaluated the COVID19 vaccination coverage of IMID patients through the COL-OSSeUM registry. This registry contains data from 1488 consecutive IMID patients with IBD, rheumatic (RHEU) or dermatological inflammatory conditions (DER) recruited at a tertiary referral centre between August and December 2018 (Fierens L, *J Crohns Colitis* 2022). Global vaccination rates were assessed at baseline as well as in 2021/2022 after the implementation of a vaccination module (Vaccinnet) in the electronic patient health record. For the present study, both basic and booster COVID19 vaccination coverage until March 2022 were reviewed. Reasons

for non-vaccinations were collected by contacting patients directly. Vaccination rates were compared with those of the adult Flemish background population (source: laatjevaccineren.be).

Results: In total, 1430 adult IMID patients (44.90% male, median age 53.94 years, 789 IBD, 604 RHEU, 37 DER) were included in the present study. By March 2022, 96.78% of IMID patients had received the COVID19 basic vaccination (96.07% IBD, 98.01% RHEU, 91.89% DER) and 91.75% at least one COVID19 booster vaccination (89.23% IBD, 95.36% RHEU, 86.49% DER). COVID19 vaccination coverage was significantly higher for RHEU patients than for IBD/DER patients (basic 98.01% vs. 95.88%, $p=0.024$; booster 95.36% vs. 89.10%, $p<0.001$). Compared to the background population, COVID19 coverage rate was higher in our IMID patients (basic 96.78% vs. 92.95%, $p<0.001$; booster 91.75% vs. 83.77%, $p<0.001$). Factors associated with COVID19 vaccination in univariate analysis are shown in Table 1.

In multivariate analysis, basic COVID19 vaccination was associated with age above 50 years [Odds ratio 3.66 (95% CI 1.82-7.39), $p<0.001$], use of thiopurines/methotrexate [2.76 (1.06-7.20), $p=0.038$] and compliance with other recommended vaccinations [3.60 (1.84-7.06), $p<0.001$]. Booster COVID19 vaccination was associated with age above 50 years [4.74 (2.99-7.53), $p<0.001$], use of thiopurines/methotrexate [2.13 (1.21-3.74), $p=0.009$] and compliance with other recommended vaccinations [3.11 (2.05-4.72), $p<0.001$]. Main reasons for absence of COVID19 vaccination included skepticism (29/46, 63.04%) and fear for adverse events (13/46, 28.26%).

		Age above 50	Sex	Higher education level	Compliance with other recommended vaccinations	Any immunosuppression	Systemic steroids	Thiopurines / methotrexate	Biological therapy	Small molecules
ALL (n=1430)	Basic vaccination	$p<0.001$	$p=0.479$	$p=0.243$	$p<0.001$	$p=0.939$	$p=1.000$	$p=0.007$	$p=0.057$	$p=0.397$
	Booster vaccination	$p<0.001$	$p=0.996$	$p=0.379$	$p<0.001$	$p=0.686$	$p=0.109$	$p<0.001$	$p=0.074$	$p=0.780$
IBD (n=789)	Basic vaccination	$p=0.001$	$p=0.274$	$p=0.099$	$p=0.002$	$p=1.000$	$p=0.089$	$p=0.628$	$p=0.700$	$p=1.000$
	Booster vaccination	$p<0.001$	$p=0.731$	$p=0.038$	$p<0.001$	$p=0.214$	$p=0.642$	$p=0.566$	$p=0.808$	$p=0.270$
RHEU (n=604)	Basic vaccination	$p=0.042$	$p=0.550$	$p=1.000$	$p=0.006$	$p=1.000$	$p=1.000$	$p=0.067$	$p=0.017$	$p=1.000$
	Booster vaccination	$p<0.001$	$p=0.232$	$p=0.428$	$p=0.003$	$p=1.000$	$p=0.815$	$p=0.110$	$p=0.030$	$p=0.618$
DER (n=37)	Basic vaccination	$p=0.072$	$p=0.584$	$p=1.000$	$p=0.554$	$p=0.562$	$p=1.000$	$p=0.632$	$p=1.000$	not applicable
	Booster vaccination	$p=0.010$	$p=0.159$	$p=1.000$	$p=0.377$	$p=1.000$	$p=1.000$	$p=0.538$	$p=1.000$	not applicable

Table 1: Factors associated with basic and booster COVID19 vaccination in univariate analysis.

Conclusion: In IMID patients, COVID19 vaccination coverage was higher compared to the background population. Factors independently associated with vaccination coverage included older age, the use of thiopurines or methotrexate, and compliance with other recommended vaccinations.

Introduction: Managing solid organ transplant (SOT) IBD patients represents a vexing problem, mainly due to concerns of immunosuppression and biologic therapies.

Aims & Methods: Retrospective analysis of 19 SOT-IBD patients between 2001-2021 in a Portuguese tertiary centre.

Results: Ten patients (53%) were male, 7 (37%) ulcerative colitis (UC), 10 (52%) Crohn's Disease (CD) and 2 (11%) unclassified colitis. Five patients (26%) were submitted to kidney transplant(KD) and 14 (76%) to liver transplant(LT). Nine patients (47%) were diagnosed with IBD after transplant, with 4 IBD post-KT. Tacrolimus and MMF were the most commonly used antirejection treatments.

Concerning CD patients, 9 were non-stricturing non-penetrating (4 ileocolic and 5 colonic), 1 was stricturing (jejuno-ileal) and 3 had perianal disease.

Three patients achieved remission under mesalazine (UC), 3 under steroids, 3 under azathioprine (AZT) and 7 under biologics. Two UC patients were submitted to colectomy due to medical therapy failure. Eight (42%) patients experienced treatment with biologics, 2 of them combined with AZT (infliximab+AZT). Five patients (26%) experienced only one biologic (3 treated only with infliximab and 2 with vedolizumab). Three patients (15%) experienced two or more biologics (1 failed to vedolizumab and is currently under ustekinumab; 1 failed to adalimumab, developed infliximab immunogenicity and is currently under vedolizumab; 1 failed to combined AZT plus infliximab, to adalimumab and to vedolizumab).

Two/8 treated with combination biologic and antirejection therapy experienced infectious complications: CMV colitis and campylobacter en-

terocolitis, both under infliximab+tacrolimus. One CD patient with LT was diagnosed with intestinal diffuse large B-Cell lymphoma (tacrolimus and recent AZT).

Conclusion: The majority of patients presented colonic disease. The risk of infection and neoplasms (mainly lymphoproliferative) should be considered in the management of this patients – that probably explains why vedolizumab was preferred in this population.

Disclosure: Nothing to disclose.

P0288

THE DISEASE SEVERITY INDEX FOR INFLAMMATORY BOWEL DISEASE IS ASSOCIATED WITH PSYCHOLOGICAL SYMPTOMS, QUALITY OF LIFE, AND PREDICTS A MORE COMPLICATED DISEASE COURSE

A. Swaminathan¹, D. Fan², G. Borichevsky³, T. Mules⁴, E. Hirschfeld³, C. Frampton³, A. Day⁵, C.A. Siegel⁶, R.B. Geary⁷

Introduction: Individuals with inflammatory bowel disease (IBD) follow a heterogeneous disease course and experience higher rates of stress, anxiety and depression compared to those without IBD.^{1,2} The Disease Severity Index (DSI)³ is a novel tool that aims to incorporate measures of IBD activity, patient reported outcomes and clinical phenotype to estimate overall disease severity. However, the ability of the DSI to predict disease complications and the presence of psychosocial comorbidity has not previously been investigated.

This study prospectively assessed the associations between the DSI and psychological symptoms, quality of life (QoL) and disease outcomes in a cohort of patients with IBD.

Aims & Methods: Patients with IBD undergoing ileocolonoscopy for disease assessment in Canterbury, New Zealand were followed prospectively for 12 months. DSI, psychological symptoms (perceived stress (perceived stress scale, PSS-10), depression (patient health questionnaire, PHQ-9), anxiety (generalised anxiety disorder scale, GAD-7)) and QoL (inflammatory bowel diseases questionnaire, IBDQ-32) scores were assessed at baseline. Endoscopically active disease included individuals with a simple endoscopic score for Crohn's disease (SES-CD) >2 and ulcerative colitis endoscopic index of severity (UCEIS) ≥2. Logistic regression was used to identify variables predicting a complicated IBD course at 12 months (composite endpoint of need for escalation of biological/immunomodulator for disease relapse, recurrent corticosteroid use, IBD-related hospitalisation and surgery). Variables reaching a pre-defined significance of p<0.01 were incorporated into multivariable regression analyses to develop a final model to predict the composite study endpoint.

Receiver operating characteristics (ROC) analyses identified the optimal DSI set point to predict a complicated disease course. This threshold was then used as a categorical value in place of a continuous DSI score in the final multivariable prediction model to assess the risk of reaching the composite study endpoint at 12 months of follow up.

Results: One hundred and seventy-two patients were recruited (100 Crohn's disease (CD), 91 female). Median age of participants was 46 years (IQR 35-59), median DSI was 21 (IQR 11-32), median IBDQ-32 was 169 (IQR 135-196) and 97 patients had endoscopically active disease at baseline.

The DSI was significantly higher in patients with symptoms of moderate-severe stress (PSS-10 >14, $p < 0.01$, $n = 84$), depression (PHQ-9 ≥ 10 , $p < 0.01$, $n = 48$), anxiety (GAD-7 ≥ 10 , $p < 0.05$, $n = 34$) and impaired quality of life (IBDQ-32 <168, $p < 0.01$, $n = 84$). The composite study endpoint was observed in 49 patients (29 Crohn's disease, 20 ulcerative colitis (UC)).

Only the baseline DSI (odds ratio (OR) = 1.05, 95% CI 1.01-1.07) and endoscopically active disease (OR = 6.12, 95% CI 1.85-20.26) were associated with a complicated IBD course on multivariable logistic regression analyses and were used in the final prediction model (Table 1). Using this model, subgroup analyses stratified by IBD subtype showed that the DSI was associated with a complicated disease course in patients with CD (OR = 1.10, 95% CI 1.04-1.16) and UC (OR = 1.08, 95% CI 1.04-1.12).

A DSI of 23 was the optimal threshold for predicting a complicated IBD course (Area under the ROC (AUROC) = 0.84, $p < 0.01$; Sensitivity 84%; Specificity 72%) and was strongly predictive of reaching the composite study endpoint (OR = 8.31, 95% CI 3.38-20.46) when incorporated into the final prediction model.

Sub-group analyses confirmed no significant differences in the performance of the DSI in predicting the composite study endpoint between individuals with CD and UC (AUROC_{difference} = 0.08, $p > 0.05$). A DSI >23 was also associated with a significantly elevated risk of having a complicated IBD course at 12 months in individuals with inactive or mild disease activity (SES-CD <7, UCEIS <5) at baseline (OR = 11.75, 95% CI 3.47-39.81) when using the final multivariable prediction model.

Factors selected for multivariable analysis*	Odds ratio (95% CI)	p value
Current steroid use at baseline assessment	0.78 (0.18-3.20)	0.71
Steroid use in the year prior to baseline assessment	1.97 (0.61-6.23)	0.26
Current biological use at baseline assessment	1.71 (0.61-4.77)	0.31
Inflammatory bowel diseases questionnaire (IBDQ-32)	1.00 (0.98-1.03)	0.82
Patient health questionnaire-9 (PHQ-9)	1.06 (0.95-1.17)	0.31
Disease severity index (DSI) ^{continuous variable}	1.05 (1.01-1.07)	0.01 **
Subjectively active IBD at baseline (HBI >4, SCCAI >5)	0.99 (0.29-3.33)	0.99
Objectively active IBD at baseline (SES-CD >2, UCEIS >2)	6.12 (1.85-20.26)	<0.01 **

Table 1. Multivariable logistic regression analysis for baseline factors associated with a complicated IBD course at 12 months. IBD = inflammatory bowel disease. HBI = Harvey-Bradshaw index. SCCAI = simple clinical colitis activity index. SES-CD = simple endoscopic score for Crohn's disease. UCEIS = ulcerative colitis endoscopic index of severity. *Selected for multivariable analysis ($p < 0.01$ on univariable regression analyses).

**Selected for final prediction model.

Conclusion: The DSI is associated with psychological distress, impaired QoL, and predicts a more complicated disease course in patients with IBD. Even in individuals in endoscopic remission or with mild disease activity, a DSI >23 is significantly associated with IBD-related complications during 12 months of follow up. The DSI is a novel tool that can be incorporated into routine IBD assessment and has the potential to allow clinicians to provide more accurate and holistic patient care.

Introduction: Cytomegalovirus (CMV) infection can worsen the prognosis of patients with active inflammatory bowel disease (IBD) and be a cause of steroid or immunosuppressive-refractory disease.

Several methods are available for the diagnosis of CMV infection, with variable sensitivities and specificities. The most reliable methods for the diagnosis are immunohistochemistry (IHC) and CMV polymerase chain reaction (PCR) in colonic tissue. Clinical significance of isolated positive PCR remains unclear.

Aims & Methods: The aim of this study is to review CMV-positive IBD patients, diagnosed by PCR and/or IHC, the adopted therapeutic approach and their clinical evolution.

We conducted a retrospective, cohort study. All biopsy samples sent from colonoscopy to check for CMV from 2017 to 2021 were reviewed. Patients with a diagnosis of CMV by PCR and/or IHC were included. Primary endpoint was describing the diagnostic techniques used and the clinical course of CMV+ patients.

Secondary endpoint was whether CMV diagnosis conditioned any baseline treatment changes/escalation. Non-IBD patients were excluded. Variables including demographics, disease related information, baseline treatment, clinical outcomes and need for antiviral treatment were collected.

Results: Out of 451 submitted biopsies, we detected 51 positive PCRs (11.3%) and 31 positive IHCs (6.7%), 11 of non-IBD patients were excluded. 44 biopsies were included in the final analysis. Of 39 PCR+ samples only 13 (36.1%) were IHC+. However, most patients with IHC+ (18) had PCR+ (13, 95.5%). Intranuclear bodies were seen in 8 of PCR+ (20.5%) patients and in 10 (55.5%) of IHC+ samples.

38 patients (86.4%) were diagnosed with ulcerative colitis (UC), while 5 (11.3%) had Crohn's disease (CD) and 1 (2.3%) unclassified IBD. Most patients had moderate-severe clinical activity (31, 70.5%) and also severe endoscopic activity (27, 71.1% of UC Mayo 3 and 100% of CD SES-CD >8). In total, 19 patients (43.2%) fulfilled criteria for steroid-refractory disease.

All of them were treated regardless of the technique used to detect CMV (17 PCR+, 8 PCR+/IHC+ and 2 PCR-/IHC+). Short-term remission occurred in 10 (52.6% patients), 3 (15.8%) required surgery and the remaining patients (6, 31.6%) needed treatment escalation to achieve long-term remission. In patients with non steroid-refractory disease, CMV was treated in severe flare-ups (9, 36%) and in 3 (33.3%) remission was achieved with antiviral treatment only. Patients who did not receive antiviral treatment (17) had mild clinical activity, CMV was assumed to be an innocent bystander and 13 (76.5%) patients remitted without baseline treatment changes. In 11 (84.6%) patients with PCR and IHC+ antiviral treatment was started. Remission rate was 45.5% (5 patients). Only 2 (15.4%) patients of this group were not treated, they had mild flare-up and responded to conventional treatment. 12 (52.2%) patients with isolated PCR+ received antiviral treatment, 8 (66.7%) with steroid refractory disease. No significant differences were observed in remission rates or in the need for surgery between isolated PCR+ treated patients (remission: 38.5%, surgery: 15.4%) and isolated PCR + untreated patients (remission: 69.2%, surgery: 7.7%).

Conclusion: In our study one third of patients with PCR+ had also IHQ+. Most of the patients who received antiviral treatment had steroid refractory disease or had both PCR and IHQ positivity. In patients with isolated PCR and a mild flare, not starting treatment could be considered.

NEUTROPHIL-LYMPHOCYTE RATIO ROLE TO PREDICT DISEASE ACTIVITY AND SEVERITY IN ULCERATIVE COLITIS

S. Berrag¹, T. Adiou¹, S. Ouahid¹, A. Touibi¹, H. Igorman¹, R. Laroussi¹, M. Moussaa¹, M. Tamzaourte¹

¹Military Hospital Mohamed V of Rabat, Gastroenterology 1, Rabat, Morocco

Contact E-Mail Address: sanaa.berrag@gmail.com

Introduction: Usual inflammatory biomarkers have been routinely used to evaluate activity and severity in ulcerative colitis (UC). But these parameters have a humble precision in reflecting UC disease activity. Therefore, finding non-invasive accessible and cost-effective biomarkers that can be used to evaluate disease activity is strongly needed for optimal management of UC.

Aims & Methods: The aim of this study is to evaluate the utility of neutrophil-lymphocyte ratio (NLR) as simple and cost-effective non-invasive biomarkers for detecting disease activity in UC patients. We conceived a retrospective study including 69 UC patients classified into two groups according to Mayo score (active UC and inactive UC). Patients were enrolled from the gastroenterology I department Military Hospital Mohamed V of Rabat over a period of 3 years (June 2019 to January 2022). The White blood cell count (WBC), NLR, LMR, C-reactive protein (CRP) and fecal calprotectin (FC) were measured.

Results: A total of 69 UC patients were included. The mean NLR values of the inactive and active patients were 1.61 ± 0.41 and 2.74 ± 1.130 , respectively ($p < 0.0001$). The NLR levels of active patients were significantly higher compared to patients with inactive UC. Spearman's correlation analysis indicated a significant positive correlations between NLR and WBC ($r = 0.289$, $p = 0.016$), faecalcalprotectin ($r = 0.578$, $p = 0.00$) and CRP ($r = 0.257$, $p = 0.033$) in the among all UC patients.

In UC active patients, NLR showed a significant positive correlation with faecalcalprotectin ($r = 0.337$, $p = 0.048$) and CRP ($r = 0.333$, $p = 0.05$). However, we found no correlation between the NLR and CRP, Faecalcalprotectin or WBC count in patients with inactive UC. A linear regression model showed that NLR remained an independent predictor of disease activity (OR: 2.8, 95%CI: 0.98–3.43, $p = 0.05$). ROC curve analysis suggested that

the optimum cut-off NLR value for active UC was 2.46, with sensitivity and specificity of 79.4 % and 66.7 % respectively (AUC: 0.46).

Conclusion: High NLR level is associated with active disease in UC. It can be considered as an additional marker to evaluate activity in UC

Introduction: Inflammatory bowel diseases (IBD) are chronic diseases with an increasing incidence in the paediatric population. Given the lifelong impact of these diseases, the transition from paediatric to adult healthcare in patients with IBD is essential to ensure the continuity of care.

Aims & Methods: We aimed to evaluate the impact of structured transition from pediatric to adult IBD services on objective patient outcomes including disease flares, admission rates, hospitalization and surgery. We further assessed the rate of medication adherence and the quality of life pre-and post-transition.

An observational, prospective study was conducted in a tertiary IBD centre and included adolescent/young adult (aged ≥ 17 years) with a confirmed diagnosis of IBD before 16 yo and in clinical remission who underwent "structured transition" ("joint transition care"). We collected demographics and clinical data in the previous 12 months before the transition and 12 months after. Patients completed the following questionnaires at recruitment: the Morisky Medication Adherence Scale and the short form health survey (SF36) Questionnaire.

Results: We recruited 41 patients (aged 18–20) in clinical remission based on Crohn's Disease Activity Index [CDAI] score 117 ± 145 for Crohn's Disease [CD] and pMayo 2.7 ± 1.4 for ulcerative colitis [UC] who had recently transitioned to adult care and completed 12 months follow-up. Demographic details were summarized in Table 1.

Characteristics	Patients (n 41)
UC	22 (54%)
CD	19 (46%)
Female	27 (66%)
Smokers	5 (12%)
L1	4 (10%)
L2	3 (7%)
L3	12 (29%)
B1	13 (32%)
B2	6 (14%)
B3	0
Perianal disease	6 (14%)
E1	2 (5%)
E2	3 (7%)
E3	17 (41%)
Duration disease (months)	68.8 ± 35.6

Table 1.

There was a significant reduction in the number of outpatient visits and in the rate of flares in the 12 months post-transition (outpatient visits pre-transition 2.3 ± 0.7 , post-transition 1.8 ± 0.8 , $p=0.005$) (exacerbations pre-transition: 1.2 ± 0.9 , post-transition 0.6 ± 0.7 , $p=0.005$) (flares pre-transition 1.2 ± 0.9 , post transition 0.6 ± 0.7 , $p=0.001$). While, there was no statistically significant difference between patients' Body Mass Index (BMI) before (22.8 ± 3.4) and after transition (23 ± 3.5 ; $p=0.72$).

Similarly, no significant difference was observed in terms of hospitalization (hospitalization pre-transition 0.2 ± 0.5 , post-transition 0.2 ± 0.4 , $p=0.6$); surgery (surgery pre-transition 0.02 ± 0.15 , post-transition 0.10 ± 0.3 , $p=0.17$); medication adherence (adherence pre-transition 1.6 ± 0.5 , post-transition 1.6 ± 0.5 , $p=0.7$); quality of life (SF-36 pre-transition 100 ± 6 , post-transition 101 ± 5 , $p=0.2$).

Conclusion: Attendance at dedicated transition clinics can contribute to the achievement of the continuity of care. Transition patients have similar BMI, rate of hospitalization, surgery, adherence to medications and quality of life pre and 12 months post-transition clinic.

Whilst there was a significant reduction in the rate of flares and thereby in the number of outpatient visits in the 12 months post-transition since most patients were in clinical remission.

Disclosure: Nothing to disclose.

Introduction: The Van Assche Index (VAI) was developed to evaluate the effectiveness of interventions on perianal fistula activity in Crohn's disease using magnetic resonance imaging (MRI).¹

A modified VAI (mVAI) was introduced to improve measurement of clinical response and intra- and interrater reliability², but recent studies suggest that further optimization is needed.³

Aims & Methods: The Perianal Fistula Activity Index (PFAI) was developed as part of a proof of concept study conducted in patients with perianal fistulizing Crohn's disease that assessed clinical and radiologic efficacy of filgotinib (FIL) (DIVERGENCE 2; NCT03077412).⁴

At the patient level, the total PFAI comprises an Inflammation Sub-Score and Anatomy Sub-Score (see Table). The PFAI differentiates from prior scoring systems by identifying all fistula tracts and branches visible on MRI at baseline and conducting pairwise scoring after treatment, aiming to allow a more comprehensive assessment of disease, including overall inflammatory burden and providing greater sensitivity to change. Pelvic MRIs conducted at baseline and Week 24 were scored using all three indices by a blinded central reader to enable index comparison.

This trial was initiated prior to the publication of the MAGNIFI-CD activity index.⁵

Results: MRIs of patients receiving FIL 100 mg, FIL 200 mg, or placebo (PBO) were scored at baseline (N=57) and week 24 (N=31) (Table). At baseline, all indices were generally balanced across treatment groups with higher scores (greater disease severity) in the FIL 200 mg group. Greater decreases were observed at week 24 in the FIL 200 mg group using the PFAI (-5.1) than the other indices (VAI, -2.1; mVAI, -2.4). At week 24, greater decreases were observed in the PFAI inflammation sub-score (FIL 200 mg: PFAI -4.1, VAI -1.6, mVAI -1.8; FIL 100 mg: PFAI -1.7, VAI -1.3, mVAI -1.0; PBO: PFAI -0.5, VAI -1.0, mVAI 0.3) than the anatomy sub-score (FIL 200 mg: PFAI -1.0, VAI -0.5, mVAI -0.6; FIL 100 mg: PFAI -0.4, VAI -0.2, mVAI -0.2; PBO: PFAI 0.3, VAI 0.2, mVAI 0.3).

Conclusion: In this small phase 2 study, the Perianal Fistulizing Activity Index was shown to enable a higher dynamic range and may be more sensitive to change in comparison to the modified Van Assche Index. More pronounced decreases in the PFAI were observed in the FIL 200 mg group compared to placebo. Use of the PFAI Inflammation subscore may be a useful tool in assessing the effectiveness of interventions on perianal fistulas in Crohn's disease. Additional studies evaluating the Perianal Fistulizing Activity Index are warranted.

Contact E-Mail Address: ma.lopes@unesp.br

Introduction: Inflammatory Bowel Disease (IBD) is an inflammatory and chronic disease, as well as non-alcoholic fatty liver disease (NAFLD). The pathogenesis of both diseases is related to gut dysbiosis and systemic inflammation, therefore, current literature has shown that IBD patients are at high risk for NAFLD. In addition, it has been observed an increase in NAFLD's incidence in the general population, however, there are few studies evaluating NAFLD's prevalence in IBD patients. This study aimed to evaluate prevalence of NAFLD and identify the clinical factors associated with it in IBD patients.

Aims & Methods: This cross-sectional, descriptive, observational study included 104 IBD patients from an IBD public outpatient in Brazil. Laboratory evaluation and clinical data were collected. The presence of NAFLD was evaluated by ultrasonography. The exclusion criteria were as follows: preexisting liver disease, history of alcohol intake >20g/day for women and >30g/day for men, and glucocorticoids treatment >20mg/day. Statistical analysis: descriptive statistics and association tests.

Results: In total, 104 patients were included, of which 50 (48.08%) were CD's patients and 54 (51.92%) UC patients. Median age was 44.83±14.31 years and the time from diagnosis was 11.41±7.82 years. Mostly, the patients were women (62.5%) and Caucasian (72.12%). Regarding the char-

acteristics of the diseases, 42% of patients with CD have ileocolonic involvement, 42% penetrating disease and 56% perianal involvement; also, most UC patients have pancolitis (62.96%). Mostly, the patients were in clinical (59.62%) and endoscopic (50.08%) remission.

Regarding medical treatment, the most used drugs were biological therapy (57.63%) and azathioprine (47.46%) in CD, and mesalamine (31.12%), azathioprine (46.67%) and biological therapy (51.11%) in UC. NAFLD group consists of 45 (43.27%) patients: 37.78% had mild steatosis; 48.89% moderate and 13.33% intense. Development of NAFLD was associated with body mass index (BMI) and laboratory biomarkers (Table 1).

	No NAFLD (n=59)	NAFLD (n=45)	P
Body Mass Index (BMI)	24.5±4.26	29.17±3.78	<0.0001
Hemoglobin	13.66±1.32 g/dL	14.48±1.62 g/dL	0.0057
AST	24.55±6.36 U/L	28.12±13.14 U/L	0.0295
ALT	18.17±7.55 U/L	27.67±16.54 U/L	<0.0001
Ferritin	84.91±143.06 ng/mL	185.57±333.95 ng/mL	0.0189
Fasting glucose	86.30±9.25 mg/dL	96.85±21.07 mg/dL	0.0054
Triglycerides	120.05±71.37 mg/dL	174.97±118.81 mg/dL	0.0016
HDL cholesterol	58.07±15.01 mg/dL	47.81±16.11 mg/dL	0.0169
Insulin	8.41±5.13 µIU/mL	13.37±8.53 µIU/mL	0.0011

Table 1. Comparison of clinical and laboratory biomarkers among IBD patients with and without NAFLD.

When comparing patients with the presence or absence of NAFLD, there was no difference between the groups regarding time since diagnosis (p=0.3595), previous surgery (p=0.5934), clinical activity (p=0.6361), endoscopic activity (p=0.0576) or medical treatment. However, in the NAFLD group, mostly, the patients were men (51.11% vs 48.89, p=0.0123) and the median age was higher (48.42±12.87 vs 42.03±14.84, p=0.0239).

Conclusion: We observed a high prevalence of NAFLD in patients with IBD. NAFLD group had higher levels of BMI, AST, ALT, fasting glucose and blood insulin, which are also associated with metabolic syndrome. Early diagnosis and appropriate nutritional orientation are necessary to prevent NAFLD related complications.

E-CONSULTS IN INFLAMMATORY BOWEL DISEASE (TELEIBD): FACILITATING COMMUNICATION BETWEEN SPECIALIZED AND PRIMARY CARE

C. Pradera Cibreiro¹, M. Ramos Alonso¹, M. Fernández López¹, G. Molina Arriero¹, M.V. Mauriz Barreiro¹, V. Ollero Pena¹, A. Echarr Piudo¹

¹Centro Hospitalario Universitario de Ferrol, Gastroenterology, Ferrol, Spain

Contact E-Mail Address: marta.ramos.alonso@sergas.es

Introduction: According to current literature, incidence and prevalence of Inflammatory bowel disease (IBD) are increasing in the last years ^{1,2}.

Although, inflammatory bowel disease is unusual in primary health care, besides its symptomatology resembles to other pathologies such functional disorders. Taken together with workload and derivation time to specialist medical staff, can be a determining factor in delays in diagnosis and medical complications ³.

The electronic consultations allows the specialist medical staff a quickly and telematic evaluation due to the analytical and clinical results from primary care (PC) ^{4,5}.

Aims & Methods: This is a retrospective study that evaluates the results of TELEII (telematic circuit care) in patients with high diagnostic suspicion of IBD between PC and IBD Unit of our health area from its implementation in August 2019 to October 2020.

The number of telematic consultations, average time to resolution, adaptation to referral criteria, complementary tests requested and diagnostic confirmation were evaluated.

TELEII establishes the issuance of a telematic consultation through the electronic clinical history when a patient meet previously established criteria.

Specialized IBD physician who evaluate the case, can advise a diagnostic or therapeutic attitude either by electronic form or face-to-face with the patient.

Results: A total number of 77 care consultations from 77 patients (58,4% females) have been made. The average age were 49,2 years and the average reponse time were 7,5 days.

After teleconsultation, 46 patients (59.7%) were not requested medical test. Lower gastrointestinal endoscopy (LGE) was performed in 25 patients, blood and faecal calprotectin testing in 7 patients, magnetic resonance (MR) or computer tomographic (CT) enterography in 6 patients.

Taking to account the criteria for referral to a specialist, a total of 15 patients (19,5%) fully met the criteria, 13 patients (16,9%) partially met the criteria and 49 patients (63,6%) did not meet it. The main reason for not meeting the criteria were the inadequate use of TELEII (53,1%).

Of the 25 LGE requested, 3 were suggestive of Ulcerative Colitis (UC) and 1 of Crohn's Disease (CD). Diagnosis of CD was confirmed in 2 patients, using MR or CT enterography.

Diagnoses were reached in 4 patients, 3 of the group that met referral criteria (20%) and 1 of the group that partially met it (7.7%).

The diagnosis was not achieved in any patient who did not partially and/or fully meet the referral criteria.

Conclusion: E-consult allows a faster and easier contact between primary care and IBD specialists. TELEIBD can be a useful tool to reduce the time between suspicion of IBD and its diagnosis and beginning of treatment. Training primary care physicians in the referral criteria of the pathway is essential to improve the functioning of the circuit.

BOWEL URGENCY COMMUNICATION GAP BETWEEN HEALTH CARE PROFESSIONALS AND PATIENTS WITH ULCERATIVE COLITIS IN THE US AND EUROPE: COMMUNICATING NEEDS AND FEATURES OF IBD EXPERIENCES (CONFIDE) SURVEY

S. Travis¹, A. Potts Bleakman², D.T. Rubin³, M.C. Dubinsky⁴, R. Panaccione⁵, T. Hibi⁶, T. Hunter Giblee², C. Kayhan², E.J. Flynn², C. Sapin², C. Atkinson⁷, S. Schreiber⁸

Introduction: Moderate to severe ulcerative colitis (UC) is associated with substantial quality of life burdens¹. The Communicating Needs and Features of IBD Experiences (CONFIDE) study aims to increase understanding of the impact of symptoms on the lives of patients with moderate to severe UC and Crohn's disease and to investigate gaps in communication with healthcare professionals (HCPs) in the United States (US), Europe (EUR), and Japan. This report focuses on patients with moderate to severe UC and HCPs from the US and EUR.

Aims & Methods: Online, quantitative, cross-sectional surveys of patients with UC and HCPs were conducted in the US and EUR (France, Germany, Italy, Spain, and UK). HCP surveys included physicians and non-physician HCPs responsible for making prescribing decisions. Moderate to severe UC was defined based on treatment, steroid use, and/or hospitalization history. Data collected included perspectives on the experience of patients with UC.

Results: A total of 200 US (62% male, mean age 40.4 years) and 556 EUR patients (57% male, mean age 38.9 years), and 200 US and 503 EUR HCPs completed the survey. According to US and EUR patients, the top 3 symptoms currently (past month) experienced were diarrhoea (63% and 50%), bowel urgency (47% and 30%) and increased stool frequency (39% and 30%). Blood in stool was reported as currently experienced by 27% and 24% of US and EUR patients, respectively. Among patients currently experiencing bowel urgency, 47% of US and 27% of EUR patients discuss this symptom at every appointment. Among those who do not discuss bowel urgency at every appointment, 74% and 75% of US and EUR patients would like to discuss this symptom more frequently with their HCP. A total of 30% and 43% of US and EUR patients that ever experienced bowel ur-

gency were not comfortable reporting it to their HCP, with 62% and 58% of these US and EUR patients feeling embarrassed talking about this symptom (Table). HCPs in both the US and EUR ranked diarrhoea (74% and 65%), blood in stool (69% and 65%) and increased stool frequency (38% and 34%) as the top 3 symptoms most reported by patients. According to US and EUR HCPs, the top 4 symptoms proactively discussed in routine appointments were blood in stool (93% and 94%), diarrhoea (90% and 91%), increased stool frequency (82% and 82%) and bowel urgency (76% and 82%). Among HCPs who did not proactively discuss bowel urgency, 47% of US and 40% of EUR HCPs expect patients to bring this up if it is an issue.

	I feel embarrassed talking about it	I feel like my HCP doesn't understand it	I don't feel like my HCP can help me with it	There isn't enough time in our appointments to talk about it	I feel like I'm wasting my HCP's time	I don't know how to explain it to my HCP	I don't know how to explain it to my HCP	My HCP makes me feel nervous/intimidated	Other
US patients, n=37	62%	5%	22%	22%	22%	11%	11%	5%	11%
EUR patients, n=107	58%	13%	22%	21%	14%	20%	11%	8%	4%

Table. Reasons for patients not feeling comfortable discussing bowel urgency with their HCPs
(Patients with UC that reported ever experiencing bowel urgency related to their UC and who were not comfortable reporting bowel urgency to their HCP)

Conclusion: Communication characteristics and gaps were similar between US and EUR patients and HCPs. Bowel urgency is the second-most reported symptom by patients with moderate to severe UC. However, this symptom is not among the HCP-perceived top 3 most reported symptoms. Although a substantial proportion of patients reported a desire to discuss bowel urgency more frequently with their HCP, some patients reported feeling embarrassed talking about it. Many HCPs who do not proactively discuss this symptom expect patients to bring this up. A communication gap was identified and highlights the under-appreciation of bowel urgency as an important symptom of UC^{2,3}.

Introduction: Moderate to severe ulcerative colitis (UC) exerts a significant burden on patients' lives¹. Patients with UC report that bowel urgency has a substantial negative impact on their quality of life and psychosocial functioning, however, this symptom is missing from most disease activity indices².

The Communicating Needs and Features of IBD Experiences (CONFIDE) study aims to increase understanding of the impact of symptoms, including bowel urgency, on the lives of patients with moderate to severe UC and Crohn's disease in the United States (US), Europe (EUR), and Japan. These data focus on patients with moderate to severe UC in the US and EUR.

Aims & Methods: Online, quantitative, cross-sectional surveys of patients with moderate to severe UC were conducted in the US and EUR (France, Germany, Italy, Spain, and UK). Data included patient perspectives on their UC symptoms and the impact on their daily lives. Moderate to severe UC was defined based on treatment, steroid use, and/or hospitalization history. Descriptive statistics summarise the data.

Results: A total of 200 US patients (62% male, mean age 40.4 years) and 556 EUR patients (57% male, mean age 38.9 years) completed the survey, with 77% and 54% currently receiving advanced therapies (biologic or novel oral therapy), respectively.

The top 3 symptoms currently (past month) experienced by US and EUR patients were diarrhoea (63% and 50%), bowel urgency (47% and 30%) and increased stool frequency (39% and 30%). Among patients who have ever experienced bowel urgency, 93% of US and 89% of EUR patients reported doing so at least once a month over the past 3 months.

Among patients who have ever experienced urge incontinence (bowel urgency-related accidents), 86% of US and 71% of EUR patients reported doing so at least once a month over the past 3 months (Table).

A total of 69% and 65% of all US and EUR patients with UC, respectively, reported wearing a diaper/pad/protection at least once a month in the past 3 months due to fear/anticipation of urge incontinence.

For patients receiving advanced therapies, similar patterns were observed for frequency of bowel urgency and urge incontinence as well as wearing diaper/pad/protection due to fear/anticipation of urge incontinence.

Among both US and EUR patients, the most common UC-related reasons for declining participation in social events were bowel urgency (43% and 30%) and fear of urge incontinence (40% and 32%).

Similarly, the most common reasons for declining participation in work/school and sports/physical exercise were bowel urgency and fear of urge incontinence.

Conclusion: Bowel urgency, which was the second-most frequently reported symptom, has an extensive impact on the lives of patients with moderate to severe UC. In this younger patient population, including patients receiving advanced therapies, almost two thirds of US and EUR

patients reported wearing diapers/pads/protection at least once a month in the past 3 months due to fear/anticipation of urge incontinence. Even if patients were not currently experiencing bowel urgency, the persistent impact of UC was demonstrated by the use of diaper/pads/protection. Both US and EUR patients reported bowel urgency and fear of urge incontinence as the top reasons for declining participation in social events, work/school, and sports/physical exercise.

	Frequency of bowel urgency (all patients who have ever experienced bowel urgency)		Frequency of urge incontinence (all patients who have ever experienced urge incontinence)		Frequency of diaper/pad/other protection use due to fear/anticipation of urge incontinence (all patients)	
	US patients (n=123)	EUR patients (n=250)	US patients (n=90)	EUR patients (n=175)	US patients (n=200)	EUR patients (n=556)
At least once a month, n (%)	114 (93)	222 (89)	77 (86)	124 (71)	137 (69)	361 (65)
Less frequently than monthly, n (%)	7 (6)	19 (8)	5 (6)	25 (14)	15 (8)	60 (11)
Not in the last three months, n (%)	2 (2)	9 (4)	8 (9)	26 (15)	48 (24)	135 (24)

* Percentages are rounded and as a result totals may not add up to 100%

Table. Frequency of bowel urgency, urge incontinence and diaper/pad/other protection use over the past 3 months*

QUALITY CRITERIA IN SCREENING COLONOSCOPY FOR COLORECTAL CANCER IN INFLAMMATORY BOWEL DISEASE

E. Afecto¹, A. Ponte¹, J.P. Laranjeira Correia¹, M.M. Estevinho¹, S. Sousa-Fernandes¹, J.C. Silva¹, T. Freitas¹

¹*Centro Hospitalar de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal*

Contact E-Mail Address: joaopaulo_laranjeira@hotmail.com

Introduction: Extensive and long-lasting inflammatory bowel disease (IBD) carries an increased risk of colorectal cancer (CRC). Despite this, CRC screening in IBD is not uniform, in part due to the absence of validated quality criteria. In this sense, a group of experts reviewed the evidence and proposed quality criteria in this context. This work intended to audit the fulfillment of the proposed quality criteria in the IBD population of a tertiary center in Portugal.

Aims & Methods: We retrospectively included patients with IBD who underwent CRC screening colonoscopy. Pre-, intra- and post-procedure criteria were evaluated, namely surveillance interval, inflammatory activity, information provided, informed consent, use of polyethylene glycol and liquid diet the day before the procedure, sedation, cecal/ileal intubation rate, adenoma detection rate [ADR], chromoendoscopy, validated scores, directed/random biopsies, withdrawal time, Boston Bowel Preparation scale, photo-documentation, follow-up instructions and identified lesions, visualization and/or resection technique).

Results: Included 84 patients, 70.2% men, mean age 55.2 years, of which 67.9% had ulcerative colitis. The majority (72.6%) underwent the exam at the appropriate interval. Of the total, 9.5% had inadequate preparation and 7.1% had significant inflammatory activity. All procedures were performed under sedation, with a cecal intubation rate of 96.4%. Chromoendoscopy was performed in 89.3%, with an ADR of 21.3%. Withdrawal time was not evaluated. The lesions identified were evaluated by the Paris classification in 31.4% and the resection technique was always described.

In the report, inflammation was evaluated using validated scores (70.4%), photodocumentation was performed (97.5%), number/location of biopsies were described (93.8%), complications were described (0 cases) and follow-up instructions were given (25 %).

Conclusion: Although the results are satisfactory, some points such as the systematic use of the Paris classification and inflammatory activity scores still need to be improved. Follow-up instructions are provided by the treating physician and as such are not provided systematically in our reports. Audits are a vital tool for improving quality in endoscopy and its implementation should be widespread.

SARCOPENIA AS A PREDICTIVE MARKER IN INFLAMMATORY BOWEL DISEASE

E. Afecto¹, S. Sousa-Fernandes¹, C. Rocha¹, J.P. Laranjeira Correia¹, M.M. Estevinho¹, A. Ponte¹, T. Freitas¹

¹Centro Hospitalar de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal

Contact E-Mail Address: joapaulo_laranjeira@hotmail.com

Introduction: Sarcopenia can occur in chronic conditions such as Crohn's Disease (CD) and has been associated with worse clinical and surgical outcomes. In this study, the authors aim to assess the prevalence of sarcopenia in CD patients and determine its prognostic value.

Aims & Methods: Patients with CD undergoing intestinal ultrasound (IUS) in our center were prospectively included. Patients with other potential causes for sarcopenia were excluded. Demographic, clinical and ultrasound data were collected. Anthropometric data were recorded: body mass index, thickness of the femoral quadriceps (by ultrasound) and the time required to transverse 4 meters. Sarcopenia was defined as a composite outcome of decreased muscle mass (quadriceps thickness <34mm in women or <36mm in men) and function (abnormal if >3.2s to transverse 4m). Patients were evaluated for symptoms (Harvey-Bradshaw score - HBI) and complications (abscess/phlegmon, fistula, stenosis, hospitalization, surgery or therapeutic intensification) at 0/3/6 months.

Results: A total of 52 patients were included (50% men), mean age 46.3 years, most with ileal disease (94.2%, L1 or L3 from Montreal classification). Almost half (48.1%) of patients had low muscle mass and 11.5% had sarcopenia. The majority (54%) had inactive IUS disease and a mean initial HBI of 2.6 (75% in clinical remission). At follow-up, 10 patients (18.5%) had an event at 3 months and 4 (7.4%) at 6 months. Muscle thickness at baseline correlates with clinical response at 3 months ($p=0.007$) and inversely with baseline HBI ($p=0.008$, $r=2.75$). Sarcopenia is associated with reduced clinical response at 3 months ($p=0.02$).

Conclusion: The assessment of muscle mass by ultrasound and function is simple to perform in an outpatient setting and allows for the identification of patients who probably need more intensive therapeutic interventions and more frequent monitoring.

Disclosure: Nothing to disclose.

Introduction: Video capsule endoscopy (ECV) has marked a turning point in the diagnostic imaging of small bowel lesions in the last two decades. It is a safe and well-tolerated diagnostic test for children but most studies of ECV apply to adults. The literature available today on the clinical use of ECV in the pediatric population is very limited.

Aims & Methods: The aim is to review the indications for ECV in the paediatric population and to analyse the therapeutic impact of its outcomes. Single-centre descriptive and retrospective study of a cohort of patients under 18 years of age who underwent VCE in a tertiary hospital from March

2017 to January 2022. Demographic, anthropometric, clinical and analytical data were collected. The study was considered complete in those in whom the arrival of ECV to the cecum was objectified. The statistical study was performed using SPSSv.28 software.

Results: Sixty patients, 53% female, aged 10.7 ± 4.37 years were included. The main indication for ECV was inflammatory bowel disease (IBD) in 34 (56.7%) patients, followed by gastrointestinal bleeding of unknown origin in 8 (13.3%). In 9 patients (15%) the self-degrading capsule was previously administered, with VCE being contraindicated in 3 (5%) due to delayed expulsion and/or deformation of the capsule.

Most children underwent liquid diet preparation the previous day (95%) and the study was complete in 45 (75%) of cases, with a higher proportion of complete studies in children with liquid diet preparation vs. those taking laxatives or a combination of laxatives and liquid diet ($p=0.017$). In 30 patients (50%) ECV was swallowed voluntarily, with differences according to age: oral ingestion was more frequent in older children (13.34 ± 3.18 years), while placement by upper endoscopy (EDA) was more frequent in younger children (7 ± 2.87 years) ($p<0.001$).

Among the 57 patients studied with ECV, 5 (8.8%) had complications: capsule retention in 3 (5.3%) and minor bleeding in 2 (3.5%) due to traumatic injury related to EDA placement. A lower proportion of complications was observed in the absence of pathological lesions in the small intestine ($p<0.001$). In 9 (15%) of the children the performance of ECV changed the diagnosis, supported by other complementary tests in all but one (88.8%). In relation to treatment, in 13 (20%) patients treatment was changed, with ECV being the only test that conditioned such a change in 5 (38.7%).

Conclusion: In our centre, VCE placement by UGE was significantly more frequent in the younger patients. Also, those who received an exclusively liquid diet the day before the VCE were more likely to have a complete exploration. Furthermore, ECV has an impact on the diagnosis and therapeutic approach to paediatric patients with digestive pathology and, although the rate of complications is higher than that described in adults, it is a safe and non-invasive technique.

POSSIBILITIES FOR DIFFERENTIAL DIAGNOSIS OF NOSOLOGICAL FORMS OF INFLAMMATORY BOWEL DISEASE USING ERYTHROCYTE AND BLOOD SERUM MEMBRANE FATTY ACIDS

M.V. Kruchinina^{1,2}, I.O. Svetlova^{1,2}, N.V. Abaltusova¹, A.V. Borisova¹, M.V. Shashkov³, A.S. Sokolova⁴, I.N. Yakovina⁵, A.A. Shestov⁶, A.A. Gromov¹

Introduction: The differential diagnosis of nosological forms in patients with inflammatory bowel diseases (IBD) is now crucial for the individual management of the patient, as each clinical case involves specific therapeutic strategies and prognoses [1].

Nevertheless, non-classical forms of both ulcerative colitis (UC) and Crohn's disease (CD) still pose a diagnostic problem, since there is no single "gold standard" for the diagnosis of IBD [1].

Therefore, between 5% and 15% of cases of IBD do not meet the strict criteria for either UC or CD [2], and in 14% of patients diagnosed with both UC and CD, the diagnosis changes over time [3].

Aims & Methods: The purpose of this research: To study erythrocyte (Er) membrane fatty acids' (FA) and blood serum (BS) FAs' levels in patients with different nosological forms of IBD (UC, CD, unclassified colitis (UCC) for possible use in differential diagnosis as biomarkers.

Materials and methods: 110 patients (average age 37.7±12.1 years) with IBD and 53 subjects of the comparison group (43.3±11.7 years) have been examined. The group of patients with IBD included patients with UC – 50 people, with CD – 41 people and 19 patients with UCC. In 42 patients (84%) with UC, 34 patients with CD (82.9%) and 11 people with UCC (57.9%), an exacerbation of the disease has been detected. The study of the composition of FAs of Er membranes and BS has been performed using a gas chromatography-mass spectrometry (GC/MS) system based on the Agilent 7000B Triple Quadrupole (USA).

Results: A study of FA levels in groups with different nosological forms of IBD using complex statistical analysis, including machine learning techniques, has made it possible to create diagnostic models that differentiate between CD, UC and UCC in the acute stage with a high degree of accuracy. The most significant for distinguishing active UC from exacerbation of CD were serum levels of C18:1;t9 (p=0.0006); C22:4n-6 (p=0.004); C20:2n-6 (p=0.009); omega-3/omega-6 PUFA ratio (p=0.02); C20:5n-3 (p=0.03) acids; the sum of two omega-3 PUFAs – C20:5n-3 and C22:6n-3 (p=0.03) acids, as well as the content of C12:0 of Er (p=0.04) (AUC 0.89; sensitivity 0.91; specificity 0.89; diagnostic accuracy 0.91). The revealed differences may be due to a greater violation of the regulation of PUFAs' desaturation in CD than in UC [4], differing profiles of significant cytokines, adiponectins in different nosological forms of IBD, which is associated with FAs' levels of serum and erythrocytes [5, 6].

The following BS FAs have been found to be relevant in distinguishing active UC from the acute stage of UCC: C18:3n-3; saturated (pentadecanoic, palmitic, stearic, arachidic); monounsaturated (C16:1;9, C18:1;9); omega-6 PUFA (C16:2, 20:4) (p=0.00000011-0.033) (AUC 0.995; sens. 0.98; spec.

0.96; diagnostic accuracy 0.97) An increase in the level of saturated FAs in UC is associated with a macrophage inflammation and lipotoxicity [7].

The levels of the following FAs were the most significant for differentiating patients with active CD from exacerbations of UCC: C18:3n-3; C16:1;9; C18:1;9; sum of SFAs; sum of USFAs; C18:0; sum of MUFAs; SFAs/USFAs ratio; SFAs/PUFA; C18:2n-6; sum of omega-6 PUFAs; C12:0; C20:0 (p=0.000000017-0.03) (AUC 0.914; sens. 0.90; spec. 0.87; diagnostic accuracy 0.91).

The significance of different lists of FAs for distinguishing UCC from UC and CD indirectly reflects the heterogeneity of patients with unclassified colitis.

Conclusion: The proposed approach seems promising for the purposes of differential diagnosis of nosological forms of IBD.

Introduction: Delays in diagnosis could be patient-related and health-system related. It has been reported that such delays increase overall complications in Inflammatory Bowel Diseases (IBD). The aim of our study was to report on the impact of delays on IBD-related adverse outcomes (AOs), as most hospitals currently face challenges with long waiting lists in the post-Covid-19 era.

Aims & Methods: New patients referred for suspected IBD to a single tertiary care centre between Jan 2013 to Dec 2017 were identified using EMR. For purposes of the study, a cut-off time was set by investigators for each delay-type based on best average hospital waiting times. The reasons for delays in patient journey until start of treatment and data on pre-defined AOs (steroid & other rescue therapies, hospitalisations, surgery) were recorded for each patient until end of June 2021.

The data were analysed using multiple Pearson correlations and Cox proportional Hazard model to determine whether there is a difference in survival without AOs between patients with and without a delay.

Results: Total of 105 patients were identified using stringent criteria (M=58; median age = 32y) with a long median follow-up of 55 months. The most frequent presenting complaints were abdominal pain (44, 41.9%), loose stools (40, 38.1%), bloody diarrhoea (37, 35.2%) and bleeding per rectum (33, 31.4%) and only 16% declared a family history. 65, 27 and 13 patients had final diagnosis of Ulcerative colitis, Crohn's disease and Unclassified colitis respectively, and analysed collectively.

In our cohort, the longest delay-types noted were - patients seeking medical attention (median= 4 months; range 1 to 84 months), arranging gastroenterology clinic review after referral from primary care (median=5 weeks; range 1 to 30 weeks), and waiting for index endoscopy (median=3 weeks; 1 to 36 weeks).

Patient stratification based on delay-type, using specific cut-off times for each showed a statistically significant difference in survival without AOs for all (when comparing delay v/s no delay).

- delay in seeking medical attention (cut-off=1m; $p=0.004$)
- delay in GP referral to specialty review (cut-off=1w; $p=0.048$)
- delay in index endoscopy (cut-off= 4w; $p=0.01$)
- delay in starting treatment (cut-off= 4w; $p=0.03$)

Conclusion:

- Several bottlenecks of delays increase AOs in IBD over the follow-up period.
- A delay as short as a week, between GP referral to specialty review, is significant in determining AOs; this has implications on specialist IBD centres particularly in the post-Covid period.

- Endoscopy units should prioritise suspected IBD patients to reduce AOs, which is likely to have implications on service delivery and planning.
- Long delays observed in patients seeking medical attention highlights the need for both primary and secondary care to undertake patient education in the community.

Introduction: Microscopic colitis (MC), is a chronic inflammatory bowel disease characterized by watery diarrhea, which substantially decreases the patient's quality of life.

Moreover, low bone density (LBD) has been associated with the disease. Furthermore, many risk factors contribute to the random coincidence of the two conditions.

Aims & Methods: Our primary aim is to assess if MC is a risk factor for LBD. We also estimated the proportions of bone mineral changes in the MC population. Our protocol was prospectively registered in PROSPERO (CRD42021283392).

We directed our literature search in five databases from inception to the 16th of October, 2021 (Pubmed, Embase, Cochrane, Scopus, Web of Science). All articles were eligible which describe histologically confirmed MC patients. We used the random-effect model to calculate pooled odds ratios (ORs) and pooled event rates with 95% confidence intervals (CI).

We assessed the risk of bias with the aid of the QUIPS tool for the prognostic question, and we applied the JBI Critical Appraisal Checklist for Prevalence Studies in the proportional measurements. To ascertain the quality of evidence for our outcomes we followed the recommendations of the GRADE working group.

Results: The systematic search yielded a total of 3046 articles. Four articles were found eligible for our quantitative synthesis. Three of them used age- and sex-matched controls to evaluate the occurrence of LBD among MC patients. We analyzed 111 MC patients with 67 LBD cases in comparison to 265 controls with 110 LBD cases. The odds for having LBD was threefold higher (OR=2.96, CI: 1.15–7.59) in the presence of MC.

The rate investigation results showed that from 276, 182 and 182 MC patients a total of 189, 92 and 20 patients had LBD, osteopenia and osteoporosis, respectively. The proportion of LBD was 0.68 (CI: 0.56–0.78), osteopenia was 0.51 (CI: 0.43–0.58) and osteoporosis was 0.11 (CI: 0.07–0.16) among the MC patients.

Most of the studies carried a high risk of bias due to the low number of study participants, while the certainty of the evidence was very low owing to the small sample sizes and because of the use of a surrogate outcome, measuring the bone mineral density.

Conclusion: LBD is strongly associated with MC, and the appearance of LBD is tripled in the presence of MC. There is a crucial need for further prospective studies with high patient numbers and long follow-up periods on this topic.

Disclosure: Nothing to disclose.

Contact E-Mail Address: dragasevicsanja@gmail.com

Introduction: Inflammatory bowel disease (IBD) is characterized by a chronic inflammatory process, which includes Crohn's disease (CD) and ulcerative colitis (UC). Non-Alcoholic Fatty Liver Disease (NAFLD) occurs in up to 40% of patients with CD and UC with the accumulation of fat in hepatocytes that affects more than 5% of the liver parenchyma. Due to the rapidly increasing prevalence of IBD, there is a tendency for NAFLD detection at the earliest period of development despite the fact that often appears without symptoms and is frequently misdiagnosed.

Although abdominal ultrasonography is an initial non-invasive diagnostic method, in order to make it faster and easier to diagnose, Hepatic Steatosis Index (HSI) and NAFLD Liver Fat Score (NAFLD-LFS) are used in clinical practice.

Aims & Methods: The aim of the study was to assess the prevalence of NAFLD using non-invasive scores in patients with newly diagnosed IBD. The study included 110 patients with CD and 113 with UC. The presence of NAFLD was assessed using two scores HSI and NAFLD-LFS. Statistical analysis was performed in the software program SPSS 21.0 (IBM SPSS Statistics, Chicago, USA).

Results: According to HSI values, the diagnosis of NAFLD was marked as highly-suspicious in 30.1% of UC patients and 37.3% of CD patients. According to NAFLD-LFS values, NAFLD is highly-suspicious in 51.3% of UC patients and in 57.3% of CB patients. The results showed no statistically significant difference in the frequency of NAFLD morbidity between CD and UC patients. For HSI $p=0.2975$, and for NAFLD-LFS $p=0.3052$.

Conclusion: Non-invasive NAFLD scores have proven to be fast, simple, and easy to apply in clinical practice. They could potentially be considered as a screening method for diagnosis of NAFLD in IBD patients and could influence further therapy modalities.

Introduction: Tryptophan (Trp) metabolism is altered in inflammatory bowel disease (IBD), with an increased demand for Trp via the kynurenine pathway. Serum Trp levels negatively correlate with disease activity in ulcerative colitis and Crohn's disease patients, suggesting that altered Trp metabolism may indicate the degree of chronic inflammation.

Whether increased Trp degradation is specific to IBD or reveals a generalized pattern among chronic inflammatory diseases (CIDs) is unknown.

Aims & Methods: We used several clinical cohorts to assess the association of Trp metabolism with CIDs.

Cohort #1: Serum Trp measurement in a multi-observation, cross-sectional cohort that includes patients diagnosed with CIDs of the gastrointestinal tract (IBD), musculoskeletal system (rheumatoid diseases, RD), and skin ($n=1410$ CID; 291 healthy controls, $n=28,849$ observations). Serum Trp measurement was performed within clinical routine laboratory diagnostics.

Cohort #2: Targeted serum metabolomics on Trp and its derivatives in $n=267$ CID patients and $n=200$ healthy controls.

Cohort #3: Targeted serum metabolomics in a longitudinal therapy response cohort, $n=133$ CID patients (IBD, $n=88$; RD, $n=36$, skin, $n=15$; 15 biological therapies).

We performed serum metabolomics at baseline, week 2, 6, and 14. Therapy responders were identified as patients who adhered to their respective biologic therapy for 12 months following initial administration. All targeted metabolomics assays were performed by LC-MS/MS using the MxP Quant 500 kit (Biocrates).

Results: Serum Trp levels were decreased in the cross-sectional cohorts across IBD and all musculoskeletal disease, yet slightly higher in serum of psoriasis patients relative to healthy controls. Trp levels correlated with disease activity in IBD patients and RD patients. Intriguingly, Trp levels appear to destabilize with disease progression, as demonstrated by the increase in Trp variability over time with therapy escalation to biologic therapy.

We assess the ratio of Trp/aromatic amino acids to normalize for dietary Trp intake, finding Trp to represent roughly one third of the aromatic amino acids in healthy controls (0.32 ± 0.03), with a significant reduction in this ratio across all CIDs tested.

Most strikingly, in our longitudinal cohort, this ratio increased over time in therapy adherers, but not non-adherers ($p = 0.0038$ and 0.39 , respectively), suggesting restoration of Trp metabolism occurs early in responders to biologic therapy – i.e., within the first 14 weeks upon therapy administration.

Conclusion: Tryptophan metabolism is perturbed across CIDs, suggesting that aberrant tryptophan metabolism is a universal feature underlying chronic inflammation. Further, early restoration of aberrant tryptophan metabolism only occurs in patients within 12-month therapy adherence indicating a unique pattern of metabolic healing that indicates thorough disease control in CID patients.

Introduction: The endoscopic Mayo score (MS) is the most frequent score used for the evaluation of inflammatory activity in Ulcerative Colitis (UC), varying from 0 to 3 points. Recently the DUBLIN score (DS) emerged, which varies from 0 to 9 points and results from the product of the MS and the disease extent, according to Montreal classification, E1-E3.

Aims & Methods: In this study we aimed to evaluate and compare the predictive ability of MS and DS for long term treatment failure. A retrospective and unicentric study was conducted, including patients with left-sided or extensive UC, asymptomatic and without the need for steroid therapy or therapy changes in the 6 months prior to undergoing total colonoscopy with calculation of MS and DS.

Treatment failure was evaluated, defined by the need for therapy changes and/or hospitalization because of disease exacerbation, over a follow-up period of a minimum of 24 months and a maximum of 84 months.

Results: A total of 204 patients were included, 104 (51%) females and with a mean age at diagnosis of 36.4 ± 12.7 years. In the initial evaluation, 48 (23.5%) were being treated with anti-TNF α medication. The mean values of MS were 1.0 ± 1.1 points and of DS were 2.2 ± 2.6 points.

During follow-up, 32 (15.7%) patients experienced treatment failure and patients initially treated with anti-TNF α medication had 2.3 times higher risk of treatment failure ($p=0.042$). MS values (AUC 0.809; $p<0.001$; with sensitivity of 0.938 and specificity of 0.529 for values equal or superior to 1) and DS values (AUC 0.789; $p<0.001$; with sensitivity of 0.844 and specificity of 0.581 for values equal or superior to 2) had good discriminative abilities in predicting treatment failure. There were no statistically significant differences in the discriminative ability between both scores ($p=0.340$).

Conclusion: MS and DS had good discriminative abilities in predicting treatment failure. However, the integration of the disease extent in the DS as a complement of MS in the evaluation of UC was not associated with a higher predictive ability of long term treatment failure.

Disclosure: Nothing to disclose.

Introduction: There is a need for non-invasive biomarkers to facilitate early and accurate diagnosis of Crohn's disease (CD). Here, we identified fecal microbial signatures in CD and examined their potential role as non-invasive biomarkers for CD.

Aims & Methods: We included 484 subjects (266 CD; 218 age- and sex-matched healthy controls) from three cohorts (two from Hong Kong and one from Australia). We performed shotgun metagenomic sequencing of stool samples and analyze bacterial composition.

We identified bacterial features associated with disease phenotype using Boruta algorithm. We used random forest algorithm for diagnostic model construction.

We further validated the performance of the model in three public datasets including 136 CD cases and 110 controls.

Results: Bacterial diversity and richness were significantly lower in CD than controls (all $P<0.01$). Principal Coordinates Analysis (PCoA) showed that the bacterial clusters in CD and controls were distinctly separated ($P<0.001$).

Compared with control samples, the genera *Firmicutes* was depleted while *Proteobacteria* and *Fusobacteriawere* enriched in CD samples. In a discovery cohort, we identified nine bacterial species that differentiated CD from controls with an area under the receiving-operator curve (AUC) of 0.90.

The discriminative ability of these nine bacterial markers was validated in an independent cohort of 300 subjects from Hong Kong and 120 subjects from Australia with AUCs of 0.76 and 0.81, respectively.

Ecological network analysis of these nine bacteria markers in three different cohorts showed co-occurring (positive) correlations among CD-depleted bacteria and co-excluding (negative) correlations among CD-enriched and CD-depleted bacteria in all three cohorts.

In our validation cohort utilizing metagenomic datasets from the United States, Netherlands, and Mainland China, our bacteria markers showed that CD can be distinguished from controls with AUCs of 0.892, 0.844 and 0.966, respectively.

Conclusion: We presented metagenomic profiling of CD fecal microbiomes across five populations and identified a universal microbial signature for CD diagnosis. This may serve as a non-invasive biomarker for early CD detection and monitoring.

ENDOSCOPIC FEATURES OF NON-IBD COLITIS

F. Pigò¹, H. Bertani¹, S. Mangiafico¹, G. Grande¹, S. Russo¹, S. Cocca¹, M. Lupo¹, R. Conigliaro¹

¹Azienda Ospedaliero Universitaria of Modena, Endoscopic Unit, Modena, Italy

Contact E-Mail Address: giuseppgrande1984@gmail.com

Introduction: The term non-IBD colitis refers to a heterogeneous group of inflammatory diseases of the colon which may be differentiated from Crohn's disease and Ulcerative Colitis by their clinical, endoscopic, and histological characteristics. Previous studies on the endoscopic aspect of non-IBD colitis are scarce, with incomplete clinical and histological information necessary for diagnosis.

Aims & Methods: The aim of this retrospective study was to describe the endoscopic appearance of non-IBD colitis in an out-patients cohort.

All cases of non-IBD colitis, in an outpatient base setting from 2018 to 2021, with a colonoscopy performed in the previous three months and complete clinical information, were enrolled. Diagnosis was based on following characteristics: age, sex, symptoms (onset, duration, severity), comorbidities, history of exposure to drugs during the three months preceding the consultation, smoking and alcohol habits, allergies, pathological familial history, laboratory evaluations, stool cultures, imaging, bowel preparation, colonoscopy findings, histologic findings, follow-up of at least six months.

The endoscopic appearance was described with various terms: hyperaemia/erythema (spots or coalescent areas of red mucosa), oedema (areas of swollen mucosa), erosions (small, shallow sores, often surrounded by a ring of red tissue, with irregular shape, like long, ragged marks), ulcers (breaks in the lining of the mucosa, small like aphthae or big with a star-shape or longitudinal), mucopurulent exudate strictly adherent to the underlying mucosa.

Results: 101 patients (63 males, age 54 years $\pm$ 19 SD) performed an outpatient colonoscopy with a final diagnosis of non-IBD colitis associated with drug-exposition in 54 cases, food allergies in 11 cases, recent or active gastrointestinal infections in 12 cases, ischemic colitis in 10 cases, segmental colitis associated diverticulosis (SCAD) in 8 cases, obstructed defecation syndrome in 4 cases and microscopic colitis in 2 cases. Drug exposition was associated with hyperaemia, erosions/ulcers in 88% of cases with involvement of right colon in 73% of cases. Recent infection was related with erosions in 60% of cases with distribution in the left colon and rectum in 88% of cases. Food allergies were associated with red spot areas/erosions in 67% of cases with involvement of all the colon. Ischemic colitis was associated with ulcers in 86% of cases located in the right or left colon. SCAD has a crescentic fold pattern (hyperemia/eodema) in 75% of cases, always in left colon. Hyperemia, erosions, and loss of vascularity were described in 90% of cases of faecal obstruction in the rectum. 2 cases of microscopic colitis presented with oedema, hyperemia in the whole colon.

Conclusion: In an out-patient cohort, drug- associated colitis is the most frequent cause of non-IBD colitis. In an appropriate clinical, laboratory and histological context, small lesions as red spot, hyperaemia and ero-

sions could be associated with drug expositions, recent infection, and food allergies. Ulcers of the colon are more frequent with ischemic colitis or drug exposition.

Introduction: Crohn's disease (CD) is an inflammatory bowel disease with chronic course and exacerbations. Diagnosis and follow-up are based on clinical activity, biomarkers, ileocolonoscopy and imaging techniques. Intestinal ultrasound (IUS) has been shown to have high sensitivity and specificity analyzing inflammatory activity in CD.

Aims & Methods: The aim of our study is to correlate IUS parameters with clinical activity and biomarkers in CD.

METHODS: Retrospective, observational, single-center study was designed. Adult patients with CD who underwent IUS between September 2020 and May 2021 were included. Exclusion criteria was exclusive colonic involvement. Examination was done by ultrasound machine (Hitachi Ascendus) with low frequency curved-array (1-5 MHz) and high-frequency linear-array (5-13 MHz) transducers.

Examination assessed bowel wall thickness, mesenteric fat hypertrophy, lymph nodes, hyperemia on color Doppler flow measured as Limberg index and length of affected segment (cm). Clinical activity score for CD was assessed by Harvey Bradshaw index (HBI). Biomarkers parameters studied were C-reactive protein (CRP) and faecal calprotectin (FC). Results are shown as percentages, median and interquartile range (IQR). Data were analysed using Spearman's correlation analysis.

Results:

		CRP	Faecal Calprotectin	Harvey Bradshaw Index
IUS parameters	Wall thickness	0.29 (0.12-0.44) *	0.35 (0.18-0.50) *	0.09 (-0.09-0.27)
	Limberg Index	0.38 (0.21-0.52) *	0.56 (0.42-0.67) *	0.11 (-0.06-0.29)
	Mesenteric fat hypertrophy	0.35 (0.18-0.50) *	0.43 (0.27-0.57) *	0.13 (-0.05-0.30)
	Lymph nodes	0.33 (0.16-0.48) *	0.43 (0.27-0.57) *	0.15 (-0.03-0.32)
	Length (cm)	0.27 (0.10-0.43) *	0.36 (0.22-0.53) *	-0.005 (-0.18-0.17)

CRP, C Reactive Protein. IUS, Intestinal Ultrasound
*p<0.05

Table 1.

121 patients were consecutively included (median age 45.6 years (IQR 33.4 – 59.6), 56.2% female). 78.5% had ileal disease and 21.5% ileocolonic involvement. At the time of IUS 17.4% of patients were not taking any maintenance treatment, 13.2% were on azathioprine, 48.8% on anti-TNF (61% adalimumab; 39% infliximab) and 8.3% on ustekinumab. 85.1% patients had HBI <6, 14.1% had moderate activity. Median CRP level was 0.334 mg/

dl (IQR 0.06-1.12), FC was 141 µg/g (IQR 35-386). Median wall thickening was 4.7 mm (range 4.1-5.6), 68.6% of patients had mesenteric fat hypertrophy and 73.55% had lymph nodes. Limberg index was 0 in 20.7%, 1 in 23.1%, 2 in 37.2% and 3 in 19% of patients. IUS determined treatment modification in 60.3% of cases: 19% started biological therapy, 15.7% changed biological target, 14.9% underwent intensification or reinduction of biological treatment, in 1.7%, treatment reduction was decided.

The Spearman's correlation between IUS parameters, clinical and biochemical markers is presented in Table 1. IUS parameters were significantly associated with faecal calprotectin and CRP level, specially Limberg Index and faecal calprotectin ($r=0.56$, $p<0.05$) and Limberg Index and CRP level ($r=0.38$, $p<0.05$). No correlation was observed between HBI and IUS parameters.

Conclusion: Through this study, significant correlation between IUS and biomarkers was observed in CD. IUS has been shown to be useful for monitoring CD activity in order to optimize patients treatment.

Disclosure: Nothing to disclose.

Introduction: Prior studies examining the effect of smoking on the risk of colitis-associated colorectal neoplasia (CRN) report conflicting results. Few studies evaluated the effect of smoking in a multivariable model and none investigated a dose-response-relationship.

We aimed to investigate the association between smoking, including possible dose-effects, and CRN in patients with inflammatory bowel disease (IBD).

Aims & Methods: We performed a prospective multicenter cohort study including adult patients with colonic IBD enrolled in a surveillance program between 2011 and 2021 (NCT01464151). The prospective follow-up period was five years. Data collection was completed until 07-2021 for all patients. The effects of smoking status (ever versus never) and pack-years at study entry on recurrent events of CRN (including indefinite, low-grade, and high-grade dysplasia and colorectal cancer) were evaluated by uni- and multivariable Prentice, Williams, and Peterson (PWP) total-time Cox proportional hazard models. In the multivariable model, adjustment for extensive disease, dysplasia prior to or at index (indefinite for dysplasia or low-grade dysplasia), primary sclerosing cholangitis, male sex, first-degree relative with colorectal cancer, and age (continuously) was performed. A PWP-total time Cox proportional hazards model assumes that the occurrence of a first event increases the likelihood of recurrent events,

the maximum number of evaluated recurrent events was three due to otherwise too few data. To account for left truncation, disease duration at study index was used as the timescale in our model.

Results: In total, for 501 of the included 576 patients at least one follow-up procedure was available (median follow-up 5 years). CRN occurred at least once during follow-up in 105 patients. Smoking status at baseline was ever smoking for 246 patients (49%), with a median number of pack-years of 9 (p25-p75 4-20, range 78). In univariable and adjusted analyses smoking status (ever versus never) was not associated with recurrent CRN risk (adjusted hazard ratio 0.97, 95% confidence interval 0.70-1.36). An increase in the number of pack-years was associated with an increased risk of recurrent CRN (adjusted hazard ratio per 10 pack-years 1.16, 95% confidence interval 1.02-1.31). Separate adjusted analyses per IBD type did not reveal differences (Table 1).

Variable	Total cohort (n=501)		UC or IBD-U (n=277)		CD (n=224)	
	HR (95% CI)	p	HR (95% CI)	p	HR (95% CI)	p
Univariable analyses						
Ever smoking (reference = never)	1.19 (0.88-1.61)	0.26	1.26 (0.84-1.90)	0.27	1.18 (0.69-2.01)	0.53
Pack-years (per 10 pack-year increase)	1.25 (1.11-1.42)	<0.05	1.23 (1.05-1.45)	<0.05	1.19 (0.96-1.49)	0.11
Adjusted analyses¹						
Ever smoking (reference = never)	0.97 (0.70-1.36)	0.88	0.99 (0.63-1.54)	0.96	0.80 (0.43-1.51)	0.48
Pack-years (per 10 pack-year increase)	1.16 (1.02-1.31)	0.27	1.09 (0.91-1.30)	0.36	1.05 (0.81-1.36)	0.73

¹: HR adjusted for extensive disease, first degree relative with colorectal cancer, primary sclerosing cholangitis, male sex, age (per year increase, restricted cubic spline with four knots), and prior or index CRN.
Abbreviations: CD=Crohn's disease; CI=confidence interval; CRN=colorectal neoplasia; HR=hazard ratio; IBD-U=inflammatory bowel disease-unclassified; n=number; UC=ulcerative colitis

Table 1: PWP-total time Cox proportional hazards model (timescale IBD disease duration)

Conclusion: This study suggests that an increase in pack-years is associated with a higher risk of recurrent CRN in patients with IBD after adjustment for confounders. No association was observed for smoking status. The suggestion of a dose-effect may be an extra motivation for patients to quit smoking.

Introduction: Sarcopenia is defined as depletion in lean muscle mass with loss of muscle strength and has been associated with poor prognosis in various diseases, including malignancies and chronic inflammatory diseases. As Crohn's disease (CD) is frequently associated with malnutrition and subsequent changes in body composition, sarcopenia has generated much interest in the last years.

Aims & Methods: Our aim was to investigate its role in predicting clinical and endoscopic outcomes in a cohort of Crohn's disease (CD) patients. All consecutive CD patients who started biological therapy between 2014 and 2020 and who had undergone abdominal magnetic resonance or computed tomography within 6 months from the beginning of the therapy were enrolled. Muscle mass was assessed through a simple and fast surrogate index (total psoas area index, TPAI), measured at the third lumbar level (L3).

Patients were grouped into sex-stratified quartiles, and patients in the lowest sex-stratified TPAI quartile were considered as being sarcopenic. Univariate and multivariate analyses were used to evaluate whether sarcopenia could predict steroid-free clinical remission (SFCR), endoscopic remission (ER), hospitalisation and surgery after twelve months of biological therapy.

Results: 358 patients were included. Sarcopenic patients were older (45.6±15.5 vs 39.2±14.6; p=0.001), with lower body mass index (22.2±4.0 vs 23.9±4.5; p=0.001), higher Charlson Comorbidity Index (1±1.3 vs 0.6±1.3; p=0.020), longer disease duration (12.8±10.1 vs 10.2±8.3; p=0.015) and higher age at diagnosis (32.7±13.5 vs 29.0±13.0; p=0.024) than non-sarcopenic patients.

After twelve months of biological therapy, sarcopenic patients had higher SES-CD (5.6±6.7 vs 2.8±4.9; p=0.008) and Rutgeerts score (3.2±1.2 vs 1.7±1.6; p=0.001), and consequently lower rates of endoscopic remission (23.5% vs 47.1%; p=0.014). Conversely, sarcopenia was not associated with SFCR (65.5% vs 70.4%; p=0.391), hospitalisation (7.8% vs 8.2%; p=0.897) and surgery (2.2% vs 6.7%; p=0.108).

After multivariate analysis, sarcopenia was identified as a predictor of lack of ER (Odds Ratio [OR]=2.77, confidence interval [CI] 1.1-7.1; p=0.033), as well as smoking (OR 2.63, CI 1.2-5.9; p=0.018) and perianal disease (OR 2.61, CI 1.2-5.7; p=0.017).

Conclusion: Sarcopenia represents a poor prognostic factor for endoscopic outcomes in CD patients who start a biological therapy, and its assessment may represent an additional tool to improve decision making. Smoking and perianal disease were also associated with poor endoscopic outcomes.

Disclosure: Nothing to disclose.

Introduction: Mucosal activity and disease extent are risk factors in ulcerative colitis (UC). Whereas mucosal activity is assessed both endoscopically and histologically, disease extent is classified by endoscopic findings.

Persistent histologic activity in endoscopically normal/quiescent mucosa is common, suggesting that endoscopic and histological distribution may not be the same and that remission status may depend on the number of biopsy sites.

Aims & Methods: To assess complete remission after 3 months of conventional treatment in new-diagnosed patients, to measure the effect of increasing number of biopsy sites on the remission rates, and to evaluate the predictive value of endoscopic and histologic activity and distribution at baseline.

Clinical, biochemical, colonoscopy, and histological data were collected at baseline (V0) and after 3 months (V3). Rates of *clinical remission* (Partial Mayo Score (PMS) ≤ 2), *mucosal healing* (Mayo Endoscopic Score (MES) ≤ 1), *histologic healing* (Nancy Histological Index (NHI) ≤ 1 in rectum, left colon and right colon), *deep remission* (clinical remission plus mucosal healing), and *complete remission* (deep remission plus histologic healing) were determined. The association between baseline variables and complete remission was evaluated by logistic regression.

Results: The study included 180 newly diagnosed patients, 51 diagnosed with proctitis, 60 with left-sided disease and 69 with pancolitis. Disease activity scores at V0, given as median and interquartile range (IQR), were as follows: PMS 5 (3-7), MES 2 (2-3), NHI 1 (0-2) in right colon, NHI 2 (0-3) in left colon, and NHI 2 (2-3) in rectum. PMS, MES and NHI all decreased significantly from V0 to V3 (p < 0.005).

Mucosal healing	Histologic healing	Patients (n)	PMS	FC (mg/kg)
Yes	Yes (all segments)	83	0 (0-1)	28.5 (18-83)
	No	50	1 (0-3)	79 (27.5-387)
	Rectal healing only	27 of 50	1 (0-3)	158 (38.5-437)
No	Yes (all segments)	4	0.5 (0-2)	227 (65-358)
	No	43	3 (2-5)	1096 (157-3000)
	Rectal healing only	5 of 43	2 (0-3)	1096 (298-1524)

Table.

At V3 mucosal healing was achieved by 133 patients, in which 83 (62.4%) of them showed histologic healing and 50 (37.6%) showed histologic activity in at least one colorectal segment. PMSs and faecal calprotectin (FC) levels were significantly higher in the latter group (p < 0.005).

In the latter group, 27 (54%) of 50 showed histologic activity only in colonic segment(s) whereas rectal biopsies were scored NHI ≤ 1 (defined as *rectal healing*). PMSs and FC levels were also significantly higher in the rectal healing group than in the group achieving histologic healing in all colorectal segments (p < 0.005).

Deep remission rate was 62.8% (113 of 180) and complete remission rate 42.2 % (76 of 180). Deep remission plus NHI ≤ 1 in rectum $\pm$ colon was observed in 52.2% (94 of 180).

Assessing the predictive value of clinical, endoscopic, and histological activity scores at baseline, the sum of segmental NHI and MES were independently associated with complete remission.

Notably, the sum of segmental NHI was higher than expected in many patients with limited disease extent, as 28 (25%) of 112 patients with proctitis and left-sided colitis also had histologic activity in proximal colonic segments.

Conclusion: Histologic activity in endoscopically normal or quiescent mucosa was common. The endoscopic evaluation of the proximal extent of the inflammation was frequently underestimated, and one-third achieving endoscopic mucosal healing had persistent histologic activity.

The complete remission rate was dependent on the number of biopsy sites and was increased by 10% if only rectal biopsies were evaluated.

Disclosure: Nothing to disclose.

Introduction: There is a growing body of evidence suggesting that visceral obesity can have a negative impact on inflammatory bowel disease (IBD). However, routine assessment of visceral obesity using the most frequently applied cross-sectional imaging methods is limited due to their costs, low availability, and lack of validation of diagnostic criteria.

Aims & Methods: To assess the prevalence of visceral obesity defined by International Diabetes Federation (IDF) anthropometric criteria in IBD patients and its relationship with IBD clinical course, disease phenotype, and proinflammatory response.

252 participants were prospectively enrolled into the study - 182 patients with IBD and 70 healthy people constituting the control group. According to the IDF criteria, we divided patients into subgroups with and without visceral obesity based on the waist circumference (waist circumference threshold for visceral obesity in Europe: ≥ 94 cm in men; ≥ 80 cm in women). IBD clinical activity was assessed using the Harvey-Bradshaw Index (for Crohn's disease) and the Partial Mayo Score (for ulcerative colitis).

Disease phenotype was defined according to the Montreal classification. The need for steroid therapy at diagnosis and/or the need for immunosuppressive/biological treatment and/or major abdominal surgery were considered to define severe IBD course.

We performed waist and hip circumference measurements in all patients using the Seca-201[®] measure and body composition analysis using the bioelectrical impedance method (TANITA-MC980 MA[®]). Concentrations of selected proinflammatory adipocytokines (CRP, hslL-1 β , hslL-6, MCP-1, resistin, visfatin, leptin) were measured by a highly sensitive ELISA method.

Results: Patients with visceral obesity constituted 20% (n=36/182) of the study group. We found no differences between IBD patients with and without visceral obesity in terms of general characteristics, the risk of develop-

ing fistulising and/or stricturing phenotype, and fulfilling the predefined criteria of severe IBD course. Additionally, we found no differences in all measured proinflammatory adipocytokines among patients with IBD when stratified the study group according to the IDF criteria for visceral obesity (except for leptin).

At the same time - CRP, hslL-6, resistin, and MCP-1 concentrations were significantly higher in both IBD subgroups (with and without visceral obesity) when compared to healthy people. As for leptin, we noted a significantly higher concentration of this adipokine in patients with IBD with visceral obesity - both compared to those with IBD without obesity and healthy people.

Conclusion: Visceral obesity, defined by IDF anthropometric criteria, is a frequent phenomenon in IBD patients, however it does not adversely affect the clinical course or the disease phenotype. Moreover, visceral obesity is not an additional proinflammatory factor in IBD, as the concentrations of several adipocytokines were not different in patients with increased waist circumference compared to those without visceral obesity. Increased leptin concentration reflects the metabolic state of patients with excessive accumulation of adipose tissue and not the inflammatory activity.

Further studies are needed to verify the most optimal definition and the most accurate diagnostic method for visceral obesity in IBD. This, in turn, could allow estimating the potential clinical relevance of diagnosing visceral obesity in IBD in routine practice.

Disclosure: Nothing to disclose.

Introduction: Atherosclerosis is the main factor for the development of cardiovascular (CV) events. Patients with systemic inflammatory conditions such as inflammatory bowel disease (IBD) are supposed to be at risk of early atherosclerosis. However, data are still contentious. IBD patients are also at risk of other comorbidities such as metabolic associated fatty liver disease (MAFLD), a well-recognized entity associated with increased CV risk.

Aims & Methods: The aim of this study is to demonstrate the impact of MAFLD on CV risk for IBD patients. Prospective cohort study of consecutive IBD outpatients (Leonnard-Jones criteria, > 1 year) was performed from October 2020 to April 2021. Of 947 patients, 50 with IBD who met criteria for MAFLD and 50 with IBD and without MAFLD were matched by sex, age and IBD location. Patients with a previous diagnosis of CV disease, type II Diabetes Mellitus and under treatment for dyslipidaemia were excluded. Fatty liver disease (FLD) was diagnosed by ultrasonography, controlled attenuation parameter (CAP[™]), fatty liver index (FLI), hepatic steatosis index (HSI) and lipid accumulation product (LAP).

To assess early atherosclerosis, alterations in Carotid Artery Intima-Media Thickness (CIMT) and SCORE as non-invasive CV risk test were performed in both groups. Statistical analysis was performed using SPSS version 26, a

binomial generalized linear model with logistic regression was performed, with CIMT alteration as dependent variable. For all tests, a two-sided p value <0.05 was considered significant.

Results: Of 100 IBD patients included, 51 (51%) were women with median age of 51.0 (IQR 41-59). There were 49 (49%) patients diagnosed of ulcerative colitis (UC) and 51 (51%) of Crohn's disease (CD). Most of the patients were former smokers (51 (51%)), had overweight or obesity (40 (40%) and 24 (24%) respectively), and an elevated waist-to-hip ratio (51 (51%)).

The most often disease location were ileocolonic disease for CD patients (43 (43%)) and pancolitis (29 (29%)) for UC. Extraintestinal disease was diagnosed in 29 (29%) of the patients. The therapies most often prescribed were mesalazine (35 (35%)) and anti-TNF (23 (23%)). Thirty-two patients (32%) had a steroid-dependent course, and 24 (24%) need surgery at any time of their course of disease.

Most of the patients had an abnormal CIMT (58 (58%)). Of all the variables obtained, only female sex (OR (CI 95%) 3.322 (1.03-10); p=0.033) and MAFLD (OR (CI 95%) 5.05 (1.71-14.92); p=0.003) were significantly associated with CIMT alterations. SCORE test did not associate with a significant CIMT alteration.

Among the different options to assess FLD, only ultrasonography and CAP were statistically associated with CIMT alterations (specificity 66%, sensitivity 62%, p=0.005).

Conclusion: Female sex and MAFLD are associated with early atherosclerosis, defined by CIMT alterations in IBD patients. Ultrasonography and CAP are better than biochemical test not only to predict FLD but also to assess CV risk.

Disclosure: Nothing to disclose.

Introduction: Patients with inflammatory bowel disease (IBD) are at increased risk of sacroiliitis. Nevertheless, sacroiliitis may go undiagnosed during follow-up. Two retrospective studies reported that detectable acute inflammatory and structural changes (fat metaplasia, ankylosis, and sclerosis) of inflammatory sacroiliitis are present in a significant proportion of IBD patients on MRE^{1,2}.

Aims & Methods: The study aims to investigate the acute inflammatory and structural changes of sacroiliitis as auxiliary findings on magnetic resonance enterography (MRE) and their presence on closely timed conventional magnetic resonance imaging (MRI) of the sacroiliac (SI) joint (MRI-SIJ). We screened IBD and spondyloarthritis (SpA) patients for the simultaneous presence of MREs and MRI-SIJs. Two radiologists blinded to the patient's identity and date of imaging evaluated MRI-SIJs and MREs on two separate occasions.

We used the SpondyloArthritis international Society (ASAS) / OMERACT definitions for MRI-SIJ. We implemented previously published standard definitions for bone marrow oedema, erosion, sclerosis, and fatty infiltration of SIJ in MREs that contains T1w and T1w post-gadolinium sequences.

Results: MRI-SIJ and MRE were present in 43 patients. The median time between the two modalities was 14 (0-89) days. Twelve patients had ASAS-defined sacroiliitis on MRI-SIJ. Radiologist-1 and radiologist-2 detected sacroiliitis on MRE in nine and eight out of these 12 patients, respectively (Table 1).

Both radiologists detected ankylosis and fatty metaplasia with a complete agreement, and sclerosis with an almost perfect agreement. Both radiologists agreed on erosions on MRI-SIJ in the same 10 cases. But the degree of agreement on erosions on MRE was weak. Radiologists did not identify acute inflammatory or structural changes on MRE in patients with a negative MRI-SIJ for these lesions.

On intra-reader analysis, Kappa values in detecting sacroiliitis on MRE-images for radiologist-1 and radiologist-2 were 0.927 (p< 0.001) and 1.000 (p< 0.001), respectively. Regarding structural changes, intra-reader Kappa value for both detecting fatty infiltration and ankylosis was 1.000 (p< 0.001) on MRE. On inter-reader analysis of both radiologists, kappa values for detecting sacroiliitis, fat metaplasia, ankylosis and sclerosis on MRE were 0.934 (P< 0.001), 1.000 (P< 0.001), 1.000 (P< 0.001), and 0.732 (p<0.001) respectively.

MRE vs. MRI-SIJ		MRE (n=43)		SI Joint MRI(n=43)		p
		Present n (%)	Absent n (%)	Present n (%)	Absent n (%)	
Radiologist 1	BME	9 (20.9)	35 (81.4)	12 (27.9)	31 (72.1)	0.125
	Fat metaplasia	13 (30.2)	30 (69.8)	13 (30.2)	30 (69.8)	1.000
	Sclerosis	5 (11.6)	38 (88.4)	5 (11.6)	38 (88.4)	1.000
	Ankylosis	1 (2.3)	42 (97.7)	1 (2.3)	42 (97.7)	1.000
Radiologist 2	BME	8 (18.6)	35 (81.4)	12 (27.9)	31 (72.1)	0.125
	Fat metaplasia	13 (30.2)	30 (69.8)	13 (30.2)	30 (69.8)	1.000
	Sclerosis	6 (14.0)	37 (86.0)	6 (14.0)	37 (86.0)	1.000
	Ankylosis	1 (2.3)	42 (97.7)	1 (2.3)	42 (97.7)	1.000

MRE: Magnetic resonance enterography; SI Joint MRI: Sacroiliac joint magnetic resonance imaging, BMO: Bone Marrow oedema (ASAS definition of sacroiliitis)

Table 1: Comparison of MRE and SI Joint MRI findings.

Conclusion: Our data supports that MRE is a useful diagnostic tool in the detection of both sacroiliitis and structural changes of SIJ. Along with intestinal findings, additional reporting of acute and structural inflammatory changes of the SI joint on a present MRE is extremely valuable and may alert gastroenterologists for the presence of previously not diagnosed axial SpA.

Introduction: The long-term natural history and impact of irritable bowel syndrome (IBS)-type symptoms on outcomes in inflammatory bowel disease (IBD) are uncertain. We assessed this in a longitudinal follow-up study of secondary care patients.

Aims & Methods: We assessed natural history of IBS-type symptoms in IBD via Rome III criteria applied at baseline, 2 years, and 6 years. We defined longitudinal disease activity as need for glucocorticosteroids or flare, escalation, hospitalisation, or intestinal resection. To assess healthcare utilisation, we recorded number of outpatient clinic attendances and investigations. We also collected anxiety, depression, and somatoform symptom scores, as well as quality of life scores during follow-up.

Results: Among 125 individuals with Rome III data at all three time points, only 41 (32.8%) never reported IBS-type symptoms. Fifteen patients (12.0%) had IBS-type symptoms at baseline that resolved, 19 (15.2%) had fluctuating symptoms, 35 (28.0%) had new onset symptoms, and 15 (12.0%) had persistent symptoms.

	Quiescent IBD	IBD with IBS-type Symptoms	IBD with Occult Inflammation	Active IBD	p Value
Glucocorticosteroid prescription or flare of disease activity (%)	59/126 (46.8)	49/82 (59.8)	31/70 (44.3)	24/30 (80.0)	0.002*
Multivariate HR for glucocorticosteroid prescription or flare of disease activity (95% CI)	1.00 (reference)	1.45 (0.96 – 2.18)	0.97 (0.60 – 1.56)	3.35 (1.93 – 5.81)†	<0.001
Escalation of medical therapy due to uncontrolled IBD activity (%)	58/127 (45.7)	43/83 (51.8)	33/77 (42.9)	34/42 (81.0)	<0.001*
Multivariate HR for escalation of medical therapy due to uncontrolled IBD activity (95% CI)	1.00 (reference)	1.15 (0.75 – 1.76)	1.00 (0.63 – 1.59)	3.01 (1.88 – 4.84)†	<0.001
Hospitalisation due to uncontrolled IBD activity (%)	16/127 (12.6)	20/83 (24.1)	14/80 (17.5)	18/61 (29.5)	0.028*
Multivariate HR for hospitalisation due to uncontrolled IBD activity (95% CI)	1.00 (reference)	2.36 (1.15 – 4.83)	1.34 (0.60 – 3.02)	2.56 (1.21 – 5.40)	0.041
Intestinal resection due to uncontrolled IBD activity (%)	6/127 (4.7)	8/83 (9.6)	5/80 (6.3)	11/62 (17.7)	0.021*
Multivariate HR for intestinal resection due to uncontrolled IBD activity (95% CI)	1.00 (reference)	1.76 (0.54 – 5.75)	1.08 (0.27 – 4.41)	3.61 (1.16 – 11.2)	0.096

* χ^2 for comparison across all four groups.

† $p < 0.01$ versus reference category.

Table 1. Clinical Outcomes of Patients According to IBD Activity Status (FC <250mcg/g) at Baseline.

Among more than 300 patients with IBD activity data, IBS-type symptoms were not associated with an increased likelihood of need for glucocorticosteroids or flare, escalation, hospitalisation, or intestinal resection. However, mean number of outpatient appointments and endoscopic investigations were significantly higher among those with IBS-type symptoms. Anxiety, depression, and somatoform symptom scores were significantly higher and quality of life scores significantly lower in those reporting IBS-type symptoms at least once during the study.

Conclusion: IBS-type symptoms affected more than two-thirds of patients with IBD during >6 years of follow-up and were associated with increased healthcare utilisation, and worse anxiety, depression, and somatoform symptom, and quality of life scores, but not adverse disease activity outcomes.

Disclosure: Nothing to disclose.

Introduction: There is increasing evidence that symptoms of anxiety and depression are associated with poor clinical outcomes in inflammatory bowel disease (IBD).

Aims & Methods: We report the trajectories of common mental disorders in IBD, the characteristics associated with these subgroups, and the effect on healthcare utilisation.

We collected complete demographic, symptom, psychological, and quality of life data in 771 patients, with repeat questionnaires at 3-monthly intervals, over 12-months of longitudinal follow up. Medical records were reviewed to collect data on disease extent and phenotype, medications, and healthcare utilisation. We recorded the number of reported flares, escalation of therapy, hospitalisation, intestinal resection due to IBD activity and death. We compared the characteristics of those with persistently normal or improving anxiety and depression trajectories with those with fluctuating, or persistently abnormal or worsening hospital anxiety and depression scale scores.

Results: Of 771 patients, persistently abnormal or worsening anxiety or depression trajectories were present in 105 (13.6%) and 53 (6.9%) of individuals, respectively. They were associated with increased antidepressant ($p < 0.001$) and opiate use ($p < 0.001$). These individuals were also more likely to have been newly diagnosed with IBD in the previous 12 months ($p = 0.001$ and 0.006 respectively), significantly more likely to report higher somatisation scores ($p < 0.001$), and had significantly lower quality of life scores ($p < 0.001$) compared with those with persistently normal or improving anxiety or depression trajectories. Individuals with worsening, or persistently abnormal anxiety or depression trajectories were also significantly more likely to require more IBD-related appointments, and more radiological and endoscopic investigations.

Conclusion: Persistently abnormal or worsening anxiety or depression trajectories were associated with higher rates of antidepressant or opiate use, more recent diagnosis of IBD, higher somatisation scores, and worse quality of life, as well as increased healthcare utilisation.

Contact E-Mail Address: irenerasmagina@gmail.com

Introduction: Inflammatory bowel diseases (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), are chronic immune-mediated diseases that usually occur in young patients and requires lifelong therapy and monitoring. Even in developed countries UC is diagnosed 1,5 years after the onset of the symptoms and CD - 3,5 years respectively. This delay in diagnosis may cause surgical complications development and severe course of IBD.

Aims & Methods: The aim of the study was to optimize the existing methods of IBD diagnosis and to create a decision support system (DSS) using artificial intelligence (AI).

300 medical histories (per 100 of UC, CD and (irritable bowel syndrome (IBS)) of patients that had been admitted to the gastroenterology department or managed in outpatient center of IBD of the NWSMU

n.a.I.I.Mechnikov (Saint-Petersburg, Russia) were analyzed. In order to determine the clinical and laboratory data that could be used in differentiation between IBS, UC and CD, we assessed gender, age, clinical symptoms of the disease (stool frequency, rectal bleeding, abdominal pain, night symptoms, weight loss, extraintestinal manifestations, fever, perianal manifestations, the history of abscesses, strictures, fistulae, surgical treatment), comorbidities, family history of autoimmune diseases and laboratory parameters (hemoglobin levels, WBC, serum protein, CRP and fecal calprotectin).

For diagnosis and differentiation of IBD, the DSS that was based on an adapted VGG16 convolutional neural network (CNN) with fast assess connections was developed. The CNN used digital endoscopic images as an input and the output was a conclusion about the presence and the type of pathology. The images were obtained with endoscope Olympus during the video colonoscopies of the patients with verified IBD and IBS.

Results: Clinical and laboratory data that were statistically significant for IBD verification were determined. The demarcation markers between IBD and IBS were loose stool, weight loss, C-reactive protein and fecal calprotectin levels ($p < 0,05$). The parameters that could help to differentiate the types of IBD were the presence of extraintestinal and perianal manifestations, anemia (more likely in patients with CD) and the presence of obvious blood in stool and leukocytosis for UC ($p < 0,05$).

In order to train the CNN to diagnose IBD, the endoscopic images were divided into two groups – images of normal mucosa and images of inflamed mucosa of the patients with UC and CD. The images were randomly divided into training ($n = 843$ images: 234 – normal mucosa, 600 – pathological mucosa) and control samples ($n = 210$ images: 60 – normal mucosa, 150 – pathology) in a 4:1 ratio. To differentiate the types of IBD, the images were divided in 9:1 ratio: training sample included 670 images (326 – CD, 344 – UC), control – 80 images (39 – CD, 41 – UC).

The CNN verified visually normal mucosa and mucosa with pathological changes with sensitivity 100%, specificity 91% and differentiated the type of IBD with sensitivity 88%, specificity 75%.

The DSS was implemented using Keras and TensorFlow open libraries in Python. The program included information about the patient, clinical and laboratory data and endoscopic image upload section.

Conclusion: DSS with the application of AI can be used as an additional tool to improve the accuracy of IBD diagnosis; however, future studies on the combination of clinical, laboratory and endoscopic data relevance for IBD diagnosis are needed.

Introduction: STARDUST is a phase 3b randomized trial comparing treat-to-target (T2T) strategy vs standard of care (SoC) in patients (pts) with Crohn's disease (CD) treated with ustekinumab (UST), which incorporated intestinal ultrasound (IUS) for the first time as an exploratory endpoint. Little is known about the association between drug exposure pharmacokinetics (PK) and IUS outcomes pharmacodynamics (PD), previously reported with biomarker and endoscopic outcomes. We report Week (W)48 results from the IUS substudy, assessing IUS endpoints and their relationship with UST exposure.

Aims & Methods: Adult pts with moderate-severe active CD unresponsive to conventional therapy and/or 1 biologic, received intravenous (IV), weight-based UST ~6mg/kg at W0 at baseline (BL); then subcutaneous (SC) UST 90mg at W8. At W16, responders (pts with ≥70-point reduction in CD activity index [CDAI]) were randomized (1:1) to either T2T or SoC and received protocol-specified SC UST every 12W or every 8W. Key IUS endpoints assessed at W4, W8, W16 and W48 (central reading): IUS response (IUSR; ≥25% bowel wall thickness [BWT] reduction from BL); BWT change from BL (mm); transmural remission (TMREM; normalization of BWT [≤3.0mm overall]), vascularization, bowel wall echo-stratification and inflammatory mesenteric fat). All IUS parameters used the most affected bowel segment at BL. Serum samples were collected to measure UST concentration at W8, W16 and W48 using validated assays.

Results: Of 77/88 pts enrolled in the substudy, 71 had BL and ≥1 post-BL IUS assessment. Changes in BWT at W8 (compared with BL) correlated significantly with BWT changes at W16 ($r=0.62$, $p<0.001$) and W48 ($r=0.46$, $p<0.001$). Likewise, serum UST levels at W8 correlated significantly with serum UST levels at both W16 ($r=0.81$, $p<0.001$) and W48 ($r=0.43$, $p=0.002$). However, changes in BWT at W8 (compared with BL) did not correlate

with serum UST levels at W8, W16 and W48 ($p>0.05$) (Table 1). Quartile (Q) analyses revealed that pts with the lowest UST levels at W8 (Q1) had a numerically lower chance of achieving IUS response by W16 (12.5% Q1 vs 39.5% Q2-Q4).

In contrast, pts with the highest UST exposure at W8 (Q4) had the highest chance numerically of achieving TMREM by W16 (38.5% Q4 vs 8.7% Q1-Q3). UST drug exposure at W8 and W16 was not associated with IUS outcomes at W48, potentially due to the design of the STARDUST trial, where dose optimization begins between W16 and W48 in many patients.

	UST serum concentration W8	UST serum concentration W16	UST serum concentration W48
Change in BWT at W8 compared with BL	$r=-0.08$ $p=0.53$	$r=0.01$ $p=0.92$	$r=-0.05$ $p=0.72$
Change in BWT at W16 compared with BL	$r=-0.10$ $p=0.47$	$r=0.02$ $p=0.91$	$r=0.08$ $p=0.60$
Change in BWT at W48 compared with BL	$r=-0.18$ $p=0.22$	$r=-0.08$ $p=0.57$	$r=-0.05$ $p=0.74$

BL, baseline; BWT, bowel wall thickness; UST, ustekinumab; W, week

Table 1 Correlation between changes in BWT and UST drug exposure.

Conclusion: In contrast to convincing evidence regarding UST PK-PD relationships in the context of biomarker and endoscopic outcomes, the association between UST exposure and IUS parameters is rather limited. Validated IUS scoring systems in large (randomized) studies should help to unravel the potential association between drug exposure and transmural healing in CD.

Introduction: Composite outcomes are frequently used as primary end-points in clinical studies, allowing smaller sample sizes and optimizing resources. A composite outcome incorporating clinical (need for surgery or hospitalization, new fistulae, abscess, or stricture) and drug-related items (>10 mg steroids per day, *de novo*AZA or methotrexate, AZA dose increase other than by weight fluctuation, swap/switch of biologics) has been reported for Crohn's disease (CD)¹.

Aims & Methods: To perform a sub-analysis of the DIRECT, a prospective, observational, multicenter study. Univariate and multivariate logistic regressions using clinical and analytical parameters were used to calculate the odds ratio (OR) of achieving the composite outcome in CD patients receiving infliximab (IFX) as maintenance therapy for two years. Fecal calprotectin (FC), C-reactive protein (CRP), and hemoglobin (Hb) levels were selected to develop a risk matrix.

Results: Overall, 285 CD patients were included; the composite outcome was reached in 57. The outcome was more common ($p < 0.05$) in patients with higher FC and CRP levels (cutoffs FC <250, 250-500 or >500 µg/g, and CRP <3, 3-10 or > 10 g/L) and in those presenting anemia during the follow-up (<12 or 13 g/dL, for women and men). These variables remained significant after adjusting for age at diagnosis, sex, disease location, and phenotype. On the other hand, IFX levels (≤ 3 µg/ml) and anti-IFX antibody-

ies (>1.7 µg/ml) did not significantly impact the development of the outcome. Regarding risk matrices, CD patients with FC <250, CRP <3, and without anemia at a single visit had an estimated probability of presenting the outcome of 6.1% (95%CI, 5.5-6.7%), while patients with FC >500, CRP >10 and anemia in at least two visits had a probability of 49.7% (95%CI, 46.3-53.1%).

Conclusion: This analysis corroborates the importance of FC, CRP, and Hb in CD monitoring, even when measured at a single time-point, and reinforces the relevance of risk matrices as point-of-care tools that may influence clinical management.

Introduction: Intestinal ultrasound (IUS) using contrast-enhanced imaging (CEUS) is an increasingly used non-invasive tool to evaluate Crohn's disease (CD) activity in addition to clinical, biochemical and stool parameters.

Aims & Methods: We aimed to assess the usefulness of CEUS in predicting inflammatory activity in CD patients and determine the relationship between its parameters and clinical, biochemical and stool parameters. Retrospective study including CD patients submitted to CEUS, with SonoVue® contrast, directed to the terminal ileum, performed by a single operator using an ultrasound Hitachi HI VISION Avius®, between April 2016 and March 2022. Qualitative and quantitative parameters from the conventional IUS analysis including wall thickness, stratification, colour Doppler and inflammatory fat were evaluated.

A quantitative measurement of contrast bowel wall enhancement, peak intensity (PI), was evaluated using CEUS. Clinical activity score was assessed by Harvey Bradshaw index (HBI). Biochemical (C-reactive protein (CRP)) and stool (fecal calprotectin (FC)) parameter were registered. The endoscopic activity was assessed with ileocolonoscopy by Simple Endoscopic Score for CD (SES-CD), graded as inactive (SES-CD <7) or active (SES-CD ≥7) and considered the gold-standard method to assess inflammatory activity.

Results: Of 57 patients, 31 (54.4%) were female with a mean age of 34±12 years. The majority had only ileal involvement (n=35, 61.4%) and the rest had ileocolonic involvement. Inflammatory, stricturing and penetrating

phenotypes were present in 24(42.1%), 22(38.6%) and 11(19.3%) patients, respectively. Only PI performed by CEUS was significantly different between patients with inactive and active endoscopic inflammatory activity (median, 5.4vs9.8, $P=0.012$, respectively) contrary to HBI (median, 4vs4, $P=0.836$, respectively), CRP (median, 754.5vs879.0, $P=0.742$, respectively), and FC (median, 10.3vs8.6, $P=0.281$, respectively). PI was significantly correlated with HBI ($r=0.301$, $P=0.023$), but not significantly correlated with CRP ($P=0.871$), and FC ($P=0.080$) values.

Conclusion: Contrast-enhanced Intestinal ultrasound is a more reliable tool to evaluate inflammatory activity in Crohn's disease than clinical, biochemical and stool parameters.

Disclosure: Nothing to disclose.

Introduction: Celiac disease is an autoimmune genetically determined disease associated with a violation of tolerance to cereals, leading to atrophy of the intestinal villi.

The combined course with IBD, as well as with other autoimmune diseases, its influence on the course of these pathologies is of particular interest in the development of the diagnosis and differential diagnosis, treatment and prevention of these pathologies.

Aims & Methods: To identify the prevalence of celiac disease in patients with inflammatory bowel disease and its impact on the clinical and endoscopic course, as well as changes in laboratory and pathomorphological parameters.

The study was conducted from January 2016 to January 2022, among 400 patients with IBD (MC 12 patients, women 8, men 4; UC 150 patients, women 71, men 79; CD 238 patients, women 120, men 118).

Patients underwent serological examination for celiac disease (in the blood AGA IgA, AGA IgG, DGP IgA, DGP IgG, anti-TTG IgA, anti-TTG IgG), endoscopy was performed with biopsy sampling for pathomorphological examination, and laboratory blood tests were performed (complete blood count, h/s CRP, homocysteine, vit. D, ANCA-indicators, α -TNF and IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-18, total protein, albumin, iron, ferritin; urinalysis and urine albumin; fecal analysis and fecal calprotectin and lactoferrin).

Results: Results: 370 patients (92.5%) underwent serological testing for celiac disease and in 89 cases (22.3%) the result was positive, the number of positive endoscopic manifestations was 112 (28% /30.3%), the number of patients with positive pathological conclusion - 89 (22.3%/24%), the number of patients with concomitant autoimmune diseases - 64 (17.3%).

Overlap "IBD+Celiac disease" in 29 cases revealed markers of ANCA-associated vasculitis (anti-BPI, anti-lizosim, anti-elastaza, anti-Katepsin G). Indicators of the studied parameters before and after the gluten-free diet are presented in table 1, table 2 and table 3.

Activity indicators	CeD+ average value before/ after	CeD+ UC n=28 before/ after	CeD+ CD n=61 before/after	CeD- average value before/after	CeD- UC n=28 before/after	CeD- CD n=61 before/after
h/s CRP (N<1mg/L)	15,6 / 2,5	12,3 / 2,7	19,1 / 2,4	6,4 / 6,4	6,8 / 6,6	5,9 / 5,7
Plateles (N150 000 - 400 000/ mm ³)	460 / 360	431 / 322	488 / 368	327 / 313	315 / 311	338 / 322
Homocystein ((N<12 μ mol/L)	17 / 9,4	15,8 / 8,8	18,1 / 10,3	10,1 / 10,1	9,3 / 9,1	10,8 / 10,5
Vitamin D (N 30-100ng/ mL)	4,7 / 22,3	4,1 / 24,5	5,3 / 25,2	21 / 21	22,5 / 22,5	19,4 / 19,5
Albumin (in urina) (N<2mg/L)	42,9 / 12,9	34,8 / 14,8	47 / 17	8,1 / 8,0	12,5 / 12,1	3,7 / 3,5
Calprotectin ((N<50 μ g/g)	834,5 / 214,5	1312 / 212	745 / 225	385 / 385	596,4 / 596,4	173,2 / 173,2
Laktoterrin (N<7,5 μ g/g)	101,5 / 8,5	139,2 / 7,2	121,7 / 8,7	27 / 27	44,6 / 44,6	9,2 / 9,2
il-8 (N< 10 pg/ml)	44,4 / 10,1	43,8 / 8,8	49,0 / 10,4	24,9 / 22,4	24,1 / 23,9	25,6 / 24,1
il-18 (N< 261 pg/ ml)	292,2 / 212,1	293,1 / 223,5	291,2 / 211,2	279,9 / 265,2	280,1 / 273,6	279,6 / 274,1

Table 1. Changes in activity in some laboratory parameters before starting a gluten-free diet and after a gluten-free diet

Conclusion: Overlap "IBD+Celiac disease" in the study group of patients was 22.3%. Overlap "IBD+Celiac disease" had higher indicators for laboratory, endoscopic and morphological activity of IBD, and it is also possible to identify markers of ANCA-associated vasculitis (anti-BPI, anti-lizosim, anti-elastaza, anti-Katepsin G).

Disclosure: no conflict of interest.

Introduction: Microscopic colitis (MC) is a chronic inflammatory disease of the large intestine, characterised by histologic lesions and an absence of destructive mucosal damage on colonoscopy, in contrast with inflammatory bowel disease like ulcerative colitis (UC).

The pathogenesis of MC is still poorly understood and there are no non-invasive diagnostic markers to aid in disease diagnosis. Fatty acid binding protein 2 (FABP2) is expressed in enterocytes and colonocytes (although to a lesser extent)¹ and is released after intestinal injury. Interleukin-10 (IL-10) is an anti-inflammatory cytokine that is reduced in inflammatory bowel diseases.²

Lipopolysaccharides (LPS) are bacterial endotoxins that promote inflammation and their presence in systemic circulation represents impaired intestinal barrier function.³

Aims & Methods: Our aim was to investigate FABP2, IL-10 and LPS as possible non-invasive diagnostic biomarkers for MC and compare their profile between MC and UC. For this purpose, we used plasma obtained from 63

patients with active MC, 52 healthy controls, 43 patients with active and 43 with inactive UC. Hjortswang criteria were used to determine disease activity in MC patients and Mayo score in UC patients.

Plasma concentrations of FABP2, IL-10 and LPS were measured using Human FABP2/I-FABP Quantikine ELISA Kit (DFBP20; R&D systems, MN, USA), Human IL-10 Quantikine ELISA KIT (D1000B; R&D systems, MN, USA), and Human Lipopolysaccharides (LPS) ELISA Kit (CSB-E09945h; Cusabio, China). Statistical significance of concentration differences between groups was determined using the Mann-Whitney U test.

Results: Plasma concentration of FABP2 was lower in healthy controls (median 1365 mg/ml) when compared with MC (median 1680 pg/ml) but the results did not reach statistical significance. However, FABP2 concentration was significantly lower in the plasma of UC patients, both active (median 1272 pg/ml, $p = 0,004$) and inactive (median 1334 pg/ml, $p = 0,001$) when compared with MC patients. The difference in FABP2 concentration between healthy controls and active or inactive UC patients was not significant.

IL-10 plasma concentration was significantly lower in active UC (median 2,58 pg/ml) than in MC patients (median 3,89 pg/ml, $p = 0,006$) and healthy controls (median 4,79 pg/ml, $p = 0,005$). IL-10 concentration was also lower in the plasma of inactive UC (median 3,04 pg/ml) and MC patients when compared with healthy controls, but the results did not reach statistical significance.

The plasma concentration of LPS was similar across all the patient groups and no significant difference was observed.

Conclusion: Plasma FABP2, IL-10 and LPS did not distinguish MC patients from healthy controls in our study. IL-10 concentration in patients with active UC was lower when compared to MC patients and healthy controls.

Contact E-Mail Address: r.loveikyte@lumc.nl

Introduction: Differentiating absolute iron deficiency from functional iron restriction is challenging in active Inflammatory Bowel Disease (IBD). Hepcidin, the systemic iron regulator, could be the key to the diagnosis and management of absolute iron deficiency. In this study, we assessed hepcidin as a diagnostic iron deficiency marker and we explored the relationship between hepcidin, inflammation, hypoxia, and iron deficiency in patients receiving induction therapy with infliximab (IFX) or vedolizumab (VEDO).

Aims & Methods: 130 patients with IBD, who received induction therapy with IFX or VEDO for active disease, were included in this cohort study. Clinical and biochemical data were extracted from medical records. Serum samples at baseline and week 6 of induction therapy were retrieved from the University Medical Center Groningen (UMCG) biobank and analysed for: hepcidin, inflammation (e.g., interleukins [IL] 6, 10, and Tumour Necrosis Factor- α [TNF- α]), oxidative stress (free thiols), and hypoxia (e.g., erythropoietin [EPO], Macrophage Inflammatory Protein-3 α [MIP-3 α]). Data were analysed by stratifying based on the response at week 14.

Response to therapy was defined by either General Physician's Assessment at week 14 of induction therapy, normalisation or at least a three-point decrease in clinical scores: Harvey-Bradshaw Index (HBI) for Crohn's Disease, Simple Clinical Colitis Activity Index (SCCAI) for ulcerative colitis. For comparison, serum samples from 50 age- and gender-matched healthy controls were obtained from the pre-donation biobank at the UMCG.

Results: At baseline, hepcidin correlated positively with ferritin and negatively with soluble Transferrin Receptor/log ferritin index [$\rho = 0.74$ and $\rho = -0.79$, respectively; $P < 0.001$ for both markers], while inflammation- and hypoxia-associated markers showed only marginal correlations. Hepcidin accurately identified absolute iron deficiency: $AUC_{(hepcidin)} = 0.89$ [95% CI: 0.82–0.95; $P < 0.001$]. In total, 75.4% of patients responded to the induction therapy. Induction with either IFX or VEDO decreased hepcidin [13.5 ng/mL vs. 9.5 ng/mL; $P < 0.001$], ferritin [45.5 ug/L vs. 37.0 ug/L, $P < 0.05$], and inflammatory markers at week 6, while transferrin increased [2.4 g/L vs. 2.5 g/L, $P < 0.001$].

In addition, hypoxia (i.e., EPO, MIP-3 α) and inflammatory markers such as faecal calprotectin, IL-6, IL-22, and TNF- α improved significantly. In contrast, none of these changes were observed in patients who did not respond to the therapy.

Conclusion: Hepcidin levels in IBD are primarily driven by iron status, even in an inflammatory state. Therefore, hepcidin could be a potential diagnostic iron deficiency biomarker that could assist therapeutic decision-making. In addition, induction therapy with either IFX or VEDO can reduce hepcidin levels, especially in patients who respond to the therapy.

P0324

C-REACTIVE PROTEIN/ALBUMIN RATIO (CAR) AS A MARKER FOR DETECTING ACUTE SEVERE ULCERATIVE COLITIS IN EGYPTIAN PATIENTS

D. Header¹, R. Abd El Halim², M. Elkeleny², E. Bedewy², A. El Lakany²

¹Alexandria University, Faculty of Medicine, Gastroenterology, Alexandria, Egypt, ²Alexandria University, Alexandria, Egypt

Contact E-Mail Address: d.ahmedellakany@yahoo.com

Introduction: The C-reactive protein/albumin ratio (CAR) is an inflammatory marker that is considered to have prognostic value in many diseases as acute severe ulcerative colitis (ASUC). A high level of the CAR is associated with increased inflammatory burden, poor prognosis, and mortality.

Aims & Methods: Our aim in the present study was to investigate the diagnostic performance of the CAR in determining the clinical severity of acute severe ulcerative colitis (ASUC).

Materials and methods: A retrospective study on 200 UC patients that were admitted to the Gastroenterology unit of the Alexandria University, over an 8-year period from January 2012 to January 2020, was conducted. Patient demographic data, laboratory values, and clinical and endoscopic disease activity scores were evaluated. C-reactive protein (CRP) and albumin levels were recorded. The CAR was calculated to determine clinical severity.

Results: Of the 200 patients, 135 (67.5%) were men and 65 (32.5%) were women. Mean age was 43.5 ± 9.8 years. Patients were divided into groups with mild, moderate, or severe disease activity and there were statistically significant differences in the CAR, the erythrocyte sedimentation rate (ESR), CRP levels, and albumin levels ($p=0.001$; $p<0.05$).

With a cut-off value of 0.6, the CAR performed best in defining patients with severe disease, with an area under the curve (AUC) of 0.985, 98% sensitivity, 100% specificity, positive predictive value of 100%, and negative predictive value (NPV) of 97%, $p<0.001$. AUC values for the diagnosis of severe disease were 0.985, 0.88, 0.72, and 0.65 for the CAR, CRP, albumin, and the ESR, respectively.

Conclusion: There was a statistically significant association between the CAR and clinical disease activity in patients with UC. The CAR is a reliable and practical tool for detecting ASUC.

RISK FACTORS OF CYTOMEGALOVIRUS COLITIS IN INFLAMMATORY BOWEL DISEASE

S. Nacer¹, F. Haddad¹, F.Z. Elrhaoussi¹, M. Tahiri Joutei Hassani¹, W. Hliwa¹, A. Bellabach¹, W. Badre¹

¹CHU Ibn Rochd, Casablanca, Morocco

Contact E-Mail Address: saramedstudies@gmail.com

Introduction: Patients with inflammatory bowel disease (IBD) are at an increased risk for cytomegalovirus (CMV) colitis. The major challenge is to differentiate between IBD flare and CMV colitis. Early detection and rapid initiation of antiviral treatment for CMV disease seems to reduce the mortality and colectomy rate.

Aims & Methods: The aim of this study was to identify risk factors for CMV colitis in IBD patients. We conducted a single center retrospective study between 2016 and 2021 including 130 active IBD (49 Crohn's disease (CD), 81 Ulcerative Colitis (UC)) patients with known CMV status. Disease activity of UC and CD was assessed by Mayo score and Harvey-Bradshaw Index (HBI) respectively.

CMV colitis was defined by the presence of clinical signs associated with inclusion bodies detected microscopically using haematoxylin and eosin (H&E) and/or CMV immunohistochemistry (IHC) staining and/or quantitative polymerase chain reaction (qPCR) in colonic biopsies with a cut-off

value of >250 copies/mg. Statistical analysis identified several independent risk factors for CMV colitis. P value <0.05 was considered statistically significant.

Results: Of the 130 patients with active IBD, 13 patients were diagnosed with CMV colitis. The median age was 36.7 years with a female to male ratio of 2. Positive CMV inclusion bodies in H&E staining were identified in 53.8% of patients. IHC staining was positive in 23% of patients and qPCR in 30.7% of patients.

The median disease duration in the CMV colitis group was shorter than that in the CMV negative group (26 versus 56 months; $p=0.001$). The median Mayo Score for patients with UC in CMV negative group was 7 compared with 10 in CMV colitis group ($p=0.026$). Patients with CD in the CMV negative group had a median HBI of 14 compared with 17 in CMV colitis group ($p=0.034$). Endoscopic findings include digging ulceration (3; 23%) longitudinal ulceration (4; 30.7%), and ulceration in map (2; 15.3%).

The presence of endoscopic ulcers turned out to be predictive factors for CMV colitis ($p=0.02$). Medications used in our patients included azathioprine, mesalazine, steroids, and anti-TNF α . They were 37.3%, 34.5%, 21.5%, and 10%, respectively. Among the 28 patients who received steroids, 7 (25%) were steroid-refractory colitis.

Higher steroid usage rate was observed in the CMV positive group compared with CMV negative group (30.8% vs 18.5%, $p=0.003$).

The use of more than two lines of immunosuppressive drugs ($p=0.001$) and steroid-refractory colitis ($p=0.001$) were risk factors for patients with IBD to develop CMV colitis.

All patients in the CMV colitis group received antiviral therapy. Nine patients showed an improvement of their clinical disease activity, 2 patients underwent a colectomy and 2 patients died because of sepsis.

Gender, age, C-reactive protein (CRP), administration of biologics (infliximab, adalimumab), antimetabolites (methotrexate, 6-mercaptopurin, azathioprine) or 5-aminosalicylates were not significantly associated with CMV colitis.

Conclusion: Overall, CMV colitis occurs in patients with UC rather than CD. The use of corticosteroid, combined immunosuppressants and severe IBD patients were identified as risk factors to CMV disease. A closely monitoring in these patients is needed to provide timely diagnosis and early antiviral treatment.

Disclosure: Nothing to disclose.

P0326

THE EFFECT OF RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM BLOCKING AGENTS ON THE 5- AND 10-YEAR DISEASE COURSE OF CROHN'S DISEASE PATIENTS WITH HYPERTENSION

C. Karime¹, J.G. Hashash², M.F. Picco², J.A. Murray³, F.A. Farraye²

¹Mayo Clinic Florida, Department of Internal Medicine, Jacksonville, United States, ²Mayo Clinic Florida, Inflammatory Bowel Disease Center, Department of Gastroenterology and Hepatology, Jacksonville, United States, ³Mayo Clinic, Gastroenterology and Hepatology, Rochester, United States

Contact E-Mail Address: chriskarime@hotmail.com

Introduction: An association between the proinflammatory renin-angiotensin-aldosterone system (RAAS) and inflammatory bowel disease (IBD) has been reported, suggesting that RAAS-blocking therapy may be beneficial in patients with IBD. Using surrogate markers of IBD severity, we aimed to retrospectively compare the 3-, 5-, and 10-year disease course of patients with Crohn's disease (CD) initiated on either angiotensin-converting enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB) therapy.

Aims & Methods: Patients with CD and hypertension who initiated therapy with an ACEI (n= 40, mean age 59.9, 55% male) or ARB (n= 40, mean age 59.9, 50% male) between 2000-2016 were enrolled and matched to controls (n= 40, mean age 57.8, 42.5% male). Matching was performed on age at CD diagnosis, CD duration before study entry, gender, body mass index, Montreal classification, and comorbid conditions (hypertension, nicotine dependence, diabetes).

Clinical (emergency department visits, hospitalizations, corticosteroid use, and biologic therapy use), radiological (computer tomography [CT], CT enterography, magnetic resonance imaging, magnetic resonance enterography), and procedural (endoscopic, IBD-related operations) data were collected as surrogate markers of IBD severity in the 3-, 5-, and 10-years following ACEI or ARB initiation. Statistical analysis was carried out by Kruskal-Wallis test followed by Dunn's post hoc test. A P-value of <0.05 was used as a criterion of statistical significance.

Results: Compared to matched controls, ARB-treated patients had a better overall 10-year disease course, with significantly fewer emergency department visits (0.91 vs. 1.70, p<0.05, - 47%) and corticosteroid prescriptions (1.06 vs. 2.88, p<0.01, - 63%). ACEI-treated patients had an overall worse disease course, with significantly more imaging studies (3.00 vs. 1.75, p<0.05, + 71%) and endoscopic procedures (2.70 vs. 1.78, p<0.01, + 52%) at 5-years, and significantly more imaging studies (6.19 vs. 3.50, p<0.05, + 77%), endoscopic procedures (5.91 vs. 3.78, p<0.01, + 56%), and IBD-related operations (0.59 vs. 0.18, p<0.05, +228%) at 10-years. ACEI-treated patients were more likely to initiate biologic therapy compared to both controls (56.0% vs. 32.3%) and ARB-treated patients (56.0% vs. 17.4%).

Conclusion: Given the known cardio- and reno-protective effect of RAAS blockade, use of ACEI and ARB therapy to manipulate proinflammatory RAAS activation in IBD is a potentially attractive option.

Our study indicates that RAAS-blocking agents may significantly affect the long-term disease course of patients with CD, even when initiated at a relatively older age. Whilst ARB therapy was found to have an ameliorating effect on CD course at 10-years, ACEI use was found to have a deleterious effect at 5- and 10-years following therapy initiation.

If confirmed in larger population studies, the presence of CD may influence choice of future antihypertensive therapy.

Introduction: In inflammatory bowel disease (IBD), the continuation of wound healing results in excessive production of extracellular proteins capable of driving disease progression. Among these proteins are the fibrillar collagens and enzymes catalyzing collagen cross-linking. The excessive deposition of collagens and their subsequent cross-linking are critical processes in intestinal fibrosis, thought to affect all IBD patients to various degrees, potentially progressing the disease. The induction of proteolysis of the cross-linked collagens may lead to regression of intestinal fibrosis, though no tools are currently available for the objective assessment of these underlying processes.

Aims & Methods: We developed a novel sandwich enzyme-linked immunosorbent assay quantifying cross-linked and protease-degraded metabolites of type V collagen (NBH-276). Several technical parameters such as the measurement range, dilution recovery, spiking recovery, inter- and intra-variability, interference (hemoglobin, biotin, and lipid), and analyte stability were evaluated. The acceptance criteria for the technical validation of the assay were a recovery of 100% ±20 and an inter-intra variability of <15%.

We evaluated the formation of type V collagen (PRO-C5) and subsequent proteolytic release by the NBH-276 biomarker in an *in vitro* scar-in-a-jar model using human intestinal fibroblast (Cellbiologics). The fibroblasts were stimulated for up to 12 days with or without 20 ng/mL of TGF-β, followed by adding 0.5 ng/mL of either MMP-9 or MMP-13 for 48 hours.

The levels of protease degraded and cross-linked metabolites of type V collagen were investigated in the serum of patients with UC (n=47) and CD (n=39) from a prospective observational study conducted at Odense University Hospital and healthy controls (HC) (n=32).

The statistical difference and ability of NBH-276 to differentiate the biomarker levels between IBD patients and the HCs were performed by Kruskal-Wallis with Dunns test for multiple comparisons and ROC analysis. The biomarker levels of the *in vitro* model were evaluated by two-way ANOVA using Dunnet test for multiple comparisons. The statistical analysis was performed by Graphpad Prism 9.3.1 (Graph Pad Software, La Jolla, CA, USA)

Results: The technical validation of the NBH-276 assay demonstrated acceptable results with recoveries of dilution, spiking, interference, and analyte stability of 100±20%. The inter-intra assay variability was 14.4% and 5.3%, respectively, and a measurement range of 1.0 – 62.8 ng/mL. Human intestinal fibroblast stimulated with 20 ng/mL TGF-β had elevated levels of PRO-C5 compared to unstimulated cells on days 4, 8, and 12 (all: p < 0.01, [60.76 ng/mL, 57.73 ng/mL, 64.84 ng/mL]). The NBH-276 biomarker was unmeasurable in the cell supernatants.

Following MMP-9 or MMP-13 cleavage of the deposited cell matrix, the measured levels of NBH-276 increased 3.2-fold (p < 0.01) and 1.9-fold (p > 0.05), respectively, compared to the uncleaved control. The serum levels of NBH-276 were found significantly elevated in patients with UC or CD compared to the HCs (all: p < 0.0001, mean differences [3.87 ng/mL and 2.19 ng/mL]). The AUROC for NBH-276 separating UC or CD patients from HCs was 0.99 (all: p < 0.0001) (see Table 1 for sensitivity and specificity).

Biomarker	Matrix	P-value	Area under the curve	Sensitivity (95% Confidence interval)	Specificity (95% Confidence interval)
PRO-C5 (Type V collagen formation)	Cell supernatant	compared to unstimulated cells on days 4, 8, and 12: $p < 0.01$			
	Cell supernatant	compared to unstimulated cells: $p > 0.05$			
CTX-V (cross-linked and protease-degraded type V collagen)	Cleaved cell matrix	compared to uncleaved control: MMP-9, $p < 0.01$; MMP-13, $p > 0.05$			
	Serum UC patients	compared to healthy controls: $p < 0.0001$	0.99	100.0% (92.4 - 100.0)	96.9% (84.3 - 99.8)
	Serum CD patients	compared to healthy controls: $p < 0.0001$	0.99	100.0% (91.0 - 100.0)	96.9% (84.3 - 99.8)

Conclusion: Our study demonstrated the biological relevance of the novel CTX-V biomarker as a cross-linked and protease-degraded fragment of type V collagen. MMP-9 induced the release of CTX-V in the fibrotic human intestinal fibroblast *in vitro* model and subsequently showed relevance in UC and CD patients. The biomarker may potentially enable a noninvasive and objective quantification of proteolysis of cross-linked type V collagen in IBD patients.

HISTOLOGIC DISEASE ACTIVITY CORRELATES WITH ENDOSCOPIC SEVERITY IN PATIENTS WITH MODERATE TO SEVERE CROHN'S DISEASE

Introduction: The role of histopathology evaluation in Crohn's disease (CD) is not precisely defined. Due to the heterogeneity of phenotypes, the discontinuity of distribution and the transmural nature of inflammation, the interpretation of histologic outcomes is complex.

Aims & Methods: To analyze how histology relates to established outcomes in CD, we examined association between histologic and endoscopic disease activity measured by frequently used scores (simple endoscopic score for Crohn's disease [SES-CD], Robarts histopathology index [RHI], global histological activity score [GHAS]) and the association between histologic or endoscopic severity with inflammatory biomarkers in a cohort of patients with moderate to severe CD. Patients (N=191) who were enrolled in a phase 2 randomized clinical trial (NCT02891226) in patients with moderate-to-severe CD were assessed at baseline (BL) for endoscopic disease location and severity as measured by SES-CD. Biopsies were obtained during BL endoscopy from the edge of the ulcers and the most inflamed mucosa in terminal ileum and 4 colonic segments (ascending, transverse, descending, rectum; N=10/patient, 2 per location with

the more severe score used), and scored by central readers blind to study treatment, timepoint, and response status using RHI and both modified and active GHAS (mGHAS: Q1, 3, 4, 5, 6; aGHAS: Q1, 4, 5, 6). Inflammatory biomarkers included fCLP and CRP; log-transformed values are used. Linear correlations between measures were determined using Pearson correlation coefficients (PCC) as exploratory analyses. Nominal p values are presented.

Results: SES-CD correlated well with all 3 histologic measures examined. While both fCLP and CRP correlated more closely with endoscopy than with histologic measures, fCLP had higher correlation with each histologic measure than CRP. 64% of patients had the same disease location at BL when measured by endoscopy or histology. Patients with endoscopic colonic disease displayed histologic ileal involvement in up to 20% of cases, while 13% of patients with endoscopic ileal disease demonstrated histologic colonic involvement (Table 1).

	Induction population N=191	Baseline endoscopic disease location			Total
		Colonic	Ileal	Ileal-colonic	
Baseline active histologic disease location	Colonic	46	0	12	58
	Ileal	3	21	15	39
	Ileal-colonic	10	4	42	56
	No active disease	5	5	7	17
	No biopsy	11	3	7	21
	Total	75	33	83	191

Number of patients with active disease at each location as determined by endoscopy or histology.

Active histologic disease at BL: modified Global Histologic Disease Activity Score >0 [GHAS; Q1, 3, 4, 5, 6] or sum of Robarts Histopathology Index [RHI] questions 2-4>0.

Modified GHAS: The score has been modified from the original publication by removing component 2 (architectural changes), 7 (presence of granuloma) and 8 (number of specific biopsies affected). Q1: Epithelial damage (0: Normal, 1: Focal Pathology, 2: Extensive Pathology); Q3: Infiltration of mononuclear cells in the lamina propria (0: Normal, 1: Moderately increase, 2: Severe increase); Q4: Infiltration of polymorphonuclear cells in the lamina propria (0: Normal, 1: Moderately increase, 2: Severe increase); Q5: Polymorphonuclear cells in epithelium (1: In surface epithelium, 2: Cryptitis, 3: Crypt abscess); Q6: Presence of erosion and/or ulcers (0: No, 1: Yes).

Active GHAS: modified GHAS excluding Q3. RHI: The score has been modified from original publication by removing component 1 (chronic inflammatory infiltrate). Q2: Lamina propria neutrophils (0: None, 1: Mild but unequivocal increase, 2: Moderate increase, 3: Marked increase); Q3: Neutrophils in epithelium (0: None, 1: <5% crypts involved, 2: <50% crypts involved, 3: >50% crypts involved); Q4: Erosion or ulceration (0: No erosion, ulceration, or granulation tissue, 1: Recovering epithelium + adjacent inflammation, 2: Probable erosion-focally stripped, 3: Unequivocal erosion, 4: Ulcer or granulation tissue).

Endoscopic disease location was determined by presence of any endoscopic lesions/inflammation at isolated ileum only, isolated colonic segments only, or at both ileal and colonic segments.

Histologic location was determined by presence of histologic inflammation at isolated ileum only, isolated colonic segments only, or at both ileal and colonic segments, independent of endoscopic activity.

Table 1: Disease location at baseline as measured by endoscopy or histology

Conclusion: Although histologic disease activity in CD, as determined by 3 different measures, correlates well with endoscopic assessment of disease, histologic involvement provides complementary information on disease distribution and extension. Further analyses are required to understand the additive role of mucosal histology in CD.

Contact E-Mail Address: merve.sivridas@mmc.nl

Introduction: There is limited evidence for therapeutic drug monitoring (TDM) in inflammatory bowel disease (IBD) patients treated with vedolizumab (VDZ) during maintenance phase. An exposure-response relation has been reported in patients treated with VDZ in the GEMINI studies. Even though this relation has been proven, TDM is not general practice in managing VDZ.

Aims & Methods: This is a prospective, observational multicenter study of patients with IBD treated with VDZ in the maintenance phase. The aim of our study was to determine whether there is a correlation between VDZ trough levels and disease activity. Patient demographics, biomarkers and serum trough levels have been collected.

Clinical disease activity has been obtained by Harvey Bradshaw Index (HBI) for Crohn's disease (CD) and Simple Clinical Colitis Activity Index (SCCAI) for colitis ulcerosa (UC). Clinical remission was determined as HBI<5 and SCCAI <3. Biochemical remission was defined as <250 mg/kg.

Results: total of 149 patients (58 CD, 91 UC) were included. VDZ levels varied from 0.1 to 74.4 mg/L. The median VDZ level in CD patients in remission was 16.5 mg/L and 16,6 mg/L in UC patients. There was no significant correlation between trough VDZ level and clinical remission in both group of patients. Neither was there an association in biochemical remission and VDZ trough levels.

Conclusion: TDM in IBD patients showed a great interindividual variability in VDZ trough levels. In this population trough VDZ levels were not associated with clinical and biochemical remission during maintenance phase.

Contact E-Mail Address: francescam.digiorgio@libero.it

Introduction: Patients with inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC), have a strong perception on the role of food and many of them change their diet after diagnosis, adopting restrictions that can lead to anxiety, stress and nutritional deficiencies.

Orthorexia nervosa is a eating behavior that follows the pathological obsession for biologically pure and healthy food. Only a few studies have addressed the topic in patients suffering from disease of the gut and there are no studies in patients with IBD.

Aims & Methods: The aim of this study is to assess the risk of orthorexia in patients with IBD. The Donini standardized questionnaire ORTO-15 test was used to assess the risk of orthorexia in consecutive patients with IBD attending the clinic or hospitalized in a tertiary referral IBD center from southern Italy. Data regarding sex, age, marital and occupational status, weight, height, BMI, IBD type (UC or CD), time of diagnosis, IBD treatment, surgical history, disease activity, gluten or/and lactose intolerance and tobacco use were also collected.

Results: 48 patients, 22 CD and 26 UC, were enrolled. A risk of orthorexia (threshold value below 40) was found in 34 (70.8%) patients, 17 (50%) CD, 24 (70.6%) male and 10 (29.4%) female, mean age 50 ± 15 years, weight 66 ± 15 Kg, BMI 24 ± 5 . 19 (55.9%) patients were married and 15 (44.1%) were single/widowed/separated/divorced. 27 (79.4%) of them were employed and 7 (20.6%) unemployed. As far as concerns education, 13 (38.2%) patients had primary school /middle school degree and 21 (61.8%) had a high school or university degree.

Most of the patients (31 i.e. 91.2%) were on biologics and 3 (8.8%) on conventional therapy. 5 patients (15.7%) had been operated on. In 28 patients (82.4%) the disease was in remission/mild activity, in 6 (17.6%) in moderate/severe activity. Only 3 patients with orthorexia (8.8%) had a diagnosed food intolerance (lactose or gluten), 15 patients (44.1%) were smokers. Body weight (lower) and marital status (single) were significantly related to the risk of orthorexia while there were no significant correlations with IBD type or disease characteristics.

Conclusion: Orthorexia is common in IBD and is related to low body weight and single status. Though not yet recognized as an eating disorder, orthorexia can impact on life style and lead to unnecessary dietary restrictions. Appropriate counselling by trained dietitians is strongly warranted in IBD clinics.

Disclosure: Nothing to disclose.

Introduction: Assessment of pouchitis is performed using the validated pouchitis disease activity index (PDAI). Including clinical, endoscopy and histology subscores, this is invasive, labour-intensive and time-consuming. We aimed to assess whether inflammatory biomarkers and quality of life questionnaires would reflect change in disease activity in these patients.

Aims & Methods: Patients with acute pouchitis were prospectively recruited at the Rabin Medical Center in Israel, a major referral center for patients with a J-pouch. Acute pouchitis was diagnosed clinically by the treating physician in a patient with compatible clinical symptoms – i.e., a combination of increase in the number of bowel movements from baseline, urgency, bleeding and pain. Patients were treated with a 2-week course of antibiotics – either metronidazole and ciprofloxacin or metronidazole and doxycycline.

Full PDAI including clinical, endoscopic and histologic evaluation was performed at baseline and following 2 weeks of antibiotic therapy. Patients had comprehensive laboratory tests including fecal calprotectin (FC) mea-

surements at both time points. Patients also filled quality of life questionnaires (short inflammatory bowel disease questionnaire - SIBDQ, inflammatory bowel disease [IBD] disk) at both time points.

Outcomes of interest included the responsiveness of FC and quality of life questionnaires to change in pouch disease activity according to the PDAI. Paired analyses were performed to compare results between the 2-time points.

Results: Twenty patients were prospectively enrolled. At enrollment, the median age was 36 years IQR [27-56], females 12 (60%). The median interval from closure of ileostomy was 7 years IQR [2-17]. Median PDAI score: 9 IQR [8-11.5], median FC: 661 ug/g IQR [425-1261], median C-reactive protein: 1.1 mg/dl IQR [0.5-1.8] and median hemoglobin: 13.2 g/dl IQR [12.1-14.1].

Following 2 weeks of antibiotic treatment, PDAI decreased significantly from a median of 9 to 5 ($p=0.007$). This was mainly attributed to significant differences in both the clinical ($p=0.01$) and endoscopic subscores ($p=0.001$) but not the histologic subscore ($p=0.1$). FC decreased significantly between the 2 time points from a median of 661 ug/g to 294 ug/g ($p=0.02$).

Likewise, both quality of life questionnaires improved significantly following antibiotic therapy: The median SIBDQ increased from 44 to 50 ($p=0.02$) and the median IBD disk score decreased from 59 to 31 ($p=0.01$). Both antibiotic regimens had comparable effects. No serious adverse events were noted.

Conclusion: We show that FC and quality of life questionnaires reflect real time changes in inflammatory pouch activity modified by therapeutic interventions.

This study validates the use of FC as biomarker sensitive to change in pouch disease activity and encourage its use when managing patients with a pouch. The data may contribute to the development of a fully validated index of pouchitis disease activity for use in clinical practice and clinical trials.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel diseases (IBD) are chronic, relapsing, inflammatory disorders of the gut. In IBD many factors might lead to malnutrition, namely decreased food intake, intestinal malabsorption, chronic faecal loss of proteins and erythrocytes, and inflammation. Disease Related Malnutrition (DRM) is a specific type of malnutrition caused by a concomitant disease¹. To date prevalence and risk factors for DRM in IBD are not well defined².

Aims & Methods: The primary aim of the study was to define the prevalence of both DRM and microelement deficiency in patients with IBD; the secondary aim was to assess variables related to DRM.

A multicentre, cross-sectional study was performed including all adult patients with IBD at 11 centers in the Lombardy District, Northern Italy, adhering to the Gruppo di Studio per le Malattie Infiammatorie Intestinali (GSMII), over an inclusion period of two weeks. Nutritional status was assessed with the Body Mass Index (BMI) and the Malnutrition Universal Screening Tool (MUST).

According to the European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines³, DRM was defined as being at risk of malnutrition (MUST ≥ 1) combined with either a BMI $< 18.5 \text{ kg/m}^2$ or unintentional weight loss $> 10\%$ indefinite of time or $> 5\%$ over the last 3 months and BMI $< 20 \text{ kg/m}^2$ if < 70 years of age, or $< 22 \text{ kg/m}^2$ if ≥ 70 years of age.

Results: Among the 295 enrolled patients (148 Crohn's disease (CD), 147 Ulcerative colitis (UC)), the prevalence of DRM was of 23%, with no statistical difference between CD and UC.

In CD, DRM patients had higher median Crohn's Disease Activity Index (CDAI) than non-malnourished patients (128.5 vs 56.0, $p < 0.0001$), no difference in Disease Activity Index (DAI) was found in UC. When compared to non-malnourished IBD patients, those with DRM had higher median C-reactive protein (CRP) levels (0.3 mg/dl vs 0.24 mg/dl, $p = 0.04$) and lower albumin (3.9 g/dl vs 4.2 g/dl $p = 0.0019$), prealbumin (20 mg/dl vs 25 mg/dl, $p = 0.0082$) and haemoglobin levels (12.8 g/dl vs 13.7 g/dl, $p < 0.0001$).

At univariate logistic regression, the variables related to DRM were: current hospitalization ($p < 0.0001$, Odds Ratio [OR] 32.14, CI 3.94-262.21), hospitalization in the previous month ($p < 0.0001$, OR 17.23, CI 6.10-48.73), serum albumin ($p = 0.002$, OR 0.37, CI 0.18-0.70), BMI ($p < 0.0001$, OR 0.63, CI 0.55-0.71), CRP ($p = 0.005$, OR 1.39, CI 1.10-1.74), CDAI for CD ($p = 0.0028$, OR 1.00, CI 1.00-1.09), and male gender ($p = 0.01$, OR 0.50, CI 0.29-0.89). At the multivariate analysis, only hospitalization in the previous month was significantly associated to DRM ($p = 0.0007$, coefficient 0.5).

In 23% of IBD patients a deficiency of at least one micronutrient was present, with no difference between UC and CD. In particular vitamin B12 deficiency (level $< 197 \text{ pg/ml}$) was present in 8 CD (5.4%) and 4 UC patients (2.7%) and folate deficiency (levels $< 3.89 \text{ ng/ml}$) in 17 CD (11.5%) and 12 UC patients (8.2%); a ferritin level $< 15 \text{ mg/dl}$ was present in 20 CD (13.5%) and 22 UC patients (in 15%).

Conclusion: DRM and microelement malnutrition are highly prevalent conditions in the IBD population. DRM in IBD seems to be associated with intestinal disease activity and recent hospitalization.

LATENT TUBERCULOSIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE CANDIDATES TO BIOLOGICS: PREVALENCE AND EFFECTIVENESS OF CHEMOPROPHYLAXIS

M. Saladino¹, L.M. Amato¹, R. Gaudiano², L. Carrozza¹, D. Brinch¹, S. Muscarella¹, P. Melatti¹, F. Di Giorgio¹, M. Cappello¹

Contact E-Mail Address: saladinomarica@gmail.com

Introduction: Screening for latent tuberculosis (LTBI) is recommended before starting biologic agents in Inflammatory Bowel Disease (IBD) because of the risk of reactivation. Anti-TB prophylaxis is mandatory in those patients with a positive screening test.

Aims & Methods: The aim of this study is to assess the prevalence of LTBI in IBD-patients candidates for biological therapy, the reliability of screening tests and effectiveness of therapy. A retrospective observational study was conducted on all IBD-patients submitted to screening for treatment with biological agents between November 2019 and April 2021 in our tertiary referral center. Patient's characteristics (type of IBD, type of biologics, screening results, history of previous TB, concomitant therapy, TB prophylaxis) were analyzed in relation to outcomes.

Results: 394 IBD-patients (254 CD, 138 UC, 2 undetermined colitis, 241 males, mean age 46 yrs) were recruited. Mean age was 56,96 (SD $\pm$ 12,09) in patients with LTBI and 44,75 (SD $\pm$ 16,35) in those negative for LTBI ($p < 0,0001$), there were no other significant differences between the two groups.

All patients were screened for LTBI: 390 through quantiFERON-TB gold and 4 through TST; 361 patients (91,6%) were negative, 27 (6,85%) tested positive. 6 cases obtained a undetermined result (1,52%), most of them on steroids; 5 of them performed a repeat test (4 quanti-FERON-TB Gold and 1 TBSpot) with a negative result.

All patients with LTBI received prophylactic treatment: 19 isoniazid (INH), 5 rifampicin (RMP), 3 a combination of both. 73.68% completed INH treatment (9.21 $\pm$ 2.55 months), 26,32% stopped therapy for adverse reactions and were switched to rifampicin. Rifampicin treatment was completed by all patients without side effects. Biologics were started after one month. The majority of patients were treated with anti-TNF alfa agents (235), vedolizumab was used in 116, ustekinumab in 43. None of the patients submitted to TB prophylaxis presented a TB reactivation while on therapy, regardless of the type of biologic, and on follow-up.

Conclusion: Our results confirm that the prevalence of LTBI in our country is low but not negligible and is related to age. Quantiferon-TB-gold is confirmed as an accurate screening method for LTBI. Chemoprophylaxis either with RMP or INH proved to be highly effective in preventing reactivation, but safety is an issue especially for INH. LTBI is not a contraindication to biologics since none of the patients experienced a reactivation.

Introduction: Inflammatory Bowel Diseases (IBD) are chronic relapsing inflammatory diseases characterized by a progressive and disabling course which requires a strict long-term monitoring and timely optimization of treatment during a disease flare. [1, 2]

The use of telemedicine has developed quickly in recent years. In particular, mobile applications (Apps) have been developed for the remote monitoring of patients with IBD to ensure a tight control of the disease. [3-5]

During COVID-19 outbreak, we start adopting telemedicine solutions (tele-visits) and we start proposing an asynchronous digital solution to remote monitoring symptoms in IBD patients, the App Care4Today IBD (Bepatient, Paris, France), free of charge for patients as sponsored by Janssen (Beerse, Belgium).

Aims & Methods: First aim of the study was to evaluate the use and trust towards Care4today IBD App among IBD patients, and to identify possible determinants influencing patients' trust. Second aim was to evaluate differences in terms of clinical outcomes and patients' contacts with health care professionals (HCPs).

We performed a retrospective real-life observational single center case control study.

From April 2021 to May 2021, we have proposed to download Care4today IBD to consecutive IBD patients, while it was not proposed to a control group of consecutive IBD patients (June-August 2021).

Ease of use, patients' satisfaction, trust and prospective for future use were assessed through a 5 points Likert scale questionnaire adapted from the validated SUTAQ (Service User Technology Acceptability Questionnaire), a score of at least 4/5 was considered as agreement. Machine learning (ML) tools, decision tree (DT) and random forests (RF), were used to identify the determinants of patients' trust.

Demographic data and disease-related characteristics were extrapolated from patient's clinical records and collected. Clinical characteristics recorded during the activation date of Care4today IBD were considered as baseline conditions. The number of contacts with HCPs in the 6 months after the App activation were reported. Contacts were defined as outpatient accesses (visits or televisits, endoscopic and ultrasound examinations) and inpatient accesses (emergency room and hospitalization).

Results: Out of 176 enrolled patients, 120 patients used the App (68.2%), and 73 (41.5%) used it actively.

Among the patients who compiled the SUTAQ (61/173, 35.2%), 86.9% of patients trusted to use the App, 65.6% would recommend it to other patients with IBD and 59% found the App simple to use. The statements "the app can allow my HCPs to better monitor my condition" and "I believe that monitoring apps can be a useful tool for managing my disease" were agreed by 83.6%, and by 70.5%, respectively.

In contrast, disagreement (93.4% giving a score <3/5, and 86.9% giving a score ≤2/5) was expressed for the statement "Apps will replace my regular health and/or social care".

Regarding the ML analysis, the DT showed the variable that has been found to influence the most patients' trust is the conviction that the app is a tool useful for better monitoring of their disease by the HCP since it

represents the root of the tree which explains the final decision; the RF confirmed that this variable influenced the most patients' trust.

Considering contacts and clinical outcomes, no significant differences were observed among the two groups.

Conclusion: Forty percent of our patients actively used the Care4today IBD App, and approximately two-thirds of the respondents proved to be well disposed to its usage, showing a good level of confidence and trust in it.

Introduction: Inflammatory bowel diseases (IBD), such as Crohn's disease (CD) and ulcerative colitis (UC), are characterized by perpetual chronic relapsing inflammation of the intestines. Due to their large heterogeneity, it is difficult to find the right therapy for the right patient. Therefore, there is a need to find novel biomarkers for the monitoring of IBD. Mucosal barrier dysfunction and aberrant mucin expression are major hallmarks in the pathophysiology of IBD [1-2].

Furthermore, mucins are highly polymorphic which results in the occurrence of several mRNA isoforms. These mRNA isoforms could translate to proteins that exhibit functional differences. Currently, little attention has been given to the importance of mucin mRNA isoforms in IBD.

The aim of our study is to investigate IBD associated mucin mRNA isoforms and their potential as novel biomarkers for the evaluation of disease activity and the identification of IBD subtypes.

Aims & Methods: To obtain this goal, RNA was extracted from colonic and terminal ileal biopsies of IBD patients (both CD and UC) that underwent an endoscopy at the Antwerp University Hospital (UZA) for clinical reasons (i.e. acute flares or surveillance endoscopy when in remission). Additionally, patients without a history of IBD undergoing an endoscopy due to a positive faecal occult blood test (FOBT) which show no endoscopic abnormalities, were included as controls (Table 1).

Biopsies from a macroscopically inflamed (if present) and non-inflamed region from the same patient were used. The quality of the RNA samples was assessed with capillary electrophoresis and quantified using Qubit fluorometric quantitation. Library preparation was performed with the PacBio Iso-Seq multiplex protocol adapted for targeted transcriptome sequencing. Targeted capture was accomplished by using a custom-designed pool of probes, developed for the capture of MUC1, MUC2, MUC3A, MUC4, MUC5AC, MUC5B, MUC6, MUC7, MUC12, MUC13, MUC15, MUC16, MUC17, MUC19, MUC20, MUC21 and MUC22 gene transcripts.

Samples were sequenced on the PacBio Sequel platform at the University of Antwerp. The data was analysed by using the isoseq3-pipeline. The resulting high-quality isoform sequences were mapped, redundant isoforms collapsed (coverage 99% and identity 95%) and additional filtering with SQANTI3 [3] was performed.

	Colonic biopsies			Ileal biopsies		
	CD	UC	Control	CD	UC	Control
Non-inflamed	11	9	6	4	1	4
Inflamed	11	10	NA	1	1	NA

Table 1: A total of 58 samples were sequenced, comprising 47 colonic and 11 terminal ileum biopsies. The samples comprise a combination of inflamed and non-inflamed biopsies of both Crohn's disease (CD) and ulcerative colitis (UC).

Results: Throughout all samples, 77 unique isoforms with a high abundance (sum of counts >40) were identified, of which the majority originated from MUC13 (27) and MUC3A (18). The read count of some isoforms seems to suggest differential isoform expression between the different IBD subtypes.

Conclusion: Next, Illumina RNA-Seq will be used to confirm this observation. Future efforts will be directed towards quantifying the isoforms of interest and correlating their expression with disease activity and IBD subtypes.

Contact E-Mail Address: mara@nordicbio.com

Introduction: Crohn's disease (CD) is a relapsing-remitting inflammatory disease of the gastrointestinal (GI) tract characterized by high infiltration of neutrophils and other immune cells into the intestinal tissue, resulting in increased proteolytic mediated extracellular matrix (ECM) remodeling, reflecting mucosal damage. Disease management has substantially improved with the emergence of biologics such as the $\alpha 4\beta 7$ -integrin inhibitor vedolizumab (VEDO). However, considering the high rate of primary non-response to VEDO in patients with CD, there is an unmet need for predictive serum biomarkers capable of determining response to treatment prior to its initiation.

Aims & Methods: The aim of this study was to investigate whether biomarkers of neutrophil activity, mucosal damage, and ECM remodeling could serve as non-invasive tools for predicting long-term response to VEDO in patients with CD. Serum levels of human neutrophil elastase (HNE)-derived fragments of calprotectin (CPa9-HNE [serum calprotectin]) and matrix metalloproteinase (MMP)-derived fragments of type I (C1M), III (C3M), IV (C4M), and VI (C6Ma3) collagen, type III collagen formation (PRO-C3), basement membrane turnover (PRO-C4) and T-cell activity (C4G), were measured using protein fingerprint assays in patients with CD (n=32) before VEDO therapy. Long-term response was defined as VEDO treatment of at least 12 months.

Results: CPa9-HNE was significantly increased at baseline in non-responders compared with responders ($P < 0.05$). Biomarkers C1M, C3M, C4M, C6Ma3, PRO-C3, C3M/PRO-C3, C4M/C4G and PRO-C4/C4G were significantly increased at baseline in non-responders compared with responders (all $P < 0.05$, Table 1).

Biomarker	Continued use n = 17	Discontinued use n = 15	p-value
C1M (ng/ml)	36.1 [25.02–49.80]	108.6 [57.47–148.45]	0.001
C3M (ng/ml)	10.5 [9.43–11.81]	15.2 [13.07–16.44]	0.006
C3M/PRO-C3	1.6 [1.42–1.80]	2.6 [1.98–3.13]	0.008
C4M (ng/ml)	24.5 [22.36–28.16]	36.5 [28.24–46.68]	0.010
PRO-C4 (ng/ml)	182.0 [170.48–203.68]	266.8 [207.20–308.26]	0.010
C4M/C4G	1.4 [0.81–1.77]	2.0 [1.40–2.44]	0.020
PRO-C4/C4G	8.4 [6.02–12.56]	14.5 [9.66–17.12]	0.033
C6Ma3 (ng/ml)	0.6 [0.53–0.84]	0.8 [0.68–1.02]	0.015
CPa9-HNE (ng/ml)	231.7 [195.32–302.60]	401.2 [281.36–452.00]	0.003

Table 1. Baseline serum biomarker levels stratified by response to VEDO. Values are displayed as medians with IQR.

All biomarkers were able to predict response to VEDO at baseline (AUC [95% CI]: C1M 0.85 [0.75–0.98]; C3M 0.79 [0.62–0.95]; C4M 0.77 [0.6–0.93]; C6Ma3 0.75 [0.58–0.92]; C3M/PRO-C3 0.78 [0.6–0.95]; C4M/C4G 0.74 [0.56–0.92]; PRO-C4/C4G 0.72 [0.54–0.9]; CPa9-HNE 0.81 [0.66–0.96]; all $P < 0.05$).

The proportion of long-term users of VEDO treatment was highest in the first tertile for all the biomarkers (73–91%), which decreased in a concentration-dependent manner across the second and third tertiles, indicating that patients with the lowest concentrations of these markers less frequently discontinued treatment at one year after initiation.

Conclusion: Baseline levels of serum biomarkers for neutrophil activity (CPa9-HNE [serum calprotectin]) and mucosal damage (C1M, C3M, C4M, C4G, C6Ma3, PRO-C4, and PRO-C3) could predict long-term response to VEDO in patients with CD. Therefore, these biomarkers could aid in early decision making concerning treatment with vedolizumab in patients with CD.

Introduction: The simultaneous increasing prevalence of nonalcoholic fatty liver disease (NAFLD) and inflammatory bowel disease (IBD) has been reported, but the effects of NAFLD on outcomes of IBD has yet to be elucidated. We investigated whether the presence of NAFLD could influence the outcomes of patients with IBD.

Aims & Methods: A total of 4,114 patients who were diagnosed as having IBD between November 2005 and November 2020 were studied. Hepatic steatosis and fibrosis was assessed using hepatic steatosis index (HSI) ≥ 30 and fibrosis-4 (FIB-4) ≥ 1.45 , respectively. Primary outcome was a clinical relapse defined as IBD-related admission, IBD-related surgery, or first use of corticosteroids, immunomodulators, or biologics agents.

Results: The prevalence of NAFLD in IBD patients was 16.7%. Patients with hepatic steatosis and advanced fibrosis were older, higher BMI and had a higher prevalence of diabetes at baseline (all $p < 0.05$).

Adjustment	By HSI ≥ 30			By FIB-4 ≥ 1.45		
	Adjusted HR	95% CI	p value	Adjusted HR	95% CI	p value
Model 1	1.510	1.161-1.964	0.002	0.705	0.504-0.986	0.041
Model 2	1.497	1.144-1.959	0.003	0.693	0.496-0.969	0.032
Model 3	1.687	1.283-2.219	<0.001	0.919	0.642-1.315	0.643
Model 4	1.697	1.291-2.230	<0.001	0.949	0.663-1.359	0.777
Model 1: age, gender, duration of inflammatory bowel disease diagnosis, and body mass index.						
Model 2: Model 1 + smoking status, hypertension, and diabetes.						
Model 3: Model 2 + white blood cell count, hemoglobin, platelet count, erythrocyte sedimentation rate, serum C-reactive protein, total bilirubin, aspartate aminotransferase, alanine aminotransferase, gamma-glutamyltransferase, and serum albumin.						
Model 4: Model 3 + ulcerative colitis disease location.						

Table 3. Adjusted HRs with 95% CIs of steatosis and significant fibrosis to predict clinical relapse in UC patients.

In our multivariable cox regression models, hepatic steatosis was independently associated with the increased risk of clinical relapse in UC (hazard ratio [HR]=1.697, 95% confidence interval [CI] 1.291–2.230; $p < 0.001$) and CD patients (HR=1.536, 95% CI 1.130–2.087; $p = 0.006$).

In contrast, Advanced liver fibrosis was not significantly associated with the risk of clinical relapse in UC and CD patients (all $p > 0.05$).

Conclusion: The hepatic steatosis was independently associated with the increased risk of clinical relapse in UC and CD patients, whereas fibrotic burden in liver was not. Further studies should investigate whether the assessment and therapeutic intervention of NAFLD improves clinical outcomes in IBD patients.

Disclosure: Nothing to disclose.

P0338

USE OF PLATELET-LYMPHOCYTE RATIO AND NEUTROPHIL-LYMPHOCYTE RATIO AS A POTENTIAL PROGNOSTIC MARKER IN IBD

O. Fagan¹, C. McGrath¹, H. Logan¹, E. Slattery¹

¹University Hospital Galway, Gastroenterology, Galway, Ireland

Contact E-Mail Address: olgafagan@gmail.com

Introduction: Platelets and Platelet-Lymphocyte Ratio (PLR) have been suggested as a non-invasive biomarker for IBD.

Aims & Methods: To assess whether neutrophil-lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) predict response in IBD patients with an acute severe flare.

IBD patients admitted with acute severe colitis between January-2017-December-2019 were assessed.

Results: 64-patients (88% (n=56) UC, 9% (n=6) CD, 3% (n=2) indeterminate) were included (55% male, 38-years (11-90years)). Of those with UC, 59% (n=33) had pancolitis, 39% (n=22) had left-sided colitis and 1 had proctitis. Amongst those with CD, 83% (n=5) had colonic disease and 17% (n=1) had ileal disease. Examining therapies received by the cohort prior to admission: 48% (n=21) had received biologic therapy, 32% (n=18) had received immunotherapy, and 3% (n=2) had underwent surgery previously. 33% (n=21) were on biologic therapy at admission.

36% (n=23) received rescue-treatment (95% infliximab, 5% ciclosporin). There was an association between total platelet count (Z-score 9.76, $P < 0.05$), NLR (Z-score 9.76, $p < 0.05$) and PLR (Z-score 9.76, $P < 0.05$) and risk of colectomy.

Patients with colectomy-free-survival at 1-year displayed lower NLR and PLR compared with those who did not (6.7 [1.1-33.0] vs 7.5 [1.7-21.00]; $p = 0.39$ and 242 [106-1438] vs 259 [155-1300]; $p = 0.11$).

Patients who received rescue-therapy (n=23), had lower week-8 PLR and NLR and persistence of drug at 6-months ($p < 0.05$). Lower platelet count and PLR at 8-weeks post rescue-therapy was a predictor of persistence of therapy at 6-months (262 [267-469] v 348 [373-558], $p = 0.01$ and 218 [82-521] v 256 [71-630], $p = 0.34$), conversely CRP was not (8 [1-36] v 2.9 [1-6], $p = 0.23$).

Conclusion: Higher platelet count, NLR and PLR on admission with acute severe colitis are associated with progression to colectomy. NLR and PLR should be considered an important prognostic tool in the assessment of acute severe colitis and when elevated should form part of decision making with respect to early escalation of rescue therapy. Platelet count and PLR at 8-weeks post rescue-therapy may also act as a biomarker for prolonged response to therapy.

Disclosure: Nothing to disclose.

P0339

DETECTION OF IRON RESTRICTED ERYTHROPOIESIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: OVERCOMING THE INFLAMMATION TANGLER

A. Aksan^{1,2}, C. Mangold³, J. Stötzel^{1,2}, K. Farrag^{1,4}, L. Tessmer^{1,4}, O. Schröder^{1,4}, J. Stein^{1,4,5}

Introduction: Serum ferritin can indirectly estimate body iron stores and is the most specific biomarker of absolute iron deficiency (AID). However, in inflammatory bowel disease (IBD) the acute-phase response can obscure AID. Patients with active IBD may also have anaemia of chronic disease (ACD), i.e., normal/increased stores but with limited iron availability for erythropoiesis (iron-restricted erythropoiesis, IRE). The European Crohn's & Colitis Organization suggests adding biomarkers to distinguish functional ID from AID in ACD.

We compared the utility of red cell indices and biochemical markers to detect IRE in IBD patients and set a decision threshold for selection of markers to discriminate AID and iron sequestration.

Aims & Methods: We aimed to compare the utility of red cell indices and biochemical markers to detect IRE in IBD patients and set a decision threshold for selection of markers to discriminate AID and iron sequestration. An observational cross-sectional study was conducted in IBD patients. Blood samples were analysed for CBC, iron status (serum ferritin, SF; transferrin saturation, TSAT; serum iron % of hypochromic red cells, %HYPO; reticulocyte haemoglobin content, CHr; soluble transferrin receptor, sTfR) and high sensitivity CRP (hs-CRP) as inflammation marker by standard methods. sTfR-F index was calculated (sTfR (mg/L)/log¹⁰ SF (µg/L)).

First, patients with SF<30µg/L were selected as controls consistent with AID to define decision thresholds for iron markers in patients with SF≥30µg/L. This decision threshold was then used to evaluate IRE in patients with SF≥30µg/L. Last, the accuracy of iron markers in the presence/absence of inflammation were assessed and a diagnostic threshold determined for each context.

Results: 312 IBD patients (159f/153m;163CD/149UC;42.7±14.5y) were enrolled; 122/312(39.1%) had inflammation. 43/312 patients with SF <30 µg/L were assigned to the AID-control group. Results in controls were: TSAT (cut-off 20%; AUC^{ROC} 0.730;sens.65%, spe.34%), %HYPO (3.5%; 0.733;42%, 93%), CHr (32pg; 0.713; 51%, 86%), sTfR (2.70mg/L; 0.775; 81%, 63%), sTfR-F (2.01; 0.914; 88%, 88%). sTfR-F was used as reference for IRE in patients with SF ≥30 µg/L.

Patient group	Value	TSAT (%)	SF (µg/L)	%HYPO	CHr (pg)	sTfR (mg/L)
All patients	AUC ^{ROC}	0.761	0.888	0.738	0.708	0.966
	Sen./Spe.%	67/71	52/79	39/96	43/92	91/87
	Cut-off	20 %	30 µg/L	3.5 %	32 pg	2.7 mg/L
Patients with inflammation	AUC ^{ROC}	0.755	0.861	0.845	0.729	0.962
	Sen./Spe.%	68/59	90/54	60/94	55/87	90/98
	Cut-off	20 %	100 µg/L	3.5 %	32 pg	3.7 mg/L
Patients without inflammation	AUC ^{ROC}	0.774	0.906	0.717	0.708	0.972
	Sen./Spe.%	67/78	56/99	32/97	38/95	97/82
	Cut-off	20 %	30 µg/L	3.5 %	32 pg	2.7 mg/L

Table 1. Accuracy of markers as detectors of IRE in patients with IBD.

Conclusion: sTfR had the best accuracy as a sole marker to detect IRE in patients with and without inflammation, with a higher cut-off in the context of inflammation. Addition of SF in patients without inflammation had additional value. The relative cost-effectiveness of the markers alone or in combination is under investigation.

RENAL INVOLVEMENT IN A COHORT OF PAEDIATRIC PATIENTS WITH INFLAMMATORY BOWEL DISEASE

A. Kourti¹, E. Stefos¹, I. Kanavaki¹, D. Bacharakis², D. Polymeros³, P. Matsota⁴, S. Fessatou¹

¹Department of Paediatric Gastroenterology, Hepatology and Nutrition, 3rd Department of Paediatrics, Attikon University General Hospital, National and Kapodistrian University of Athens, Athens, Greece, ²Nephrology Unit, Department of Internal Medicine, Attikon University General Hospital, National and Kapodistrian University of Athens, Athens, Greece, ³Attikon University Hospital - Department of Hepatogastroenterology, 2nd Department of Internal Medicine, Athens, Greece, ⁴Second Department of Anesthesiology, Attikon University Hospital, National and Kapodistrian University of Athens, Athens, Greece

Contact E-Mail Address: sfessatou@yahoo.gr

Introduction: Inflammatory Bowel Disease (IBD) is a chronic, relapsing inflammatory disorder that predominantly affects the gastrointestinal tract. Renal involvement in IBD is rather uncommon and ranges from 4-23% in adults and 1-2% in children with IBD. It can be explained by different mechanisms – IBD activity independent, IBD activity dependent, metabolic consequences, amyloidosis and medication adverse effects. In our study we aimed to describe the spectrum of renal involvement in our IBD patients.

Aims & Methods: This is a retrospective analysis of renal function of paediatric IBD patients that are being followed in our pediatric gastroenterology department during the last three years.

Results: The study involved 75 IBD patients, aged 4-17years old. 44% were male and 56% female, 67% had Crohn's Disease (CD) and 33% Ulcerative Colitis (UC). Of these IBD patient's renal involvement was observed from urinalysis in 12 (16% - 8 with CD and 4 with UC): 7 patients had only proteinuria, 3 proteinuria and hematuria and 2 proteinuria and glycosuria. Further investigation with renal ultrasound, nephrolithiasis tests, timed 24-hour urine collection for quantitative measurement of protein excretion, serum urea, creatinine, C3/C4 and antinuclear antibody testing (ANA) was performed. The severity of IBD was recorded based upon PCDAI and PUCAI scores. Four patients underwent renal biopsy (table). Of all the 12 patients: in 4 patients renal damage was due to medication adverse effect (reversed after discontinuation of mesalazine), 2 had glomerulone-

phritis (IgA nephropathy and focal segmental glomerulonephritis), 1 had thin basement membrane disease, and another one had pyelonephritis in combination with chronic active tubulointerstitial nephritis, possible due to mesalazine. Three patients had IBD-related dependent renal involvement and 1 resulted in chronic renal failure due to amyloidosis.

Patient/ Disease	Ur / Cr	Pro	Bld	Glu	Disease activity	5-ASA	Further tests	Biopsy	Intervention
1-UC	normal	+1	-	+2	PUCAI 20	Yes	normal	No	IBD-dependent renal involvement
2-CD	normal	+1	-	-	PCDAI <10	Yes	normal	No	Recession after discontinuation of mesalazine
3-CD	normal	+2	-	-	PCDAI <10	Yes	normal	No	
4-CD	Elevated	+2	-	-	PCDAI <10	Yes	normal	No	
5-CD	Ur normal	+1	-	-	PCDAI <10	Yes	normal	No	
6-CD	Normal	+1	-	-	PCDAI <10	No	Takayasu arteritis,	Yes	Normal renal function
7-CD	normal	+3	+2	-	PCDAI <10	No	PET-scan (+) glomerulonephritis Severe Proteinuria IgA Nephropathy	Yes	
8-UC	Elevated Cr at acute episode of pyelonephritis	+2	+1	-	PUCAI 30	Yes	Urinary casts	Yes	Recession after discontinuation of mesalazine and chemoprophylaxis for urinary tract infections
9-CD	normal	+1	+2	-	PCDAI <10	No	normal	No	Thin basement membrane disease
10-CD	normal	+2	-	-	PCDAI 25	Yes	normal	No	Discontinuation of mesalazine IBD-related dependent renal involvement
11-CD	Elevated Cr	+1	-	+1	PCDAI 20	Yes	normal	No	Discontinuation of mesalazine IBD-related dependent renal involvement
12-UC	Elevated Ur, Cr	+3	-	-	PUCAI 20	Yes	Severe proteinuria	Yes	Chronic renal failure

Table: Laboratory tests, renal biopsy and diagnosis in paediatric IBD patients with renal involvement.

Conclusion: A high index of clinical suspicion is needed for the early diagnosis and prevention of IBD-related renal manifestations and complications.

Disclosure: Nothing to disclose.

P0341

A PHARMACIST-LED POST INDUCTION REVIEW CLINIC IMPROVES COMPLIANCE WITH KEY PERFORMANCE INDICATORS FOR PATIENTS NEWLY STARTED ON BIOLOGIC THERAPIES IN INFLAMMATORY BOWEL DISEASE

D. Al-Zarrad¹, A. Chana¹, L. Dyall¹, U. Meade¹, N. Arebi¹, N. Kamperidis¹

¹St Marks Hospital- London Northwest University Healthcare NHS Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: dania.al-zarrad@nhs.net

Introduction: Biologic therapies induce and maintain long term remission in Inflammatory Bowel Disease. 30% of patients fail to respond to induction regimens.¹ Early identification of these patients avoids unnecessary drug exposure with associated costs. The IBD standards as per registry² recommends a post-induction, and a 12 monthly review for all newly initiated biologic therapy as a key performance indicator (KPI). We therefore set up a dedicated Post Induction Review (PIR) clinic to meet the KPI and evaluated its clinical effectiveness.

Aims & Methods: The PIR clinic was independently run by an IBD specialist pharmacist, following a period of training under physician supervision. Data was captured using a pro-forma documenting baseline demographics, disease status, previous and current medical therapy, and response using disease activity indices (Harvey-Bradshaw index for Crohn's disease (CD), and Partial Mayo score for Ulcerative colitis (UC)).

The primary outcome was the proportion of patients who attended a PIR, and a 12-month review, according to the summary of product characteristics (SPC) for each biologic.

Secondary outcomes were appropriate escalation of non-responders and significant adverse drug reactions to a physician and relevant documentation of disease activity indices. 50 consecutive patients, who attended the new PIR clinic between September 2020 to January 2021, were compared with 30 randomly selected biologic patients from 2019-2020 (control group).

Results: The CD and UC populations are 32(64%) CD patients in PIR clinic were compared to 17 (57%) in the control group and UC patients 18(36%) in PIR compared to 13(43%) in control group. Median time from starting biologic to PIR clinic was 10 weeks compared to 11.5 weeks in the control group.

Table 1 summarises the comparative outcomes between PIR clinic patients versus those started on biologic therapy prior to the PIR clinic. Three patients were excluded from PIR group when analysing documented disease activity scores due to prior surgeries/stomas. Prior to introduction of PIR clinic programme it was challenging to track patients newly started on biologics.

There was an overall improvement with PIR being conducted in line with the SPCs for infliximab, adalimumab, ustekinumab and vedolizumab (UC). The PIR assessment following induction with CD was slightly delayed compared to control: the reasons for this include lack of appointment slots, and administrative issues with the appointment bookings.

More importantly there was a marked improvement of escalation in therapy for non-responders within 1 month from 3% to 50%; and in 12 months follow-up arranged from 73% to 98%.

	Pre-PIR clinic (Control) N=30	PIR Clinic N=50
PIR review as per the SPC		
Infliximab (at weeks 10-12)	3 (27%)	6 (55%)
Adalimumab (at week 10)	0 (0%)	2 (40%)
Vedolizumab CD (at weeks 6-8)	1 (33%)	2 (22%)
Vedolizumab UC (at weeks 8-10)	1 (14%)	9 (90%)
Ustekinumab (at weeks 14-16)	0 (0%)	1 (7%)
Documented disease activity indices	4 (13%)	8 (16%)
Primary non-response and escalation to physician with change in therapy made within 1 month	1 (3%)	2 (50%)
12 months follow-up arranged after initiating biologic treatment	22 (73%)	49 (98%)

Table1: Comparative summary of the KPIs for biologic therapy of the PIR clinic outcomes, and prior to initiation of the PIR clinic programme

Conclusion: To our knowledge, this is the first study looking the effectiveness at a dedicated pharmacist-led PIR clinic with a general improvement in KPI. This model of care can be implemented in other similar healthcare settings and utilise skills mix of the IBD team.

Future attention will be focused on improving the PIR assessments for CD patients started on vedolizumab this is due to the fact that an additional dose can be given at week 10.

PREDICTIVE MODEL FOR OUTCOMES IN INFLAMMATORY BOWEL DISEASE PATIENTS ON MAINTENANCE INFLIXIMAB THERAPY

R. Wong¹, P. Charilaou¹, A. Hemperly², L. Qin³, Y. Pan¹, P. Mahtani¹, R. Longman¹, B. Boland², P. Dulai², A. Holmer², D. Lukin¹, S. Singh², M. Valasek⁴, W.J. Sandborn², E. Scherl¹, N. Vande Casteele², R. Battat¹
¹Weill Cornell Medicine, Dept of Medicine, Division of Gastroenterology and Hepatology, New York, United States, ²University of California San Diego, Department of Medicine, Division of Gastroenterology, La Jolla, United States, ³Weill Cornell Medicine, Dept of Pathology, New York, United States, ⁴University of California San Diego, Department of Pathology, La Jolla, United States

Contact E-Mail Address: rew9046@nyp.org
Introduction: No data exist on predictors of outcomes for inflammatory bowel disease (IBD) patients on maintenance infliximab (IFX) therapy, or on models using validated histologic data and drug levels in maintenance.
Aims & Methods: To create a prediction model of future outcomes in IBD patients on maintenance IFX.
Adults on maintenance (≥ week14) IFX with serum trough concentration within 90 days of colonoscopy with biopsy were included. Ileostomy or ileal pouch-anal anastomosis were excluded. Patients who discontinued IFX after drug level measurement were included only if outcomes existed >90 days post baseline, were off IFX <90 days, and were not on new therapy for >90 days. Data were collected through chart review. A blinded pathologist provided histologic scoring (Robarts Histopathologic Index (RHI)). The primary composite endpoint (negative outcome) was either IBD-related surgery, hospitalization or objective inflammation (endoscopic activity simple endoscopic score-Crohn's Disease ≥3, Mayo endoscopic score ≥1 for ulcerative colitis), or if unavailable, fecal calprotectin ≥50ug/g, or C-reactive protein (CRP) ≥1.0).
Multivariable analysis included predictors of the primary outcome with p<0.1 on univariable analysis. IFX levels and RHI thresholds were determined using receiver operator characteristic curve (AUC). A clinical prediction score was created based on each variable's odd ratios on multivariable analysis. The model was trained on an internal cohort (Weill Cornell Medicine) and externally validated (University of California, San Diego).
Results: In 81 included patients (internal cohort n=48, external n=33), both cohorts had similar characteristics, RHI scores, and IFX concentrations. Baseline IFX <9.3 ug/mL (AUC 0.64, p=0.04) and RHI >12 (AUC 0.60, p=0.07) were optimal thresholds to predict negative outcomes. They were also the only variables with p<0.1 on univariable analysis (Table 1).
Other predictors were not significant, including female (OR 0.90, 95% CI 0.28-2.88, p=0.863), age (OR 1.01, 95% CI 0.98-1.05, p=0.494), Crohn's disease (OR 0.90, 95% CI 0.28-2.8, p=0.853), baseline active endoscopic disease (OR 3.26, 95% CI 0.77-13.8, p=0.109), baseline clinical remission

(OR 1.03, 95% CI 0.32-3.33, p=0.960), baseline steroid use (OR 0.79, 95% CI 0.22-2.88, p=0.725), baseline immunomodulator use (OR 0.7, 95% CI 0.18-2.76, p=0.610), baseline IBD surgery (OR 1.67, 95% CI 0.36-7.67, p=0.512), baseline IFX clearance (mL/day) (OR 0.13, 95% CI 0-35.02, p=0.472), CRP (OR 0.37, 95% CI 0.1-1.37, p=0.137), and fecal calprotectin (OR 2.17, 95% CI 0.26-17.89, p=0.473). On multivariable analysis both IFX<9.3ug/mL and RHI>12 met model inclusion criteria (Table 1).
The 2-variable clinical predictive scoring model had good discrimination for negative outcomes for training (AUC 0.71, 95% CI 0.57-0.84) and external (AUC 0.73, 95% CI 0.57-0.89) cohorts.
In the joint cohort (n=81), IFX <9.3ug/mL (OR 5.3, 95% CI 1.9-14.8, p=0.01) and RHI score >12 (OR 3.4, 95% CI 1.1-10.3, p=0.03) were significantly associated with the primary outcome. Observed scores of 0, 1 and 2 predicted risks for negative outcomes of 15% (external)-23% (internal), 46% (internal)-50% (external), and 75% (external)-100% (internal), respectively.
The model performed similarly well on the joint cohort for objective inflammation (AUC=0.71 (0.60-0.82), IFX<9.3ug/mL (OR 3.7, 95%CI 1.3-10.8, p=0.02), RHI>12 (OR 4.4, 95%CI 1.5-13.4, p=0.008). IFX drug level alone performed similarly well to the unbiased 2-variable model (internal cohort: complete model: AUC 0.70 [0.55-0.85] vs. IFX alone: AUC 0.65 [0.51-0.79], p=0.5, external cohort: complete model: AUC 0.70 [0.52-0.88] vs. IFX alone: AUC 0.71 [0.54-0.87] p=0.9).

	Univariable Analysis	Univariable Analysis	Multivariable Analysis	Multivariable Analysis
Predictor	OR [95% CI]	p-value	OR [95% CI]	p-value
IFX Drug Level <9.3 ug/mL	3.61 [1.06-12.25]	0.039	4.31 [1.16-16.03]	0.029
RHI Score >12	3.26 [0.89-14.91]	0.072	4.57 [0.907-20.97]	0.051

Scoring system (OR rounded to closest 0.5 and divided by 4.5):
IFX Drug level <9.3ug/mL = 1 point, RHI >12 = 1 point

Table 1. Multivariable Prediction Model for IBD-related Hospitalization/ Surgery or Objective Inflammation

Conclusion: In patients on maintenance IFX therapy, a model using IFX concentration and RHI score predicted patient outcomes. Maintenance IFX concentrations alone performed similarly well.
Disclosure: Nothing to disclose.

P0343
TOXIN GENE POLYMERASE CHAIN REACTION ASSAY FOR CLOSTRIDIoidES DIFFICILE CAN BE AN INDICATOR SUGGESTING THE NEED FOR RAPID ESCALATION OF TREATMENT IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE
S. Kim¹, J. Jung², H.-J. Lee¹, J.P. Im¹, J.S. Kim¹, S.-J. Koh¹
¹Seoul National University College of Medicine, Internal Medicine and Liver Research Institute, Seoul, Korea (Republic of), ²Seoul National University College of Medicine, Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: seulji.k@snu.ac.kr
Introduction: Toxin gene polymerase chain reaction (PCR) assay for *Clostridioides difficile* (*C.difficile*) is the most sensitive test among the diagnostic methods for *C.difficile* infection (CDI) and thus, PCR positivity could be a true infection, but it could also simply be colonization. Although there have been several studies on the incidence rate of CDI in IBD patients and the prognosis of CDI co-occurrence with IBD, there have been no studies on the meaning of the *C. difficile* PCR test result itself in patients with IBD regardless of CDI symptoms.

Aims & Methods: This study aimed to elucidate the role of toxin gene PCR assay for *C.difficile* in predicting the course of inflammatory bowel disease (IBD). This study also investigate the potential factors associated with the PCR positivity in patients with IBD.

This is a retrospective single-center cohort study at Seoul national university hospital from 2020 to 2021. Patients with IBD who underwent stool analysis with Toxin gene PCR of *C.difficile* were retrospectively enrolled. Medical records were reviewed and data including IBD subtype, extent, severity and medications were collected. Patients were followed for 180 days after the date of PCR test to assess the clinical course of IBD.

Results: A total of 156 patients with IBD who underwent a *C.difficile* toxin PCR test were enrolled in this study, including 123 with ulcerative colitis (UC) and 33 with Crohn's disease (CD). Among them, the PCR-positive rate was 16.03%.

Further analyzing the PCR-positive patients, 76% of patients were treated for CDI and 24% of those did not receive treatment. 89% of the treated patients received oral vancomycin, and 11% of patients received metronidazole.

Although there was no significant difference in baseline IBD severity between the PCR positive group and the PCR negative group, the patients with PCR positivity had a statistically significant increase in drug escalation for IBD treatment within 180 days after PCR test (48% in PCR positive group vs 4.58% in PCR negative; $P=0.006$).

This result was maintained even after adjusting through inverse probability of treatment weighting (IPTW) based on the propensity score. In the multivariable analysis, treatment with azathioprine was the only risk factor associated with PCR positivity in patients with IBD (OR 5.19, CI 1.32-23.3, $P=0.023$).

Conclusion: *C.difficile* toxin PCR positive IBD patients showed a significantly higher rate of treatment escalation, regardless of IBD severity. Therefore, it is important to carefully monitor PCR-positive IBD patients and to intervene in treatment quickly without delay, keeping in mind that PCR-positive IBD patients are more likely to worsen symptoms. Further research is needed on the underlying mechanism between PCR positivity and the course of IBD.

Disclosure: Nothing to disclose.

P0344

HIGHER ADALIMUMAB TROUGH LEVELS ARE ASSOCIATED WITH HISTOLOGIC REMISSION AND MUCOSAL HEALING

R. Wong¹, L. Qin², Y. Pan¹, P. Mahtani¹, R. Longman¹, D. Lukin¹, E. Scherl¹, R. Battat¹

¹Weill Cornell Medicine, Dept of Medicine, Division of Gastroenterology and Hepatology, New York, United States, ²Weill Cornell Medicine, Dept of Pathology, New York, United States

Contact E-Mail Address: rew9046@nyp.org

Introduction: Therapeutic drug monitoring is a mainstay in Crohn's disease (CD) and ulcerative colitis (UC). Data demonstrate that elimination of histologic inflammation is associated with improved outcomes.^{1,2} Recent data found reduced efficacy of adalimumab (ADA) to achieve histologic remission defined using the Robarts Histopathologic Index (RHI).³

A plausible explanation for suboptimal histologic outcomes may be inadequate drug exposure. However, data on the relationship between serum adalimumab concentrations and histologic outcomes with validated indices are lacking.

Aims & Methods: Aim: To perform the first real-world study assessing the relationship between adalimumab concentrations and a validated histologic disease activity index.

Patients from a tertiary IBD center with adalimumab (ADA) trough drug concentrations measured during maintenance therapy (≥ 14 weeks), and colonoscopy with biopsy performed within 90 days from 2013-2020 were included. Chart review was performed for demographic data and disease characteristics. RHI scores were assigned to biopsies by a blinded pathologist. Rates of endoscopic (CD: absence of ulcers, UC: Mayo endoscopic score <2) and histologic (RHI = 0) remission were assessed. Mucosal healing (MH) was defined as achieving both endoscopic and histologic remission.

The primary analysis evaluated the relationship between drug concentration and histologic remission using receiver operating characteristic curve analysis. Outcome proportions were compared above and below identified optimal (youden) thresholds using Fisher's exact test. Serum ADA concentrations were measured using homogeneous mobility shift assay (Prometheus Laboratories, San Diego).

Results: Thirty-six patients were included (26 CD, 9 UC, Table 1). Median cohort age was 34 years old, and 56% were female. The median ADA drug concentration was 11.1ug/mL (IQR: 7.0-15.5ug/mL). Median time from treatment initiation to drug concentration measurement was 103 weeks (Table 1).

The area under the curve for ADA concentrations to identify histologic remission was 0.80 (95% CI 0.61-0.99). The optimal ADA concentration was ≥ 16.3 ug/mL (sensitivity 70%, specificity 90%). Patients with ADA ≥ 16.3 ug/mL had higher histologic remission rates (78%) compared to lower ADA concentrations (14%, $p=0.002$). ADA ≥ 16.3 ug/mL had higher endoscopic remission (100%) compared to lower ADA levels (57%, $p=0.04$). ADA ≥ 16.3 ug/mL also had higher MH rates (86%) compared to lower levels (12%, $p=0.001$).

	N (%)
Median Age at Drug Level (years)	34
Gender (female)	20 (0.56)
Type of IBD	
Crohn's Disease	26 (0.72)
Ulcerative Colitis	9 (0.25)
Indeterminate Colitis	1 (0.02)
Adalimumab	
Median Drug Level Concentration (ug/mL) [IQR 25-75]	11.1 [7.0-15.5]
Median Dose (mg)	40
Median Frequency (every X weeks)	2
Median Weeks of Therapy (wk)	103
Endoscopy	
CD: Presence of ulcers (lack of remission)	7/24 (0.29)
UC: Mayo Score <2 (presence of remission)	1/4 (0.25)
Histology	
RHI score = 0 (histologic remission)	10/30 (0.33)
Median RHI Score	8.5
Mucosal Healing	
Endohistologic Remission	8/24 (0.33)

Table 1. Cohort Demographics (n=36)

Conclusion: These first real-world data on the relationship between adalimumab concentrations and RHI demonstrate higher adalimumab drug concentrations are strongly associated with histologic remission and MH. A serum ADA concentration that is higher than traditional targets (≥ 16.3 ug/mL) is needed for histologic remission.

Contact E-Mail Address: a.r.bourgonje@umcg.nl

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are characterized by intestinal inflammation and increased extracellular matrix (ECM) remodeling, which are key pathophysiological mechanisms in patients with IBD and strongly interrelated and may culminate into mucosal damage. Alterations in intestinal ECM turnover as well as macrophage and neutrophil activity may be reflected by secreted products that are released into the circulation.

In this study, we aimed to investigate associations between serum biomarkers of neutrophil activity (serum calprotectin) and collagen degradation (mucosal damage), and biochemical and endoscopic disease activity in patients with IBD.

Aims & Methods: Serological biomarkers of collagen formation (PRO-C3, PRO-C4, PRO-C6), matrix metalloproteinase (MMP)-mediated collagen degradation (C1M, C3M, C4M, C4G, C6Ma3) and intestinal inflammation (VICM [macrophage activity], human neutrophil elastase-derived fragment of calprotectin (CPa9-HNE [serum calprotectin, neutrophil activity])) were measured using neo-epitope protein fingerprint technology in 100 patients with IBD (CD: $n=44$; UC: $n=56$). Biochemical disease activity was assessed using C-reactive protein (CRP) levels and available faecal calprotectin (FCal) levels. Endoscopic disease activity was determined using the Simple Endoscopic Score for CD (SES-CD) and Mayo endoscopic subscore for UC.

Results: C1M strongly associated with elevated CRP levels (defined as $>5\text{mg/L}$, $P<0.001$) in patients with IBD and significantly associated with faecal calprotectin levels in patients with UC (Spearman's $\rho=0.75$, $P<0.001$). In patients with CD, C1M reasonably discriminated between patients with mild and moderate-to-severe endoscopic disease activity (AUC=0.73, $P=0.01$), whereas this discrimination was more subtle in patients with UC (AUC=0.68, $P=0.08$). CPa9-HNE levels were significantly increased in patients with elevated CRP levels ($P=0.002$ for both CD and UC) and associated best with faecal calprotectin levels in patients with CD compared with UC (CD: $\rho=0.43$, $P=0.06$; UC: $\rho=0.20$, $P=0.45$).

Finally, CPa9-HNE levels were able to discriminate between mild and moderate-to-severe endoscopic disease activity in patients with CD (AUC=0.75, $P<0.01$).

Conclusion: C1M and CPa9-HNE levels associate with biochemical (CRP, FCal) and endoscopic disease activity in patients IBD, where C1M demonstrated higher accuracy in UC and CPa9-HNE appeared to be more useful

in CD. Therefore, C1M and CPa9-HNE could serve as surrogate biomarkers for the assessment of disease activity in patients with UC and CD, respectively. Our results should be validated in additional prospective, larger patient cohorts to corroborate these findings.

THE ROLE OF TIM-4 IN THE PATHOGENESIS OF ULCERATIVE COLITIS IN MICE

Y. Xie¹, F. Wang²

Contact E-Mail Address: xieyong_tfahoncu@163.com

Introduction: Ulcerative colitis (UC) is a type of chronic, idiopathic, and immune-mediated inflammatory bowel disease. Currently, no available therapies can control symptoms adequately in UC patients. T cell immunoglobulin and mucin domain 4 (Tim-4) is a novel immune regulatory molecule that can participate in the immune process and maintain immune homeostasis. However, the role of Tim-4 in UC is unclarified.

Aims & Methods: The present study aimed to explore the certain role of Tim-4 in the occurrence and development of UC. BALB/c mice were subjected to experimental acute dextran sodium sulphate (DSS) colitis. Mice were treated with anti-Tim-4 mAb or a control antibody.

Results: Administration of anti-Tim-4 antibody to mice attenuate colitis compared with administration of a control antibody. After blocking, TLR4/NF- κ B signaling pathway was significantly down-regulated, and Treg cells and M1/M2 tended to normalize.

Furthermore, Firmicutes were decreased and Bacteroidetes, Proteobacteria and campylobacter were increased in experimental colitis mice induced by DSS. The abundance of intestinal microorganisms in mice was increased, and the bacterial colony structure was similar to that of healthy mice.

Conclusion: High expression of Tim-4 was thought to contribute to the pathogenesis and an underlying mechanism of UC. Targeting the Tim-4/TLR4/NF- κ B axis may be a promising novel therapeutic strategy for UC.

Disclosure: The authors declare no conflict of interest.

PROTEOMIC ANALYSES DO NOT REVEAL SUBCLINICAL INFLAMMATION IN FATIGUED PATIENTS WITH QUIESCENT INFLAMMATORY BOWEL DISEASE

A.R. Bourgonje¹, S.J. Wichers¹, S. Hu^{1,2}, H.M. van Dullemen¹, M.C. Visschedijk¹, K.N. Faber¹, E.A.M. Festen¹, G. Dijkstra¹, J.N. Samsom³, R.K. Weersma¹, L.M. Spekhorst¹

Introduction: Fatigue is a common and clinically challenging symptom in patients with inflammatory bowel diseases (IBD). While fatigue occurs most often in patients with active disease, up to 50% of patients with quiescent disease still report significant fatigue of unknown etiology. Here, we aimed to investigate whether fatigue in patients with quiescent IBD is reflected by circulating inflammatory proteins, that in turn might reflect ongoing subclinical inflammation.

Aims & Methods: Ninety-two (92) different inflammation-related proteins were measured in plasma of 350 patients with quiescent IBD (188 Crohn's disease [CD]; 162 ulcerative colitis [UC]). Quiescent IBD was defined as clinical (Harvey-Bradshaw Index [HBI] <5 or Simple Clinical Colitis Activity Index [SCCAI] <2.5) and biochemical remission (C-reactive protein [CRP] <5 mg/L) at time of sampling. Fatigue severity was assessed on a visual analogue scale (VAS).

Results: None of the analysed plasma proteins were differentially abundant between mildly (1st quartile, Q1) or severely (4th quartile, Q4) fatigued patients under a false discovery rate of 10%. Considering nominal significance ($P < 0.05$), however, leukemia inhibitory factor receptor (LIF-R) concentrations were inversely associated with severe fatigue, also after adjustment for confounding factors ($P < 0.05$).

Although solely LIF-R showed weak ability to discriminate between mild (Q1) and severe (Q4) fatigue (area under the curve [AUC]=0.61, 95% CI: 0.53-0.69, $P < 0.05$), a combined set of the top seven (7) fatigue-associated proteins (LIF-R, vascular endothelial growth factor-A [VEGF-A], glial-derived neurotrophic factor [GDNF], interleukin-20 receptor subunit alpha [IL-20RA], Delta and Notch-like epidermal growth factor-related receptor [DNER], T-cell surface glycoprotein CD5 [CD5], and extracellular newly identified receptor for advanced glycation end-products binding protein [EN-RAGE], also known as protein S100-A12, all $P < 0.10$) was observed to have reasonable discriminative performance (AUC=0.82 [95% CI: 0.74-0.91], $P < 0.01$).

Conclusion: Fatigue in patients with IBD is not clearly reflected by distinct circulating inflammatory protein signatures, which suggests that subclinical immune activation as defined by the studied panel of inflammatory proteins could not be detected. Reduced shedding of the LIF-R protein could be related to fatigue in IBD through modification of the oncostatin-M (OSM) signaling pathway, or through induction of pro-inflammatory phenotypes of T-cells, macrophages, or neural cells. Future studies are warranted to investigate other proteomic or metabolic markers that may accurately reflect fatigue in quiescent IBD, which might represent alternative pathophysiological pathways.

P0348

ASSOCIATION OF SERUM VITAMIN D LEVELS WITH DRUG TROUGH CONCENTRATIONS AND ANTI-DRUG ANTIBODY LEVELS DURING INFlixIMAB THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

O. Schütte¹, L. Tessmer^{2,3}, J. Stötzel^{1,2}, O. Schröder^{2,3}, N. Awal², A. Aksan^{1,2}, J. Stein^{2,3,4}

¹Justus-Liebig University, Institute of Nutritional Science, Giessen, Germany, ²Interdisciplinary Crohn-Colitis Centre Rhein-Main, Frankfurt am Main, Germany, ³DGD Clinics Sachsenhausen, Department of Gastroenterology and Clinical Nutrition, Frankfurt am Main, Germany, ⁴Institute of Pharmaceutical Chemistry, Goethe University, Frankfurt am Main, Germany

Contact E-Mail Address: ayscak@gmail.com

Introduction: Vitamin D (vitD) status is a well-recognised risk factor implicated in inflammatory bowel disease (IBD). Genetic polymorphisms in the vitD receptor [VDR] were shown to be linked to susceptibility to IBD, while low vitD levels in patients with IBD have been associated with active inflammation, disease severity, poor quality of life, and adverse clinical outcomes.

Previous mechanistic studies have suggested that protective effects of higher vitD levels in patients with IBD are in part mediated through anti-inflammatory cytokine profiles and antimicrobial peptides.

Previous observations point to a possible effect of pre-treatment vitD levels on patient response to anti-tumour necrosis factor alpha [TNF- α] therapy.

Aims & Methods: The aim of this study was to explore potential effects of serum vitD levels on treatment response to infliximab (IFX) in patients with IBD. A cross-sectional retrospective study was conducted using medical records and routine blood samples of patients with IBD.

Blood samples were analysed for standard blood count, total 25OH vitD and inflammation parameters (high sensitivity C-reactive protein, hsCRP; and/or faecal calprotectin, fcal) were detected in blood and stool using standard methods. Serum anti-TNF- α trough concentrations (IDX-TC) and levels of anti-drug antibodies to anti-TNF- α (IFX-ADA) were detected using IDKmonitor® ELISA system, Immundiagnostik AG, Bensheim, Germany. Inflammation was characterised by enhanced levels of the inflammatory biomarkers hsCRP (≥ 5 mg/L) and/or fcal (≥ 250 µg/g).

Biochemical remission was defined by clinical remission in association with normal levels of both of these biomarkers. IFX was administered at a dose of 5-10 mg/kg every 8 weeks over an observation period of 64 weeks. A low IFX-TC was defined as <3µg/mL and a high IFX-TC as >7µg/mL. Positive IFX-ADA levels were defined as >100 AU/mL.

Results: 86 patients with IBD (42f/44m;57CD/29UC;41.3±13.9y) were enrolled. Of these, 24/86(27.9%) had inflammation and 31(36.0%) had vitamin D deficiency at the start of IFX treatment. 71/86(82.6%) patients were treatment naïve. Of the 86 patients, 68 (79.1%) received a treatment dose of 5mg/kg and 18 (20.9%) a dose of 10 mg/kg. VitD deficiency and insufficiency were detected in 31/86(36.0%) and 20/86(23.3%) patients, respectively. Patients with vitD deficiency had significantly lower IFX-TCs during follow-up, independent of the IFX dose per kg.

Moreover, the proportion of patients with positive IFX-ADA titres was found to be significantly higher in patients with VitD deficiency than without (17% vs. 4%, respectively, $p < 0.05$). Serum IFX-TCs at week 8 of treatment correlated positively with baseline vitD levels ($r = 0.374$, $p < 0.05$).

Conclusion: Our results indicate that in patients with IBD treated with IFX, serum vitD concentrations are related not only to drug trough levels but also, importantly, to the development of IFX-ADAs. Serum vitD should be screened prior to therapy and monitored throughout, with a view to maintaining levels within a normal or high-normal range.

Introduction: Inflammatory bowel diseases (IBD) are characterized by an unregulated immune response leading to intestinal inflammation. At present, accurate monitoring of intestinal inflammation depends mainly on clinical indices (symptoms and blood parameters) and endoscopy, in conjunction with histological and radiological imaging techniques. These tests are mostly invasive, time-consuming, and expensive.

Therefore, a simple, reliable, accurate, and non-invasive test, with the ability to differentiate IBD from other gastrointestinal conditions and to monitor disease activity and treatment, will have important clinical implications. It is well-established that expression of several cytokines, such as TNF- α , IL-1 β and IL-6, correlate with the inflammation and the disease activity.

Aims & Methods: Therefore, our aim was to identify cytokines with potential biomarker quality.

Blood and biopsy samples were collected from 87 active IBD patients and 35 controls without IBD. Inclusion criteria included change of therapy or initiation of new treatment for IBD patients. Organoid culture (OC) was generated from 5 clinically active IBD patients and 5 controls. Cytokine Array was used to analyse cytokine expression patterns. Total protein and mRNA were isolated from biopsies and from OCs. Protein levels were measured by ELISA and gene expression by qRT-PCR in serum, mucosa and in OCs. Immunofluorescence (IF) staining was used to observe the presence and localisation of cytokines.

Results: The cytokine array showed that plasminogen activator inhibitor 1 (PAI-1) was one of the cytokines, which was detected in most inflamed biopsy samples, but not in controls.

Furthermore, the detection number was significantly lower in samples from the non-inflamed part of the colon. Serum and mucosal PAI-1 concentrations were significantly higher in patients with endoscopically

and clinically active disease compared to inactive patients and controls. Whereas no significant difference was observed between Crohn's-disease and ulcerative colitis patients. Correlation analysis revealed that serum PAI-1 level correlates with disease activity.

In addition, IF staining of the biopsy samples revealed a significantly higher percentage of PAI-1 positive cells in the inflamed mucosa compared to the control. *Ex vivo* organoids recapitulated the findings in biopsy samples. The gene expression of PAI-1 was significantly lower in patients responding to anti-TNF- α therapy, than in the non-responder patients, whereas the protein level significantly decreased after the initiation of therapy compared to non-responders.

Conclusion: Our findings suggest that serum and mucosal PAI-1 expression correlates with the disease activity in IBD patients, suggesting that it could be utilized to monitor disease activity and possibly therapy response.

Disclosure: Nothing to disclose.

P0350

USE OF HAEMATOLOGICAL IRON PARAMETERS ALONE OR IN COMBINATION TO DETECT IRON DEFICIENCY IN INFLAMMATORY BOWEL DISEASE

C. Mangold¹, L. Tessmer^{2,3}, K. Farrag^{2,3}, O. Schröder^{2,3}, A. Aksan^{2,4}, J. Stein^{2,3,5}

¹Goethe University Frankfurt, Faculty of Medicine, Frankfurt am Main, Germany, ²Interdisciplinary Crohn-Colitis Centre Rhein-Main, Frankfurt am Main, Germany, ³GKD Clinics Sachsenhausen, Department of Gastroenterology and Clinical Nutrition, Frankfurt am Main, Germany, ⁴Justus-Liebig University, Institute of Nutritional Science, Giessen, Germany, ⁵Institute of Pharmaceutical Chemistry, Goethe University, Frankfurt am Main, Germany

Contact E-Mail Address: ayscak@gmail.com

Introduction: Iron deficiency (ID) is among the most common extraintestinal manifestations of inflammatory bowel disease (IBD). The European Crohn's and Colitis Organization (ECCO) last updated guidelines on ID diagnosis in 2015, recommending diagnosis of ID in IBD patients to be based on only one iron parameter, namely ferritin. It is likely that ID is still under-detected in IBD patients, due in particular to a lack of awareness of subtle clinical symptoms among physicians, imprecisions of laboratory tests and difficulties in interpreting these accurately.

Aims & Methods: We aimed to investigate which sole parameter or combination of parameters can best predict ID in patients with IBD. A retrospective cross-sectional study was conducted using routine blood samples from patients with IBD. Blood samples were analysed for CBC, iron status (serum ferritin, SF; transferrin saturation, TSAT; mean corpuscular volume, MCV), the inflammation parameter high sensitivity CRP (hsCRP) and soluble transferrin receptor (sTfR) by standard methods. A multiparameter index test (MCV, TSAT, SF) was performed to detect ID when at least 2 of the 3 parameters indicated ID. sTfR ferritin index (sTfR-F) was calculated (sTfR (mg/L)/log¹⁰ SF (μ g/L)). Cut-off values for TSAT (<20%) and SF (<30 μ g/L or <100 μ g/L) were defined according to ECCO guidelines and for MCV (80fL) according to the literature. Criteria taken to indicate absolute ID (AID) were hsCRP <5mg/L, SF 30 μ g/L and TSAT <20%, while functional ID (FID) was denoted by hsCRP $\geq$ 5mg/L, SF <100 μ g/L and TSAT <20%.

Results: 240 IBD patients (120f/120m;120CD/120UC;42.9 $\pm$ 14.6y) were enrolled. Of these, 71/240(29.6%) had inflammation. 47/240 patients had ID, of whom 25/47 had FID and 22/47 had AID. ROC analysis was performed to compare different parameters as detectors of ID and to summarise the performance of each respective parameter (Table 1).

In the absence of inflammation, a combination of the common markers TSAT and SF <30µg/L is sufficient to detect a large majority of cases of ID. In patients with inflammation, TSAT and SF <100µg/L in combination still detect the majority of ID cases. However, addition of MCV, which showed high specificity regardless of inflammation, was found to add additional value to the diagnosis, especially in the context of inflammation ($p<0.001$).

Patient group	Outcome	MCV	TSAT	SF	sTfR	sTfR-F
All patients	AUC ^{ROC}	0.810	0.985	0.850	0.820	0.878
	Sens./Spe. %	25.0/98.7	100.0/89.2	53.3/94.3	47.5/94.7	65.0/88.8
Patients with inflammation	AUC ^{ROC}	0.729	1.000	0.806	0.755	0.866
	Sens./Spe. %	20.0/96.3	100.0/86.3	96.0/55.6	34.8/96.2	43.5/96.2
Patients without inflammation	AUC ^{ROC}	0.843	0.991	0.970	0.948	0.987
	Sens./Spe. %	31.6/99.0	100.0/95.6	89.5/96.2	76.5/92.9	100.0/88.9

Table 1. Analytical performance of iron status parameters to detect ID in patients with IBD with/without co-presence of inflammation.

Conclusion: Of those parameters studied, none was suitable to diagnose ID in patients with IBD when taken alone. Independent of whether there was active inflammation, TSAT and SF seemed to adequately define ID; however, in both cases the addition of MCV had additional value, and particularly so when inflammation was present.

The additional value of sTfR (or sTfR-F) is questionable due its high cost and limited availability. However, prospective large-scale studies are needed to evaluate whether determination of sTfR and sTfR-F could be worthwhile.

Contact E-Mail Address: nathan.constantine-cooke@ed.ac.uk
Introduction: Faecal calprotectin (FCAL) is a neutrophil degranulation product associated with mucosal inflammation in Crohn's disease (CD). Escalation with an anti-TNF therapy on the basis of clinical symptoms combined with biomarkers in patients with early CD results in better clinical and endoscopic outcomes than symptom-driven decisions alone¹. Indeed, normalisation of FCAL (<250 µg/g) within one year of diagnosis is associated with better long-term outcomes².
Aims & Methods: We aimed to:
1. Determine if five-year FCAL profiling could identify "classes" of CD patients associated with Montreal disease progression, hospitalisation, and surgery.
2. Assess if membership of these classes was associated with factors at diagnosis (e.g. treatment and disease phenotype).
Demographic, clinical, follow-up data and FCAL results were extracted from the Lothian IBD registry, a rigorously phenotyped database of all IBD patients receiving secondary care from NHS Lothian³. All CD patients diagnosed between 2005 and 2017 with FCAL >250 (µg/g) at diagnosis, a followup FCAL within one year, and an additional FCAL within five years of diagnosis were included.
Latent class mixed models, an extension of linear mixed effects models with class-specific fixed effects, were used to model and group FCAL trajectories. Fixed and random effects of this model were modelled using natural cubic splines: permitting flexible models.
Akaike information criterion, Bayesian information criterion, alluvial plots, and plots of mean class trajectories were used to decide the optimal number of classes. Log-rank tests of Kaplan-Meier estimators were used to test for associations between class membership and poor disease outcomes. Chi-squared tests, Fisher's exact test and ANOVA were used to find possible associations between class membership and variables available at diagnosis and treatments prescribed within one year of diagnosis.
Results: Of 1390 incident CD cases, 356 subjects met the study inclusion criteria, who had 2856 FCAL measurements (median 7 per subject) within five years of diagnosis. Four latent classes were found to be the most appropriate.
Class 1 and 3 were both characterised by decreasing trajectories. Class 1 decreased almost immediately, whilst class 3 decreased at one year after diagnosis.
Class 4 demonstrated a remitting, relapsing trajectory whilst class 2 demonstrated consistently FCAL. Class membership was significantly associated with hospitalisation, Montreal disease progression, and a composite endpoint but not surgery.
Of variables typically available at diagnosis, smoking status and the presence of upper gastrointestinal inflammation were all found to be significantly associated with class membership.

Significant associations between class membership and both biologic and thioprine prescriptions were found with less biologic and thioprine treatments being prescribed for class 2.

Conclusion: Latent class mixed models are highly effective for identifying latent classes within the CD population from FCAL profiles and have potential for being deployed as a risk prediction tool.

This approach also allows common trajectories to be generated in a data driven approach. In the future, these models should be applied to a larger cohort including ulcerative colitis patients in addition to a validation cohort.

COMPARISON OF CLINICAL IMPROVEMENT AS MEASURED BY TWO QUALITY-OF-LIFE INDEXES: A POOLED ANALYSIS OF VEDOLIZUMAB RANDOMIZED CLINICAL TRIALS IN INFLAMMATORY BOWEL DISEASE

E. Louis¹, P. Kamble², D. Lindner³, C. Agboton⁴

¹CHU Liège and Liège University, Gastroenterology, Liège, Belgium, ²Takeda Pharmaceuticals Inc., Global Evidence and Outcomes-Gastroenterology, Marlborough, United States, ³Takeda Pharmaceuticals, Zurich, Switzerland, ⁴Takeda Pharmaceuticals, Dept. of Medical Affairs, Zurich, Switzerland

Contact E-Mail Address: christian.agboton@takeda.com

Introduction: Improvement in Quality of life (QoL) is an ultimate therapeutic goal for disease management in ulcerative colitis (UC) and Crohn's disease (CD) as recommended by STRIDE II and SPIRIT initiatives.^{1,2}

The aim of this analysis was to better understand the capacity of the 32-item inflammatory bowel disease questionnaire (IBDQ) and its 10-item short version (SIBDQ) in evaluating response to treatment. IBDQ improvement is generally defined as a change of the total score by >16 points (>9 for SIBDQ) and remission is defined as IBDQ score of ≥170 or more (≥60 for SIBDQ).

Aims & Methods: This was a post-hoc analysis, pooling data across six Phase 3 studies of vedolizumab IV or SC in UC (3 studies) and CD (3 studies), five of which were randomized controlled trials (RCTs), and one single-arm study in CD.³⁻⁵ The pooled dataset included VARSITY⁶, the only study in UC with an active control arm (adalimumab). In the five RCTs, patients were

randomized at Week 6, except in VARSITY where a treat-through design was used. The 3 time points studied include Week 0 (baseline), Week 26 or 30, and Week 52. Comparisons of the IBDQ and SIBDQ were based on observed data.

Results: The pooled dataset included 1458 patients with UC and 974 patients with CD for whom IBDQ data was reported at least once. Of these, 892 patients with UC were in the vedolizumab group, 384 in the active control group, and 182 in the placebo arm. In CD patients, 808 received vedolizumab and 166 placebo.

Across all studies, the IBDQ showed that in UC and CD together, 75.5% of vedolizumab-treated patients reported an improvement at Week 52, and 63.7% were in IBDQ remission at Week 52 compared with 68.7% (IBDQ improvement) and 46.0% (IBDQ remission) for patients receiving placebo. In UC, IBDQ improvement was generally higher for vedolizumab-treated patients (71.8%) than for patients in the placebo (61.7%) or active control groups (50.8%).

In CD, the difference between vedolizumab and the control group was less visible, with 81.3% showing improvement at Week 52 on vedolizumab vs. 75.0% for control group.

In vedolizumab patients, SIBDQ-based remission was observed less frequently than IBDQ-based remission at Week 52, with proportions of 50.3% (UC) and 37.7% (CD) for SIBDQ, compared with 65.4% (UC) and 60.9% (CD) for IBDQ-based remission.

A similar pattern was observed in placebo control patients with proportions of 24.5% (UC) and 27.9% (CD) for SIBDQ-based remission compared with 40.4% (UC) and 51.0% (CD) for IBDQ. Both scales showed good concordance, with SIBDQ-based remission matching IBDQ-based remission in 84.4% of patients (22.5% Yes/Yes and 61.9% No/No), and SIBDQ-based improvement matching IBDQ-based improvement in 89.9% of cases (70.0% Yes/Yes and 19.9% No/No) [Table].

All patients, all visits, UC+CD		IBDQ-based remission (n=5712)	
		Yes	No
SIBDQ-based remission	Yes	22.5%	0.0%
	No	15.6%	61.9%
		IBDQ-based improvement (n=3219)	
		Yes	No
SIBDQ-based improvement	Yes	70.0%	0.4%
	No	9.8%	19.9%

Bold text denotes concordance

Table. Concordance between IBDQ and SIBDQ.

Conclusion: This first analysis showed a slightly different dynamic for the SIBDQ and IBDQ, especially in CD. The 2 scales served their purpose of monitoring the QoL of patients; however concordance between the two scales for remission was lower than for improvement.

Introduction: Filgotinib (FIL) is a once-daily, oral, preferential JAK1 inhibitor approved for the treatment of ulcerative colitis (UC). In SELECTION, FIL 200 mg (FIL200) was efficacious in inducing and maintaining clinical remission vs placebo (PBO) in patients with moderately to severely active UC.¹

Increased faecal calprotectin (FC) has been associated with the risk of relapse and is broadly used as a non-invasive monitoring tool in patients with UC. We assessed the operating properties of FC as a prognostic marker of the response to treatment with FIL200.

Aims & Methods: SELECTION was a phase 2b/3, double-blind, randomized, PBO-controlled trial (NCT02914522) comprising two induction studies and one maintenance study.¹

Using Mann-Whitney U tests and receiver operating characteristic (ROC) curves with comparison of areas under the curve (AUC), these *post hoc* analyses evaluated the ability of median FC concentration and FC concentration thresholds vs histological and endoscopic assessments to discriminate Mayo Clinic Score (MCS) response, endoscopic response and endoscopic remission after induction (week 10), and clinical remission after maintenance (week 58) treatment with FIL200.

Results: FC concentration at baseline was not a strong prognostic factor for MCS response at week 10 (median [interquartile range (IQR)] µg/g, yes: 1450 [561–3056] vs no: 1211 [455–2734], $p=0.0938$), whereas FC concentration at week 10 was associated with MCS response (median [IQR] µg/g, yes: 209 [68–720] vs no: 1133 [347–2101], $p<0.0001$), endoscopic response (yes: 102 [41–301] vs no: 756 [211–1741], $p<0.0001$) and endoscopic remission (yes: 59 [29–186] vs no: 527 [148–1598], $p<0.0001$) at week 10.

Using a cut-off of 250 µg/g to create a binary outcome, FC <250 µg/g (FC250) at week 10 was associated with a MCS response at week 10 (yes: $n=340$ [positive predictive value (PPV): 75.9%]; no: $n=454$ [negative predictive value (NPV): 61.5%]).

Combining FC250 with symptomatic outcomes (partial MCS [pMCS] remission) improved both the PPV (79.8%) and NPV (73.5%) for MCS response at week 10. FC250 was associated with an endoscopic response at week 10 (PPV: 42.2%; NPV: 90.4%; ROC curve AUC: 0.724 [95% confidence interval: 0.693–0.754]). The combination of FC250 with pMCS remission at week 10

was prognostic for clinical remission at week 58 with a higher AUC than that of either endoscopic response, Geboes histological remission, FC250 or pMCS remission alone (Table 1).

		ROC curve				Logistic regression	
		Yes	No	PPV	NPV	AUC (95% CI)	Odds ratio (95% CI) p value ^a
FC250	Yes	51 (47.2%)	57 (52.8%)	47.2%	–	0.606	2.440
	No	22 (26.8%)	60 (73.2%)	–	73.2%	(0.536–0.676)	(1.316–4.525)
pMCS remission	Yes	61 (42.1%)	84 (57.9%)	42.1%	–	0.576	2.290
	No	13 (24.1%)	41 (75.9%)	–	75.9%	(0.516–0.636)	(1.131–4.638)
Endoscopic response	Yes	37 (50.7%)	36 (49.3%)	50.7%	–	0.606	2.472
	No	37 (29.4%)	89 (70.6%)	–	70.6%	(0.536–0.676)	(1.359–4.495)
Geboes histological remission	Yes	32 (45.1%)	39 (54.9%)	45.1%	–	0.559	1.661
	No	42 (33.1%)	85 (66.9%)	–	66.9%	(0.489–0.629)	(0.915–3.014)
FC <250 µg/g and Geboes histological remission	Yes	27 (50.0%)	27 (50.0%)	50.0%	–	0.570	1.957
	No	46 (33.8%)	90 (66.2%)	–	66.2%	(0.502–0.637)	(1.031–3.714)
FC <250 µg/g and Geboes histological remission and endoscopic response	Yes	20 (60.6%)	13 (39.4%)	60.6%	–	0.581	3.018
	No	53 (33.8%)	104 (66.2%)	–	66.2%	(0.523–0.640)	(1.394–6.536)
FC <250 µg/g and pMCS remission	Yes	45 (51.7%)	42 (48.3%)	51.7%	–	0.629	2.870
	No	28 (27.2%)	75 (72.8%)	–	72.8%	(0.558–0.700)	(1.568–5.252)

Clinical remission = endoscopic subscore of ≤1, rectal bleeding subscore of 0 and a reduction of ≥1 point in stool frequency subscore from induction baseline to achieve a subscore of ≤1.

pMCS = sum of rectal bleeding, stool frequency and physician's global assessment subscores.

pMCS remission = pMCS of ≤1.

Endoscopic response = endoscopic subscore of ≤1.

Geboes histological remission = grade 0 of ≤0.3, grade 1 of ≤1.1, grade 2A of ≤2A.3, grade 2B of 2B.0, grade 3 of 3.0, grade 4 of 4.0, and grade 5 of 5.0.

^aAll p values are nominal.

AUC, area under the ROC curve; CI, confidence interval; FC, faecal calprotectin; FC250, FC <250 µg/g; FIL200, filgotinib 200 mg; NPV, negative predictive value; pMCS, partial Mayo Clinic Score; PPV, positive predictive value; ROC, receiver operating characteristic.

Table 1. Prognostic value of FC concentration and invasive and non-invasive assessments at week 10 for clinical remission at week 58 in patients receiving FIL200.

Conclusion: FC concentration following induction with FIL200 is associated with a short-term response. The combination of FC250 and pMCS remission at week 10 may be a good, non-invasive prognostic marker of clinical remission at week 58. These findings raise the possibility that some patients could avoid undergoing endoscopy at early time points with the use of close biomarker and symptom monitoring.

MEASURING ADALIMUMAB AND INFLIXIMAB TROUGH LEVELS FROM FINGER PRICK BLOOD WITH A RAPID POINT-OF-CARE ASSAY

L. Brosi¹, C. Reinhard¹, J. Afonso¹, T. Schuster¹, C.-B. Gerhold¹, B. Ricken¹

¹BÜHLMANN Laboratories AG, Schönenbuch, Switzerland

Contact E-Mail Address: jpa@buhlmannlabs.ch

Introduction: Several studies demonstrated a positive correlation between anti-TNFα drug trough levels and the therapeutic outcome of inflammatory bowel disease (IBD) patients. Commercially available rapid assays support laboratories in the fast and easy detection of adalimumab (ADL) and infliximab (IFX) concentrations.

A hindrance for true point-of-care (POC) use is the assay's dependency on serum as analyte matrix, because serum preparation from whole blood requires laboratory equipment and is time-intensive. Therefore, in this work ADL and IFX lateral flow assays that can process capillary blood and venous whole blood are presented.

Included in the assay kits are all components that are needed to generate a measurement without further sample preparation steps or additional laboratory equipment. The assays can be run on an easy-to-use desktop lateral flow reader.

Aims & Methods: We designed a lateral flow assay kit for the analysis of ADL and IFX in capillary blood and (EDTA) whole blood specimen, respectively. The POC kits consist of disposable capillaries for blood collection from finger prick blood or venous whole blood and transfer to dropper bottles that are prefilled with chase buffer. Sample and chase buffer are mixed by gently flipping the tube, before the mixture is applied on the lateral flow test cassette. For matrix agreement studies EDTA whole blood, whole blood without anticoagulant and capillary blood were spiked with ADL and IFX and partially used for plasma and serum preparation.

Serum and plasma samples were analysed with the Quantum Blue® Adalimumab and Infliximab assays, while the corresponding whole blood and EDTA whole blood, as well as spiked capillary blood samples were analysed with the newly developed POC sample preparation system.

Additionally, linearity, within-run precision and robustness experiments were performed with the POC ADL and IFX assays to demonstrate suitability for routine use.

Results: Good comparability between all tested matrices including capillary blood to serum was demonstrated. Both POC assays revealed a bias of less than 15 % at the clinical decision points for ADL (5 µg/mL and 12 µg/mL) and IFX (3 µg/mL and 7 µg/mL). Linearity for POC ADL and POC IFX rapid assays is given over a measuring range of 1.3 – 35 µg/mL and 0.4 – 20 µg/mL, respectively. Within-run precision determined with spiked EDTA whole blood samples was between 6 – 18 % and 6 – 20 % for the POC ADL and POC IFX rapid assays, respectively. Robustness experiments revealed that capillary and EDTA whole blood samples can be used within 20 minutes after dilution with chase buffer. This also allows a certain flexibility at the clinician's site.

Conclusion: Two POC assays for the determination of ADL and IFX in capillary or venous whole blood samples were successfully developed. Both assays can be used by non-laboratory professionals with time to results of only 15 minutes and without the need for additional laboratory equipment. The excellent agreement to serum trough levels shows that the here presented POC assays are ideal for ADL and IFX therapeutic drug monitoring analysis in a clinician's office or an infusion site.

REAL-TIME CLASSIFICATION OF CROHN'S DISEASE CLINICAL REMISSION BY HEALTH-RELATED QUALITY OF LIFE (HRQOL) QUESTIONNAIRES IN COMBINATION WITH BIOMARKERS: DATA FROM A REAL-WORLD PROSPECTIVE INCEPTION COHORT

T. Sharar Fischler^{1,2}, I. Goren^{1,2}, J. Ollech^{1,2}, R. Barkan^{1,2}, T. Pfeffer Gik^{1,2}, B. Raykhel^{1,2}, Y. Kutukov^{1,2}, A. Friedenberg^{1,2}, M.H. Pauker^{1,2}, Y. Broitman^{1,2}, Y. Snir^{1,2}, H. Bana^{1,2}, I. Avni-Biron^{1,2}, I. Dotan^{1,2}, H. Yanai^{1,2}

Introduction: Patient centered outcomes assessment is required by global regulatory authorities in Crohn's disease (CD) trials. However, the optimal instrument, outcome(s) and their utility in practice are not yet defined. Here we aimed to evaluate the contribution of two health-related quality of life (HRQoL) questionnaires in the classification of clinical remission (CR) compared to active disease (non-remission) in a prospective cohort of patients with CD.

Aims & Methods: This was a cross-sectional analysis of HRQoL questionnaires of patients with newly diagnosed CD from a prospective inception cohort (2018-2020). Analysis was done on comprehensive data collected from this cohort who is followed and cared by a multidisciplinary team (including IBD-oriented gastroenterologist determining treatment plans, an IBD nurse, and a dietitian). All patients in the cohort are scheduled for semi-annual study visits for additional assessment and data collection. After 1-year from diagnosis these patients were assessed for CR that was defined by a composite of: Crohn's disease activity index (CDAI) < 150, no active perianal disease, steroid-free, no treatment escalation and no hospitalizations > 3 months. In parallel, biomarkers (C-reactive protein [CRP] and fecal calprotectin [FC]) and HRQoL measures were captured. HRQoL was evaluated by two questionnaires: the short IBD questionnaire (SIBDQ) and patient reported outcome 2 (PRO2). These scores were individually assessed as a diagnostic test for CR by logistic regression models and receiver operating characteristic (ROC) curve analysis.

Results: Out of 120 enrollees, 85 completed 1-year follow-up: female 50.6%, median age 27 years (IQR 22-39), active smokers 16.5%, median BMI 21.7 kg/m² (IQR 20.1-25.2). At diagnosis: inflammatory phenotype (B1) 72.9%, complex perianal disease 11.8%, extra-intestinal manifestation 29.4%, all patients with active disease of whom 55.3% with moderate-severe CD (CDAI>220).

During the first year after diagnosis 62.3% were treated with a biologic therapy and 7% required surgery. After 1-year from diagnosis 61.1% attained CR. Biomarkers were lower among patients who were in CR vs those with active disease (FC- 49.5 [IQR:13.5-141.7] vs 230 [IQR: 84-440], $p=0.002$, CRP- 0.17 [IQR: 0.06-0.6] vs 0.46 [IQR: 0.12-1.53], $p=0.005$, respectively). Similarly, SIBDQ and PRO2 scores were significantly favorable among those patients who attained CR (59 [IQR: 53-64] vs. 43 [IQR:34-58.2], and 1.42 [IQR:0-4.7] vs 7.7 [IQR: 3.1-15], respectively, both $p<0.001$). Modeling individual HRQoL scores with and without specific biomarkers revealed that the optimal predictor for our stringent definition of CR was a combination of PRO2 score and FC levels. The model yields a ROC with an area under the curve (AUC) of 0.871 (95% CI 0.796-0.946) and with a discrimination slope of 39%. If electing a specificity of 97% and sensitivity of 82% the usage of the model may result in a 43% drop in routine physician visits with only 3.4% (1/29 patients) probability to make a mistake and wrongly assess a patient as a remitter (false negative).

Conclusion: Combination of PRO2 and FC had a high discriminatory ability between patients in CR vs active disease in a real-world inception cohort of patients with newly diagnosed CD. Application of this model in clinical practice may contribute to decision making based on specific thresholds for improved patient allocation (i.e. remote / IBD-nurse) rather than intense routine physician visits. Thus, utilization of this model may impact health policy and monitoring plans for patients with CD.

Disclosure: Nothing to disclose.

CRP TO ALBUMIN RATIO AND NEUTROPHIL TO LYMPHOCYTIC RATIO AS A PREDICTOR OF MUCOSAL HEALING IN EGYPTIAN PATIENTS WITH ULCERATIVE COLITIS TREATED WITH BIOLOGICAL THERAPY

M. Eltabbakh¹, Y. Abd El Razek¹, S. Abdelrahman¹, A. Al Breedy¹

¹Ain Shams University, Tropical Medicine, Hepatology and Gastroenterology Department, Cairo, Egypt

Contact E-Mail Address: dr_tabbo84@yahoo.com

Introduction: There is some evidence of a possible role of some serum biomarkers in the ulcerative colitis setting, in particular concerning disease severity. Many patients experience loss of response to biological therapy during the first year of therapy. An early predictor of clinical remission and mucosal healing is needed.

Aims & Methods: Objectives: To evaluate the role of non-invasive biomarkers as an early predictor of mucosal healing in ulcerative colitis patients treated with biological therapy.

Methods: This was a prospective cohort study starting from January 2020 till January 2021. We included ulcerative colitis cases started biological therapy at our IBD unit at tropical medicine department, Ain Shams University, Egypt. We excluded patients on corticosteroids more than 20 mg/day. Mayo score and Mayo endoscopic score were used to assess the severity of the disease. Each patient was followed up at week 12 and week 24 from starting therapy to assess response to treatment. Ileocolonoscopy examination was repeated at week 24 to assess mucosal healing. Endoscopic mucosal healing was measured by Mayo endoscopic sub score (0 or 1 points). The following indices were calculated at starting treatment: Neutrophil-Lymphocytic ratio(N/L), platelet lymphocytic ratio(P/L), CRP/Albumin ratio and platelet monocyte ratio(P/M).

Results: Twenty patients with ulcerative colitis were included in our study. The mean age of the studied cases was 33.75±9.6. Most of our cases were females (60%). Most of our cases (65%) had clinical response at 6 months follow up. Mucosal healing achieved in seven cases only after six months follow up.

There was a significant decrease in median N/L ratio in 6 months follow up (Median baseline was 2.62 with IQR (1.87 – 6.5), at 3 months was 2.26 (1.54 – 4.06) while at 6 months was 1.85 (1.28 – 2.8)($P=0.044$). Median PLT/L ratio significantly decreased at 6 months (142.37 (115.81 – 212.11) in comparison to 3 months and baseline (239.17 (122.77 – 326.25) and 263.75 (146.95 – 432.64) respectively ($P=0.019$)). Median PLT/M ratio was 823.33 (516.7 – 1760.65) at starting treatment while it decreased significantly 787.5 (550.17 – 1560) and 541.93 (396.32 – 748.03) at 3 months and 6 months respectively ($P=0.035$).

Also, Median CRP/albumin ratio decreased significantly at 6 months 2.56 (0.81 – 3.59) and 3 months 2.32 (1.2 – 3.88) while it was 4.57 (1.48 – 18.29) at starting treatment with biological treatment ($P=0.026$). In relation to mucosal healing at 6 months; Baseline median N/L ratio was significantly associated with mucosal healing (1.84) while it was (5.57) in cases who did not achieve mucosal healing ($P=0.016$). Also, Baseline median CRP/albumin ratio was significantly associated with mucosal healing (1.67) in comparison to (14.29) in patients who did not achieve mucosal healing ($P=0.036$).

		Mucosal healing		Test value	P- value	Sig.
		No (13)	Yes (7)			
N/L ratio	Median (IQR)	5.57 (2.2 – 9.17)	1.84 (1.5 – 2.53)	-2.417#	0.016	S
	Range	0.74 – 11.19	0.86 – 2.86			
PLT/L ratio	Median (IQR)	257.5 (141.79–388.89)	298.42 (152.11–476.39)	-0.674#	0.501	NS
	Range	106.21 – 576.67	103.79 – 594.29			
PLT/M ratio	Median (IQR)	605.41 (466.25 – 1730)	1040 (602 – 1845)	-0.991#	0.322	NS
	Range	356.67 – 5070	412.86 – 1890			
CRP/ Albumin	Median (IQR)	14.29 (1.62 – 20.36)	1.67 (1.35 – 3.33)	-2.100#	0.036	S
	Range	1.34 – 33.13	0.86 – 5.81			

S:Significant NS: Non-Significant

#:Mann-Whitney test

Table.

Conclusion: CRP/albumin ratio and N/L ratio at starting treatment with biological treatment in patients with ulcerative colitis may be considered as a useful non invasive markers for prediction of mucosal healing at six months follow up.

Disclosure: Nothing to disclose.

ARTIFICIAL INTELLIGENCE IN HISTOPATHOLOGICAL DIAGNOSIS OF IBD – A PILOT STUDY

P. Čačić¹, A. Demirovic^{2,3}, M. Subašić⁴, L. Žužak⁴, S. Pelajić¹, A. Biščanin^{1,2}, V. Tomasić¹, Z. Dorosulić¹, D. Kralj¹, D. Ogresta¹, F. Babić¹, B. Krušlin^{2,3}, D. Hrabar^{2,1}

¹Sestre Milosrdnice University Hospital Center, Department of Gastroenterology and Hepatology, Zagreb, Croatia, ²University of Zagreb, School of Medicine, Zagreb, Croatia, ³Sestre Milosrdnice University Hospital Center, Ljudevit Jurak Clinical Department of Pathology and Cytology, Zagreb, Croatia, ⁴University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia

Contact E-Mail Address: petra.cacic@gmail.com

Introduction: Diagnosis of IBD is made upon a combination of clinical, endoscopic, histological, biochemical and radiographic features. The lack of the gold standard and inter-observer variability, especially in endoscopic and histological analysis, makes it even more challenging. Moreover, according to studies, 10-15% of IBD cases remain unclassified (IBDU). According to the results of an International Workshop on the initial histopathologic diagnosis of colitis, expert gastrointestinal pathologists correctly identified 64% of cases with CD and 74% of cases with UC, with even lower rate among non-expert gastrointestinal pathologists. Therefore, we aimed to develop a convolutional neural network (CNN)-based system for histopathological automatic distinction between CD and UC.

Aims & Methods: Single tertiary center retrospective study was performed. A total of 2255 histology images (200x magnification) of 27 colon biopsies from 23 patients, collected between 2010 and 2020 were analysed. Minimum duration of follow up was 26 months. Diagnosis at the end of follow up was presumed as definitive and patients with IBDU at the end of follow up were excluded from analysis. At the moment of sampling 11 patients were classified as UC, 10 as CD and 2 were unclassified. At the end, one patient with UC was reclassified to CD, and in IBDU group both patients were reclassified to UC.

Histology slides were digitalized using microscope digital camera Olympus UC 90 and Olympus cellSens Dimension Software package. A 46 layer convolutional neural network for image classification was used. Image dataset was split for 3-fold cross validation. Every fold had constitution of training (75%, 70% and 80%) and validation datasets (25%, 30% and 20%). The performance of the model was measured by calculating the area under the receiving operating characteristic curve (AUC), sensitivity, specificity, positive and negative predictive values (PPV and NPV).

Results: Mean AUC was 72.3%. The best model was able to automatically distinct CD from UC with an accuracy of 76.1%; sensitivity of 70%; specificity of 89%; PPV 93.4%; NPV 57.7%. The time it takes to classify one histology image is approximately 0.135 seconds.

Conclusion: Although the performance of our model was similar to pathologists, it should be interpreted with great caution due to small sample size. Application of AI methods in histopathology of inflammatory disease is still very limited because of complexity, variations in the stainability of individual cases, small but significant variations in slides preparation technique between centers etc. However, deep learning technologies are rapidly progressing, and AI models may become a useful tool in the pathology of IBD.

Disclosure: Nothing to disclose.

P0358

THERAPEUTIC DRUG MONITORING: STANDARDIZATION OF PROMONITOR QUICK IFX AND PROMONITOR QUICK ADL POINT OF CARE TESTS WITH WHO INTERNATIONAL STANDARDS FOR THE QUANTIFICATION OF INFLIXIMAB AND ADALIMUMAB IN WHOLE BLOOD AND SERUM

A. Ametzazurra¹, J. Pascual¹, L. Del Río¹, A. Urigoitia¹, D. Nagore¹, M.B. Ruiz-Argüello¹

¹Progenika Biopharma, Grifols, R&D, Derio, Spain

Contact E-Mail Address: amagoia.ametzazurra@progenika.grifols.com

Introduction: Promonitor Quick IFX and Promonitor Quick ADL are rapid point of care lateral flow tests (LFT) based on a sandwich immunoassay for the quantification of infliximab (IFX) and adalimumab (ADL), respectively, in human whole blood (finger prick or venous) or serum.

These tests are to be used as an aid in Therapeutic Drug Monitoring (TDM) of inflammatory bowel disease (IBD) and rheumatic patients under anti-TNFα therapy. The international standards (IS) developed by World Health Organization (WHO) for IFX and ADL allow harmonization and comparability among different assays.

Aims & Methods: Objectives: The aim of this study, was to show that Promonitor Quick IFX and Promonitor Quick ADL can measure either reference or biosimilar drugs, as well as to evaluate the agreement of Promonitor Quick IFX and Promonitor Quick ADL tests and the WHO IS.

Methods: Clinical and Laboratory Standards Institute EP10-A3 guidelines were followed to estimate the bias of Promonitor Quick assays when used to quantify IFX or ADL in samples containing the reference drugs, biosimilars or the WHO IS. Briefly, whole blood was spiked with four known concentrations of IFX or ADL, including current clinical decision levels. Ten replicates were measured of each level along two days.

Promonitor Quick IFX was evaluated using the reference drug, SB2 and CT-P13 biosimilars, and the WHO IS (NIBSC 16/170).

Promonitor Quick ADL was evaluated using the reference drug, ABP501 and SB5 biosimilars, and the WHO IS (NIBSC 17/236).

Results were obtained in combination with the automated portable reader PQreader.

Results: Bias was estimated by comparing the observed concentration of drug spiked whole blood samples. Each biosimilar was compared to the reference at the different drug levels tested. Results showed that Promonitor Quick IFX and Promonitor Quick ADL are able to measure equivalently any molecule (see Table below).

The accuracy or closeness of the agreement between the result provided by Promonitor Quick IFX and Promonitor Quick ADL and the true value of the measurand was assessed by measuring the IS developed by the WHO (see Table). Similar results were obtained when serum matrix was used.

Promonitor Quick IFX bias results					Promonitor Quick ADL bias results			
IFX concentration (µg/mL)	Bias (%)				ADL concentration (µg/mL)	Bias (%)		
	CT-P13	SB2	GP1111	WHO IS		ABP501	SB5	WHO IS
3	14%	3%	4%	8%	3	17%	2%	3%
7	9%	0%	5%	15%	5	13%	3%	12%
10	1%	5%	6%	8%	8	2%	2%	7%
					10	5%	17%	10%

Table. Bias results in whole blood samples.

Each molecule was compared to the reference drug.

Conclusion: Promonitor Quick IFX and Promonitor Quick ADL allow monitoring of patients treated with IFX and ADL, respectively, with just a finger prick sample. Both tests can quantify reference and biosimilar drugs with

equivalent results. Moreover, comparable results were obtained with the WHO IS, and thus, demonstrate that Promonitor Quick tests are suited to accurately determine drug levels at the clinical decision points in both whole blood and serum, proving to be an effective and valuable tool in TDM and immediate decision making in the doctor office or hospitals.

Disclosure: The authors are Progenika Biopharma - Grifols employee.

Contact E-Mail Address: amagoia.ametzazurra@progenika.grifols.com

Introduction: The goal of this study was to validate the use of capillary blood in a real point-of-care (POC) setting for patients under adalimumab treatment by using Promonitor Quick ADL lateral flow test. Results were compared to the Promonitor ELISA reference technique in serum samples used by centralised laboratories. In addition, the use of serum samples with Promonitor Quick ADL test in comparison with Promonitor-ADL ELISA was validated.

Aims & Methods: A prospective, observational study was designed to evaluate the performance of a rapid test (Promonitor Quick ADL, Progenika, Spain). 137 adalimumab treated rheumatology consecutive patients (167 samples) were recruited in two hospitals in Galicia, Spain. Prior to the injection, a finger prick and a serum sample were obtained and analysed. Results were read with the automated portable PQreader instrument. Additionally, the same serum sample was subsequently analysed with the ELISA test for comparative purposes.

Qualitative (positive (PPA) and negative (NPA) agreements) and quantitative (Pearson correlation and bias) performance of the Promonitor Quick ADL test was compared to ELISA, as well as between different specimens following CLSI EP09-A3.

Results: Overall agreement between Promonitor Quick ADL finger prick and ELISA test was 95% (94% PPA; 100% NPA). The quantitative comparison showed a good correlation (Pearson correlation coefficient: 0.7 and observed bias: 17%) (Table 1).

Similar results were also observed when serum was used with either the Promonitor Quick ADL or the ELISA tests (98% overall agreement, 0.8 correlation coefficient; 2% bias) (Table 1).

Qualitative Comparison				
	N*	PPA	NPA	overall
POC finger prick vs ELISA	160	94%	100%	95%
POC serum vs ELISA	166	97%	100%	98%
Quantitative Comparison				
	N*	Pearson correlation	Bias	
POC finger prick vs ELISA	78	0.7	17%	
POC serum vs ELISA	87	0.8	2%	

*Only samples in the common measurement range for both methods considered.

Table 1. Performance results. ADALIMUMAB DRUG

Conclusion: Promonitor Quick ADL can be used to reliably quantify adalimumab in capillary blood or serum samples and results are comparable to those obtained with the reference ELISA technique. The use of the rapid POC test with finger prick will allow clinicians to monitor their patients in a fully decentralized mode to aid in the decision-making process.

Disclosure: A. Ametzazurra, J. Pascual, L. Del Río, D. Nagore and MB. Ruiz-Argüello are Progenika Biopharma - Grifols employee.

THE IMPACT OF DRUG LEVELS TO ANTI-TNF AND ANTI-INTEGRIN AGENTS ON COVID-19 VACCINE RESPONSE IN PATIENTS WITH IBD

J. Doherty¹, R. Stack², N. O'Morain², M. Tosetto³, R. Inzitari⁴, D.J. Daghfal⁵, P. Doran⁴, C. O'Morain⁶, G.A. Doherty⁷

Contact E-Mail Address: jaynedohertie@hotmail.com

Introduction: Patients with IBD receiving biologic agents, especially anti-TNF agents have reduced response rates to COVID-19 vaccination [1]. The reason for this is unclear and whether a patient's drug levels at the time of vaccination impacts vaccine response is unknown.

Aims & Methods: To determine if a patients drug level to biologic agents at the time of COVID-19 vaccination impacts antibody response.

IBD patients and healthy controls (HC) were recruited prospectively from five centres and quantitative antibody responses and drug levels assessed following COVID-19 vaccination.

Results: 270 IBD patients and 116 HCs were recruited. Median age was 39.5 years. 145 patients were treated with anti-TNF therapy. Median anti-spike protein (SP) immunoglobulin (Ig)G levels post-complete vaccination in our IBD cohort was significantly lower than HC (2,613 AU/mL versus 6,871 AU/mL, $p < 0.001$). IBD patients receiving anti-TNF therapy had significantly lower anti-SP IgG levels (2,445AU/mL) than those not receiving TNF-inhibitors (3868AU/mL) ($p < 0.001$). 99 patient's treated with infliximab, 24 with adalimumab and 12 with vedolizumab had drug levels at the time of vaccination.

	IBD Cohort (n=270)	Adequate drug levels	Low Drug Levels	p value
Median age (IQR)	39.5			
Male gender	160 (59.3%)			
Crohn's Disease	155 (55.5%)			
Anti-TNF therapy	145 (53.7%)			
Median Infliximab levels	8.9 µg/ml			
Median Adalimumab levels	12.2 µg/ml			
Median Vedolizumab levels	11.5 µg/ml			
Median Spike Protein Ab levels post vaccination (AU/mL)	2613	3018	2235	0.16

Table.

We found no significant correlation between SP IgG levels post-vaccination against COVID-19 and IFX levels (correlation co-efficient -0.17, $p = 0.09$), adalimumab levels (correlation co-efficient -0.28, $p = 0.24$), vedolizumab levels (correlation co-efficient -0.11, $p = 0.74$) or positive antibodies to inf-

liximab (correlation co-efficient -0.15, $p = 0.6$). Although a slight numerical difference, low drug levels to biologic agents did not impact subsequent SP IgG levels. Median SP IgG levels in patients with low drug levels were 3081AU/mL versus 2235AU/mL in those with adequate levels ($p = 0.16$).

Conclusion: Although IBD patients receiving anti-TNF agents have reduced antibody response to vaccination against COVID-19 a patients drug levels at the time of vaccination does not appear to impact antibody response for those receiving anti-TNF or anti-integrin agents. We are currently exploring other mechanisms of action for the reduced response seen in IBD patients.

ANORECTAL DISORDERS AMONG IBD PATIENTS IN REMISSION, WITH FECAL INCONTINENCE AND TREATED WITH BIOLOGICS – PILOT STUDY FROM A TERTIARY REFERRAL CENTER

M. Jelakovic¹, K. Grubelic Ravic¹, A. Ladic¹, N. Turk¹, A. Barišić¹, D. Anzulović Grgic¹, S. Cukovic-Cavka^{1,2}, M. Brinar^{1,2}, Z. Krznaric^{1,2}

²University of Zagreb, School of Medicine, Zagreb, Croatia

Contact E-Mail Address: mislavjelakovic@gmail.com

Introduction: Anorectal disorders and fecal incontinence (FI) are highly prevalent in inflammatory bowel disease (IBD) patients with reports in literature ranging from 20-80%. However, there is limited data on anorectal disorders among IBD patients with FI who are in remission and treated with biologics.

Aims & Methods: In this cross-sectional observational study we have included IBD patients, treated with biologics through our out-patient clinic. Demographics and medical data were collected from electronic medical charts, while patients were screened for FI using the St. Mark's incontinence score (SMIS). Significant FI was characterized as SMIS ≥ 6 . High resolution anorectal manometry (HRAM) following London protocol and classification was used for detection of anorectal disorders (AD). Descriptive and analytical statistical analysis was used.

Results: We included 100 patients (43 female/57 male) in clinical remission treated with biologics, median age 41 years (range 18-70), 41 patients had ulcerative colitis (UC) and 59 had Crohn's disease (CD). Median disease duration was 7 years (range 1-32). Significant FI was identified in 53 patients (53%) out of which 92.45% were in biochemical and 35.85% in endoscopic remission. FI was more prevalent among CD patients (64.1%) compared to UC (33.9%), but the difference did not reach statistical significance. There was no significant correlation between FI and gender, type or number of biologics or disease duration.

There was a significant positive correlation with age ($r=0.2457$, $p<0.05$), especially for patients older than 50 years of age who also had significantly higher average SMIS scores compared to younger patients (13.6 ± 5.4 vs 11.5 ± 2.9 ; $t=2.1$; $p<0.05$). HRAM was conducted in seven patients with significant FI (SMIS 10.6 ± 2.3), out of which 3 had dyssynergia with anal hypotension, 3 had isolated dyssynergia and one had isolated rectal hypersensitivity.

Conclusion: Based on our findings we can conclude that FI is highly prevalent among IBD patients in clinical, but also in endoscopic remission with increased risk with older age. Among these patients AD are common, especially anal hypotension and dyssynergia. Further studies are needed to better understand the prevalence and treatment options of AD in this population.

Disclosure: Nothing to disclose.

Introduction: Sarcopenia is a progressive and generalised reduction in skeletal muscle mass and strength and it is associated with increased adverse outcomes. Age-related sarcopenia is termed primary sarcopenia. Muscle loss secondary to inactivity, systemic diseases (inflammatory, neoplastic or organ failure) or malnutrition is termed secondary sarcopenia. In the course of Inflammatory Bowel Disease (IBD), the risk of sarcopenia is increased due to increased systemic inflammation and malabsorption.

Aims & Methods: This study aims to investigate the risk, prevalence, severity and associated factors of sarcopenia in IBD patients. Consecutive IBD patients meeting the ECCO (European Crohn's and Colitis Organisation) diagnosis criteria under the follow-up of the outpatient gastroenterology clinic of our tertiary center were invited. Patients with physical disability, pregnancy, osteoporosis and active malignancy were excluded. Healthy subjects without any immune or chronic inflammatory disorders were enrolled as a control group. The risk of sarcopenia was assessed via SARC-F (Strength, assistance with walking, rising from a chair, climbing stairs, and falls) questionnaire. Muscle strength was assessed by measurement of handgrip strength with the Jamar hydraulic hand dynamometer. Body composition including lean muscle mass was assessed with bioimpedance analysis (BIA). Physical performance was assessed by a 4-meter usual gait speed (UGS) test. European Working Group on Sarcopenia in Older People (EWGSOP) algorithm is applied to diagnose sarcopenia and determine the severity.

Results: A total of 121 patients with IBD, and 50 healthy controls were included. Patient and control groups had similar age and sex distribution. In IBD group 56 patients were diagnosed with Crohn's Disease (CD), and 64 patients were diagnosed with ulcerative colitis (UC). The Median SARC-F questionnaire score of IBD patients was higher than health controls (1 vs 0 $p=0.000$). IBD patients displayed a significant reduction in mean appendicular skeletal muscle mass (ASM: 25.5 ± 6.0 vs 28.2 ± 5.2 ; $p=0.006$), and appendicular skeletal muscle mass/height² (ASM/Height²: 9.4 ± 2.1 vs 9.9 ± 0.9 ; $p=0.033$). Gait Speed Test performance was significantly lower in IBD patients [1.06 (0.95-1.21) vs 3.51 (2.86-3.91) $p=0.000$]. According to EWGSOP cut-offs, 13 (10.7%) patients had clinical suspicion of sarcopenia, 19 (15.7%) had probable sarcopenia, and two (2%) had definite sarcopenia. Sarcopenia prevalence was not found to be correlated with disease activity, disease type, steroid use within the last year, and biological treatment.

	Crohn's Disease (n=45)	Ulcerative Colitis (n=56)	Healthy controls (n=50)
Appendicular skeletal muscle mass	26.0± 5.4	25.0± 6.5	28.1± 5.26
Muscle strength	31.8 ± 11.8	30.3 ± 11.6	33.1±10.8
Body mass index (Mean±SD)	25.1 ± 4.6	27.3 ± 4.7	24.9 ± 3.4
L1 ileal	20 (%37.0)	-	-
L2 colonic	2 (%3.7)	-	-
L3 ileocolonic	32 (%57.3)	-	-
E1 proctitis	-	3 (%5.6)	-
E2 left colitis	-	36 (%66.7)	-
E3 extensive colitis	-	18 (27.1)	-

Table 1: Disease localisation, muscle mass and strength of patients

Conclusion: Appendicular skeletal muscle mass, handgrip strength, and gait speed were significantly lower in patients with IBD compared to healthy controls. Although clinical suspicion of sarcopenia was detected in more than 15% of IBD patients, only two of them were eventually diagnosed with sarcopenia. For further assessment of the relation between appendicular skeletal muscle mass and the factors related to IBD, a larger sample size is required.

Introduction: Some data confirm that risk of pancreatic damage in inflammatory bowel disease (IBD) is higher than in general population. The changes of pancreatic structure can be described by certain criteria in endosonographic examination (EUS).

Aims & Methods: To compare and assess the structural pancreatic alterations by Rosemont EUS criteria in chronic pancreatitis (CP) and IBD.

56 CP patients and 24 IBD patients without significant clinical pancreatic signs were examined (UC-15 persons and CD-9 persons). All patients underwent EUS with an assessment of parenchymatic and ductal structures of pancreas according to Rosemont EUS classification.

Results: In IBD patients hyperechoic bands in the pancreatic parenchyma, dilated lateral branches of main pancreatic duct (MPD), hyperechoic contour of pancreas, and areas of adjacent lobular structures were more often detected. In accordance with the Rosemont classification "definitive" CP was established in 25% of IBD cases, "suspected" CP in 25% of cases, "possible" CP in 33.3% and no EUS signs of CP were found in 16.7%. All changes were expressed in pancreatic head and body only. The normal EUS picture of the pancreatic tail was preserved in most of the examined patients.

In CP patients pseudocysts of pancreatic tail and body, MPD dilatation, intraductal calcifications and calcifications in lateral branches were observed. In total EUS-signs such as "definitive" CP were detected in 46% of CP patients, 26% - "suspected" CP, 28% - "possible" CP.

Disease	Definitive CP Abs (%)	Suspected CP Abs (%)	Possible CP Abs (%)	No SP symptoms Abs (%)
CP	25 (46%)	14 (26%)	15 (28%)	0
IBD	6 (25%)	6 (25%)	8 (33.3%)	4 (16.7%)

Table. Frequency of pancreatic EUS damages (Rosemont classification) in IBD and CP patients

Totally, different pancreatic damages of various severity was found in 83.3% of IBD patients. In this group Rosemont pancreatic parenchyma signs were detected in 59% of cases and ductal changes in 41% of cases. While in CP the parenchyma was affected in 36% of cases and the ducts in 64% of cases.

Conclusion: EUS data demonstrate different pancreatic structural changes in CP patients (mainly ducts) and in IBD patients (mainly parenchyma). Thus, EUS confirms the high frequency of predominantly parenchymal structural changes in IBD patients who didn't demonstrate clinical pancreatic manifestations. We believe that EUS can identify latent pancreatic alteration in IBD.

Disclosure: Nothing to disclose.

Introduction: The TRANS-IBD RCT is designed to provide strong evidence of the impact of transitional care on quality of life and patient management, increasing physician-patient satisfaction, and ongoing education. The primary outcome is measured with the IMPACT-III questionnaire, that is already adapted in Hungary.

Secondary outcomes include measurement of drug adherence (MARS), self-efficacy (IBDSES-A), transition readiness (TRAQ and STARx-A, STARx-P), patient satisfaction (CACHE), and not lost to follow-up, disease activity.

Aims & Methods: Our aim was to perform a cross-cultural adaptation of the questionnaires used in the TRANS-IBD RCT. As a step in the adaptation process based on international guidelines, an English-Hungarian and then a Hungarian-English translation was made, with the correction of linguistic and cultural dissonances. In the final step, ten randomly selected adolescents assessed the comprehensibility.

The Hungarian version of the questionnaires was tested among adolescents with inflammatory bowel disease in a pre-defined age group from nine Hungarian gastroenterology centres. R statistic program was used in the statistical analysis (R version 4.1.0, R Core Team, Vienna, Austria, 2021).

Internal consistency was determined by Cronbach's alpha coefficients. To assess if the model fits the original model, confirmatory factor analysis (CFA) was conducted, root Mean Square Error of Approximation (RMSEA), Comparative Fit Index (CFI), and Tucker-Lewis Index (TLI) were used.

Results: A total of 122 adolescents completed the questionnaires (47% male, mean age 17.12 [min-max: 14-19]). Linguistic translation and semantic evaluation of the questionnaires were not a problem during the adaptation process.

During the cultural evaluation, an item related to health insurance was modified in the TRAQ questionnaire and items related to appointment keeping were deleted in STARx questionnaires. During the comprehensibility interviews, some misunderstandings were identified and corrected accordingly. The final versions of the questionnaires were comprehensible to our population in terms of both content and language.

During the statistical analyses modification was made in IBD-SES due to an error in the CFA analyses. In the MARS, IBD-SES and TRAQ questionnaire, Cronbach's α scores were found good (0.864; 0.729; 0.865, respectively), while in the CACHE questionnaire the score was rated as excellent (0.906). The internal consistency was unacceptable in STARx-A, and questionable in STARx-P (0.415 and 0.693, respectively). The test-retest reliabilities were satisfactory in MARS, IBD-SES, CACHE and in the STARx questionnaires ($r=0.814$; $r=0.819$; $r=0.892$; $r=0.787$; $r=0.788$, respectively), while it remained under the acceptable level in TRAQ ($r=0.034$). Except in the STARx questionnaires, the confirmatory factor analyses show statistically acceptable results.

Conclusion: Adaptation of questionnaires is essential to conduct a clinical trial that provides high scientific evidence. The Hungarian MARS, IBD-SES, TRAQ, and CACHE questionnaires are feasible, reliable, reproducible, and comparable with the original validated versions.

The adaption of the STARx tools was not successfully accomplished, thus the future evaluations with the translated STARx surveys are not comparable with any international results.

Disclosure: Nothing to disclose.

INFLAMMATORY BOWEL DISEASE WITH CONCOMITANT ENDOMETRIOSIS: FREQUENCY AND CHARACTERIZATION IN A CASE-CONTROL PROSPECTIVE STUDY

B. Neri¹, C. Russo², M. Mossa¹, R. Mancone¹, F. Pizzi¹, A. Selntigia², E. Calabrese¹, C. Exacoustos², L. Biancone¹

¹Università degli Studi di Roma Tor Vergata, Medicina dei Sistemi, Unità di Gastroenterologia, Rome, Italy, ²Università degli Studi di Roma Tor Vergata, Scienze Chirurgiche, Unità di Ginecologia, Rome, Italy

Contact E-Mail Address: benedettoneri@gmail.com

Introduction: Inflammatory bowel disease (IBD) and endometriosis are immuno-mediated chronic inflammatory diseases observed in young women, sharing some of the clinical manifestations (i.e. abdominal pain). The possible association between endometriosis and IBD is undefined.

Aims & Methods: In a multidisciplinary approach, we aimed to assess, in prospective matched-control study, the frequency of endometriosis in IBD patients (pts) with compatible symptoms. Secondary end point was to assess differences in terms of characteristics of endometriosis and -related symptoms in pts with vs without IBD.

All female IBD pts in childbearing age referring symptoms compatible with endometriosis were enrolled and referred to dedicated gynecologists for transvaginal ultrasonography. Each IBD pt with endometriosis (Case) was retrospectively matched for age (± 5 yrs) and body mass index (BMI) (± 1) with 3 Controls with endometriosis but no-IBD.

Inclusion criteria for Cases were:

1. Female gender;
2. Age ≥ 18 and ≤ 55 years;
3. Well-defined diagnosis of IBD;
4. Regular follow-up;
5. Symptoms compatible with endometriosis;
6. Consent.

Inclusion criteria for Controls were:

1. Female gender;
2. Age ≥ 18 and ≤ 55 years;
3. Well defined diagnosis of endometriosis.

Exclusion criteria for Cases and Controls were:

- 1) Pregnancy;
- 2) Menopause.

Characteristics of IBD, endometriosis and adenomyosis were classified according to standard criteria. The study was approved by the Ethic Committee. Data were expressed as median [range]. The Student-t Test and χ^2 test were used for comparisons.

Results: Endometriosis was diagnosed in 19 (57.9%) out of 28 IBD pts with compatible symptoms. Overall, 76 pts with endometriosis were assessed (age, yrs: 38 [24-53]; BMI 21.5 [17.3-41.6]), including 19 pts with IBD and 57 with no-IBD. These 19 IBD pts included 10 (52.6%) Crohn's Disease (CD), 9 (47.4%) Ulcerative Colitis (UC) (IBD duration: 14[1-35] yrs).

CD extent included: ileum in 3 (30%), colon in 1 (10%), ileum-colon in 6 (60%) pts. CD behavior was non-stricturing non-penetrating in 5 (50%), stricturing in 3 (30%), penetrating in 2 (20%) pts, with perianal disease in 3 (30%). UC extent included proctitis in 2 (22.2%), left-sided in 3 (33.3%), pancolitis in 4 (44.4%)pts.

Cases and Controls were comparable in terms of age (38 [25-53] vs 38 [24-48] yrs; $p=0.42$), BMI (21.6 [17.3-41.6] vs 21.2 [18.3-41.4]; $p=0.58$), frequency of dysmenorrhea (16 [84.2%] vs 45 [78.9%]; $p=0.86$), dyschezia (7 [36.8%] vs 12 [21.1%]; $p=0.28$), dysuria (3 [15.8%] vs 3 [5.3%]; $p=0.32$). Dyspareunia was significantly more frequent in Cases vs Controls (14 [73.7%] vs 26 [45.6%], $p=0.03$).

At transvaginal ultrasonography, deep infiltrating endometriosis was significantly more frequent in Cases vs Controls, being observed in all the 19 [100%] IBD pts and in 44 [77.2%] non-IBD controls ($p=0.02$). The high frequency of rectal endometriosis observed in IBD pts (7 [36.8%]), did not differ from Controls (12 [24.6%]; $p=0.1$). Adenomyosis was observed in 13 (68.4%) Cases and in 25 (43.8%) Controls ($p=0.06$).

Conclusion: In the tested IBD population, half of IBD pts with compatible symptoms showed endometriosis with a high rate of rectal endometriosis. A higher frequency of dyspareunia and deep infiltrating endometriosis (observed in all Cases) was observed in IBD vs non-IBD controls. Endometriosis should be searched in IBD pts with compatible symptoms, often mimicking IBD activity.

Introduction: Malnutrition is a very common and underappreciated complication in patients with inflammatory bowel diseases (IBD), which represent a high-risk population for malnutrition, even in patients in remission. However, little statistical information is available on the predictors of malnutrition.

Aims & Methods: The aim of this study is to assess nutritional status in a cohort of IBD patients and to determine predictive factors of malnutrition. This is a cross-sectional study conducted in the hepato-gastroenterology department of the Sahloul University Hospital over a period of one year. This study included 105 patients followed for IBD diagnosed on clinical, endoscopic and/or histological criteria at least 6 months before the start date of the study. We evaluated associations between demographic and clinical characteristics and risk of malnutrition assessed by the Malnutrition Universal Screening Tool (MUST-score). This tool includes body mass index (BMI), recent weight loss, and whether the patient will have no nutritional intake for more than 5 days.

Results: Our study included 105 patients, of whom 77 patients (73.3%) had Crohn's disease and 28 patients had ulcerative colitis (26.7%). The mean age at data collection was 38.6 ± 15.8 years. Our population was divided into 48 males (45.7%) and 57 females (54.3%), 52 non-smokers, 23 smokers and 30 ex-smokers. Only 15 patients (14.3%) were in an acute phase of their disease, including 10 patients with anorexia in the last 5 days. Thirty seven patients (35.2%) were overweight, 47 patients (44.8%) had a normal BMI and 21 patients (20%) were considered underweight. Using the MUST score, 43 (41%) patients were classified as low risk of malnutrition and 62 (59%) were classified as medium or high risk. In univariate analysis: Crohn's disease, disease activity, and use of immunomodulators and steroids were significantly associated with an increased risk of malnutrition (respectively $p=0.001$; $p=0.006$; $p=0.001$; $p=0.021$).

Conclusion: The MUST score is an easy tool to assess the risk of malnutrition in IBD patients.

Crohn's disease, disease activity, and use of immunomodulators and steroids are significant predictors of under nutrition risk. Therefore, assessment and screening for malnutrition should be routinely included in IBD clinical practice.

Disclosure: Nothing to disclose.

Contact E-Mail Address: hazalsalva@gmail.com

Introduction: Monitoring the disease activity with a non-invasive and accurate scale was still challenging in Perianal Fistulizing Crohn's Disease (PFCD). Machine learning-based prediction models have been increasing in number for evaluation of disease activity in inflammatory bowel disease (IBD). Magnetic resonance imaging (MRI) is still the gold standard technique in the diagnosis and assessment the disease activity in PFCD.

Aims & Methods: This study aims to describe the clinical characteristics and radiological scores of PFCD patients and generate a data-driven machine learning predictive model for radiological healing.

Primary endpoints for response were MAGNIFI-CD ≤ 6 and a decrease in Van Assche Index (VAI) radiologic scores after Anti-TNF treatment.

Secondary endpoints were the need for intraabdominal surgery and clinical fistula response. The PFCD patients who were followed-up in our IBD-specific out-patient clinic with a perianal MRI before and after the Anti-TNF treatment were included in the study. MAGNIFI-CD Score and VAI were calculated before and after the treatment.

Demographic and clinical data including smoking habits, Montreal Classification, Parks Fistula Classification, seton history, proctitis/rectitis history, stenosis history, history of abscess, Harvey-Bradshaw Index (HBI) and Perianal Disease Activity Index (PDAI) clinical were collected. A predictive machine learning model was generated by using ElasticNet Regression which utilizes both Lasso (L1 norm) and Ridge (L2 norm) regularizations.

Results: A total of 47 PFCD patients were enrolled in the study. The median age was 40 years (19 – 74) and 20 (42.6%) were female. The median time between the first and last perianal MRI was 19 months (4 – 98).

Seventeen patients had simple fistulas and 26 patients had complex fistulas. According to the Park classification, 28 patients had intersphincteric, 7 patients had transsphincteric, 11 patients had intersphincteric and transsphincteric fistulas. Thirty-one patients' VAI scores was decreased following the treatment and 16 patients' scores stayed the same or increased. According to the MAGNIFI CD score, 29 (61.7%) of patients were in remission following the treatment. Nine patients had intra-abdominal surgery during follow-up. The need for intraabdominal surgery was higher in the group with a history of an abscess ($p=0.008$). The clinical remission rate according to the HBI was significantly higher in patients with clinical fistula response ($p=0.044$).

According to our novel machine learning model, MAGNIFI-CD score prior to the treatment, rectal involvement and hyperintensity values of VAI, age at diagnosis, Parks fistula type, seton history, post-fistula antibiotic treatment and hypoalbuminemia were significant in predicting radiological progression and intraabdominal surgery requirement.

The mean squared error obtained by the model in the training data was 3.97, the variance in the score predicted by the model was 66%. The mean squared error obtained by the model in the test data is 8.23, the variance in the target variable can be explained 54%.

Conclusion: Our novel machine learning model performed promising prediction of fistula healing in PFCD by using radiological variables including pre-treatment total MAGNIFI-CD score, rectal involvement and hyperintensity values of pre-treatment VAI. Clinical scores and these parameters might be used together to predict prognosis during follow-up.

Disclosure: Nothing to disclose.

SARS-COV-2 INFECTION DOES NOT WORSEN THE CLINICAL COURSE OF INFLAMMATORY BOWEL DISEASE: A 1-YEAR PROSPECTIVE CASE-CONTROL STUDY

B. Neri¹, G. D'Agostini¹, S. Salvatori¹, M. Mossa¹, F. Bettin¹, L. Montesano¹, I. Marafini¹, E. Lolli¹, E. Calabrese¹, G. Monteleone¹, L. Biancone¹

¹Università degli studi di Roma Tor Vergata, Medicina dei sistemi, Unità di Gastroenterologia, Rome, Italy

Contact E-Mail Address: benedettoneri@gmail.com

Introduction: Whether SARS-CoV-2 infection may worsen the long-term outcome of Inflammatory bowel disease (IBD) is currently undefined.

Aims & Methods: In a prospective single center, case-control study, we aimed to investigate the possible role of SARS-CoV-2 infection as a risk factor for a worse clinical outcome of IBD at 1-year (yr).

From March to April 2021, all IBD pts with recent (<2 months) SARS-CoV-2 infection (Cases) were enrolled. Each Case was matched with 4 IBD Controls with no history of SARS-CoV-2 infection (Controls). All pts were followed-up for 1 yr. Inclusion criteria for Cases were: 1) age ≥18-≤85 yrs; 2) well-defined diagnosis of IBD; 3) SARS-CoV-2 infection <2 months; 4) written consent. Exclusion criteria was pregnancy.

Inclusion criteria for Controls were:

1. Age ≥18-≤85 yrs;
2. Well-defined diagnosis of IBD;
3. Written consent.

Exclusion criteria were:

1. Pregnancy;
2. History of SARS-CoV-2 infection.

IBD characteristics and activity were assessed at baseline and at 1 yr, according to standard criteria. Data were expressed as median [range]. The Student-t Test and χ^2 test were used for comparisons and univariate logistic regression model for assessing risk factors for IBD relapse (OR [95%CI]).

Results: The analysis included 122 IBD pts: 29 (23.7%) Cases and 93 (76.3%) Controls (150 enrolled IBD pts: 22 did not met the inclusion criteria, 6 lost at follow-up). Clinical characteristics were comparable between the 2 groups: age (43 [30-69] vs 52 [20-82] yrs; $p=0.08$), gender (F) (16 [55%] vs 62 [67%]; $p=0.36$), IBD duration (14 [2-38] vs 14 [1-45]; $p=0.99$), smoker status (5 [17.2] vs 16 [17.2]; $p=0.78$), IBD type (UC 12 [41%] vs 47 [51%]; $p=0.51$), UC extent (proctitis 5 [17%] vs 12 [13%]; $p=0.45$), left-sided (2 [7%] vs 15 [16%]; $p=0.49$), pancolitis 5 [17%] vs 15 [16%]; $p=0.76$), CD site (ileum 7 [24%] vs 25 [27%]; $p=0.51$); colon 2 [7%] vs 5 [5%]; $p=0.72$), ileum-colon 6 [21%] vs 13 [14%]; $p=0.81$), upper GI (2 [7%] vs 2 [2%]; $p=0.62$), CD behavior (non-stricturing non-penetrating 3 [10%] vs 11 [12%]; $p=0.84$); stricturing (10 [34%] vs 19 [20%]; $p=0.34$); penetrating (4 [14%] vs 13 [14%]; $p=0.95$); ongoing thiopurines in 11 (38%) vs 29 (31%); $p=0.65$), ongoing biologics in 11 (38%) vs 36 (39%); $p=0.88$) pts.

At baseline, IBD was active in 9 (31%) Cases vs 18 (19%) Controls ($p=0.28$). During 1-yr, the frequency of clinical relapse was comparable between Cases vs Controls (7 [24%] vs 16 [17%]; $p=0.57$), also when subgrouping symptoms (diarrhea, rectal bleeding, abdominal pain, fever; $p=0.57$). The same finding was observed for steroids use ($p=0.51$), biologics

withdrawal ($p=0.96$), IBD-related hospitalizations ($p=0.96$). At univariate analysis, risk factors for clinically active IBD during 1-yr included activity at baseline (3.7 [1.3-9.8]; $p=0.008$) and female gender (4.5 [1.7-11.8]; $p=0.02$), but not SARS-CoV-2 infection (1.6 [0.59-4.46]; $p=0.34$). Ongoing biologic therapy was a protective factor against IBD activity during 1-yr (0.28 [0.09-0.9]; $p=0.03$).

Conclusion: In a prospective case-control study, SARS-CoV-2 infection did not increase the risk of IBD relapse within 1-yr vs IBD control pts with no history of infection.

Introduction: Despite considerable therapeutic advances in the management of Crohn's disease (CD) over the past two decades, its course and complications remain unpredictable. Indeed, CD is associated with significant nutritional deficiencies and metabolic disturbances, including sarcopenia, defined as a loss of muscle strength and quantity, which represents a major health burden by reducing substantially the quality of life.

Aims & Methods: The aim of this study was to assess the prevalence and to determine the associated factors of sarcopenia during CD.

We conducted a retrospective single-center study, including patients followed for CD over a 7-year period [2014 - 2021]. Clinico-biological data, disease severity, and long-term outcomes (surgery and disease course) were collected.

Measurement of the psoas muscle area has been applied to estimate lean muscle mass as a surrogate marker of sarcopenia, these measurements were performed on computed tomography (CT) by calculating the total psoas area at the third lumbar vertebra level. Then, the total psoas area index (TPAI) was calculated using the equation: $TPAI (mm^2/m^2) = (Left Psoas Area (mm^2) + Right Psoas Area (mm^2)) / Height (m^2)$. Sarcopenia was defined by a TPAI less than 385 mm^2/m^2 for female patients and 545 mm^2/m^2 for male patients.

Results: In total, 50 patients were enrolled with a mean age of 44.3 years [20-82], a median disease duration of 106 months and a sex ratio M/F of 3.16. Sarcopenia was observed in 14 patients (28%) with a mean TPAI of 612 mm^2/m^2 [1763 - 206].

Compared with patients without sarcopenia, sarcopenic patients are more likely to have a severe malnutrition ($p=0.026$), they had a significantly lower BMI ($p=0.039$); lower ferritin levels ($p=0.026$); lower hemoglobin levels ($p=0.036$); hyponatremia ($p=0.028$) and a lower creatinine level ($p<0.0001$).

Sarcopenia was independent of disease location and extent. Regarding CD phenotype, we found that a structuring behaviour in the CD was significantly associated with the sarcopenia ($p=0.046$).

Moderate to severe CD activity, as assessed by the Crohn's Disease Activity Index (CDAI) and the Harvey Bradshaw Index (HBI), was associated with sarcopenia with a p -value of 0.03 and 0.05 respectively for both indices. When analysing, the AUROC of CDAI and HBI in predicting the presence of sarcopenia in CD was 0.634 and 0.676 respectively, with a cutoff of 183 for CDAI and 5 for HBI.

During the follow up, more patients with sarcopenia required biotherapy ($p=0.01$). Patients who underwent surgery was not in a higher risk of sarcopenia, however sarcopenia was identified as a predictive factor of the occurrence of postoperative complication with p -value = 0.05.

Conclusion: In our study, almost third of CD patients were sarcopenic. Our results suggest that sarcopenia was associated with the activity of the disease, structuring phenotype, increasing biological treatment need and major risk of postoperative complications. Systematic screening and treatment in this context should be recommended to improve the course of the disease. New potential therapeutic approach that can regulate the gut-muscle axis in inflammatory bowel disease should be investigated.

SUPERB MICRO-VASCULAR IMAGING FOR PREDICTING THE ACTIVITY OF TERMINAL ILEUM LESIONS IN PATIENTS WITH CROHN'S DISEASE

H. Shimazaki¹, M. Nasuno¹, T. Hamada¹, H. Nagasawa¹, K. Sugiyama^{2,1}, M. Miyakawa¹, H. Tanaka¹

Introduction: Assessing blood flow in the bowel wall using the coloured Doppler technique for gastrointestinal ultrasonography is useful for evaluating intestinal activity in patients with Crohn's disease (CD). However, the major limitation of this technique is its sensitivity to low blood flow velocities and small vessels. Superb micro-vascular imaging (SMI) is a technique for assessing slow and micro-vascular blood flow. Currently, very few studies have evaluated intestinal activity in patients with CD using the SMI techniques.

Aims & Methods: This study aimed to compare ultrasound images obtained by SMI with endoscopic findings obtained by endoscopy, specifically in the terminal ileum of patients with CD. We retrospectively collected the data of patients with CD who underwent ultrasonography between September 2020 and December 2021 at our clinic and whose terminal ileum could be evaluated through ileocolonoscopy within 3 months before or after ultrasonography. Patients with a history of small bowel resection were excluded from this study.

Lesions in the terminal ileum were classified into four groups according to endoscopic findings (1: no ulcers, 2: aphthous ulcers [<5 mm], 3: small ulcers [5–20 mm] and 4: large ulcers [>20 mm]). Ultrasonography was performed using Aplio a550 (Canon Medical Systems Corp., Tochigi, Japan). Scanning of the small bowel was initiated by defining the terminal ileum laying ventrally on the psoas muscle and then following its course in the proximal direction to the maximum extent possible.

Blood flow signals in the intestinal wall of the terminal ileum were evaluated using SMI. The scan of SMI was initially performed using a 5-MHz convex probe, following which a more detailed scan of the affected area was performed using a 9.2-MHz linear probe. The parameter settings of SMI were as follows: colour velocity of 1.2 cm/s and colour frequency of 4 MHz. We used a simple unique score, categorised into four grades (grade 0:

no blood flow signals, grade 1: short signals, grade 2: longer signals and grade 3: longer signals reaching the mesentery), to evaluate SMI signals. Endoscopic findings and SMI grades were compared to investigate SMI signals predicting lesions in the terminal ileum.

Results: This study included 140 patients (median age, 28.5 years; median disease duration, 5.6 years), of which 32 were women. At the time of CD diagnosis, 10 patients had ileitis, 103 had ileocolitis and 27 had colitis. The median Harvey–Bradshaw index value was 2.0. Endoscopic findings of no ulcers, aphthous ulcers, small ulcers and large ulcers were revealed in 66, 40, 21 and 13 patients, respectively. SMI grades 0, 1, 2 and 3 were observed in 104, 19, 6 and 11 patients, respectively. Intestinal lesions on endoscopic findings, including aphthous, small or large ulcers, were observed in 42%, 74%, 83% and 100% of the patients with SMI grades 0, 1, 2 and 3, respectively.

Furthermore, small or large ulcers were observed in 10%, 58%, 67% and 82% of the patients with SMI grades 0, 1, 2 and 3, respectively. Small or large ulcers were observed in 67% of the patients with SMI grade 1 or above. The sensitivity and specificity of SMI grade 1 or above for predicting small or large ulcers were 70.6% and 88.7%, respectively.

Conclusion: The activity of lesions in the terminal ileum in patients with CD increased as the SMI grade increased. All patients with SMI grade 3 had some intestinal lesions. Only 10% of the patients with SMI grade 0 had small or large ulcers. This study showed that SMI grade 1 or above indicated small or large ulcers with 88.7% specificity.

Contact E-Mail Address: laterza.lucrezia@gmail.com

Introduction: Predicting clinical outcomes represents a major challenge in Crohn's disease (CD). Radiomics provides a method to extract quantitative features from medical images and may successfully predict clinical course, however its application in CD is still scarce.

Aims & Methods: The aim of this study is to evaluate the use of radiomics to predict the need for surgery at 10 years in a cohort of CD patients.

We retrospectively selected a cohort of CD patients with available CT scan enterographies and a 10-year follow up. Typical lesions of CD were segmented in each CT scan. An open-source R library (Moddicom) was used to extract radiomic features from each segmented lesion.

A logistic regression model based on selected radiomic features was developed to predict 10-year surgery. The model was evaluated by computing the area under the curve (AUC) of the receiver operating characteristic curve, sensitivity, specificity, positive and negative predictive values (PPV, NPV).

Results: We enrolled 30 patients, with 44 CT scans and 93 lesions. We extracted 217 radiomic features from each lesion.

The developed model was based on two radiomic features (intensity variance and normalized grey-level non-uniformity from the grey-level run length matrix) and presented an AUC (95% CI) of 0.83 (0.73-0.91) in predicting 10-year surgery. Sensitivity, specificity, PPV and NPV of the radiomic model were equal to 0.72, 0.90, 0.79, 0.86, respectively.

Conclusion: Radiomics could be a helpful tool to identify patients with high risk for surgery and needing a stricter monitoring or therapy intensification.

Disclosure: Nothing to disclose.

Introduction: Differentiation between inflammatory and fibrotic bowel strictures remains a holy grail in Crohn's disease (CD) management, primarily because of the therapeutic implications. Stricture characterisation in CD patients is further hampered by the co-occurrence of inflammation and fibrosis in various degrees.

Currently, there are no validated imaging tools to differentiate fibrotic from inflammatory or mixed strictures, but several new techniques, such as magnetization transfer magnetic resonance imaging (MT-MRI) and magnetic resonance texture analysis (MR-TA), seem promising.

Aims & Methods: To investigate these possible new imaging techniques for stricture management, we assessed the performance of magnetization transfer (MT) magnetic resonance imaging (MRI) and texture analysis (TA) of T2-weighted images. Temporal MT and T2-weighted magnetic resonance (MR) images were correlated with histology as the gold standard in a model of gut fibrosis resulting from chronic colitis induced in C57BL/6J mice by cyclic administration of dextran sulfate sodium.

The performance of MT-MRI and TA was validated in the same model with an antifibrotic therapy administered to one group of mice. To check the translatability of the results, MR enterography images of patients with CD who underwent bowel surgery were retrospectively analyzed and matched with histopathology.

Results: The MT-MRI and TA entropy correlated with fibrosis on the histopathology ($r=.85$ and $.81$, respectively). However, TA entropy was superior to the MT-MRI for quantifying the progression of fibrosis (linear regression $R^2=.93$) because the MT-MRI signal was severely biased due to coexisting inflammation. The effect of the successful antifibrotic therapy was efficiently captured using TA entropy. Finally, TA entropy was a valid parameter to detect and grade intestinal fibrosis in axial T2-weighted MR images of patients with CD.

Conclusion: Based on the applied model of relapsing-remitting colitis, which allowed the study of coexisting inflammation and progressive fibrosis, we demonstrated that although MT-MRI and TA entropy are highly promising surrogate markers of intestinal fibrosis, TA entropy performed better in monitoring and quantifying fibrotic lesions in the presence of concomitant inflammation.

Introduction: With the recent progress in endoscopic interventions and the establishment of the Surveillance for Colorectal Endoscopic Neoplasia Detection and Management in Inflammatory Bowel Disease Patients: International Consensus Recommendations (SCENIC) consensus, endoscopic resection is gaining acceptance as a treatment option in patients with ulcerative colitis (UC). Therefore, the importance of detection of neoplasia in the early stage is increasing. However, lesion detection in patients with UC is difficult because of the effect of inflammation, it may be characterized by a distinct "bottom-up" growth pattern, and even expert endoscopists have relatively little experience with such cases.

Nowadays, some computer-aided detection (CADE) Systems during colonoscopy have been introduced into clinical practice for non-UC patients. The systems have been reported to raise the adenoma detection ratio.

Aims & Methods: The aim of this study is to assess the usefulness and limitations of the computer-aided detection (CADE) system in surveillance colonoscopy in patients with UC. This single-center retrospective pilot study included 180 consecutive patients with UC who underwent colonoscopy between April 20, 2021.

All colonoscopies were performed using high-definition endoscopes. In this study, the artificial intelligence (AI) algorithm of CADE has used the modified algorithm of EndoBRAIN-EYE (Cybernet system corp.), which is already on the market for targeting non-UC patients: all training images of (AI) algorithm were obtained from non-UC patients.

The overall white light endoscopy (WLE) images of eligible patients were collected and analyzed for the presence of neoplasia by the CADE system. The golden standard of the presence of neoplasia was defined as the lesion with pathologists diagnosed as neoplasia.

Results: The 180 cases analyzed included 33 lesions (4 UC-associated neoplasia, 22 sporadic neoplasia, and 7 sessile serrated lesions), lesions indicated for treatment that was detected by the endoscopist and confirmed by pathology. The macroscopic types based on the SENIC consensus were sessile in 8 cases, Superficial elevated in 22 cases, flat in 1 case, and depressed in 2 cases.

A total of 5078 images were analyzed (with lesions: 105 images, without lesions: 4973 images). The diagnostic accuracies of CADE were sensitivity 87.6%, specificity 84.8%, accuracy 84.8%, positive predictive value 10.8%, and negative predictive value 99.7%. The positive predictive value was significantly low because CADE specifically recognized mucosa with high inflammatory activity and inflammatory polyps as target lesions.

Conclusion: The CADE system specifically designed for surveillance colonoscopy of patients with UC needs to be developed.

Introduction: The Lémann index (LI) is a unique tool that measures cumulative bowel damage in Crohn's disease (CD) and is composed of surgical procedures and severity and extent of bowel lesions according to endoscopy and MR enterography. (1) Aim of this study is to investigate factors associated with cumulative bowel damage using Lemann index in adult population with CD.

Aims & Methods: Aim of this study is to investigate factors associated with cumulative bowel damage using Lemann index in adult population with CD.

In this cross-sectional study on 178 CD patients LI was calculated evaluating 20 small bowel, 7 large bowel and 3 upper GI segments. For each segment bowel resections, inflammatory, stricturing or penetrating lesions were taken into account. Global MaRIA (gMaRIA) index was calculated using following parameters on 6 bowel segments on MR enterography: bowel wall thickness, ulcers, edema and relative contrast enhancement.

Longstanding disease was defined as ≥10 year disease duration. Disease activity was defined as CRP>5 or HBI≥5. Extent and disease behaviour was assessed using Montreal classification.

Results: This study included 320 CD patients [age 35 (25-47), 55.3% males, disease duration 7 (1-14) years, BMI 21.7 (17.6-24.9) kg/m²]. There were 103 (40%) surgically naïve and 112 (44.6%) patients with longstanding disease. Multivariate analysis on total population, adjusted for age, gender, BMI, smoking status, CRP, disease behaviour and extension, biological therapy, gMaRIA score, and HBI revealed independent predictors of elevated LI which were BMI ($\beta=-0.257$, $p<0.018$), disease duration ($\beta=0.113$, $p=0.045$) and prior surgery ($\beta=5.370$, $p<0.001$). Due to expected influence of prior surgery on cumulative bowel damage, separate analysis was performed on surgically naïve patients.

Multivariate analysis adjusted for aforementioned variables revealed following independent positive predictors; current smoking ($\beta=1.135$, $p=0.009$), perianal disease ($\beta=1.436$, $p=0.016$) and gMaRIA score ($\beta=0.087$, $p<0.001$).

Conclusion: Cumulative bowel damage is one of major concerns for both patients and clinicians. Using validated Lémann index and adjusting for multiple important confounding factors, we have revealed longer disease duration, prior surgery and lower BMI as important risk factors for cumulative bowel damage. Since surgical procedures contribute significantly to the LI, it is important to determine risk factors of cumulative bowel damage in surgically naïve patients, which were smoking status, perianal disease and higher gMaRIA score, i.e. radiological disease activity. This risk factors in CD could stratify patients at high risk for complicated course of disease.

Introduction: Clinical and magnetic resonance imaging (MRI) features associated with perianal fistula closure in Crohn's disease (CD) are controversial and recently degree of fibrosis along with disease activity (MAGNIFI-CD index) have been suggested to be predictive of long-term clinical outcome.

Aims & Methods: This study aimed to analyze clinical and MRI features associated with positive long-term outcome. Positive long-term outcome was defined as the absence of surgery or hospitalization requested by perianal fistulizing CD during follow-up. CD patients with perianal disease performing MRI between 2016 and 2019 in a tertiary center were kept for

analysis. One senior and one junior radiologist performed retrospectively a blind-review of disease activity (MAGNIFI-CD index and modified Van Assche index) and degree of fibrosis. Clinical features were collected retrospectively.

Results: Fifty-two patients were analyzed: 33 female, median age 36 years $\pm$ 1,81, median follow-up duration 37,75 months $\pm$ 1,94. Positive clinical outcome was observed in 36 patients (69,23%). Median MAGNIFI-CD index was lower in patients with positive long-term clinical outcome compared to patients with negative outcome (10,75 vs. 16,50, $p < 0,01$). Similarly, a lower modified Van Assche index was found in patient with positive clinical outcome ($p < 0,05$).

In addition, patients with positive long-term outcome presented more frequently improvement in T2-weighted images ($p < 0,01$) and lower C-reactive protein (CRP) level compared with patients with negative clinical long-term outcome (5,60 vs. 34,60 mg/L, $p < 0,05$). Last, degree of fibrosis failed to predict long-term clinical outcome in this study.

Conclusion: In this study, disease activity (MAGNIFI-CD index and modified Van Assche index) but not degree of fibrosis was predictive of long-term clinical outcome along with CRP levels.

Disclosure: Nothing to disclose.

Introduction: Tofacitinib is an oral small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). Tofacitinib induction treatment has been shown to improve work productivity in patients with UC. However, the relationship between disease activity and work productivity in the tofacitinib OCTAVE clinical programme has not been described.

Aims & Methods: We aimed to evaluate the relationship between Mayo score and Work Productivity and Activity Impairment-Ulcerative Colitis (WPAI-UC) score among patients in the Phase 3 studies evaluating tofacitinib as induction or maintenance therapy for UC (OCTAVE Induction 1&2 [NCT01465763, NCT01458951]; OCTAVE Sustain [NCT01458574]). Relationships between Mayo score (total and subscores) and WPAI-UC components (absenteeism, presenteeism, productivity loss and activity impairment) were estimated using a repeated measures longitudinal model in which Mayo score/subscore was a continuous anchor and WPAI-UC was the outcome (ie a linear relationship was imposed between the outcome and anchor). In sensitivity analyses, Mayo score was used as a categorical anchor to assess the linearity assumption (which did not impose any functional relationship between outcome and anchor). Productivity loss encapsulates absenteeism and presenteeism and thus is the most comprehensive WPAI-UC component. Analyses used all available pooled data from patients receiving tofacitinib or placebo.

Results: Relationships between total Mayo score and WPAI-UC

components were very similar when using the Mayo score as a continuous anchor, compared with a categorical anchor, supporting the linearity assumption. The relationship between total Mayo score and productivity loss was robust, with total Mayo scores of 0 and 12 corresponding to productivity loss scores of 12.7% (95% CI 9.9, 15.5) and 67.1% (64.5, 69.6), respectively (Table).

For every 1- or 3-point decrease in disease activity measured by total Mayo score (0–12), productivity loss (0–100%) improved by 4.5% (4.2, 4.9) and 13.6% (12.5, 14.7), respectively. Similar trends were observed between total Mayo score and activity impairment and presenteeism; the relationship with absenteeism was weak. Similar relationships were observed between individual Mayo subscores and WPAI-UC components.

	Productivity loss, least squares mean, % (95% CI)
Total Mayo score	
0	12.7 (9.9, 15.5)
1	17.2 (14.7, 19.7)
2	21.7 (19.5, 23.9)
3	26.3 (24.4, 28.2)
4	30.8 (29.1, 32.5)
5	35.3 (33.8, 36.8)
6	39.9 (38.5, 41.3)
7	44.4 (43.0, 45.8)
8	48.9 (47.4, 50.5)
9	53.5 (51.8, 55.2)
10	58.0 (56.0, 60.0)
11	62.5 (60.3, 64.8)
12	67.1 (64.5, 69.6)
Point increase in total Mayo score	
1	4.5 (4.2, 4.9)
2	9.1 (8.3, 9.8)
3	13.6 (12.5, 14.7)

The WPAI-UC is a self-administered six-item survey that generates four metrics: absenteeism (work time missed), presenteeism (impairment whilst working), productivity loss (overall work impairment from the combination of absenteeism and presenteeism) and activity impairment (non-work activity impairment). WPAI component scores are expressed as percentages, with a higher percentage indicating greater impairment and less productivity.

The Mayo score measures disease activity by assessing stool frequency, rectal bleeding, endoscopy and Physician Global Assessment. Total Mayo score ranges from 0 to 12 points (each subscore ranges from 0 to 3), with higher scores indicating more severe disease activity. CI, confidence interval; UC, ulcerative colitis; WPAI-UC, Work Productivity and Activity Impairment-Ulcerative Colitis.

Table. Percentage of productivity loss at each total Mayo score in patients with UC in OCTAVE Phase 3 induction and maintenance studies (main model with total Mayo score as a continuous anchor)

Conclusion: In patients with UC in the induction and maintenance studies, robust relationships between Mayo score (total and subscores) and productivity loss were observed. These post hoc clinical trial data may not be fully generalisable to clinical practice.

Introduction: Tofacitinib is an oral small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). Tofacitinib induction treatment has been shown to improve work productivity in patients with UC. However, the relationship between health-related quality of life (HRQoL) and work productivity in the tofacitinib OCTAVE clinical programme has not been described.

Aims & Methods: We aimed to evaluate the relationship between Inflammatory Bowel Disease Questionnaire (IBDQ) domains and Work Productivity and Activity Impairment-Ulcerative Colitis (WPAI-UC) components among patients in the Phase 3 studies evaluating tofacitinib as induction or maintenance therapy for UC (OCTAVE Induction 1&2 [NCT01465763, NCT01458951]; OCTAVE Sustain [NCT01458574]).

Relationships between IBDQ (total and domain scores) and WPAI-UC components (absenteeism, presenteeism, productivity loss and activity impairment) were estimated using a repeated measures longitudinal model in which IBDQ domain score was a continuous anchor and WPAI-UC component score was the outcome (ie a linear relationship was imposed between the outcome and anchor).

In sensitivity analyses, IBDQ domain score was used as a categorical anchor to assess the linearity assumption (which did not impose any functional relationship between outcome and anchor). Productivity loss includes absenteeism and presenteeism and thus is the most comprehensive WPAI-UC component. Analyses used all available pooled data from patients receiving tofacitinib or placebo.

Results: Relationships between IBDQ total score and WPAI-UC components were very similar when using the IBDQ total score as a continuous anchor, compared with a categorical anchor, supporting the linearity assumption. The relationship between IBDQ total score and productivity loss was robust, with IBDQ total scores of 224 and 32 (higher score = better HRQoL) corresponding to a 5.6% (95% CI 3.4, 7.8) and 100.7% (97.3, 104.1) impact, respectively (Table).

For every 16-point increase in IBDQ total score, productivity loss (0–100%) improved by 7.9% (7.5, 8.4) (Table). Similar trends were observed between IBDQ total score and activity impairment and presenteeism; the relationship with absenteeism was weak. Similar relationships were observed between IBDQ domains and WPAI-UC components.

	Productivity loss, least squares mean, % (95% CI)
IBDQ total score	
32	100.7 (97.3, 104.1)
40	96.8 (93.6, 99.9)
60	86.9 (84.2, 89.5)
80	76.9 (74.7, 79.2)
100	67.0 (65.3, 68.8)
120	57.1 (55.7, 58.5)
140	47.2 (46.1, 48.4)
160	37.3 (36.2, 38.4)
180	27.4 (26.1, 28.8)
200	17.5 (15.8, 19.2)
220	7.6 (5.5, 9.7)
224	5.6 (3.4, 7.8)
Point decrease in IBDQ total score	
1	0.5 (0.5, 0.5)
16	7.9 (7.5, 8.4)

The WPAI-UC is a self-administered six-item survey that generates four metrics: absenteeism (work time missed), presenteeism (impairment whilst working), productivity loss (overall work impairment from the combination of absenteeism and presenteeism) and activity impairment (non-work activity impairment). WPAI component scores are expressed as percentages, with a higher percentage indicating greater impairment and less productivity.

The IBDQ evaluates disease-related quality of life by 32 items over four domains: bowel (total domain score ranges from 10 to 70), emotional (total domain score ranges from 12 to 84), social (total domain score ranges from 5 to 35) and systemic (total domain score ranges from 5 to 35). For the total score (ranges from 32 to 224) and each domain, a higher score indicates a better quality of life.

CI, confidence interval; IBDQ, Inflammatory Bowel Disease Questionnaire; UC, ulcerative colitis; WPAI-UC, Work Productivity and Activity Impairment-Ulcerative Colitis

Table. Percentage of productivity loss at IBDQ total scores in patients with UC in OCTAVE Phase 3 induction and maintenance studies (main model with IBDQ total score as a continuous anchor)

Conclusion: In the induction and maintenance studies, robust relationships between IBDQ (total and domain scores) and productivity loss were observed. These post hoc clinical trial data may not be fully generalisable to clinical practice.

Contact E-Mail Address: joanatorres00@gmail.com

Introduction: Tofacitinib is an oral small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). Avoidance of colectomy remains an important goal of UC therapy, and there are known factors associated with increased risk of colectomy.¹

Aims & Methods: This post hoc analysis assessed baseline characteristics and presence of risk factors for colectomy among patients who underwent colectomy in the tofacitinib OCTAVE clinical programme (NCT01465763; NCT01458951; NCT01458574; NCT01470612). Incidence rates (IRs; unique patients with events per 100 patient-years [PY] of exposure) were assessed in 3 cohorts: Induction (placebo [PBO] or tofacitinib 10 mg twice daily [BID]), Maintenance (PBO, tofacitinib 5 or 10 mg BID) and Overall (patients who received ≥ 1 dose of tofacitinib 5 or 10 mg BID in the Phase 3 or open-label, long-term extension [OLE] studies). Risk factors assessed were: age < 40 years at diagnosis, extensive colitis, severe endoscopic disease (Mayo endoscopic subscore of 3), hospitalisation for colitis within 12 months, C-reactive protein > 3 mg/L and serum albumin < 3.5 g/dL.¹

Results: In total, 14 patients underwent colectomy: 3/1139 in the induction studies (tofacitinib 10 mg BID: n=2; PBO: n=1), 3/593 in the maintenance study (PBO: n=3) and 8/944 in the OLE study (tofacitinib 10 mg BID: n=8; per protocol patients were not in remission at baseline). IRs per 100 PY (95% confidence intervals; exposure) were: Induction: PBO, 2.47 (0.06, 13.74; 40.55 PY) and tofacitinib 10 mg BID, 1.26 (0.15, 4.55; 158.72 PY); Maintenance: PBO, 2.90 (0.60, 8.47; 103.48 PY), tofacitinib 5 mg BID, 0.00 (0.00, 2.48; 148.77 PY) and tofacitinib 10 mg BID, 0.00 (0.00, 2.35; 157.31 PY); Overall: tofacitinib all, 0.34 (0.16, 0.63; 2915.95 PY). Baseline characteristics of patients who underwent colectomy, including treatment duration and risk factors for colectomy, are summarised (Table); all had ≥ 1 risk factor and prior tumour necrosis factor inhibitor (TNFi) exposure.

Conclusion: Colectomies were infrequent in the OCTAVE clinical programme, all were in patients with prior TNFi exposure and most patients had multiple risk factors. For induction responders, the fact that colectomies only occurred in patients who received PBO and not tofacitinib in the maintenance study supports the importance of continued active therapy in patients with moderate to severe UC. This analysis was limited by the low number of colectomies and potential underestimation due to case report form identification without adjudication.

Contact E-Mail Address: neasamcgettigan@hotmail.com

Introduction: Physical exercise has many potential benefits in IBD including an improvement in quality of life, favourable body composition changes, anti-inflammatory effects, and improved psychological health. The WHO recommends 150–300 minutes of moderate-intensity or 75–150 minutes of vigorous-intensity aerobic physical activity per week for adults aged 18–65 years.

Patients with IBD have a significant decrease in exercise tolerance compared with healthy individuals. Exercise as an adjuvant treatment modality in IBD is underutilised and data are required in patients with active IBD.

Aims & Methods: Aim:

1. To assess physical activity levels, attitudes, and barriers to exercise in patients with IBD.
2. To assess the willingness of IBD patients to engage in an exercise programme.
3. To assess the frequency of body image issues in our IBD patients.

Method: Anonymous patient surveys were completed at Beaumont and Connolly Hospitals Dublin, Ireland.

Surveys were distributed in the outpatient clinics, infusion suites and inpatient wards between October and December 2021. Descriptive statistics, χ^2 testing and Pearson's correlations was completed using Minitab17. $P < 0.05$ denoted statistical significance.

Results: Data were analysed for 203 patients of which 62% ($n=126$) had an underlying diagnosis of Crohn's disease. Over half of respondents were male ($n=115$) with mean self-reported weight of 83kg. Mean weight among females was 76 kg ($n=88$). Reportedly 71% exercise regularly, for an average of 3.2 days/week and 59 mins/day of exercise.

Men exercise for longer than women on exercise days (60 minutes, $n=108$ versus 40 minutes, $n=82$, Mann-Whitney U test= 0.0005) and UC participants exercise for longer than CD participants (60 minutes, $n=61$ versus 45 minutes, $n=105$, Mann-Whitney U test= 0.044).

The most common activity was walking (74%). A post-diagnosis change in exercise behaviour was found in 66% with three-quarters exercising less. Principal barriers to exercise included lack of energy (54%), IBD symptoms (33%), toilet access concerns (31%), joint pains (31%) and time constraints (31%). Body image issues were common (62%) and associated with female gender ($p=0.007$) and age < 45 years ($p=0.02$).

Mean importance of exercise was 4, Std. dev. 0.97 (scale 0-5, 5 very important) and importance correlated with number of exercise days ($r=0.394$, $p<0.001$).

Exercise variable	Result N (%)
Regular exercise (N, %)	
Yes	148 (73%)
No	55 (27%)
No. of days of exercise/week	
Total Responses	148/148 (100%)
Mean, Std. dev.	4, 1.42
No. of minutes exercising/day	
Total Responses	140/148 (95%)
Median, IQR	60, 41.25-60
Rating of exercise importance (0-5)	
Total Responses	197/203 (97%)
Mean, Std. Dev.	4, 0.97
Benefits of exercise (N, %)	
Feel physically better	181/196 (92%)
Improved energy	165/196 (84%)
Improved mood	182/196 (93%)
Relief of anxiety	165/190 (87%)
Preferred location of exercise (more than one answer allowed)	
Total responses	201/203 (99%)
Outdoors	141/201 (70%)
At home	40/201 (20%)
At the Gym	49/201 (24%)
Difficulty adhering to exercise programmes	
Total Responses	198/203 (98%)

Std. dev.- standard deviation, IBD- inflammatory bowel disease, dx- diagnosis

Table 1. Results of Exercise Behaviour

Conclusion: The majority of patients meet the WHO physical activity guidelines. Body image issues are common and associated with gender and younger age. IBD patients have exercise adherence issues and exercise less because of their disease. Fatigue is a significant barrier to exercise. These data demonstrate an impact of IBD on patient-reported ability to exercise. A pilot programme of physician-supervised exercise in addition to standard care in patients with active IBD is underway to determine impact on patient attitudes, disease-related outcomes and body composition (NCT05174754).

Contact E-Mail Address: lalbina@inbox.ru

Introduction: Patients with inflammatory bowel diseases (IBD) could develop thromboembolic complications (TEC) more frequently, compared with the general population.

Aims & Methods: The objective was to determine the value of the D-dimer concentration and to evaluate the role of heparin prophylaxis on the risks of clinically significant TEC in patients with severe attack of total ulcerative colitis (UC).

Materials and methods: The study included patients with severe total ulcerative colitis (UC) who were hospitalized from April 2019 to May 2020 in the department of treatment of IBD of the State Medical Institution of the Moscow Clinical Scientific Center named after A.S. Loginov. During 2019-2020, 217 patients with severe total UC were examined: in 2019 – 98 patients, in 2020 – 119 patients. The concentration of D-dimer [N=0.0-0.50 mcg/ml] was determined in all patients at the time of hospitalization by micro-latex agglutination. Clinically significant TEC were visualized by Ultrasound and CT.

In 2020, according to research plan, all patients with a severe attack of total UC were treated with low-molecular-weight heparins, regardless of the presence or absence of proven high-risk factors for TEC. A regression analysis of TEC risks was carried out depending on the D-dimer concentration.

Results: TEC during the follow-up period occurred in 18 patients (8.3%); no lethal outcomes were documented. The level of D-dimer in the group of patients with TEC ranged from 1.0 to 3.8 mcg/ml, in the group of patients without a TEC ranged from 0.1 to 1.8 mcg/ml. The risk of TEC is higher in the group of patients with D-dimer concentration more than 0.50 mcg/ml (RR - 0.062; 95% CI 0.113 - 0.034; χ^2 - 105.292; $p < 0.001$). A strong correlation was established between the D-dimer level and the TEC risk ($r=0.88$; $p < 0.001$).

In 2019, clinically significant TEC were determined in 14 (14.3%) patients. In 2020, the clinically significant TEC were determined in 4 (3.4%) patients. (RR - 4.250; 95% CI 1.445 - 12.497; χ^2 - 8.431; $p = 0.004$).

Conclusion: In hospitalized patients with UC, D-dimer values had a strong correlation with the risk of a TEC. Prevention with low-molecular-weight heparins significantly reduces the risks of TEC in patients with severe total UC.

Disclosure: Nothing to disclose.

Introduction: The effect of antidepressant therapy on Inflammatory Bowel Disease (IBD) remains controversial. This trial aimed to assess whether adding venlafaxine to standard therapy for IBD improved the quality of life (QoL), mental health and disease activity in IBD patients with anxious and depressive symptoms.

Aims & Methods: A prospective, randomized, double-blind, placebo-controlled clinical trial was conducted. Participants diagnosed with IBD with symptoms of anxiety/depression were randomly assigned to receive either venlafaxine 150 mg daily or equivalent placebo and followed for 6 months. Inflammatory Bowel Disease Questionnaire (IBDQ), Mayo score, Crohn's disease activity index (CDAI), Hospital Anxiety and Depression Scale (HADS) and blood examination were completed before the enrollment, during and after the follow-up. Mixed linear models and univariate analyses were used to compare groups.

Results: Forty-five IBD patients were included, of whom 25 were randomized to receive venlafaxine. The mean age was 39.76 (SD=11.30) years old. 25 (55.6%) was male. Venlafaxine showed a significant improvement on QoL ($p < 0.001$) and disease course ($p = 0.035$), a greater reduction in HADS (anxiety: $p < 0.001$, depression: $p < 0.001$), Mayo scores ($p < 0.001$) and CDAI ($p = 0.006$) 6 months. Venlafaxine had no effect on IL-10 expression, endoscopic scores, relapse rate and use rate of biologics and corticosteroids, but did reduce serum level of ESR ($p = 0.003$), CRP ($p < 0.001$) and TNF- α (0.009).

Conclusion: Venlafaxine has a significantly beneficial effect on QoL, IBD activity and mental health in IBD patients with comorbid anxious or depressive symptoms. (Chinese Clinical Trial Registry, ID: ChiCTR1900021496.)

Introduction: Patients on immunosuppressive drugs have been excluded from COVID-19 vaccines trials, creating concerns regarding their efficacy in this setting.

Aims & Methods: Effectiveness and Safety of COVID-19 Vaccine in Patients with Inflammatory Bowel Disease (IBD) Treated with Immunosuppressive or Biological Drugs (ESCAPE-IBD) is a prospective, multicentre study promoted by the Italian Group for the study of Inflammatory Bowel Disease.

We present data on serological response eight weeks after the second dose of COVID-19 vaccination in IBD patients and healthy controls (HCs).

Results: 1076 patients with IBD and 1126 HCs were analyzed. Seropositivity for anti-SARS-CoV-2 IgG was reported for most IBD patients, even if with a lesser rate compared with HCs (92.1% vs. 97.9%; $p < 0.001$). HCs had higher antibody concentrations (median OD 8.72 [IQR 5.2-14.2]) compared to the whole cohort of IBD patients (median OD 1.54 [IQR 0.8-3.6]; $p < 0.001$) and the subgroup of IBD patients ($n = 280$) without any treatment or on aminosalicylates only (median OD 1.72 [IQR 1.0-4.1]; $p < 0.001$). IBD patients treated with anti-TNFs showed significantly lower median anti-SARS-CoV-2 IgG levels compared with those without any treatment or on aminosalicylates only (OD 1.30 [IQR 0.7-3.0] vs. 1.72 [IQR 1.0-4.1]; $p < 0.001$), those treated with Vedolizumab (OD 1.78 [IQR 1.1-4.1]; $p = 0.001$), and Ustekinumab (OD 1.71 [IQR 0.9-4.9]; $p = 0.03$).

Conclusion: Although most IBD patients showed seropositivity after two doses of COVID-19 vaccines, the magnitude of the humoral response was significantly lower than in HCs.

Differently from other studies, these findings seem to be mostly unrelated to the use of immune-modifying treatments. Regarding COVID-19 vaccination, patients with IBD should be regarded as a whole as a "frail" category, therefore requiring booster/additional doses of COVID-19 vaccine. (ClinicalTrials.govID:NCT04769258).

Introduction: Ustekinumab (UST) is a p40 inhibitor of interleukin 12/23 approved to treat moderately to severely active ulcerative colitis (UC).

Aims & Methods: Retrospective and descriptive study of patients with ulcerative colitis treated with ustekinumab ($N = 16$) from July 2018 to September 2021 in the Inflammatory Bowel Disease Unit of our Hospital.

The primary objective was to analyze the efficacy: clinical remission (CR) and biological remission (BR), persistence with the drug and need for dose optimization.

The secondary objective was to determine the efficacy of UST in articular manifestations in ulcerative colitis.

Results: Basal characteristics of patients and disease are summarized in Table 1.

The mean duration of treatment with UST is 17.81 months (SD 12.57). 81.30% of patients were started on UST without concomitant use of corticosteroids.

Clinical remission (partial Mayo score <2 and no subscore >1) was achieved in 25% in Week 4 (4 out of 16 subjects), 50% in Week 8 (8/16), 69.2% in Week 16 (9/13), 54.5% in Week 24, 90% in Month 12 (9/10) and 87.5% in Month 18.

Rectal bleeding, present in 81.30% of patients in the beginning, disappeared in half of them in Week 4.

Partial Mayo score decreased during the follow-up ($p < 0.001$). The median level of fecal calprotectin (FC) at the index visit was 1214.63 mg/kg (SD 954.67), and had a tendency towards normalization ($p = 0.064$). Biological remission (FC <150 mg/kg) was achieved in 56.25% of subjects at the end of follow-up. Fecal calprotectin decrease principally occurred from Week 16. In 11 patients (68.75%), the dose was optimized every 4 weeks, because of secondary non-response or partial response. Clinical remission and biological remission (FC <150 mg/kg) was accomplished in 86.6% and 45.45% of them respectively.

87.50% of subjects who had been started on UST continue treatment at the end of follow-up.

6 patients (37.5%) suffered from articular manifestations (5 peripheral arthritis, 1 ankylosing spondylitis), that improved in 83.3% after initiation of UST.

No significant adverse events were detected.

Age (years)	49.74 (SD 17.04)
Duration of the disease (years)	11.96 (SD 9.87)
Basal partial Mayo score	5.75 (SD 2.08)
Gender	
Male	9 (56.30%)
Female	7 (43.80%)
Extension of ulcerative colitis	
Proctitis	3 (18.80%)
Left colitis	11 (66.80%)
Extended colitis	2 (12.50%)
Extra-intestinal manifestations	
Yes	6 (37.50%)
No	10 (62.50%)
Basal Mayo endoscopic score	
1	1 (10.00%)
2	4 (40.00%)
3	5 (50.00%)
Previous biological therapy	
≥2 biological drugs :	8 (50.00%)
≥2 anti-TNF + VDZ :	5 (31.25%)
≥2 anti-TNF + VDZ + TOFA:	2 (12.50%)
1 biological drug	6 (37.50%)
Naïve	2 (12.50%)
Maintenance dose	
90 mg sc every 4 weeks	6 (37.50%)
130 mg iv every 4 weeks	5 (31.25%)
90 mg sc every 8 weeks	3 (18.75%)
90 mg sc every 12 weeks	2 (12.50%)
VDZ: vedolizumab. TOFA: tofacitinib	

Table 1. Characteristics of patients and disease

Conclusion: - UST is an effective treatment to achieve and maintain long-term clinical and biological remission in patients with ulcerative colitis.

- Biological remission is accomplished in half of the patients and FC decreases mainly after Week 16.

- Treatment optimization because of secondary non-response or partial response is effective in achieving clinical remission, but not so effective in achieving biological remission.

- UST may be useful in the treatment of articular manifestations, especially in peripheral arthritis, although further research is needed.

Disclosure: Nothing to disclose.

Introduction: Serious infections have been observed in patients with inflammatory bowel disease (IBD) on anti-TNF use, but to what extent these infections are due to anti-TNF or the disease activity per se is hard to disentangle. Earlier studies on the risk of infections related to anti-TNF use have shown varying results and data from randomised controlled trials (RCTs) and observational studies are conflicting. While RCTs have rarely demonstrated any excess risks of infections, such risk increases have been reported in observational studies¹⁻⁵.

One of the reasons for the contrasting results may be that the untreated placebo group used in RCTs has a higher proportion of patients with active disease. The enrichment of severely sick (untreated) comparators makes it harder to demonstrate an increased risk of infection among treated patients.

Observational studies more often have a longer follow-up and thereby greater statistical power to detect small differences and rare events. There are several other challenges in appropriately determining the risk of serious infection. In addition to anti-TNF and immunomodulating agents (azathioprine, 6-mercaptopurine and methotrexate), disease activity, corticosteroid use, opioids, malnutrition, co-morbidity and age are all potential confounders potentially predisposing to infections⁶.

Aims & Methods: We aimed to describe how the rates of serious infections change before and after anti-TNF initiation in flaring IBD and thereby shed light on the role of anti-TNF (as opposed to that of disease activity) for the risk of infection. IBD patients naïve to anti-TNF treatment were identified at five centers participating in the Swedish IBD Quality Register, and their medical records examined in detail. Serious infections, defined as infections requiring in-patient care, the year before and after the start of anti-TNF treatment were evaluated.

Results: Among 980 patients who started their first anti-TNF therapy between 1999 and 2016, the incidence rate of serious infections was 2.19 [95% CI: 1.43-3.36] per 100 person-years the year before and 2.11 [95% CI: 1.33-3.34] per 100 person-years one year after treatment start. This corresponded to an incidence rate ratio one year after anti-TNF treatment of 0.97 [95% CI: 0.51-1.84]. Compared to before anti-TNF therapy, the incidence of serious infection was significantly decreased more than one year after treatment (Incidence rate ratio 0.56 [95% CI: 0.33-0.95], $p = 0.03$).

Time (years)	Incidence rate per 100 person years	95% Confidence interval
-1- <0	2.19	1.43-3.36
0- <1	2.11	1.33-3.34
1- <2	0.89	0.51-1.57
2- <3	0.32	0.13-0.76
3- <4	0.34	0.16-0.76
4- <5	0.36	0.16-0.79
5- <6	0.48	0.24-0.96
6- <7	0.13	0.03-0.52
>7	0.13	0.03-0.53

Table 1 The annual incidence rate of serious infections among IBD patients the year before start of anti-TNF treatment (-1- <0) and during anti-TNF treatment (0- <1, 1- <2 etc.).

Conclusion: In conclusion, in this real-world study from five Swedish centers caring for both urban and rural areas, the rate of serious infections in IBD patients was equally high the year before and the year after start of anti-TNF treatment and significantly lower beyond the first year of anti-TNF treatment. Healing the mucosa may outweigh the adverse immunosuppressive effect on the risk for infection and emphasizes the importance of treating the underlying disease. The findings are applicable when assessing the risk and benefits of therapies together with the patient.

Introduction: The composition of the gut microbiome is associated with disease course and response to therapy in inflammatory bowel diseases (IBD).[1,2] Different effects of various antibiotic classes on immunogenicity towards anti-TNF agents were recently demonstrated.[3] We aimed to assess the association between antibiotic treatment and persistence of biologics therapy.

Aims & Methods: Data from the epidemiology group of the Israeli IBD research nucleus (epi-IIRN) were used. All patients treated with infliximab, adalimumab, vedolizumab, or ustekinumab were included in the analysis. Multivariable cox proportional hazards models with time varying covariates were developed for each biologic therapy to assess the association between antibiotic use and treatment non-persistence, defined as cessation of drug purchases for more than 6 months. The multivariable models included medical treatments including antibiotics, hospitalizations, surgical procedures and laboratory results. Exposure was defined as a drug dispensation or event in the year prior to each time point during the time at risk.

Results: We included 13,513 patients who received at least one biologic. Median ages at treatment initiation ranged between 24 and 28. Most treated patients had Crohn's disease ranging between 59% of patients treated with vedolizumab and 95% of patients treated with ustekinumab. Rates of previous biologic therapy ranged between 19% in infliximab and 96% for ustekinumab. Median times at risk ranged between 1.2 and 2.1 years for ustekinumab, and infliximab respectively. Treatment cessation event were 28, 29, 34, and 39 events per 100 patient years for ustekinumab, adalimumab, vedolizumab, and infliximab respectively. Macrolides and fluoroquinolones were associated with reduced risk of infliximab discontinuation, while metronidazole use increased risk for infliximab cessation (Table 1). Cephalosporins and fluoroquinolones were associated with adalimumab cessation, whereas fluoroquinolones were associated with vedolizumab cessation (Table 1). Antibiotics were not significantly associated with durability of ustekinumab treatment.

Survival Models (aHR, 95% CI)*	Infliximab (n=7,639)	Adalimumab (n=8,686)	Vedolizumab (n=3,232)	Ustekinumab (n=1,246)
Antibiotics	0.98 (0.92, 1.04)	1.03 (0.97, 1.10)	1.07 (0.95, 1.20)	0.90 (0.72, 1.13)
Penicillin	0.98 (0.92, 1.04)	1.03 (0.97, 1.10)	1.03 (0.91, 1.16)	0.85 (0.66, 1.09)
Penicillin-BLI	1.02 (0.95, 1.09)	1.03 (0.96, 1.10)	1.06 (0.95, 1.20)	1.00 (0.80, 1.25)
Cephalosporin	1.00 (0.94, 1.08)	1.10 (1.03, 1.18)	1.04 (0.92, 1.18)	1.09 (0.86, 1.38)
Fluoroquinolones	0.88 (0.82, 0.94)	1.11 (1.03, 1.18)	1.16 (1.03, 1.31)	0.96 (0.76, 1.22)
Macrolides	0.87 (0.80, 0.94)	0.97 (0.90, 1.05)	0.97 (0.85, 1.11)	1.06 (0.82, 1.36)
Metronidazole	1.13 (1.05, 1.20)	1.00 (0.94, 1.08)	1.00 (0.88, 1.14)	0.89 (0.68, 1.15)
Tetracyclin	0.94 (0.80, 1.09)	1.03 (0.89, 1.19)	0.82 (0.63, 1.05)	0.91 (0.59, 1.40)

* Two survival models were developed for each biologic with different primary effects: 1. Any antibiotic exposure; 2. Each antibiotic class as a separate variable.

Table 1. Adjusted hazard ratios for treatment cessation for all antibiotics (model 1) and each antibiotic separately in a combined model (model 2).

The following covariates were included in all models: Crohn's disease; previous biologic therapy; surgery (time varying); hospitalization (time varying); immunomodulators (time varying); steroids (time varying); purchase of a different biologic agent (time varying); albumin (time varying, per 1 g/dL); hemoglobin (time varying, per 1 g/dL).

Conclusion: Specific antibiotic classes are distinctively associated with treatment persistence of biologic agents. These observations may be partially mediated by the effects of antibiotics on immunogenicity, whereas further research is needed to mechanistically understand other associations. Nonetheless, these data suggest a need to customize antibiotic choice in biologics-treated IBD patients.

Introduction: Anti-IL23p19 inhibitors are emerging as promising treatment options for ulcerative colitis (UC). Mirikizumab (miri) is a humanized, IgG4 monoclonal antibody directed against the p19 subunit of IL-23, a key mediator in the pathogenesis of inflammatory bowel diseases.

Aims & Methods: We assessed the induction efficacy and safety of miri with a Phase 3, multi-center, randomized, parallel-arm, double-blind, placebo (PBO)-controlled trial (LUCENT 1; NCT03518086) in patients with moderately to severely active UC (Modified Mayo Score 4-9 points and centrally read Mayo endoscopic subscore ≥ 2) who had inadequate response, loss of response, or intolerance to corticosteroids, immunosuppressants, biologic therapies, or tofacitinib.

Adult patients (N=1281) were randomized in a 3:1 ratio to receive blinded intravenous administration of 300 mg miri or PBO every 4 weeks for 12 weeks. Randomization was stratified by biologic failure status, baseline (BL) corticosteroid use, BL disease activity as measured by modified Mayo score, and world region.

The primary objective was to test the hypothesis that miri was superior to PBO in inducing clinical remission at Week 12.

Key secondary objectives were clinical response, endoscopic remission, symptomatic remission, clinical response in biologic-failed patients, histologic-endoscopic mucosal improvement, and improvement in bowel urgency at Week 12. (see table for endpoint definitions).

Results: Overall, 1162 patients (miri: 868, PBO: 294) were included in the analysis. BL characteristics (mean age, years [SD], miri: 42.9 [13.9], PBO: 41.3 [13.8]; disease duration, mean years [SD], miri: 7.2 [6.7], PBO: 6.9 [7.0]; and modified Mayo score, n [%]: moderate (4-6), miri 404 [46.5], PBO: 138 [47.1]; and severe (7-9), miri: 463 [53.3], PBO: 155 [52.9]) were balanced across the two treatment groups.

A significantly greater proportion of patients treated with miri achieved clinical remission at Week 12 (miri: 24.2%; PBO: 13.3%; $\Delta=11.1$ [99.875%CI: 3.2, 19.1]; $p=0.00006$). Miri-treated patients achieved all key secondary endpoints, including a significantly greater average reduction in bowel urgency severity compared to PBO ($p<0.00001$).

The frequencies of treatment-emergent adverse events (TEAEs) in miri-treated patients were similar to PBO (miri: 426 [44.5%], PBO: 148 [46.1]). The most common TEAEs reported (miri, PBO) were nasopharyngitis (39 [4.1%], 10 [3.1%]), anemia (32 [3.3%], 19 [5.9%]), headache (32 [3.3%], 9 [2.8%]), and ulcerative colitis (17 [1.8%], 24 [7.5%]).

There were numerically fewer serious adverse events (miri: 27 [2.8%], PBO: 17 [5.3%]) and discontinuations due to adverse events (miri: 15 [1.6%], PBO: 23 [7.2%]) in miri-treated patients compared to PBO. There were 2 colon malignancies in the miri arm (0.2%) and no deaths during the treatment period.

	Treatment groups	
	Placebo IV N=294	Miri 300 mg IV N=868
Clinical Remission, % patients	13.3	24.2
Common risk difference vs. placebo (99.875% CI)		11.1 (3.2, 19.1)*
Clinical Response, % patients	42.2	63.5
Common risk difference vs. placebo (99.875% CI)		21.4 (10.8, 32.0)**
Clinical Response (Bio-Failed), % patients	29.7	54.6
Common risk difference vs. placebo (99.875% CI)		25.0 (9.0, 41.1)**
Endoscopic Remission, % patients	21.1	36.3
Common risk difference vs. placebo (99.875% CI)		15.4 (6.3, 24.5)**
HEMI, % patients	13.9	27.1
Common risk difference vs. placebo (99.875% CI)		13.4 (5.5, 21.4)**
Symptomatic Remission, W4 % patients	12.9	21.8
Common risk difference vs. placebo (99.875% CI)	27.9	9.2 (1.4, 16.9)***
Symptomatic Remission, W12 % patients		45.5
Common risk difference vs. placebo (99.875% CI)		17.5 (7.5, 27.6)**
Urgency NRSDBL, LSMΔBL	-1.6	-2.6
LSM difference vs. placebo (99.875%CI)		-0.95 (-1.5, -0.4)**

All outcomes are for Week 12 except Symptomatic Remission Week 4. *p=0.00006;

p<0.00001; *p=0.00064

Clinical remission: Stool frequency (SF) subscore = 0 or 1 with a ≥1-point decrease from BL, and Rectal bleeding (RB) subscore = 0, and Endoscopic subscore (ES) = 0 or 1 (excluding friability)

Clinical response: decrease in modified Mayo score of ≥2 points and ≥30% decrease from BL, and decrease of ≥1 point in the RB subscore from BL or an RB score of 0 or 1

Clinical response (bio-failed): clinical response in patients who had previously failed biologic or tofacitinib therapy

Endoscopic remission: ES = 0 or 1 (excluding friability)

HEMI (histologic-endoscopic mucosal improvement): Histologic improvement, defined using Geboes scoring system with neutrophil infiltration in <5% crypts, no crypt destruction, and no erosions, ulcerations, or granulation tissue; and endoscopic remission

Symptomatic remission: SF = 0, or SF = 1 with a ≥1-point decrease from BL and RB = 0

Urgency NRS (numeric rating scale)ΔBL: least square mean change in urgency NRS from BL. Mixed Model for Repeated Measures (MMRM) was used to compare the treatment groups for bowel urgency improvement; for all other endpoints, the Cochran-Mantel Haenszel (CMH) test was used to compare the treatment groups while adjusting for the stratification factors; a p value of 0.00125 was considered significant.

Table: Primary and key secondary outcomes

Conclusion: In this phase 3 UC study, 300mg miri IV demonstrated statistically significant and clinically meaningful improvements vs PBO in all primary and key secondary endpoints across clinical, endoscopic, histologic, and symptomatic measures, with an acceptable safety profile.

Introduction: Patients with Crohn's disease (CD) often require multiple biological therapies due to loss of response(1). Anti-TNF drugs are generally used as first-line biologic followed by a switch of class. Ustekinumab (UST), an IL-12/23p40 antagonist is used often after anti-TNF failure (2). The aim of the study was to report on outcomes of UST therapy with a median follow-up period of nearly 24 months.

Aims & Methods: All CD patients who commenced UST therapy were identified from EMR at a tertiary referral centre between January 2017 and December 2021. All relevant demographic and clinical data were collected. Data on clinical response (defined as a downgrade in disease activity based on clinician assessment & biochemical parameters), steroid-free duration, and long-term response to UST at 52 and 104 weeks were recorded.

Response was assessed clinically supported by biomarker, cross-sectional imaging, colonoscopic data and sustained maintenance of UST. The data were analysed and statistical analysis carried out using the IBM® SPSS® Statistics software package Version: 28.0.0.0.

Results: Total of 147 CD patients (M=65, 44%; median age 38years) were included in the analysis with a median follow up-period of nearly 24 months (range 5-67 months). 82 (56%) patients had stricturing (B2), penetrating (B3) and perianal phenotype at baseline and 50 (34%) had undergone previous resection/s. 109 (75%) had documented moderate to severe disease activity and 139 (95%) patients were exposed to atleast one biologic prior to treatment with UST. 34 (23%) patients were on concomitant thiopurines at start of treatment.

Of the 147 patients, 143 (97%) in our cohort showed clinical response to UST and all remained on treatment at the end of follow-up period. The distribution of patients as per disease activity at baseline, 52 and 104 weeks is illustrated in table 1. An improvement in haemoglobin levels was observed post-therapy with UST, which was statistically significant at 104 weeks ($p<0.001$), with corresponding significant reduction in faecal calprotectin levels (median reduction from 976 mcg/g to 333 mcg at 104w; $p<0.001$).

Among patients with B2, B3 and perianal disease, nearly 90% responded to UST and remained steroid-free; less than 10% needed surgery for IBD-related indication in this sub-group during follow-up period, with no pause in UST before or after surgery. Almost all patients with history of previous resections responded and remained on UST. Only 13(8.8%) patients had side-effects which were directly attributed to UST therapy.

Assessment Time Point	Mild/Clinical Remission	Moderate Disease Severity	Severe Disease
Baseline	38	52	57
Week 52	53	38	20
Week 104	38	13	06

Table 1:Disease activity of patients during the study period.

Conclusion: UST is an effective therapeutic option in patients with CD who have failed previous biologic therapy. In our cohort with a large proportion of patients with complicated and refractory disease, clinical response was observed regardless of their previous exposure status to biologics, and disease phenotype. UST appears to be well tolerated with a reasonable safety profile. The consistent response rates even after prolonged treatment periods mean that clinicians could safely continue UST for longer durations, to manage CD particularly when options are limited.

SWITCHING INTRAVENOUS TO SUBCUTANEOUS INFLIXIMAB WAS SAFE AND SUCCESSFUL SHORT TERM IN ULCERATIVE COLITIS AND CROHN PATIENTS – A BELGIAN SINGLE CENTER EXPERIENCE

L. Cornelis¹, E. De Jonckere¹, E. Lernout¹, J. Bossuyt², H. Vanpoucke³, D. De Wulf¹, L. Desomer¹, F. Baert¹

Introduction: Subcutaneous (SC) infliximab CT-P13 (IFX) has recently been registered for the treatment of moderate-to-severe inflammatory bowel disease (IBD). The SC route is an attractive option for patients. However, many open questions remain on how to safely switch patients from maintenance IV to SC administration.

Aims & Methods: To assess switching from IV to SC Infliximab therapy in IBD patients through clinical and biochemical evaluation.

Starting April 2021 for ulcerative colitis (UC) and September 2021 for Crohn patients in durable remission (no symptoms, normal labs and calprotectin) on eight-weekly (or six-weekly) infliximab and therapeutic IFX trough level were offered the option to switch to SC therapy. All patients are monitored prospectively every 3 months with PRO's (with Awell app), labs including IFX concentrations and faecal calprotectin every 6 months. These data were added to our medical file system (HIX) and specific IBD database (URCARE).

Results: April 28 of the year 2022, 57 (40% UC, 60% Crohn) of 127 IBD patients on IFX have chosen to switch to SC IFX therapy with 50 patients (40% UC, 60% Crohn) passing 3 months follow-up, 29 patients (57% UC, 43% Crohn) 6 months and 19 patients (100% UC, 0% Crohn) 9 months respectively (median follow-up 9 months for UC, 5 months for Crohn). Median body weight was 72 kg (range 52-105). Concomitant IBD medication were as follows azathioprine (5), mesalamine (7), beclomethasone (1) or methotrexate (2). The UC cohort median age was 37 years (range 21-74), M:F ratio = 10:13, 50% proctitis, 35% left sided colitis and 15% pancolitis. The Crohn cohort median age was 39 years (range 18-70), M:F ratio = 18:16, 40% small bowel only, 22% colon only and 38% small bowel and colon. Hitherto all patients stayed into deep remission according to clinical Mayo score, CRP and calprotectin. Results are shown in Table 1.

	Last IV dose	3 months follow up	6 months follow up	9 months follow up
	IV	SC		
	N = 57	N = 50	N = 29	N = 18
CRP (mg/L) (±SD)	1.3 (±11.8)	1.2 (±10.8)	1.2 (±1.9)	1.6 (±5.9)
Thrombocytes (x10 ³ /μL) (±SD)	244 (±65)	248 (±57.7)	258 (±71)	247 (±45)
Faecal calprotectin (μg/g) (±SD)	41 (±444)	18 (±77)	21 (±304)	64 (±53)
IFX trough concentration (μg/mL) (±SD)	5.8 (±3)	12 (±2.5)	11 (±2.5)	12 (±0.04)

IFX = Infliximab, IV = intravenous, CRP = C-reactive protein

Table 1.

Median levels of CRP, thrombocytes and calprotectin remained stable from at last IFX infusion to 3,6 and 9 months follow up after switching to SC therapy. IFX serum concentrations doubled after 3 months and remained stable during further follow up. One patient was pre-emptively optimised to weekly injection because of very low serum concentrations (0.7 μg/mL) after 3 months of SC therapy, all other patients are still on standard dose (120 mg SC biweekly) irrespective of body weight. Local pain and injection site reactions were reported in 19% and 10% of patients respectively.

Conclusion: Switching UC and Crohn patients in deep remission and adequate trough levels from maintenance IV to SC infliximab therapy was successful and safe short term. A proportion of patients experienced pain and or injection site reactions. All patients continued SC treatment without request to switch back to IV.

Disclosure: Nothing to disclose.

Introduction: Etrasimod (ETR), a once-daily, oral, selective sphingosine 1-phosphate receptor modulator in clinical development for immune-mediated inflammatory disorders including ulcerative colitis, Crohn's disease, eosinophilic esophagitis, atopic dermatitis, and alopecia areata, is a substrate of cytochrome P450 (CYP)2C8, CYP2C9, and CYP3A4, and to a minor extent, CYP2C19 and CYP2J2. ETR has the potential for drug-drug interaction with CYP2C8, CYP2C9, and CYP3A4 when coadministered with inhibitors or inducers of these enzymes.

This open-label Phase 1 study evaluated the pharmacokinetics (PK) and safety of ETR in the presence of fluconazole (moderate CYP2C9 and CYP3A4 inhibitor; strong CYP2C19 inhibitor), gemfibrozil (strong CYP2C8 inhibitor), or rifampin (moderate CYP2C8 and CYP2C9 inducer; strong CYP3A4 and CYP2J2 inducer).

Aims & Methods: Fifty-six healthy male and female volunteers (18-55 years) were assigned to 1 of 3 treatment groups, each with 2 dosing periods separated by a 7-day washout.

On Day 1 (Period 1), Groups A and B received a single dose of ETR 1mg whereas Group C received a single dose of ETR 2mg. From Days 8–22 (Period 2), Groups A and B received fluconazole once daily (QD) (400mg on Day 8; 200mg on Days 9–22) and gemfibrozil 600mg twice daily, respectively, and a single dose of ETR 1mg on Day 12, whereas Group C received rifampin 600mg QD and a single dose of ETR 2mg on Day 15.

Primary endpoints were plasma C_{max} , AUC_{0-168h} , and $AUC_{0-\infty}$ of ETR in the presence and absence of fluconazole, gemfibrozil, or rifampin. Log-transformed primary PK parameters for ETR were compared using analysis of variance with treatment as fixed effect and participant as random effect.

Results: In the presence of fluconazole or gemfibrozil, there was little impact on ETR C_{max} , but AUC_{0-168h} and $AUC_{0-\infty}$ were mildly-to-moderately increased (Table).

Analyte	C_{max} (ng/mL) GLSMR (90% CI)	AUC_{0-168h} (ng*h/mL) GLSMR (90% CI)	$AUC_{0-\infty}$ (ng*h/mL) GLSMR (90% CI)
Group A (n = 18): [Etrasimod + Fluconazole] / [Etrasimod]			
Etrasimod	1.12 (1.09–1.16)	1.62 (1.52–1.72)	1.84 (1.71–1.99)
Group B (n = 18): [Etrasimod + Gemfibrozil] / [Etrasimod]			
Etrasimod	1.12 (1.06–1.19)	1.27 (1.20–1.35)	1.36 (1.26–1.46)
Group C (n = 18): [Etrasimod + Rifampin] / [Etrasimod]			
Etrasimod	1.24 (0.82–1.88)	0.53 (0.49–0.56)	0.51 (0.47–0.54)

$AUC_{0-\infty}$, area under the plasma concentration-time curve from time 0 to infinity; AUC_{0-168h} , AUC from time 0 to 168 hours; CI, confidence interval; C_{max} , maximum plasma drug concentration; GLSMR, geometric least squares mean ratio.

Table. Statistical Comparison of Etrasimod Plasma Exposure Measures in the Presence and Absence of Fluconazole, Gemfibrozil, or Rifampin.

Geometric mean $t_{1/2}$ of ETR increased from 42 to 87 hours in the presence of fluconazole and from 45 to 70 hours in the presence of gemfibrozil.

When administered in the presence vs absence of rifampin, ETR C_{max} only slightly increased while AUC_{0-168h} and $AUC_{0-\infty}$ moderately decreased. Geometric mean $t_{1/2}$ of ETR decreased by ~50% in the presence of rifampin. All treatments were generally well tolerated. All treatment-emergent adverse events (AEs) were mild or moderate.

One participant discontinued the study due to AEs. No abnormalities were found in laboratory parameters, vital signs, or 12-lead electrocardiograms.

Conclusion: The results of this study are consistent with CYP2C8, CYP2C9, and CYP3A4 being involved in ETR metabolism with no single enzyme appearing to dominate its elimination. The involvement of multiple CYP isoforms reduces the likelihood of ETR having a clinically relevant drug interaction, particularly when only a single CYP isoform is strongly or moderately inhibited/induced by a coadministered drug.

Disclosure: C. A. Lee, Y. Tang, L. Villa-Caballero, K. Shan, A. Randle, and J. S. Grundy are employees of Arena Pharmaceuticals, a wholly-owned subsidiary of Pfizer Inc, New York, NY, USA.

A PHASE 1 DRUG INTERACTION STUDY EVALUATING THE EFFECTS OF ITRACONAZOLE ON THE PHARMACOKINETICS, SAFETY, AND TOLERABILITY OF ETASIMOD IN HEALTHY VOLUNTEERS

C.A. Lee¹, A. Ramaiya¹, Y. Tang¹, A. Sapone¹, K. Gilder¹, A. Randle¹, J.S. Grundy¹

¹Arena Pharmaceuticals, a wholly-owned subsidiary of Pfizer Inc, New York, San Diego, United States

Contact E-Mail Address: clee@ARENAPHARM.COM

Introduction: Etrasimod (ETR) is a once-daily, oral, selective sphingosine 1-phosphate receptor modulator in clinical development for immune-mediated inflammatory disorders including ulcerative colitis, Crohn's disease, eosinophilic esophagitis, atopic dermatitis, and alopecia areata. ETR is a substrate of cytochrome P450 (CYP)2C8, CYP2C9, and CYP3A4, and to a minor extent, CYP2C19 and CYP2J2.

ETR was previously evaluated in the presence and absence of fluconazole (moderate inhibitor of CYP2C9 and CYP3A4; strong inhibitor of CYP2C19). ETR exposure measures (AUC_{0-168h} and $AUC_{0-\infty}$) increased moderately up to 84% in the presence vs absence of fluconazole, likely due to inhibition of both CYP2C9 and CYP3A4.

To determine the relative contribution of CYP3A4, the pharmacokinetics (PK) and safety of ETR in the presence of itraconazole (strong inhibitor of CYP3A4) were evaluated in this open-label Phase 1 study.

Aims & Methods: Eighteen healthy male and female volunteers (18-55 years) received a single dose of ETR 1mg on Day 1. Starting on Day 10, participants received 200mg itraconazole solution (10mg/mL) once daily for 13 days and a single dose of ETR 1mg on Day 14.

Primary endpoints were plasma C_{max} , AUC_{0-last} , and $AUC_{0-\infty}$ of ETR in the presence and absence of itraconazole. Log-transformed primary PK parameters for ETR were compared using analysis of variance with treatment as fixed effect and participant as random effect.

Results: The presence of itraconazole had little impact on single-dose peak exposure (C_{max}) of ETR, but mildly increased total exposure measures (AUC_{0-last} and $AUC_{0-\infty}$) of ETR by up to 32% (Table). These changes were not considered clinically relevant. Geometric mean $t_{1/2}$ of ETR also mildly increased from 37 to 44 hours in the presence of itraconazole. All treatments were generally well tolerated.

All treatment-emergent adverse events were mild. No abnormalities in laboratory parameters, vital signs, or 12-lead electrocardiogram assessments were noted.

Analyte	C _{max} (ng/mL) GLSMR (90% CI)	AUC _{0-∞} (ng•h/mL) GLSMR (90% CI)	AUC _{0-∞} (ng•h/mL) GLSMR (90% CI)
	[Etrasimod + Itraconazole] / [Etrasimod]		
Etrasimod	1.06 (1.02–1.11)	1.31 (1.26–1.37)	1.32 (1.27–1.38)

AUC_{0-∞}, area under the plasma concentration-time curve from time 0 to infinity; AUC_{0-last}, AUC from time 0 to last quantifiable concentration; CI, confidence interval; C_{max}, maximum plasma drug concentration; GLSMR, geometric least squares mean ratio.

Table. Statistical Comparison of Etrasimod Plasma Exposure Measures in the Presence and Absence of Itraconazole.

Conclusion: The results of this study demonstrate that CYP3A4 is one of several CYP isoforms, along with CYP2C8 and CYP2C9, primarily involved in the disposition of ETR. The involvement of multiple CYP isoforms reduces the likelihood of ETR having a clinically relevant drug interaction, particularly in cases where only a single CYP isoform is strongly or moderately inhibited/induced by a coadministered drug.

MODEL-PREDICTED LYMPHOCYTE RESPONSE AND RECOVERY PROFILES FOR THE SPHINGOSINE 1-PHOSPHATE RECEPTOR MODULATORS OZANIMOD AND ETASIMOD

C.A. Lee¹, T. Waterhouse², M. Heathman², D.A. Oh¹, H.K. Komori¹, J.S. Grundy¹

¹Arena Pharmaceuticals, a wholly-owned subsidiary of Pfizer Inc, New York, San Diego, United States, ²Metrum Research Group, Tariffville, United States

Introduction: Sphingosine 1-phosphate (S1P) receptor modulators inhibit lymphocyte egress from lymph nodes, thereby reducing the number of peripheral circulating lymphocytes and their subsequent recruitment to sites of inflammation. Ozanimod (OZA) is an S1P receptor modulator approved for multiple sclerosis and ulcerative colitis. The lymphocyte response following OZA treatment is mainly driven by the pharmacokinetic (PK) exposure of its active metabolite (CC112273). Etrasimod (ETR) is an S1P receptor modulator in clinical development for ulcerative colitis, Crohn's disease, eosinophilic esophagitis, atopic dermatitis, and alopecia areata. Exposure-response models describing observed/published PK and pharmacodynamic (PD) data can be useful tools for multiple purposes including facilitating comparisons between compounds.

Here we present model-predicted lymphocyte response profiles for once-daily dosing of OZA and ETR as well as lymphocyte recovery profiles following drug discontinuation.

Aims & Methods: A population PK/PD model of lymphocyte response to OZA over time was developed from published summary-level data for CC112273 PK profile and an OZA lymphocyte E_{max} model. Initial model simulation predicted a mean baseline lymphocyte count of 1.97x10⁹/L (slightly higher than the observed mean baseline in the OZA RADIANCE study [1.83x10⁹/L]); thus, a correction factor of 0.93 was applied to subsequent OZA simulations.

A population PK/PD model of lymphocyte response to ETR over time was developed using data from 7 Phase 1 studies in healthy volunteers and 2 Phase 2 studies in participants with either ulcerative colitis or atopic dermatitis. Simulations from both models of 10,000 virtual participants given OZA (initial 7-day dose titration: 0.23mg on Days 1–4, 0.46mg on Days 5–7, 0.92mg on Day 8 and thereafter for 11 weeks) or ETR (2mg for 12 weeks) were produced and compared.

Results: Model-predicted lymphocyte response over time approximately (≥90%) reached median steady-state lymphocyte nadir within 24 days for OZA vs within 5 days for ETR.

After drug discontinuation, the predicted time for lymphocyte counts to return to the lower end of the normal range (of either 0.8x10⁹/L or 1.0x10⁹/L for 90% of virtual participants) was 48 and 81 days, respectively, for OZA and 2 and 4 days, respectively, for ETR. The model predicted results for OZA appear generally consistent with similar observed lymphocyte findings reported in its drug label.

Conclusion: Model predictions of lymphocyte response and recovery profiles indicate that ETR, when compared to OZA, is expected to achieve lymphocyte nadir more quickly as well as require less time to recover to the normal range after drug discontinuation.

Rapid drug washout and reconstitution of the immune system may be desirable when considering resolution of infection, switching therapies, and family planning.

HEALTHCARE UTILISATION WITH USTEKINUMAB TREATMENT IN A REAL-WORLD COHORT IN NORTH WEST LONDON: AN ANALYSIS BY AGE AND LINE OF THERAPY

N. Kamperidis¹, M. Shah², S. Young², M. Deshpande³, S. Sweeney³, N. Arebi⁴

¹St Marks Hospital, London, United Kingdom, ²Imperial College Health Partners, London, United Kingdom, ³Janssen-Cilag, Medical Affairs, High Wycombe, United Kingdom, ⁴St Marks Hospital, Dept. of Gastroenterology, London, United Kingdom

Contact E-Mail Address: nkamperidis@yahoo.com

Introduction: Treatment options for moderate to severe Crohn's disease (CD) are evolving. Inherent limitations of clinical trial data related to generalisability of results and restricted outcome measures, are well recognised. Effectiveness studies to include older age groups, the effect of previous exposure to other therapies and other outcomes relevant to patients and healthcare services, offer an understanding of the role of drugs in clinical practice.

Aims & Methods: We aim to describe healthcare utilisation in a real-world cohort of CD patients treated with ustekinumab.

This retrospective cohort study used de-identified data from the prospectively-maintained Whole Systems Integrated Care (Discover) dataset across a population of over 2.5million in Northwest London (NWL)¹. Adult patients with a diagnosis of CD prescribed ustekinumab between 1/1/2016 and 31/3/21 were included. Resource use was captured until 31/12/21.

Outcomes relating to healthcare utilisation, including elective (EL), non-elective hospital admission (NEL) and IBD-related surgery, were analysed according to age at initiation of ustekinumab and previous exposure to other biological drugs during the study period.

Results: 6,251 patients with CD were identified, of which 115 patients prescribed ustekinumab were included.

12% (14/115) were ≥60 years old at ustekinumab prescription. Overall, 25% (29/115) received ustekinumab as a first biologic, 49% (56/115) were as second-biologic and 26% (30/115) were as third-biologic or later. Patient demographics are described in Table 1.

Overall, 177 EL admissions and 122 NEL admissions were recorded in the cohort.

For the 18-59 age group, 67% (91/101) patients prescribed ustekinumab had EL admissions during the study period (median 2 visits), 47% (47/101) NEL admissions (median 2 visits) and 20% (20/101) IBD-related surgery. In the older patient group (≥ 60 years), 50% (7/14) had EL admissions (median 1 visit), 50% (7/14) NEL admissions, (median 2 visits), and 14% (2/14) IBD-related surgery.

When ustekinumab was prescribed as a first, second or third + biologic, the proportion of patients with EL admissions was 52% (15/29), 66% (37/56) and 77% (23/30) respectively with a median of 1, 2 and 2 visits. The proportion recorded for NEL admissions was 45% (13/29), 46% (26/56) and 50% (15/30) respectively each with a median of 2 visits. First-, second- and third + biologic groups experiences IBD-related surgery in 17% (5/29), 21% (12/56) and 17% (5/30) respectively.

	Gender, female N (%)	Age, years median (range)	BMI, kg/m2 median (range)	Ethnicity, white n (%)
Overall cohort (n=115)	57 (50%)	36.0 (18.0-83.0)	23.1 (13.5-39.8)	61 (53%)
≥ 60 years old (n=14)	9 (64%)	-	27.0 (16.9-35.5)	9 (64%)
18- 59 years old (n=101)	48 (48%)	-	22.5 (13.5-39.8)	52 (51%)
1 st biologic (n=29)	16 (55%)	33.0 (18.0-69.0)	23.1 (15.6-35.5)	13 (45%)
2 nd biologic (n=56)	26 (46%)	40.5 (23.0-83.0)	24.5 (13.5-38.2)	32 (57%)
3 rd + biologic (n=30)	15 (50%)	36.5 (24.0-68.0)	23.2 (13.5-39.8)	16 (53%)

Table 1. Patient demographics for whole cohort and subgroups.

Conclusion: In this population cohort, hospital admission and IBD-related surgery rates for older CD patients (≥ 60 years) prescribed ustekinumab were comparable to 18-59 age group. Patients who received ustekinumab as a first biologic during the study showed a numerically lower rates of elective hospital admission compared to those prescribed ustekinumab as a later line of therapy. Further analysis will determine whether this reflects comparable effectiveness for ustekinumab in older people with CD and better outcomes when used as a first line agent.

IMPACT OF THE HLA-DQA1*05 ALLELE ON LOSS OF RESPONSE AND PRESENCE OF ANTI-DRUG ANTIBODIES TO USTEKINUMAB IN CROHN'S DISEASE AND ULCERATIVE COLITIS PATIENTS

T. Ahmad¹, M.D. Martín-Arranz², B. Brinkman³, C. Gasink⁴, M. Guan⁵, A. Hart⁶

Contact E-Mail Address: tariq.ahmad1@nhs.net

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) patients (pts) with the HLA-DQA1*05 allele and treated with infliximab or adalimumab have a 2-fold risk of anti-drug antibody (ADA) development and subsequent loss of response (LOR). ADA levels to ustekinumab (UST) are comparatively low, at rates <5% in CD and UC through 5 and 3 years in the UNIFI and UNIFI trials.

In UNIFI, the proportion of pts in remission in each dose group decreased by only approximately 5% each year from years 1 through 5. The relationship between the HLA-DQA1*05 allele and UST on ADA development and LOR has not been examined.

Aims & Methods: The UNIFI and UNIFI studies assessed the safety and efficacy of UST induction and maintenance therapy in pts with moderate-to-severe CD and UC, respectively. The cohort comprised pts randomized to UST maintenance as well as delayed responders from the nonrandomized maintenance cohorts from both studies. 343 CD and 332 UC pts had both clinical and genetic data. Pts were genotyped on the Illumina Infinium HumanOmni5.0 (UNIFI) and HumanOmni2.5 (UNIFI) platforms. Utilizing genotype data from chromosome 6, HLA imputation was performed with the Michigan Imputation Server high-resolution HLA reference panel.¹ Antibodies were detected using a drug-specific, drug-tolerant, electrochemiluminescent immunoassay on the Meso Scale Discovery platform.^{2,3} Pts who had ADA detected at 1 or more visits through week (wk) 44 were considered to be positive to ADA.

Two statistical models evaluated association between HLA-DQA1*05 and wk44 LOR or ADA status with PLINK 2.0, $\alpha = 0.05$. The first adjusted for sex, age, and top 5 ancestry principal components (PCs) derived from genetic data, and the second added baseline immunomodulator.

Results: HLA-DQA1*05 allele was detected in 43.15% (148/343) of UNIFI pts and 39.16% (130/332) of UNIFI pts. HLA-DQA1*05 was not significantly associated with UST LOR or ADA positive status in UNIFI or UNIFI regardless of baseline immunomodulator use (Table).

		P-values (based on logistic regression)	
		Response at Week 44	ADA
UNIFI	Model 1 (adjusting for sex, age, and top 5 ancestry principal components)	0.96	0.25
	Model 2 (adjusting for sex, age, top 5 ancestry principal components, and baseline immunomodulator use)	0.95	0.23
UNIFI	Model 1 (adjusting for sex, age, and top 5 ancestry principal components)	0.69	0.85
	Model 2 (adjusting for sex, age, top 5 ancestry principal components, and baseline immunomodulator use)	0.72	0.84

Table. HLA-DQA1*05 allele association results for UNIFI and UNIFI

No meaningful differences were seen in clinical response at wk44 per HLA-DQA1*05 allele carriers vs non-carriers (63.6% [89/140] vs 64.6% [122/189] in UNITI and 73.8% [96/130] vs 74.3% [150/202] in UNIFI, respectively). Similarly, no meaningful differences were seen in ADA positivity through wk44 in pts who had the allele vs those who did not have the allele (2.8% [2/71] vs 3.8% [4/105] in UNITI and 5.5% [6/109] vs 3.9% [7/178] in UNIFI, respectively, 4.4% vs. 3.9% in combined cohorts).

Conclusion: The HLA-DQA1*05 allele was not associated with UST LOR over 44 wks with adequate power in both cohorts. HLA-DQA1*05 was likewise not associated with ADA, although power to detect significance was only ~19% in UNITI and UNIFI for a 2-fold effect given the overall low ADA rate of 4.1%.

Adjusting for immunomodulator use also did not result in any meaningful difference between the HLA-DQA1*05 allele and either LOR or ADA. Thus HLA-DQA1*05 positive pts with IBD, particularly those in whom an immunomodulator is contraindicated, might be attractive candidates for treatment with UST rather than infliximab and adalimumab.

REAL-WORLD EVIDENCE OF THE EFFECTIVENESS AND SAFETY OF USTEKINUMAB FOR THE TREATMENT OF CROHN'S DISEASE: SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL STUDIES

C. Rubín de Célix¹, M. Chaparro Sanchez², J.P. Gisbert^{*1}

¹Hospital Universitario de La Princesa, IIS-Princesa, Universidad Autónoma de Madrid and CIBERehd, Gastroenterology Unit, Madrid, Spain

Contact E-Mail Address: cristina.rubin.92@gmail.com

Introduction: Ustekinumab is a fully human monoclonal IL-12/23 p40 antibody approved for moderate to severe Crohn's disease (CD). Evidence on the outcomes of ustekinumab in real-world CD patients is needed.

Aims & Methods: The aim of this meta-analysis was to evaluate the effectiveness and safety of ustekinumab in CD reported by observational studies. Bibliographical searches were performed in PubMed and EMBASE. Selection: observational studies assessing the effectiveness and safety of ustekinumab in CD.

Exclusion criteria: studies using ustekinumab exclusively as a prophylaxis for the postoperative recurrence or perianal disease. Data synthesis: effectiveness by intention-to-treat (random effects model). Data were stratified by: study design, population included, dose administered and prior treatment with biologics.

We evaluated the dose optimization requirement, the median time to the intensification and the dose optimization response/remission rate. We also evaluated predictors of response. To assess the quality of the observational studies we used the Newcastle-Ottawa Scale.

Results: A total of 63 studies (8,529 patients) were included, almost all focused on biologic experienced patients. Response was achieved in 60% of patients in the short-term (8-12 weeks; 95% confidence interval, 54-67%), 64% in the medium-term (16-24 weeks; 57-71%), and 64% in the long-term (48-52 weeks; 52-74%). Remission was achieved in 37% (28-46%) in the short-term, 42% (36-49%) in the medium-term and 45% (37-53%) in the long-term. Endoscopic remission rate in the medium-term was 24% (13-34%), and 33% (25-40%) in the long-term.

All the performed sub-analyses (study design, the population included, the administered dose of ustekinumab and prior treatment with biologic drugs) did not adequately explain between-study heterogeneity. Nearly one third of the patients needed ustekinumab dose optimization, and in 60% of them it was effective. Eighteen percent of patients lost response during follow-up.

The most frequent predictors of poor clinical response were previous biologic exposure, stricturing or penetrating behaviour, and high Harvey-Bradshaw score at first dose. Twenty-five percent of patients developed adverse events (AEs), the most frequent being infections (4%). Most of the AEs were mild, leading to treatment withdrawal in 7% of the cases.

Conclusion: Ustekinumab is an effective and safe therapy in real-world refractory CD patients. Dose optimization is frequently required, being effective in a high percentage of cases. Our results underline that the clinical benefit of ustekinumab seems to be higher in observational studies compared with clinical trials.

Introduction: Ustekinumab (UST) is an IL-12/23p40 inhibitor approved for treatment of Crohn's disease and ulcerative colitis (UC). In the UNIFI maintenance study of patients (pts) with moderate to severe UC, >90% of pts who achieved clinical response or remission at week (wk) 44 were not receiving corticosteroids, an important therapeutic goal. In this analysis, we describe the corticosteroid-sparing effects of UST treatment through 4 years (yrs) among pts who were treated in the UNIFI long-term extension (LTE).

Aims & Methods: Overall, 523 intravenous UST induction responders were randomized to subcutaneous (SC) maintenance therapy (placebo [PBO], n=175; UST 90mg every 12 wks [q12w], n=172; or UST 90mg q8w, n=176). A total of 284 UST pts completed wk44 and were treated in the LTE. PBO pts were discontinued after study unblinding.

Based on investigator's clinical judgement of UC disease activity, pts in the LTE were eligible to receive a dose adjustment starting at wk56: PBO to q8w, q12w to q8w, and q8w to q8w (sham adjustment). Pts in PBO or q8w groups were only eligible for dose adjustment or sham dose adjustment before unblinding.

Efficacy was evaluated using symptomatic remission (Mayo stool frequency subscore of 0 or 1 and a rectal bleeding subscore of 0). During the maintenance study, all pts receiving corticosteroids at maintenance baseline were required to initiate tapering.

Through wk200 of the LTE, symptomatic remission endpoints were calculated with treatment failure and missing data nonresponder imputation, and dose adjustment was not considered to be a treatment failure. Missing corticosteroid dose data were managed using last observation carried forward.

Results: Of the 284 pts randomized to UST and treated in the LTE, 139 were receiving corticosteroids at maintenance baseline. Of these, 90.6% (n=126) were no longer receiving corticosteroids at wk200. The average prednisone-equivalent (P.Eq) corticosteroid dose among pts receiving corticosteroids at maintenance baseline in the q8w group was 15.4 mg/day and 1.7, 2.3, and 2.8 mg/day at wks44, 152, 200, respectively. In the q12w group, average P.Eq doses were 15.4, 1.2, 3.6, and 4.0 mg/day, respectively.

Rates of corticosteroid-free symptomatic remission at wk200 were generally similar for the q8w and q12w maintenance doses (Table 1). Of the UST-treated pts who were in symptomatic remission at wk200, 94/96 (97.9%) in the q12w group and 91/96 (94.8%) in the q8w group were corticosteroid free.

Analysis	90 mg UST SC q12w ^a	90 mg UST SC q8w ^a	Combined UST ^a
Randomized patients in maintenance who were treated in the LTE, N	141	143	284
Patients in symptomatic remission, n/N (%)^{d,e,f}			
Week 44	117/141 (83.0%)	119/143 (83.2%)	236/284 (83.1%)
Week 200	96/141 (68.1%)	96/143 (67.1%)	192/284 (67.6%)
Patients in symptomatic remission and not receiving corticosteroids, n/N (%)^{d,e,f}			
Week 44	111/141 (78.7%)	115/143 (80.4%)	226/284 (79.6%)
Week 200	94/141 (66.7%)	91/143 (63.6%)	185/284 (65.1%)
Patients in symptomatic remission and not receiving corticosteroids among patients receiving corticosteroids at maintenance baseline, n/N (%)^{b,c,d,e,f}			
Week 44	49/68 (72.1%)	56/71 (78.9%)	105/139 (75.5%)
Week 200	39/68 (57.4%)	47/71 (66.2%)	86/139 (61.9%)
Patients who were able to eliminate the use of corticosteroids, n/N (%)^{b,c}			
Week 44	61/68 (89.7%)	65/71 (91.5%)	126/139 (90.6%)
Week 200	61/68 (89.7%)	65/71 (91.5%)	126/139 (90.6%)

LTE, long-term extension; q8w, every 8 weeks; q12w, every 12 weeks; SC, subcutaneous; UST, ustekinumab. ^aRandomized group at maintenance Week 0 regardless of whether patients had a dose adjustment during the LTE. ^bPatients who had a missing value in corticosteroid use at the designated visit had their last available value carried forward to the designated visit. ^cDenominator is the number of patients who were receiving concomitant corticosteroids at maintenance baseline. ^dSymptomatic remission is defined as a stool frequency subscore of 0 or 1 and a rectal bleeding subscore of 0. ^ePatients who had both stool frequency and rectal bleeding subscores missing at a visit were considered not to be in symptomatic remission for that visit. ^fPatients who had an ostomy or colectomy, or discontinued study agent due to lack of therapeutic effect or due to an adverse event of worsening of ulcerative colitis prior to the designated visit were considered not to be in symptomatic remission.

Table 1. Symptomatic remission and corticosteroid-sparing effects in patients who were randomized to UST in maintenance and were treated in the long-term extension.

Conclusion: UST maintenance therapy, with both q8w and q12w dosing regimens, was effective in reducing and eliminating the use of corticosteroids in pts with UC through 4 yrs. The majority of pts in symptomatic remission were corticosteroid free through 4 yrs of treatment with UST.

Introduction: Ustekinumab (UST) is an IL-12/23p40 antagonist approved for treatment of moderate-to-severe ulcerative colitis (UC). Here we report the final results of the UNIFI long-term extension (LTE) study, with efficacy and safety through 4 years (yrs) of subcutaneous (SC) UST treatment.

Aims & Methods: Overall, 523 intravenous UST induction responders were randomized to SC maintenance therapy: 175 SC placebo (PBO); 172 UST 90mg every 12 weeks (q12w); 176 UST 90mg q8w. The nonrandomized population included UST induction nonresponders at week (wk) 8 who received SC UST, responded 8wks later, and continued to receive UST q8w, and responders to PBO induction who received SC PBO. Patients (pts) who completed wk44 were eligible to continue treatment in the LTE. PBO pts were discontinued after study unblinding.

Starting at wk56, randomized pts with UC worsening could adjust to q8w. Efficacy was evaluated in UST-randomized pts (n=284) using symptomatic remission (Mayo stool frequency subscore of 0 or 1 and a rectal bleeding subscore of 0). Safety was evaluated for all 588 pts treated in the LTE, including randomized and nonrandomized populations.

Results: Among all pts randomized to UST at maintenance baseline (intent-to-treat population with nonresponder imputation for missing data and treatment failure criteria), 55.2% were in symptomatic remission at wk200 (biologic naïve 67.2%; biologic failures 41.6%; Table 1); 53.2% of pts achieved corticosteroid-free symptomatic remission at wk200. Overall, 42.7% of biologic failure and 18.8% of biologic naïve pts who were ran-

domized to UST and treated in the LTE discontinued treatment between wks44 and 200. Among randomized pts who continued UST in the LTE, 67.6% were in symptomatic remission at wk200; 72.9% of those in clinical remission at wk44 were in symptomatic remission at wk200; and 85.1% of pts with observed data at wk200 were in symptomatic remission. Safety events were similar among UST-treated pts compared with PBO throughout the study.

From maintenance wk0-220, pts receiving UST and PBO had 1647.4 and 301.7 pt-yrs of follow-up, respectively, and safety events per 100 pt-yrs of follow-up for UST vs PBO were adverse events (AEs): 214.45 vs 288.04, serious AEs: 7.22 vs 10.61, and serious infections: 2.00 vs 3.31.

During the final yr of the LTE, no deaths or major cardiovascular events were reported in UST pts. Among UST pts, 2 cases of colorectal cancer and 1 case of cytomegalovirus were reported.

Analysis	90 mg UST SC q12w ^b	90 mg UST SC q8w ^b	Overall UST
Symptomatic remission in the ITT population^{c,d,e}(treatment failure and missing data nonresponder imputation)			
Week 44, n/N (%)	107/172 (62.2)	119/176 (67.6)	226/348 (64.9)
Week 200, n/N (%)	96/172 (55.8)	96/176 (54.5)	192/348 (55.2)
Symptomatic remission in biologic naïve^f patients			
Week 44, n/N (%)	68/95 (71.6)	57/79 (72.2)	125/174 (71.8)
Week 200, n/N (%)	62/95 (65.3)	55/79 (69.9)	117/174 (67.2)
Symptomatic remission in biologic failure^f patients			
Week 44, n/N (%)	34/70 (48.6)	57/91 (62.6)	91/161 (56.5)
Week 200, n/N (%)	30/70 (42.9)	37/91 (40.7)	67/161 (41.6)
Corticosteroid-free symptomatic remission^{c,d,e,g}			
Week 44, n/N (%)	105/172 (61.0)	116/176 (65.9)	221/348 (63.5)
Week 200, n/N (%)	94/172 (54.7)	91/176 (51.7)	185/348 (53.2)
Symptomatic remission in patients treated in the LTE (treatment failure and missing data nonresponder imputation)^{d,e}			
Week 44, n/N (%)	117/141 (83.0)	119/143 (83.2)	236/284 (83.1)
Week 200, n/N (%)	96/141 (68.1)	96/143 (67.1)	192/284 (67.6)
Symptomatic remission up to the time of dose adjustment with treatment failure rules applied in patients treated in the LTE^d (modified as observed^h)			
Week 44, n/N (%)	117/141 (83.0)	119/143 (83.2)	236/284 (83.1)
Week 200, n/N (%)	58/65 (89.2)	73/89 (82.0)	131/154 (85.1)

AE, adverse event; ITT, intent-to-treat; LTE, long-term extension; q8w, every 8 weeks; q12w, every 12 weeks; SC, subcutaneous; TNF, tumor necrosis factor; UC, ulcerative colitis; UST, ustekinumab

^a Symptomatic remission is defined as a stool frequency subscore of 0 or 1 and a rectal bleeding subscore of 0.

^b Randomized group at maintenance Week 0 regardless of whether or not patients had a dose adjustment during the long-term extension.

^c Patients who had a prohibited change in UC medication, an ostomy or colectomy, or used a rescue medication after clinical flare, or discontinued study agent due to lack of therapeutic effect or due to an AE of worsening of UC prior to the Week 44 visit were considered not to be in symptomatic remission at Week 44.

^d Patients who had an ostomy or colectomy, or discontinued study agent due to lack of therapeutic effect or due to an AE of worsening of UC after Week 44 and prior to Week 200, were considered not to be in symptomatic remission at Week 200.

^e Patients who had both stool frequency and rectal bleeding subscores missing at a visit were considered not to be in symptomatic remission for that visit.

^f Efficacy was evaluated only in patients with a history of biologic failure to ≥1 biologic (anti-TNFα or integrin antagonist) and those who were biologic naïve; 7 UST q12w and 6 UST q8w patients who were biologic-experienced but did not have documentation of biologic failure are excluded.

^g Patients who had a missing value in corticosteroid use had their last value carried forward.

^h The observed data excluded patients with missing data and had not had treatment failure (i.e., an ostomy or colectomy, or discontinued study agent due to lack of therapeutic effect or due to an AE of worsening of UC) prior to the designated visit.

Table 1. Symptomatic remission^a rates during the LTE in randomized patients

Conclusion: Pts receiving SC UST generally maintained clinical benefit through 4yrs. No new safety signals were observed.

VIRTUAL BIOLOGICS CLINIC: A STREAMLINED MULTI-DISCIPLINARY TEAM (MDT) APPROACH TO IMPROVE INFLAMMATORY BOWEL DISEASE (IBD) CARE

J. Gertner¹, S. Mann¹, S. Maung¹, Y.M. Thu¹

¹Barnet Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: supyaephyomaung.su@gmail.com

Introduction: The challenges of IBD patients on biologics include complex decision making, securing funding and logistics of administration.

Aims & Methods: Aims: To assess the impact of a Virtual Biologics Clinic (VBC) on clinical decision making and patient outcome.

Methods: Electronic records of IBD patients at Barnet Hospital were retrospectively reviewed. Patients discussed at VBCs conducted by IBD consultant gastroenterologists, nurses and pharmacists from 09/2019 to 01/2022 were included.

Results: 66 patients were reviewed, 2 excluded due to misdiagnosis and death. 24 patients had UC and 40 Crohn's disease; 48% were female and median age was 43.

Of those with UC, 58% had left sided disease only, 42% had pancolitis. Clinically, 55% had mild to moderate disease and 45% moderate to severe. Of those with Crohn's, 80% had terminal ileal disease, 63% colonic disease and 30% perianal disease. 43% had stricturing disease and 38% fistulating disease. Clinically, 30% had mild disease, 50% moderate and 20% severe. 80% of all patients used biologics previously with infliximab (63%), adalimumab (49%), vedolizumab (20%) or ustekinumab (12%). Previous treatments also included azathioprine in 67% of patients, mesalazine 25%, 6-mercaptopurine 16%, methotrexate 8%, sulfasalazine 2%, and tofacitinib 2%.

At VBC, 67% patients were on biologics: infliximab (20%), adalimumab (19%), vedolizumab (14%), or ustekinumab (14%). 92% of patients on infliximab had drug levels and/or antibodies measured.

Of those tested, none had positive antibodies. 81% had faecal calprotectin available and 50% of those had results >1000µg/g; 28% had endoscopies of which there was quiescent disease in 6%, mild 22%, moderate 33%, severe 22%, stricturing 11% and suboptimal views 6%. 44% of endoscopies had histology confirming active disease.

Reasons for VBC discussion were inadequate disease control (64%), funding review (9%), remission (2%), reactions to biologics (3%), or other (22%).

Outcomes from VBC were to switch biologics (23%), continue current treatment (22%), escalate frequency or dose (14%), stop biologics (13%), rediscuss after further investigations (8%), start biologics (6%), re-initiate biologics (5%) or other (9%).

60 VBC outcomes were confirmed as actioned. 1 was not actioned due to patient choice, 2 are pending and 1 patient was uncontactable.

At latest follow up 52% showed clinical response or were in remission and 34% were clinically symptomatic. 14% of patients are awaiting follow up.

Conclusion: VBC is an effective resource for clinical decision making in IBD patients requiring biologics.

Over half the patients reviewed following VBC showed at least clinical improvement.

VBC is a robust approach of ensuring multifaceted management plans are actioned.

IMPACT OF BIOLOGIC THERAPIES AND SMALL MOLECULES ON THE RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN ULCERATIVE COLITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

M. Shehab¹, A. Alkazemi², F. Alrashed², P.L. Lakatos³, T. Bessissow³

Contact E-Mail Address: Dr_mshehab@hotmail.com

Introduction: The risk of major adverse cardiovascular events (MACE) in patients with ulcerative colitis (UC) receiving biologic therapies and small molecules is not well documented in the literature.

The aim of this systematic review and meta-analysis is to estimate the risk of MACE in adult patients with UC receiving biologic therapies and small molecule therapy.

Aims & Methods: We systematically searched PubMed/Midline, Cochrane Central Register of Controlled Trials, Scopus, and Embase databases to identify eligible studies that assessed the risk of MACE in patients with UC on biologic therapies or small molecules (age ≥18 years). Eligible studies were phase 3, randomized placebo or active-controlled trials (RCTs).

Our primary outcome was the risk for MACE in patients receiving biologic therapies or small molecules during induction and maintenance phases of RCTs. Random effects model was used to calculate pooled odds ratios (ORs) and 95% CIs. I² statistics was used to assess heterogeneity.

Results: Overall, 45 RCTs involving 22,007 patients with UC were included in our systematic review and meta-analysis. 14,193 (64.5%) patients were receiving biologic therapies and 7,814 (35.5%) patients were receiving small molecules.

There was no statistically significant difference in risk of MACE associated with the use of biologic therapies/small molecules during induction and maintenance therapies; infliximab (OR 0.71, 95% CI 0.23–2.21), adalimumab (OR 0.95, 95% CI 0.05–2.57), etrolizumab (OR 0.93, 95% CI 0.21–4.10), golimumab (OR 0.36, 95% CI 0.21–4.10), ustekinumab (OR 0.31, 95% CI 0.04–2.54), vedolizumab (OR 0.44, 95% CI 0.09–2.15), filgotinib (OR 0.39, 95% CI 0.05–3.08), ozanimod (OR 0.52, 95% CI 0.03–8.30), tofacitinib (OR 1.63, 95% CI 0.28–9.42) and upadactinib (OR 0.31, 95% CI 0.04–2.52).

Conclusion: Biologic therapies and small molecules are not associated with major adverse cardiovascular events (MACE) in ulcerative colitis.

Disclosure: Nothing to disclose

P0399

EARLY INTERVENTION WITH BIOLOGICS IN CROHN’S DISEASE - HOW EARLY IS EARLY?

J. Revés¹, A. Mascarenhas², M.J. Temido³, B. Morão¹, A.C. Bravo¹, B. Abreu¹, C. Nascimento¹, C. Frias Gomes¹, A.R. Franco², R.R. Mendes², C. Palmela¹, M.L. Gloria¹, P. Narra Figueiredo³, F. Silva Portela³, J. Torres¹

Contact E-Mail Address: joanareves94@gmail.com

Introduction: Post-hoc analysis from randomized controlled trials (RCTs) has shown that early intervention (< 24 months) with biologic therapy is associated with better outcomes in Crohn’s disease (CD). We aimed to assess the best time for early biologic therapy initiation.

Aims & Methods: Multicentric retrospective cohort study including newly diagnosed CD patients that started biologic treatment within 24 months from diagnosis. The primary outcome was a composite of switching biologic, hospitalization due to a CD flare and need for intestinal surgery. The secondary outcomes were clinical remission (Harvey-Bradshaw Index - HBI<5), endoscopic healing - EH (SES-CD<3 or absence of ulcers) and transmural healing - TH (absence of active inflammation, extra-enteric signs and CD-related complications), assessed at 12±6 months after therapy initiation. Analysis was performed using cox regression and logistic regression.

Results: 125 patients were included (61% males), with a median age at diagnosis of 26yo (IQR 20-42). Most frequently (46%) patients presented with ileocolonic disease (L3) and 62% had a non-complicated (B1) phenotype. Seventy-two (58%) patients started biologic within 6 months from diagnosis and 102 (82%) within 12 months. The median follow-up time was 33 months (IQR 19-60).

All patients were started on anti-TNF and 52% on combination therapy. Forty-four (35%) patients experienced the primary outcome after a median time of 11 months (IQR 6-22) - 22% switched biologic, 14% were hospitalized and 10% needed surgery.

There was no significant difference in the time to the primary outcome between patients who started biologic ≤6months vs >6 months (HR 1.69, 95%CI 0.90-3.17, p=0.1) and between patients who started biologic ≤12months vs >12 months (HR 0.90, 95%CI 0.41-1.96, p=0.8).

Clinical remission and EH rates were high (86% and 53%, respectively), although there were no significant differences according to the time of initiation of biologic therapy (except for a slight difference between patients

who started biologic ≤6 months and patients who started biologic 13-18 months from diagnosis). The TH rate was 29% and there was no difference between groups (Table 1).

In a multivariate logistic regression analysis adjusted for gender, age at diagnosis, B2/B3 phenotype, perianal disease at diagnosis and use of combination therapy, the time of initiation of biologic treatment (in 6 months categories) remained a non-significant predictor for the achievement of clinical remission (OR 0.76, 95%CI 0.45-1.26, p=0.3), EH (OR 1.03, 95%CI 0.64-1.66, p=0.9) or TH (OR 1.16, 95%CI 0.63-2.14, p=0.6).

Secondary outcomes	≤6 months	7-12 months	13-18 months	19-24 months	p-value*
Clinical remission (Harvey-Bradshaw Index <5)	90% (64/71)	81% (25/31)	67% (8/12)	91% (10/11)	0.1
Endoscopic healing (SES-CD <3 or absence of ulcerations)	53% (27/51)	63% (15/24)	25% (2/8)	57% (4/7)	0.3
Transmural healing (absence of active inflammation, no extra-enteric signs, and no CD-related complications)	25% (14/55)	42% (8/19)	33% (3/9)	0% (0/4)	0.3

*p-value remained non-significant (>0.05) when comparing between groups, except for clinical remission in patients who started biologic ≤6 months and patients who started biologic 13-18 months from diagnosis (90% vs 67%, p=0.03).

Table 1 - Rates of clinical remission, EH and TH according to the time of initiation of biologic therapy

Conclusion: Starting biologic within 24 months of diagnosis is associated with high rates of clinical remission and EH, although TH was obtained in less than 30% of the patients. We found no differences between outcomes and earlier initiation of biologic therapy.

Introduction: The use of biosimilar adalimumab (ADA) is effective and safe in inflammatory bowel disease (IBD). Switching from the originator to a biosimilar has been successful in multiple IBD cohorts, although clinical data on switching between ADA biosimilars is still rare.

At the end of 2020, a non-medical switch to biosimilar ADA became mandatory in Hungary due to reimbursement policy changes of the National Health Insurance Fund of Hungary (NEAK).

Aims & Methods: The aim of the present study was to evaluate short- and medium term clinical efficacy, drug sustainability and safety comparing non-medical switches from the originator to biosimilar ADA, and between ADA biosimilars. 276 consecutive patients on maintenance ADA therapy (n=205 Crohn's disease[CD], n=71 ulcerative colitis[UC], male/female:n=110/166) were included between September 2019 and December 2020. Data on clinical efficacy, biomarkers and adverse events were collected 8-12 weeks prior switch, at baseline, 8-12 weeks and 20-24 weeks after switch. Drug sustainability following the switch was evaluated at a median 40(IQR:35-42) weeks follow-up.

Results: A total 174 patients underwent a non-medical switch from the originator to a biosimilar, and 102 patients had a biosimilar-to-biosimilar switch. No significant difference was found in clinical remission rates at week 8-12 prior/ baseline /week 8-12 and week 20-24 after switch in patients switching from originator to biosimilar(87.3%/88.5%/86.5%/85.7%) or biosimilar to biosimilar(74.5%/78.4%/85.3%/79.8%).

Among patients in clinical remission at switch/baseline, 93.4% sustained clinical remission at week 8-12 and 89.9% up to week 20-24 in the originator-to-biosimilar group. In the biosimilar-to-biosimilar switch group, 96.3% sustained clinical remission at week 8-12 and 84.9% up to week 20-24. Mean CRP levels were unchanged during follow-up in both cohorts(p=0.856 and p=0.525).

Drug survival was similar between the two cohorts with a probability of 91.6%(SE: 2.2) and 87.0%(SE:3.4) to stay on drug after 40 weeks(log-rank:0.96; p=0.327). Five adverse events were reported, three of them leading to treatment discontinuation.

Conclusion: Clinical benefit was sustained following non-medical switch from originator to biosimilar, or between biosimilars in adalimumab treated IBD patients. Drug sustainability following the switch was high and not different between the two groups.

Disclosure: Nothing to disclose.

Contact E-Mail Address: g.dhaens@amsterdamumc.nl

Introduction: Patients with CD suffer from symptoms that negatively impact their health-related quality of life (HRQOL). In GALAXI 1, a ph2, double-blind, PBO-controlled study of guselkumab (GUS), a selective IL-23 antagonist, for the treatment of pts with moderately to severely active CD who had inadequate response or intolerance to conventional therapies (corticosteroid, immunosuppressant) and/or biologics (tumor necrosis factor antagonist, vedolizumab), HRQoL was evaluated using the Patient-Reported Outcomes Measurement Information System (PROMIS)-29.

Aims & Methods: GALAXI has a treat-through design with pts remaining on randomized treatment (GUS or ustekinumab [UST]) through Wk48. Pts were randomized 1:1:1:1:1 into 5 arms for induction: GUS 200, 600, or 1200mg IV at Weeks (Wks) 0, 4, 8; UST ~6mg/kg IV at Wk0 and 90mg SC at Wk8; or PBO IV. At Wk12, pts transitioned to maintenance as follows: GUS 200mg IV→100mg SC q8w, GUS 600mg IV→ 200mg SC q4w, GUS 1200mg IV→ 200mg SC q4w, PBO non-responders→ UST ~6mg/kg IV→ 90mg SC q8w, and PBO responders→ PBO SC q4w. UST pts continued 90mg SC q8w. Pts randomized to PBO were not included in Wk48 analyses.

PROMIS-29 consists of 7 domains (depression, anxiety, physical function, pain interference, fatigue, sleep disturbance, and social participation) and a pain intensity 0-10 numeric rating scale (NRS). The raw score of each domain is converted into a standardized T-score with a general population mean of 50 and standard deviation (SD) of 10. For physical function and social participation, higher scores indicate better outcomes, while for all other symptom domains like anxiety, higher scores indicate worse outcomes. Clinically meaningful improvement was defined as ≥3-point improvement in pain NRS score and ≥5-point (or 1/2 SD of population) improvement in each domain T-score.

Results: Among pts randomized and evaluated in the primary efficacy analysis, mean PROMIS-29 domain scores were similar between treatment groups at baseline with functional domain score <50 and symptom domain scores >50, indicating impaired HRQOL (Table 1).

Pts treated with GUS had greater improvement in all 7 domain scores at Wk12 compared with PBO. GUS treatment resulted in continued improvement in domain scores from Wk12 to Wk48. For the GUS combined group, mean change from baseline in domain T-scores at Wk12 and Wk48 were

	Placebo (N=61)	GUS 200 mg IV q4w →100 mg SC q8w (N=61)	GUS 600 mg IV q4w →200 mg SC q4w (N=63)	GUS 1200 mg IV q4w →200 mg SC q4w (N=61)	UST ~6 mg/kg IV →90 mg SC q8w (N=63)
Anxiety T-score^{a,b}					
Baseline, mean (SD)	57.68 (10.004), N=57	56.43 (9.344), N=60	56.94 (9.843), N=63	57.29 (9.455), N=61	54.25 (9.068), N=63

*Nominal p-value <0.05 for guselkumab vs placebo at Wk 12. **Nominal p-value <0.001 for guselkumab vs placebo at Wk 12.

^aPatients who had a prohibited change in concomitant Crohn's disease medication, a Crohn's disease-related surgery, or discontinued study agent due to lack of efficacy or an AE of worsening Crohn's disease prior to the designated analysis timepoint had their baseline value carried forward from that timepoint onwards. Patients who had discontinued study agent due to any other reasons prior to the designated analysis timepoint had their observed data used, if available, from that timepoint onwards.

^bPatients who had insufficient data to calculate PROMIS-29 domain score at the designated analysis timepoint did not have their missing data imputed.

NOTE: No comparisons between ustekinumab and placebo were made at Wk 12. No treatment comparisons were made at Wk 48. The p-values for the comparisons of each guselkumab treatment group with the placebo group at Wk 12 were based on MMRM analysis including change from baseline in PROMIS-29 domain score as the response; treatment group, visit, baseline PROMIS-29 domain score, BIO-Failure status (yes, no), baseline CDAI stratification (≤300, >300), an interaction term of visit with treatment group and an interaction term of visit with baseline PROMIS-29 domain score as explanatory variables.

P0401 Table 1. Change from BL at Wk12 and Wk48 for PROMIS-29 Scores

-4.91 and -5.58 for anxiety, -3.96 and -4.53 for depression, -6.95 and -8.41 for fatigue, -8.05 and -11.57 for pain interference, 3.92 and 5.65 for physical function, -4.30 and -5.73 for sleep disturbance, and 5.73 and 7.81 for ability to participate in social roles and activities; mean change from baseline in pain intensity NRS scores at Wk12 and Wk48 were -2.52 and -3.19. GUS-treated pts achieved clinically meaningful improvement in fatigue T-scores (45.9-63.5%), pain interference T-scores (52.5-71.4%) and pain intensity NRS score at Wk48 (56.4-70.2%).

Conclusion: Induction and maintenance treatment with GUS was effective in improving HRQoL as measured by PROMIS-29 domains in pts with moderately to severely active CD at Wk48.

Introduction: Ozanimod (OZA), an oral small molecule sphingosine 1-phosphate (S1P) receptor modulator with high affinity to S1P₁ and S1P₅, prevents lymphocyte migration to the intestines through S1P receptor internalization. OZA is approved for treating moderately to severely active ulcerative colitis (UC) in Europe and the United States. True North (TN; NCT02435992), a randomized, double-blind, placebo (PBO)-controlled phase 3 trial, showed the efficacy and tolerability of OZA in patients (pts) with UC. Pts with pancolitis may have increased symptomatology and a higher risk of colectomy than pts with left-sided UC.

Aims & Methods: This TN post hoc analysis assessed the effect of baseline endoscopic disease distribution (left-sided vs pancolitis) on clinical outcomes in UC pts treated with OZA. In TN, pts were randomized to OZA

0.92 mg (equivalent to OZA HCl 1 mg) once daily or PBO (Cohort 1) or received open-label OZA (Cohort 2) during the induction period (IP). Pts with clinical response to OZA at Week 10 in either cohort were randomized to double-blind OZA or PBO for the maintenance period (MP). This analysis assessed efficacy outcomes at Weeks 10 (IP) and 52 (MP).

Results: Overall, baseline demographics and disease characteristics were similar between left-sided and extensive UC pts. OZA was more effective than PBO in left-sided and extensive UC pts at Week 10 for all evaluated clinical outcomes (Table).

Treatment effects (OZA vs PBO based on the Cochran-Mantel-Haenszel [CMH] test, stratified by corticosteroid [CS] use at screening and prior anti-tumor necrosis factor use) were generally similar for left-sided and extensive UC pts at Week 10: clinical remission (odds ratio [OR] 4.1 [95% CI 1.9-9.0]; $P=0.0001$ and 2.8 [95% CI 1.0-7.6]; $P=0.0387$), clinical response (3.0 [1.9-4.7]; $P=0.0001$ and 2.3 [1.3-4.2]; $P=0.0066$), endoscopic improvement (2.9 [1.6-5.0]; $P<0.001$ and 2.5 [1.1-5.7]; $P=0.024$), and mucosal healing (5.4 [1.9-15.4]; $P=0.0006$ and 2.1 [0.7-6.5]; $P=0.1675$), respectively. At Week 52, continuous OZA was more effective than OZA-PBO in left-sided and extensive UC pts (Table).

CS remission was achieved in 30.9% and 17.2% OZA-OZA and OZA-PBO left-sided UC pts, and in 33.3% and 15.7% OZA-OZA and OZA-PBO extensive UC pts. Treatment effects (OZA-OZA vs OZA-PBO based on CMH test stratified by remission status at Week 10 and CS use at Week 10) were generally similar for left-sided and extensive UC pts: clinical remission (OR 2.7 [95% CI 1.6-4.5]; $P=0.0003$ and 2.8 [95% CI 1.3-6.2]; $P=0.0084$), clinical response (2.4 [1.5-3.8]; $P=0.0003$ and 2.0 [1.0-3.9]; $P=0.0468$), endoscopic improvement (2.4 [1.5-3.9]; $P<0.001$ and 2.8 [1.3-6.1]; $P=0.007$), CS-free remission (2.3 [1.3-4.0]; $P=0.0040$ and 3.4 [1.5-8.0]; $P=0.0035$), and mucosal healing (2.4 [1.4-4.2]; $P=0.0022$ and 4.0 [1.6-10.6]; $P=0.0033$), respectively.

		IP: Cohort 1		IP: Cohort 2	MP	
Number (%) of pts achieving clinical outcomes		PBO	OZA 0.92 mg	OZA 0.92 mg	OZA-PBO	OZA-OZA
Left-Sided Subgroup (n=639)	Clinical remission	8/134 (6.0%)	55/268 (20.5%)	57/237 (24.1%)	29/157 (18.5%)	57/152 (37.5%)
	Clinical response	36/134 (26.9%)	138/268 (51.5%)	130/237 (54.9%)	65/157 (41.4%)	95/152 (62.5%)
	Endoscopic improvement	18/134 (13.4%)	83/268 (31.0%)	70/237 (29.5%)	45/157 (28.7%)	74/152 (48.7%)
	Mucosal healing	4/134 (3.0%)	38/268 (14.2%)	29/237 (12.2%)	25/157 (15.9%)	47/152 (30.9%)
Extensive Subgroup (n=373)	Clinical remission	5/82 (6.1%)	24/161 (14.9%)	20/130 (15.4%)	13/70 (18.6%)	28/78 (35.9%)
	Clinical response	20/82 (24.4%)	67/161 (41.6%)	63/130 (48.5%)	28/70 (40.0%)	43/78 (55.1%)
	Endoscopic improvement	8/82 (9.8%)	34/161 (21.1%)	30/130 (23.1%)	15/70 (21.4%)	31/78 (39.7%)
	Mucosal healing	4/82 (4.9%)	16/161 (9.9%)	13/130 (10.0%)	7/70 (10.0%)	21/78 (26.9%)

Table.

Conclusion: OZA was more effective than PBO in both left-sided and extensive UC at Weeks 10 and 52. Treatment effects of OZA were similar between left-sided and extensive UC pts across most clinical endpoints.

Introduction: Ozanimod (OZA), an oral sphingosine 1-phosphate (S1P) receptor modulator, is approved for the treatment of moderately to severely active ulcerative colitis (UC) in Europe and the United States. OZA induces S1P receptor internalization in lymphoid tissue, reducing lymphocyte egress to inflamed tissue.

The prevalence of inflammatory bowel disease (IBD) is increasing in the older population; currently, 25%–30% of patients (pts) with IBD are aged ≥60 years.^{1,2} Older pts, who generally have more comorbidities than younger pts, represent an understudied population in IBD.

Aims & Methods: This post hoc analysis from the phase 3 True North (TN) trial (NCT02435992)³ examined the efficacy and safety of OZA in pts aged <60 y and ≥60 y. Pts were randomized to double-blind OZA 0.92 mg (equivalent to OZA HCl 1 mg) or placebo (PBO; Cohort 1) or received open-label OZA (Cohort 2) during the 10-week (wk) induction period (IP). Pts with clinical response to OZA at Wk 10 were re-randomized to double-blind OZA or PBO for maintenance through Wk 52.

Efficacy endpoints (clinical remission, clinical response, endoscopic improvement, and mucosal healing) were assessed at Wks 10 and 52; adjusted treatment differences for OZA vs PBO were calculated using the Cochran-Mantel-Haenszel test. Treatment-emergent adverse events (TEAEs) and adverse events of special interest (AESIs) were assessed throughout the study.

Results: A total of 562 pts aged <60 y (OZA, n=376; PBO, n=186) and 83 pts aged ≥60 y (OZA, n=53; PBO, n=30) from Cohort 1 and 315 pts (<60 y) and 52 pts (≥60 y) from Cohort 2 were included in this analysis. During maintenance, 196 pts (<60 y) and 34 pts (≥60 y) continued on OZA treatment; 196 pts (<60 y) and 31 pts (≥60 y) were re-randomized to PBO.

Demographics and baseline disease characteristics were generally well balanced across treatment and age groups, but older pts had less-extensive disease, lower baseline fecal calprotectin levels, and more polypharmacy.

Adjusted treatment differences favored OZA vs PBO and were generally similar between the age groups across all efficacy endpoints at Wks 10 and 52. PBO response rates were higher in older vs younger pts. During IP, incidence of TEAEs with OZA in Cohorts 1 and 2 was lower in older (36% and 31%) vs younger pts (41% and 41%). Rates of serious TEAEs were similar in older (6% and 4%) vs younger (4% and 7%) pts, and TEAEs leading to treatment discontinuation were comparable in older (2% and 6%) and younger pts (3.5% and 3.5%).

With continued OZA treatment during maintenance, TEAEs occurred more frequently in older (56%) vs younger (48%) pts; however, serious TEAEs were less frequent in older pts (3% vs 6%). TEAEs leading to treatment discontinuation were similar in older (3%) vs younger (1%) pts.

AESIs were generally low overall, with the most common being infection (≥60 y: 2 pts vs <60 y: 3 pts), hepatic effects (≥60 y: 0 pts vs <60 y: 2 pts), macular edema (≥60 y: 1 pt vs <60 y: 0 pts), malignancy (≥60 y: 0 pts vs <60 y: 2 pts), and pulmonary effects (≥60 y: 0 pts vs <60 y: 1 pt). One death from acute respiratory distress syndrome due to viral pneumonia occurred during IP in an older pt (64y) on OZA but was deemed unrelated to treatment.

Conclusion: OZA is a safe, tolerable oral treatment option for older UC patients with an absence of concerning serious adverse events. Further, efficacy in older patients was comparable to younger patients. A key limitation of this study is the small sample size warranting future studies with larger, real-world cohorts.

ASSOCIATION BETWEEN ABSOLUTE LYMPHOCYTE COUNT AND OZANIMOD EFFICACY AND SAFETY IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS: RESULTS FROM THE PHASE 3 TRUE NORTH STUDY

S. Harris¹, R. Maddux¹, C. Wu¹, S. Hu¹, A. Petersen¹

¹Bristol Myers Squibb, Princeton, United States

Contact E-Mail Address: sarah.harris@bms.com

Introduction: Ozanimod, a sphingosine 1-phosphate (S1P) receptor modulator selectively targeting S1P₁ and S1P₅, is approved in Europe and the United States for the treatment of moderately to severely active ulcerative colitis (UC). Binding with ozanimod results in internalization of S1P₁ receptors, reducing egress of lymphocyte subsets into circulation with preservation of immunosurveillance. Ozanimod demonstrated efficacy and safety in the phase 3 True North trial in patients with moderately to severely active UC (NCT02435992).

Aims & Methods: This analysis assessed the association between absolute lymphocyte count (ALC) and ozanimod efficacy and safety during the induction and maintenance periods of True North. Patients were randomized to double-blind ozanimod 0.92 mg (equivalent to ozanimod HCl 1 mg) or placebo once daily (Cohort 1) or received open-label ozanimod 0.92 mg once daily (Cohort 2) during the 10-week induction period; patients with a clinical response to ozanimod at Week 10 were re-randomized to double-blind ozanimod or placebo for maintenance through Week 52. Clinical outcomes (rectal bleeding score [RBS], stool frequency score [SFS], composite Mayo score, Physician's Global Assessment [PGA] score, and endoscopy score) were assessed at baseline and Weeks 10 and 52. Efficacy endpoints (clinical remission, clinical response, endoscopic improvement, mucosal healing, and histologic remission) were also assessed at Weeks 10 and 52. Occurrence of treatment-emergent adverse events (TEAEs) and ALCs were evaluated at baseline and Weeks 5, 10, 18, 28, 40, and 52.

Results: A total of 645 patients received double-blind ozanimod (n=429) or placebo (n=216), and 367 received open-label ozanimod during induction; 230 and 227 ozanimod-treated patients were re-randomized to ozanimod and placebo, respectively, for maintenance. Baseline ALC was not significantly correlated with clinical outcome at Weeks 10 or 52 as measured by changes from baseline RBS, SFS, Mayo score, PGA score, and endoscopy score in patients who received ozanimod or placebo.

Additionally, baseline ALC was neither predictive nor prognostic for Weeks 10 and 52 responses based on all efficacy endpoints assessed. Reductions from baseline in mean ALC occurred by Week 5 with ozanimod and were significantly greater in patients who received ozanimod (53-54%) vs placebo (2.3%; $P<0.001$). ALC plateaued by Week 10 and was maintained through Week 52 in patients on continuous ozanimod. ALC returned to placebo levels by Week 52 in patients who switched to placebo during maintenance. Change in ALC at Week 10 was generally not significantly correlated with changes in clinical outcomes at Weeks 10 or 52.

Additionally, change in ALC at Week 5 was not predictive of Week 10 response, and change in ALC at Week 10 was not predictive of Week 52 response based on all efficacy endpoints assessed. Reductions from baseline in ALC at all weeks were similar in ozanimod-treated patients with or without ≥ 1 TEAE and with or without infection-related TEAEs.

Conclusion: ALC reductions, which were reversed upon treatment discontinuation, occurred with ozanimod and were not associated with occurrence of TEAEs, including infections. Baseline ALC was not predictive or

prognostic for response, nor were reductions in ALC. These findings support the use of ALC as a pharmacodynamic biomarker but not as a prognostic biomarker in UC or as a predictive biomarker for ozanimod.

IMPACT OF OZANIMOD ON FECAL CALPROTECTIN LEVELS AND THE ASSOCIATION WITH OZANIMOD EFFICACY IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS: RESULTS FROM THE PHASE 3 TRUE NORTH STUDY

S. Harris¹, R. Maddux¹, Y. Li², S. Hu¹, C. Wu¹, A. Petersen¹

¹Bristol Myers Squibb, Princeton, United States, ²Parexel International, Durham, United States

Contact E-Mail Address: sarah.harris@bms.com

Introduction: Ozanimod, a sphingosine 1-phosphate (S1P) receptor modulator, is approved in Europe and the United States for the treatment of moderately to severely active ulcerative colitis (UC). Ozanimod demonstrated efficacy in the phase 3 True North trial in patients with moderately to severely active UC (NCT02435992).

Infiltration of neutrophils in intestinal mucosa contributes to inflammation in inflammatory bowel diseases. Calprotectin, which is released by neutrophils, reflects neutrophilic activity and is useful in monitoring disease activity in UC.

Aims & Methods: This analysis assessed the effect of ozanimod on fecal calprotectin (FCP) levels and the association with ozanimod efficacy in True North. During the 10-week induction period, patients were randomized to double-blind ozanimod 0.92 mg (equivalent to ozanimod HCl 1 mg) or placebo once daily (Cohort 1) or received open-label ozanimod 0.92 mg once daily (Cohort 2).

Patients with clinical response to ozanimod at Week 10 were re-randomized to double-blind ozanimod or placebo for maintenance through Week 52. Efficacy endpoints (clinical remission, clinical response, endoscopic improvement, mucosal healing, and histologic remission) and FCP levels were assessed at Weeks 10 and 52.

Results: Change in FCP from baseline to Week 10 was assessed in 517 patients who received double-blind ozanimod (n=347) or placebo (n=170), and 293 who received open-label ozanimod. Patients on ozanimod demonstrated reductions from baseline in FCP at Week 10, which was significant vs placebo ($P<0.001$, both cohorts) (Table). FCP reductions were significantly greater in patients with vs without clinical response at Week 10 in all treatment groups ($P<0.001$, all groups) (Table).

Change in FCP from baseline to Week 52 was assessed in 149 patients remaining on ozanimod and 109 who switched to placebo. FCP levels remained low through Week 52; patients on continuous ozanimod had significantly greater FCP reductions at Week 52 vs patients who switched to placebo ($P=0.0002$) (Table).

FCP reductions were significantly greater in patients with vs without clinical response at Week 52 in the ozanimod and ozanimod-placebo groups ($P<0.01$, both groups) (Table).

Significantly greater reductions from baseline in FCP occurred with ozanimod vs placebo at Weeks 10 and 52 regardless of prior biologic or tumor necrosis factor inhibitor exposure ($P<0.05$, all groups). Baseline FCP level was predictive of clinical response and histologic remission at Week 10 ($P<0.05$, both endpoints). Reduction from baseline in FCP at Week 10 was predictive and prognostic for all endpoints except clinical response at Week 52 ($P<0.05$, all endpoints).

FCP adjusted mean percent change (95% CI)	Induction (Week 10)		Maintenance (Week 52)		
	Cohort 1		Cohort 2		
	Placebo (n=170)	Ozanimod (n=347)	Ozanimod (n=293)	Ozanimod-placebo (n=109)	Ozanimod-ozanimod (n=149)
All patients	18.8 (-11.6, 59.6)	-59.3 (-67.1, -49.7)	-71.6 (-77.2, -64.5)	-70.7 (-79.6, -57.7)	-87.7 (-91.0, -83.3)
Responders ^a	-48.7 (-68.7, -16.0)	-83.9 (-87.8, -78.8)	-86.2 (-89.5, -81.8)	-81.5 (-87.8, -71.7)	-91.0 (-93.7, -87.1)
Nonresponders ^b	54.9 (12.4, 113.5)	-12.1 (-32.4, 14.4)	-33.3 (-50.9, -9.5)	-10.5 (-53.6, 72.9)	-75.4 (-85.9, -57.2)

^aResponders are patients who achieved clinical response at Week 10 for the induction period and at Week 52 for the maintenance period. ^bNonresponders are patients who did not achieve clinical response at Week 10 for the induction period and at Week 52 for the maintenance period.

Table. Change from baseline in FCP at Weeks 10 and 52

Conclusion: Ozanimod led to FCP reductions, indicative of decreases in intestinal neutrophil levels. Baseline FCP was predictive of ozanimod response. FCP reductions were predictive for ozanimod response and prognostic for UC. These findings may help support the use of FCP as a predictive biomarker for ozanimod response and prognostic biomarker in UC.

COMBINATION THERAPY IS NOT ASSOCIATED WITH IMPROVED RATES OF CLINICAL OR ENDOSCOPIC REMISSION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH USTEKINUMAB OR VEDOLIZUMAB

A.W. Jeffrey¹, S. Picardo¹, S. Menon¹, K. So¹, K. Venugopal¹

¹Royal Perth Hospital, Department of Gastroenterology, Perth, Australia

Contact E-Mail Address: angus.jeffrey@health.wa.gov.au

Introduction: Combination therapy with Anti-TNF and immunomodulators has been demonstrated to be superior than monotherapy in Crohn's Disease (CD) and Ulcerative Colitis (UC). This is due to mechanistic effects of immunomodulators as well as reducing immunogenicity. Lower rates of immunogenicity have been found with Ustekinumab (UST) and Vedolizumab (VDZ). Emerging data suggests combination therapy is not required for these agents, however there is no data from the Australian cohort.

Aims & Methods: The aim of this retrospective cohort study was to determine if there was a difference in clinical and endoscopic outcomes for UST or VDZ as a monotherapy compared to a combination with thiopurines or methotrexate. Primary outcome was clinical remission or response as calculated by partial MAYO score (remission <3, response is a decrease >1) for UC or Harvey Bradshaw Index for CD (remission <5, response is a decrease >2) at week 14, 26 and 52. Secondary endpoints were treatment failure or relapse, and endoscopic remission at one year, where treatment failure or relapse is a combination endpoint of need for dose escalation, reinduction, ceasing biologic, and IBD related hospital admission or surgery.

Results: 85 patients on VDZ (61 with UC, 24 with CD) and 74 on UST (all with CD) were identified at a single centre in Australia between October 2015 and March 2022. Of these patients, 53 (72%) on UST and 56 (66%) on VDZ were treated with monotherapy. With the combination therapy, 16 (76%) on UST received thiopurines and 5 (24%) methotrexate compared

to 26 (90%) and 3 (10%) on VDZ respectively. There was no difference in clinical response or remission for VDZ monotherapy compared to combination therapy (Table 1) at Week 12 or 26 (p=0.38, p=0.83). Similarly, there was no difference in outcome for UST at the same intervals (p=0.21, p=0.74). At Week 52, 42 (82%) of patients on VDZ monotherapy had clinical response or remission compared to 21 (91%) on combination therapy (p=0.32). For UST this was 29 (97%) and 14 (88%) respectively (p=0.23). Remission and response rates were calculated from those patients who were still on treatment and had data available at each time interval. Treatment failure or relapse at one year occurred in 13 (23%) of patients on VDZ monotherapy compared to 5 (19%) on combination therapy (p=0.80). For UST this was 11 (21%) and 5 (24%) respectively (p=0.17). 52 patients on VDZ and 28 patients on UST had an interval colonoscopy at approximately one year. 23 (66%) patients on VDZ monotherapy and 14 (78%) on combination therapy achieved endoscopic remission (p=0.36). For UST this was 14 (70%) and 5 (63%) respectively (p=0.70).

Outcome	Number of Patients	Combination (%)	Number of Patients	Monotherapy (%)	p-value	Number of Patients	Combination (%)	Number of Patients	Monotherapy (%)	p-value
Vedolizumab						Ustekinumab				
Clinical Response or remission	29		56			21		53		
Week 12	27	19 (70%)	44	35 (80%)	0.38	14	13 (93%)	45	35 (78%)	0.21
Week 26	25	20 (80%)	50	41 (82%)	0.83	18	16 (89%)	42	36 (86%)	0.74
Week 52	23	21 (91%)	51	42 (82%)	0.32	16	14 (88%)	30	29 (97%)	0.23
Endoscopic Remission	18	14 (78%)	35	23 (66%)	0.36	8	5 (63%)	20	14 (70%)	0.70
Treatment Failure or Relapse	29	5 (19%)	56	13 (23%)	0.80	21	5 (24%)	53	11 (21%)	0.17

Table 1. Outcomes for Patients with Inflammatory Bowel Disease on Vedolizumab or Ustekinumab Monotherapy or in combination with another Immunomodulator.

Conclusion: For patients with IBD who are commencing either VDZ or UST, monotherapy is effective at achieving both clinical response or remission and endoscopic remission up to one year from starting treatment.

Disclosure: Nothing to disclose.

Introduction: Acute severe ulcerative colitis (ASUC) is a life-threatening disease.¹ Even after recovery, maintenance treatment is required for a long time, and re-exacerbation of ulcerative colitis can occur frequently.² A high CRP level is a poor prognostic factor in ASUC and increases the likelihood of colectomy.³⁻⁵

However, there are insufficient studies on the prediction of readmission due to exacerbation of ulcerative colitis.

Aims & Methods: We retrospectively included patients who were hospitalized at four tertiary medical centers for ASUC management between January 2015 to December 2020, and data on the underlying disease, disease activity, treatment method and readmission due to ulcerative colitis aggravation were checked.

Results: A total of 145 patients (mean age 44.4 years, 68 female) were investigated. Initial partial mayo score, mayo endoscopic sub-score, ulcerative colitis endoscopic index of severity scores were 7.6±0.8, 2.7±0.5, and 6.0±1.4, respectively. When divided into two groups with an initial CRP level above 5 and below, there was no significant difference in baseline characteristics.

Variables	cHR	95% CI	p-value	aHR	95% CI	p-value
Age	0.97	0.94-0.997	0.03			
Sex, male	0.67	0.33-1.36	0.26			
CRP ≥ 5	2.83	1.42-5.65	<0.01	2.38	1.26-4.49	<0.01
Albumin	0.89	0.47-1.70	0.73			
WBC	1.00	1.00-1.00	0.29			
Platelet	1.00	0.997-1.001	0.25			
UCEIS	0.95	0.76-1.20	0.68			
Partial Mayo score	0.94	0.63-1.40	0.75			
CCI	1.81	0.97-3.38	0.06			

aHR, adjusted hazard ratio; cHR, crude hazard ratio; CCI, Charlson comorbidity index; CI, confidential interval; CRP, C-reactive protein; UCEIS, ulcerative colitis endoscopic index of severity; WBC, white blood cell

Table 1. Univariate and multivariate analysis of risk factors for increased readmission due to exacerbation of ulcerative colitis using cox-regression.

However, in the group with CRP≥5, longer hospital stay (18 versus 12 days, p<0.01), lower albumin levels (3.1 versus 3.5 mg/dL, p<0.01), higher leukocyte counts (10652 versus 9148 /mm³, p=0.02), and higher platelet counts (417 versus 364 x10³/mm³, p=0.03) were observed compared with CRP<5. Readmission occurred in 69 (47.6%) patients on the median of 531 days (range, 7-4019).

The cumulative incidence rate of readmission at 1, 6, 12, 24 months were 2.8%, 12.4%, 19.3%, and 27.6%, respectively. Significantly more readmissions occurred in Kaplan Meier analysis in patients with CRP≥5 (p<0.01). In Cox regression analysis, readmission more frequently occurred in patients with CRP≥5 compared to patients with CRP<5 (aHR 2.38, CI: 1.26-4.49, p<0.01).

Conclusion: A total of 47.5% of readmission due to exacerbation of ulcerative colitis occurred during follow-up after ASUC recovery. High initial CRP levels were associated with readmissions for exacerbation of ulcerative colitis.

Introduction: Tofacitinib is a pan-JAK inhibitor approved for the treatment of moderate-severe ulcerative colitis (UC). We aimed to assess the rates of clinical response at week 8, and biochemical response, steroid-free clinical remission, and endoscopic healing at week 26 to tofacitinib in patients with mostly treatment-refractory moderate-severe UC.

Aims & Methods: This was a retrospective analysis of prospectively collected data extracted from the notes of patients with moderate-severe UC who were treated with tofacitinib in the last 2 years in 8 Greek IBD centers and who had a follow up of at least 26 weeks after initiation of treatment. Tofacitinib was administered at a dose of 10 mg *bid* for 8 weeks followed by a maintenance dose of 5mg *bid* thereafter. Week-8 clinical response was defined as the reduction in the partial Mayo score of at least 2 points, without concomitant use of any steroid preparation [budesonide, prednis(ol)one, or methylprednisolone]. Steroid free clinical remission at week 26 was defined as a partial Mayo score of ≤1 points without concomitant use of any steroid preparation. Biochemical response at week 26 was defined as any reduction in fecal calprotectin or plasma C-reactive protein concentrations over their baseline levels. Mucosal healing at week 26 was defined as Mayo endoscopic sub-score of ≤1. A safety list of all reported adverse events was completed. Treatment discontinuation due to adverse events was considered as treatment failure, whereas patients needing escalation of the maintenance dose were also considered as non-responders.

Results: Overall, 74 patients (41 males), aged (mean, SD) 39.2 (15.4) years and disease duration of (mean, SD) 10.6 (9.7) years were included. UC was extensive in 47, left-sided in 24, and proctitis in 3 patients. Four patients were naïve to biologics, whereas 12, 28 and 30 patients had failed treatment with 1, 2 and 3 biologics, respectively. Clinical response at week 8 was seen in 58 patients (78.4%). Biochemical response and steroid free clinical remission at week 26 were seen in 32 (43.2%) and 31 (41.9%) patients, respectively. Endoscopy at week 26 was performed in 28 patients and endoscopic healing was seen in 13 (46.4%) patients. Adverse events which did not lead onto treatment discontinuation occurred in 7 patients (hyperlipidemia n=5, elevated liver enzymes n=2). One patient experienced pulmonary embolism and treatment was discontinued.

Conclusion: In this retrospective real-world cohort tofacitinib demonstrated clinical response at week 8 in more than three quarters and steroid free clinical remission at week 26 in almost half of the patients with treatment refractory moderate-severe UC.

Disclosure: Nothing to disclose.

Introduction: The effectiveness of vedolizumab and ustekinumab for the treatment of complex perianal fistula (CPF) in Crohn's disease (CD) patients has been barely studied.

Aims & Methods: To evaluate drug persistence, the effectiveness, and safety of vedolizumab and ustekinumab in CPF.

Retrospective, multicenter study conducted in 43 Spanish sites. Patients who had received vedolizumab or ustekinumab for the indication of active CPF and had started the study drugs at least 6 months before study entry, were included. Patients who received both drugs were included in both groups for the data analysis. Clinical remission was defined according to Fistula Drainage Assessment Index (no drainage through the fistula upon gentle pressure) according to physicians' assessment.

Results: 155 patients were included (39% women, mean age at CD diagnosis 28 years, 96% previously exposed to anti-TNFs): 136 patients received ustekinumab, and 35 vedolizumab (16 patients had been treated with both drugs). Of the 136 patients who received ustekinumab, 95% had been previously treated with anti-TNFs. The indications for ustekinumab were: anti-TNF failure in 68% of the patients, anti-TNFs intolerance in 15%, vedolizumab failure in 10%, and other reasons in 6%. At ustekinumab start, 82% of the patients had also active luminal disease and 30% had undergone a surgical procedure on the CPF just before starting the treatment. The median follow-up time was 27 months (IQR=15-38). A total of 19% (24/136) of the patients discontinued ustekinumab during follow-up. The incidence rate of ustekinumab discontinuation was 8% per patient-year (95%CI=5-11%). Ustekinumab persistence was: 89% at 1 year, and 82% at 2 years. In the short-term, remission was achieved in 54% of the patients –median time to achieve clinical remission was 6 months (IQR=4-9)– of them, 27% (20/74) relapsed during follow-up. The incidence rate of relapse was 11% (95%CI=7-17%) per patient-year. The probability of relapse was: 10% at 1 year, and 25% at 2 years. In the multivariable analysis, no variable was associated either with the likelihood of discontinuation or with the risk of relapse. 6% of the patients on ustekinumab had adverse events, most of them mild. Of the 35 patients who received vedolizumab,

100% had been previously treated with anti-TNFs. The indications for vedolizumab were: anti-TNF failure in 74% of the patients, anti-TNF intolerance in 14%, ustekinumab failure in 7%, and other reasons in 3%. At vedolizumab start, 8% of the patients had also active luminal disease and 37% had undergone a surgical procedure on the CPF just before starting the treatment. The median follow-up time was 19 months (IQR=9-31). A total of 63% (22/35) patients discontinued vedolizumab. The incidence rate of vedolizumab discontinuation was 33% per patient-year (95%CI=22-45%). Vedolizumab persistence was: 65% at 1 year, and 42% at 2 years. In the short-term, remission was achieved in 46% of the patients –median time to achieve clinical remission was 8 months (IQR=3-8)– of them, 20% (3/19) relapsed during follow-up. The incidence rate of relapse was 7% (95%CI=2-19%) per patient-year. In the multivariable analysis, no variable was associated either with the likelihood of discontinuation or with the risk of relapse. 8% of the patients had adverse events, all mild.

Conclusion: Ustekinumab and vedolizumab seem to be effective for CPF, inducing clinical remission in about half of the patients, although a relevant proportion of patients withdraw the treatment over time. The safety profile of both drugs is good.

EFFECT OF A GLUTEN-FREE DIET ON THE DISEASES SEVERITY, QUALITY OF LIFE, AND INFLAMMATORY MARKERS AMONG PATIENTS WITH MILD TO MODERATE ULCERATIVE COLITIS: A TRIPLE-BLIND RANDOMIZED PLACEBO-CONTROLLED TRIAL

F. Alborziavanaki¹, R. Hadi², N. Aletaha², N. Ebrahimi², A. Mirolyaii¹

Contact E-Mail Address: mynameisrezahadi@gmail.com

Introduction: Dietary regimen has been introduced as an important underlying factor in ulcerative colitis disease. Some patients have also reported symptoms associated with using a specific diet. The aim of the present study was to investigate the effect of a gluten-free diet on disease severity, quality of life, and inflammatory markers in patients with ulcerative colitis.

Aims & Methods: In this triple-blind randomized placebo-controlled clinical trial, we evaluated the effect of a gluten-free regimen on the ESR, CRP, fecal calprotectin, disease severity, and quality of life in patients with mild to moderate ulcerative colitis. Patients' quality of life and severity of symptoms were evaluated using Inflammatory Bowel Disease Questionnaire (IBDQ) and Simple Clinical Colitis Activity Index (SCCAI) respectively. Patients received this regimen for six weeks and were evaluated before and after receiving it. Data were analyzed using SPSS version 22.

Results: Mean (standard deviation) age of patients (n=26) was 39.31 (9.34) years. Among our patients there were 19 (73.1%) females. In both study groups, mean ESR, CRP, quality-of-life (IBDQ) and SCCAI severity score decreased, after receiving diet. These decreases were stronger in intervention group, but none of them were statistically significant. Additionally, both in the control and intervention groups, mean fecal calprotectin increased. However, none of the changes were statistically significant (P-Value> 0.05).

Conclusion: Although in our study, inflammatory markers, quality of life, and disease severity improved in the gluten-free group compared to the control group, but none of the changes were statistically significant. It is too early to suggest the gluten-free diet as a safe and beneficial regimen for UC patients and still, there is a need for further investigations with larger sample sizes in the context of clinical trial and cohort studies, to obtain more reliable results.

ONE YEAR OF USTEKINUMAB THERAPY IMPROVES NUTRITIONAL STATUS IN PATIENTS WITH CROHN'S DISEASE

L. Bertani¹, C. D'Alessandro¹, M. Fornili², F. Coppini¹, F. Zanzi¹, F. Geri¹, M.G. Mumolo³, L. Ceccarelli³, L. Baglietto², M. Bellini¹, F. Costa³, N. de Bortoli¹

Introduction: Patients with Crohn's disease (CD) display high rates of nutritional deficiencies and metabolic imbalances, primarily due to mucosal damage induced by inflammation. In particular, the loss of lean muscle mass configures a condition known as sarcopenia, which is not necessary associated with a low Body Mass Index (BMI). The presence of sarcopenia has been associated with a worst outcome of IBD. At present, no studies evaluated the impact of Ustekinumab (UST) in terms of its effects on body composition.

The aim of this study was to evaluate whether UST treatment could modify the parameters of body composition assessed by Bioelectrical Impedance Assay (BIA) in patients with CD. In particular, we evaluated phase angle, which represents the most clinically established impedance parameter and it might be considered as a reliable and optimal marker of nutritional status.

Aims & Methods: We enrolled all consecutive CD patients treated with UST prospectively, following the current guidelines. BIA was performed at baseline and at week 48, assessing Body Cellular Mass (BCM), total body water, phase angle and BMI. At the same time-points, a colonoscopy was performed in order to evaluate the therapeutic outcome in terms of mucosal healing, defined as a Simple Endoscopic Score for CD <2. We evaluated also clinical remission, defined as a Harvey-Bradshaw Index <5 at week 48.

Results: Out of 44 patients enrolled, 26 (59%) presented clinical remission and 22 (50%) achieve mucosal healing at the end of follow up. No significant differences were observed at baseline in all the BIA parameters between responders and non-responders. Phase angle increased over time in responders, while this was not observed in non-responders (test for the interaction between time and outcome, p-value=0.010 and 0.008 for clinical remission and mucosal healing, respectively). The same differential increase was observed for BCM (test for the interaction between time and outcome, p-value=0.037 and 0.076 for clinical remission and mucosal healing, respectively). No other significant differences were observed regarding the other BIA parameters.

Conclusion: UST therapy seems to be able to modify body composition of patients with CD. In particular, the increase in phase angle in responders suggests that a significant improvement of nutritional status occurred in these patients. Our results are in line to what was shown by a previous study performed in patients with psoriasis treated with UST.

Disclosure: None of the authors have conflicts of interest regarding this study

Introduction: Phase III trials have demonstrated the efficacy of risankizumab in moderate-to-severe Crohn's disease (CD), but no real-world data are currently available. We aimed to assess the short-term effectiveness and safety of risankizumab in patients with CD.

Aims & Methods: From April 2021 to March 2022, all patients with refractory luminal CD treated with risankizumab in 18 French GETAID centres were retrospectively included. The primary endpoint was steroid-free clinical remission at week 12 (Harvey-Bradshaw (HB) score <5).

Secondary endpoints included clinical response (≥ 3 -point decrease of HB score and/or (HB) score <5), biological remission (CRP ≤ 5 mg/L), morphological response (endoscopy, MRI or intestinal ultrasound), need for CD-related surgery, and adverse events.

Results: Data at week 12 were available for 70 patients. All (100%) had been previously exposed to anti-TNF agents, 64/70 (92%) to vedolizumab and 68/70 (97%) to ustekinumab. All patients were exposed to at least three biologics and 45/70 (65%) had previous intestinal resection. All but two (68/70, 97%) received 600 mg intravenous induction at weeks 0-4-8. At weeks 12, clinical response was observed in 55/70 (78%), clinical remission and steroid-free clinical remission in 40/70 (57%) and 31/70 (44%), respectively. Absence/mild abdominal pain with normal stool frequency was noted in 20/70 (29%) patients. Twenty-five patients had extra-intestinal manifestations at baseline versus 13 at week 12. Biological remission was observed in 38/70 (54%) patients. Among the 17 patients with colonoscopy, MRI or IUS at both baseline and week 12, response was observed in nine. Seven (10%) patients discontinued risankizumab and 5 (7.4%) underwent surgery during follow-up. In multivariable analysis, steroids at risankizumab initiation (Odds Ratio (OR), 0.24; 95%CI, 0.06 - 0.89; p=0.037) and non-smoker status (OR, 7.01; 95%CI, 1.26 - 59.0; p=0.04) were significantly associated with steroid-free clinical remission at weeks 12. Adverse events occurred in 10/70 (14%) of patients and serious adverse events in 3/70 (4.3%) of patients.

Conclusion: In a cohort of highly refractory patients with CD with multiple prior drug failures including ustekinumab, risankizumab induction provided clinical response in about 3 out of 4 patients and steroid-free clinical remission in about 40%.

BIOLOGICALS AND SMALL MOLECULE COMBOTHERAPIES: PROMISING EXPERIENCE IN REFRACTORY IBD PATIENTS

P. Juillerat^{1,2}, M. Martinho Grueber¹, P. Michetti^{1,3}

¹La Source-Beaulieu Crohn's and Colitis Center, Gastroenterology, Lausanne, Switzerland, ²Bern University Hospital, Gastroenterology, Bern, Switzerland, ³Lausanne University Hospital, Gastroenterology, Lausanne, Switzerland

Contact E-Mail Address: pjuillerat@gesb.ch

Introduction: It has been hypothesized that combination of two biologics or with a small molecule could "break the ceiling" of the efficacy (~60%) of currently available biological therapies for IBD patients. The best combinations and their safety are, however, unknown.

Aims & Methods: A chart review of Inselspital, Bern University hospital, of IBD patients on combination therapy have been performed. Data on disease phenotype, previous treatment and efficacy and safety of the new combinations have been collected and studied to help moving forward the use of this armamentarium.

Results: Among 18 identified IBD patients (39% women, 10 ulcerative colitis, 8 Crohn's disease) with extended and refractory luminal disease (indication) who received 21 combination therapies between June 2017 and November 2021. They suffered from steroid-dependency and half of them were refractory to at least two anti-TNF alpha agents. These treatments have been started after a median duration of disease of 6 years (range 1-25) for a mean period of combo treatment of 11 months (range 1-52), 8 were still ongoing. Various combotherapies and clinical response (arrows; red=bad, green=good response) are presented in Table 1.

Disease	Type of combo	Success	Duration (range)	Adverse events (AE)
ulcerative colitis	5x Vedo/ Tofa	2/5 (40%)	5 mois (1-11)	None
	3x Vedo/ Anti-TNFs	1/3 (33%)	8 mois (1-12)	None
	3x Vedo / CysA.	2/3 (66%)	8 mois (6-11)	None
	1x Ustek/ CysA	1/ 1 (100%)	16 mois	None
Crohn's disease	4x Ustek/ Anti-TNFs	4/ 4 (100%)	3 mois (1-9)	Left parotide tumefaction, eczema
	2x Ustek/ JAK	2/2 (100%)	14 mois (2-25)	Lymphopenia (2x), skin mycosis, otitis media Non Hodgkin lymphoma
	3x Vedo/ Anti-TNFs	2/3 (66%)	37 mois (6-52)	None
IBD	14x Vedo, 10x Anti-TNFs, 7x Ustek, 7x JAKs, 4x CysA	13/ 19 (68%) partial or complete response CRP -11, Calpro - 1234	~ 12 months (1-52)	2 Infections, 4 Minor AE, 1 SAE (Lymphoma)

Table 1.

A partial or complete response was observed in 15/21 therapies (71%) with a mean decrease of CRP of 11 mg/l (range+23 to -59) and calprotectin of 399 mcg/g (range 0 – 1745) among the responders. Concerning safety, 2 infections (otitis media, skin mycosis), 1 non hodgkin Lymphoma and 4 minor adverse events (tumefaction left parotide, eczema, 2x lymphopenia) have been reported, mostly when small molecules have been involved.

Conclusion: Ustekinumab combined with anti-TNF agents in Crohn's disease is more effective than vedolizumab and tofacitinib in ulcerative colitis. Combining with small molecules increases the risk of lymphopenia, of cancer (1 case of non hodgkin lymphoma) and minor infections in severe refractory and steroid-dependent inflammatory bowel disease patients.

Contact E-Mail Address: abs.rao@doctors.org.uk

Introduction: Delays in diagnosis could be due to patient-related and health-system related factors. The impact of such delays in Inflammatory Bowel Diseases (IBD), particularly on biological therapies, continues to be a subject of interest.

The aim of the study was to investigate if delays could predict need for biologics and report on related adverse outcomes (AOs).

Aims & Methods: New patients referred for suspected IBD to a single tertiary care centre between Jan 2013 to Dec 2017 were identified using EMR. For purposes of the study, delay-types and cut-off times for each type was set by investigators based on best average hospital waiting times. The reasons for delays until start of treatment were recorded; data on the start of biologics, duration, and reasons for switch (if required) were recorded. The data were analysed using multiple Pearson correlations and Cox proportional Hazard model to determine whether any delay-type/s could predict need for biologics and compare the risk between patients with or without a delay.

Results: Total of 105 patients were identified using stringent criteria (M=58; median age=32y) with a long median follow-up of 55 months. 65, 27 and 13 patients had final diagnosis of Ulcerative colitis, Crohn's disease, and Unclassified colitis respectively, and were analysed collectively.

In our cohort, a model that combined delay in seeking medical attention, and time taken from specialty review to index endoscopy exhibited the best predictive power with average AUROC of 0.67.

When individual delay-types were analysed, it was noted that most delay-types increased the risk of biologic use-

a. Delay in seeking medical attention [OR-1.08 (1.03 1.17)]

b. Delay from GP referral to specialty review [OR-1.10 (1.0 1.23)]
 c. Delay from specialty review to index endoscopy [OR-1.09 (1.01 1.21)]
 On further analysis of patient-related delay and health-system related delays, there was a statistically significant increase noted in the risk of requiring biologics at any time during the follow-up period.
 Survival without biologics when there is a delay of >2 weeks in seeking medical attention was statistically significant ($p=0.042$) and so was survival without biologics when there is delay of >6 weeks from GP referral to index endoscopy procedure ($p=0.021$).

Conclusion: The risk of requiring biologic therapy is higher in those patients who have faced any type of delay in their diagnosis of IBD. A patient-related delay of >2weeks and cumulative health-system related delay of >6weeks increase the risk of requiring biologic therapy at any time during their follow-up.
 Both primary and secondary care must work to reduce any delays as this has long-term implications for patients and economic implications for the health care providers.

Disclosure: Nothing to disclose.

Introduction: Thiopurine co-therapy with anti-tumour necrosis factor alpha (anti-TNF α) agents is associated with higher anti-TNF α drug levels and reduced immunogenicity in patients with Inflammatory Bowel Disease (IBD). However, the 6-thioguanine nucleotide (6-TGN) threshold level required to confer this benefit remains unclear.

Aims & Methods: This study aimed to evaluate the relationship between serum 6-TGN levels and trough levels of infliximab (IFX) and adalimumab (ADA) in IBD patients on combination therapy. We performed a retrospective multicentre study of IBD patients receiving combination anti-TNF α and thiopurine maintenance therapy for at least 3 months duration with stable doses for at least 2 months. All 6-TGN levels measured within 3 months prior to or on the same date as IFX or ADA trough levels, between January 2015 and August 2021, were included. Undetectable 6-TGN levels (<5pmol/8x10⁸ RBC) were excluded.

Primary outcomes were IFX and ADA levels. Secondary outcomes were antibodies to IFX (ATI) or ADA (ATA). Spearman's rho was used to correlate 6-TGN and anti-TNF α levels. Receiver operator characteristic curves were

used to define the optimal 6-TGN cut-off levels associated with therapeutic anti-TNF α levels ($\geq 5\text{mcg/ml}$ for IFX, $\geq 7.5\text{mcg/ml}$ for ADA), using the Liu index. The Mann-Whitney U test was used to compare 6-TGN levels between patients with and without detectable ATI.

Results: A total of 743 paired 6-TGN and anti-TNF α levels (640 IFX, 103 ADA) from 354 patients (263 IFX, 91 ADA) were included. 363/640 (57%) IFX levels and 65/103 (63%) ADA levels were measured in patients on standard anti-TNF α dosing (5mg/kg every 8 weeks for IFX, 40mg every 2 weeks for ADA). The median 6-TGN level was 252pmol/8x10⁸ RBC, median IFX level was 6.45mcg/ml and median ADA level was 7.70mcg/ml. 6-TGN and IFX levels were significantly positively correlated ($\rho=0.132$, $p=0.0008$), however the correlation between 6-TGN and ADA levels was not significant ($\rho=0.145$, $p=0.143$).

The optimal 6-TGN cut-off that predicted therapeutic IFX levels was 261pmol/8x10⁸ RBC (area under the curve (AUC) 0.57, sensitivity 0.58, specificity 0.56) for patients on standard IFX dosing and 227.5pmol/8x10⁸ RBC (AUC 0.58, sensitivity 0.57, specificity 0.58) for patients on escalated IFX dosing.

The optimal 6-TGN cut-off that predicted therapeutic ADA levels was 245pmol/8x10⁸ RBC (AUC 0.57, sensitivity 0.62, specificity 0.53) for patients on standard ADA dosing and 201pmol/8x10⁸ RBC (AUC 0.63, sensitivity 0.80, specificity 0.46) for patients on escalated ADA dosing. Seven patients had detectable ATI. Patients with ATI had significantly lower 6-TGN levels compared to those without ATI (median 6-TGN 133 vs 253pmol/8x10⁸ RBC, $p=0.010$). No patients had detectable ATA.

Conclusion: 6-TGN levels are associated with IFX trough levels, however the association between 6-TGN and ADA levels remains unclear. Target 6-TGN levels in the lower end of the therapeutic 6-TGN range may be adequate to maintain therapeutic anti-TNF α levels, particularly in patients on escalated anti-TNF α dosing.

However, the optimal 6-TGN cut-offs associated with therapeutic IFX and ADA levels that were calculated from our multicentre data showed poor predictive ability, and may differ depending on individual laboratory assays.

Disclosure: Nothing to disclose.

INCREASE IN CIRCULATING T AND B LYMPHOCYTE SUBSETS AFTER TREATMENT WITH THE POTENT, SELECTIVE, ORAL, SMALL MOLECULE $\alpha_4\beta_7$ INHIBITOR MORF-057 IN HEALTHY SUBJECTS

A. Hussain¹, M. Mangada¹, J. Wong¹, A.S. Ray¹, G. Bain¹

¹Morphic Therapeutic, Waltham, United States

Contact E-Mail Address: ali.hussain@morphictx.com

Introduction: The expanding role of small molecule drugs in modulating the immune system provides innovative opportunities in targeting autoimmune diseases. Unraveling the complex molecular mechanisms behind immune trafficking have aided in the development of tissue-specific therapeutic agents. Patients experiencing chronic inflammation in their gut have benefited from biologics targeting the $\alpha_4\beta_7$ /MAdCAM-1 axis. Integrin heterodimer $\alpha_4\beta_7$ is expressed on a subset of lymphocytes, mediating their extravasation upon binding to the corresponding gut-specific ligand MAdCAM-1. Inhibiting this interaction blocks lymphocytes from infiltrating into the intestinal lamina propria, leading to measurable increases in their circulating levels.^{1,2,3}

In this study, we explored target engagement and lymphocyte trafficking as pharmacodynamic (PD) readouts in healthy subjects treated with an orally administered, small molecule inhibitor of $\alpha_4\beta_7$ MORF-057.

Aims & Methods: A randomized, double-blinded, placebo-controlled multiple ascending dose (MAD) study (NCT04580745) was conducted on 21 healthy subjects (16 active + 5 placebo) to evaluate the safety, tolerability, and pharmacokinetics (PK) of MORF-057. Subjects recruited in the MAD study were grouped into 3 cohorts based on MORF-057 treatment dosages (25 mg BID, 50 mg BID, 100 mg BID). Blood was serially collected to assess PK/PD readouts over a period of 14 days.

Changes in $\alpha_4\beta_7$ receptor occupancy (RO) and lymphocyte trafficking were explored using flow cytometry-based assays on days 0 (pre-treatment), 1, 7, and 14. Whole blood samples were assayed under physiological conditions to quantify $\alpha_4\beta_7$ occupancy. PBMC samples were isolated to quantify CD4+ naïve, CD4+ central memory (T_{CM}), CD4+ effector memory (T_{EM}) T cells, and switched memory B cells (B_{SM}). Post-treatment PBMC data were normalized to baseline pre-treatment levels for comparison with placebo using the Mann-Whitney U test.

Results: On Day 14, trough $\alpha_4\beta_7$ RO was high in all groups and saturating (RO > 99%) in the 100 mg BID cohort (Table). Subjects receiving MORF-057 100 mg BID had a significant increase in their circulating levels of β_7 + CD4+ T_{CM} cells. Similarly, β_7 high CD4+ T_{EM} subset showed an increasing trend in circulation for the 100 mg BID dose group. As for the β_7 + B_{SM} cell subset, the percent change from baseline was significantly greater for the top two dose groups. No significant changes in naïve B and naïve CD4+ T cells were observed in all dose groups.

	POOLED PLACEBO (n=5)	25 mg BID (n=5)	50 mg BID (n=6)	100 mg BID (n=5)
CD4+ memory T cells trough RO (%)	0	91	93	>99 (n=4)
LYMPHOCYTE SUBSET CHANGES				
CD4+ β_7 + central memory T cells	97.1	94.8	104.5	114.6*
CD4+ β_7 high effector memory T cells	93.1	88.3	100.7	113.2
β_7 + switched memory B cells	98.1	103.2	105.0*	116.7**

* p<0.05, ** p<0.01 based on Mann-Whitney U test, active vs. placebo

T_{CM} : CD3+CD4+CD45RO+CD27+; T_{EM} : CD3+CD4+CD45RO+CD27-; B_{SM} cells: CD19+CD27+IgD-

Table. Baseline-normalized median of β_7 + lymphocyte subsets and $\alpha_4\beta_7$ RO after treatment with MORF-057 BID for 14 days.

Conclusion: Healthy subjects receiving MORF-057 for a period of 14 days in the top dose group achieved saturation of $\alpha_4\beta_7$ receptors and statistically significant increases in circulating ITG β_7 expressing CD4+ T_{CM} , and B_{SM} lymphocyte subsets. Effects observed were consistent with those reported for biologic inhibitors of the same pathway in patients and establish proof-of-biology for MORF-057.⁴

Introduction: Filgotinib (FIL) is generally well tolerated in patients with ulcerative colitis (UC), independent of dose, disease history, prior biologic failure, and age group^{1,2}.

Data from the ORAL-SURVEILLANCE study (NCT02092467)³ suggested that, in patients with active rheumatoid arthritis (RA) aged ≥50 years with ≥1 cardiovascular (CV) risk factor, the pan-JAK inhibitor tofacitinib has a higher risk of major adverse cardiovascular events (MACE) and malignancies compared with TNF inhibitors. It is unclear whether a preferential JAK1 inhibitor, such as FIL, may also increase the risk of these events in patients with active UC.

Aims & Methods: In absence of sufficient data from a high-risk UC population, we report an exploratory analysis of adverse events of special interest (AESI) using integrated FIL RA data from Phase 2 (NCT01668641, NCT01894516), Phase 3 (NCT02889796, NCT02873936, NCT02886728), and long-term extension (LTE) studies: DARWIN 3 Phase 2 LTE, NCT02065700; FINCH 4 Phase 3 LTE, NCT03025308, in a patient population at higher-risk for CV events (aged ≥50 years with ≥1 CV risk factor).

Population CV risk factors similar to ORAL-SURVEILLANCE were selected, including: a history of dyslipidemia, diabetes or CV disease, hypertension, ischemic vascular conditions, peripheral vascular disease, extra-articular manifestations of RA, or current smokers. Censored exposure-adjusted incidence rates (EAIR)/100 patient-years of exposure for MACE, venous thromboembolism (VTE), malignancies excluding nonmelanoma skin cancer (NMSC), NMSC, (serious) infections, and deaths were determined. The analysis set included data available through January 2022 for DARWIN 3 and FINCH 4 LTEs.

Results: Overall, the higher-risk population included 1484 patients, mean age 62.1 years (536 [36.1%] aged ≥65 years), 291 (22.5%) were current smokers, and 904 (60.9%) received background methotrexate (MTX); baseline (BL) MTX was higher in the FIL100 vs FIL200 group (66.6 vs 54.6%) and other BL demographics were balanced.

In this population, numerically higher EAIRs for malignancies (excluding NMSC), NMSC, serious infections, and deaths were observed for patients receiving FIL200; 95% confidence intervals (CI) overlapped with the FIL100 dose (Table).

For MACE, incidence was numerically lower in the FIL200 versus FIL100 group, and for VTE incidence was the same in both dose groups, with overlapping 95% CIs.

EAIR per 100 PYE (95% CI) n (%)	Filgotinib 100 mg q.d. (PYE=1849.7) (N=692)	Filgotinib 200 mg q.d. (PYE=2803.7) (N=870)
MACE*	0.6 (0.3, 1.1) 11 (1.6)	0.5 (0.3, 0.9) 14 (1.6)
Myocardial infarction	0.2 (0.1, 0.6) 4 (0.6)	0.1 (0.0, 0.3) 3 (0.3)
VTE*	0.2 (0.1, 0.6) 4 (0.6)	0.2 (0.1, 0.5) 6 (0.7)
Malignancies (excluding NMSC)	1.0 (0.6, 1.5) 18 (2.6)	1.2 (0.8, 1.7) 33 (3.8)
NMSC	0.3 (0.1, 0.7) 6 (0.9)	0.6 (0.4, 1.0) 18 (2.1)
Serious infections	2.6 (1.9, 3.4) 47 (6.8)	2.9 (2.3, 3.6) 81 (9.3)
Infections	35.9 (32.4, 39.8) 367 (53.0)	38.8 (35.6, 42.1) 555 (63.8)
TEAEs leading to death	0.8 (0.5, 1.3) 15 (2.2)	1.4 (1.0, 1.9) 39 (4.5)

*Positively adjudicated MACE/VTE (adjudication cut-off for higher-risk population: 30 November 2021), VTE (deep venous thrombosis/pulmonary embolism). AESI, adverse event of special interest; CI, confidence interval; CV, cardiovascular; EAIR, exposure-adjusted incidence rate; MACE, major adverse cardiovascular event; NMSC, nonmelanoma skin cancer; PYE, patient-years of exposure; q.d., once daily; RA, rheumatoid arthritis; VTE, venous thromboembolism.

Table. EAIR and frequency of treatment emergent AESI in a selected population of patients with RA (≥50 years old, ≥1 CV risk)

Conclusion: In absence of data in a higher-risk UC population, exploratory analysis of safety events in the RA population at higher risk of CV events may inform the safety of FIL in UC. In this RA population, the incidence rate of MACE, VTE and malignancies was similar with both doses. A numerically higher incidence of NMSC, serious infections and deaths was observed in the high dose group versus the low dose group. The ongoing LTE and real-world studies in RA and UC will continue to investigate the safety of FIL in these populations.

Introduction: The effectiveness and safety of switching from adalimumab reference to biosimilar in patients with inflammatory bowel disease (IBD) has been barely studied.

Aims & Methods: Aims: The aims of the present study were:

1. To compare persistence on adalimumab treatment over time in IBD patients who maintained adalimumab reference [non-switch cohort (NC)] vs. those who switched from adalimumab reference to adalimumab biosimilar [switch cohort (SC)];
2. To compare loss of effectiveness of adalimumab treatment in the NC vs. SC;
3. To identify factors associated with discontinuation of adalimumab therapy;
4. To identify the factors associated with relapse in both cohorts; and,
5. To evaluate the safety of both strategies.

Methods: Retrospective, observational, multicenter study conducted at 26 Spanish sites. Patients under adalimumab reference who were in clinical remission at standard dose of adalimumab reference, and in whom adalimumab was the first anti-TNF administered, were included. Clinical remission was defined as a Harvey-Bradshaw index ≤ 4 points in Crohn's disease, a partial Mayo score ≤ 2 in ulcerative colitis, and the absence of fistula drainage despite gentle finger compression in perianal disease. The follow-up time was at least 6 months since start of study observation period. The Kaplan-Meier with log-rank test was used to evaluate the cumulative incidence of treatment discontinuation. Cox regression model was used to investigate factors potentially associated with treatment discontinuation.

Results: A total of 505 patients were included (45% women, 87% Crohn's disease): 229 in the SC and 276 in the NC. The median follow-up was 12 months in the SC and 23 months in the NC ($p < 0.01$). The incidence rate of adalimumab discontinuation was 10% [95% confidence interval (95%CI)=6-14%], and 7% (95%CI=5-10%) per patient-year in the SC and in the NC, respectively ($p = 0.035$). The probability of maintaining adalimumab was 92% at 12 months and 77% at 24 months in the SC, and 97% at 12 months and 86% at 24 months in the NC.

In the multivariable analysis, the switch to adalimumab biosimilar, adjusted for the level of C-reactive protein at baseline, was not associated with therapy discontinuation. 18% of the patients relapsed in the SC vs. 21% in

the NC. The incidence of relapse was 17% (95%CI=13-23%) in the SC, and 12% (95%CI=10-16%) per patient-year in the NC ($p=0.04$). The cumulative incidence of relapse was 11% at 12 months and 38% at 24 months in the SC, and 11% at 12 months and 22% at 24 months in the NC. In the multi-variable analysis, the switch to adalimumab biosimilar (adjusted by type of IBD) was associated with a higher risk of relapse ($HR=1.5$, 95%CI=1.008-2.36). Four percent of the patients had adverse events in the SC vs. 8% in the NC ($p>0.05$).

Conclusion: The incidence rate of relapse was slightly higher in the SC; however, this fact had no impact on persistence on the drug. Switching from adalimumab reference to adalimumab biosimilar was safe.

ANTI-INFLAMMATORY AND BARRIER STABILIZING EFFECTS OF A HERBAL COMBINATION MEDICINE OF MYRRH, COFFEE CHARCOAL AND CHAMOMILE FLOWER EXTRACT IN A MULTI-COMPONENT CELL MODEL OF THE INFLAMED INTESTINAL MUCOSA

L. Schiller^{1,2}, B. Lipowicz², C. Vissienon^{1,2}

¹Leipzig University/Medical Faculty, Institute of Medical Physics and Biophysics, Leipzig, Germany, ²Repha GmbH Biologische Arzneimittel, Langenhagen, Germany

Contact E-Mail Address: cica.vissienon@uni-leipzig.de

Introduction: Myrrhinil-Intest®, a herbal medicinal product consisting of myrrh (*Commiphora myrrha* (Nees) Engl.), coffee charcoal (*Coffea arabica* L.) and chamomile flower dry extract (*Matricaria chamomilla* L.), has been used for decades to treat various gastrointestinal diseases. Recent clinical studies suggest its use in remission maintenance therapy of ulcerative colitis and led to its inclusion as a complementary therapeutic option in the German S3-Guideline Ulcerative Colitis. The underlying pharmacological mechanisms have not yet been fully elucidated.

Aims & Methods: Aim of the present study was to assess the influence of the individual components of Myrrhinil-Intest® and their threefold combination on inflammatory cross-talk between immune and intestinal epithelial cells as well as resulting intestinal barrier impairments using a complex co-culture cell model. To model the intestinal mucosa, epithelial cell like Caco-2 and goblet cell like HT29-MTX cells were differentiated on transwell inserts and inflammatory stimulation was realized by co-cultivation with LPS-activated human macrophages for 48 h.

At the same time treatment with different concentrations of the plant extracts (0.1-500 µg/mL) or budesonide (0.1 µM) as positive control was performed. Barrier function was evaluated by measurements of transepithelial electrical resistance (TER). Secretion of cytokines (IL6, TNF) as well as chemokines (IL8, MCP-1) and lipid mediator PGE₂ was quantified by ELISA.

Results: The individual plant extracts and their combined application showed concentration-dependent inhibitory effects on the release of pro-inflammatory mediators from stimulated cells to a varying extent with myrrh extract being most effective component. TER of inflamed monolayers was restored to baseline level upon treatment with myrrh, coffee charcoal and the ternary combination. The effects were comparable to treatment with budesonide. Synergistic and additive interactions were observed after combined application of all three plant extracts.

Conclusion: Thus, the herbal components of Myrrhinil-Intest® inhibited the inflammatory communication between immune and intestinal epithelial cells and counteracted the intestinal barrier impairment. In addition, synergistic and additive pharmacological interactions of the single components aid the overall effect and reinforce the use of their combined application in IBD therapy.

Introduction: STARDUST is a phase 3b randomized trial comparing two treatment strategies with ustekinumab (UST) in patients (pts) with Crohn's disease (CD): treat-to-target (T2T) using early endoscopic assessment vs standard of care (SoC).

The primary endpoint, safety, and efficacy data of STARDUST from Week (W)48 and the long-term extension (LTE; W48–W104) have been published previously.^{1,2}

Here, we describe results from the LTE period for health-related quality of life (HRQoL) measures and the effect of UST on work productivity and activity impairment at W104, comparing T2T and SoC.

Aims & Methods: Adult pts with moderate–severe active CD, received iv, weight-based UST ~6mg/kg at W0; then sc UST 90mg at W8. At W16, CD Activity Index (CAI) responders (≥70-point reduction in CAI) were randomized 1:1 to either T2T or SoC and received sc UST 90mg, every 12W/8W (up to 4W in the T2T arm) as per the protocol. From W48, pts entering LTE could continue to receive sc UST up to W104 with further protocol-guided dose adjustment (de-escalation/escalation).

This analysis assessed changes from baseline (BL) in the following HRQoL measures at W104: Inflammatory Bowel Disease Questionnaire (IBDQ), EuroQoL 5-Dimension 5-Level (EQ-5D-5L), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) tools, Hospital Anxiety and Depression Scale (HADS-A and -D), the Work Productivity and Activity Impairment (WPAI) questionnaire and time lost from work. Percentage of pts with IBDQ response (an increase of ≥16 points in IBDQ score from BL) and remission (IBDQ score ≥170) at W104 are also presented. Results are presented as observed and shown only for pts entering LTE (modified randomized analysis set).

Results: Of 440 pts randomized to T2T or SoC at W16, 74 discontinued before W48. Of the remaining 366 pts completing W48, 43 discontinued and did not enter LTE. At W48, 323 pts (T2T, n=147; SoC, n=176) entered LTE and 82.3% and 80.1% of pts in T2T and SoC arms, respectively, completed 104W of treatment. At W104, similar percentages of pts in T2T and SoC arms had an IBDQ response (89.4% and 84.8%, respectively) and remission (76.1% and 71.2%, respectively). Comparable changes from BL in IBDQ, EQ-5D-5L (visual analogue scale and index score), FACIT-F, HADS-A and -D and WPAI were seen in both arms at W104; percentages of pts with WPAI 7-point improvement from BL per domain were also similar (Table 1).

Work productivity loss	31/41 (75.6), (59.7; 87.6)		32/43 (74.4), (64.4; 83.8)			
Activity impairment	87/110 (79.1), (70.3; 86.3)		101/130 (77.7), (72.6; 83.4)			

The mRAS includes all patients who entered the LTE period (from W48 to W104).

^aData analysed as observed. ^bAbsolute value. ^cWPAI 7-point improvement is defined as a decrease of 7 points per domain.

Only patients with non-missing baseline value and at least one non-missing post-baseline value during the main treatment period are included in the analysis. N at baseline and at W104 is the number of subjects with a non-missing value for the parameter at the specified time point. N for change from baseline is the number of subjects with non-missing values at both baseline and W104 time point.

BL, baseline; CI, confidence interval; EQ-5D-5L, EuroQoL 5-Dimension 5-Level; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HADS-A (-D), Hospital Anxiety and Depression Scale – Anxiety subscale (- Depression subscale); HRQoL, Health-Related Quality of Life; IBDQ, Inflammatory Bowel Disease Questionnaire; LTE, long-term extension; mRAS, modified randomized analysis set; SoC, standard of care; T2T, treat to target; VAS, visual analogue scale; W, week; WPAI, Work Productivity and Activity Impairment.

Table 1. Changes from BL in HRQoL and WPAI measures at W104 (mRAS)

At W104, pts on average lost 2.2 and 2.3 fewer days from work due to CD vs BL in T2T and SoC arms, respectively. At W104, 60.9% and 68.7% in T2T and SoC arms were in employment vs 61.6% and 63.4% at BL, respectively.

Conclusion: STARDUST LTE is the first UST efficacy study to use an algorithm-driven dose adjustment. Over 80% of pts responding to induction and receiving maintenance treatment with UST from both T2T and SoC arms achieved IBDQ response at the end of 2 years of follow-up.

Both treatment strategies improved HRQoL (including fatigue, depression and anxiety scales). Work productivity improvements and reduced time lost from work were maintained up to W104 in pts with CD.

Introduction: Vaccination is the most effective method to prevent and control the SARS-CoV-2 infection. Recommendations consider patients with inflammatory bowel disease (IBD), Crohn's disease (CD) and ulcerative colitis (UC), a high-priority population to COVID-19 vaccine administration. There were a lot of concerns about vaccination safety in the setting of biological and immunomodulatory drugs.

The purpose of this study was to present data on safety about anti-SARS-CoV-2 vaccination in a cohort of IBD patients. These are data of an ongoing multicenter study assessing effectiveness and safety of COVID-19

vaccines in patients with IBD treated with immunomodulatory or biological drugs (ESCAPE-IBD) sponsored by the Italian Group for the study of Inflammatory Bowel Disease (IG-IBD - ClinicalTrials.gov Identifier: NCT04769258).

Aims & Methods: Anti-SARS-CoV-2 vaccination was administrated to 809 IBD patients. Afterwards completed vaccination, telephone or in-person interviews were conducted from February to July 2021 by gastroenterologists from referral center to report local and/or systemic adverse events (AEs) related to vaccination. Data on medical history and treatment was collected from electronic health records. Of these 809, 346 patients were surveyed on the pandemic burden and the main reason for hesitancy in Covid-19 vaccination. Chi-square test was used to compare categorical variables. Logistic regression was used to assess the relationship between disease-related characteristics and the onset of AEs.

Results: 809 patients, 456 CD and 353 UC, regularly followed in IBD unit, were enrolled. All patients received a complete SARS-CoV-2 vaccination cycle. Most of them (68%) were in biological or immunomodulatory therapy. About 45% of patients had at least one side effect, following the first dose (10%), the second (15%) or both doses (20%). Local pain at site of injection (24%), fatigue (33%) and fever (30%) were the three most common AEs. Flares of the underlying IBD were not reported. The vast majority of AE were mild and lasted only a few days. No serious AEs were reported and no patient was hospitalized. Logistic regression analysis revealed that female gender ($p<0.001$), younger age ($p=0.001$), seroconversion ($p=0.002$) and comorbidity ($p<0.001$) were significantly associated with the occurrence of AEs.

Furthermore the survey showed that the pandemic did not affect IBD at all in 37.5%, and a lot in 9.2% of participants. The majority (95%) of patients welcomed the possibility of getting vaccinated; only 7% feared the vaccine's influence on the course of the IBD. The main concerns were the possibility of adverse effects (33%) and the failure to achieve immunity (17%), few for the type of vaccine (3%) and for the need to a further booster (6%). Almost all patients (99%) felt safer to have vaccinated at their IBD reference center.

Conclusion: The short-term vaccine reactions experienced in this cohort of IBD patients were mostly self-limiting, including local pain at the injection site, fatigue and fever. We found a high acceptance rate and a good safety profile of SARS-CoV-2 vaccination in our cohort.

Disclosure: Nothing to disclose.

Introduction: Limited data is available regarding long-term effectiveness of SARS-CoV-2 vaccines in patients with immune-mediated inflammatory diseases (IMIDs) on immunosuppressive therapy. Whether the persistence of vaccine-induced humoral immunity differs between IMID patients and the general public is currently unknown.

Aims & Methods: IMID patients on immunosuppressive medication and healthy controls were enrolled in the prospective, observational Nor-vaC study. Serum samples were collected at two time points following two dose SARS-CoV-2 vaccination (first assessment within 6–48 days and second within 49–123 days). Sera were analysed for antibodies binding the receptor-binding domain (RBD) of the SARS-CoV-2 Spike protein. Anti-RBD <200 BAU/ml were defined as low levels. The estimated percent reduction in anti-RBD standardised to 30 days was calculated and factors associated with reduction were identified in multivariable regression models.

The aims of the study were to compare the persistence of anti-Spike antibodies following two SARS-CoV-2 vaccine doses between IMID patients and healthy controls, and to identify predictors of antibody decline.

Results: A total of 1097 patients (190 Crohn's disease, 129 ulcerative colitis, 400 rheumatoid arthritis, 189 psoriatic arthritis, 189 spondyloarthritis) (median age 54 years [IQR 43–64]; 56% women) and 133 controls (age 45 years [35–56]; 83% women) provided blood samples within the defined intervals (median 19 days [IQR 15–24] and 97 days [86–105] after second vaccine dose). Of the patients, 464 used tumor necrosis factor inhibitor (TNFi) monotherapy, 259 TNFi + metabolite inhibitor(s), 212 methotrexate monotherapy, 42 interleukin inhibitors, 34 vedolizumab, 29 rituximab, and 23 janus kinase inhibitors. Antibody levels were significantly lower in patients compared to controls at both assessments, with median anti-RBD 1468 BAU/ml [IQR 500–5062] in patients and 5514 BAU/ml [2528–9580] in controls ($p<0.0001$) and 298 BAU/ml [IQR 79–500] in patients and 715 BAU/ml [28–2870] in controls ($p<0.0001$), at first and second assessment respectively. At the second assessment, anti-RBD antibody levels decreased below 200 BAU/ml in 452 (41%) patients and in 1 (0.8%) control ($p<0.0001$) (Table). The percentage change in anti-RBD levels were -86 % in patients and -77 % in controls ($p<0.0001$). In the multivariable regression analyses, patients had a greater decline in anti-RBD levels compared to controls β -3.7 (95% CI -6.0, -1.4) ($p<0.001$). Use of TNFi in mono- or combination therapy was associated with the greatest decline compared to controls, β -6.1 (95% CI -8.1, -4.1) and β -6.4 (-8.4, -4.2) respectively ($p<0.001$).

Conclusion: Within four months after the second vaccine dose, anti-Spike antibody levels declined considerably in both IMID patients and controls. Patients had lower antibody levels at the first assessment and a more

pronounced decline compared to controls, and were consequently more likely to have low antibody levels four months after the second vaccine dose. Our results support that IMID patients lose humoral protection and need additional vaccine doses sooner than healthy individuals.

Contact E-Mail Address: filizakyuz@hotmail.com

Introduction: Inflammatory Bowel Diseases (IBD) rate has increased over the years. Compared to those who started at an early age, the course of the disease and treatment response remain uncertain in this age group.

Aims & Methods: Aims: We aimed to evaluate the disease course, treatment response and prognosis of late and early-onset patients with IBD.

Material and Method: In this study, the files of 1060 patients diagnosed with IBD and followed for more than 6 months were retrospectively evaluated in last 5 years. Thirty-nine patients (3.6%) with late-onset (≥60 years) were included in the study. As the control group, 50 early-onset patients with similar demographic findings with the late-onset patient group were included.

Demographic features, treatment-related side effects and toxicities, mortality rates, complication development, disease activity, endoscopic and clinical remission were compared between the early and late-onset groups. SCCAI and CDAI scores were used for clinical remission. Endoscopic activity was evaluated by Mayo and SES-CD scores.

Results: The mean age of the patients at the time of diagnosis was 49.2±17.5 years, and 53 (59.6%) were male. The mean age of late-onset patients at diagnosis was 66.3±5.5 years, and the mean age of early-onset patients at diagnosis was 35.8±10.7 years. Twenty-five (64.1%) of 39 late-onset patients were UC, 14 (35.9%) CD; Of 50 early-onset patients, 28 (56.0%) were UC and 22 (44.0%) CD.

The mean follow-up time of the late-onset patients was 75.1±53.1 months, and the mean follow-up period of the early-onset patients was 103.9±38.5 months. Clinical (94% vs. 86.8%) and endoscopic remission rates (49% vs. 33.3%) and AZT toxicity (28% vs 20.5%) were similar in early and late-onset patients, respectively.

Mortality rate in late-onset IBD (33.3% vs. 2%, OR: 24.5, CI: 3-197.8; p=0.001) and complication rate in late-onset UC were higher (32% vs. 7.1%, OR: 6.1, CI: 1.1-32.3; p=0.024) than in the early-onset patients. Although the development of malignancy was higher in the late-onset patient group than in the early-onset patients, it was not statistically significant (15.4% vs. 6%, p>0.05).

Age of onset (years)	Crohn's Disease			Ulcerative Colitis		
	<60	≥60	p	<60	≥60	p
AZT toxicity, n (%)	6 (27.3)	3 (21.4)	0.506	8 (28.6)	5 (20)	0.345
Biologic side effect, n (%)	5 (22.7)	1 (7.1)	0.228	3 (10.7)	1 (4)	0.350
AZT use, n (%)	22 (100)	11 (78.6)	0.051	19 (67.9)	11 (44)	0.070
Complication, n (%)	11 (50)	3 (21.4)	0.085	2 (7.1)	8 (32)	0.024
Mortality, n (%)	0 (0)	3 (21.4)	0.051	1 (3.6)	10 (40)	0.001
Biologic use, n (%)	15 (68.2)	5 (35.7)	0.058	10 (35.7)	4 (16)	0.094
Intestinal malignancy, n (%)	0 (0)	1 (7.1)	0.389	0 (0)	1 (4)	0.472
Extraintestinal malignancy, n (%)	0 (0)	1 (7.1)	0.389	3 (10.7)	5 (20)	0.288

Table: Clinical features of two groups

Conclusion: Clinical course and drug toxicity were similar in both groups. The mortality rate is higher in late-onset patients. The rate of development of malignancy is higher in the late-onset age group. Therefore, malignancy follow-up is important in this patient group.

Disclosure: Nothing to disclose.

Contact E-Mail Address: colman.rj@gmail.com

Introduction: Post hoc analysis of the SONIC trial found superior efficacy of standard dosing infliximab (IFX) combined with azathioprine (combo) compared to IFX monotherapy (mono) in adults with active CD, with more favorable pharmacokinetics (PK) on combo treatment (1).

Currently, many paediatric centers are increasingly using mono IFX with proactive therapeutic drug monitoring (pTDM) to minimise toxicity risks associated with thiopurine use.

The aim of this study was to evaluate whether combo has PK benefits over pTDM mono IFX, comparing drug exposure expressed as area under concentration curve (AUC), trough concentrations (TL) and IFX clearance (CL) between combo and pTDM mono IFX treated patients.

Aims & Methods: This PK analysis included CD patients who had drug concentrations measured as part of two prospective studies. Combo patients received labeled IFX (5mg/kg at 0, 2 and 6 wks followed by every 8 wks) with immunomodulator (IMM) in the TISKids study (2). In contrast, the mono patients received IFX in the observational REFINE study where pTDM was standard of care (3).

Inclusion criteria for the PK analysis were a weighted Paediatric CD Activity Index (wPCDAI) >40, age 3-17 years and body weight (BW) >10kg at baseline. Combo TL (Sanquin, ELISA) and mono TL (LabCorp, ECLIA) were assessed at week 6, 14 and 22 at trough (dose 3, 4 and 5). ECLIA is a drug-tolerant assay for antibodies to IFX (ATI) detection while the Sanquin ELISA is drug-sensitive (ATI was tested if IFX <3 µg/mL). A population PK model was built using a combined dataset from both cohorts with non-linear mixed effects modeling software using stepwise covariate modeling (objective function value >10.83, $P < 0.001$). IFX CL, AUC, TL and ATI were compared between the two groups using Wilcoxon Rank tests.

Results: The combined cohort consisted of 80 patients (64% combo), 52.5% female, median age 14 (IQR 11-16). The PK analysis included 264 TL and 92 peak concentrations. At baseline, the mono group had a higher wPCDAI 70 (62.5-80) vs 59 (47.5-70; $P < 0.01$), more prednisone use (79% vs 4%, $P < 0.01$) and lower serum albumin 2.9 g/dl (2.5-3.3) vs 3.7 (3.3-4.0; $P < 0.01$). IFX starting dose was 6.2mg/kg (5.3-7.8) vs 5.1 (5.0-5.3; $P < 0.01$) in mono vs combo.

A 2-compartment PK model with a negative correlation between albumin and CL and positive correlations between BW, erythrocyte sedimentation rate (ESR) and CL as well as BW and V1 adequately described the observed concentration data. For a patient with BW 65 kg, average CL and central volume of distribution (V1) were 0.39 L/d and 5.5 L, with corresponding interpatient variability of 31% and 28%. The use of IMM did not explain the interpatient variability in CL.

Moreover, there was no difference in median combo CL 0.29L/d (0.23-0.35) vs 0.30(0.23-0.40) mono CL ($P = 0.45$). There was also no significant difference between induction exposure ($AUC_{infusion1-4}$) 75,876µg*h/ml (60,719-96,168) combo vs 75,518(62,521-96,520; $P = 0.81$) mono, infusion-4 TL

4.4µg/ml (2.3-7.7) vs 4.7(2.4-8.5; $P = 0.77$) and infusion-5 TL 5.6µg/ml (3.2-8.8) vs 4.8(1.8-9.6; $P = 0.41$). While not a PK covariate of CL, 1 mono patient discontinued IFX due to ATI. No combo patients had ATI detected. There was higher CL during steroid use (most stopped by infusion-3), but there were no differences in CL or TLs at infusion-4 or 5 by steroid exposure. There was no difference in change of wPCDAI over time.

Conclusion: This study suggests that there are no PK differences (TL and CL) between mono- and combo therapy in newly IFX started paediatric CD patients, though steroids were initially used during IFX induction without IMM. As clinical outcomes and ATI were more difficult to compare due to heterogeneous study designs, head-to-head clinical trials of early optimised dosing vs combo therapy are needed to further assess efficacy.

Introduction: Acute severe ulcerative colitis (ASUC) is a life-threatening condition that requires immediate hospitalization. The early identification of patients who are unlikely to benefit from intravenous corticosteroids (IVS) therapy is one of the main concerns in the management of ASUC.

Aims & Methods: This study aimed to determine early predictors of failure to corticosteroids in patients with ASUC. We performed a retrospective analysis of 121 patients admitted with ASUC to a single gastroenterology centre (Hospital of Lithuanian University of Health Sciences Kaunas Clinics) during 2010-2020. ASUC was defined by the Truelove & Witts criteria. Patients' demographic and clinical data on the disease and the results of laboratory (lowest and highest) and instrumental examinations were collected. Albumin and C-reactive protein (CRP) levels were recorded at baseline, on the 3rd day of hospitalization, and on the 3rd day after IVS initiation.

Results: 119 patients initially received IVS; 2 patients underwent emergency colectomy on the first day. Sixty-four (53%) were females, with a median age of 33 (IQR 27-49) years. 70 (59%) patients were successfully treated with IVS, while 49 (41%) fail to respond to steroid therapy: 40 (34%) patients received second-line rescue therapy (26 with cyclosporine, 14 with infliximab), 15 (12%) patients underwent surgery during hospitalization, while colectomy rate increased to 16% at follow-up (median duration of 47 (23-88) months). 30 day-mortality rate was 1.6%.

The presence of cytomegalovirus (CMV) infection was associated with an increased risk of steroid resistance: CMV DNR in plasma was detected in 13 (27%) patients in steroid-resistant group vs. 7 (10%) in steroid-responsive group ($p = 0.018$).

Comparing these two groups, other factors predicting steroid resistance were newly diagnosed ulcerative colitis (less than a year ago, $p = 0.024$), the presence of high endoscopic activity (Mayo 3, $p = 0.003$), the use of prednisolone prior to admission ($p = 0.004$) and previous treatment with biological agents ($p = 0.017$).

Other factors, such as the presence of *Clostridium difficile* infection, previous treatment with azathioprine did not differ significantly between groups. Comparing the laboratory findings, the strongest predictor of corticosteroids responsiveness was the CRP/albumin ratio at day 3 after IVS initiation (median value was 0.52 (0.19-0.92) in steroid-responsive group vs. 1.26 (0.61-2.98) in steroid-resistant group, $p<0.001$).

Also, the CRP/albumin ratio differed significantly between groups already at baseline ($p=0.031$), while day 1 CRP or albumin alone were relatively poor markers ($p=0.073$ and $p=0.081$, respectively).

Conclusion: High CRP/albumin ratio at day 3 after steroid initiation may be a good prognostic criterium for identifying patients who may not respond to steroid therapy in hospital. Previous use of prednisolone or biologic therapy, cytomegalovirus infection, newly diagnosed ulcerative colitis, and high endoscopic activity also associated with non-responsiveness to steroids in ASUC.

Disclosure: Nothing to disclose.

Introduction: Biologic therapy resulted in a significant positive impact on the management of inflammatory bowel disease (IBD) however data on the efficacy and side effects of these therapies in the elderly is scant.

Aims & Methods: To evaluate retrospectively the drug sustainability, effectiveness, and safety of the biologic therapies in the elderly IBD population. Consecutive elderly (≥ 60 years old) IBD patients, treated with biologics (infliximab [IFX], adalimumab [ADA], vedolizumab [VDZ], ustekinumab [UST]) followed at the McGill University Inflammatory Bowel Diseases Center were included between January 2000 and 2020.

Efficacy was measured by clinical scores at 3, 6-9 and 12-18 months after initiation of the biologic therapy. Patients completing induction therapy were included. Adverse events (AE) or serious adverse events (SAE) were collected during and within three months of stopping of the biologic therapy.

Results: We identified a total of 147 elderly patients with IBD treated with biologics during the study period, including 109 with Crohn's disease (CD) and 38 with ulcerative colitis (UC). Patients received the following biologics: IFX (28.5%), ADAL (38.7%), VDZ (15.6%), UST (17%). The mean duration of biologic treatment was 157.5 (SD= 148) weeks. Parallel steroid therapy was given in 34% at baseline, 19% at 3 months, 16.3% at 6-9 months and 6.5% at 12-18 months.

The remission rates at 3, 6-9 and 12-18 month were not significantly different among biological therapies. Kaplan-Meier analysis did not show statistical difference for drug sustainability ($p=0.195$), time to adverse event

($p=0.158$) or infection rates ($p=0.973$) between the four biologics studied. The most common AEs that led to drug discontinuation were loss of response, infusion/injection reaction and infection.

Conclusion: Current biologics were not different regarding drug sustainability, effectiveness, and safety in the elderly IBD population. Therefore, we are not able to suggest a preferred sequencing order among biologics.

Disclosure: Nothing to disclose.

Introduction: Thiopurines (azathioprine [AZA], 6-mercaptopurine [MP]) and other immunomodulators (IM) are used in the treatment of ulcerative colitis (UC). Filgotinib (FIL) is a once-daily, oral, Janus kinase 1 preferential inhibitor approved in Europe and Japan for the treatment of UC.

The efficacy and safety of FIL in adults (18-75 years) with moderately to severely active UC was evaluated in the phase 2b/3 randomized, double-blind, placebo (PBO)-controlled SELECTION study (NCT02914522).¹

Aims & Methods: This *post hoc* analysis aimed to assess the impact of protocol-accepted concomitant thiopurine use on the efficacy and safety of FIL treatment in SELECTION. Patients, including those already receiving IM, were randomized (2:2:1) in two cohorts (A: biologic-naïve; B: biologic-experienced) to receive FIL 200 mg (n=507), FIL 100 mg (n=562) or PBO (n=279) for 11 weeks (induction).

At week 10, patients achieving clinical remission (Mayo endoscopic subscore ≤ 1 , rectal bleed [RB] subscore 0 and stool frequency subscore ≤ 1) or Mayo Clinic Score (MCS) response (≥ 3 -point and 30% reduction in MCS from baseline with a ≥ 1 -point decrease in RB subscore or an absolute RB subscore of ≤ 1) to FIL (n=664) were re-randomized to continue assigned FIL or PBO for 47 weeks (maintenance). IM dose had to be stable until week 10; no IM dosing guidance was given for maintenance.

We assessed efficacy and safety data at weeks 10 and 58 in patients with (+IM, includes AZA [81.8%], MP [10.8%] or methotrexate [7.4%]; n=352) or without (-IM; n=996) concomitant IM.

Results: At week 10, clinical remission was achieved by a similar proportion of patients treated with FIL 200 mg with or without concomitant IM in both cohorts A (+IM, 26.0% [non-stratified risk difference vs PBO (RD), 6.5% (95% CI: -11.2-24.2)]; -IM, 26.2% [RD, 12.6% (95% CI: 2.3-22.9)]) and B (+IM, 11.3% [RD, 1.9% (95% CI: -13.3-17.1)]; -IM, 11.5% [RD, 8.8% (95% CI: 2.7-14.8)]).

Proportion of patients achieving MCS response at week 10 was also similar across these subgroups in both cohort A (+IM, 65.8% [RD, 14.5% (95% CI: -6.1–35.2)]; -IM, 66.9% [RD, 22.1% (95% CI: 9.1–35.1)]) and B (+IM, 61.3% [RD, 39.4% (95% CI: 18.3–60.6)]; -IM, 50.5% [RD, 34.1% (95% CI: 23.6–44.6)]).

At week 58, clinical remission rates for patients receiving FIL 200 mg were similar in patients with or without concomitant IM (+IM, 39.6% [RD, 28.5% (95% CI: 8.0–49.0)]; -IM, 36.3% [RD, 25.0% (95% CI: 13.3–36.8)]). The proportion of patients achieving MCS response at week 58 with FIL 200 mg was also similar across these subgroups (+IM, 62.3% [RD, 21.5% (95% CI: -3.9–47.0)]; -IM, 68.5% [38.9% (95% CI: 24.9–53.0)]).

Over 58 weeks, the proportion of patients receiving FIL 200 mg who experienced adverse events was similar with or without concomitant IM (Table). There were two deaths in patients receiving FIL 200 mg, one each in the +IM and -IM groups; neither was considered related to treatment.

Induction	FIL 200 mg				FIL 100 mg				PBO	
Maintenance	FIL 200 mg		PBO		FIL 100 mg		PBO		PBO	
AEs, n (%)	+IM (n=57)	-IM (n=145)	+IM (n=28)	-IM (n=71)	+IM (n=44)	-IM (n=135)	+IM (n=25)	-IM (n=66)	+IM (n=30)	-IM (n=63)

Introduction: Up to 50% of patients with Inflammatory Bowel Disease (IBD) experience at least one extraintestinal manifestation during their life among whom musculoskeletal manifestations (arthralgia and arthritis) are the most common

Aims & Methods: This study aims to explore the role of synovial histological assessment in the therapeutic management of IBD patients with clinical signs of peripheral articular involvement. A retrospective study enrolling consecutive IBD patients receiving TNF α inhibitor, with concomitant joint involvement was performed from April 2015 to October 2020. At baseline, each patient underwent synovial-tissue (ST) biopsy for the semi-quantitative assessment of synovitis degree through H&E-based Krenn score (KSS) by trained pathologist, blinded to clinical characteristics. Clinical IBD activity was evaluated with Harvey Bradshaw Index for Crohn's disease (CD), and Partial Mayo Score for Ulcerative colitis (UC).

Based on ST findings, 4 different therapeutic interventions were done:

1. Addition of a conventional disease modifying antirheumatic drug (DMARD);
2. Switch to another anti-TNF α ;
3. Swap to other biological class or,
4. Addition of a second biological drug. Patients were followed in an out-patients clinical setting to record treatment response within 12 months.

Results: 46 IBD patients (31 CD; 15 UC) with median age of 46 years [IQR 35-53 years] and a median of disease duration of 8 years [IQR 4-16 years] were included. At enrollment all patients showed clinical signs of peripheral arthritis.

Overall, 31 patients (67%) had at least histologically proven low-grade synovitis (J_h+), defined as a KSS ≥ 2 . IBD patients were stratified based on baseline ST (J_h+ / J_h-) and IBD activity (B+/B-) as follows: B- J_h+ (22 patients), B+ J_h+ (9 patients) and B- J_h- (15 patients) respectively. The rate of B- J_h+ patients under anti-TNF α and paradoxical arthritis was 82%.

Considering the whole cohort, 12(54%) IBD patients added a DMARD among whom 33% achieved joint remission at 12 months while one patient swapped to other biological class, resulting in joint remission.

In the B+ J_h+ group, 4(44%) patients maintained the baseline therapy, resulting in no joint remission while one patient added a second biological drug, achieving joint remission. In the B- J_h- group, 7(46%) patients added a cDMARD of whom 39% achieved articular remission; conversely, 4 (27%) patients did not modify the baseline therapy of whom 75% achieved joint remission. Finally, the persistence on the therapeutic strategy was 60% at the median follow-up of 42.5 months (IQR 23.5-57.2).

Conclusion: The semiquantitative evaluation of synovial inflammation is a useful tool which might help physicians to better address therapeutic intervention, especially for IBD patients with mild/remission bowel activity or paradoxically developed arthritis

Disclosure: Nothing to disclose.

THE IMPACT OF SARS-COV-2 PANDEMIC IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW OF CLINICAL DATA

K. Shaban¹, M. Mohamed²

¹Royal Blackburn, Blackburn, United Kingdom, ²Royal Liverpool, Gastroenterology, Liverpool, United Kingdom

Contact E-Mail Address: dr.mohamedab93@gmail.com

Introduction: Coronavirus disease 2019 (COVID-19) and its consequences on individuals with inflammatory bowel diseases (IBD) are not yet fully understood despite the fact that evidence on this topic are rapidly evolving.

Aims & Methods: This comprehensive study of clinical data aims to enhance the gastroenterologists' ability to manage inflammatory bowel disease during these Covid-19 pandemic dominated times.

Until November 2021, a thorough search of PubMed and Embase for published data served as the primary source for the examined research, which was solely composed of English-language sources. Additionally, websites

of gastroenterology societies and organizations dedicated to inflammatory bowel disease (IBD) were searched for consensus statements and recommendations for patients and clinicians (IBD).

The information sources, the search strategy, and the eligibility criteria of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statements were followed

Results: There are 1560 publications on this subject, including 30 randomized controlled trials, including 64,259 patients with inflammatory bowel disease (IBD). There are twenty-four studies (n = 51,920) that examined the effect of COVID 19 on inflammatory bowel disease (IBD) management. Crohn's disease affected 52.9% of patients, ulcerative colitis affected 42.0%, and indeterminate colitis affected 5.1%.

These trials showed that the use of corticosteroids, azathioprine, or mesalamine was related to adverse outcomes, but the use of anti-TNFs was linked to improved outcomes.

Seven randomized controlled trials evaluated the safety and efficacy of the COVID-19 vaccine in inflammatory bowel disease (IBD) patients and found that vaccination was extremely effective, with a seroconversion rate of 96.49% and no significant increase in adverse outcomes when compared to the general population.

Conclusion: Patients with inflammatory bowel disease (IBD) are at an increased risk of severe COVID-19 infection. There is a substantial influence on the management of inflammatory bowel disease (IBD) patients during the pandemic, as certain IBD drugs have been connected with a worsening of outcomes. Although the COVID vaccine has been shown to be effective, additional research is needed to determine the long-term consequences of COVID 19 infection and vaccination.

A PILOT FEASIBILITY STUDY OF A NOVEL WHOLE-FOOD, SULPHIDE-REDUCING (5-SURE) DIET STRATEGY FOR THE TREATMENT OF SYMPTOMS IN PATIENTS WITH AN ULCERATIVE-COLITIS POUCH

Z. Ardalan¹, C.K. Yao², M. Sparrow¹, P.R. Gibson³

¹Alfred Health, Gastroenterology, Melbourne, Australia,

Contact E-Mail Address: chu.yao@monash.edu

Introduction: There is an unmet need for dietary therapies that target physiological and pathogenic mechanisms underlying symptoms of a poorly functioning ileo-anal pouch and in pouchitis to improve clinical outcomes in these patients. A novel whole-food diet was recently developed called 'the 5-strategies to a SULphide REDucing' (the 5-SURE) diet that theoretically reduces pouch water content and corrects imbalances in pouch microbial metabolite production, namely less toxic hydrogen sulphide (H₂S), more carbohydrate fermentation^{1,2}. Tolerability of this diet requires assessment.

Aims & Methods: This pilot study aimed to assess tolerability of a 5-SURE diet in patients with an ileoanal pouch and its effects on pouch microbial metabolic activities and clinical indices. Patients with an ulcerative colitis (UC) pouch on stable pouch therapies received dietary counselling to (i) increase oligosaccharide intake whilst (ii) restricting osmotically-active carbohydrates, (iii) reduce total & (iv) animal protein and (v) minimise sulphate/sulphite preservatives over 5 weeks. Tolerability and acceptability were assessed using a 100mm visual analogue scale and a Diet Satisfaction Questionnaire³ at the end of 5 weeks. Changes in faecal metabolites (faecal SCFA, branched-chain fatty acids (BCFA), pH and ammonia), clinical indices (clinical pouch disease activity index and pouch obstructed defecation symptom scores) including faecal calprotectin were also measured at baseline and post-intervention. Faecal BCFA was used as a proxy for faecal H₂S in the absence of reliable measurements.

Results: Of the 12 patients (6 men, mean age 55 years) enrolled, one with a known anastomotic stricture withdrew following partial bowel obstruction. Median tolerability scores were high (78[IQR:21-93]), with 82% patients reporting excellent tolerability and high diet satisfaction scores (mean±SD:38±4/total score 50) at week 5. Overall adherence was excellent in 8/11 (73%). The 5-SURE diet did not alter faecal SCFA, pH or ammonia (Table 1) but successfully decreased faecal BCFA excretion by 14% (p=0.03). Faecal BCFA:SCFA ratio fell by median [IQR] of 60[11-80%] (p=0.02), but these were no longer significant after correction for multiple comparisons. Moreover, improvements in clinical PDAI scores were observed in 8/11 (73%) after 5 weeks, with trends for improved pouch obstructed defecation scores (p=0.03) and pouch frequency (p=0.09). No changes in faecal calprotectin were detected in the overall group at week 5 (p=0.72) but there was a tendency for calprotectin to fall (p=0.07) when patients with high baseline calprotectin (>1500µg/g) were excluded.

	Baseline	Week 5	p-value
Faecal short-chain fatty acid, µmol/g	106.8 ± 23.1	105.6 ± 29.2	0.32
Faecal branched-chain fatty acids, µmol/g	0.56 ± 0.53	0.33 ± 0.30	0.03
Faecal ammonia, µmol/g	22.7 ± 8.6	19.5 ± 8.5	0.12
Faecal pH	6.0 ± 0.3	6.1 ± 0.3	0.25
Clinical indices			
Clinical PDAI scores	3 ± 1	2 ± 1	0.06
Pouch emptying frequency, n	7 [5-8]	5 [5-6]	0.09
Pouch obstructed defecation score	6 [4-8]	4 [3-4]	0.04
Faecal calprotectin, µg/g	292 [176-527]	205 [148-310]	0.72

Values are shown as mean± SD or median [IQR]

Table 1. Changes in pouch microbial fermentation markers and clinical indices following 5 weeks of a 5-SURE diet.

Conclusion: The novel 5-SURE diet was highly tolerated and acceptable, with the potential to promote a more favourable microbial metabolite profile within the pouch. Signals for symptom improvement and inflammation were detected in a proportion of UC-pouch patients but larger, randomised controlled studies are needed.

FROM INTRAVENOUS TO SUBCUTANEOUS INFLIXIMAB – A TRANSITION LEADING TO CHANGES?

M.J. Temido¹, A.E.P. Silva¹, M. João², R. Pimentel¹, C. Correia¹, S. Lopes¹, S. Mendes¹, P. Narra Figueiredo¹, F. Silva Portela¹

Introduction: A new subcutaneous (sc) formulation of Infliximab has recently been approved. The transition from intravenous (iv) to sc infliximab can reduce costs and improve patients' convenience, but prospective data about pharmacokinetics and immunogenicity is limited. This formulation may lead to more stable plasmatic levels of IFX and, as a consequence, to less formation of anti-drug antibodies.

Aims & Methods: We aim to compare symptomatic and analytic efficacy and tolerability of sc IFX and to assess whether the formulation results in higher plasmatic levels of IFX (IFXpl). A prospective single center cohort study was performed. Patients with either CD or UC, aged 18 years or older, stable clinically, undergoing maintenance therapy with iv IFX (5mg/kg every 7-8 weeks) for more than 6 months were switched.

The administrations of sc IFX were 120mg every 2 weeks. A clinical and analytical evaluation was performed at day 0 (d0) and at weeks 2 (w2), 8 (w8) and 16 (w16) after the initiation. IFXpl and anti-drug antibodies were also measured at these time points.

Results: 36 patients (24 with CD and 12 with UC) were included. 50% of patients were concomitantly taking azathioprine (aza). All the patients maintained clinical remission (CR). C-reactive protein and FCP maintained approximately the same values in d0, w2, w8 and w16. Median IFXpl at d0, w2, w8 and w16 were respectively 4.9±3.2, 9.7±3.8, 20±4.8 and 19.76±8ug/mL. A statistically significant difference between IFXpl at different time points was found (d0 Vs w2 and w2 Vs w8). Aza led to a statistically significant difference in the IFXpl on d0, but not on w2, w8 or w16. Greater body weight was statistically associated with lower IFXpl on w2 and w16, but not on d0 or w16, both in the univariate and in the multivariate analysis. No patient developed anti-drug antibodies. No severe drug adverse effects were documented. Three patients developed infusion site reactions. Two patients developed arthralgias of undetermined significance. One patient returned to iv Infliximab for personal choice.

Conclusion: Transition from iv to sc showed no signs of loss of CR. Biological markers were similar before and after the transition. Aza influences iv IFXpl, but not sc ones. Body weight influences IFXpl. IFXpl are w2 are still lower than expected considering the results at w8.

Introduction: Inflammatory digestive system diseases can have a severe effect on the physical and mental health of the patients. Moreover, psychosocial factors can modify the behaviour linked to disease and influence treatment.

Aims & Methods: The aim of our systematic review and meta-analysis is to evaluate the efficacy and safety of psychological interventions in patients suffering from inflammatory digestive system diseases. The systematic search was conducted in three major databases (MEDLINE, CENTRAL, EMBASE) for various psychological interventions applied for all digestive system diseases.

Only randomized controlled trials were eligible. Anxiety and depression were assessed right after the last intervention provided to the patients. Due to the differences in the questionnaires used, the Hedges' g method was used to calculate the pooled effect size with 95% confidence interval (CI). Subgroup analysis was conducted for diseases assessed by at least 3 studies. Our protocol was prospectively registered on PROSPERO (CRD42021282965).

Results: The systematic search yielded a total of 13212 articles, resulting in 60 eligible RCTs for the qualitative synthesis. 39 studies were conducted in patients with inflammatory bowel disease (IBD). Further studies included patients with gastroesophageal reflux disease, peptic ulcer, hepatitis, cirrhosis, pancreatitis and cystic fibrosis. Interventions included Cognitive Behavioral Therapy, Psychotherapy, Hypnosis, stress reduction, psychoeducation and psychological nursing.

Psychological interventions proved to have a medium to large effect on depressive symptoms measured at the end of the intervention ($g = -0.68$; CI: 1.11 to -0.25); $I^2 = 91\%$; CI: 89%-94%), while in the IBD subgroup a small to medium effect was observed (-0.40 ; CI: -0.78 to -0.02). Symptoms of anxiety were also significantly reduced; in overall a large effect was seen ($g = -0.86$; CI: -1.29 to -0.42), while in the IBD subgroup a small to medium effect was detected (-0.36 ; CI: -0.60 to -0.12).

Conclusion: Psychological interventions effectively reduce depressive symptoms and anxiety in inflammatory digestive system disease and are effective in IBD patients. Further studies are needed to assess the efficacy of certain psychological interventions in all gastroenterological inflammatory diseases for more detailed recommendations.

Disclosure: Nothing to disclose.

Contact E-Mail Address: vedo415@anaxomics.com

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are chronic immune-mediated bowel diseases (IBD), often treated with immunomodulators and anti-inflammatory antibody-based biological drugs. Among the spectrum of approved treatments is vedolizumab (VDZ), a gut-selective anti-lymphocyte trafficking (GSALT) humanised monoclonal antibody which binds $\alpha 4\beta 7$ integrin expressed on circulating lymphocytes, selectively preventing their migration into the gut mucosa and thus reducing inflammation.

As there is evidence suggesting that biologic drugs, and particularly VDZ, may be more effective in CD patients with colonic involvement vs. CD patients with ileal-only disease location, there is a need to understand the mechanisms underlying these differences.

To explore the potential impact of CD disease location on VDZ outcomes, we explored publicly available gene-expression data. The objective was to address the question whether disease location alters mucosal immune responses, and/or trafficking patterns in a way that could lead to a differential response to VDZ in different intestinal segments.

Aims & Methods: Patients' gene-expression data were collected from the publicly available dataset GSE16879, which includes sixty patients with active IBD, (19 with colonic CD and 18 with ileal CD), and a control group of 12 CD patients (6 with colonic involvement and 6 with ileal involvement) who underwent endoscopy for polyp screening.

Results: The analysis of publicly available gene-expression data has identified a potential impact of disease location on a set of key proteins involved in neutrophil, monocyte and eosinophil migration, as well as neutrophil chemoattraction. Specifically, genes such as ANXA1, VCAM1, ICAM1 and CCL24 show different expression patterns depending on the locations of disease. A lower constitutive expression of VCAM1, ICAM1, CCL24 adhesion and migration proteins coupled with higher expression of ANXA1, which have been observed to play a protective role in IBD, have been observed in colonic CD. Together, these results may suggest a higher efficacy of VDZ in CD in colonic segments vs. ileal locations.

Conclusion: Our results suggest a potential increased response to VDZ in the colon when compared to the ileum, likely due to gut regional-specific chemoattractant gene expression profiles.

CROHN'S DISEASE (CD): THE PREDICTIVE VALUE OF MONTREAL CLINICAL PATTERNS, AND BIOLOGICAL TREATMENT IN A LATIN AMERICAN IBD REFERENCE CENTER

A.M. Sambuelli¹, P. Tirado¹, S. Huernos², S.M. Negreira¹, A. Gil², M.J. Rohwain², S. Goncalves², I. Candel²

¹IBD Section - Bonorino Udaondo Gastroenterology Hospital, Gastroenterology, Buenos Aires, Argentina, ²Bonorino Udaondo Gastroenterology Hospital, IBD Section Gastroenterology, Buenos Aires, Argentina

Contact E-Mail Address: alicia.sambuelli@gmail.com

Introduction: CD is a potentially disabling condition, with a high rate of complications and surgical requirements. Biological treatments have revolutionized CD management, but their efficacy and predictive factors have been reported variable in different casuistic, influenced by genetic, phenotypic, and socioeconomic conditions, which should be locally analyzed worldwide.

Aims & Methods: To describe by a retrospective study in a Latin American IBD reference center, clinical features of CD casuistic, predictive Montreal patterns for surgical risk, and efficacy of biologics and immunosuppressants. Surgical risk of Montreal classification groups, as well as, biological and immunomodulator (IMM) treatment (thiopurines) in the prevention of first major surgery were estimated.

Clinical patterns were evaluated as predictive factors at the basal time (up to 90 days from the debut) in:

Age at diagnosis (A) A1:≤16yrs, A2:17-40, A3:>40,

Behavior (B): nonstricturing nonpenetrating (B1), stricturing (B2), penetrating (B3), perianal disease modifier (p),

Location (L): L1:ileal, L2: colonic, L3: ileocolonic, L4: upper G.I.

Incidence rates of surgery and preventive treatment efficacy were estimated by a Cox regression model.

Results: 598 CD pts (M 313, F 285) with mentioned available data, CD median duration 13.9 yr (IQR 7.1-21.2) were analyzed.

Montreal patterns A1: n 93 (15.6%), A2:n 335 (56.0%), A3:n 170 (28.4%), B1:n 523 (87.5%), B2:n 52 (8.7%), B3:n 23 (3.8%) L1:52 (8.7%),L2:n 368 (61.5%), L3:n 176 (29.4%), L4:iUGI: n 2 (0.33%) and L4 combined with L1, L2, L3: n 47 (7.9%), Perianal disease (p) n 286 (47.8%).

Major surgery was performed in 304/598 pts (50.8%). Globally, 264/598 patients (44.1%) received biologics in any time (45 only induction and 219 patients also maintenance), ≥ two biologics: 12.7%, Anti-TNFs > 90% (access reasons).

Before first surgery, biologics were indicated in 202 pts, 34 of them received only induction and 168 induction plus maintenance.

Kaplan Meier estimates: major surgery incidence rate: 5.1 per 100 person/ yrs., median survival without surgery: 14.2 yrs. Significant variables of Cox model for surgical risk were:

B1 HR 1 (reference),

B2 HR 3.03 (95%CI 2.14-4.29, p=0.000),

B3 HR 3.27 (95%CI 2.03-5.29, p=0.000),

L2 HR 1 (reference),

L1 HR 2.025 (95%CI 1.37-2.99, p=0.000),

L3 HR 2.51 (95%CI 1.95-3.23, p=0.000),

A1 HR 1 (reference),

A2 HR 1.48 (95%CI 1.05-2.10, p=0.027),

A3 HR 1.89 (95%CI 1.27-2.83, p=0.002),

Biologics (mainly anti-TNFs used by access reason): only induction HR 1.49 (95%CI 1.005-2.195, p=0.047), induction plus maintenance HR 0.388 (95% CI 0.27-0.55), p=0.000. Non-significant variables involved in the risk for surgery were: gender, perianal complication, and IMM treatment.

Conclusion: In our CD population, we found:

1. Montreal patterns associated with surgical risk (fistulizing and stricturing behaviors), ileal and ileocolonic locations, and A2, but also A3 (debut beyond 40 yrs) which is unusually described,
2. Biologics showed a reduction in surgical risk (as expected induction plus maintenance versus only induction).

Disclosure: No conflict of interest.

Introduction: Corticosteroids (CS) have been an important therapeutic milestone for treating inflammatory conditions such as inflammatory bowel diseases (IBD). While in some situations, CS use might be unavoidable, steroid excess poses the patient at a significant risk for irreversible side effects [1].

However, the proportion of IBD patients with steroid use in a real-world setting among different geographies and in particular in Germany that face steroid excess remain unclear.

We aim to evaluate the proportion of German IBD patients experiencing steroid use/dependency as well as risk-associated factors on patient and study site level.

Aims & Methods: IBD-DICE was a multicentre, international cross-sectional study to evaluate determinants and consequences of steroid excess in IBD patients. In Germany, a total of 384 IBD patients (53.6% CD, 45.8% UC, 0.5% IBD-U) with quiescent or active disease were consecutively enrolled at 15 IBD-experienced sites from Sep – Dec 2021.

Data on CS use (orally administered prednisolone and/or budesonide) were captured by a web-based steroid assessment tool (SAT) in addition to a patient questionnaire (PQ) to evaluate additionally the patient's perspective on steroids. SAT and PQ data were available for 359 IBD patients. Steroid dependency was defined as more than 1 steroid course within the last 12 months and/or no reduction of steroids within the last 3 months without recurrent disease activity.

Results: The majority of the 384 documented patients presented with quiescent (36.5%, n = 140/384) or mild (35.4%, n = 136/384) disease activity rather than moderate (23.4%, n = 90/384) or severe disease activity (4.7%, n = 18/384). Of all patients, 35.9% (n=138/384) received oral steroids (prednisolone/budesonide) over the past 12 months. CS use was higher in UC patients (43.2%, n=76/176) than in CD (29.1%, n=60/206; p = 0.004, Chi-square test) (2/2 IBD-U patients received CS).

Notably, 58.0% (n = 80/138) of all patients on CS had received more than 1 course of CS (prednisolone/budesonide) and/or could not taper CS within 3 months after CS initiation and were therefore deemed steroid-dependent (table 1).

In other words, 20.8% (n = 80/384) of all documented patients were steroid-dependent. Interestingly, when patients were asked for their CS use, 82.5% (n = 296/359) as opposed to the above mentioned 35.9% (reported by investigator in SAT) disclosed CS use over the past 12 months.

Parameter % (n)	IBD patients (n = 384) (documented via SAT by physician)
CS use (prednisolone/budesonide)	35.9 (138/384)
CS dependency	20.8 (80/384)

Table 1. Steroid use over the past 12 months in IBD patients of the German IBD-DICE cohort

Conclusion: We found that in our German cohort, steroid use as assessed by the physician occurred in 35.9% of all patients and steroid dependency in 58.0% of the documented IBD patients with CS, respectively. There might be a discordance between patient and physician reported CS use. These data suggest that routine monitoring of CS use might increase awareness for steroid burden in IBD patients.

Introduction: STRIDE II guidelines identify symptom relief as important short and intermediate treatment goals. The most burdensome symptoms reported by patients with Crohn's disease (CD) are abdominal pain (AP) and increased stool frequency (SF). Risankizumab (RZB) was shown to be well-tolerated and superior to placebo (PBO) for inducing and maintaining clinical remission and endoscopic response in patients with moderate-to-severe CD.^{1,2}

This post-hoc analysis examined improvements in the patient reported outcomes (PROs) of AP score (APS) and SF with RZB induction and maintenance dosing and their correlation with endoscopic outcomes.

Aims & Methods: PROs using pooled data from the ADVANCE/MOTIVATE induction studies¹ for the PBO and RZB 600 mg intravenous (IV) treatment groups, and data from the RZB withdrawal (PBO subcutaneous [SC]) and

BL = baseline; Endoscopic remission = SES-CD ≤4 and at least 2-point reduction from baseline; Ulcer-free endoscopy = SES-CD ulcerated surface subscore =0 in patients with subscore ≥1 at baseline; a)Intent-to-treat (ITT) population Includes randomized patients who (ADVANCE/MOTIVATE) received at least one dose of study drug during the 12-Week Induction Period, and had an SES-CD of ≥6 (≥4 for isolated ileal disease) or who (FORTIFY) received IV risankizumab for 12 weeks in the induction study and at least one dose of study drug in FORTIFY sub-study 1 and had an SES-CD of ≥6 (≥4 for isolated ileal disease) at baseline of induction. b)Calculations were based on non-responder imputation with no special data handling for missing data due to COVID-19 pandemic. 95% CI and p-value for adjusted response rate difference compared to PBO calculated according to the Cochran-Mantel-Haenszel test adjusted for strata.

P0437 Table.

360 mg RZB SC treatment groups from the FORTIFY maintenance study², were examined. AP and number of liquid or very soft stools were recorded in a daily diary; AP was rated as none (=0), mild (=1), moderate (=2), or severe (=3). AP remission (AP ≤1) and SF remission (SF ≤2.8) were assessed. Tetrachoric correlations, used to assess the statistical correlation between two dichotomous variables, were applied to measure the association between PROs and achievement of endoscopic remission and ulcer-free endoscopy (see Table footnotes for endpoint definitions) at Weeks 12 and 52.

Results: Significantly more patients receiving 600 mg RZB IV versus PBO reported improvements from baseline (BL) in SF and APS at Weeks 4, 8, and 12 (p-values <0.001). Of patients reporting AP ≥1 at Induction BL, significantly more patients receiving RZB treatment achieved APS =0 at Weeks 8 and 12 compared to PBO (p-values [p] ≤0.001). Similarly, of

patients reporting SF >2.8 at BL, significantly more patients receiving RZB treatment achieved SF ≤1 at Weeks 4, 8 and 12 compared to PBO (p-values ≤0.004). At Week 52 of maintenance, more patients achieved AP remission (p <0.05) and SF remission (p <0.01) with RZB 360 mg SC compared to RZB withdrawal (PBO SC). More patients also achieved complete resolution of symptoms (APS =0 [p =0.05], or SF ≤1 [p =0.006], or AP =0 and SF ≤1 [p =0.02]). AP remission at Week 12 was weakly correlated with endoscopic remission (r=0.19; p <0.001) and ulcer-free endoscopy (r=0.17; p =0.001) at Week 12. Similarly, weak/moderate correlations of SF remission with these endoscopic outcomes were observed at Week 12 (r=0.34 [p <0.001] and r=0.35 [p <0.001], respectively). At Week 52, moderate correlations were observed with endoscopic remission or ulcer-free endoscopy and AP remission (r=0.55 [p <0.001] and r=0.50 [p <0.001]) or SF remission (r=0.59 [p <0.001] and 0.48 [p <0.001]).

Conclusion: CD-related PROs improved with RZB induction therapy, and RZB maintenance dosing led to AP and SF remission. Symptom improvements and endoscopic outcomes were moderately correlated, underscoring the importance of an objective measure to assess disease activity.

P0438

COMPARATIVE ANALYSIS OF ORIGINATOR VERSUS BIOSIMILAR COUNTERPARTS WHEN TREATING ULCERATIVE COLITIS

M. Thoo¹, C. Ng¹, D. Baldock², P. Robinson², E. Baynton²

¹Ipsos, Kuala Lumpur, Malaysia, ²Ipsos, London, United Kingdom

Contact E-Mail Address: elizabeth.baynton@ipsos.com

Introduction: The aim of this study is to investigate originator and bio-similar (bsx) drug usage in ulcerative colitis (UC) patients, examine if and where differences exist, as well as examine any changes in prescribers' attitudes towards both product types.

Aims & Methods: A multi-centre online medical chart review study of patients with UC was conducted between Jan-Mar and Jul-Sep 2019, 20 and 21 among UK, FR, DE, IT & ES gastroenterologists practicing across hospital and private practices. Recruited from a large access panel, physicians were screened for duration of practice in their specialty and caseload. Respondents completed a 3 part survey; doctor demographics, perceptual questionnaire and patient record forms of their next 4 UC patients seen following receipt of the survey.

Results: The total number of sampled gastroenterologists recruited in this survey, plus the collective total of reported UC patients treated with advanced therapy (biologics/targeted oral therapies) are in Table 1.

Survey Year	2019	2021	2022
Sampled gastroenterologists	287	264	247
Reported UC advanced therapy patients	1637	1601	1566

Table 1. Physician and patient sample size

Reported UC patients treated with adalimumab and infliximab originator products declined over time (% patient share of reported sample - 2019: 41.1%, 2020: 24.6%, 2021: 21.5%) while those treated with bsx versions directionally increased (2019: 29.7%, 2020: 38.9%, 2021: 38.3%). This is in line with changes observed with stated physician access to biologic therapies when treating UC. Access to originator products among sampled gastroenterologists declined from 2019 to 2021 (% sampled physicians citing access - 2019: 96.3%, 2020: 90.5%, 2021: 87.5%), while access to bsx versions directionally increased, surpassing that of the originators in 2020 and 2021 (2019: 91.7%, 2020: 95.7%, 2021: 95.1%).

Disease remission rates among reported bsx treated UC patients increased over time (% patients - 2019: 63.2%, 2020: 67.8%, 2021: 71.0%) but decreased for those treated with originator products (2019: 77.9%, 2020: 75.9%, 2021: 74.1%). Reported bsx treated patients had higher Mayo

scores than originator treated patients in 2019 (Mean: bsx 4.0 vs originator 3.2, respectively; $p \leq 0.01$) but in 2020, Mayo scores of originator treated patients were greater than that of bsx treated patients (2020 Mean: bsx 3.6 vs originator 4.0, $p \leq 0.05$).

Reasons for choosing the originator product for treatment were also different to that of bsx treated patients; in the reported bsx treated cohort, a higher proportion of gastroenterologists cited 'inhibited disease progression' as a reason for choosing a bsx product vs patients reported in the originator treated patient cohort (% patients- bsx 2019: 41.8%, 2020: 41.1%, 2021: 39.8%; originator-2019: 42.8%, 2020: 34.4%, 2021: 32.9%; respectively). 'To induce mucosal healing' was also selected more frequently as a reason for choosing a bsx product vs the originator (bsx vs originator- 2019: 55.8% vs 43.4%; 2020: 46.7% vs 37.6%, 2021: 50% vs 35.4%, respectively; $p \leq 0.01$).

Conclusion: From the sample surveyed, there is evidence of a change in bsx and originator prescribing when treating UC; gastroenterologists cite increasing access to bsx products, which may go some way in influencing levels of familiarity. There is evidence to suggest that gastroenterologists are more likely to prescribe bsx products for efficacy reasons, such as inducing remission and impacting clinical disease scores used to monitor patients' disease e.g., Mayo score. Further investigation using comparator cohort is warranted.

Disclosure: Nothing to disclose.

P0439

USTEKINUMAB PERSISTENCE IN THE TREATMENT OF CROHN'S DISEASE, FISTULIZING CROHN'S DISEASE AND ULCERATIVE COLITIS

B. Bressler¹, J. Jones², T. S.H. In³, T. Lan⁴, C. Iconaru⁴,

J.K. Marshall⁵

¹University of British Columbia, Department of Medicine, Vancouver, Canada, ²Dalhousie University, Department of Medicine, Halifax, Canada, ³Janssen Inc, Toronto, Canada, ⁴IQVIA Solutions Canada Inc., Kirkland, Canada, ⁵McMaster University, Department of Medicine and Farncombe Family Digestive Health Research Institute, Hamilton, Canada

Contact E-Mail Address: marshallj@mcmaster.ca

Introduction: Data on the real-world effectiveness of ustekinumab (UST) in the treatment of inflammatory bowel disease (IBD), including Crohn's disease (CD), fistulizing Crohn's disease (FCD) and ulcerative colitis (UC), are limited. Persistence on therapy is a measure of real-world treatment success. Previous studies of persistence of UST treatment in patients with IBD have been limited by relatively small sample size or relatively short follow-up.

Aims & Methods: The aim of this study was to estimate the persistence of UST treatment among adult patients with CD, FCD or UC, and to identify factors that impact treatment persistence.

Using data from a national patient support program that captures patients treated with UST in Canada, a retrospective study was conducted on adult patients with CD or FCD who initiated UST treatment between January 1, 2017 and July 31, 2021, and adult patients with UC who initiated UST treatment between February 1, 2020 and July 31, 2021. Treatment persistence, defined as time from a patient's first recorded pharmacy fill for UST to discontinuation (gap between two pharmacy fills > 20 weeks) or censoring, was described using the Kaplan-Meier (KM) method. The impact of patient characteristics at index (age group, sex, region, year of treatment initiation, and biologic-naïve status) on persistence was explored by stratified analyses and multivariable Cox proportional hazards models.

Results: 8,724 patients with CD (mean age 46.8 years; 55.2% female; 36.0% biologic-naïve), 276 patients with FCD (mean age 45.4 years; 55.4% female; 20.7% biologic-naïve), and 1,291 patients with UC (mean age 45.9

years; 47.1% female; 24.9% biologic-naïve) were included. Persistence rates for patients with CD were 82.9%, 71.4%, 64.1%, and 59.7% at 1, 2, 3, and 4 years, respectively. Among patients with UC, 76.5% were persistent at 1 year, and 69.5% at 1.5 years. Stratified by prior IBD-indicated biologic experience, biologic-naïve patients had higher persistence than biologic-experienced patients (Table). This difference was significant among patients with CD based on the multivariable Cox regression model (hazard ratio: 0.72; confidence interval: 0.65-0.79).

	Total patients, n	1 year, % (n at risk)	1.5 year, % (n at risk)	2 years, % (n at risk)	3 years, % (n at risk)	4 years, % (n at risk)
Patients with CD	8,724	82.9% (5,476)	76.4% (4,190)	71.4% (2,971)	64.1% (1,248)	59.7% (504)
Biologic-naïve	3,143	87.2% (1,869)	80.6% (1,399)	76.7% (968)	70.6% (376)	66.0% (159)
Biologic-experienced	5,581	80.8% (3,607)	74.2% (2,791)	68.8% (2,003)	61.1% (872)	56.7% (345)
Patients with FCD	276	84.1% (178)	76.8% (133)	70.9% (95)	64.9% (39)	63.1% (14)
Biologic-naïve	57	87.3% (33)	84.1% (25)	76.5% (16)	76.5% (8)	76.5% (6)
Biologic-experienced	219	83.4% (145)	75.1% (108)	69.7% (79)	62.6% (31)	60.3% (8)
Patients with UC	1,291	76.5% (452)	69.5% (125)	-	-	-
Biologic-naïve	322	81.2% (93)	73.1% (30)	-	-	-
Biologic-experienced	969	75.3% (359)	68.5% (95)	-	-	-

Table. KM-derived ustekinumab persistence, by indication and biologic-naïve status

Conclusion: This study reports the long-term real-world persistence of UST in a large population of patients with IBD. Over half of patients with CD were estimated to remain on UST therapy after 4 years of treatment, and biologic-naïve patients with CD was shown to have significantly better persistence than biologic-experienced patients.

Introduction: Upadacitinib (UPA) is an oral selective and reversible Janus kinase inhibitor. UPA 45 mg once daily (QD) has demonstrated superior efficacy to placebo and a favorable safety profile following an 8-week induction therapy in patients with moderately to severely active ulcerative colitis (UC) in two double-blinded, randomized induction trials U-ACHIEVE Induction (NCT02819635) and U-ACCOMPLISH (NCT03653026).^{1,2}

Aims & Methods: Patients who did not achieve a clinical response (Adapted Mayo score decrease of ≥ 2 points and $\geq 30\%$ from baseline, plus a ≥ 1 point decrease in rectal bleeding score [RBS] or absolute RBS ≤ 1) following an initial 8 weeks' UPA 45 mg QD treatment in the induction trials were eligible to receive an additional 8-week, open-label extended treatment with UPA 45 mg QD. Patients with a clinical response following completion of the extended induction (Week 16) were re-randomized 1:1 to UPA 15 mg QD or UPA 30 mg QD in the U-ACHIEVE Maintenance trial (NCT02819635).

This analysis evaluated the efficacy and safety of UPA following extended induction treatment (UPA 45 mg QD for 16 weeks) and subsequent maintenance treatment (UPA 15 mg QD or UPA 30 mg QD for 52 weeks).

Results: Of the patients who received UPA 45 mg QD in the induction trials, 125 did not achieve a clinical response at 8 weeks and received a further 8 weeks' induction treatment. At Week 16, 73/125 (58.4%) subsequently responded and were re-randomized to maintenance UPA 15 mg QD or UPA 30 mg QD. Among 16-week responders who entered the maintenance trial, a greater proportion of patients who received UPA 30 mg QD vs UPA 15 mg QD achieved the primary endpoint of clinical remission at 52 weeks (43.6% vs 26.5%, respectively), and the secondary endpoints of clinical response (78.1% vs 49.1%, respectively) and endoscopic improvement (51.3% vs 34.3%, respectively) at 52 weeks (Table).

A similar pattern was seen across all clinical, endoscopic, and histologic endpoints (Table). At Week 52, the proportions of patients with serious adverse events (AEs) were 2.9% with UPA 15 mg QD and 10.0% with UPA 30 mg QD. Selected AEs of special interest with UPA 15 mg QD and UPA 30 mg QD included serious infection (2.9% vs 5.0% of patients, respectively), herpes zoster (0% vs 5.0%, respectively), adjudicated major adverse cardiovascular events (0% vs 2.5%, respectively), and non-melanoma skin cancer (NMSC; 0% vs 2.5%, respectively). No adjudicated venous thromboembolic events or cases of malignancy excluding NMSC were reported with either UPA dose.

Conclusion: Extended induction treatment for an additional 8 weeks with UPA 45 mg QD induced a response in over half of patients with UC who did not achieve a response after 8 weeks. The benefit of maintenance therapy in delayed responders was demonstrated with both UPA doses, although UPA 30 mg QD provided a greater benefit than UPA 15 mg QD. UPA was well tolerated with no new safety signals and selected AEs of special interest were reported infrequently with both maintenance doses.

Primary and key secondary endpoints, %	UPA 45 mg QD at Week 16 (induction) ^a (N=125)	UPA 15 mg QD at Week 52 (maintenance) ^b (N=34)	UPA 30 mg QD at Week 52 (maintenance) ^b (N=39)
Primary endpoint: Clinical remission ^c	5.6	26.5	43.6
Clinical response at end of induction ^d	58.4	N/A	N/A
Maintenance of clinical response ^e	N/A	(N=25) 49.1	(N=32) 78.1
No abdominal pain	40.0	38.2	48.7
No bowel urgency	30.4	32.4	59.0
Endoscopic improvement ^f	14.3	34.3	51.3
Endoscopic remission ^f	4.9	12.2	17.9
Histologic-endoscopic mucosal improvement ^g	11.0	21.9	41.0
Mucosal healing ^h	3.4	12.0	12.8
Among patients who achieved clinical remission at the end of induction:		(N=3)	(N=4)
Clinical remission ^c	N/A	0	100
Clinical remission ^c and corticosteroid free for ≥90 days immediately prior to Week 52	N/A	0	100
Among patients who achieved endoscopic improvement at the end of induction:		(N=7)	(N=9)
Endoscopic improvement ^f	N/A	42.9	66.7

Data are presented for the ITT population comprising patients who achieved a clinical response with 16-week UPA 45 mg QD induction therapy and were re-randomized to receive UPA 15 mg or 30 mg QD maintenance therapy.

^aTwo patients were excluded from analysis owing to site non-compliance as prespecified in the statistical analysis plan.

^bIncluded patients who had completed, or had the potential to complete, 52 weeks' maintenance treatment.

^cPer Adapted Mayo score ≤2; stool frequency subscore ≤1 and not greater than induction baseline, RBS=0, and ES ≤1.

^dInduction therapy (UPA 45 mg QD): Clinical response, defined as a decrease in Adapted Mayo score ≥2 and ≥30% from induction baseline, plus a decrease in RBS ≥1 or an absolute RBS ≤1, at Week 16. Maintenance therapy (UPA 15 mg or 30 mg, QD): Maintenance of clinical response at Week 52 among patients who achieved clinical response at the end of the 16-week induction therapy.

^eES ≤1.

^fES=0.

^gES ≤1 and Geboes score ≤3.1.

^hES=0 and Geboes score <2.

ES, endoscopic subscore; ITT, intent-to-treat; N/A, not applicable; QD, once daily; RBS, rectal bleeding subscore; UPA, upadacitinib.

P0441

AN ANALYSIS OF HIGHER SECONDARY EFFICACY FAILURE RATES AMONG ULCERATIVE COLITIS PATIENTS WHEN COMPARING THE EU TO THE US

L. Fendrick¹, P. Zimmerman¹
¹Spherix Global Insights, Gastroenterology, Exton, United States

Contact E-Mail Address: paul.zimmerman@spherixglobalinsights.com

Introduction: This retrospective analysis of gastroenterologist-provided patient records for ulcerative colitis (UC) compares patients who recently switched advanced therapies due to secondary efficacy failure in the European Union (EU) and United States (US) with a discussion of continued higher prescribing rates for tumor necrosis factor inhibitors (TNFi) in the EU.

Aims & Methods: In August-September 2021, Spherix conducted a retrospective EU (France, Germany, Italy, Spain, and the United Kingdom) patient chart audit of 717 patients with UC who had switched from one biologic/JAK inhibitor agent to another in the previous four months. 289 EU gastroenterologists submitted this patient-level data, including the therapy patients were switched from and the reasons for that switch to have taken place, via a GDPR and HIPAA-compliant audit form.

In July-September 2021, Spherix conducted a retrospective US patient chart audit of 629 patients with UC who had switched from one biologic/JAK inhibitor agent to another in the previous four months. 196 US gastroenterologists submitted this patient-level data, a process identical to the method used in the EU. The aim is to profile differences between the EU5 and US in secondary efficacy failure rates in relation to TNFi prescribing levels in both regions.

Results: Secondary efficacy failure was the primary reason for switching therapies for 29% of EU UC patients, making it the leading reason for switching in the EU. In the US, secondary efficacy failure was indicated as

the primary reason for switching in 16% of UC patients, falling third on the list of reasons for switching. The past four years of EU UC switching patient chart data show that secondary efficacy has been the leading primary reason for switching (2018- 32%, 2019- 36%, 2020- 28%, 2021- 29%). However, in the US, these rates have decreased over the same period (2018- 23%, 2019- 25%, 2020- 18%, 2021- 16%).

Coinciding with these differences, TNFi prescribing for UC has remained high in the EU5, due to the availability of biosimilars for both infliximab and adalimumab. 96% of EU patients who switched due to secondary efficacy failure were switched from a TNFi (2018- 97%, 2019- 89%, 2020- 95%, 2021- 96%). In the US, TNFi prescribing relative to other classes of therapy has declined. In 2021, 79% of US patients who switched due to secondary efficacy failure were switched from a TNFi (2018- 96%, 2019- 89%, 2020- 87%, 2021- 79%).

Conclusion: Switching therapies due to secondary efficacy failure has remained high, along with the rates of switching from TNFi therapies in the EU. In contrast, the US, with less TNFi prescribing in the absence of an adalimumab biosimilar, also has notably less therapy switching due to secondary efficacy failure. Further analysis of the potential impact of TNFi therapies on secondary efficacy failure is recommended with potential impacts on both the US and EU UC markets.

LONG-TERM TREATMENT PERSISTENCE WITH INFLIXIMAB IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A REAL-WORLD STUDY

M.G. Gonçalves¹, T. Carvalho¹, J.P. Monteiro Almeida Pereira², A. Guimarães¹, P. Antunes¹, B.M. Gonçalves¹, J.B. Soares¹, A. Rebelo¹, R. Gonçalves¹

¹Braga Hospital, Gastroenterology, Braga, Portugal, ²Unidade Local de Saúde de Matosinhos, Gastroenterologia, Águeda, Portugal

Contact E-Mail Address: margaridagoncalves21@gmail.com

Introduction: Infliximab was one of the first biologic treatment options for patients with inflammatory bowel disease (IBD). Long-term outcome studies of anti-TNF therapy with an observation time longer than 5 years are limited.

Aims & Methods: The authors intend to assess length of treatment persistence with Infliximab and also identify independent predictors for treatment failure. This was a single-center and retrospective study that included patients who received infliximab (either on induction or maintenance regimen), as first biologic therapy, between 2012 and 2015. Kaplan-Meier analysis with log-rank test was used to describe treatment persistence. With multi-variable Cox regression analysis, independent predictors for treatment persistence were investigated.

Results: During the study period 176 patients were included (134 with Crohn's disease, 40 with ulcerative colitis and 2 with unclassified IBD) with a mean age at diagnosis of 27.7±12.2 years. Sex distribution was balanced (51.7% female vs 48.3% male). Median time from diagnosis to infliximab was 38 months (IQ 16-94.5) and the median time of follow-up (until suspension or last visit) was 13.2 years (IQ 10.2-18.2).

At the end of follow-up 79 patients (44.9%) were still on Infliximab, with a median treatment persistence of 8.1 years (IQ 4.9-12.9). The main reasons for discontinuation were treatment failure (53.6%) and side effects (30.9%). Female gender, longer duration of disease and the presence of

immunomodulator at the beginning of Infliximab were identified as independent predictors on Cox Regression (OR 1.74, p=0.013, OR 0.98, p<0.001 and OR 1.75, p=0.30, respectively). These independent predictors remain valid in the sub-analysis of patients with Crohn's disease.

Conclusion: Treatment persistence with Infliximab in inflammatory bowel diseases was limited, mainly due to treatment failure and side effects. Gender, duration of disease prior biological therapy and immunomodulator influence infliximab treatment persistence.

Disclosure: Nothing to disclose.

Introduction: QingDai (QD) is a herbal extract used in traditional Chinese medicine. QD has been shown to be effective for ulcerative colitis (UC) in randomized controlled trials and retrospective reports from Japan. However, experience with QD for UC in the West is extremely limited. We aimed to describe the effectiveness and safety of QD in a national cohort of patients with UC followed at tertiary referral centers.

Aims & Methods: A retrospective study. We included adult patients who received QD for active UC (simple colitis clinical activity index (SCCAI)≥3) between January 2018 and January 2022 at five participating centers. A majority of patients received QD in a combination with curcumin. Clinical, biochemical and endoscopic data were retrieved from patients' medical records.

The primary outcome was clinical response at the end of induction (up to 16 weeks from the start of the treatment). Clinical response was defined as an improvement of SCCAI≥ 3 points; clinical remission as SCCAI≤2. C-reactive protein (CRP), fecal calprotectin (FC) levels and endoscopic Mayo score before and after treatment were compared when available. Starting corticosteroid or biologic treatment, hospitalization due to disease exacerbation, colectomy, discontinuation of treatment due to an adverse event or missing follow-up data were considered treatment failures.

Results: A total of 82 patients were included [median age-32, interquartile ratio (IQR)-23-41], 47 (57.3%) female; disease extent- 16 (20.5%)-proctitis, 28 (35.9%)- left-sided, 34 (43.6%) – pancolitis]. Forty one (54.7%) patients were biologics naïve, 10 (12.9%) failed ≥ 3 biologics or small molecules. Median SCCAI was 6 (5-9), CRP- 5 (2-17) mg/L, fecal calprotectin levels – 698 (320 -1190) mg/g and endoscopic Mayo score- 2. At treatment onset, 27 (41.5%) were treated with corticosteroids and 28 (34.1%) with a bio-

logic or small molecule. The initial QD dose was 1 g/d in 68 (82.9%) and 2g /d in 14 (17.1%) of the patients. QD was initiated in combination with curcumin in 77 (95.1%) of the patients.

Last induction follow-up occurred after 8 (8-12) weeks. At the end of induction, 64 (78%) responded to treatment, including 52 (63.4%) that achieved clinical remission. At the end of induction, median SCCAI was 2 (1-3) ($p<0.001$), CRP-2 (1-5) mg/L ($p=0.003$, 22 patients with paired measurements), FC levels -75 (12-139, 35 patients) mg/g ($p<0.001$) and median endoscopic Mayo score -1 (0-2) ($p=0.03$, 12 patients). Two (2.3%) patients experienced headaches and 5 (6.1%) – mild liver function elevations that resolved spontaneously or following QD discontinuation (2 patients).

Conclusion: In this multicenter retrospective cohort, QD treatment (frequently combined with curcumin) was effective for induction of clinical response and remission in 78% of patients, including biologic-experienced patients. All adverse events were mild and resolved either spontaneously or after QD discontinuation.

Our results suggest QD as a potential effective and safe agent for induction of response and remission in patients with active UC.

Disclosure: Nothing to disclose.

SWITCH FROM INTRAVENOUS TO SUB-CUTANEOUS INFLIXIMAB IN INFLAMMATORY BOWEL DISEASE: WHICH CONSEQUENCES FROM A PHARMACOKINETIC PERSPECTIVE?

C. Tron¹, B. Franck¹, M.-C. Verdier¹, F. Lemaître¹, G. Bouguen²
¹Rennes University Hospital, Pharmacology Department, Rennes, France, ²CHU Pontchaillou, Service des Maladies de l'Appareil Digestif, Rennes, France

Contact E-Mail Address: guillaume.bouguen@chu-rennes.fr

Introduction: Therapeutic drug monitoring (TDM) of infliximab is routinely performed in many centers to optimize treatment response in patient with inflammatory bowel disease (IBD). While the pharmacokinetic of intravenous formulation (IV) has been extensively described and therapeutic range have been reported, few data are available regarding the actual infliximab exposure reached with the new subcutaneous formulation (SC).

Aims & Methods: The aim of this work was to compare exposures in patients switched from IV to SC infliximab.

A retrospective monocentric study was conducted in stable patients with IBD switched from IV to SC infliximab between March 2021 and February 2022 in the Gastroenterology department of Rennes University Hospital. Paired-trough concentrations (C₀) measured

i) after the last IV injection and;

ii) at steady state after initiation of SC injections, were collected from routine TDM.

All infliximab concentrations measurements were centralized in the same laboratory. It allowed estimating the exposure reflected by the area under the curve of concentrations of infliximab versus time (AUC). Exposure between to administrations (AUC_{0-8weeks}) and exposure normalized to eight weeks (AUC_{0-8weeks}) were derived using population pharmacokinetics modelling [1,2].

Results: A total of 119 patients were switched from infliximab IV to SC during the study period. The patient self-administrates SC infliximab at home, so visits to the hospital are less frequent. Eventually, concentrations at steady state after switch (> 2 months after the switch) were available for seven-five patients at the time of the data analysis. SC dosage was 120 mg/2 weeks (n=65) or /1 week (n=10). Median [range] of C₀ were 4.7 µg/mL [<0.2 -19.4] for IV and 20.8 µg/mL [<0.2 -64.1] for SC ($p<0.0001$). AUC_{0-8weeks} were also different between both formulations (32378 µg.h/mL [11364-59409] for IV and 8010 µg.h/mL [3320-11400] for SC, $p<0.0001$). However, median

AUC_{0-8weeks} were similar before and after the switch (33333 µg.h/mL [17857-91314] for IV and 32451 µg.h/mL [12279-84181] for SC, $p=0.3$). A poor correlation was observed between IV/SC C₀ ($r^2=0.08$, $p=0.01$) and IV/SC AUC_{0-8weeks} ($r^2=0.11$, $p=0.002$). Both formulations displayed an high inter-patient variability of C₀ (Coefficients of variation: 69.5 % for IV and 53.8 % for SC).

Conclusion: This study provides useful data to interpret TDM results in the era of SC infliximab. Intravenous therapeutic range based on C₀ should not be applied to SC infliximab. While globally exposures (AUC_{0-8weeks}) are similar between the two formulations, they may unpredictably change after the switch from an individual perspective. Further study are required to precise the target range of concentrations of SC infliximab.

Contact E-Mail Address: irenita.rm@gmail.com

Introduction: Tofacitinib (TF) is a partially selective JAK inhibitor with anti-inflammatory and immunomodulatory effect approved by the EMA in 2018 in moderate-severe UC. Minor side effects have been described and there are two alerts for venous thromboembolic phenomena in patients >50 years with rheumatoid arthritis and doses of 10 mg/12 hours and for risk of malignancies and infections.

Aims & Methods: Retrospective analysis of UC patients treated with TF in our center from April 2018 to November 2021. Safety and adverse effects are analyzed.

Results: Seventy-one patients (45% female) were included. Median age 48 years (18-83) with 16% >60 years. 12 patients smokers (16%), 3 diabetics (4%), 11 with AHT (15%), 13 with dyslipidemia (18%) and 8 with BMI >30 (12%). History of ischemic heart disease in 4 patients (6%) and thromboembolic phenomena in 2 (1 venous thrombosis associated with PICC and 1 pulmonary thromboembolism in the context of sepsis). Previous neoplasms in 5 cases (7%): 1 breast cancer, 1 melanoma, 1 thyroid and 2 non-melanoma skin cancers. Side effects were observed in 11 patients (15.5%), including digestive intolerance, pruritus, lymphopenia, herpes zoster, renal failure and dyslipidemia. Adverse effects were the reason for definitive discontinuation of the drug in 4 patients, temporary discontinuation in 3 and dose reduction in 2 patients. There was no secondary mortality.

Conclusion: - In our series, Tofacitinib shows an acceptable safety profile.

- The prevalence of side effects is low but may condition drug withdrawal.

- No thromboembolic phenomena or cardiovascular events were detected in our series.

Disclosure: None.

Introduction: Ustekinumab (UST) is approved for treatment of moderately to severely active ulcerative colitis (UC) in many countries, including Asia. However, the long-term efficacy and safety in an Asian population still remain unclear.

This analysis is aimed to assess the efficacy and safety of UST in the Asian subpopulation in the UNIFI long-term extension (LTE).

Aims & Methods: UNIFI, a Phase 3, randomized, double-blind, placebo-controlled trial consisting of an 8-week induction study and a 44-week re-randomized withdrawal maintenance study with a 4-year LTE, evaluated UST in patients with moderately to severely active UC. In this report, all patients who continued into the LTE were followed up to 3 years (Week 152). The patients on the placebo arm were discontinued when the study was unblinded after Week 44. Efficacy was evaluated using symptomatic remission (defined as a Mayo stool frequency subscore of 0 or 1 and a rectal bleeding subscore of 0). All adverse events (AEs) were summarized for long-term safety assessment.

Results: A total of 87 randomized patients in maintenance were treated in the LTE with either subcutaneous (SC) placebo (n=34 [39.1%]), UST 90 mg SC every 12 weeks (n=24 [27.6%]), or UST 90 mg SC every 8 weeks (n=29 [33.3%]). Of the 53 randomized patients who were treated with UST, 31 (58.5%) and 28 (52.8%) patients were in symptomatic remission at Week 44 and Week 152 in the combined UST group, respectively (Table 1). Of note, all patients who achieved symptomatic remission were corticosteroid-free (Table 1).

The average duration of follow up from Week 0 through the final safety visit was 138.9 weeks and 88.0 weeks in the combined UST and placebo groups, respectively. Among the combined UST group (n=69), safety events (per hundred patient-years) from maintenance Week 0 through final safety visit included: AEs, 240.9; serious AEs, 10.9; infections, 99.3; and serious infections, 2.2. Among the placebo group (n=34), safety events (per hundred patient-years) from maintenance Week 0 to the final safety visit included: AEs, 314.6; serious AEs, 7.0; infections, 125.2; and serious infections, 1.7. Non-melanoma skin cancers (per hundred patient-years) were 0.5 in the combined UST group and 0.0 in the placebo group. No deaths were reported and 9 (22.0%) patients discontinued UST (due to AEs [n=2; 9.1%], lack of efficacy [n=3; 7.3%], no improvement in UC disease activity 16 weeks after dose adjustment [n=1; 2.4%], and other [n=3; 13.6%]) during LTE.

	Week 44 – UST 90 mg SC			Week 152 – UST 90 mg SC		
	q12w ^a (n=24)	q8w ^a (n=29)	Combined (n=53)	q12w ^a (n=24)	q8w ^a (n=29)	Combined (n=53)
Symptomatic remission ^{b,c,d}	66.7 (16/24)	51.7 (15/29)	58.5 (31/53)	62.5 (15/24)	44.8 (13/29)	52.8 (28/53)
Symptomatic remission and not receiving CS ^{b,c,e,f}	66.7 (16/24)	51.7 (15/29)	58.5 (31/53)	62.5 (15/24)	44.8 (13/29)	52.8 (28/53)

All data are presented as % (n/N). Combined UST 90 mg data (n=53) include UST 90 mg SC q12w (n=24) and 90 mg SC q8w (n=29).
 AE, adverse event; CS, corticosteroid; q8w, every 8 weeks; q12w, every 12 weeks; SC, subcutaneous; UC, ulcerative colitis; UST, ustekinumab.
^aRandomized group at maintenance Week 0 regardless of whether patients had a dose adjustment during the long-term extension.
^bSymptomatic remission is defined as a stool frequency subscore of 0 or 1 and a rectal bleeding subscore of 0.
^cPatients who had both stool frequency and rectal bleeding subscores missing at a visit were considered not to be in symptomatic remission for that visit.
^dPatients who had an ostomy or colectomy, or discontinued study drug due to lack of therapeutic effect or due to an AE of worsening of UC prior to the designated visit were considered not to be in symptomatic remission.
^ePatients who had a missing value in corticosteroid use had their last value carried forward.
^fPatients who had a prohibited change in UC medication, on ostomy or colectomy, or used a rescue medication after clinical flare, or discontinued study agent due to lack of therapeutic effect or due to an AE of worsening of UC prior to the Week 44 visit were considered not to be in symptomatic remission.

Table 1. Key clinical efficacy in Asian patients randomized in maintenance who were treated during the long-term extension.

Conclusion: Long-term efficacy and safety of UST in an Asian subpopulation with moderately to severely active UC were confirmed in this study. Symptomatic remission was maintained without any new safety findings in Asian patients through 3 years. Overall, the safety and efficacy profiles of UST in an Asian subpopulation are consistent with the overall study population previously reported.

Introduction: Biological drugs used for inflammatory bowel disease (IBD) are detected in breast milk at a concentration below 10% of the maternal serum concentration and have therefore been considered as permitted drugs. However, warnings have recently been published regarding vaccination with live agents in children whose mothers receive infliximab during lactation.

Aims & Methods: To assess the risk of serious adverse events related to the administration of live vaccines in children exposed to biological drugs *in utero* and/or whose mothers were receiving biological agents during lactation.

Children born to IBD mothers from DUMBO registry were included. DUMBO is a prospective, observational and multicentre registry, which enrolls pregnant women with IBD over 5 years in 70 centres in Spain¹.

Data on treatment during gestation, type of lactation, breastfeeding, end-date of breastfeeding, maternal treatments during breastfeeding, and serious adverse events in children from birth are being prospectively included contacting with the mothers every-3-months.

Following the Spanish immunization calendar, rotavirus vaccine is (voluntarily) administered at 2, 4 and 6 months (3rd dose only with Rotateq¹); measles, mumps and rubella (MMR) at 12 months and 3-4 years of age; and varicella at 15 months and 3-4 years of age.

Results: 526 newborns were included (51% female). 56% of the mothers had Crohn's disease. 10% of the children were premature, and 10% had low birth weight. 29% were born by C-section. 198 children (38%) had been exposed to biologics during pregnancy (28% to anti-TNF, 2% to vedolizumab, and 8% to ustekinumab).

Of the children exposed to biologics, 88% were exposed during the 2nd trimester, and 73% during the 3rd trimester. The median follow-up of children from birth (still ongoing) was 12 months at the time of data analysis (IQR=6-18 months).

The percentage of children who had been vaccinated according to the recommended schedule was above 95% at all visits up to 24 months of follow-up. Of the children who had been exposed *in utero* to biologics during the 3rd trimester of gestation, 65 (47%) had already received the 1st dose

of rotavirus, 61 (44%) the 2nd dose, and 19 (14%) the 3rd dose; 63 (45%) the first dose of MMR; and 42 (30%) the 1st dose of varicella vaccine. No serious adverse event was observed in children associated with the administration of these vaccines. From birth, 73% of infants were breastfed (55% exclusively breastfed). The percentage of breastfed children was 49% at 6 months, 33% at 12 months, 28% at 18 months, and 18% at 24 months. During breastfeeding, 23% of the mothers were under biological therapy: 17% anti-TNF agents, 4% ustekinumab, and 2% vedolizumab. From children breastfed at least until month 6 and whose mothers were under biologics, 40 (60%) received the 1st and 2nd dose of rotavirus vaccine, and 11 (17%) the 3rd dose.

From children breastfed at least until month 12 and whose mothers were under biologics, 35 (97%) received the 1st dose of MMR vaccine; and from children breastfed at least until month 15 and whose mothers were under biologics, 21 (84%) received the 1st dose of varicella vaccine. No serious adverse event related to live vaccine was reported in our cohort.

Conclusion: Administration of live virus vaccines from 12 months of age in children born to IBD mothers and exposed to biological drugs *in utero* and/or during breastfeeding seems safe and should not be recommended against vaccination or breastfeeding. Rotavirus vaccine (under 6 months of age) appears to be equally safe in these children.

Introduction: Corticosteroids (CS) are the most commonly prescribed first-line drugs, for the induction of remission in moderate to severe Crohn's disease (CD) or Ulcerative Colitis (UC) relapse. However, CS dependency and refractoriness are a significant clinical problem associated with numerous side effects.

Despite intensive research, CS still generate a challenge for personalized medicine by causing resistance or dependence in a significant proportion of patients. Identification of molecular markers of CS response is of paramount importance. The ABCB1 gene codes for P-glycoprotein, a transporter involved in the metabolism of CS.

Aims & Methods: The aim of this study is to investigate the contribution of polymorphisms of the ABCB1 gene to response to CS therapy in IBD patients.

Ninety-five patients with moderate to severe CD or UC who had been treated with a first course of corticosteroid therapy with a minimum follow up of 3 months, between January 2005 and December 2020 were retrospectively reviewed at Sahloul Hospital of Sousse in Tunisia and were genotyped. DNA was extracted from blood samples. Three of the most frequent Single nucleotide polymorphisms (SNP) of the ABCB1 gene were genotyped: C1236T, G2677T/A, and C3435T.

Patients were evaluated and classified as dependent, resistant, or responsive to CS therapy. Resistant or dependent patients were classified as non-responders.

The relation between CS therapy response and the genetic polymorphisms considered was examined using univariate and multivariate analysis.

Results: Fifty-nine CD (62.1%) and 36 UC (37.9%) were enrolled in our study. The mean age was 38.7 +/- 12.7 years with extremes [18-81]. At 3 months, 58 patients (61.1%) were classified as responder to CS therapy and 37 patients (38.9%) were classified as non-responders to CS therapy including 25 CS refractoriness (26.3%) and 12 CS dependency (12.6%). CT and TT genotypes of the C1236T polymorphism of the ABCB1 gene were associated with a non-response to corticosteroid therapy (64.9% vs 43.1%, p=0.038) in univariate analysis. The C1236T polymorphism was also associated with risk of CS resistance (68% vs. 41.3%, p= 0.037). No polymorphism was associated with risk of CS dependence (p=0.335).

In multivariate analysis, the C1236T polymorphism of the ABCB1 gene was associated with a risk of non-response to CS therapy (OR= 2.518 95% CI [1.100-6.328]; p=0.04) and with a risk of refractoriness to CS therapy (OR= 2.99; IC95% [1,164-8,423] ; p=0,038).

Conclusion: Our study showed that the polymorphism C1236T of the ABCB1 gene was associated with a risk of non-response to CS therapy and CS refractoriness.

A genetic study of the polymorphisms of other genes involved in the pharmacogenetics of CS would allow individualization of treatment and optimization of management by proposing an algorithm for predicting IBD patients at risk of non-response to CS.

Introduction: Autologous hematopoietic stem cell transplantation [AH-SCT] is a therapeutic option for patients with refractory Crohn's disease [CD]. Although the safety of the procedure has been improved over the last decade, AH-SCT is still burdened by high adverse event rate due to chemotherapy toxicity and immunosuppression.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of AH-SCT by using a cyclophosphamide (Cy)-free mobilization regimen followed by a standard conditioning approach.

A prospective observational study was conducted at Hospital Clínic of Barcelona in refractory CD patients undergoing AHSCT. Outpatient regimen with G-CSF 12-16 µg/kg/daily for 5 days was used for mobilization. Patients who failed to achieve >2x10⁶ CD34⁺ cells received Plerixafor 240 µg/d (1-2 doses). For conditioning, Cy and ATG were administered according to standard protocols. After transplant, patients were followed-up at regular intervals. Colonoscopy and/or magnetic resonance imaging were performed at baseline and at weeks 26, 52, 104 after AHSCT. Crohn's Disease Activity Index (CDAI) and SES-CD were used for clinical and endoscopic disease assessment.

Results: From June 2017 to April 2022, 14 refractory CD patients were enrolled (9F, median age 40 yr, median CDAI 204, median SES-CD 13); all of them achieved successful mobilization (median collected CD34⁺ cells 7.7x10⁶±2.8) and were transplanted. Patients were followed-up during a median of 106 months [range 0-236 months]. No SAEs or CD worsening were observed during mobilization. The proportion of patients in clinical remission (CDAI<150) was 71% at 6 months, 50% at 1 yr and 60% at 2 yr. Median SES-CD was 6 at 6 months and 9 at 1 yr. The proportion of patients who restarted CD therapy for clinical relapse and/or endoscopic/radiological activity was 14% at 6 months, 30% at 1 yr and 40% at 2 yrs. AEs and SAEs during and after conditioning were comparable to previous series, being neutropenic fever the most frequently observed (54%). Colectomy due to refractory severe relapse was needed in one patient at 70 weeks from transplant.

Conclusion: Cy-freemobilization is feasible and safe in refractory CD patients undergoing AHSCT but early relapse is observed in a significant proportion of patients. While representing an improvement on safety, studies exploring early reintroduction of drugs to decrease relapse rate after transplant are warranted.

Introduction: Intravenous (IV) infliximab is a first line treatment for moderate or severe flare of inflammatory bowel disease. Recently a new formulation of infliximab with subcutaneous (SC) administration has been developed and approved for this indication.

Aims & Methods: From March 2021, 14 patients diagnosed with inflammatory bowel disease (Crohn's disease-CD- or ulcerative colitis-UC), in clinical remission for at least 6 months with IV infliximab who had needed previous intensification, either because of a reactive therapeutic drug monitoring and loss of response, or because of a proactive drug monitoring (trough levels <3µg/ml), were switched to SC infliximab.

We analyzed retrospectively from the start of SC infliximab until week 8 and 24 after switch, fecal calprotectin levels (FC), C reactive protein (CRP), concomitant treatment, trough levels, treatment adherence, need for intensification or relapse, and adverse events.

Results: Four patients (28.57%) were diagnosed with CD, ten (71.4%) were diagnosed with UC. Patient's baseline characteristics are described in table. Median duration of IV treatment was 53 months (IQR 33-59). Reasons for starting infliximab were corticoid dependence in 6 patients (42,8%), corticorefractoriness in 6 (42,8%) and topdown strategy in B3 phenotype with Crohn's disease in 2 (14,3%). Reasons for intensification were: loss of response in 5 patients (35,7%), intensified induction in one (7,1%), proactive therapeutic drug monitoring in 8 (57,14%).

Eleven patients (78.57%) were still in an intensified regimen when switched. All patients were in clinical and biochemical remission (FC<150 µg/g and CRP<5 mg/dl) before switch. Twelve patients (86%) were in clinical and biochemical remission with standard infliximab doses, without any differences between CRP and FC levels in week 8 nor 24. 2 patients relapsed. Three patients of the 9 who were in combo therapy (33%) could withdraw immunosuppressors. Median basal infliximab trough levels before switch were **6.98µg/ml** (0.20; 20.10); median trough levels in week 8 after switch were **14.12** (9.86; 37.88) (**p=0.003**); median trough levels in week 24 were **10.49** (1.31; 24.12) (**p>0.05**). There were no adverse events.

Baseline characteristics	N=14
Age (years), median (IQR)	49,5 (38-64)
Weight (kg), median (IQR)	70 (61-80)
Sex (male), n (%)	99,5 (53-262)
Concomitant treatments, n (%)	13 (92,8%)
Corticoids, n(%)	0 (0%)
Topical salicylates, n (%)	10 (71,42%)
Immunomodulators, n (%)	9 (64,28%)
Duration in clinical remission (months), median (IQR)	48 (23-58)
Current intensification when switched, n (%)	11 (78,57%)

Conclusion: In our centre, switching from IV to standard dose SC infliximab maintained clinical and biochemical remission in most patients that previously needed intensified regimen, improving trough levels, without any adverse events, being able to withdraw immunosuppression in 33% of them. These findings provide potential therapeutic insights into SC infliximab as a monotherapy agent for inflammatory bowel disease.

Introduction: Ustekinumab (UST) is approved for treatment of moderately to severely active Crohn's disease (CD) in many countries, including Asia. However, the long-term efficacy and safety in Asian populations still remain unclear.

This analysis aimed to assess the efficacy and safety of UST in the Asian UNITI/IM-UNITI subpopulation through 5 years of UST treatment in the long-term extension (LTE).

Aims & Methods: UNITI/IM-UNITI, a Phase 3, randomized, double-blind, placebo-controlled trial consisting of two 8-week induction studies and a 44-week re-randomized withdrawal maintenance study followed by a 4-year LTE, evaluated UST in patients with moderately to severely active CD.

This study analyzed 63 Asian patients who entered the LTE at Week 44 and were followed up to 5 years (Week 252). The patients on the placebo arm were discontinued when the Week 44 data were unblinded.

Clinical remission (defined as CD Activity Index [CDAI] score <150) and clinical response (defined as a reduction in CDAI score ≥100) were assessed for long-term efficacy. All adverse events (AEs) were summarized for long-term safety.

Results: A total of 63 Asian patients (mean age at induction baseline, 34 years; males, 76.2%) entered the LTE and were treated with either subcutaneous (SC) placebo (8 [12.7%]), UST 90 mg SC every 12 weeks (22 [34.9%]), or UST 90 mg SC every 8 weeks (33 [52.4%]) from maintenance Week 0 through Week 252. Of the 55 patients who were treated with UST, 33 (60.0%) were in clinical remission and 45 (81.8%) were in clinical response at Week 44 in the combined UST group (Table 1).

At Week 252, 18 (32.7%) were in clinical remission and 25 (45.5%) were in clinical response in the combined UST group (Table 1). All patients who were in clinical remission were corticosteroid-free at Week 252, except for 1 patient in the UST 90 mg SC every 8 weeks group (Table 1).

The average duration of follow-up from Week 0 through the final safety visit was 208.4 weeks and 90.9 weeks in the combined UST and placebo groups, respectively.

Among the 55 patients in the combined UST group, safety events (per hundred patient-years) from maintenance Week 0 through the final safety visit included: AEs, 267.2; serious AEs, 23.1; infections, 98.4; and serious infections, 4.5. Among the 8 patients in the placebo group, safety events (per hundred patient-years) from maintenance Week 0 through the final safety visit included: AEs, 278.9; serious AEs, 14.3; infections, 71.5; and serious infections, 0. A total of 8 patients (14.5%) discontinued UST due to AEs (all due to a worsening of CD). No deaths or malignancies were reported.

	Week 44 – UST 90 mg SC			Week 252 – UST 90 mg SC		
	q12w ^a (n=22)	q8w ^b (n=33)	Combined (n=55)	q12w ^a (n=22)	q8w ^b (n=33)	Combined (n=55)
Clinical remission ^{c,d}	54.5 (12/22)	63.6 (21/33)	60.0 (33/55)	31.8 (7/22)	33.3 (11/33)	32.7 (18/55)
Clinical remission and not receiving corticosteroids ^{c,d,e}	-	-	-	31.8 (7/22)	30.3 (10/33)	30.9 (17/55)
Clinical response ^{f,g}	86.4 (19/22)	78.8 (26/33)	81.8 (45/55)	54.5 (12/22)	39.4 (13/33)	45.5 (25/55)

Data are presented as % (n/N). Combined UST 90 mg data (n=55) include UST 90 mg SC q12w (n=22) and 90 mg SC q8w (n=33).

-, data not available; AE, adverse event; CD, Crohn's disease; CDAI, Crohn's Disease Activity Index; IV, intravenous; LTE, long-term extension; q8w, every 8 weeks; q12w, every 12 weeks; SC, subcutaneous; UST, ustekinumab.

^aPatients who were in clinical response to UST IV induction dosing who were randomized to receive UST 90 mg q12w SC treatment upon entry into maintenance and did not meet loss of response criteria from Week 8 through Week 32; and includes patients who were not in clinical response to placebo IV induction dosing, received UST 130 mg IV at Week 0, achieved clinical response at Week 8, and initiated UST 90 mg q12w SC.

^bPatients who were in clinical response to UST IV induction dosing and were randomized to receive UST 90 mg q8w SC treatment upon entry into maintenance; patients who were randomized upon entry into maintenance and did meet loss of response criteria from Week 8 through Week 32 and received UST 90 mg q8w SC thereafter; and includes patients who were not in clinical response to UST IV induction dosing, received UST 90 mg SC at Week 0, achieved clinical response at Week 8, and initiated UST 90 mg q8w SC.

^cPatients who had a prohibited CD-related surgery or discontinued study drug due to lack of efficacy or due to an AE indicated to be of worsening CD prior to the designated analysis timepoint are considered not to be in clinical remission, regardless of their CDAI score.

^dPatients who had insufficient data at the designated analysis timepoint are considered not to be in clinical remission.

^ePatients who had a missing value in corticosteroids use at the designated analysis timepoint had their last value carried forward.

^fPatients who had a prohibited CD-related surgery or discontinued study drug due to lack of efficacy or due to an AE indicated to be of worsening CD prior to the designated analysis timepoint are considered not to be in clinical response, regardless of their CDAI score.

^gPatients who had insufficient data at the designated analysis timepoint are considered not to be in clinical response.

Table 1. Clinical efficacy in all Asian patients who entered the LTE.

Conclusion: Long-term efficacy and safety of UST in an Asian subpopulation with moderately to severely active CD were confirmed in this study. Clinical remission and clinical response were maintained without any new safety findings through 5 years. Overall, the safety and efficacy profiles of UST in an Asian subpopulation are consistent with the overall study population previously reported.

Introduction: More and more studies have focused on dual-targeted therapy on refractory IBD or extraintestinal manifestations these days but till now data on the efficacy and safety of dual-targeted therapy on either Crohn's disease or ulcerative colitis is still exiguous. Moreover, studies on the mechanisms of dual-targeted therapy are rare.

Given that different drug molecules target various action sites in an inflammatory cytokine network in the immune microenvironment, dual-targeted therapy may be counted to reach a complementary strategy for IBD.

Aims & Methods: Through a search of multiple electronic databases by the end of April 15, 2022, emerging data on the safety, effectiveness and current clinical development status of novel targeted drugs on refractory IBD were summarized in this review.

By dividing the therapeutic agents into "Therapeutic Agents Targeting Cellular Signaling Pathways" and "Therapeutic Agents Targeting Leukocyte Trafficking" according to the different therapeutic targets in addition by classing therapeutic agents targeting cellular signaling pathways into "JAK-dependent" and "JAK-independent", the mechanisms of targeted therapy were explored and summarized. Furthermore, 32 studies related to dual-targeted therapy were included in this review, including 2 RCTs, which classified the existing dual-targeted treatments according to mechanisms.

Results: The combination of drugs targeting the JAK-dependent pathway with TNF- α and leukocyte trafficking with TNF- α achieved more clinical and endoscopy remission in patients. The former combination was relatively safe.

Furthermore, the latest RCT demonstrated that the combination with guselkumab and golimumab is more effective than either approach alone. However, it seems impossible from our data to give a clear recommendation on which combination should be used as the now available data are not comparable.

Conclusion: In conclusion, given its efficacy and safety, the combination of drugs targeting the JAK-dependent pathway and TNF- α seem especially attractive. According to in being understanding on the advantages, shortcomings and research prospects of different targeting combinations, the

possible mechanisms of dual-targeted therapies were deduced so as to conceive a theoretical framework for clinical decision-making and further drug development and research on IBD.

BURDEN OF BOWEL URGENCY ACROSS SPECIFIC TREATMENT GROUPS AMONG CROHN'S DISEASE PATIENTS – REAL WORLD GLOBAL STUDY ANALYSES

R. Atreya¹, M. Protic², P. Streit³, S. Hartz⁴, H. Knight⁵, S. Barlow⁶, F. Hennessy⁶, T. Hunter Gible⁶

Contact E-Mail Address: raja.atreya@uk-erlangen.de

Introduction: Bowel urgency (BU) is a sudden and immediate need to have a bowel movement, a common symptom in Crohn's disease (CD) patients. The pathophysiology /mechanism of BU in CD is very complex. BU may persist despite treatment for CD and when disease is considered inactive^{1,2}.

This study explored differences in disease burden among CD patients with BU based on their treatment pathway.

Aims & Methods: Data were extracted from the Adelphi Disease Specific Programme for CD³, a point-in-time survey of gastroenterologists (GIs) and patients from Jan 2020-Mar 2021 in Germany, France, Spain, Italy, UK and US. GIs provided patient demographics, clinical characteristics and treatment history. The same patients were invited to complete the Short Inflammatory Bowel Disease Questionnaire (SIBDQ), EQ-5D and Work Productivity and Activity Impairment (WPAI) questionnaire. Three patient subgroups were identified: never received targeted therapy (biologics and JAK inhibitors) (TT-naïve), receiving first TT currently (1L TT) and receiving TT with prior TT use (TT-exp). Within these groups, patients currently experiencing BU, reported by physicians, with current treatment duration >3 months, were included. ANOVA, chi-square and/or Kruskal-Wallis tests were used to compare across groups.

Results: Of the CD patients in the TT-naïve (n=643), 1L TT (n=994) and TT-exp (n=404) groups, 17%, 13% and 15% experienced BU, respectively (Table). 9% of the TT-naïve group were flaring vs. 15% 1L TT and 29% TT-exp patients (p=0.0024). Steroid use was higher in the TT-naïve group (45%) vs. 15% 1L TT and 12% TT-exp (p<0.0001). The patient reported outcome measures indicated substantial and similar quality of life impairment across all patients with BU (Table).

Conclusion: This study confirmed that a substantial proportion of patients with CD across all three groups still experience BU despite receiving treatment. Since BU is known to negatively impact patients' quality of life, there is a therapeutic need to address this symptom.

CHANGES IN QUALITY OF LIFE IN IBD PATIENTS DURING VEDOLIZUMAB THERAPY- RESULTS FROM THE PATIENT SUPPORT PROGRAM IN THREE REFERRAL CENTERS IN SERBIA

A. Sokic Milutinovic^{1,2}, T. Jovicic², O. Latinovic Bosnjak³, S. Markovic^{4,2}, T. Jovicic³, T. Knezevic Ivanovski⁴, I. Jovicic¹

¹University Clinical Center Serbia, Clinic for Gastroenterology and Hepatology, Belgrade, Serbia, ²University of Belgrade - Faculty of Medicine, Belgrade, Serbia, ³Clinical center of Vojvodina, Clinic for Gastroenterology and Hepatology, Novi Sad, Serbia, ⁴University Hospital Zvezdara, Department of Gastroenterology and Hepatology, Belgrade, Serbia

Contact E-Mail Address: asokicmilutinovic@gmail.com

Introduction: Patients with inflammatory bowel disease (IBD) often report impaired quality of life (QoL). Decrease in QoL is seen both in ulcerative colitis (UC) and Crohn disease (CD) patients. Biologic therapy induces remission in a significant number of IBD patients and has been repeatedly associated with improvement of QoL.

Aims & Methods: We conducted an observational study in three referral IBD centers in Serbia. We aimed to assess patients' perception of the effects of vedolizumab (VDZ) therapy on specific symptoms (fatigue, urgency, abdominal pain, weight loss), social interactions and overall QoL, but also to identify reasons for therapy discontinuation in the first 12 months of VDZ therapy.

We included 296 patients (153 males, mean age 50±12) in the study. UC was diagnosed in 184, while remaining 112 had CD. Patients filled a standardized questionnaire at the 1st dose, after 6 and after 12 months of therapy, and answers were given for a 14 day period. Occurrence of symptoms, possibility of interacting socially as planned and QoL were assessed using the 5 grade Likert scale. Patients were offered patient support program (PSP), in which an IBD nurse and an IBD specialist were available twice a week for phone consultations.

Results: Our results revealed that patients were diagnosed with IBD 12.5±9.5 years before starting VDZ therapy. In 153 patients VDZ was introduced as 1st line therapy (40 CD, 113 UC), in 86 as 2nd line (38CD, 48UC), while in 57 patients VDZ was 3rd or 4th line of biologic therapy (34CD, 23UC). After 6 months of therapy in CD patients, QoL was improved (p=0.006) and urgencies were significantly less frequent (p=0.004). In UC patients, a significant decrease in frequency of abdominal pain (p=0.04), urgency (p=0.000) and fatigue (p=0.004) were reported together with increased possibility of participating in social interactions (p=0.008) and a significant increase in QoL (p=0.004).

No significant difference was observed for any of the parameters analyzed between 6 and 12 months of VDZ therapy. After 6 months of VDZ therapy and participation in patient support program, both CD and UC patients reported significant improvement in terms of communication and support from family members (p=0.006 for CD and p=0.021 for UC).

In 27 (9.1%) patients therapy was stopped during the first year, 21 (7%) had loss of response, and 6 moved. Out of 21 patient with loss of response, VDZ was 1st line in 12 and 2nd line therapy in 5 patients.

Conclusion: In patients on biologic therapy with VDZ, both UC and CD, self-perceived QoL as significantly improved after 6 months of therapy. Patients with UC reported significant reduction in frequency of abdominal pain, urgency and fatigue.

On the other hand, patients with CD did not report significant decrease in frequency of symptoms apart from urgencies. We feel that participation in PSP resulted in increased support for IBD patients from family members. PSP could be a valuable tool for empowering IBD patients.

Introduction: Anti-TNF agents are widely using to both remission induction and maintaining for mild to severe intestinal and extra-intestinal involvements. The effectiveness and safety of these agents were evaluated frequently in clinical trials. Real life experience provides additional information about the treatment in the context of the daily patient care.

Aims & Methods: The aim of this study was to assess the treatment choices, short and long term response, treatment duration and the safety of anti-TNF agents in patients with CD. IBD diagnosis established with clinical, biochemical, endoscopic, and histologic findings.

We enrolled the patients retrospectively who were following up at our IBD specific gastroenterology out-patient clinic between October 2006 and April 2019. Patients who completed induction doses of at least one anti-TNF treatment included to the study. We collected demographic and clinical data from the electronic hospital database and hardcopy patient files.

Primary outcomes of this study are short term and long-term efficacy. Secondary outcomes are the safety of treatments and indications of anti-TNF initiation.

Results: An of 870 CD patients were screened, 236 were exposed to anti-TNF and 200 patients were included for the final analysis. Median follow-up period under anti-TNF treatment was 55 months (range: 4 - 168).

A total of 133 patients were received infliximab, 97 were received adalimumab and 11 were received certolizumab as first-, second- or third-line treatment. Six patients (4.2%) were primary unresponsive (PU) and 15 (10.6%) patients were secondary unresponsive (SU) to infliximab.

Three patients (2.8%) were PU and 14 patients (13.3%) were SU to adalimumab. Two (18%) patients were PU and 1 (9%) patient was SU to certolizumab. Complete response and partial response rates were respectively seen as 51.3% and 43.3% for infliximab users, 59.7% and 36,1% for adalimumab users, 36.4% and 45.5% for certolizumab users.

There was no difference seen between three agents in complete and partial response rates ($p=0.281$). Remaining on the same anti-TNF agent for infliximab and adalimumab at the end of the first year was 64.5 and 87.3% respectively.

Patients who were treated with adalimumab was seen to continue on same agent more common in 1st year when compared to infliximab ($p=0.000$). The most common indication of anti-TNF treatment was fistula formation (47.7%, $n=87$). Complete healing was seen in 20 (15.9 %) patients and partial healing was seen in 43 (34.1%) patients.

However, 63 (50.0%) patients had no response to anti-TNF treatment (Table 1). Perianal disease was seen in 103 (51.5%) patients. In patients with perianal disease, 5 (4.9%) had perianal abscess, 56 (54.4%) had perianal fistula and 42 (40.8%) had both abscess and fistula formation.

Severe allergic reaction was seen in 8 patients with infliximab and in 4 patients with adalimumab exposure. Treatment cessation due to serious adverse reactions was seen in 21 patients who exposed to infliximab and in 11 patients who exposed to adalimumab.

	Infliximab (n=43)	Adalimumab (n=29)	Certolizumab (n=4)
Complete closure	27.9% n=12	6.9% n=2	--
Partial closure	23.3% n=10	6.9% n=2	25% n=1
Improvement in fistula drainage	20.9% n=9	10.3% n=3	--
No response	27.9% n=12	72.4% n=21	75% n=3

Table 1. Fistula response according to anti-TNF agents.

Fisher's Exact Test; value:19,39 $p=0.004$

Conclusion: Two thirds of the patients had response to anti-TNF treatment, no significant difference was seen in between agents. Half of the patients has fistulising disease and fifty percent of them were non-responder.

Disclosure: Nothing to disclose.

CYTOMEGALOVIRUS INFECTION IN PATIENTS WITH ACTIVE ULCERATIVE COLITIS - A PROSPECTIVE OBSERVATIONAL STUDY

J. Szlak¹, A. Magdziak², A. Mroz³, P. Wieszczy¹, E.S. Zagorowicz¹

¹Maria Skłodowska-Curie National Research Institute of Oncology, Department of Oncological Gastroenterology, Warsaw, Poland,

²Maria Skłodowska-Curie National Research Institute of Oncology, Department of Microbiology, Warsaw, Poland, ³Maria Skłodowska-Curie National Research Institute of Oncology, Department of Pathology and Laboratory Medicine, Warsaw, Poland

Contact E-Mail Address: jakub.szlak@gmail.com

Introduction: The role of cytomegalovirus (CMV) infection and its influence on the course of ulcerative colitis (UC) has been evaluated mostly in retrospective studies with small groups of patients and different definitions of CMV infection.

Aims & Methods: We aimed to prospectively evaluate frequency of CMV infection in hospitalised patients with exacerbation of UC along with subsequent colectomy rate in patients with and without CMV. Frequency of hospitalizations, the need of treatment modification and quality of life were also compared in the two groups.

The study group comprised of consecutive patients admitted to Department of Oncological Gastroenterology between 2016 to 2019 with moderate or severe exacerbation of ulcerative colitis measured by endoscopic and full Mayo score. In every patient tissue samples from colon were subjected to immunohistochemistry (IHC) analysis. Patients were asked to fill in the Inflammatory Bowel Disease Questionnaire (IBDQ).

Follow-up involved out-patients visits, hospitalisations, analysis of available medical records and telephone contact with patients. Relationship between categorical variables was examined with the use of chi-square statistic test or Fisher's exact test depending on the size of subgroups.

Results: The final analysis involved 84 patients who fulfilled the inclusion criteria. The median follow-up in the group was 2,1 years (range 0.3-3.6 years). The CMV IHC result was positive in 16 (19%) cases. Severe endoscopic lesions on index colonoscopy - Mayo score 3 - were more frequent in the CMV IHC positive group as compared in the CMV IHC negative group (81.2% vs 51.5%; $p=0.048$) just as using corticosteroids before the admission (81,2% vs 54.4%; $p=0.015$).

Colectomy was performed in 20 patients (23.8%). There were no difference in colectomy rate between the groups with positive (25%) and negative (23.5%) CMV IHC result($p=1.0$).

Similarly, no significant difference was found in the frequency of hospitalizations and the perceived quality of life in IBDQ. The percentage of patients who subsequently started biological treatment was significantly higher in the CMV IHC negative group than in the group with positive results (58.8% vs 18.8%; $p=0.005$).

Conclusion: Colectomy rate in consecutive patients hospitalized because of UC exacerbation was similar in the group with CMV IHC positive and the group with CMV IHC negative results. Previous steroid treatment and severe colonic mucosal lesions on index endoscopy were more frequent in patients with CMV infection. Routine screening for CMV is not justifiable. Detection of CMV infection in high risk groups and its treatment may prevent escalation of anti-inflammatory treatment.

LOW CONCENTRATION OF CITRATE IN AN ADALIMUMAB FORMULATION DOES NOT IMPACT THE INTENSITY OF INJECTION SITE PAIN: EVALUATION FOLLOWING A SINGLE DOSE OF GP2017, A LOW CONCENTRATION ADALIMUMAB BIOSIMILAR VERSUS HIGH CONCENTRATION ADALIMUMAB CITRATE-FREE FORMULATION IN HEALTHY VOLUNTEERS

J.C. Rondon¹, C. Fey², O. von Richter², J. Fan³, F. Furlan², L. Lemke²

¹Clinical Pharmacology of Miami, LLC, Miami, United States, ²Hexal AG (A Sandoz company), Holzkirchen, Germany, ³Sandoz Inc., Princeton Corporate, Princeton, United States

Contact E-Mail Address: fabrizio.furlan@sandoz.com

Introduction: Multiple factors such as formulation, injection process, injection devices and several patient-related factors contribute to injection site pain following subcutaneous (s.c.) administration of a medicine.¹ There are conflicting results regarding the local tolerance of adalimumab (ADL) formulations containing citrate buffer, thereby creating uncertainties among health care professionals as well as patients.^{1,2}

We compared the local tolerance of SDZ-ADL (GP2017), a low-concentration biosimilar ADL (50 mg/ml) with low citrate (1.2 mM), to a high-concentration (100 mg/ml) citrate-free ADL formulation (HC/CF-ADL) in healthy volunteers.

Apart from the difference in citrate concentrations and presence of saline in GP2017, both the study formulations were composed of the same compounds and were dispersed in identical devices (prefilled syringes).

Aims & Methods: A total of 330 subjects were treated in the study; 168 subjects received a single dose of 40 mg/0.8mL s.c. injection of GP2017 and 162 received a single dose of 40 mg/0.4 mL of HC/CF-ADL. The injection site pain (ISP) was evaluated by the subjects using a Visual Analogue Scale (VAS) of 0-100 mm (representing a range from no pain to unbearable pain) immediately after the injection and at 15- minutes and 4-hours post injection on Day 1. VAS scores between 0-4 mm were considered no pain and 5-44 mm as mild pain.³

Time point	Statistics	HC/CF-ADL N=162	SDZ-ADL N=168
Immediately after injection	Mean (SD)	5.2 (7.35)	7.6 (9.89)
	Median	3.0	4.0
	Min-Max	0-50	0-60
15 Minutes post-dose	Mean (SD)	2.8 (3.01)	3.3 (4.27)
	Median	2.0	2.0
	Min-Max	0-18	0-27
4 Hours post-dose	Mean (SD)	2.8 (3.03)	2.5 (2.48)
	Median	2.0	2.0
	Min-Max	0-15	0-13

The scale of pain at the injection site as assessed on the Visual Analogue Scale (0 mm-100 mm) is between 'no pain' and 'unbearable pain'.

HC/CF-ADL, high concentration/citrate free-adalimumab; N= total number of subjects treated; SD, standard deviation; SDZ-ADL, Sandoz adalimumab

Table 1. Injection Site Pain assessed using Visual analogue scale (0-100mm)

Results: The mean scores for both groups were lower than 10 mm at all time points. Immediately after the s.c. injection, the mean [SD] pain VAS score was comparable between study groups (SDZ-ADL group: 7.6 mm [9.89]; HC/CF-ADL group: 5.2 mm [7.35]). Similarly, at 15-minutes and 4-hours post dose, there was no clinically meaningful difference in the mean pain VAS score in both the study groups (Table 1).

Overall, the ISP was considered as mild immediately after injection. The low mean VAS scores at 15 minutes and 4-hours post injection do not suggest of any ISP.

Conclusion: The ISP was comparable following administration of SDZ-ADL or HC/CF-ADL, showing that there is no impact of a low concentration of citrate buffer on ISP.

DIAGNOSTIC DELAY AND ECONOMIC BURDEN IN IBD: A SINGLE-CENTRE EXPERIENCE IN PATIENTS TREATED WITH BIOLOGICS

A. Todeschini¹, C. Angelini², R. Tessari², A. Ossato², G. Lunardi³, A. Geccherle¹, T. Zuppin², A. Variola¹

¹IRCCS Sacro Cuore Don Calabria, IBD UNIT, Negrar di Valpolicella, Italy, ²IRCCS Sacro Cuore Don Calabria, Hospital Pharmacy, Negrar di Valpolicella, Italy, ³IRCCS Sacro Cuore Don Calabria, Central Laboratory, Negrar di Valpolicella, Italy

Contact E-Mail Address: ale_tode@hotmail.com

Introduction: Inflammatory bowel diseases (IBDs), Crohn's disease (CD) and ulcerative colitis (UC), are chronic and immune-mediated diseases with a relapsing-remitting trend. The overall incidence of these diseases is increasing. However, it is estimated that more than one third of patients experienced symptoms for more than one year before diagnosis. Delay in IBD diagnosis has several clinical, therapeutic and economic implications. Early diagnosis and proper treatment are the cornerstones for improving the standard of care for these patients.

Aims & Methods: This study aims to evaluate the diagnostic delay in patients with IBD and to analyze the clinical and economic burden of the delay in IBD diagnosis in patients treated with biological drugs. An observational and retrospective study was performed in IBD patients, regularly followed in our IBD Unit. Data regarding delay in IBD diagnosis were assessed through a questionnaire evaluating the disease course. Moreover, data about biologics dispensation were obtained from the medical records in the period 2014-2020.

Results: 606 IBD patients were enrolled. The median delay in IBD diagnosis was 5.0 months (IQR:1.0 11.0); it was statistically lower in UC patients (4 months (IQR: 1.0 12.0)) compared to CD (6 months (IQR: 2.0 12.0)) (p =0.041). Of these 606, 229 patients were treated with biological therapy; in this subgroup 58.9% showed a diagnostic delay. The statistical analysis showed that the diagnostic delay was statistically significant associated with biological drugs (p=0.041).

Conversely, there was no association with surgical treatment. Moreover, it has appeared that the diagnostic delay is associated, with a trend of statistical significance, with need to switch or swap to other biologics (p=0.058).

Regarding economic burden, patients with delayed diagnosis have significantly higher median annual cost of biological therapy than patients without diagnostic delay (€7179.26 vs € 5131.51 $p=0.009$).

Conclusion: The diagnostic delay in IBD represents a challenge with clinical, therapeutic and economic impact.

It's crucial to cooperate with general practitioner and gastroenterologists not dedicated to IBD in order to reduce the diagnostic delay and guarantee an effective, appropriate and early treatment that will improve the patients' quality of life and meanwhile reduce the health care system costs.

COMPARATIVE OUTCOMES AND SAFETY OF BUDESONIDE-MMX VERSUS PREDNISOLONE FOR ULCERATIVE COLITIS AND POSSIBLE GENETICAL PREDICTORS OF SIDE-EFFECTS

T. Resál¹, K. Mangó², P. Bacsur³, K. Szántó³, Á. Milassin³, M. Rutka⁴, A. Balint³, S. Zoltán³, K. Farkas³, K. Monostory², T. Molnár⁵

¹University of Szeged, I. st Department of Internal Medicine, Szeged, Hungary, ²Eötvös Loránd University, Budapest, Hungary, ³University of Szeged, Department of Medicine, Szeged, Hungary, ⁴University of Szeged, Department of Internal Medicine, Szeged, Hungary, ⁵University of Szeged, Department of Internal Medicine, Szeged, Hungary

Contact E-Mail Address: resal.tamas@med.u-szeged.hu

Introduction: Budesonide-MMX is an orally administered topically active corticosteroid, with high first-pass metabolism through the cytochrome P450 isoenzymes CYP3A4 and CYP3A5, resulting in a favourable side effect profile. Nevertheless, a number of patients treated with budesonide-MMX faced with systemic steroid side effects. CYP3A5*3 and CYP3A4*22 genotypes result in decreased, while CYP3A5*1 and CYP3A4*1B genotypes result in increased expression.

As increased metabolism result in higher degradation of the budesonide-MMX, it may potentially cause lower efficacy. Budesonide-MMX homogeneously releases the active drug along the whole colon, resulting in wider range of usage in mild-to moderate UC.

Aims & Methods: We aimed to compare the safety profile of the budesonide-MMX with orally administered methylprednisolone focusing on endocrine, mineral, bone and lipid metabolism and change in body composition.

Our second goal was to assess difference in the efficacy of disease extents of UC, in addition, how the different CYP genotypes affect the efficacy and safety profile of the treatment.

This was an observational prospective cohort study conducted at our tertiary center. Inclusion criteria was mild to moderate IBD. Oral budesonide-MMX 9 mg was administered until 8 weeks, and oral methylprednisolone (tapered by 4 mg per week from a maximum dose of 1 mg/bwkg) over an 8-to 12-week period. Blood tests were obtained and body composition was measured at inclusion and after 8 weeks of the therapy.

Electrolytes, cholesterol, triglyceride, CRP, beta-crosslap, leukocyte and serum hormone levels (cortisol, dehydroepiandrosterone [DHEA], DHEA-sulfate, osteocalcin) were monitored to follow metabolic and hormonal changes. In addition, CYP450 (CYP3A5 and CYP3A4) enzyme genotypes were assessed in the budesonide group.

Results: In total, 58 IBD patients were included in our prospective cohort study, 19 patients (68.4% UC) received orally administered methylprednisolone and 39 UC patients budesonide-MMX. In total, 31.6% UC patients had pancolitis, and 50% of the CD patients had colonic disease. In both groups the clinical indices decreased following the treatment regimen ($p<0.05$). Budesonide-MMX is effective in all extents of UC ($p<0.05$). Follow-

ing the budesonide-MMX treatment, the cortisol ($p<0.001$), DHEA ($p<0.05$) and DHEAS ($p<0.001$) levels decreased, while cholesterol increased ($p<0.001$). No further significant difference was observed. DHEA was lower in the methylprednisolone group ($p<0.001$) compared to budesonide-MMX, while beta-crosslap ($p<0.05$), weight gain ($p<0.05$), and increase in BMI was higher ($p<0.05$).

In the budesonide-MMX group no adverse event was observed, while in the methylprednisolone group 3 patients (15.7 %) developed Cushingoid appearance. 3 patients have CYP3A5*1/*3 genotype, and 16 have CYP3A5*3/*3, and no significant difference was observed among them. Only 1 patient have CYP3A4*1B genotype, while the rest have CYP3A4*1, hence, no statistics could be performed.

Conclusion: Budesonide-MMX is an effective treatment in mild-to moderate UC, regardless of the extensions. In addition, as budesonide have systemic steroid effects, the administration of the drug should be with more precaution, even though it has been shown to be safer than methylprednisolone. Due to the small number of patients and genetic homogeneity, further data is required to assess the role of CYP genotypes.

EFFECTS OF AN ESTABLISHED SPECIALIST INFLAMMATORY BOWEL DISEASE NURSING SERVICE ON PATIENT OUTCOMES, QUALITY OF CARE AND HEALTHCARE COSTS

N. Yu¹, K. Wu¹, T. Samyue¹, S. Fry¹, A. Stanley¹, A. Ross¹, R. Malcolm¹, W. Connell^{1,2}, E. Wright^{1,2}, N.S. Ding^{1,2}, O. Niewiadomski¹, M. Lust¹, J. Schulberg^{1,2}, E. Flanagan^{1,2}, M.A. Kamm^{1,2}, C. Basnayake^{1,2}

Contact E-Mail Address: natalieyu24@gmail.com

Introduction: Inflammatory bowel diseases (IBD) are complex chronic gastrointestinal conditions that are best managed by a multidisciplinary team in a dedicated IBD service. Within this team, specialist IBD nurses play a critical role in supporting the delivery of high quality patient care. Despite this, few studies have examined the impact of an IBD nurse service on patient outcomes, particularly in the modern biologic era.

Aims & Methods: Our study aimed to evaluate the effects of our IBD nursing service on patient outcomes, quality of care and healthcare costs. We performed a retrospective audit of all IBD nurse encounters with patients, documented over a 12-month period from 1 October 2020 to 30 September 2021 at a tertiary referral centre. The IBD unit employs 3.2 full time equivalent specialist IBD nurses, including a nurse practitioner, who support a team of 13 IBD subspecialist gastroenterologists. Each IBD nurse encounter was classified in terms of the context in which it occurred, activity performed and outcome it led to.

All encounters were assigned to one context, but some encounters were assigned to multiple activities and outcomes. An economic analysis was performed to estimate cost savings to the health service.

Results: There were 2537 IBD nurse encounters (53% female, median age 38 years, 70% Crohn's disease, 77% on biologic drug therapy) with 682 patients (median 3 encounters each). 41% of encounters were IBD nurse-initiated contacts with patients, 34% were patient-initiated contacts with the IBD nurse helpline (26% via email, 8% via phone), 21% were therapeutic drug monitoring follow-up contacts with patients, 3% were gastroenterologist or doctor-initiated contacts with IBD nurses and 1% were patient contacts through the IBD nurse practitioner outpatient clinic. IBD nurse contacts most commonly involved clinical assessments (66%), providing

education, counselling or updates about the patient's disease, investigations or therapy (47%) and reviewing investigation results (38%). Many encounters involved biologics-related activities (30%), organising investigations (30%) and preventive care assessments (20%).

A gastroenterologist was consulted for advice in 35% of contacts. Interventions by the IBD nurses led to the avoidance of 29 emergency department (ED) visits, 1944 outpatient clinic (OPC) visits and 118 general practitioner (GP) visits, representing an estimated AUD \$956,441.32 saved.

After deducting costs of the IBD nurse service, a net estimated saving of AUD \$579,202.13 was achieved. IBD nurse contacts also led to four direct ward admissions, 30 ED visits advised, 86 OPC visits expedited and 374 GP visits advised. They facilitated faster access to investigations (29%), improved patient knowledge (28%), supervision of biologics (25%), medication changes (19%), preventive care recommendations (17%), flare or symptom management (13%) and faster access to allied clinicians (2%). Of the 318 patients who had a preventive care assessment, IBD nurses recommended pneumococcal vaccinations in 72%, skin cancer screening in 66%, bone density testing in 53% and flu vaccinations in 47%.

Conclusion: An IBD nurse service provides significant value in improving patient outcomes, quality of care, and reducing healthcare costs. This study supports the expanding role of IBD nurses in the modern biologic era and the need for greater funding and integration of IBD nurses into specialised IBD clinical services.

Introduction: Bowel urgency (BU; sudden or immediate need to have a bowel movement) is a common and burdensome symptom for patients with ulcerative colitis (UC)^{1,2}.

BU was assessed in mirikizumab (miri; an IL-23p19inhibitor) Phase 3 LUCENT studies in moderately to severely active UC (NCT03518086, NCT03524092) using the validated Urgency Numeric Rating Scale (UNRS). UNRS measures BU severity in the past 24 hours from 0 (no urgency) to 10 (worst possible urgency)².

Psychometric evaluation of the UNRS showed Clinically Meaningful Improvement (CMI) is ≥ 3 point change; Remission is a score of 0 or 1³. This analysis evaluated the proportions of patients in LUCENT studies achieving BU CMI and BU Remission.

Aims & Methods: The modified intent-to-treat (mITT) population (patients receiving ≥ 1 dose of miri or placebo (PBO); N= 1281) was randomized at induction study baseline in a 3:1 ratio to IV doses of 300mg miri or PBO every 4 weeks (Q4W) during induction (W0, 4, and 8).

Patients achieving Clinical Response, measured by Modified Mayo Score (MMS), to miri during induction were re-randomized at W0 of the maintenance study in a 2:1 ratio to subcutaneous (SC) 200mg miri or PBO Q4W through W40 (52 weeks of treatment). Patients recorded their UNRS score daily in an e-diary. Mean weekly UNRS scores were calculated from diary

data if ≥ 4 days of data were available. Rates of BU CMI and BU remission in the miri v PBO groups were compared at W12 (induction) in the mITT population with a baseline UNRS score ≥ 3 , and W52 (maintenance) among miri clinical responders at W12 with a baseline UNRS score ≥ 3 . Cochran-Mantel-Haenszel tests with non-responder imputation for missing values were used for all treatment comparisons.

Results: Patient population: mean age 43 years, 60% male, disease duration 7 years; 63.0% left-sided colitis; 36.3% pancolitis; 46.7% moderate disease (MMS 4-6); 53.2% severe disease (MMS 7-9). Significantly higher proportions of miri versus PBO patients achieved BU CMI (48.7% v 32.2%) and BU remission (22.1% v 12.3%) at W12 (both $p < 0.001$; Table) in the induction study. Similarly, at W40 of maintenance, significantly greater proportion of miri patients achieved BU CMI (65.2% v 41.9%) and BU remission (43.3% v 25.7%) compared to PBO among miri induction responders (both $p < 0.001$; Table).

	Induction (W12 Analysis)			Maintenance (W40 Analysis)		
	300mg miri IV N= 868	PBO IV N= 294	P-value	200mg miri SC N= 365	PBO SC N= 179	P-value
Baseline bowel urgency W0 UNRS Score (Mean $\pm$ SD)	6.1 $\pm$ 2.2	6.2 $\pm$ 2.2	-	6.0 $\pm$ 2.2	6.2 $\pm$ 1.9	-
UNRS change from baseline (LSM $\pm$ SE)	-2.6 $\pm$ 0.083 ^a	-1.63 $\pm$ 0.141 ^a	$p < 0.00001^a$	-3.8 $\pm$ 0.139	-2.7 $\pm$ 0.202	$p < 0.001^b$
Bowel urgency clinically meaningful improvement ^c (N [%])	395 [48.7%] ^e	89 [32.2%] ^e	$p < 0.001^a$	219 [65.2%] ^f	72 [41.9%] ^f	$p < 0.001^a$
Bowel Urgency Remission ^d (N [%])	179 [22.1%] ^e	34 [12.3%] ^e	$p < 0.001^a$	158 [43.3%] ^f	46 [25.7%] ^f	$p < 0.001^a$

^aResults previously disclosed at ECCO 2022; D'Haens et al. J Crohn's Colitis. 2022;16(Supplement 1): i028-i029.

^bTreatment comparison is from a mixed model for repeated measures model that contains treatment, baseline value, visit, interaction of baseline value by visit, interaction of treatment by visit, and stratification factors.

^cBowel urgency clinically meaningful improvement is defined as a reduction in the UNRS of ≥ 3 points.

^dBowel urgency remission is an UNRS score of '0' or '1'.

^eComparisons between miri and PBO at W12 are shown for patients with a baseline UNRS score ≥ 3 ; N=811 for 300mg miri and N= 276 for PBO.

^fComparisons between miri and PBO at W40 are shown for miri induction responders with a UNRS score ≥ 3 at baseline; N= 336 for 200mg miri and N=172 for PBO.

^gCochran-Mantel-Haenszel tests with non-responder imputation were used for treatment comparisons.

Abbreviations: miri=mirikizumab IV = intravenous; LSM = least squares mean; PBO = placebo; SC = subcutaneous; SD = standard deviation; UNRS = Urgency Numeric Rating Scale.

Table. Assessment Bowel Urgency Clinically Meaningful Improvement and Remission in Patients Treated with Mirikizumab v Placebo at Weeks 12 and 40.

Conclusion: Miri had a highly significant and clinically meaningful benefit on reducing bowel urgency, one of the most disruptive UC symptoms. The Urgency Numeric Rating Scale usefully quantified the baseline level and change in bowel urgency after treatment across a spectrum of severity.

PERI-PARTUM INFECTIONS AMONG WOMEN WITH INFLAMMATORY BOWEL DISEASE

B. Narkis¹, E. Hadar¹, S. Barbash-Hazan¹, O. Houry¹, V. Shay², J. Ollech², H. Yanai², I. Dotan², I. Avni-Biron²

¹Rabin Medical Center, Helen Schneider Hospital for Women, Petah Tikva, Israel, ²Rabin Medical Center, IBD Center, Division of Gastroenterology, Petah Tikva, Israel

Contact E-Mail Address: irit.biron@gmail.com

Introduction: Pregnant patients with inflammatory bowel diseases (IBD) are frequently treated with immunomodulatory agents and may be at increased risk of adverse outcomes, including peripartum infections.

Aims & Methods: Our aim was to examine the risk for peripartum infections in patients with IBD compared to controls and identify potential risk factors associated with peripartum infections in these patients.

This retrospective cohort study compared peripartum infection rates and associated risk factors between pregnant women with and without IBD. Study population included women attending a dedicated joint maternal-fetal medicine and gastroenterology clinic for pregnant women with IBD between 2012 - 2019 at the Rabin Medical Center in Israel, a major referral center for patients with IBD. For each patient, 5 women without IBD were matched according to the newborn's birth date (± 2 years), age, parity, and body mass index.

Peripartum infection was defined as any one of the following: chorioamnionitis, maternal fever ($>38^{\circ}\text{C}$) detected during labor or post-partum hospitalization, and positive culture taken during the hospitalization.

Results: Overall, 195 pregnant women with IBD (ulcerative colitis - 72 [37%], Crohn's disease - 123 [63%]) were matched with 888 controls. Mean disease duration - 8.4 ± 7.02 years. IBD therapy, used by 81%, included most frequently 5-aminosalicylic acid (44%) and tumor necrosis factor inhibitors (27%).

Peripartum infections were observed in 15 (7.7%) patients, and 49 (5.5%) controls ($p=1.00$).

No medication significantly increased the likelihood of peripartum infection. Cesarean delivery was more likely among women with IBD but was not associated with an increased risk of peripartum infection.

Maternal characteristics	IBD n=195	No IBD n= 888	p-Value
Maternal age, years	32.1 $\pm$ 4.72	32.1 $\pm$ 4.50	0.89
Body Mass Index, Kg/m ²	22.5 $\pm$ 5.08	22.8 $\pm$ 5.3	0.46
Gestational Weight Gain, kg	7.1 $\pm$ 5.68	11.3 $\pm$ 5.50	<0.05
Smoking	12 (6.2%)	37 (4.2%)	0.23
Mode of Conception:			
Controlled Ovarian Hyperstimulation	10 (5.1%)	22 (2.5%)	0.14
Assisted Reproduction	11 (5.6%)	54 (6.1%)	
Nulliparity	72 (36.9%)	338 (38.1%)	0.77
T1DM/T2DM	2 (1%)	79 (8.9%)	<0.05

Data presented as mean $\pm$ standard deviation for continuous variable and as n (%) for categorical variables
 IBD - Inflammatory Bowel Disease
 T1DM/T2DM - Type 1 or Type 2 Diabetes Mellitus

Table 1: Baseline Characteristics.

Conclusion: Peripartum infections were comparable in patients with IBD and controls. This reassuring data augments existing knowledge of obstetrical outcomes in IBD patients and contributes to the discussion between caregivers and patients.

Disclosure: Nothing to disclose.

P0463

IMPACT OF MIRIKIZUMAB TREATMENT ON HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CROHN'S DISEASE: A PHASE 2 STUDY ANALYSIS USING THE SF-36

V. Jairath¹, T. Hibi², L. Shan Chan³, T. Hunter Gible³, H. Carlier³, X. Zhou⁴, M. Protic³, D.T. Rubin⁵

¹Western University & London Health Sciences Centre, Division of Gastroenterology, Ontario, Canada, ²Kitasato Institute Hospital IBD Research and Treatment, Keio University, Tokyo, Japan, ³Eli Lilly and Company, Indianapolis, United States, ⁴Syneos Health, Strategic Resourcing, Clinical Solutions, Morrisville, United States, ⁵University of Chicago Medicine, Chicago, United States

Contact E-Mail Address: vjairath@uwo.ca

Introduction: Mirikizumab (miri), a p19-directed IL-23 inhibitor, showed efficacy in studies of moderately to severely active ulcerative colitis (UC; Phase [Ph]2¹ and 3²) and Crohn's disease (CD; Ph2³). In the Ph2 UC study, miri improved health-related quality of life (HRQoL) assessed by the 36-Item Short Form Health Survey (SF-36)⁴, a patient-completed questionnaire measuring 8 domains (physical/social functioning, mental/general health, role-physical and -emotional, bodily pain, and vitality) and summary physical and mental component scores (PCS and MCS, respectively).

This analysis evaluated miri effects on SF-36 in the Ph2 randomised, double-blind, parallel, placebo (PBO)-controlled study in patients with moderately-to-severely active CD (NCT02891226).

Aims & Methods: *12-Week(W) Induction:* 191 patients were randomized 2:1:1:2 to 4 treatment arms: intravenous (IV) PBO, 200, 600, or 1000mg miri every 4 weeks (Q4W; W0, 4, and 8). *40-W Maintenance:* For miri induction dose, patients achieving ≥1-point improvement in Simple Endoscopic Score for CD (SES-CD) at W12 were re-randomized 1:1 to double-blind maintenance treatment from W12 to W48: continuation of induction IV treatment assignment (IV-IV; N=41) or subcutaneous (SC) 300mg miri Q4W (IV-SC; N=46).

Due to small sample sizes, maintenance IV arms and SC arms were pooled. W12 SES-CD non-improvers (N=30) and patients receiving PBO during induction (N=59) received IV 1000mg miri Q4W from W12 to W48. No statistical comparisons were made between miri treatment groups in the maintenance period. SF-36 was assessed at baseline and at W4,12,16, 24, 32, 44, and 52.

Results: Statistically significant improvement in MCS was observed at W4 (600mg dose level) and at W12 (all dose levels), whereas statistically significant improvements in PCS were observed only at W12 (600 and 1000mg dose levels) compared to PBO (Table).

Though statistical comparisons were not made between treatment groups during maintenance, comparison of mean changes in MCS and PCS suggest that improvements during induction were sustained or further numerically increased with miri maintenance treatment, even in induction SES-CD non-improvers (Table).

Conclusion: These data show that miri treatment improves HRQoL in patients with moderately to severely active CD and suggest an earlier impact on mental compared to physical well being. Maintenance treatment effects were numerically consistent or increased compared to induction effects, even among more refractory patients.

These findings will be validated in the ongoing miri Ph3 CD study (NCT03926130). Proinflammatory signals can induce anxiety and depressive symptoms; better understanding of how the effects of anti-inflammatory treatment on the gut-brain axis may improve mental and physical subjective wellbeing requires additional mechanistic studies⁴.

Induction Period	Mental Component Score (MCS)				Physical Component Score (PCS)			
	PBO (N=64)	200 mg IV miri (N=31)	600 mg IV miri (N=32)	1000 mg IV miri (N=64)	PBO (N=64)	200 mg IV miri (N=31)	600 mg IV miri (N=32)	1000 mg IV miri (N=64)

Introduction: There is a scarcity of data regarding the role of histopathology evaluation in Crohn's disease (CD) and how it relates to endoscopy. Mirikizumab (miri) has shown efficacy in Ph2 studies in CD and ulcerative colitis (UC).

Aims & Methods: We explore the agreement of histologic response and remission with endoscopic outcomes after 12 and 52 weeks of treatment with miri in a phase 2 randomized clinical trial (SERENTIY; NCT02891226) in patients with moderate-to-severe CD. Patients were randomized 2:1:1:2 across 4 treatment arms (PBO, 200, 600, 1000mg miri) administered intravenously (IV) every four weeks (Q4W) at Weeks 0, 4, and 8. Those who received miri and achieved ≥ 1 point improvement from baseline (BL) at W12 in Simple Endoscopic Score for Crohn's Disease (SES-CD) were re-randomized 1:1 into double-blind maintenance to continue their IV dose assignment Q4W (IV/IV) or to 300mg miri SC Q4W (IV/SC); due to small numbers, maintenance IV arms were pooled for analysis. W12 non-improvers and all induction PBO patients received 1000mg miri Q4W from W12 through W52. Biopsies were obtained during endoscopy at W0, 12 and 52 from the edge of the ulcers and the most inflamed mucosa in terminal ileum and 4 colonic segments (ascending, transverse, descending, rectum; N=10/patient, 2 per location with the more severe score used), and scored by central readers blind to study treatment, timepoint, and response status. Histologic endpoints were defined post-hoc but prior to performing the analyses (see Table footnotes for definitions). Cohen's Kappa Coefficient was used to evaluate the degree of agreement of two measures.

Results: At Week 12, there was an overall 69.6% agreement in histologic and endoscopic response, and 84.2% agreement between histologic remission and endoscopic remission (Table). After 52 weeks of miri treatment, the agreement between histologic and endoscopic response was 61.9%, while the agreement between histologic and endoscopic remission was 70.6% (Table).

Interestingly, in every comparison, the percentage of patients achieving the histologic outcome but not the endoscopic outcome was greater than that of patients achieving the endoscopic outcome but not the histologic outcome.

	Histologic Response					Histologic Remission			
	Week 12 N=158		Week 52 N=126			Week 12 N=158		Week 52 N=126	
	Values n (%)		Values n (%)			Values n (%)		Values n (%)	
Endoscopic Response	No	Yes	No	Yes	Endoscopic Remission	No	Yes	No	Yes
No	72 (45.6)	36 (22.8)	29 (23.0)	24 (19.1)	No	122 (77.2)	19 (12.0)	72 (57.1)	20 (15.9)
Yes	12 (7.6)	38 (24.1)	23 (18.3)	50 (39.7)	Yes	6 (3.8)	11 (7.0)	17 (13.5)	17 (13.5)
Endpoint agreement*	110 (69.6)		79 (62.7)		Endpoint agreement*	133 (84.2)		89 (70.6)	
K coefficient (95% CI)	0.38 (0.24, 0.52)		0.23 (0.06, 0.40)		K coefficient (95% CI)	0.38 (0.19, 0.57)		0.28 (0.09, 0.46)	

*Endpoint agreement = where endoscopic and histologic response or endoscopic and histologic remission have the same value (NO or Yes for both). Assessed by Cohen's Kappa coefficient. Histologic response: absence of neutrophils in lamina epithelia, absence of epithelial damage, erosions and ulceration or decrease of either RHI or active GHAS (sum Q1, 4, 5, 6 >0) of $\geq 50\%$. Histologic remission: absence of mucosal neutrophils (epithelium and lamina propria), epithelial damage, erosions, and ulceration (GHAS Q1=Normal, GHAS Q4=Normal, GHAS Q5=Absent, and GHAS Q6=No or sum of RHI Q2-4 = 0 when total RHI ≤ 3 .)

Table: Association of histologic and endoscopic endpoints at Week 12 and Week 52

Conclusion: Histologic and endoscopic outcomes demonstrated fair association after both 12 and 52 weeks of miri treatment. Histologic endpoints, despite the stringent criteria, appear to be more sensitive to change than endoscopic endpoints. However, variability of biopsy sampling may be an additional factor contributing to these differences.

Introduction: Inflammatory bowel diseases (IBD), comprised of Crohn's disease (CD) and ulcerative colitis (UC), are chronic inflammatory disorders of the gastrointestinal tract. Patients with IBD commonly suffer from symptoms that impact quality of life (QoL) parameters such as pain, fatigue, and stress.

Physical activity has positive effects on general well-being and stress; and may modify perceived pain, stress, sleep quality, and bowel circadian rhythm. In particular, physical activity that target the abdomen may assist in intestinal blood flow and therefore is thought by some to positively affect patient-reported outcomes. However, the effect of routine physical activity on disease measures and patient's QoL is currently unknown.

Aims & Methods: The aim of this pilot study was to examine the effect of routine, abdominally targeted, physical exercise sets, designed exclusively for IBD patients, on patients' QoL and clinical response.

Methods: This is a randomized, controlled, double-blinded pilot study that assessed the effect of a set of specific abdominally targeted physical exercises, in comparison to a control exercise regimen, on patient's clinical disease activity and QoL. A set of three repeating videos of exercises, sequenced and performed by a trained and experienced yoga instructor, were available online for patients to follow daily from their home. Each exercise regimen included explicit drills inspired by yoga poses, postulated to increase blood flow to the abdomen. Before and after a 1 month intervention, patients were assessed for disease activity using the Harvey Bradshaw Index (HBI) or simple clinical colitis activity index (SCCAI), and for QoL by the PROMIS questionnaire.

Results: The study included 19 mild-moderate patients with IBD (9 CD, 10 UC), mean age 21.7±4.2 years, randomized to perform either intervention (n=12) or control (n=7) set of exercises. No differences were observed

between groups at baseline in clinical or demographic parameters. Upon completion, patients training with the interventional videos, but not with the control videos, reported significant improvements in clinical scores. Among patients with CD in the interventional arm, the HBI score decreased from 6.3±0.8 to 2.8±0.4 (p<0.05), while in the control group, the average HBI score remained unchanged (5.3 ±0.2 and 5.3 ±0.4). Similarly, in patients with UC in the interventional group, SCCAI score decreased significantly from 4.7±0.7 to 2.5±0.7 (p<0.05), while in the control group SCCAI decreased from 5.7±0.9 to 4.0±0.8 (p=NS).

Correspondingly, among patients in the interventional group, significant improvements in several QoL parameters were detected after 1 month of training. Thus, the number of daily liquid stools (2.8±0.6 vs. 1.2±0.5, p<0.01), self-perceived pain intensity (3.8±1.0 vs. 1.3±0.6, p<0.001) and fatigue score (13.0±1.1 vs. 9.1±1.6, p<0.05) were all improved after 4 weeks of participation in the study. This is in contrast to the control group where no significant change occurred in these symptoms after 4 weeks of daily exercises: number of daily liquid stools (2.6±0.7 vs. 2±0.6, p=NS), self-perceived pain intensity (3.7±0.8 vs. 3.1±0.6, p=NS), or fatigue score (13.6±0.7 vs. 11.8±0.6, p=NS). No differences were observed in sleep disturbances between the two groups.

Conclusion: Routine, abdominally targeted, physical activity can significantly improve IBD clinical scores and symptoms. Despite our small cohort and short duration of study, these preliminary results suggest a positive effect of physical exercise in IBD and prompt further study.

Introduction: Patients with Inflammatory Bowel Disease (IBD) frequently receive immunomodulating treatment, which may render them at increased risk of an attenuated immune response upon vaccination. In this study, we assessed the effects of different types of commonly prescribed immunosuppressive medications on the serological response after vaccination against SARS-CoV-2 in patients with IBD.

Aims & Methods: In this prospective observational cohort study, IgG antibody titers against SARS-CoV-2 were measured 2-10 weeks after completion of standard vaccination regimens in patients with IBD. Clinical characteristics, previous history of SARS-CoV-2 infection, type of vaccine (mRNA- or vector-based) and medication use were recorded at the time of sampling. Subsequently, a chemiluminescent microparticle immunoassay was used for the quantitative determination of IgG antibodies against the receptor-binding domain (RBD) of the S1 subunit of the spike protein of SARS-CoV-2.

Results: Three hundred and twelve (312) patients with IBD were included (172 Crohn's disease [CD] and 140 ulcerative colitis [UC]). Seroconversion (defined as titer of >50 AU/ml) was achieved in 98.3% of patients. Antibody concentrations were significantly lower in patients treated with TNF-α-antagonists vs. non-users of TNF-α-antagonists (geometric mean [95% confidence interval]: 2204 [1655-2935] vs. 5002 [4089-6116] AU/ml,

$P < 0.001$). In multivariable models, use of TNF- α -antagonists ($P < 0.001$), vector vaccines ($P < 0.001$), age (> 50 years) ($P < 0.01$) and CD ($P < 0.05$) were independently associated with lower anti-SARS-CoV-2 antibody titers. In patients who received mRNA vaccines, users of thiopurines (either prescribed as monotherapy or in combination with biologicals) demonstrated significantly lower antibody titers compared to those who were thiopurine non-users ($P < 0.05$).

Conclusion: Despite reassuring findings that most patients with IBD have detectable antibodies after anti-SARS-CoV-2 vaccination, TNF- α -antagonists were found to be strongly associated with an attenuated IgG antibody response after vaccination against SARS-CoV-2, independent of vaccine type, the time elapsed after vaccination and blood sampling, prior SARS-CoV-2 infection and patient age. Patients treated with thiopurines and receiving mRNA-based vaccines demonstrated lower anti-SARS-CoV-2 antibody titers compared with non-users. This specific subgroup of patients treated with TNF- α -antagonists may benefit from active booster vaccine prioritization, preferably with mRNA-based vaccines.

Disclosure: Gerard Dijkstra received research grants from Royal DSM and speaker's fees from Janssen Pharmaceuticals, Takeda, Pfizer and Abbvie. Introduction: Inflammatory bowel disease (IBD) is characterized by the activation of proinflammatory cytokines such as tumor necrosis factor- α (TNF). TNF antagonists have shown a radical transformation in the management of IBD. However, there is a substantial number of patients who do not respond to anti-TNF agents, and many patients experience a loss of response over time. It is vital to differentiate these responders and non-responders from the initiation of treatment as the reason for failure and their treatment strategies differ.

Aims & Methods: Methods: Formalin-fixed, paraffin-embedded (FFPE) mucosal biopsies of IBD patients with the luminal disease, collected at the time of initiation of biologics were used in this study. Samples were stratified into three groups according to treatment response: Responders

(treated with anti-TNF for a minimum of 3 years with no relapse of disease), Primary non-responders (PNR, relapse within the first year of treatment), and Secondary non-responders (SNR, minimum 3 years of treatment with no relapse, then subsequent loss of response). Discontinuation of the treatment for the sample cohort was not due to the formation of anti-drug antibodies or any other side effects.

TNF mRNA was analyzed in tissue sections by RNAscope in situ hybridization (ISH). The ISH signal dots were seen in both lamina propria and in lymphoid follicles (LF) and were measured by image analysis. TNF mRNA expression estimates were obtained as area fractions with and without LF.

Results: Significant differences in the TNF mRNA levels were observed between adults and children in analysis with and without LF ((Median values for adults and children with LF are 0.17 and 0.09 ($P = 6.82 \times 10^{-3}$) and without LF are 0.13 and 0.09 ($P = 0.03$)). In children, we found a significant difference in TNF levels between responders and SNRs in areas without LF, (Median values for Responders and SNRs are 0.07 and 0.17 ($P = 0.05$)), and between PNRs and SNRs (Median values for PNRs and SNRs are 0.07 and 0.17 ($P = 0.05$)).

Conclusion: It is concluded that TNF mRNA levels are higher in adult's than children's IBD tissue, that the contribution to the expression is not linked to LF in children, and that SNR among children has higher TNF mRNA levels than responders and PNR.

Estimating the level of local TNF mRNA prior to anti-TNF treatment may help stratification of the IBD patients into dosage-regulated groups. It is suggested that TNF antagonist dose intensification is considered for children with high TNF mRNA expression estimates from the start of treatment.

Disclosure: Nothing to disclose.

Introduction: Mirikizumab (miri) is a humanized immunoglobulin G4 (IgG4) monoclonal antibody directed against the p19 subunit of IL-23 which was efficacious and well tolerated in a phase 2 randomized clinical trial (AMAG; NCT02891226) in patients with Crohn's disease (CD).¹ Fatigue is common in patients with CD and negatively impacts quality of life.² We

previously reported that fatigue improved in patients with CD receiving miri in the AMAG study in all treatment arms.³ The association between changes in clinical and inflammatory markers and changes in fatigue might reveal the mechanism of fatigue relief.

Aims & Methods: Patients (N=191) with moderately to severely active CD were randomized 2:1:1:2 into 4 treatment arms (placebo, 200 mg, 600 mg, and 1000 mg miri), administered intravenously every four weeks at Weeks (W) 0, 4, and 8. At W12 patients were switched from placebo to miri and re-randomized between miri doses based on response.

Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) questionnaire, which has been validated for use in patients with inflammatory bowel disease.

Endoscopic response was defined as $\geq 50\%$ reduction from baseline in total Simplified Endoscopic Activity Score for Crohn's Disease. For continuous variables, Pearson's correlation coefficients, 95% confidence intervals, and p-values were calculated. Cohen's conventions were used to assess strength of correlations (>0.5 is strong, 0.3 to ≤ 0.5 is moderate, 0.1 to <0.3 is weak, and <0.1 is insubstantial).⁴

Analysis of covariance was used to assess the relationship between change in FACIT-F and endoscopic response at the same timepoint adjusting for baseline FACIT-F values. Data were pooled for all treatment arms including placebo.

Results: Overall, mean change in FACIT-F scores for patients with and without endoscopic response at W12 were 8.1 and 7.2, respectively ($p=0.33$) and at W52 were 13.9 and 13.7, respectively ($p=0.54$). At W12, change in FACIT-F showed a moderate but statistically significant correlation with change at the same timepoint in Crohn's Disease Activity Index (CDAI) total score ($r=-0.404$), abdominal pain ($r=-0.380$), and stool frequency ($r=-0.354$). Weak but statistically significant correlations were observed with calprotectin ($r=-0.269$), and C-reactive protein ($r=-0.165$) (Table).

At W52, change in FACIT-F was moderately but significantly correlated with change in CDAI total score, abdominal pain, and stool frequency (Table).

Clinical Measure	Week 12 (N=191)			Week 52 (N=176)		
	Pearson corr.	95% CI	p-value	Pearson corr.	95% CI	p-value
Total Score						
CDAI	-0.404	(-0.530, -0.259)	<0.0001	-0.492	(-0.614, -0.346)	<0.0001
SES-CD	-0.146	(-0.290, 0.004)	0.0572	-0.076	(-0.238, 0.090)	0.3702
Hematocrit (%)	-0.039	(-0.194, 0.119)	0.6319	0.152	(-0.016, 0.312)	0.0756
Hemoglobin	-0.011	(-0.167, 0.145)	0.8916	0.120	(-0.049, 0.282)	0.1638
Fecal calprotectin (log)	-0.269	(-0.419, -0.105)	0.0015	-0.175	(-0.342, 0.003)	0.0544
C-reactive protein (log)	-0.165	(-0.310, -0.013)	0.0331	-0.151	(-0.310, 0.016)	0.0756
Abdominal pain average score	-0.380	(-0.504, -0.240)	<0.0001	-0.438	(-0.565, -0.292)	<0.0001
Stool frequency average score	-0.354	(-0.481, -0.212)	<0.0001	-0.290	(-0.437, -0.128)	0.0006

Table. Correlation of change in FACIT-F with change in clinical measures

Abbreviations: CDAI=Crohn's Disease Activity Index; corr=correlation; N=number of patients in the analysis (including patients with non-missing change scores); FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue; SES-CD=Simplified Endoscopic Activity Score for Crohn's Disease.

Table.

Conclusion: Considering the limitation of the posthoc analysis and design of this Phase 2 trial, improvements in fatigue were significantly associated with improvement in CDAI score, abdominal pain, and stool frequency

in patients with CD. Although fatigue has been hypothesized to be mediated in part by inflammatory cytokines,⁵ our data showed no consistent relationship of improvement in fatigue with changes in objective markers of disease activity, suggesting the possibility of alternative or additional mechanistic processes for fatigue in CD.

Introduction: Although adalimumab (ADM), golimumab (GOL), infliximab (IFX), tofacitinib (TFC), ustekinumab (UST) and vedolizumab (VDZ) have been shown efficacious for the treatment of moderate-to-severe ulcerative colitis (UC), data for ulcerative proctitis (UP, inflammation up to 15cm from the anal verge) are scarce.

Aims & Methods: We conducted a multicentric retrospective study in patients with active UP (Mayo endoscopy sub-score of ≥ 2) in order to evaluate the outcome of biological therapy (ADM, GOL, IFX, UST, and VDZ) and small molecules (TFC). The total Mayo score was available both at baseline and at week 20. The primary endpoint was steroid-free clinical remission at week 20 without prior need for dose optimization. Clinical remission was defined as a total Mayo score ≤ 2 with no individual sub-score >1 . Next, we evaluated discontinuation-free survival. We collected demographic, clinical, biochemical, endoscopic and treatment-related data, and evaluated their relationship with both short- and long-term outcome. Both binary logistic and Cox regression analysis were performed for the overall cohort as well as for the bio-naïve patients.

Results: In total 168 consecutive patients (48% male, median age 41 (IQR 32-53) years) undergoing 225 courses of therapy for UP (38 ADM, 15 GOL, 54 IFX, 10 UST, 99 VDZ, 9 TFC) in 19 centres between February 2005 and October 2021 were included. Forty percent of the patients (68/168) had a more extensive disease in the past, and 137/168 (81.6%) patients were bio-naïve.

At baseline, the median (IQR) total Mayo score was 8 (7-9) and 44.9% had an endoscopic Mayo sub-score of 3. At week 20, 34.7% patients (78/225) achieved the primary endpoint of steroid-free clinical remission without prior need for dose optimization.

In multivariate analysis, treatment with vedolizumab, a normal baseline CRP and a Mayo endoscopic sub-score of 2 (vs. 3) were associated with the primary endpoint (Table 1).

In the subpopulation of bio-naïve patients, vedolizumab and a Mayo endoscopic sub-score of 2 (vs. 3) were the only independent factors associated with the primary endpoint. After a median (IQR) follow-up of 15.8 (5.0-37.9) months, 112/225 (49.8%) had discontinued the advanced therapy. In multivariate analysis, discontinuation-free survival was significantly higher in patients treated with vedolizumab, both in the overall cohort as in bio-naïve patients.

In the overall cohort, patients who never had a more extensive disease also had a better discontinuation-free survival. Only three patients developed a serious adverse event related to the advanced therapy, namely one tuberculosis infection, one pneumonia and one infusion reaction.

	Overall cohort (n=225)		Bio-naïve (n=137)	
	Primary endpoint Odds ratio (95% CI), p-value	Discontinuation-free survival Odds ratio (95% CI), p-value	Primary endpoint Odds ratio (95% CI), p-value	Discontinuation-free survival Odds ratio (95% CI), p-value
Vedolizumab	3.20 (1.75-5.85), p<0.001	2.03 (1.36-3.05), p<0.001	4.86 (2.29-10.34), p<0.001	2.02 (1.15-3.57), p=0.015
Normal baseline CRP	2.12 (1.00-4.48), p=0.049	-	-	-
Baseline Mayo endoscopic sub-score 2 (vs. 3)	1.88 (1.02-3.48), p=0.044	-	2.40 (1.11-5.18), p=0.026	-
Never more extensive disease	-	1.63 (1.12-2.36), p=0.010	-	1.49 (0.91-2.43), p=0.114

Table 1: Independent predictors of steroid-free clinical remission at week 20 (primary endpoint) and discontinuation-free survival in the overall population and patients who were bio-naïve

Conclusion: Biological therapies and small molecules are a safe treatment for patients with UP. At week 20, one third of patients achieved steroid-free clinical remission rate without prior need of dose optimization. Half of the patients continued the drug after a median follow-up of 16 months. Vedolizumab was the only independent predictor of both short- and long-term outcome.

Introduction: Crohn's disease (CD), an inflammatory bowel disease, is usually treated pharmacologically, but lifetime risk for surgical interventions due to complications such as fibrostenotic lesions or perforations remains high. The rate of postoperative recurrence (POR) in patients with Crohn's disease (CD) is reported in up to 75% within the first year after surgery and remains of significant importance despite novel therapies.(1) According to current guidelines, thiopurines and anti-tumor necrosis factor (anti-TNF) therapy should be administered depending on risk factors, including histological findings as well as other patient characteristics, to prevent POR.(2) However, the benefit of such preventive immunosuppressive therapy has been questioned lately.(3,4)

Thus, we set out to evaluate the effect of novel immunosuppressants on postoperative endoscopic recurrence rates in two high-volume referral centers.

Aims & Methods: In this real life multicenter study, we assessed the effectiveness of currently available immunosuppressive therapy to prevent endoscopic POR after surgery due to CD complications. We collected data from 328 patients after surgery between 01/2010 and 12/2021 at two referral centers (Medical University of Vienna and Klinik Landstrasse, Vienna) of which 151 (46%) patients had available endoscopy results. Endoscopic-POR (E-POR) was defined as occurrence of endoscopically detected disease activity according to the Rutgeerts' score (i2-i4).(3)

Results: In total, 87 (57.6%) patients had received at least one conventional immunosuppressant and/or biological, including azathioprine or anti-TNF agents (table 1) starting directly after surgery. Additional intermittent systemic corticosteroids were necessary in a total of 28 (8.5%) patients. In total, E-POR was found in 69 (45.7%) patients.

In terms of immunosuppressive therapy, the lowest rate of E-POR was observed in 19/44 (43.2%) patients who received anti-TNF therapy, followed by n=4/9 (44.4%) patients with combined long-term immunosuppressants, n=7/15 (46.7%) ustekinumab, n=1/2 (50%) with other medications (6-Mercaptopurine, Mycophenolate mofetil), n=3/5 (60%) vedolizumab, and n=8/12 (66.7%) azathioprine monotherapy.
