In multivariate analysis, neither relatively novel treatments with ustekinumab (adjusted odds ratio, OR 0.83, confidence interval 95% CI: 0.27-2.58, p=0.753) or vedolizumab (OR 0.49, 95% CI 0.08-3.12, p=0.447), nor conventional treatment with anti-TNF therapy (OR 0.96, 95% CI 0.44-2.09),

p=0.918), azathioprine (OR 0.37, 95%CI 0.10-1.34, p=0.128) or other medications (OR 0.73, 95%CI 0.44-12.19, p=0.826) showed a significantly lower or higher risk for E-POR compared to no treatment.

Immunosuppressants	Multivariate odds ratio (95% CI)	p-value
Azathioprine(n=12)	0.37 (0.10-1.34)	0.128
Anti-TNF therapy (n=44)	0.96 (0.44-2.099)	0.918
Ustekinumab (n=15)	0.83 (0.27-2.58)	0.753
Vedolizumab (n=5)	0.49 (0.08-3.12)	0.447
Other medications (n=2)	0.73 (0.44-12.19)	0.826
Combined treatment (n=9)	0.91 (0.22-3.72)	0.898

Conclusion: The rate of E-POR in this retrospective real-life study is comparable to other studies, however, initiating long-term immunosuppression and biological therapies has not been associated with lower risk for endoscopic recurrence. Novel studies are warranted to identify eligible subgroups for specific treatment options.

Introduction: Fecal microbiota transplantation (FMT) has been shown as a highly effective and safe treatment for recurrent clostridium difficile infections (CDI) with reliable and potential role in induction of remission in patients with ulcerative colitis (UC). Washed microbiota transplantation (WMT) is a promising methodology have been applied in China since 2016,

using an automatic purification system (GenFMter), aiming to decrease the processing time for preservation of living bacteria, deliver a precise enriched dose of fecal microbiota and reduce adverse events [1]. Clinical factors that contribute to FMT response in UC need to be widely investigated especially with the limited data about the FMT efficacy in IBD.

Aims & Methods: A protocol of multiple transfusions of WMT through either mid-gut or colonic transendoscopic enteral tubing (TET) was applied to patients with ulcerative colitis in our tertiary referral center. We utilized a promising approach based on a solid data-driven method, data envelopment analysis (DEA) which is a mathematical approach for efficiency evaluation of decision system [2,3].

Recently, DEA has been applied to evaluate the performance of medical procedures and treatment plans [4,5]. In this work, the WMT was evaluated at the patients level by taking into account a combination of WMT's inputs and outputs. The set of inputs in DEA-based analysis were related to patient characteristics, UC disease characteristics including severity, extension, and medications.

Considering patients' response and WMT- related adverse events (AEs) together as outputs, we generated an overall efficiency index to classify the patients based on their relative efficiency performance across the input variables. The supper efficiency DEA model was then applied to rank the patients and thereby to select the best 15% of the patients in order to study their characteristics.

Within the proposed WMT-decision system that retrospectively analyzed the evolution of UC patients treated with WMT, we aimed to identify the specific variables that potentially contribute to the best performance of WMT.

Results: A total of 200 patients received WMT, 85 (42.5%) achieved clinical remission, 80 (40%) had a clinical improvement and 35 (17.5%) failed to achieve response, with related AEs were observed in 31 (15.5%).

Using DEA method, we identified the most efficient patients who achieved clinical remission with minimum adverse events, these patients' and UC characteristics (severity, behavior, extension) are presented in table (1).

We found that 96.6%, 83.3% of patients with the best response to WMT had mild or moderate stage of UC, at the time of WMT, according to clinical and endoscopic Mayo score respectively, with 83.3% of them classified as E1, E2 for UC extension. Mild AEs occurred in 10% (3/30), including mild abdominal pain and fever, all of them were self-limiting, with no serious adverse events.

Characteristics	Results
Age, years, mean ± SD	41.83 ± 17.3
Male Gender, n (%)	18 (60%)
BMI, mean ± SD	20.29 ± 3.23
Mayo clinical score before WMT, mean ± SD	5.20 ± 2.89
Mild	13 (43.3%)
Moderate	16 (53.3%)
Severe	1 (3.4%)
Mayo endoscopic score before FMT, mean ± SD	1.77 ± 0.88
Mild	16 (53.3%)
Moderate	9 (30%)
Severe	5 (16.7%)
Extension of UC, n (%)	
E1, proctitis	12 (40%)
E2, left-sided colitis	13 (43.3%)
E3, pancolitis	5 (16.7%)
Treatment history, n (%)	
5-ASA	26 (86.7%)
Corticosteroid	9 (30%)
Immunosuppressants	1 (3.3%)
Anti-TNF antibody	2 (6.7%)

Table 1.

Conclusion: WMT appears to be a safe and promising therapy for UC patients, taken into consideration the location, clinical and endoscopic severity of UC. Using DEA method to evaluate the impact of clinical factors on FMT could help to identify UC patients who are more likely to response to this therapy.

Introduction: Interleukin-23 (IL-23) is a key inflammatory mediator implicated in the pathogenesis of Crohn's disease (CD). We assessed the efficacy of selective IL-23 and IL-12/23 inhibitors in patients with moderate-to-severe CD.

Aims & Methods: MEDLINE, Embase, and the Cochrane library (CENTRAL) were searched from inception to October 2021 for randomized, placebo- or active comparator-controlled induction and/or maintenance trials of selective IL-23 and IL-12/23 inhibitors in pediatric and adult patients with CD. The primary outcome was the proportion of patients achieving clinical remission. Secondary outcomes were clinical response, endoscopic remission, and endoscopic response. Data were pooled using a random effects model and pooled risk ratios (RRs) and 95% confidence intervals (CIs) were calculated for each outcome.

Results: Eighteen studies (10 induction, 2 maintenance, 6 induction/maintenance) were included. Ten studies assessed IL-12/23 inhibitors (ustekinumab [UST], briakinumab [BRI], and apilimod mesylate [AM]) and eight studies assessed IL-23 inhibitors (brazikumab [BRA], risankizumab [RIS], guselkumab [GUS], and mirikizumab [MIR]).

All studies except two were placebo-controlled; in these studies, two active agents (UST vs. adalimumab) and two doses of the same agent (UST) were evaluated, respectively. Only one study included paediatric patients. Compared to placebo, UST (RR 1.89, 95% CI 1.51-2.35), RIS (RR 1.90, 95% CI 1.55-2.33), GUS (RR 3.40, 95% CI 1.77-6.54), and MIR (RR 2.94, 95% CI 1.30-6.62) were statistically superior for inducing clinical remission (Crohn's Disease Activity Index Score [CDAI] <150). BRI (RR 1.88, 95% CI 1.16-3.30), UST (RR 1.73, 95% CI 1.49-2.01), RIS (RR 1.83, 95% CI 1.56-2.16), GUS (RR 1.69, 95% CI 1.69-4.66), and MIR (RR 2.16, 95% CI 1.31-3.55) were statistically superior to placebo for induction of clinical response (100-point CDAI reduction).

Among the agents assessed for induction of endoscopic remission (UST, RIS, GUS, and MIR), RIS (RR 3.43, 95% CI 2.04-5.77) and MIR (RR 10.0, 95% CI 1.38-73.4) were statistically superior to placebo. Endoscopic response data were available for UST, RIS, GUS, and MIR. A statistically significant difference was observed between RIS (RR 2.86, 95% CI 2.16-3.79), GUS (RR 3.17, 95% CI 1.46-6.92), and MIR (RR 3.46, 95% CI 1.66-7.20) relative to placebo. Maintenance of clinical remission was assessed in five agents (BRI, UST, BRA, RIS, and AM). UST (RR 1.73, 95% CI 1.34-2.23) and RIS (RR: 1.32, 95% CI 1.07-1.63) were statistically superior to placebo for this outcome.

With respect to clinical response (100-point CDAI reduction), UST reached the level of statistical significance (RR 1.46, 95% CI 1.22-1.74) compared to placebo while single studies of AM and BRA failed to show this effect. Maintenance of endoscopic remission was assessed for three agents (BRA, UST, and RIS). RIS demonstrated statistical significance over placebo for this outcome (RR 2.67, 95% CI 1.74-4.11). Endoscopic response data were available from single maintenance studies of BRA (RR 2.02, 95% CI 0.13-30.53), UST (RR 4.17, 95% CI 0.55-31.45), and RIS (RR 2.14, 95% CI 1.57-2.93); only RIS was found to be statistically superior to placebo.

Conclusion: Drugs targeting IL-23 are effective for inducing and maintaining clinical remission in patients with moderate-to-severe CD.

Contact E-Mail Address: anh@surrozen.com

Introduction: WNT/b-catenin signaling promotes intestinal stem cell renewal which is essential for intestinal epithelial homeostasis and regeneration. There is a clear unmet need for agents that directly repair and regenerate the intestinal epithelium for the treatment of ulcerative colitis as mucosal healing has been associated with lower steroid use, reduced hospitalizations and longer-term remission. SZN-1326 is a tetravalent, bispecific antibody that binds specifically to low-density lipoprotein receptor-related protein 6 (LRP6) and Frizzled 5 (FZD5) and/or Frizzled 8 (FZD8). LRP6, FZD5 and FZD8 are expressed across many tissues, but FZD5 receptors are highly enriched on the intestinal epithelium including stem and progenitor cells.

Aims & Methods: The aims of these Good Laboratory Practice (GLP) toxicity studies conducted in Sprague-Dawley rats and cynomolgus monkeys were to evaluate the nonclinical safety and toxicokinetic profile. In both species, SZN-1326 was intravenously (IV) administered once per week for 13 consecutive weeks with a 4-week recovery period at doses of 0-, 3-, 10-, 30- and 75 mg/kg.

An additional group received 30 mg/kg SZN-1326 subcutaneously (SC) once weekly for 13 weeks. Assessments included clinical observations, clinical pathology, histopathology, toxicokinetics (TK), and immunogenicity.

Results: SZN-1326 was well-tolerated with no drug-related adverse effects observed when administered IV or SC. The No Observed Adverse Effect Level (NOAEL) was the highest dosage of 75 mg/kg/week (IV) with no SZN-1326 related adversity observed at 30 mg/kg/week (SC) in both species. Minimal, non-adverse, and reversible decreases in reticulocytes, hemoglobin, hematocrit, red blood cells and platelets and minimal increases in blood urea nitrogen (BUN) were observed in Sprague-Dawley rats. No SZN-1326-related effects in hematology, coagulation, clinical chemistry, or urinalysis were identified in the cynomolgus monkeys. The TK of SZN-1326 was consistent with monoclonal antibodies with serum exposure proportional to dose.

The estimated SC bioavailability in the rat was poor (11%) but good (55%) in the monkey. In both species, the incidence of anti-drug antibodies (ADA's) ranged from ~10 to 50% and had minimal impact on drug exposure except for rats dosed SC.

Conclusion: SZN-1326 has a favorable safety profile in 13-week rat and cynomolgus monkey GLP toxicology studies. The minimal, non-adverse, clinical pathology findings in rats were not correlated with any macro- or microscopic histopathological changes. Thus, the NOAEL is the highest IV administered dosage of 75mg/kg/dose with no SZN-1326 related adversity observed at 30 mg/kg dosed SC.

LONG-TERM TREATMENT PERSISTENCE OF ADALIMUMAB AND USTEKINUMAB IN BIO-NAÏVE PATIENTS WITH CROHN'S DISEASE: A RETROSPECTIVE DATABASE STUDY

A. Biščanin¹, V. Tomasic¹, F. Babić¹, P. Čačić¹, Z. Dorosulic¹, D. Kralj¹, D. Ogresta¹, D. Hrabar¹

¹Sestre milosrdnice University Hospital Center, Department of Gastroenterology and Hepatology, Zagreb, Croatia

Contact E-Mail Address: alen.biscanin@gmail.com

Introduction: Recent head-to-head studies have shown that both adalimumab (ADA) and ustekinumab (UST) are highly effective in treatment of bio-naïve Crohn's disease (CD) patients with similar rates of clinical and endoscopic remission at week 52.

On the other hand, time to treatment discontinuation was longer with UST vs ADA in post hoc analysis. Aim of this study was to provide real-world evidence on long-term comparative persistence among bio-naïve CD patients treated with ADA vs UST for a minimum period of six months.

Aims & Methods: A single-center, non interventional, retrospective cohort review study (January 2015-January 2022) was performed on real-life data of adult bio-naïve CD patients who were treated with adalimumab (160/80 mg SC at BL/W2, then 40 mg SC every 2 Ws) or ustekinumab (6 mg/kg IV at BL then 90mg SC every 12 Ws) for a minimum of 6 months. Patient characteristics were assessed using descriptive statistics.

Continuous variables were analysed using Mann-Whitney test and categorical variables using Chi-square test. Treatment persistence was assessed using Kaplan-Meier analysis and Log-rank test, while Cox proportional hazards regression model was used to identify potential independent predictors of persistence.

Results: A total of 70 bio-naïve participants with CD (47.1% male, median of age 36 (IQR 27.5)) were included in the analysis. The median of disease duration prior to biologic induction was 61 (IQR 112.5) months. Among the studied cohort, ADA was administered in 68.6% of patients. Corticosteroid usage at the start of biologic was observed in 28.6% of participants (without difference between ADA and UST group ($\chi^2(1, N=70)=0.17$, $P=0.68$)). Dose escalation was observed in 39.1% and 27.3% of ADA and UST group of patients respectively (without difference between ADA and UST group ($\chi^2(1, N=68)=0.592$, $P=0.34$)).

There was no significant difference in persistence between ADA and UST ($\chi^2(1, N=70)=0.317$, $P=0.57$). After 36 months, persistence rates for ADA and UST were 61.9% and 76.3% respectively. Statistically significant predictor (BMI, age, gender, disease duration, corticosteroid treatment during the biologic induction period, smoking status) for biologic's discontinuation wasn't found.

Conclusion: In a Croatian real-world setting, after 36 months of treatment, although persistence was numerically higher for UST versus ADA, comparable overall long-term persistence rates were observed in bio-naïve CD patients treated with ADA or UST.

Disclosure: Nothing to disclose.

Contact E-Mail Address: bruce.sands@mssm.edu

Introduction: The inflammatory bowel disease questionnaire (IBDQ) is a measure of health-related quality of life (QoL), with higher scores indicating greater QoL. In a prior phase 2 study (NCT02589665), mirikizumab, an anti-IL23p19 antibody, demonstrated efficacy and improvement in IBDQ scores in participants with moderately to severely active ulcerative colitis (UC).¹

Aims & Methods: This analysis evaluated the effect of mirikizumab vs placebo on IBDQ scores in participants with moderately to severely active UC who had failed prior conventional or biologic therapy in a Phase 3, double-blind, 12-week induction study (LUCENT-1/NCT03518086) followed by a 40-week maintenance study (LUCENT-2/NCT03524092) for a total of 52 weeks of continuous therapy.

Participants (N=1162) in LUCENT-1 were randomized 3:1 to receive 300mg mirikizumab or placebo intravenously once every four weeks (Q4W). Participants (N=544) who achieved Modified Mayo Score Clinical Response to mirikizumab by Week 12 of induction were re-randomized 2:1 in LUCENT-2 to subcutaneous mirikizumab 200mg or placebo Q4W during the maintenance period.

Randomization was stratified by previous biologic therapy failure, baseline corticosteroid use, and region. Additionally, LUCENT-1 stratification included baseline disease activity, and LUCENT-2 included LUCENT-1 clinical remission status. The least squares mean change from baseline in IBDQ scores at Week 12 of induction and Week 40 of maintenance was determined using analysis of covariance models. Baseline was Week 0 of therapy and stratification factors and baseline scores were used as covariates. The Minimal Clinically Important Difference (MCID) was defined as an improvement of ≥16 points in the total IBDQ score (IBDQ response) and IBDQ remission as a total score ≥170 points.²

IBDQ response and remission were calculated using non-responder imputations. Treatments were compared using the common risk difference (risk diff).

Results: Mirikizumab treatment resulted in a significantly greater improvement from baseline in the IBDQ total and domain scores vs placebo at both Week 12 of induction and Week 40 of maintenance (52 weeks of treatment) (Table).

The proportions of participants who achieved an IBDQ response was significantly greater for those treated with mirikizumab vs placebo at Week 12 (risk diff = 17.1 [95% confidence interval: 10.7, 23.5]) and Week 40 (29.5 [21.0, 37.9]). Significantly greater proportions of participants receiving mirikizumab achieved IBDQ remission at Week 12 (18.1 [11.8, 24.4]) and Week 40 (28.5 [20.1, 37.0]) vs placebo (all evaluations and timepoints: p<0.001).

	IBDQ Total Score ¹		IBDQ Response ² Score Improvement ≥16		IBDQ Remission ² IBDQ Total Score ≥170	
	LSM Change from BL (SE)	LSM Diff (SE)	n (%)	Risk Diff (95% CI)	n (%)	Risk Diff (95% CI)
LUCENT-1 Week 12 of Induction						
PBO IV Q4W (N=294)	25.21 (1.80)		164 (55.8)		117 (39.8)	
Miri 300 mg IV Q4W (N=868)	38.42 (1.11)	13.21 (2.01)*	631 (72.7)	17.1 (10.7, 23.5)*	499 (57.5)	18.1 (11.8, 24.4)*
LUCENT-2 Week 40 of Maintenance (52 Weeks of Continuous Therapy) of Miri Induction Responders						
PBO SC (N=179)	24.51 (2.77)		88 (49.2)		77 (43.0)	
Miri 200 mg SC (N=365)	49.75 (2.10)	25.24 (3.09)*	289 (79.2)	29.5 (21.0, 37.9)*	264 (72.3)	28.5 (20.1, 37.0)*

Abbreviations: BL=baseline; CI=confidence interval; Diff=difference; IBDQ=Inflammatory Bowel Disease Questionnaire; IV=intravenous; LSM=least squares mean; Miri=mirikizumab; n=number of patients in the specified category; N=number of patients in the analysis population; PBO=placebo; Q4W=every 4 weeks; Risk Diff=common risk difference; SC=subcutaneous; SE=standard error

¹Inflammatory Bowel Disease Questionnaire domains and total scores were evaluated by analysis of covariance with modified baseline observation carried forward and adjustment for covariates.

²Inflammatory Bowel Disease Questionnaire-based measurements for clinical response and remission were analyzed using non-responder imputation. The common risk difference was the stratification-adjusted difference in the proportion of participants receiving mirikizumab minus the proportion of participants receiving placebo.

*p<0.001

Table. LUCENT-1 and LUCENT-2 Trials Change from Baseline in the Inflammatory Bowel Disease Questionnaire.

Conclusion: Participants with moderately to severely active UC reported significantly greater improvements in IBDQ scores at induction and maintenance with mirikizumab compared to placebo. Over 75% of participants achieved a clinically meaningful improvement in QoL, as measured by IBDQ response, at the end of the 52 weeks of mirikizumab treatment.

LONG TERM SAFETY AND EFFICACY OF THIOPURINES WITHDRAWAL IN IBD PATIENTS

D. Shbita¹, E. Koiffman², D. Ben-Hur², M. Waterman², R. Weisshof²
¹Rappaport Faculty of Medicine, Israel Institute of Technology, Haifa, Israel, ²Rambam Medical Center, Department of Gastroenterology, Haifa, Israel

Contact E-Mail Address: dima.301@hotmail.com

Introduction: The optimal duration of thiopurine treatment for patients with inflammatory bowel disease (IBD) is unknown. Prolonged thiopurine treatment is correlated with risk of lymphoma, skin cancer and infection¹. Conversely, discontinuation of thiopurine treatment may lead to a recurrence of active inflammation².

Aims & Methods: We aimed to assess the safety of discontinuation of thiopurine treatment and discover factors that can predict the outcome of treatment cessation.

This is a retrospective study conducted in a tertiary hospital that included patients with inflammatory bowel disease who discontinued thiopurine treatment during complete clinical remission. All patients included had follow up for at least 2 years. The patients were followed until the last clinic visit or until documented disease relapse defined as requiring introduction of new therapy, dose escalation, rescue therapy with corticosteroids, hospitalization, or surgery.

A Kaplan Meier curve was used for survival analysis. In addition, a uni-variant analysis was performed to determine factors that predict recurrence. P value <0.05 was defined as statistically significant

Results: 46 patients were included in the cohort. 50% males, 80% Crohn's disease. The median age at diagnosis was 25 and at thiopurine cessation 34 (table 1). Eighty percent the patients had concomitant therapy during thiopurines termination and 10.86% had drug related adverse events. After thiopurine withdrawal, 37% of patients experienced a relapse. The median time to relapse among relapses was 15.8 months. Relapse free probability was 95.65% 6 months after treatment withdrawal, 84.7% after one year and 67.3% after 36 months.

One patient was hospitalized after thiopurines termination and two patients required surgery. Current or past smoking, IBD subtype, concomitant anti-TNF therapy, or male gender were not associated with disease relapse after univariate analysis (Hazard ratio [HR] 0.42, 95% confidence interval [CI] [0.12 -1.49], 0.21[0.02-1.62], 1.45[0.46 - 4.49], 1.02 [0.33 - 3.13], and 1.01[0.38-2.64] respectively. All not statistically significant).

Male gender, n (%)	23 (50)
IBD type	Crohn's - 37 (80.4) Ulcerative colitis - 9 (19.6)
Age at diagnosis (median), yr	25
Age at TP end (median), yr	34
Current smoker, n (%)	12 (26)
Disease behaviour Crohn's patients, (%)	inflammatory 12 (32.4) stricture 12 (32.4) penetrating 13 (35.2)
TP treatment duration (median), months	5
Drug related adverse events, n (%)	5 (10.86)
CRP, mg/dL, median (IQR)	0.5 (0.225-1.4)
Calprotectin, median (IQR)	71.9 (44-141)

Table 1: Clinical and Demographic Characteristics of the Population

Conclusion: Thiopurine discontinuation appears safe with most of the patients remaining in remission at 36 months

A PH-SENSITIVE OPIOID PROVIDES SUSTAINED AND SAFE PAIN RELIEF BY TARGETING THE ACIDIFIED LAYERS OF THE INFLAMED COLON

Introduction: Adequate pain control during flares of inflammatory bowel disease relies mainly on opioids whose prevalent and long-term use are limited by serious side effects. Acute administration of a novel pH-sensitive opioid agonist, called NFEPP², was shown to provide analgesic effects in the inflamed acidified colon without immediate opioid typical on-target side effects³.

However, the effects of repeated application of NFEPP during the evolution of acute colitis when tissue-pH can vary remain elusive.

Aims & Methods: Acute colitis in male C57BL/6 mice was induced via 2.5% dextran sulphate sodium (DSS) dissolved in drinking water for 5 days. Mice were then randomly assigned to either vehicle, NFEPP or fentanyl treatment. NFEPP, fentanyl (each opioid at 0.4 mg/kg) and vehicle (0.5% DMSO) were administered s.c. twice daily over 5 days followed by a final injection at day 6. Visceral nociception was assessed by visceromotor responses (VMRs) to colorectal distension at different time points during acute colitis. Gastrointestinal side effects were evaluated using:

1. Oral contrast-enhanced abdominal CT-scans (before/after treatment) and defecation assessments to analyze gastrointestinal transit and functional colon motility in-vivo and;
2. Isometric tension recordings of colonic longitudinal muscle contractile activity in-vitro.

Side effects within the cardiorespiratory system were additionally analyzed based on pulse oximeter measurements.

Finally, inflammation of the colon was examined by combining histological analysis, myeloperoxidase activity assays and whole tissue pH measurements. Selective visualization of acidified microenvironments within the inflamed colon was achieved by using pH low insertion peptides (pHLIP) combined with confocal imaging.

Results: NFEPP decreased VMRs to colorectal distension over the entire course of acute DSS colitis (day 6: 40.5% reduction, $p < 0.001$, $N = 5$, compared to baseline). However, strongest VMR inhibition was observed at day 3 (66.7% reduction, $p < 0.05$, $N = 5$, compared to baseline), consistent with the peak of inflammation (MPO: 4.6 U/mg tissue, $p < 0.001$, $N = 9$; Histo-Damage-Score: 2.7, $p < 0.001$, $N = 9$; colon pH: 6.3, $p < 0.01$, $N = 5$, all compared to healthy control). Treatment with NFEPP had no effect on gastrointestinal transit (GIT: $p = 0.60$, $N = 5$, compared to baseline) and fecal output ($p > 0.99$, $N = 6$, compared to vehicle) whereas fentanyl blocked gastrointestinal motility (GIT: $p < 0.05$, $N = 6$, compared to baseline; fecal output: $p < 0.05$, $N = 6$, compared to vehicle). In-vitro colonic contractile responses induced by electrical field stimulation were reduced in fentanyl treated mice ($N = 9$) compared to NFEPP (10 Hz: $p < 0.05$, $N = 6$).

Visualization of acidified areas within the inflamed colon using pHLIP indicated a decreased pH in the mucosa/submucosa, but less signal in the muscle layer (mucosa/submucosa vs. muscle layer: $p < 0.01$, $N = 8$). These findings were in keeping with little or no effect of NFEPP on the muscle layer and thus no significant effect on colon motility.

Fentanyl reduced blood oxygen saturation (15 min: 85%, $p < 0.01$, $N = 6$, compared to baseline) and caused a sustained reduction in heart rate (60 min: Δ BPM -91.8 from baseline, $p < 0.01$, $N = 6$) at day 2 whereas NFEPP had no effect on oxygen saturation ($p > 0.99$, $N = 6$, compared to baseline) and revealed less effect on heart rate (15 min: Δ BPM -75.6 from baseline, $p < 0.01$, $N = 6$) with a recovery after 60 min ($p = 0.23$).

Conclusion: NFEPP provides in a preclinical mouse model effective and targeted analgesia throughout the course of acute colitis without altering gastrointestinal transit, colon motility and blood oxygen saturation.

Introduction: In the search for new treatment options for ulcerative colitis (UC), exposure to the porcine whipworm *Trichuris suis* ova (TSO) has previously shown a favorable immune response that may improve UC with few side effects. Large phase-2 studies on UC patients treated with TSO are needed.

Aims & Methods: A single-center, randomized, double-blinded, placebo-controlled, phase-2b clinical trial of 7500 TSO compared to placebo, initiated in 2018 and completed in 2022 at Hvidovre Hospital, Copenhagen, Denmark. Moderately active UC patients with Mayo score (MS) 6-10 and fulfilling all in- and exclusions were included from hospitals, through advertisements and referrals.

Primary aim: To demonstrate if oral administration of 7500 TSO every two weeks for 24 weeks compared to placebo could induce clinical remission ($MS \leq 2$).

Secondary aims: Clinical response defined at 24 weeks as:

- i. A reduction in MS (≥ 4 points),

- ii. Complete steroid-free clinical remission ($MS \leq 2$),
- iii. Endoscopic remission (endoscopy sub-score ≤ 1), and;
- iv. Symptomatic remission (stool frequency sub-score ≤ 1 and rectal bleeding sub-score = 0) at 12 and 24 weeks and (v) partial MS over time (week 0-24).

Main outcome measures are presented as risk ratios (RR) with corresponding confidence intervals (CI) and p-values (p).

Results: Out of 207 screened UC patients, we included 119 moderately active UC patients and randomly allocated 1:1 to receive TSO (n=60) or placebo (n=59). Here, intention-to-treat (ITT) analysis (n=119) and complete steroid-free (CSF) subgroup analysis (n=60) are presented.

Primary outcome: At week 24, clinical remission was achieved in 30% of TSO-treated patients compared to 34% of placebo-treated patients (RR=0.89; CI:0.52–1.50; p=0.80, ITT).

Secondary outcomes: At week 24, clinical response showed no differences between TSO and placebo treatment in

- i. Reduction of MS (RR=0.98; CI:0.64–1.52; p=1.00, ITT), (RR=1.19; CI:0.67–2.11; p=0.74, CSF),
- ii. Complete steroid-free clinical remission (RR=1.18; CI:0.60–2.33; p=0.83, CSF),
- iii. Endoscopic remission (RR=1.02; CI:0.68–1.54; p=1.00, ITT), (RR=1.41; CI:0.82–2.43; p=0.30, CSF), or;
- iv. Symptomatic remission (RR=1.31 at week 12; CI:0.95–1.81; p=0.15, ITT), (RR=1.21 at week 24; CI:0.78–1.86; p=0.50, ITT).

However, in the CSF analysis of symptomatic remission, patients treated with TSO were able to induce remission at week 12 (RR=2.09; CI:1.17–3.73; p=0.01) but not at week 24 (RR=1.41; CI:0.82–2.43; p=0.30) and in (v) the analysis of partial MS over time (week 0-24) the TSO group differed from the placebo group (p=0.04, ITT), (p=0.21, CSF).

Surprisingly, in the placebo group, 43% (ITT) and 41% (CSF) achieved endoscopic remission in comparison to 34% (ITT) and 33% (CSF) who achieved clinical remission at week 24.

Harms: The majority of Adverse Events (AEs), AEs=475 (210 related and 265 not related), were symptoms of UC. Of 23 Serious Adverse Events (SAEs), 12 SAEs were seen in the TSO group, all were considered not related to TSO and primarily due to aggravation of UC. Both SAEs and AEs do not raise any safety concerns.

Conclusion: Compared to placebo, TSO treatment was not superior in achieving clinical remission at week 24 in moderate UC patients or in achieving:

- i. Clinical MS reduction,
- ii. Complete steroid-free clinical remission or endoscopic remission at week 24 compared to placebo.

However, TSO treatment induced symptomatic remission at week 12 but not at week 24 and improved partial MS over time. Of notice, the study may be compromised by a high placebo effect and exposure to corticosteroids. *ClinicalTrials.gov ID: NCT03565939*.

Disclosure: The trial was sponsored by ParaTech A/S and co-funded by Copenhagen University Hospital Hvidovre.

Gennimatas", Gastroenterology Department, Athens, Greece, ³Medical School of National and Kapodistrian University of Athens School of Health Sciences, General Hospital of Athens "Laiko", Gastroenterology Department, Athens, Greece

Contact E-Mail Address: sbrakas@yahoo.gr

Introduction: Loss of response in Ustekinumab has not been extensively studied. In the majority of cases empirical dose intensification every 4 weeks rather than therapeutic drug monitoring is used as a measure to regain response. According to several studies almost 58% of patients can regain response with this approach.

Aim of this study was the recording of the percentage of patients receiving intensified regimen of ustekinumab as well as the basic characteristics of these patients.

Aims & Methods: This is a retrospective study with recording of patients currently in Ustekinumab treatment from 3 tertiary centers. Data regarding disease extension, location, behavior, reason of intensification, duration of treatment before intensification were recorded

Results: A total of 74 patients with Crohn's disease (CD) were enrolled. 19 patients were classified as L1, 3 as L2 and 52 as L3 according to Montreal classification for disease location. Only 1 patient received Ustekinumab every 12 weeks (1.3%).

Of the 74 patients, 9 (12.1%) were on intensified dose every 4 weeks. Of the patients in need of intensification, 3 had Montreal B3, 2 B2 and 4 B1, while in terms of localization, 7 had L3 and 2 L1. The reason for intensification was partial response in 3 patients and disease exacerbation in 6 patients. The average time of need for intensification from the start of treatment was 17 months. Intensification was accompanied with corticosteroids in 8/9 patients

Conclusion: 12.1% of CD patients on Ustekinumab treatment need intensified treatment to maintain response, while only 1.2% of patients are on the 12-week dosing regimen. The majority of patients also received steroids during intensification.

Disclosure: Nothing to disclose.

P0481

IDENTIFICATION OF TARGET USTEKINUMAB LEVELS IN MAINTENANCE THERAPY IN INFLAMMATORY BOWEL DISEASE

C. McDonald¹, H. Kerr¹, E. Gibbons², A. O'Toole¹, S. Patchett¹, T. Lukose¹, G. Harewood¹, D. Cheriyan¹, O. Kelly², K. Boland¹
¹Beaumont Hospital, Gastroenterology, Dublin, Ireland, ²James Connolly Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: ciaranmac53@hotmail.com

Introduction: Ustekinumab (UST), a human monoclonal antibody that binds the p40 subunit of IL-12 and IL-23, is licensed for induction and maintenance therapy of moderate to severe inflammatory bowel disease (IBD). To date, little data have been published on a potential association between ustekinumab trough concentrations and mucosal healing in order to guide treatment strategies and appropriate dosing for clinicians.

Aims & Methods: **Aim:** To identify maintenance target ustekinumab trough concentrations associated with mucosal healing and response in IBD.

Methods: This is a multicentre retrospective observational study of patients on UST for management of Crohn's Disease (CD) or Ulcerative Colitis (UC) between 2016 and 2021. Trough ustekinumab levels and antibody titres were analysed in patients on maintenance drug using a drug-tolerant assay. Mucosal response was determined using a combination of faecal calprotectin (FC), endoscopic and radiological assessments.

Mucosal response (MR) was defined as > 50% reduction in faecal calprotectin, reduction in segmental Mayo score by at least 1 Mayo point or > 50% reduction in segmental simple endoscopic score for Crohn's disease (SES-CD) score. Mucosal healing (MH) was defined as faecal calprotectin <200 µg/ml, global SES-CD score < 5 or segmental Mayo score 0-1. Median trough levels were analysed using Kruskal-Wallis test and logistic regression was used to determine sensitivity and specificity of levels predicting mucosal response.

Results: Fifty-three patients on maintenance ustekinumab were included in this study. The majority were female (64.2%) with a median age of 40 years (range 21 – 78 years). The vast majority of patients had previously been treated with a biologic (90.5%). Crohn's disease represented 88.7% (n=47) of the cohort. Disease distribution was predominantly ileocolonic (L3) (60.4%, n= 32) and 24.5% (n=13) had a history of perianal disease. Over one-third of patients (n=34, 64.2%) were on higher than standard dosing of 90 mg every 8 weeks with a highest dose of 180 mg every 8 weeks (n=1, 2%). Mean trough levels were 6.4 mcg/ml and no antidrug antibodies were detected in all 53 patients.

Patients with mucosal healing (n=32) had significantly higher mean UST levels (7.3 µg/ml, SD 6.0) compared to those with no response (1.1 µg/ml, SD 0.67; n=11, p<0.0001. The median time from induction to assessment of UST trough levels was 14 months (SD 9.95). An UST serum trough level > 2.5 µg/ml was associated with MH with a sensitivity of 100% and specificity 91% (likelihood ratio 10.7).

Similarly, MR compared with non-response identified that serum trough levels >2.5 µg/ml was associated with endoscopic improvement or > 50% reduction in faecal calprotectin (sensitivity 100%, specificity 90.5%, likelihood ratio 10.5)

Conclusion: This multi centre study demonstrates that higher ustekinumab trough levels are associated with higher levels of mucosal healing and response in a predominantly non biologic naïve population across all groups. While 15% (n=10) patients were treated with concurrent immunomodulator therapy, this had no significant impact on likelihood of achieving mucosal healing (p=0.4). The median time to UST levels from induction was 14 months. No anti- drug antibodies were detected in all 53 samples with this immunogenicity data comparing favourably with current data on anti- tumour necrosis factor (TNF) biologics.

Further prospective studies are required to correlate target maintenance trough levels and the optimal time to dose-escalate in order to improve patient outcomes, as well as the potential impact of dual biologic therapy or concurrent immunomodulator use in patients with IBD.

Disclosure: Nothing to disclose.

REAL WORLD EXPERIENCE OF USTEKINUMAB IN A WEST OF IRELAND COHORT

O. Fagan¹, V. Madhu¹, C. McGrath¹, A. Keogh¹, E. Slattery¹, M. Hussey¹

¹University Hospital Galway, Gastroenterology, Galway, Ireland

Contact E-Mail Address: olgafagan@gmail.com

Introduction: A subset of patients with IBD do not respond to USTE at standard dose of 90mg every 8-weeks. Data is lacking on the efficacy of shortening the interval between dosing and overall long term efficacy.

Aims & Methods: The aim was to evaluate the outcome of patients with inflammatory bowel disease (IBD) receiving Ustekinumab (USTE) treatment. We performed a retrospective study examining all IBD patients treated with USTE from February-2017 to February-2022. Data were obtained from electronic health records.

Results: 72 IBD patients were assessed: 74% (n=53) Crohn's disease (CD), 25% (n=18) Ulcerative colitis (UC), 1% (n=1) Indeterminate. 43% male, with a median age of 43-years (range: 17-97-years). Of those with CD, 26% (n=14) had small bowel disease, 25% (n=13) had colonic disease, 47% (n=25) ileocolonic disease and 3% (n=2) had isolated perianal disease. Amongst the CD patients, 23 patients (32%) had previous surgery. Regarding UC, 17% (n=3) had proctitis, 33% (n=6) had left sided colitis and 50% (n=9) had pancolitis. The median treatment duration was 4-months (2-36) and 21-months (2-62) for UC and CD patients respectively.

Overall, 59 patients (82%) had received at least 1 previous biologic agent and 39% (n=28) had failed 2 or more biologic agents. All patients received IV induction dosing with a median cumulative induction dose of 390mg (range 240-520mg). In all, 26% (n=19) were on immunomodulators and 35% (n=25) concomitant steroids at induction.

Clinical response at 12-weeks was seen in 85% (n=54) [19% (n=10) UC, 81% (n=44) CD]. Average Partial-Mayo-score and Harvey-Bradshaw-Index-score prior to the introduction of USTE (6.8 and 8.8) improved to 1.7 and 3.6 respectively following commencement of USTE.

Of those with a minimum of 6-months treatment duration (n=55), 85% (n=45) had sustained response. Of those with a minimum of 12-months treatment duration (n=45), 78% (n=35) have also had a sustained treatment response.

In all, 16% (n=12) of the total cohort stopped USTE therapy of which the majority (67%, n=8) had a primary non-response, 16% (n=2) had a secondary loss of response and 16% (n=2) were lost to follow-up.

Furthermore, 54% (n=7) went on to have surgery, 15% (n=2) were placed on an alternative biologic and 23% (n=3) were lost to follow-up. Of those that remained on USTE at 12-months (n=35), numerically more, 54% (n=19) underwent dose escalation compared to 42% (n=5) who failed treatment (p=0.4).

Prior biologic exposure (p=0.6), concomitant immunomodulator (p=0.3) and steroid use at the time of induction (p=0.2) were not associated with sustained response at 12 months. Interestingly, small bowel disease involvement appeared to be associated with lower response rates at 12-months amongst non-responders compared with responders (83% vs. 20%, p=0.05, 95% CI -0.064-0.01)

Amongst UC patients, 61% (n=11) have completed a minimum of 12-weeks of treatment to date, 82% (n=9) of which have had a clinical response and remain on therapy at 6-months.

Conclusion: Ustekinumab is an efficacious therapy for IBD and in particular a promising therapy for UC. Dose-escalation is a common but effective strategy in the use of USTE.

Disclosure: Nothing to disclose.

Introduction: Advanced oral small molecule therapies, including Janus kinase (JAK) inhibitors and sphingosine-1-phosphate (S1P) receptor modulators, are expanding the therapeutic armamentarium for inflammatory bowel disease (IBD).

Aims & Methods: MEDLINE, Embase, the Cochrane CENTRAL Register of Controlled Trials, conference proceedings, and trial registries were searched to October 15, 2021. Randomised, placebo-controlled trials (RCTs) of JAK inhibitors and S1P receptor modulators in adult patients with Crohn's disease (CD) or ulcerative colitis (UC) were eligible. Clinical, endoscopic, histologic, and safety outcomes were extracted and pooled using a random-effects model. Statistical heterogeneity was quantified using the I^2 statistic, with values below 50% representing low heterogeneity.

Results: A total of 25 RCTs (6 CD, 19 UC) were included. Patients were randomised to placebo (n=1685), a JAK inhibitor (tofacitinib, n=1879; peficitinib n=176; upadacitinib, n=732; TD-1473, n=31; SHR0320, n=123; filgotinib, n=1199; ritilecitinib, n=150; brepocitinib, n=152) or an S1P receptor modulator (ozanimod, n=928; etrasimod, n=214; amiselimod, n=40; and KRP203, n=17). In UC, there was a statistically significant difference in clinical (risk ratio [RR] 3.33, 95% confidence interval [CI] 2.12-5.23, $I^2=57\%$) and endoscopic remission (RR 4.05, 95% CI 2.15-7.60, $I^2=51\%$) rates at 8-10 weeks when JAK inhibitor treatment was compared to placebo. JAK inhibitor therapy was also statistically superior to placebo for induction of clinical (RR 1.91 95% CI 1.49-2.44, $I^2=66\%$) and endoscopic (RR 2.73 95% CI 1.68-4.42, $I^2=72\%$) response. For histologic remission and response, a statistically significant difference was observed when filgotinib (remission: RR 1.86 [95% CI 1.34-2.60] $I^2=0\%$) and upadacitinib (response: RR 6.76 [95% CI 2.24-20.42]) were compared to placebo. Pooled data (52-58 weeks) demonstrated that tofacitinib and filgotinib were statistically superior to placebo for maintaining clinical (RR 2.92, 95% CI 2.18-3.92, $I^2=0\%$) and endoscopic remission (RR 2.75, 95% CI 1.50-5.04, $I^2=53\%$). S1P modulator therapy was statistically superior to placebo for induction of clinical (RR 2.96, 95% CI 1.91-4.59, $I^2=0\%$), endoscopic (RR 2.39 95% CI 1.07, 5.33] $P<0.03$, $I^2=0\%$), and histologic remission (RR 2.21, 95% CI 1.48-3.32, $I^2=0\%$). In CD, pooled analyses demonstrated that there was a statistically significant difference between JAK inhibitor therapy and placebo for induction of clinical (RR 1.38, 95% CI 1.04, 1.84, $I^2=14\%$), but not endoscopic (RR 2.83, 95% CI 0.76, 10.56, $I^2=15\%$), remission. Patients with IBD were not at a statistically significantly higher risk of experiencing an adverse event when

treated with a JAK inhibitor (UC: RR 1.05, 95% CI 0.91-1.20, $I^2=63\%$; CD: RR 1.05, 95% CI 0.94-1.17, $I^2=0\%$) or an S1P receptors modulator (UC: RR 1.04, 95% CI 0.91-1.20, $I^2=0\%$; CD: RR 1.22, 95% CI 0.85-1.75), relative to placebo.

Conclusion: JAK inhibitors and S1P receptor modulators are effective for inducing clinical and endoscopic remission in UC. Filgotinib, upadacitinib, ozanimod, and etrasimod are also associated with improved histological outcomes in UC. JAK inhibitors are effective for inducing clinical remission in CD but may not provide a benefit for maintenance of remission. S1P receptor modulators do not appear to provide a benefit for induction of remission in CD. S1P receptor modulators have not been assessed for maintenance in CD. Both classes of advanced small molecules have an acceptable safety profile in IBD.

Contact E-Mail Address: begrosal@gmail.com

Introduction: The original formulation of Adalimumab contained citrate, an inactive ingredient associated with injection-related pain. This formulation was changed onto citrate free in 2016. Adalimumab biosimilar started its commercialization in 2018, after having proved its efficacy and safety profile compared to the originator drug. Some of these new biosimilars contained citrate.

The present study aimed to analyse the tolerance compared to originator, citrate-free (ADA-CF) drug in patients with inflammatory bowel disease (IBD) in clinical remission who switched to a biosimilar containing citrate (ADA-C).

Aims & Methods: Prospective, observational and single-center study. All patients with IBD in clinical remission on ADA-CF (Humira®) for more than 3 months and switching to biosimilar ADA-C (Hyrimoz®) were included and followed-up during at least 3 months.

Primary outcome: To evaluate tolerance to ADA-C formulation after switch. Secondary outcomes: To describe the rates of drug cessation due to intolerance and associated anticipatory anxiety prior to self injecting, and to identify predictive factors of poor tolerance to the drug. Demographic data collected from hospital intranet. Visual Analogue Scale (VAS) score was used to measure pain. Telephonic interviews were performed to assess side effects after injection and anticipatory anxiety.

Results: A total of 37 patients were included, 54% women, mean age 40.3 (17-61). Baseline characteristics are shown in Table 1.

Regarding tolerance comparing ADA-CF to ADA-C formulation, pain presence was more frequent in ADA-C formulation (38% vs 73%, p<0.002). In terms of pain severity as per VAS score, ADA-CF formulation pain was mild 30% (11) or moderate 16% (6), whereas citrate formulation pain was mild 3% (1), moderate 46% (17) and severe 24% (9), p<0.001.

After having switched, 22% (8) patients expressed suffering from anticipatory anxiety prior to self-injecting compared to 3% (1) when they were on ADA-CF, p=0.016.

All the patients continued on treatment at the end of follow-up (37.3 weeks IQR (36-38.9). No differences were found in flushing after injection (16% vs 19%, p>0.05). No statistical association was found between pain and baseline characteristics of the patients.

Age at switch, years, median (IQR)	40.3 (17-61)
IBD, n (%)	
Crohn's disease (CD)	33 (89)
Ulcerative colitis (UC)	4 (11)
Extra intestinal manifestations, n (%)	7 (18.9)
Current treatment, n (%)	
Aminosalicylates	6 (16.2)
Immunosuppressant	11 (29.7)
Previous biologic treatment, n (%)	
Infliximab	15 (40.5)
Adalimumab dose at switch, n (%)	
40 mg/ every other week	36 (97.3)1 (2.7)
40 mg/weekly	

Table 1.

Conclusion: Citrate formulation of Adalimumab is associated with higher pain at the site of injection and increased anticipatory anxiety prior to self-injecting compared to citrate-free formulation. However, poorer tolerance was not related with drug cessation in the short term. Long-term follow-up would be needed to confirm these results.

Disclosure: Nothing to disclose.

Introduction: Short-chain fatty acids, including acetate and butyrate, have gained interest as potential therapeutic targets in inflammatory bowel diseases. Of these, butyrate has been most extensively studied primarily due to its anti-inflammatory properties. Acetate might be of additional interest due to its lower toxicity and cross-feeding potential with butyrate-producing bacteria. In fact, the beneficial effects of acetic acid production by *Saccharomyces cerevisiae* var. *boulardii* (*Sb*) for its antimicrobial potency have been shown by Offei et al. (2019).

To evaluate the importance of its acetic acid production for attenuation of inflammation in colitis, several *Sb* strains with different acetate production levels have been constructed. Hence, the aim of this pre-clinical study was to evaluate the effect of genetically modified *Sb* strains with different levels of acetate production in a DSS-induced mice model of colitis.

Aims & Methods: Nine week old female C57/BL6 mice (N=120) were allocated to 12 treatment groups receiving either regular drinking water or 2.75% DSS in combination with PBS, Baker's yeast (non-probiotic control), SDH1, a non-acetate producing *Sb* strain, ENT, the *Sb* Enterol strain with transient acetate production (probiotic control), SbP, a high acetate producing *Sb* strain (5 g/L) and ENT3, a super high acetate producing *Sb* strain (8.5 g/L). Disease activity including weight loss, diarrhoea and the presence of occult blood was scored daily.

On day 7, the DSS groups were transferred to regular drinking water and on day 14 mice were sacrificed and blood was collected for cytokine and chemokine analysis with Mesoscale's pro-inflammatory panel 1. Statistics were performed using GraphPad Prism 9 (One-way ANOVA for parametric data and Kruskal-Wallis tests for non-parametric data).

Results: Disease activity, determined by the area under the curve, was significantly lower for strain SbP compared to PBS and Baker's yeast (p=0.015 and p=0.011 respectively). Remarkably, *Sb* strain SDH1 showed significantly higher disease activity compared to the *Sb* strains ENT (p=0.0009), SbP (p<0.0001) and ENT3 (p=0.0001). At sacrifice, the colon weight/length-ratio was borderline significantly decreased with for ENT and SbP compared to the *Sb*SDH1 strain (p=0.06 and p=0.08 respectively).

Moreover, macroscopical damage scores were significantly lower for SbP ($p=0.002$) and ENT3 ($p=0.02$) compared to Sb SDH1. Additionally, these damage scores for SbP were significantly lower than PBS ($p=0.048$) and Baker's yeast ($p=0.033$). Significantly lower IL1 β , IL2 and IL4 concentrations for SbP and ENT3 compared to Sb SDH1 and ENT were observed (all $p<0.05$). In contrast, IL10, TNF α and KC/GRO were significantly lower for the DSS subgroups on Sb SDH1 and ENT compared to DSS subgroups on SbP and ENT3, and even to DSS+PBS for IL2 and 4 (all $p<0.05$).

Finally, compared to PBS no differences (all $p>0.05$) were observed between groups of healthy mice for disease activity, colon weight/length ratio and macroscopical damage score.

Conclusion: Engineered high acetate producing *Sb* strains showed a trend towards improved attenuation of DSS-induced colitis compared to the parent *Sb* strain on disease activity. Unexpectedly, the engineered *Sb* strain, that did not produce acetate at all, increased inflammation.

Moreover, a mixed pro-inflammatory serum profile was observed potentially pointing in the direction of another mechanism based on acetate accumulation. Furthermore, healthy mice did not show side effects indicating the strains to be safe. Thus, our data indicate a role for *Sb*-produced acetate in attenuating inflammation.

Introduction: Vedolizumab (VDZ) for subcutaneous injection have been approved for use in Europe in 2020. Good efficacy and tolerability have been proven in the pivotal trials. However, real-world data on the subcutaneous of VDZ are scarce.

Aims & Methods: We therefore aimed to determine treatment adherence and efficacy of IBD patients in remission and with residual disease activity at the time of the switch. Patients treated for IBD in a tertiary care centre and an outpatient clinic from 07/2020 to 12/2021 were retrospectively analysed.

Laboratory parameters and data on treatment adherence were collected via the electronic patient file. Vedolizumab trough levels concentrations as well as disease activity after switch from intravenous to subcutaneous injections was monitored. Patients were followed up until week 20.

Results: One hundred and three patients were included. Forty-five patients were female (44.6%), 60 patients (58.3%) were diagnosed with ulcerative colitis. Most patients with CD were previously exposed to another biologic agent and had received more Vedolizumab (VDZ) infusions prior to the switch.

Forty patients had residual disease activity at the time of the switch. We observed an increase of VDZ trough levels from baseline to week 8 and week 20 for patients in remission and with residual activity at switch.

Furthermore, we observed a significant reduction in fecal Calprotectin levels in patients with residual disease activity at switch at week 20. Vedolizumab trough level of 13.25, 17.8 and 35.15 ug/ml at baseline, week 8 and week 20 were identified to discriminate between remission and disease activity in our cohort.

Conclusion: The subcutaneous application of VDZ proved to be safe and efficient in achieving adequate trough levels and reduce disease activity even in patients with residual disease activity.

CROHN'S DISEASE PATIENTS WITH USTEKINUMAB-INDUCED REMISSION ARE CHARACTERIZED BY HIGH BASELINE IL23 RECEPTOR EXPRESSION IN THE LAMINA PROPRIA TH1 CELLS

S. Onali¹, A. Di Petrillo¹, A. Favale¹, C. Carpineti¹, M. Cadoni¹, E. Loddo¹, M.C. Fantini¹

¹University of Cagliari, Medical Sciences and Public Health, Monserrato (CA), Italy

Contact E-Mail Address: amalia.dip@unica.it

Introduction: Crohn's disease (CD) is a chronic relapsing disorder of the gastrointestinal tract characterized by excessive inflammation sustained by the induction and expansion of Th1 and Th17 cells. IL12 and IL23 play a pivotal role in the maturation and expansion of Th1 and Th17 cells respectively¹ and Ustekinumab (UST), a fully humanized monoclonal antibody, which neutralizes both IL12 and IL23 by binding the common subunit p40, is currently used for the therapy of CD patients (pts)².

To be effective UST needs, in addition to the expression of target cytokines, the presence of cells responsive to either or both IL12 and IL23 thus implying that the expression of IL12 and IL23 receptors on inflammatory cells is a necessary condition for UST to work.

Aims & Methods: The purpose of this study was to assess the correlation between the expression of IL12 and IL23 receptors in the lamina propria mononuclear cells (LPMC) from CD pts at baseline and the clinical disease activity evaluated after 16 weeks of therapy with UST.

This is an ongoing prospective, observational, single-center open-label study. All CD pts, in regular follow-up at the UOC of Cagliari, with clinical indication to receive UST for active luminal disease were enrolled. All pts had baseline endoscopy to confirm disease activity by Simple Endoscopic Score-CD (SES-CD). LPMCs were isolated from biopsies collected from the most inflamed areas and analyzed by flow cytometry. Th1 cells were defined as: CD45+CD3+CD4+CXCR3+ CCR6-, Th17 as CD45+CD3+CD4+CCR6+ CXCR3-, Th1/Th17 as CD45+CD3+CD4+CXCR3+ CCR6+³. Innate lymphoid cells (ILCs) subsets were also analyzed. iLC1 were defined as CD45+Lin-CD127+CD161- and iLC2/3 as CD45+Lin-CD127+CD161+⁴. IL12 receptor-beta-2 (IL12Rb2) and IL23 receptor (IL23R) expression was analyzed in all the described cell populations. Results were associated with clinical response (defined as a decrease in Harvey-Bradshaw Index (HBI) by at least 3 points from baseline) and clinical remission (HBI<5) at week 16. Differences between groups were analyzed by Mann-Whitney test and statistical significance was considered for p<0.05.

Results: From April 2019 to April 2022, 12 CD pts were enrolled. One patient was not considered for analysis due to inability to obtain LPMC. 11 CD pts (M 6; mean age 51,3 yrs) were analyzed. Montreal Classification was: L1 (n=6) L2 (n=3) L3 (n=2); B1 (n=4) B2 (n=3) B3 (n=4) p(n=4). All pts were previously treated with anti-Tumor Necrosis Factor α . Median baseline SES-CD was 10 (range 5-14).

Baseline HBI and C-reactive protein (CRP; nv 0,5mg/dL) diminished at week 16 from 10.5 ($\pm$ 3.7) to 5.8 ($\pm$ 4.2) and from 13.2 ($\pm$ 26.1) to 2.9 ($\pm$ 3.5) respectively. Baseline expression of IL12Rb2 and IL23 was compared between pts who achieved remission at week 16 (i.e. remitters) and those who did not (non-remitters).

There was no difference in Th subgroups frequency between remitters and non-remitters. Similarly, IL12Rb2 and IL23R were equally expressed by Th17 and Th1/Th17 cells from remitters and non-remitters pts. In Th1 cells, IL23R expression was higher in the remitters group (18.0%) as compared to non-remitters (5.8%; p=0.009). IL12Rb2 expression in Th1 cells was similar between the groups.

Neither iLC1 and iLC2/3 frequency nor IL12Rb2 and IL23R expression in iLC1 and iLC2/3 differed between remitters and non-remitters groups of pts.

Conclusion: In CD pts treated with UST, baseline expression of IL23R in the lamina propria Th1 cells was more expressed in pts who were in remission at week 16 as compared to those who still had active disease at this time point.

Introduction: Although histological remission is not a formal therapeutic target for ulcerative colitis (UC), it is acknowledged to be highly associated with improved long-term outcomes. Several histological indices, validated to different extents, are available, including Nancy Index (NI), Robarts Histopathology Index (RHI) and Geboes score (GS). In these *post hoc* analyses of patients treated with filgotinib (FIL; an oral, once-daily preferential JAK1 inhibitor) or placebo (PBO) in SELECTION, we evaluated histological remission by derived NI, RHI and continuous GS, as well as measured categorical GS histological remission, and assessed the concordance between endoscopic/Inflammatory Bowel Disease Questionnaire (IBDQ) outcomes and categorical GS remission. In addition, we evaluated the correlation between endoscopic/IBDQ scores and continuous GS.

Aims & Methods: SELECTION (NCT02914522) was a phase 2b/3 double-blind, randomized, PBO-controlled trial assessing the efficacy and safety of FIL in patients with moderately to severely active UC.¹ Patients were randomized at baseline to receive FIL 200 mg (FIL200), FIL 100 mg (FIL100) or

PBO through to week 10 (induction). Induction responders were re-randomized to their assigned FIL dose ('FIL200-FIL200' or 'FIL100-FIL100') or PBO ('FIL200-PBO' or 'FIL100-PBO') through to week 58 (maintenance). SELECTION reported outcomes of categorical GS remission, endoscopic remission (Mayo endoscopic subscore [MES]=0), endoscopic response (MES=0 or 1) and IBDQ remission (IBDQ total score >170) at weeks 10 and 58.

In these *post hoc* analyses categorical GS² was converted to continuous GS, RHI and NI.³ Rates of histological remission (defined as: NI=0; RHI ≤3; categorical GS=2a ≤1.1, and 0 for grades 2b, 3.0, 4.0 and 5.0; continuous GS ≤6) in each treatment arm were reported at weeks 10 and 58. Concordance between endoscopic/IBDQ outcomes and categorical GS remission was assessed using baseline, week 10 and week 58 data from all treatment arms combined. Spearman's rank correlation coefficient (R_s) was used to quantify the correlation of MES (0–3) and IBDQ total score (32–224) with continuous GS (0–22). No imputation of missing data was used.

Results: Rates of histological remission, endoscopic response and remission, and IBDQ remission at weeks 10 and 58 for each treatment arm are shown in Table 1.

Endoscopic response and IBDQ remission showed higher negative predictive values (NPVs) than positive predictive values (PPVs) for categorical GS remission. The correlation between MES and continuous GS was $R_s=0.55$, and between IBDQ total score and continuous GS was $R_s=-0.34$.

Outcome measure	Induction (week 10)			Maintenance (week 58)			
	FIL200 (n=469)	FIL100 (n=518)	PBO (n=249)	FIL200– FIL200 (n=143)	FIL200– PBO (n=41)	FIL100– FIL100 (n=101)	FIL100– PBO (n=40)
Proportion of patients achieving histological remission, %							
Categorical GS ^a (measured)	29.4	20.3	14.5	53.1	31.7	47.5	40.0
NI=0 (derived measure)	29.4	20.3	14.5	53.1	31.7	47.5	40.0
RHI ≤3 (derived measure)	35.4	26.8	20.4	59.2	36.6	54.0	45.0
Continuous GS ≤6 (derived measure)	21.5	14.5	8.0	42.7	26.8	40.6	30.0
Proportion of patients achieving endoscopic and IBDQ outcomes, %							
MES=0	8.3	4.3	3.2	20.3	14.6	22.8	17.9
MES=0–1	26.9	21.1	16.1	53.8	36.6	45.5	43.6
IBDQ total score >170	50.6	38.9	26.7	76.9	63.4	74.3	77.5
Concordance between outcomes of interest and categorical GS remission^a							
Outcome measure	Sensitivity ^b , % (95% CI)	Specificity ^c , % (95% CI)	Positive predictive value ^d , % (95% CI)	Negative predictive value ^e , % (95% CI)	Accuracy ^f , % (95% CI)		
Endoscopic remission	21.7 (18.2–25.5)	99.0 (98.5–99.4)	82.1 (74.5–88.2)	85.6 (84.2–86.9)	85.4 (84.1–86.7)		
Endoscopic response	56.6 (52.2–61.0)	94.0 (93.0–94.9)	66.7 (62.1–71.2)	91.1 (89.9–92.2)	87.4 (86.2–88.6)		
IBDQ remission	59.8 (55.4–64.1)	78.2 (76.5–79.8)	37.1 (33.7–40.5)	90.1 (88.7–91.3)	74.9 (73.3–76.5)		

95% CIs were calculated using the Clopper–Pearson method.

^aDefined as GS=2a ≤1.1, and scores of 0 for grades 2b, 3.0, 4.0 and 5.0.

^bSensitivity=TP/(TP+FN).

^cSpecificity=TN/(TN+FP).

^dPositive predictive value=TP/(TP+FP).

^eNegative predictive value=TN/(TN+FN).

^fAccuracy=(TP+TN)/(TP+TN+FP+FN).

TP defined as outcome measure giving remission when categorical GS status is remission.

TN defined as outcome measure not giving remission when categorical GS status is not remission.

FP defined as outcome measure giving remission when categorical GS status is not remission.

FN defined as outcome measure not giving remission when categorical GS status is remission.

CI, confidence interval; IBDQ, inflammatory bowel disease questionnaire; FIL100, filgotinib 100 mg; FIL200, filgotinib 200 mg; FN, false negative; FP, false positive; GS, Geboes score; MES, Mayo endoscopic subscore; NI, Nancy Index; PBO, placebo; RHI, Roberts Histopathology Index; TN, true negative; TP, true positive.

Table 1. Outcome measures at week 10 and 58, and concordance between outcomes of interest and categorical GS remission.

Conclusion: FIL200 was efficacious in inducing and maintaining histological remission. Absence of IBDQ remission and endoscopic remission were associated with absence of histological remission, with high NPVs.

Nevertheless, the lower PPVs than NPVs suggest the need for histological assessment even when endoscopic and health-related quality of life improvements are achieved, as disease activity may still be present.

EFFECTIVENESS OF POLYMERIC EXCLUSIVE ENTERAL NUTRITION AS AN ADJUNCT TO STANDARD OF CARE IN PATIENTS WITH ACUTE SEVERE ULCERATIVE COLITIS

L. Willmann¹, K. Tognolini¹, D. Subhakaran¹, H. Kuo¹, J. Edwards¹, A. Dorrington¹, D. Shukla¹, N. Ishaq¹, H. Moattar¹, M. Bhullar¹, P. Kakkadasam Ramaswamy¹, W. Mohsen¹

Contact E-Mail Address: lawillmann@gmail.com

Introduction: Intravenous corticosteroids (IVCS) are the mainstay of treatment in acute severe ulcerative colitis (ASUC) patients. Exclusive enteral nutrition (EEN) with a semi-elemental formula has been shown to enhance corticosteroid responsiveness in ASUC patients.¹The effectiveness of polymeric EEN in ASUC has not been studied.

Aims & Methods: Aim: To assess the effectiveness and tolerability of polymeric EEN as an adjunctive therapy to current standard of care (SOC) in ASUC patients.

Methods: Between September 2021 - March 2022, 21 consecutive adults hospitalized with ASUC (meeting Truelove and Witts' criteria) received 7 days of polymeric EEN (Ensure Plus) in addition to current SOC. Outcomes were compared to a historical SOC cohort of 38 patients (admitted 2016 - 2020) matched for sex, disease extent, smoking status, biologic and steroid use prior to admission, and number of additional Truelove and Witts' criteria present.

The primary outcome was corticosteroid failure defined as requiring medical rescue therapy or colectomy. The decision to initiate rescue therapy was made at the treating physician's discretion as per international guidelines.

Results: A total of 59 patients were included (EEN n = 21, SOC n = 38). Female gender [EEN: 11 (52.4%), SOC: 21 (55.3%), $P = 1$], median age [EEN: 35 years (IQR 26-41), SOC: 29 years (IQR 24-43), $P = 0.59$] and median disease duration [EEN: 0.9 years (IQR 0-3.1), SOC: 0.9 years (IQR 0.1-5), $P = 0.76$] were similar in both groups. In the EEN group, 15/21 (71.4%) failed to respond to IVCS and required rescue therapy in comparison to 16/38 (42.1%) patients who required rescue therapy in the historical SOC group, $P = 0.029$ [crude RR 1.69 (95%CI 1.07-2.68), crude OR 3.43 (95%CI 1.11-10.51), NNT(harm) 3.41 (95%CI 1.82- 26.43)].

However, after adjusting for sex, disease duration, disease extent, smoking status and current biologic use, the adjusted OR 3.49 (95%CI 0.52-23.37, $P = 0.17$) and the adjusted RR 2.13 (95%CI 0.71-6.43, $P = 0.536$) were not statistically significant. In the EEN group, patients received medical rescue therapy with infliximab (n = 12, 80%), ciclosporin (n = 1, 6.6%), and tofacitinib (n = 2, 13.3%).

None of the patients underwent direct colectomy. In the SOC group, mode of rescue therapy was infliximab (n = 14, 87.5%), ciclosporin (n = 1, 6.25%), and colectomy (n = 1, 6.25%). The total 7 day course of EEN was completed by 19/21 (90%) patients, and 2 patients discontinued EEN treatment (1 due to abdominal discomfort, 1 due to palatability). Stool frequency, CRP and albumin levels on days 3 and 7, and length of hospital stay, did not significantly differ between the groups.

	Total Admissions N=59	EEN N=21	SOC N=38	p value
Median duration of hospital stay (IQR), days	8 (6-10)	8 (7-10)	8 (6-10)	0.63
Disease Extent, n (%)				
Left sided colitis	5 (8.5%)	2 (9.5)	3 (7.9)	1
Pancolitis	54 (91.5%)	19 (90.5)	35 (92.1)	
Oral steroids prior to admission, n (%)	16 (27.1)	6 (28.6)	10 (26.3)	1
Current biologic use, n (%)	16 (27.1)	7 (33.3)	9 (23.7)	0.54
Median stool frequency at admission, n (IQR)	10 (8-15)	10 (8-12)	10 (8-15)	0.34
Median CRP at admission (IQR), mg/L	53 (30-117)	53 (35-152)	56 (28-106)	0.89
Median serum albumin at admission (IQR), g/L	32 (28-36)	30 (27-34)	33 (29-37)	0.20
Median admission Calprotectin (IQR), mcg/g	2500 (1600-3800)	2300 (1600-3500)	2600 (1600-5900)	0.54
Median UCEIS score at admission	5 (4-6)	5.5 (5-6)	5 (4-6)	0.41

Table: Clinical, biochemical and endoscopic parameters between the two groups (on admission and during hospital stay).

Conclusion: Polymeric EEN is well tolerated in patients with ASUC. More patients in the EEN group failed to respond to IVCS and required medical rescue therapy as compared to the SOC group. Further randomized controlled studies are required to determine the benefit of polymeric EEN as an adjunctive therapy to standard of care in ASUC.

Introduction: Opioid exposure in inflammatory bowel disease (IBD) is associated with premature mortality, yet exposure in IBD increasing. International guidelines have been introduced to rationalise opioid use. While opioids may improve acute pain, long term exposure is rarely beneficial and is associated with side effects. We conducted a multicentre audit aiming to evaluate opioid use and associated factors in patients with IBD.

Aims & Methods: Data were collected from consecutive patients (Oct 21-Mar 22) attending IBD clinics at 12 hospitals across most regions of the UK. Opioid exposure (>2 weeks in the past 12 months), associated factors and concurrent medical management were assessed and analysed.

Results: Of 1362 individuals, 53.0% were female, the median age range was 41-45 yrs and 47.8% had Crohn's disease (CD). Opioid exposure occurred in 11.7% of individuals with 5.0% of the overall cohort reporting IBD as the indication. In the whole cohort 7.8% received codeine and 3.5% strong opioids. Within the opioid exposed group the total number of opioid medications that an individual received was ≥ 3 in 3.3%, 2 in 11.2% and 1 in 85.5%. Antidepressants, gabapentinoids and/or NSAIDs were co-prescribed in 39.7% of those exposed to opioids.

In the opioid exposed group 43% of patients believed they were taking opioids primarily for IBD. Of these 30.8% did not have an objective disease assessment with imaging or colonoscopy in preceding year. Those with objective assessment had evidence of active inflammation in 72.3%, evidence of scarring/adhesions in 17.0% and no evidence of either in

10.6%. Among opioid-exposed patients, 65.8% had comorbidities and ≥ 2 in 15.5% patients. Musculoskeletal (MSK) disease was the most common co-morbidity (62.5%), of which 31.2% had inflammatory arthritis.

Factors associated with opioid exposure on multivariable regression analysis were previous surgery (RR 2.56 [95% CI 1.75-3.74]), while UC (versus CD RR 0.45 [95%CI 0.30-0.67]) and male sex (versus female RR 0.45 [95% CI 0.32-0.65]) were associated with less opioid exposure. Age and disease duration were not associated with opioid exposure.

Pain services reviewed 25% of opioid-exposed patients. We observed significant variations by site with referral rates to pain services ranging from none to 100%. Opioid weaning was attempted in 43% of cases only.

Conclusion: In an analysis of unselected IBD patients attending clinic, just over one tenth had been exposed to opioids in the past year. Co-existent MSK co-morbidities were common, other factors associated with opioid exposure included a diagnosis of CD, female sex, previous surgery. Referral to pain services varied between sites and opioid weaning was attempted in less than half of cases. IBD services should aim to identify patients at risk of opioid exposure, reducing exposure when possible and help to access alternative and more effective pain management solutions.

ORAL IRON THERAPY WITH IRON MALTOL VERSUS FERROUS SULPHATE IN INFLAMMATORY BOWEL DISEASE: INTRA-INDIVIDUAL COMPARISON INDICATES LEVEL PEGGING ON INCREASE IN PLASMA HEPcidIN LEVELS

Introduction: Current anaemia guidelines for patients with inflammatory bowel disease (IBD) recommend oral rather than intravenous iron therapy unless patients have severe anaemia, active inflammation or intolerance to oral iron (OI). In IBD, however, OI causes gastrointestinal side-effects and iron absorption is often poor.

Moreover, OI supplements induce an increase in plasma hepcidin that persists for 24h, which impairs iron absorption from supplements given later the same or the next day.

Aims & Methods: We aimed to measure and compare changes in hepcidin levels for 4h following ingestion of oral ferrous vs. ferric iron and to consider implications for the optimisation of OI dosing to maximise intestinal absorption. A comparative, single-centred, open clinical trial with cross-over design was conducted. Diagnosis of anaemia was based on WHO definitions: Hb<13g/dL for men and <12g/dL for women. Iron deficiency was defined as ferritin <100 mg/L, CRP ≥ 5 mg/L and Hb > WHO cut-offs. Plasma CRP level ≥ 5 mg/dL was taken as evidence of inflammation.

To evaluate iron absorption capacity, patients took two oral absorption tests two weeks apart: at the first study visit, with iron(II)-glycine-sulphate complex (Ferro sanol®) and at the second visit, with iron(III)-maltol (Feracru®), or vice-versa. The oral absorption tests took place in the morning after overnight fasting and baseline testing of plasma iron and hepcidin levels. Patients took a 30mg iron tablet, and blood was drawn after 60 and 120 min. After a very low-iron lunch (potato soup, bread) the same protocol was repeated. The area under the curve [AUC] for iron absorption

was calculated for 60 and 120 min from a.m. and p.m. baselines. Blood samples were analysed at Immundiagnostik AG Diagnostic Laboratory, Bensheim using LC/MS/MS.

Results: Of 23 IBD patients enrolled (12f/11m;11CD/12UC;45.1 $\pm$ 14.7y), 7/23(30.4%) had inflammation. After the 1st administration, a significant increase in plasma iron was detected compared to baseline, even in patients with inflammation, in both ferrous sulphate and iron maltol groups ($p<0.001$). In the afternoon, after the 2nd iron dose, plasma iron increased insignificantly in the iron maltol group ($p=0.538$), while it decreased significantly in the ferrous sulphate group ($p=0.011$). Iron absorption capacity a.m. ($p=0.644$) and p.m. ($p=0.280$) were not statistically different in the two groups. In both the ferrous sulphate and the iron maltol groups, plasma hepcidin values were significantly increased at p.m. baseline prior to the second iron dose ($p<0.001$). Whereas in the morning, plasma hepcidin levels correlated negatively with iron absorption capacity independent of inflammatory status (-0.408 , $p<0.05$), in the afternoon, since both groups showed no increase in plasma iron, there was no significant correlation (-0.253 , $p=0.130$).

Conclusion: Both ferrous sulphate and iron maltol resulted in an increase in plasma hepcidin levels, thus impairing iron absorption after the second daily dose. In IDA, the intake of oral iron supplements leads to an acute hepcidin increase for 24 hours - regardless of whether ferric(III) or ferrous(II) iron is ingested, and even if hepatic hepcidin expression is strongly suppressed by iron deficiency and erythropoietic drive. Alternate day dosing of oral iron supplements in anaemic IBD patients may be preferable.

THE BENEFICIAL EFFECTS OF INCREASING DIETARY FIBER CONSUMPTION ON CLINICAL FLARE AND INFLAMMATORY MARKERS AMONG PATIENTS WITH CLINICALLY QUIESCENT INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE LONGITUDINAL STUDY

P. Sathirawich¹, O. Sattayalertyanyong¹, P. Pramyothin², I. Thaisittikul³, N. Pausawasdi¹, R. Sarasak², P. Phaophu¹, N. Subdee¹, S. Manatsathit¹, P. Charatcharoenwittaya¹, J. Limsrivilai¹

Contact E-Mail Address: phalat_s@hotmail.com

Introduction: The effect of dietary fiber on inflammatory bowel disease (IBD) is less well defined. This prospective longitudinal study aimed to determine the effect of dietary fiber intake on clinical relapse rate and changes in fecal calprotectin levels in clinically quiescent IBD patients.

Aims & Methods: Sixty-one IBD patients were included, comprising 23 Crohn's disease patients and 38 ulcerative colitis patients. Clinical manifestations and nutritional habits were evaluated at the beginning of the study and weeks 6th, 18th, 30th, 48th, and 54th. Fecal calprotectin was measured at baseline, and weeks 6th, 30th, and 54th. Fecal microbiota was measured at baseline, weeks 6th and 54th or the time that clinical flare was noticed. A nutritionist counseled all participants to increase their dietary fiber consumption and interviewed with a food questionnaire at each visit.

Furthermore, dietary intake was assessed with food photographs taken three days a week before each appointment. A significant change in dietary fiber consumption was defined as a relative change in fiber intake of >25% from baseline. The patients were divided into three groups based on whether their fiber consumption rose, remained steady, or decreased over the follow-up period relative to their baseline. The time to clinical flare was estimated using the Kaplan-Meier method, and a log-rank test was used to compare the clinical flare rate between groups. A linear mixed model was performed to explore the correlation between fecal calprotectin and dietary fiber intake while adjusting for a follow-up visit and patient set as a random intercept.

Results: At baseline, the average dietary fiber consumption was 7.78 g/day (IQR, 5.68-11.9). During the 54-week follow-up, 20 (32.8%) patients increased their fiber intake by a mean of 3.82±2.57 g/day, 28 (45.9%) patients did not modify their fiber intake, and 13 (21.3%) patients decreased their fiber intake by a mean of 12.2±18.0 g/day. At the 54th week, the overall cumulative rate of the clinical flare was 27.7%. The cumulative clinical flare rate was significantly higher in the decreased fiber intake group than in the increased fiber intake group (60.4% vs. 16.9%, $p=0.01$).

Furthermore, increased fiber intake was associated with decreased fecal calprotectin levels; every 1 g increase in fiber intake per day was associated with a decrease in fecal calprotectin of 12.51 mg/g feces (95%CI, 1.0-24.0, $p=0.03$).

According to subgroup analyses, the effect was more pronounced in ulcerative colitis than in Crohn's disease. No significant difference in microbiota diversity change was observed across different groups of fiber intake at the end of study.

Age – mean(SD)	43.39(13.71)
Male gender	39(63.93%)
Crohn's disease : Ulcerative colitis	23(37.70%) : 38(62.30%)
Hb (g/dL) – mean(SD)	13.50(1.75)
Fecal calprotectin (mg/kg of feces) – median(IQR)	168(47-804)
Current medications	
5-ASA	49(80.33%)
Corticosteroids (≤ 10 mg of prednisolone)	23(37.70%)
Immunomodulators	45(73.77%)
Biologics	9(14.75%)

Conclusion: Increasing dietary fiber consumption is independently associated with clinical benefits in IBD patients, including a decreased likelihood of clinical flare and improvements in inflammatory markers of the disease.

Introduction: Early relapse in paediatric Crohn's disease (CD) is associated with more severe disease course. The microbiome may play a crucial role in disease development. We have previously shown that a Bayesian approach can predict clinical course in children with CD following the first year after diagnosis with high accuracy when ensuring samples were truly treatment-naïve. We hypothesize that directly targeting the microbiome in high-risk individuals will improve clinical response to standard of care (SOC) induction therapy in a subgroup of patients with a relapse-associated microbiome profile.

We report on initial findings on feasibility of a multicentre pilot study on different continents with treatment allocation based on stool sample results at baseline determined in Canada for all participants.

Aims & Methods: This is a 52-week, multicentre, randomised, controlled, open-label, add-on pilot study to test the feasibility of a larger trial evaluating the efficacy of adjuvant antibiotic therapy in 20 paediatric patients with mild-to-moderate-CD (10<PCDAI≤37.5). SOC induction treatment consists of the Crohn's Disease Exclusion Diet+Partial Enteral Nutrition (CDED+PEN). Relapse-associated microbiome signatures at week 0 are evaluated using 16S rRNA gene sequencing and a previously generated Bayesian predictive model from BioMiCo based on baseline stool sample results.

Patients will be allocated to treatment groups (A1,A2,B,C) depending on their disease activity and relapse-associated microbiome at week 4 (table 1). Subjects in group A2 or C will receive a combination of azithromycin 7.5mg/kg for 5 days/week for 4 weeks and 3 days/week for another 4 weeks, along with metronidazole 20 mg/kg/day for 8 weeks.

The purpose of this pilot trial is to assess feasibility of a multicentre trial on different continents with treatment allocation at week 4 based on stool sample results at baseline (16S rRNA sequencing at Dalhousie University, Canada). Primary outcomes will assess feasibility of treatment allocation and possible efficacy of add-on antibiotic treatment in children with high

risk for relapse by assessing sustained remission (PCDAI $\leq$ 10, no need for re-induction) at 52 weeks. Exploratory outcomes will include changes in PCDAI, inflammatory and microbiome markers and patient reported outcomes.

Disease activity at week 4	Relapse-associated microbiome	Treatment group	SOC induction treatment	Study intervention
Remission	Yes	A1	Crohn's Disease Exclusion Diet	n.a.
		A2		Azithromycin + Metronidazole
	No	B		n.a.
No remission	Yes / No	C		Azithromycin + Metronidazole

Table.

Results: As of April 29th 2022, 12 patients have been enrolled in The Netherlands. Baseline stool sample prediction results were available at week 4 in 11/12 patients. The one exception was due to a technical problem with the sequencing run, and final results became available at the end of week 4. Three out of 11 patients were predicted to be non-responders: one has not reached week 4 yet; one stopped CDED after 1 week due to persisting symptoms and declining to continue diet; one was not in remission at week 4 and started additional antibiotics and is now in sustained low-calprotectin remission after 26 weeks (with CDED+PEN phase 3 maintenance only).

Conclusion: Initial results of our pilot study show that allocation at week 4 based on stool sample results obtained at baseline can be feasible. Future results of this pilot study will provide on distribution of relapse-associated microbiome, inform power calculation for a larger trial, and include possible efficacy of add-on antibiotic therapy.

Disclosure: Nothing to disclose.

EFFECTIVENESS OF USTEKINUMAB AS INDUCTION THERAPY FOR CHRONIC ANTIBIOTIC REFRACTORY POUCHITIS

A. Outtier¹, E. Louis², O. Dewit³, G. Schops¹, J. Sabino¹, B. Verstockt¹, S. Vermeire¹, M. Ferrante¹

¹UZ Leuven, Leuven, Belgium, ²CHU Liège and Liège University, Liège, Belgium, ³UCL Saint Luc, Brussels, Belgium

Contact E-Mail Address: an.outtier@uzleuven.be

Introduction: Up to 10% of patients with ulcerative colitis who undergo a proctocolectomy with ileal pouch-anal anastomosis will develop chronic antibiotic refractory pouchitis (CARP).¹

As there is a large unmet need in the management of these patients, we evaluated the efficacy and safety of induction therapy with ustekinumab (UST) for this indication.

Aims & Methods: We performed a prospective, Belgian, multicentre, open-label study of patients with CARP. Patients received a weight-range-based infusion of UST at baseline (~6mg/kg) and one subcutaneous injection of 90mg UST at week 8. The first 4 weeks, ciprofloxacin 500mg BID was added as bridging therapy, but need of antibiotics thereafter was regarded as treatment failure. Patients underwent pouchoscopy at baseline and week 16, with assessment of the modified pouchitis disease activity index (mPDAI).

The primary endpoint was the proportion of patients achieving clinically relevant steroid-free remission (mPDAI $\leq$ 5 and reduction by $\geq$ 2 points from baseline) at week 16. Secondary endpoints at week 16 were the proportion of patients achieving response (reduction of mPDAI by $\geq$ 2 points from

baseline), change in symptomatic and endoscopic mPDAI subscore, and change in C-reactive protein (CRP) and faecal calprotectin levels compared to baseline. Descriptive statistics and paired nonparametric tests (Wilcoxon signed-rank) of changes from baseline were performed.

Results: We report 22 patients (59% male, median age 42.2 years, median time after surgery 8.2 years) who were enrolled in the study. Twelve (54.5%) patients had previously been treated with biologics (anti-TNF, n=9; vedolizumab, n=7; tofacitinib, n=1) for CARP (table 1). At week 16, clinically relevant steroid-free remission was reached in 27.3% and response in 54.5% of patients.

A significant decrease in total mPDAI (8 (7-9.5) vs. 7 (4-9), $p<0.01$), clinical subscore (3 (2-4) vs. 2 (1-3), $p<0.01$), and endoscopic subscore (5 (4-6) vs. 4 (3-6), $p=0.03$) was observed at week 16. Faecal calprotectin (293 (186.3-572.3) vs. 195 (92.8-863.3) mg/kg, $p=0.63$) and CRP (4.2 (1.8-7.5) vs. 3.7 (1.8-9.5) mg/L, $p=0.82$) levels did however not decrease significantly. Three serious adverse events (hospitalization for subobstruction, worsening pouchitis and choledocholithiasis) were recorded, but were not considered related to UST.

Male, n (%)	13 (59)
Age at treatment initiation, years, median (IQR)	42.2 (32.2-52.3)
Time since colectomy, years, median (IQR)	8.2 (3.1-16.4)
Previous therapies prior to colectomy, n (%)	
Anti-TNF	15 (68.2)
Vedolizumab	5 (22.7)
Tofacitinib	3 (13.6)
Previous therapies for pouchitis, n (%)	
5ASA (topical/systemic)	6 (27.3)
Steroids (topical/systemic)	17 (77.3)
Immunomodulators	8 (36.3)
Anti-TNF	9 (40.9)
Vedolizumab	7 (31.8)
Tofacitinib	1 (4.5)
Concomitant therapy during induction, n (%)	
Steroids (topical/systemic)	3 (13.6)
Immunomodulators	1 (4.5)

Table 1. Baseline disease characteristics.

Conclusion: In this open-label pilot study in patients with CARP, induction therapy with UST showed a clinical and endoscopic effect in half of the patients, but was not associated with changes in inflammatory biomarkers. Placebo-controlled studies are needed for further positioning UST in the treatment algorithm of CARP.

OUTCOME PREDICTORS FOR VEDOLIZUMAB THERAPY IN CROHN'S DISEASE PATIENTS IN A REAL-WORLD SETTING

S.J. Han¹, J.H. Ji¹, J. Park¹, E.-A. Kang¹, S.J. Park¹, J.H. Cheon¹, T.i. Kim¹, J.J. Park¹

¹Severance Hospital, Yonsei University College of Medicine, Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: sjhan92@gmail.com

Introduction: Although vedolizumab (VDZ), a humanized monoclonal antibody against α4β7-integrin, has shown efficacy in Crohn's disease (CD), outcome data are limited in the Asian population in a real-life setting. Our study aimed to determine the predictor for clinical outcomes in patients with CD undergoing VDZ therapy in a real-life setting.

Aims & Methods: We performed a retrospective cohort study of CD patients who received VDZ therapy at a tertiary referral center in Seoul, Korea, between April 2017 and July 2021. We defined clinical remission as CD Disease Activity Index (CDAI) under 150 without concomitant corticosteroid use. Patients could keep vedolizumab treatment with or without dose optimization.

Clinical and serologic variables were included in the analysis. Each potential prognostic factor was compared using a log-rank test, and multivariate analysis was performed using cox regression.

Results: Altogether, 50 patients with CD were enrolled. The mean age of patients was 38 years, and most of the patients (98%) showed moderate disease activity. Anti-TNF naive patients were 11 (22%), and 39 (78%) have used anti-TNF in the past. At the initiation of vedolizumab, 15 patients (30%) had concomitant corticosteroids use, and 38 patients (78%) received immunomodulator therapy.

Forty-three (86%) patients achieved steroid-free remission at a median of 119 days (Interquartile range 95-382 days). The patients were treated with vedolizumab for median days of 598 days (IQR 405-1156 days). 30 patients (60%) keep VDZ treatment with median days of 1002 days (IQR 489-1470 days).

In multivariate Cox analysis for accelerated steroid-free remission, baseline CDAI score (hazard ratio [HR] 0.994, 95% CI; 0.988-1.000) and ESR (HR 0.991, 95% CI; 0.982-1.000) are significant factors for rapid remission. Whereas concomitant use of immunomodulator (HR 0.291, 95% CI; 0.116-0.732) and no hypoalbuminemia (≥3.3g/dL) (HR 0.352, 95% CI; 0.137-0.902) were associated with persistent use of vedolizumab. There was no VDZ discontinuation due to adverse drug reactions.

Conclusion: VDZ offers an effective treatment option for CD patients in real-life settings. Low baseline CDAI score and ESR are related to rapid remission. Meanwhile, concomitant use of immunomodulators and no hypoalbuminemia are associated with persistent use of VDZ in CD patients.

FISTULOUS SKIN METASTASES IN CROHN'S DISEASE: A CASE REPORT AND REVIEW OF THE LITERATURE

T. Elger¹, H.C. Tews¹, J. Loibl¹, J. Werner², K. Drexler³, S. Haferkamp³, K. Guelow¹, C. Kunst¹, A. Kandulski¹, M. Müller-Schilling¹

Introduction: Metastatic Crohn's disease is a rare disease characterized by various granulomatous skin lesions without contact to the gastrointestinal tract. Due to a lack of evidence, there is no standard of care. Therapeutic approaches include immunosuppressive agents including corticosteroids and azathioprine as well as monoclonal antibodies directed against inflammatory cytokines like TNF.

Case Report: A 29-year-old woman presented to the dermatology department of our university hospital with marked abdominal, blind-ending, subcutaneous fistulas and abscesses. Fine tissue workup revealed multiple epithelioid cell granulomas. There was no evidence of infection or rheumatologic disease such as sarcoidosis. The suspected diagnosis was metastatic Crohn's disease. The patient responded to Infliximab (monoclonal anti TNF antibody). This had to be discontinued due to an allergic reaction. Treatment with Adalimumab (monoclonal anti TNF antibody) subsequently did not result in clinical remission, and, therefore, therapy was switched to Ustekinumab (monoclonal anti IL12/IL23 antibody). An intestinal manifestation of Crohn's disease could not be detected so far.

Aims & Methods: More than 300 publications were screened for diagnostic and therapeutic approaches according to metastatic Crohn's disease.

Results: Various cases with cutaneous and genital manifestations were found in the literature review. The majority had concomitant luminal bowel involvement.

Conclusion: Metastatic Crohn's disease is a rare disorder, which is presenting with various phenotypes and thus is difficult to diagnose. Involved sites show granulomatous lesions in the histologic examinations. Treatment includes biologicals such as anti-TNF antibodies and surgical options. In our case, we have decided to treat the patient with Ustekinumab.

Disclosure: Nothing to disclose.

Introduction: There are limited data in real-life of ustekinumab (USK) used in ulcerative colitis (UC). The aim of this study was to assess the effectiveness and safety in clinical practice of USK in UC in the medium and long-term.

Aims & Methods: Observational study in UC patients who received USK at the recommended dose based on weight ~6 mg/kg IV week 0.90 mg SC week 8 and maintenance 90 mg SC every 8 or 12 weeks and with 1 year of follow-up. The partial Mayo score (PMS) was used to assess clinical remission (PMS ≤ 2). The PMS, C-reactive protein (CRP) and faecal calprotectin (FC) values were recorded at baseline and after 8, 16, 24 and 52 weeks. Dose adjustment was performed by the measure of UST trough levels by ELISA, when patient lost clinical and/or biochemical response and the levels were low (<1.3 µg/ml). Demographic, clinical, biochemical and endoscopic data, previous treatments, adverse events (AEs), surgeries and hospitalizations, were documented.

Results: Twenty-three patients with UC were analysed. (Table 1). All patients had received previous biological treatment: 52% ≥ 2 anti-TNF, 65% vedolizumab and 30% JAK inhibitors. Treatment discontinuation occurred in 3 patients (13%). The persistence was 83% and 79% at 6 and 12 months (Figure 1). During follow-up, 12 patients (52%) maintained standard dose of USK. Dose adjustment was performed in 13 patients (56%): 3 (13%) required intravenous UST reinduction and 10 (43%) required dose escalation (8 by shortening the interval between doses and 2 by switching to intravenous USK administration). Clinical remission was reached in 61%, 58%, 56%, 79% of the patients after 8, 16, 24, 52 weeks, respectively. Normal CRP (<5mg/L) and FC (<150 µg/g) levels were achieved in 76%, 93% and 80% and in 35%, 31% and 40% of patients after 8, 24, 52 weeks, respectively. Five of 6 patients who had endoscopy before and after treatment showed endoscopic Mayo subscore ≤ 1. There were 2 AEs, 1 hospitalization, and 1 colectomy during follow-up.

Characteristic	N = 23
Gender Male/Female	8 (35%)/15 (65%)
Age (years)	44 (33, 51)
Disease duration (years)	7.8 (5.3, 14.4)
Extent of disease E1-E2-E3	1 (4%), 10 (44%), 12 (52%)
Extra-intestinal manifestations	6 (26%)
Immunosuppressant at baseline	7 (30%)
Corticosteroids at baseline	10 (43%)
Partial Mayo score at baseline	5 (3, 7)
CRP at baseline (mg/L) /FC at baseline (µg/g)	8.1 (4.1, 29.7) / 2276 (1641, 3569)

Table 1. Characteristics of study population. Data are expressed as median (interquartile range), or number (%).

Conclusion: This study demonstrates the safety as well as the clinical, biological and endoscopic effectiveness of USK adjusted by levels in real life in a highly refractory UC cohort.

Disclosure: Nothing to disclose.

Contact E-Mail Address: j.jagt1@amsterdamumc.nl

Introduction: Anti-TNF treatment is increasingly used in moderate to severe paediatric inflammatory bowel disease (IBD). However, a subset of children develop anti-drug antibodies (ADA) against anti-TNF agents, which can result in worsening symptoms, decreased mucosal healing, and ultimately even to progression to bowel resection. Data on the optimal management and predictive factors of ADA, are not yet determined in paediatric IBD.

Aims & Methods: In this retrospective cohort study, we aimed to evaluate treatment interventions to overcome ADA in children with IBD. Secondary aim was to investigate predictive factors of ADA development. Children 4-18 years old, diagnosed with IBD and were prescribed anti-TNF agents including infliximab and adalimumab between January 2006 and November 2021, were included in two tertiary centres.

Primary outcome was the suppression of ADA (<12 AU/mL) after treatment intervention, comprising dose optimisation, switch to another anti-TNF agent, adding an immunomodulator (IM) or alternative treatments in ADA positive children.

Secondary outcomes included predictors of ADA development. These predictive factors were tested by using Cox proportional-hazards model.

Results: A total of 298 paediatric IBD patients (215 Crohn's disease; 71 ulcerative colitis; 12 IBD-unclassified) on anti-TNF therapy (288 infliximab; 10 adalimumab) were included. Fifty-seven patients (19.1%) developed ADA after a median time of 16.4 months (IQR 7.0 – 25.2) following initiation of anti-TNF treatment: 51 to infliximab and 6 to adalimumab (after a switch from infliximab for other reasons than ADA).

Total duration of treatment on anti-TNF agents for the 298 patients was 885 person-years. The incidence rate of ADA was 6.44 per 100 person-years. The interventions to overcome ADA and the effect on ADA suppression is depicted in Table 1.

In the group of patients with ADA <50 AU/mL (*n* = 31), 20 patients continued on the initial anti-TNF agent (dose optimisation, IM addition, or both). Of these patients, 90% and 80% had suppressed ADA and sustained treatment response at 6 and 24 months, respectively.

In patients with high ADA levels >50 AU/mL (*n* = 26) who underwent dose optimisation (*n* = 6), IM addition (*n* = 1) or both (*n* = 4), 45% and 36% of subjects had ADA suppression and continued on the initial anti-TNF agent at 6 and 24 months, respectively. The development of ADA against anti-TNF was positively associated with female sex (hazard ratio [HR] 2.22, 95% CI 1.27 – 3.85, *P* = 0.005) and the presence of infusion reactions (HR 2.94, 95% CI 1.59 – 5.44, *P* = 0.001).

Conclusion: In this real-life cohort of children with IBD, around 20% of patients developed ADA against anti-TNF agents. Our data suggest that dose optimisation and/or IM addition for low-level ADA (<50 AU/mL) is an effective intervention to suppress ADA and prevent loss of response, while this was effective in only one-third of patients with high ADA (response at

24 months). Female sex was predictive of ADA development. A more sex-specific approach might therefore be considered to lower the risk of ADA in female patients.

Disclosure: Nothing to disclose.

Type of intervention	ADA level (UE/mL), median (IQR)	Patients with ADA tested after intervention, n	Median days (IQR) from ADA until subsequent ADA test	ADA suppressed	ADA not suppressed
Continued on same anti-TNF agent (n = 33)	31 (24 – 115)	30*	84 (56 – 156)	18	12
Dose optimization (n = 20)	31 (24 – 94)	17*	84 (55 – 116)	9	8

BERBERINE SUPPLEMENTATION SIGNIFICANTLY IMPROVED ANTI-TNFA EFFICACY IN MURINE COLITIS MICE HUMANIZED WITH NON-RESPONDER GUT MICROBIOTA

L. Liu¹, L. Liang², Y. Chen²

¹Shenzhen Hospital, Southern Medical University, Gastroenterology, Shenzhen, China, ²Nanfang Hospital, Southern Medical University, Gastroenterology, Guangzhou, China

Contact E-Mail Address: 13246837972@163.com

Introduction: Immunotherapy based on anti-TNFα mAb has emerged as a promising treatment option for a variety of autoimmune illnesses. However, only a small percentage of ulcerative colitis (UC) patients benefit from it. A growing body of evidence supports the gut microbiota's critical involvement in immune system development. Berberine, a natural plant alkaloid derived from a variety of species, has been shown to regulate gut microbiota imbalance.

Aims & Methods: As a result, we set out to investigate the role of berberine in increasing anti-TNFα mAb efficacy as well as the processes that underpin it.

The C57BL/6 mice were given an antibiotic cocktail (ABX) to deplete the endogenous gut microbiota before being humanized with feces from anti-TNFα non-responders and responders. 3.0% dextran sulphate sodium (DSS) was given to these mice to test the pro-healing efficacies of anti-TNFα coupled with or without berberine. The intestinal immune microenvironment and mucosal repair after therapy was studied using flow cytometry, RT-PCR, and immunohistochemistry. 16S rRNA amplicon sequencing

and gas chromatography-mass spectrometry (GC-MS) analyses were used to assess the gut microbiota profiles and levels of short-chain fatty acids (SCFAs). Fecal microbiota transplantation (FMT) was used to further investigate the influence of gut microbiota on anti-TNFα mAb efficacy after berberine supplementation.

Results: In compared to mice humanized with feces from responded UC patients, animals humanized with feces from non-responded UC patients had considerably lower anti-TNFα mAb efficacy.

However, berberine dramatically increased anti-TNFα mAb efficacy in dextran sulfate sodium (DSS)-induced colitis animals humanized with non-responders gut microbiota. And M2-like macrophage infiltration and repolarization were increased in the pro-inflammatory colonic microenvironment in mice treated with anti-TNFα and berberine. When macrophages were deleted in vivo with clodronate liposomes, the pro-healing effect of anti-TNFα mAb combined with berberine was reduced. Berberine increased gut microbial diversity and exerted favorable control over microbial composition, 16S rRNA amplicon sequencing revealed.

Additionally, we identified novel bacterial modules that were much more abundant in the anti-TNFα mAb & berberine group and were composed of butyrate-producing bacteria, indicating a good immunotherapy response. Meanwhile, GC-MS analysis demonstrated that berberine altered the body's SCFA butyrate concentration.

Additionally, butyrate was found to be sufficient to boost M2-like macrophage polarization and thus the potency of anti-TNFα mAb. Also, the FMT assay demonstrated that berberine's effects were flora-dependent. Notably, the therapeutic effects of berberine were established in mice humanized with anti-TNFα mAb-resistant patients' gut microbiota.

Conclusion: Berberine aided anti-TNFα mAb efficacy in UC by influencing the differentiation of M2-like macrophages in the local immunological milieu, which was possibly mediated via the metabolite butyrate.

Disclosure: Nothing to disclose.

Introduction: Ulcerative colitis (UC) can result in a high prevalence of bowel movement urgency (BU), significantly reducing patient quality of life. Whether early BU improvement is associated with later clinical endpoint improvements was examined in patients (pts) treated with mirikizumab (miri).

Aims & Methods: BU in pts with moderately to severely active UC was evaluated in the Phase 3 randomized placebo (PBO)-controlled 12-week induction (LUCENT-1) and 40-week maintenance (LUCENT-2) trials with miri, an IL23-p19 monoclonal antibody. Pts received miri 300mg IV or PBO

during induction. Week 12 (W12) miri responders were rerandomized at LUCENT-2 study baseline (BL) to miri 200mg subcutaneous or PBO. BU was measured using the 11-point Urgency Numeric Rating Scale (UNRS) from 0 (absent) to 10 (worst possible). Pts' UNRS scores were averaged from the 7 consecutive days prior to visit.

Association of pts with BU Clinically Meaningful Improvement (CMI; UNRS $\geq$ 3 decrease) or BU Remission (UNRS=0 or 1) between BL and week 4 with the proportion of pts achieving clinical response, and clinical, endoscopic, or symptomatic remission at end of induction W12, was assessed.

For pts who achieved clinical response at W12, analyses were repeated for the end of maintenance (W52 of continuous treatment [LUCENT-2 W40]) based on W12 (LUCENT-2 BL) BU status. Pts with UNRS<3 at BL were not included. Non-response imputation was used for missing data.

Logistic regression models with treatment, urgency (BU CMI or BU Remission), treatment-by-urgency group interaction, and stratification factors were fitted to examine association between early urgency improvement and later clinical endpoints. Fisher's Exact test assessed within group treatment differences.

Results: Treatment-by-urgency group interactions were not statistically significant across clinical outcomes for induction and maintenance (all $p>0.05$). For induction, both treatment (all $p\leq 0.001$ for CMI) and urgency status (all $p<0.02$) were statistically significant main effects.

This suggests pts experiencing BU CMI or BU Remission at W4 were consistently more likely to achieve clinical response, and clinical, endoscopic, or symptomatic remission at W12 for both PBO and miri groups. For remission, only the treatment main effect was statistically significant across clinical outcomes (all $p<0.001$).

This suggests that among miri induction clinical responders (enriched population), BU CMI or BU Remission at end of induction (W12) was not associated with later maintenance efficacy outcomes (W52). Miri-treated pts achieved higher rates of clinical response, and clinical, endoscopic, or symptomatic remission at W52 compared with PBO regardless of BU CMI or BU Remission at W12 (Table).

Conclusion: Early BU Improvement, CMI or Remission, was associated with better clinical outcomes during induction for both miri and PBO pts, showing BU is a sensitive predictor of early clinical outcomes. Among miri induction responders, miri consistently provided better maintenance of response and remission rates.

IN PATIENTS WITH CROHN'S DISEASE, FECAL CALPROTECTIN DROP-SLOPE DURING INDUCTION WITH USTEKINUMAB CAN AFFECT ITS LEVELS AND DISCRIMINATE THE NEED FOR INTENSIFICATION AT WEEK 52

A. Mínguez Sabater¹, B. Mateos¹, E. Sáez-González¹, M. Iborra¹, I. Moret¹, A. Cañada², L. Tortosa¹, G. Bastida¹, M. Aguas¹, E. Cerrillo¹, P. Nos¹, B. Beltrán¹

Introduction: Ustekinumab (UST) intensification during Crohn's Disease (CD) treatment is becoming quite usual in clinical practice. Little is known about early intensification maintenance regimens and their drug levels utility in discriminating CD-response and the need of further intensification.

Aims & Methods: To analyze the evolution of UST levels in an intensified maintenance regimen, their capacity to discriminate response according to inflammatory parameters and to indicate the need of further intensification. This is a retrospective study with 43 moderate/severe active CD patients (Harvey- Bradshaw Index [HBI] ≥ 4 and Fecal Calprotectin [FC] >250 $\mu\text{g/g}$) who received UST induction treatment (induction dose of 6mg/kg IV,

plus dose of 90mg SC at week 8). Patients received maintenance treatment (90mg SC/8 weeks) and were followed during 52 weeks. They were classified according to the response obtained at first year in: responders (R) (HBI <3 and FC $<200\mu\text{g/g}$), non-responders (NR) (HBI ≥ 4 and FC $>250\mu\text{g/g}$), and intensification

group (IG) (partially responders that needed UST intensification to every 4 weeks). HBI, FC, C-Reactive Protein (CRP) and UST levels data were collected at baseline (w0), week 8 (w8), week 16 (w16) and during the first 52 weeks (w52) of maintenance. IG was followed 12-26 weeks after intensification (al).

Results: Half of the patients (48.8%) were male. Most of them (97.7%) had received previous anti-TNF- α treatment (53.49% >2 anti-TNF- α). Median age of patients at the moment of starting UST was 51 (37.5, 58.5) years. Median disease duration was 11 (7.5, 23) years. Location of disease was ileal in 30% of patients and ileocolic in 53%. One third of the patients associated perianal disease and 41% were smokers. The only demographic factor associated to non-response was ileocolic location. Table 1 shows the evolution of inflammatory parameters and UST levels according to response. A Pearson correlation ($r=0.62$) between higher FC drop (baseline-w16) and higher drug levels at w16 was observed. Biological markers decrease is able to discriminate UST NR during induction, however neither biological markers nor UST levels are able to discriminate between deep remission R and those who will need intensification. R shows a higher UST levels at w52 compared to IG. IG showed a significant increase of UST levels (a mean of 5.39 points) and a significant drop of FC and HBI (a mean of 115.62 and 2.27 points respectively) after intensification. Those patients reported clinical improvement, however they could not reach a FC $<250\mu\text{g/g}$, which could need longer period of time to decrease.

	UST LEVELS ($\mu\text{g/ml}$)				FC ($\mu\text{g/g}$) / CRP (mg/l)			
	w8	w16	w52	al	w0	w16	w52	al
R (n=15)	13.36 (10.1)	2.19 (1.2)	4.37 (2.21)	---	923.3 (670.4) / 4.34 (4.3)	180.1* (129.7) / 2.49* (1.6)	159.1* (167.71) / 1.06* (0.64)	--- / ---
NR (n=15)	8.47 (9.48)	3.07 (2.71)	---	---	1708.06 (1095.2) / 10.66 (8.85)	1401.6 (976.3) / 18.95 (17.8)	---	---
IG (n=13)	11.63 (9.75)	2.42 (0.97)	2.23+ (0.84)	7.61^ (3.1)	1013.2 (450.9) / 10.15 (17.4)	493.7* (407.12) / 7.23 (9.48)	554.7 (529.69) / 5.72 (8.15)	366.5^ (421.8) / 4.28 (4.22)

Table 1. Data: mean (SD); * $p < 0.05$ w16 or w52 vs. w0 in the same group and parameter; + $p < 0.05$ R vs. IG w52; ^ $p < 0.05$ IG w52 vs al.

Conclusion: FC drop-slope is associated to higher levels of UST at the end of induction. UST levels at w52 are useful to discriminate those patients who will benefit from UST intensification to every 4 weeks.

Disclosure: Nothing to disclose.

Introduction: A significant percentage of patients with inflammatory bowel disease (IBD) require treatment with intravenous (IV) biological agents and specifically infliximab or vedolizumab. In the near future it will be possible to change the route of administration of these molecules, as their subcutaneous forms (SC) will be available, allowing the infusion units to be decongested and patients to be relieved of repeated admissions to the hospital.

The purpose of this study is to record whether patients under IV treatment desire this change and what factors influence their decision.

Aims & Methods: An anonymous, simplified questionnaire was given to patients under IV biological agents in 3 tertiary Gastroenterology clinics. Epidemiological characteristics (age, sex, disease, years of illness, current treatment, previous treatment) were collected and the questionnaire aimed at the acceptance or not of change of treatment from IV to SC molecule if it was available as well as the main factors influencing this choice.

Results: In total, the questionnaire was answered by 93 patients (52 with Crohn and 41 with ulcerative colitis) of which 71 (76.34%) received IV Infliximab and 22 (23.66%) IV Vedolizumab. Of the total patients, 31 (33.33%) answered that they would not like a change in SC form, while 62 (66.67%) that they would like to change to a SC form.

The main reasons for staying in IV were:

- a. Closer monitoring by the treating physician (39%),
- b. Feeling safe - fewer side effects and complications (33%) and
- c. Higher efficacy (9.09%).

On the contrary, the main factors for accepting the change of treatment in SC form were:

- a. Ease of administration (46%),
- b. Occupational-social flexibility (38.71%).

No correlation was found between patients' desire for a change in route of administration and age or previous subcutaneous exposure.

Conclusion: 2/3 of the patients in IV biological agent would accept the change of the route of administration, from IV to SC form with the same molecule. The key factors for this choice seem to be ease of delivery and professional-social flexibility. Age and previous exposure to a SC biological agent does not appear to be related with the desire to change from intravenous to subcutaneous drug.

Disclosure: Nothing to disclose.

THE VEDOLIZUMAB CLINICAL DECISION SUPPORT TOOL FOR CROHN'S DISEASE EFFECTIVELY PREDICTS CLINICAL REMISSION AT 54 WEEKS IN A "REAL WORLD" SETTING

K. Chalakatevaki¹, G. Kokkoti¹, E. Papathanasiou², N. Kioulos¹, M. Gizis¹, S.L. Chatzinikolaou¹, I. Koutsounas¹, S. Michopoulos², E. Zampeli², G. Bamias¹

¹3rd Department of Internal Medicine "Sotiria" Hospital, National and Kapodistrian University of Athens, Gastroenterology Unit, Athens, Greece, ²Alexandra Hospital, Dept. of Gastroenterology, Athens, Greece

Contact E-Mail Address: kchalakatevaki@gmail.com

Introduction: A clinical decision support tool (CDST) was designed and validated based on data acquired from the GEMINI and VICTORY study in order to predict the possibility of clinical response in patients with active Crohn's who received Vedolizumab (VDZ). Further evaluation of the tool's credibility in larger cohorts is mandatory before its application in every day clinical practice.

Aims & Methods: The primary aim of the study is to evaluate the effectiveness and application of the clinical decision support tool in every-day clinical practice regarding Greek patients with active Crohn's disease who received VDZ and their response to therapy. Secondary aim is to determine the utility of the CDST in patients with active Crohn's disease who received Ustekinumab (UST).

Methods: We collected retrospective data of patients with active Crohn's disease treated with VDZ or UST from Sotiria and Alexandra Hospitals. The patients were separated based on their CDST score in high (CDST>19), intermediate (13<CDST≤19) and low (CDST≤13) possibility of clinical remission. Their clinical response was assessed on week 54 of treatment.

Results: In total 58 patients with active Crohn's disease who received VDZ were assessed, out of which 14 were excluded due to lack of data. The remaining 44 were divided into the groups mentioned above (high, intermediate and low).

Only one patient was enrolled in the low probability group and therefore was not included for further evaluation. In the high probability group, 29 patients were enrolled, out of which 24 (82%) achieved clinical remission on week 54 while in the intermediate probability group 14 patients were enrolled out of which 6 (43%) achieved clinical remission.

The difference between the high and intermediate group was found to be statistically significant ($P<0.01$). Similarly, 96 patients with active Crohn's disease who received UST were assessed, out of which 27 were excluded due to lack of data, while the remaining 69 were divided into three groups based on their CDST score. In the high probability group 33 patients were enrolled out of which 23 (69%) achieved clinical remission on week 54, while 34 were enrolled in the intermediate probability group out of which 25 (73%) achieved clinical remission.

The difference between the high and intermediate groups was not statistically significant ($P=0.73$). Only two patients were enrolled in the low probability group and were excluded from further evaluation.

Conclusion: Very few patients who show low probability of response based on the CDST receive treatment with VDZ or UST. Our study confirms the credibility of the CDST as a mean to predict the patients' clinical response in receiving VDZ but not UST. The tool may prove to be a useful clinical indicator in the choice of biological treatment in patients with active Crohn's disease.

MEDICAL TREATMENT OF VEO-IBD EXPOSES CHILDREN TO CRITICAL EXCIPIENTS – RESULTS FROM A RETROSPECTIVE OBSERVATIONAL SINGLE CENTER ANALYSIS

C. Pallauf¹, E. Klucker², T.G. Le Thi², J. Pachmayr¹, T. Schwerd², M. Pinter-Hitzl¹

¹Paracelsus Medical University (PMU), Institute of Pharmacy, Salzburg, Austria, ²Dr von Hauner Kinderspital, LMU Klinikum, Department of Pediatrics, Munich, Germany

Contact E-Mail Address: monika.pinter-hitzl@gmx.at

Introduction: Excipients as constituents of medicines can potentially impact drug safety and efficacy in pediatric patients due to their immature metabolic system. ¹Children diagnosed with very early onset inflammatory bowel disease (VEO-IBD) before six years of age could be susceptible to excipients' effects due to their young age and the lack of age-specific IBD formulations.

Aims & Methods: The aim of this study was to analyze the exposure to potentially critical excipients in induction and maintenance therapy of VEO-IBD in order to support patient safety and to improve pediatric drug therapy.

A retrospective observational study was conducted at the Dr. von Hauner children's hospital of the LMU Munich. Medical records of all VEO-IBD patients hospitalized between 2015 and 2021 receiving oral, rectal and parenteral medication were included in this study. Daily exposure to potential critical excipients aspartame, lactose, polyethylene glycol, polysorbate 80, propylene glycol, sodium benzoate, sorbitol, sucrose and sulfites was evaluated. Cumulative excipient exposure levels in pediatric patients were documented and compared to threshold levels set by the European Medicines Agency (EMA) or published safe levels.

Results: A total of 16 VEO-IBD patients (median age 3.0 years, range 0.8 – 6.4 years of age; 4 female, 12 male) were included in the study. Treatment of the study population included mesalazine, prednisolone, methylprednisolone, azathioprine, budesonide, methotrexate, vedolizumab, adalimumab, omeprazole, vitamin D and calcium. All patients were exposed to at least two critical excipients during the observed treatment period. Exposure levels of excipients above the thresholds set by the EMA or respective safe levels have been observed for oral and rectal medicines administered in combination or when used as an off-label treatment.

Oral drugs exposed the patient to lactose, propylene glycol and sodium benzoate above the recommended safe levels. Rectal therapies contained preservatives like sodium benzoate, sodium metabisulfite and potassium metabisulfite. In detail, 4/16 patients were exposed to lactose above a threshold of 5.71 mg/kg/per dose, 4/16 patients were exposed to potassium metabisulfite above a respective safe level of 0.12 mg/kg/d, 1/16 patient was exposed to propylene glycol above a threshold of 50 mg/kg/d, 4/16 patients were exposed to sodium metabisulfite above a respective safe level of 0.1 mg/kg/d, 4/16 patients were exposed to sodium benzoate above a respective safe level of 0.5 mg/kg/d and a 13/16 patients were exposed to oral sucrose. Combination of vitamin D and calcium contained high amounts of sucrose or sorbitol.

Conclusion: We found VEO-IBD children exposed to high levels of potentially critical excipients. Levels of potentially irritating preservative potassium metabisulfite were exceeding up to 8-fold the recommended threshold and propylene glycol exceeded the safe level by a factor of 2 in

drug therapy of VEO-IBD patients. In order to improve drug therapy and consequently patient safety in VEO-IBD it is important to raise awareness on excipient levels which might reach proinflammatory activities and contribute to treatment refractoriness or impact on therapy tolerance.

Tailored formulations for pediatric drug therapy in VEO-IBD should be considered, such as replacing Vitamin D/calcium combinations with sugar-free formulations, to improve patient safety. Overall, there is a strong need for pediatric formulations of drug products and support by clinical pharmacist in VEO-IBD therapy and beyond.

Introduction: Inflammatory bowel diseases (IBD) are a group of chronic inflammatory intestinal diseases with an autoimmune background, cyclic nature altering between active and quiescent state that markedly impair the quality of patient's life. In obese IBD patients an overgrowth of white mesenteric adipose tissue release results in a number of adipokines as biomarkers of an inflammatory response.

Recently, we have reported that the mesenteric adipose tissue overgrowth as a result of obesity induced by a high-fat diet feeding of rodents leads to a deterioration of the course of experimental colitis, but the role of extensive physical activity in experimental colitis in obesity has not been elucidated. Intestinal alkaline phosphatase (IAP) is an important apical brush border enzyme dephosphorylating bacterial lipopolysaccharide (LPS) of pathogenic bacteria during stressful conditions but the potential protective impact of IAP supplementation to exercising obese mice with colitis as well as the changes in gut microbiota and expression of barrier proteins have not been studied before.

Aims & Methods: Two major series of C57BL/6 male mice were fed ad libitum high-fat-diet (HFD, 70% energy from fat, series A) or standard diet (SD, 10% energy from fat, series B) (Altromin, Lage, Germany) for 12 weeks and subjected to forced treadmill exercise (15 min/day in 6 weeks, Panlab, Harvard Apparatus, MA, USA) with or without the intragastric treatment with IAP (200 U/day) followed by induction of trinitrobenzene sulfonic acid (TNBS) colitis.

Following 4 days after colitis induction, the animals of both groups were anesthetized and the colonic blood flow (CBF) was examined by Laser Doppler flowmetry, the disease activity index (DAI), histology of intestinal mucosa was examined and the composition of intestinal microbiota was determined in stool samples collected from mice by Next-Generation Sequencing.

The blood and biopsies of colonic mucosa was excised for the determination of pro- and anti-inflammatory cytokines using Luminex microbeads and the expression of intestinal barrier proteins ZO-1, Muc2, Claudin-4 and -8 has been evaluated by RT-PCR.

Results: The forced physical activity significantly increased DAI index and significantly raised the colonic level and leptin, MCP, TNF- α , IL-6 and IL-17a while decreasing the IL-2 levels in obese mice with colitis, these effects being significantly reduced by the treatment with IAP which significantly improved the gross and histologic appearance of colonic mucosa. The predominance of Bacteroidetes and Firmicutes was observed at the phylum level in IAP-treated mice along with the relative proportion of Firmicutes in favor of higher content of Verrucomicrobiota. At genus level, the lower level of pathogenic Clostridia was noticed in IAP-treated HFD-fed mice as compared to SD controls. Both, Campilobacterota and Deferribacterota were more common in HFD group with TNBS colitis but lower level of Odoribacteria with shift to predominance of Bacteroides and Parabacteroides was observed in IAP-treated obese mice. The mRNA expression for ZO-1, Muc2 and Claudin-8 and -4 was downregulated in HFD-fed exercising mice as compared to SD group and these effects were reversed by IAP administration.

Conclusion: IAP treatment ameliorates the exacerbation of murine colitis induced by forced physical activity due to improvement of diversity of intestinal microbiota, the favorable effect on the expression of tight junction proteins and the downregulation of proinflammatory biomarkers in colonic mucosa (Support:UMO-2015/19/B/NZ4/03130 by the National Centre of Science in Poland).

Introduction: The Crohn's Disease (CD) exclusion diet (CDED), is a whole-food diet which has been shown to induce remission and decrease objective markers of inflammation in pediatric and adult CD populations.

Aims & Methods: We aimed to describe our real-world experience with the CDED, in a tertiary referral center for IBD patients. This retrospective cohort study, performed at the Inflammatory Bowel Disease (IBD) Unit of the Tel Aviv Medical Center, collected data from all CD patients with clinically active disease, defined by a Harvey Bradshaw Index (HBI) ≥ 5 , who were referred for the CDED by their treating physician. Medical, nutritional and anthropometric data was collected from dietician clinic visits and medical records throughout the three phases of the diet. Clinical and biomarker improvement, response and clinical remission were determined

Results: 220 CD patients were referred for the CDED. 124 patients were excluded due to incomplete documentation (5%), previous CDED experience (13%), unwilling to adhere to diet or loss to follow up (28%). Patients who did not initiate the CDED were significantly older and had higher BMI, but did not differ otherwise from patients who initiated the CDED.

The remaining 96 patients initiated the CDED, 48 (50%) of whom had a clinically active disease and were included in the study. The mean age of the cohort was 35.4 (± 16.35) years with a mean duration of disease

of 9.1 (± 8.8) years. 28 patients (58%) were female and mean body mass index (BMI) at diet initiation was 21.9 (± 3.5) kg/m². Most patients had ileal (62.5%) or ileocolonic (35%) disease location. 12 patients (25%) had a stricturing phenotype and 16 patients (33%) had undergone prior CD surgery. 21 patients (44%) were on CDED alone and 21 (44%) started CDED as an adjunctive therapy or bridge to advanced therapy.

Indications, adaptations for and adherence to the CDED n, (%)	Clinical remission (n=30)	No clinical remission (n=18)	P-value
CDED alone	17, (56.7)	4, (22.2)	0.060
Adjunctive therapy	7, (23.3)	4, (22.2)	
Bridge therapy	4, (13.3)	6, (33.3)	
With steroids / antibiotic	2, (6.7)	4, (22.2)	0.940
Partial enteral nutrition	13, (43.3)	8, (44.3)	
Low fiber – adaptations for post-surgical or stricturing disease	10, (33.3)	4, (22.2)	0.412
High adherence to the CDED	23, (76.7)	9, (50.0)	0.058
High adherence to mandatory foods	22, (78.6)	9, (50.0)	0.049

Table 1: Comparison of indications, adaptations to CDED and adherence to diet of patients following 6 weeks of the CDED based on remission status

Table 1 details the indications for, adaptation of and adherence to the CDED in the patient cohort. At week 6, clinical remission was achieved in 30 patients (62.5%) and 14 (46.6%) patients, maintained remission by week 12. HBI improved by an average of 3.7 $\pm$ 3.5 and Fcal decreased by 668 $\pm$ 1284mg/kg (n=19) by week 12 of the CDED. There were no significant differences in baseline disease phenotype, severity or BMI between remitters and non-remitters. There was a positive association between high adherence to the CDED and clinical remission at week 12, when adjusting for age, gender, disease duration, BMI, and baseline HBI score (OR=7.6, 95%CI 1.07-55.2, P=0.043). Most patients were highly adherent (n=32, 67%) to the diet and only three patients reported intolerance to the diet due to palatability issues.

Conclusion: These encouraging data indicate that the CDED may be an effective adjunct intervention for multiple CD presentations and indications. These findings should be further validated in a larger, prospective studies

Introduction: Biologic therapies are the standard of care for moderate-to-severe ulcerative colitis (UC). For patients who do not respond to conventional treatment, first-line biologics involve either an anti-TNF or an anti-integrin (vedolizumab).

However, a significant proportion of patients do not respond or secondarily lose response to these drugs. Ustekinumab, an interleukin 12/23 inhibitor, and tofacitinib, a pan-JAK inhibitor, have recently completed the ther-

apeutic arsenal after failure of a previous biologic therapy. However, there are few objective data to guide the therapeutic decision between these two molecules after failure of both anti-TNF and anti-integrin therapy.

Aims & Methods: In this study, our aim was to compare the efficacy of ustekinumab and tofacitinib in achieving clinical remission in real-life conditions, using a propensity score-matched analysis of a retrospective cohort of UC patients who had previously failed both anti-TNF and vedolizumab.

Results: Ninety-three UC patients were enrolled in 4 French tertiary centers: 41 received ustekinumab, 52 received tofacitinib. Both groups were comparable at baseline, particularly in terms of disease severity, with a mean disease duration of 8 years, 60% of pancolitis, and 41% of steroid-dependent patients. The mean treatment persistence was 11.5 months with ustekinumab, and 10.7 months with tofacitinib. Prior to statistical adjustment, neither treatment was found superior in achieving clinical remission. Clinical remission rates at induction (week 12) were 28.2% for ustekinumab and 35.6% for tofacitinib, and of 19% and 30% at week 54, respectively.

Overall, treatment failure occurred for 69.2% of patients treated with ustekinumab, and for 64.7% of patients treated with tofacitinib, with primary non-response for 30.8% and 33.3% of patients, respectively. Colectomy rates were comparable between the two groups, occurring for 12.2% of ustekinumab patients and 3.8% of tofacitinib patients.

In univariate analysis, age over 60 years was significantly associated with ustekinumab treatment, with an odds ratio (OR) of 7.7 (CI95 [1.5 - 39]); and a history of primary non-response to first-line biologics was associated with tofacitinib treatment, with an OR of 3.47 (CI95 [1.37 - 8.78]).

These variables were therefore included in the propensity score. After adjustment, neither treatment was significantly superior for induction and maintenance of clinical remission. In terms of safety, no unexpected side effects were reported in this work.

Conclusion: This multicenter real-life study confirms, in a homogeneous cohort of patients, that ustekinumab and tofacitinib are two valid options for third-line therapy in refractory UC. Despite the use of a propensity score, it was not possible to highlight a difference in terms of clinical remission between these two molecules.

A trend towards superiority of tofacitinib over ustekinumab was observed, especially in terms of colectomy rates, although our study lacked statistical power to reach significance.

However, in these multidrug-resistant patients, reported induction efficacy rates were high and colectomy rates low, suggesting that third-line biologic therapy is an acceptable alternative to surgery in refractory UC.

Disclosure: Nothing to disclose.

Introduction: ELISA (Enzyme-Linked Immunosorbent Assay) is the most commonly used technique for the determination of infliximab (IFX) levels in patients with inflammatory bowel disease (IBD). The main limitations of the ELISA are that it requires a specialized laboratory and accumula-

tion of several dozen samples to reduce the cost of each determination to an acceptable level, thereby delaying the results. The development of rapid tests could circumvent these delays and allow earlier determination of IFX levels to guide the patient's biological therapy. Few studies have been conducted to demonstrate the effectiveness of rapid tests against the ELISA.

Aims & Methods: **Aim:** The objective of this study is to compare the reference technique (ELISA) for quantifying IFX levels to a rapid "point-of-care" (POC) test.

Material and methods: The IFX levels of 135 IBD patients on maintenance IFX treatment were analyzed. The samples were obtained prior to infusion of IFX (trough levels) and were analyzed using both methods. For the ELISA, PromonitorIFXv2[®] kits from Progenika Biopharma (Derio, Spain) were used. The POC test, a rapid immunochromatographic analysis: the PromonitorQuick[®] IFX system, was also from Progenika Biopharma. For the POC test, only a capillary sample from the patient's fingertip was needed and the results were obtained within 20 minutes.

The quantitative comparison of the techniques was performed using Bland-Altman plots and Student's t-test. A p-value of <0.05 was considered statistically significant. The 95% concordance limits were calculated using the mean $\pm$ 1.96*SD. The correlation was assessed using the Pearson correlation coefficient (r).

Results: The median IFX concentration was 5.9 μ g/mL (RIC 0.035-14.4 μ g/mL) using the ELISA test and 3.90 μ g/mL (RIC 1-15.9 μ g/mL) using the POC test. The correlation between the results of both tests was high (r=0.84, p<0.001). The mean difference between ELISA test and POC test was 1.46 μ g/mL (p<0.001). The Bland-Altman plot indicates that at concentrations above 8 μ g/mL the POC test underestimates the IFX concentration.

Conclusion: This rapid immunochromatographic POC test showed a high degree of correlation with the ELISA reference test indicating the POC test was reliable. It also has the potential advantage of more rapid results.

Disclosure: Nothing to disclose.

Introduction: Microscopic colitis (MC) is a chronic inflammation of the colon that causes chronic, non-bloody watery diarrhoea. Patients with MC can have abdominal pain, faecal incontinence and weight loss, symptoms that heavily impair their quality of life. Forms of MC are collagenous colitis (CC) and lymphocytic colitis (LC).

According to the literature data, 40 to 50 % of patients with MC treated with the standard therapy protocol (budesonide 9 mg through 6-8weeks) have relapsed within one year of therapy discontinuation.

Aims & Methods: Standard ileocolonoscopy with colonic biopsies was performed due to chronic diarrhea on 220 patients and on 74 patients histologically MC was confirmed.

24 patients with histologically confirmed MC (both histologic types included, LC and CC) were treated with the standard protocol (6-8weeks) and 50 patients of the second group were treated according to a modified therapeutic protocol (24 weeks – first 8 weeks 9 mg per day , 8-16 week 6 mg per day , 16-24 week 3 mg per day). Comparison of standard and modified therapy protocol results in achieving MC remission and maintaining it within one year of discontinuation of treatment was performed.

The achievement of clinical remission was monitored according clinical criteria (Hjortswang criteria), followed by its duration within one year in both groups of patients.

Results: During one year in the standard protocol patients group, disease relapse occurred in 45% of cases.

In the group of patients treated according to the modified therapy protocol,disease relapse occurred in 5% of patients during one year.

Conclusion: According to our results, the modified therapeutic protocol showed significantly better results in maintaining clinical remission in patients with MC at follow-up after one year.

Further studies are needed in order to optimize treatment options for MC.

Introduction: Recently, subcutaneous vedolizumab (scVDZ) formulation has been approved for the treatment of Inflammatory Bowel Disease (IBD). In the randomized controlled trials for Crohn Disease (CD) and ulcerative colitis (UC), scVDZ formulation was comparable to intravenous (ivVDZ) one in terms of efficacy and safety.

Aims & Methods: The aim of our study was to evaluate the safety and the effectiveness of switching IBD patients (pts) in clinical remission from ivVDZ to scVDZ in a real-life setting. In this prospective cohort study, we collected data on consecutive IBD pts in steroid-free clinical remission who switched from ivVDZ to scVDZ from September 2021 to April 2022 at our IBD-Unit center. Demographic characteristics, baseline and 12-weeks follow-up clinical activity and C-reactive protein (CRP) levels, and adverse events (AEs) were recorded.

Clinical IBD activity was evaluated with Harvey Bradshaw Index (HBI) for CD, and Partial Mayo Score (PMS) for UC. The primary outcome of the study was to evaluate steroid-free clinical remission plus biochemical remission (CRP <5 mg/l) at week 12.

Results: 94 pts (42 CD, 52 UC, median age 52 years [IQR 42-67.2]) switched from ivVDZ to scVDZ-maintenance therapy. Median duration of disease was 11.5 years [IQR 7-18.2] and median duration of ivVDZ treatment was 36.5 months [IQR 16-52.2]; hence, 51/94 pts (54.2%) were anti-Tumor Necrosis Factor-α exposed. Most of pts (94.7%) were on every 8-weeks maintenance therapy. At baseline, 46 (85.2%) UC pts and 36 (85.7%) CD pts had normal CRP levels. 78/94 (82.9%) pts (35 CD, 43 UC) reached the 12-weeks follow up visit. Of 66/78 pts (84.6%) with normal CRP values at baseline, 58/66 (87.9%) pts maintained clinical steroid-free remission and normal CRP values at 12-weeks follow up. Eleven AEs were recorded: 3 SARS-COV2 infections, 1 dental abscess, 4 mild injection site reactions, 1 diffuse urticarial reaction, and 1 new onset of arthralgia. Eight pts (10.3%) discontinued scVDZ: 3 pts for AEs, 3 for disease flare and 2 for pts' preference.

Conclusion: Switching from ivVDZ to scVDZ can be considered a reasonably safe and effective treatment in maintaining remission in IBD pts at 12 weeks. Thus, recent availability of scVDZ can possibly permit an improvement of the quality of life of the pts and an abatement of the health care costs due to less frequent accesses to outpatient department for intravenous infusions.

However, larger real life studies with longer follow up to confirm the long term efficacy, tolerability and safety to scVDZ are needed.

Disclosure: Nothing to disclose.

RETROSPECTIVE ONE-CENTER STUDY COMPARING SAFETY AND EFFICACY OF IRON FORMULATIONS (FERRIC DERISOMALTOSE AND CARBOXYMALTOSE) IN GASTROENTEROLOGICAL PATIENTS

E.M. Tulewicz-Marti¹, G. Rydzewska^{1,2}

¹Central Clinical Hospital of Ministry of Interior and Administration, Department of General Medicine and Gastroenterology with Inflammatory Bowel Disease Subdivision, Warsaw, Poland, ²Jan Kochanowski University, Collegium Medicum, Kielce, Poland

Contact E-Mail Address: e.tulewicz@gmail.com

Introduction: Iron deficiency anaemia (IDA) and iron deficiency (ID) are common medical problems in gastroenterology departments. However, the choice of iron formula often depends on the concern in the case of the safety of these drugs for patients, especially women during pregnancy.

Aims & Methods: The aim of this study was to evaluate security profile and the efficiency of iron formulations ferric carboxymaltose (FCM, Ferinject®) and ferric derisomaltose (DIM, Monover®) among gastrointestinal patients.

The present retrospective study examined data of the patients who received IV iron between January 2020 and December 2021 at the Central Clinical Hospital, Warsaw, Poland. Patients demographic data, dosage, adverse drug reactions (ADR) and haemoglobin follow-up were collected from electronic medical records, studied and finally compared.

Results: We analysed data from 241 scheduled iron administrations. In total 183 patients had IV iron administered (53.6% (98) had Crohn's disease, 41% (75) ulcerative colitis, 1.1% (2) Inflammatory Bowel Disease (IBD) unclassified and 4.4% (8) had anaemia caused by Gastric Antral Vascular Ectasia (GAVE), celiac disease or iron deficiency anaemia during the study; what is more 2 patients with IBD were pregnant). 37% (68) of patients had previous history of the form of allergy.

Mean age was 35.6 (SD=12.0). DIM was applied in 80.5% (194 infusions) and FCM in 19.5 % (47 infusions). The mean level of ferritin before IV iron administration was 29.8 µg/L (SD=56.6). 10 patients were needed to be given a blood transfusions before IV iron administration because of a severe anaemia.

Mean haemoglobin level in the whole studied group before IV iron was 10.2 g/dL (SD=1.5): 9.3 (1.4) g/dL in FCM and 10.4 (1.4)g/dL in DIM (p=0.001) and after IV iron 12.1 (SD=1.9) g/dL, including after FCM- 11.1 (1.7) g/dL and DIM- 12.2 (1.9) g/dL respectively (p=0.018). 18.8% (22) patients needed another IV iron replacement in 2-3 months - 25% patients (n=4) after FCM and 17.7% (n=17) after DIM; p=0.50). In 2.4% (6 patients) ADR were observed (including one during FCM infusion) and they included dizziness, faintness, skin problems (rash, skin itchiness), sensation of dyspnoea, pressure in the chest, sensation of hot and hypotension, which were successfully recovered after IV antihistamines and corticoids and further hospitalization was not required. None of the patients who suffered from side effects of IV iron had previous history of allergy to medication.

Conclusion: This study supports data that IV iron formulas are safe in all patients including pregnant women with IBD. Iron IV administration achieved optimal haemoglobin levels in most patients, however some of them needed another IV iron infusion.

Moreover, patients after IV iron administration require strict follow-up in order to control and early symptoms of IDA or ID be detected to plan another replacement urgently.

Disclosure: No conflict of interest.

Contact E-Mail Address: ayal.red@gmail.com

Introduction: Inflammatory bowel disease related symptoms have limiting and often disabling consequences on patients' life. Pain is a predominant symptom in individuals with Crohn's Disease (CD), and in up to 87% of patients with IBD, chronic pain is a growing problem and has a large impact on quality of life. In addition, Poor sleep is associated with adverse health consequences and was shown to be associated with subclinically active inflammatory bowel diseases (IBD). Altered sleep patterns in IBD patients were associated with frequent disease flares and lower quality of life.

The aim of this study was to assess the effect of cannabis use on chronic pain and sleep quality in patients with CD.

Aims & Methods: We conducted a prospective observational cohort study enrolling 127 CD patients who were prescribed medical cannabis. Patients who changed medication during the trial, reported use of cannabis 3 months before the trial, or failed to follow up were excluded from the analysis. Patients filled questionnaires at baseline and after 3 and 6 months of therapy. Sleep quality was measured using the Pittsburgh Sleep Quality Index (PSQI). Pain intensity was measured using pain visual analog scale (VAS).

Results: A total of 127 patients with CD were included, of these x(y%) were male, with a median age of y (range) and a median disease duration of x years (range). The median prescribed cannabis dose was X grams, with a median of x grams of CBD and y grams of THC per month.

Patients reported a reduction in pain intensity with a decrease in mean pain VAS score at 3 months (6.1±0.4 vs 5.2±0.4, p≤0.01) and (6.1±0.4 vs 4.8±0.4, p=) at 6 month, compared to baseline. Pittsburgh Sleep Quality Index (PSQI) for sleep (from 7.7±0.5 to 6.2±0.5, p≤0.001).

Disease severity also decreased significantly according to the Harvey Bradshaw index (HBI, from 8.3±0.7 to 6.5±0.5, p≤0.001).

After 6 months of MC therapy; VAS, PSQI and HBI scores did not change further, in comparison to 3 months therapy (4.8±0.4, 6.5±0.6, and 6.3±0.5; respectively. p=NS).

Conclusion: MC significantly improves how patients perceive their pain, disease severity and sleep quality. Ongoing experiments to determine fecal calprotectin levels will hint to CB's effect on intestinal inflammation.

Disclosure: Nothing to disclose.

P0513

FACTORS INFLUENCING INFLIXIMAB FAILURE IN ANTI-TNF NAIVE CHILDREN WITH ACTIVE ULCERATIVE COLITIS

H. Atta¹, R. Muhammed¹¹Birmingham Children's Hospital, Gastroenterology, Birmingham, United Kingdom

Contact E-Mail Address: huda.atta@nhs.net

Introduction: Infliximab is an effective treatment for moderate to severe ulcerative colitis in children. We aimed to identify factors that influence remission at week 52

Aims & Methods: Aim: To evaluate predictors at diagnosis and post IFX induction for achieving/maintaining remission at week 52

Methods: Retrospective study of 50 consecutive children with ulcerative colitis managed with Infliximab at Birmingham Children's Hospital with follow-up for at least one year after commencing Infliximab treatment. All patients had Infliximab level and antibody levels documented as requested by the clinician.

Clinical remission was assessed using by Paediatric Ulcerative Colitis Activity Index (PUCAI). Steroid-free remission was defined as patients in clinical remission without the need for any forms of steroid therapy in the previous 3 months. Statistical analysis was done using SPSS Statistics 28.0.1

Results: 50 patients treated with Infliximab (biosimilar Infliximab) as their primary biological treatment for active ulcerative colitis. One patient had infusion reaction after one infusion of Infliximab. Clinical remission was achieved in 31/49 (63%) patients at week 12. 38/49 (78%) were in steroid-free clinical remission at week 52.

Table 1 shows the comparison between patients who remained in steroid-free clinical remission at week 52 and patients not in steroid-free remission at week 52 or discontinued Infliximab before week 52.

	Patients in steroid-free clinical remission at week 52 (n=38)	Patients not in steroid-free clinical remission at week 52 or discontinued Infliximab before week 52 (n= 11)	P value
Age at diagnosis in years (mean)	10.9	11.36	0.34
PUCAI at diagnosis (mean)	49.3	58.18	0.078
CRP (mg/L) at diagnosis	7.4	26.87	0.022*
Patients on Combined Therapy (n)	30	7	0.29
PUCAI at week 12 (mean)	6.71	20.45	0.003*
Patients in clinical remission at week 12 (n)	27 (71%)	4 (36%)	0.036*
IFX level (µg/mL) category			
<5	8	0	0.23
5-10	7	2	
>10	23	9	
Anti-infliximab antibodies (AU/mL) at week 12(Mean)	10.2	4.9	0.076
Number of patients with anti-infliximab antibodies	5	0	0.2
Patients needed modification of IFX dose	32 (84%)	6 (55%)	0.09

Table 1.

Of the 31 patients in clinical remission at week 12, 27 continued to remain in steroid-free remission at week 52. 4/31 had secondary loss of response to Infliximab (1 changed to adalimumab, 1 had re-induction with infliximab, 1 had treatment with budesonide and 1 had added treatment with mesalazine).

Of the 18 patients not in clinical remission at week 12, 11 (61%) achieved steroid-free clinical remission by week 52. 2/18 needed colectomy and another 2 patients were switched to different treatment (1 to cyclosporine and 1 to adalimumab). 3/18 remained on Infliximab till week 52, however did not achieve steroid-free remission by week 52.

Factors influencing steroid-free remission at week 52 were elevated CRP at diagnosis ($p = 0.022$) and clinical remission at week 12 ($p = 0.036$). Combination therapy with immunomodulators or Infliximab levels or anti-infliximab antibody levels did not correlate with steroid-free remission at week 52.

Conclusion: Infliximab treatment failure is uncommon in children with ulcerative colitis and is predicted by high CRP levels at diagnosis and failure to achieve clinical remission at week 12 after commencing Infliximab treatment.

PROACTIVE INFLIXIMAB IS MORE EFFECTIVE THAN VEDOLIZUMAB IN INDUCING FECAL CALPROTECTIN REMISSION IN INFLAMMATORY BOWEL DISEASE

I. Botto¹, S. Bronze¹, I. Rodrigues¹, J. Serrazina¹, S.R. Fernandes¹, S. Bernardo¹, A.R. Gonçalves¹, A.I. Valente¹, P. Moura Santos¹, L. Correia¹, R.T. Marinho¹¹Centro Hospitalar Universitário Lisboa Norte, Serviço de Gastreenterologia e Hepatologia, Lisboa, Portugal

Contact E-Mail Address: sergiobronze@campus.ul.pt

Introduction: Current evidence suggests that vedolizumab (VDZ) may be as effective as infliximab (IFX) in inflammatory bowel disease. It is unknown if proactive therapeutic drug monitoring (PTDM) of IFX may improve these results.

Aims & Methods: Case-control study including consecutive patients with primary response to conventional IFX (n=70), proactive IFX (n=148), and VDZ (n=95). PTDM was performed at week 14 and every other infusion, aiming at a trough level between 5-10 µg/mL. The primary outcome was fecal calprotectin (Fc) remission (<250 µg/g) at 1 year of treatment. Secondary outcomes included Fc remission at week 14 (proactive IFX/VDZ), and clinical remission, treatment discontinuation, hospitalization, and surgery at 1-year of follow-up.

Results: Proactive IFX was superior to conventional IFX and VDZ in inducing Fc remission at 1-year (69.4% vs 47.1% vs 37.9%, $P=0.003$ and $P<0.001$). Results remained significant in biologic naïve patients (70.8% vs 44.4% vs 51.4%, $P=0.001$ and $P=0.043$) but comparisons between conventional IFX and VDZ were not significant ($P=0.265$ and $P=0.664$). In multivariate analysis correcting for prior biologic exposure, proactive IFX was more effective than conventional IFX (OR 2.480 95%CI[1.367-4.499], $P=0.003$) and VDZ (OR 3.467 95%CI[1.578-7.617], $P=0.002$) in inducing Fc remission. Amongst secondary outcomes, only clinical remission was significant between proactive IFX and VDZ in the overall cohort (80.4% vs 55.8%, $P<0.001$) and in biologic naïve patients (80.2% vs 62.9%, $P=0.043$). Fc remission at 1-year was associated with better results in most secondary outcomes.

Conclusion: Proactive IFX was superior to VDZ in inducing Fc remission at 1-year, which associated with improved clinical outcomes.

Disclosure: Nothing to disclose.

EFFECTS OF REPEAT INFLIXIMAB TO STEADY STATE ON BLOOD PROINFLAMMATORY BIOMARKERS TNFA, IL-6, IFN γ AND NITRITE/NITRATE IN CROHN'S DISEASE

A. Touny¹, D.-L. Webb¹, P.M. Hellström¹

¹Uppsala University, Medical Sciences/Gastroenterology, Uppsala, Sweden

Contact E-Mail Address: per.hellstrom@medsci.uu.se

Introduction: Crohn's disease is an incurable gastrointestinal inflammation causing a significant burden for patients. It is a heterogeneous disease derived by a cascade of inflammatory reactions. Currently, biological agents are promising and achieving optimum disease management.

The aim of the study was to longitudinally follow the biomarker response to infliximab in order to differentiate the most adequate therapeutic marker.

Aims & Methods: A total of 46 patients with moderate-to-severe Crohn's disease were investigated for their response to infliximab. They received infliximab (5 mg/kg) throughout multiple time points of infusion visits which were coupled with subsequent follow-up visits one week post each infusion. Harvey-Bradshaw Index (HBI), a questionnaire assesses the degree of the disease activity, was reported by patients before and after treatment. Patients' serum samples that were drawn during infusion and follow-up visits were analyzed for the major disease-driving inflammatory biomarkers.

Analysis involved measurement of nitrite/nitrate (NOx) concentration by the nitrite/nitrate assay, in addition to, measurement of TNF α , IL-6, and IFN γ by MesoScale ELISA technique. As controls, 63 healthy subjects were used and their serum samples were analyzed for the same biomarkers.

Results: The analysed biomarkers displayed different response patterns to infliximab. Whereas TNF α reflected the treatment with infliximab, IFN γ displayed a short-term passing response to infliximab, and IL-6 a more protracted response.

NOx levels decreased significantly throughout the infliximab infusions approaching the concentration range of healthy controls. NOx showed a superior stable response to infliximab compared with the other studied proinflammatory cytokines. HBI scores dropped significantly after infliximab treatment.

Infliximab is efficacious in maintaining NOx levels downregulated over time. NOx could be useful as a main diagnostic biomarker and in monitoring therapeutic response. The drop in HBI scores post treatment demonstrates the inhibition of disease activity with remission and improvement of patients' quality of life.

Conclusion: Infliximab treatment is efficacious in maintaining NOx levels downregulated over time, while other biomarkers were found to show variable responses in parallel with infliximab treatments. NOx could be useful as a main diagnostic biomarker and in monitoring a long-standing therapeutic response. The drop in HBI scores post treatment demonstrates the inhibition of disease activity with remission and improvement of patients' quality of life.

Contact E-Mail Address: sbrakas@yahoo.gr

Introduction: Loss of response in vedolizumab has not been extensively studied, but the estimated annual risk is around 13%. In the majority of cases empirical dose intensification every 4 weeks rather than therapeutic drug monitoring is used as a measure to regain response. According to the literature almost 50% of patients can regain response with this approach. Aim of this study was the recording of the percentage of patients receiving intensified regimen of vedolizumab as well as the basic characteristics of these patients.

Aims & Methods: This is a retrospective study with recording of patients currently in vedolizumab treatment from 3 tertiary centers. Data regarding disease extension, location, behavior, reason of intensification, duration of treatment before intensification were recorded.

Results: A total of 59 patients with inflammatory bowel disease (IBD) under vedolizumab therapy were enrolled; 22 with Crohn's disease (CD) and 37 with ulcerative colitis (UC). Six of the CD patients were classified as L1, 2 as L2 and 14 as L3. 20 of the UC patients were classified as extended colitis, 17 with left-sided colitis and none with proctitis. Out of the 59 patients with IBD, 13 were receiving vedolizumab every 4 weeks and one patient every 6 weeks. Intensified dosing was used in 9 (24.3%) of the 37 patients with UC and in 4 (18.2%) of those with CD. The reason for dosing intensification was primary non-response in 2 patients, partial response in 9 patients and disease exacerbation in 2 patients. Only in 1 case vedolizumab was returned to the initial dosing scheme of every 8 weeks. Seven patients received corticosteroids before dose-intensification, whereas six patients did not.

Conclusion: Approximately 20% of IBD patients under vedolizumab therapy need intensified dosing scheme to maintain response.

Disclosure: Nothing to disclose.

Contact E-Mail Address: gveereman@gmail.com

Introduction: Enteral nutrition (EN) is increasingly used for treating pediatric Crohn's disease (CD). We retrospectively studied the use of EN in Belgium and to assess the effect of diet on disease activity and growth. The Belgian Society for Pediatric Gastroenterology and Nutrition (BESPGHAN) is currently implementing the Improve Care Now (ICN) registry for Belgian CD patients. The ICN registry collects clinical data at each outpatient visit, including nutritional and growth status and the use of EN.

Aims & Methods: The medical files of Belgian pediatric patients (<18 yrs old) diagnosed with CD and identified to be included in the newly implemented ICN registry were analyzed from 2015 to 2020 for disease classification, use of EN, growth delay and BMI. Eleven variables were selected from the dataset. The response variable was BMI (kg/m²). The predictor variables were Modulife program diet, exclusive enteral nutrition (EEN), any specific diet (milkfree, lactosefree, glutenfree, meat free, excluding processed foods, including supplements), dietician involved, treatment, age at diagnosis, disease location and behavior, growth delay.

Statistical analysis was conducted using the SPSS software v.28. Pie plots with %, mean and SD were calculated for BMI. Independent samples t-tests were used to compare BMI based on variables with 2 groups or ANOVA for more than 2 groups. A p-value < 0.05 was considered significant. Effect size was calculated for each variable as well as power analysis.

Results: Data were collected from the databases of UZ Brussel, ULB, UCL and CHC Liège during the period 2015 – 2020.

The final dataset consisted of 124 patients (39.5% UZBrussel, 43.5% UCL and 17% CHC Liege). We found no association between disease location or behavior and BMI (p 0.566 & 0.864 respectively). Growth delay was significantly associated with BMI (p < 0.05).

Patients not needing biological treatment had a statistically higher BMI (p-value < 0.001). A large proportion of patients (81%) received EEN but results showed no statistical significance between those who were exposed or not (p-value = 0.667 > 0.05).

In contrast, the Modulife program led to a significantly better BMI (19.8 ± 3.8 vs. 17.5 ± 3.9 p = 0.004) and patients on any type of specific diet had a mean BMI 19.7 ± 3.9 compared to the others with BMI 17.3 ± 3.1 (p = 0.005). Involving a dietician showed a trend for better mean BMI (20.1 ± 3.9) compared to not (mean BMI 18.9 ± 3.9).

Conclusion: Results indicate no relationship between using a diet and age, disease location, behavior or growth, indicating the lack of criteria for implementing nutritional therapy. However, the use of Modulife program or any specific diet were associated with improved BMI.

Disclosure: Nothing to disclose.

Introduction: Corticosteroid therapy is still widely used to treat active ulcerative colitis (UC). The composition of the intestinal microbiome has been shown to influence treatment response to biologics in UC. We therefore investigated microbiome composition and metabolic processes during systemic corticosteroid therapy in patients with active UC and its association to treatment response.

Aims & Methods: Investigator-initiated, prospective, multi-centre study. UC patients were eligible if suffering from active disease (Lichtiger score ≥ 4) and scheduled for treatment with systemic corticosteroids. Patient characteristics and clinical scores were assessed and serum and stool samples collected at the time of steroid initiation (V1) and after one month (V2).

Patients were divided into responders (decrease of Lichtiger score ≥ 50%) and non-responders to corticosteroids at V2. 16s rRNA sequencing was performed from fecal samples, data were analysed with QIIME 2 and microbial community metabolic processes were predicted using parsimonious flux balance analysis.

Results: 93 patients (45% females) with active UC were included in the analysis. 69 patients (74%) responded to corticosteroid treatment, 24 patients (26%) did not respond. Before treatment initiation, both groups could not be distinguished by microbiome composition or function. Responders longitudinally experienced varied beta diversity and an increase of the beneficial genera *Blautia*, *Anaerostipes* and *Bifidobacterium* as well as an increase of predicted butyrate production. Non-responders had only minor longitudinal taxonomic changes with an increase of *Streptococcus salivarius*. After one month of corticosteroid therapy, responders had lower alpha diversity, distinct microbiome composition with higher abundance of the genus *Anaerostipes* and a trend to increased predicted butyrate synthesis compared to non-responders.

Conclusion: Response to systemic corticosteroids in active UC is characterized by microbiome restoration and enhanced butyrate production, probably as an indirect effect of reduced intestinal inflammation.

We were however unable to find specific predictive microbiome makers that could forecast response to therapy.

CUTANEOUS MANIFESTATIONS IN BIOLOGICAL-TREATED PEDIATRIC INFLAMMATORY BOWEL DISEASE: A 10 YEARS' EXPERIENCE FROM A TERTIARY CENTER

Z. Shchomak¹, S. Azevedo¹, L. Rodrigues¹, A.S. Cordeiro Fernandes dos Santos¹, H. Loreto¹, P. Mourato¹, A.I. Lopes¹

¹Centro Hospitalar Lisboa Norte, Department of Pediatrics, Gastroenterology Unit, Lisbon, Portugal

Contact E-Mail Address: zakhar.shchomak@gmail.com

Introduction: The advent of biological therapy has greatly improved the treatment of inflammatory bowel disease (IBD). However, biological agents, particularly anti-tumor necrosis factor-alpha (TNF-α) agents, can induce a wide variety of skin eruptions, including eczema, paradoxical psoriasis, cutaneous infections, among others.

It is important to recognize and treat these conditions appropriately and in the case of severe lesions, the biological may need to be discontinued. Only few data have been so far reported in pediatric population.

Aims & Methods: The aim of this study is to describe the cutaneous manifestations associated with biologic treatment of pediatric IBD within the last ten years in a tertiary center. A retrospective chart review (period between 2011-2022) was performed concerning patients ≤ 18 years with newly IBD diagnosis who developed new-onset lesions while treated with biological therapy.

Results: Eleven children from a total of 33 (33%) (25 with Crohn's disease, 7 with ulcerative colitis and 1 with IBD unclassified) developed cutaneous manifestations. The median age was 13,6 years (range 0,5-17,1), 6 (45%) were male and the median time from the start of biological treatment to development of lesions was 8,7 months (range 1,8-26,1).

The skin manifestations included 9 cases of paradoxical psoriasis (2 with associated folliculitis and 1 with eczema) and 2 cases of recurrent folliculitis. 9/11 (82%) were observed in dermatology outpatient clinic and 3/9 (33%) of these have required a biopsy.

The most frequently associated agents were adalimumab (7) and infliximab (4). The severity of lesions led to biologic agent discontinuation in 4 patients, all of them treated with adalimumab. In all patients, severe paradoxical psoriasis was observed and IBD was in remission at the time of onset of the skin lesions. In three of these 4 patients, a switch to another biological agent was required and in one patient to azathioprine.

Clinical improvement was observed in 2 patients that switched to ustekinumab and in one who switched to azathioprine. In two patients (1 treated with infliximab who developed recurrent folliculitis, and another treated with adalimumab who developed paradoxical psoriasis) the switch to another biological agent was due to IBD control failure.

Both, experienced subsequent clinical improvement of clinical lesions (vedolizumab and ustekinumab, respectively). Five of the remaining patients have responded to standard dermatological care.

Conclusion: Cutaneous manifestations associated with biological treatment were common in our series and led to biologic agent discontinuation in 12% of the patients, similarly to other recent series. The agent most frequently associated with cutaneous lesions was adalimumab and the

most common lesion was paradoxical psoriasis. In the most severe cases, the switch to alternative class biological agent may be effective in controlling the skin lesions and maintaining disease remission. The pathogenic mechanisms of paradoxical psoriasis are still poorly understood, but our preliminary findings suggest that cutaneous manifestations do not seem to be associated with the severity of IBD.

Disclosure: Nothing to disclose.

IMPACT OF BIOLOGIC ERA ON COLECTOMY RATE OF ULCERATIVE COLITIS; ASSESSMENT OF 22 YEAR IN A TERTIARY REFERRAL CENTER COHORT FROM A DEVELOPING COUNTRY

B. Tukek¹, O.K. Bakkaloglu¹, İ. Hatemi¹, A.F. Celik¹, Y. Erzin¹
¹Istanbul University Cerrahpasa, Istanbul, Turkey

Contact E-Mail Address: o.k.bakkaloglu@gmail.com

Introduction: We aimed to evaluate the effect of biologic era on colectomy rates and determine colectomy-related factors in our 22-year-old ulcerative colitis (UC) cohort.

Aims & Methods: Our tertiary referral center UC cohort was retrospectively evaluated. Biologic therapy in UC was reimbursed in our country in 2009 whereas its use was more frequent in our center since 2012 [first anti-TNF's than followed by vedolizumab (2017) and ustekinumab (2018)]. The patients were grouped and compared considering 2012 as a turning point of pre and post biologic era. Two patient subgroups were selected from the cohort: one consisted of patients whose follow-up finished before 2012 and the other consisted of patients with follow-up starting at/after 2012. Patients with less than 6 months of follow-up were excluded.

Results: The total number of patients of our cohort was 1058 with a median follow-up of 4 years. %35 of patients had pancolitis and half of the whole group required steroid at any point. Among steroid users, frequency of unresponsiveness was 4% and dependence was 28%.

	Pre-2012 Patient Group (n=205)	Post-2012 Patient Group (n=633)	p value
Sex (Female, %)	42	47	0.149
Age at Diagnosis (Mean ± SD years)	37 ± 13	35 ± 13	0.220
Follow-up Duration (median, month) (minimum>6 months)	31	37	0.08
Smoking (ever, %)	42	24	<0.001
Active Smoker	20	18	0.175
Ex-Smoker	22	7	<0.001
Initial extension (Paris) E1/E2/E3/E4 (%)	12/49/11/28	16/40/14/30	0.704
Maximum extension (Paris) E1/E2/E3/E4 (%)	11/46/9/34	13/37/15/36	0.245
Extension progressed during follow-up (%)	7	11	0.164
Steroid course need (ever) (%)	50	51	0.784
Steroid unresponsiveness (%)	3	2	0.560
Steroid dependency (%)	19	11	0.004
Steroid course/year (median)	1,1	0,6	0.025
Maximal treatment (%)			
5-ASA	71	56	<0.001
Immunomodulatory	28	19	0.004
Biologic	-	26	-
Minimum CRP under max. treatment step (median, mg/L)	3	1.4	<0.001
Mucosal remission under max. treatment (%)	46	57	0.048
Disease duration at colectomy (median, month)	46	38	0.404
First Year Colectomy Rate (%)#	5	0.3	<0.001
Total Colectomy rate (%)	12	2	<0.001

Table 1: Comparison of clinical features and colectomy rates of two non-overlapping independent patient sub-groups.

For the whole group: 38% of the patients received immunomodulatory therapy and 20% received biologics (of which were 64% Infliximab, 59% Adalimumab, 15% Vedolizumab, 4% Ustekinumab). Before 2012 biological therapy was less than 1%, but increased up to 25% after 2012. Total colectomy rate (including malignancy related cases) was 5.8% and disease activity related colectomy was 4.8% (n=51) in the whole group. Colectomy rate before and after 2012 was 6% (n=28) and 2.7% (n=23) respectively showing significant difference ($p<0.001$).

Table 1 shows the comparison of pre- and post-biologic era patients. Both total and 1st year colectomy rates were lower in the biologic era patients. Disappearance of this significance^{#(Table 1)} at the 4th year of disease duration suggests that biological era delay or rescue early colectomies. In the Cox regression analysis of the whole group, failure to achieve mucosal remission, a best achieved CRP value $>3\text{mg/L}$ under maximal treatment, steroid dependency, steroid unresponsiveness, and an increased number of steroids needing relapses per year were found to be independently associated with colectomy.

Conclusion: To our best knowledge, our current study discloses the colectomy decreasing effect of biologic era from a developing country for the first time. Although achievement of mucosal remission and/or (as a novel target) CRP $<3\text{mg/L}$ under were associated with reduced colectomy risk in the whole cohort, the frequency of colectomy was particularly decreased in the biological era. Treatment, modalities, and cessation of smoking between each era, as well as the effect of biological therapy, may have influence on this result.

Disclosure: Nothing to disclose.

Introduction: Loss of response to infliximab or adalimumab in ulcerative colitis occurs frequently and dose escalation may aid in regaining clinical benefit. This study aimed to systematically assess the annual loss of response and dose escalation rates for infliximab and adalimumab in ulcerative colitis.

Aims & Methods: A systematic search was conducted from January 2000 to July 2021, for studies reporting loss of response and dose escalation during infliximab and/or adalimumab use in ulcerative colitis patients with primary response. Annual loss of response and dose escalation rates and clinical benefit after dose escalation were calculated. Subgroup analyses were performed for studies with one-year follow-up (cut-off ≤ 65 weeks).

Results: We included 50 unique studies assessing loss of response (infliximab: n=24, adalimumab: n=21) or dose escalation (infliximab: n=21, adalimumab: n=16). The pooled annual loss of response for infliximab was 10.1% (95% CI [7.1-14.3]) and 13.6% (95% CI [9.3-19.9]) for studies with one-year follow-up.

The pooled annual loss of response for adalimumab was 13.4% (95% CI [8.2-21.8]) and 23.3% (95% CI [15.4-35.1]) for studies with one year follow-up. Annual pooled dose escalation rates were 13.8% (95% CI [8.7-21.7]) for infliximab and 21.3% (95% CI [14.4-31.3]) for adalimumab, regaining clinical benefit in 72.4% and 52.3%, respectively.

Conclusion: Annual loss of response was 10% for infliximab and 13% for adalimumab, with higher rates during the first year. Annual dose escalation rates were slightly higher than loss of response, with clinical benefit 72% (infliximab) and 52% (adalimumab). Uniform definitions are needed to provide more robust evaluations.

Contact E-Mail Address: lorantgonczi@gmail.com

Introduction: Few population-based studies have investigated the long-term colectomy rates of ulcerative colitis (UC). The present study is a continuation of the Veszprem IBD population based cohort with a follow-up of the incidence and disease course for over 40 years.

Aims & Methods: Our aim was to analyze the long-term colectomy rates over different therapeutic eras in a prospective population-based database from Veszprem Province, including incident UC patients.

Data of 1,370 incident UC patients were analyzed (male/female: 702/668; median age at diagnosis: 37 years(y) [IQR: 26-51]), with a median of 17y (IQR 9-24) follow-up. Patient inclusion lasted between January 1, 1977 and December 31, 2018. Patient follow-up ended December 31, 2020.

Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up. Disease extension was evaluated based on the Montreal classification. Colectomy rates were examined in three different eras based on time of diagnosis: cohort-A, 1977-1995; cohort-B, 1996-2008; and cohort-C, 2009-2018.

Results: The overall colectomy rate was 76/1,370 patients during the total follow-up. The cumulative probability of colectomy in the total population was $4.1\pm 0.6\%$ after 10 years, $6.3\pm 0.8\%$ after 20 years, and $8.8\pm 1.2\%$ after 30 years. Disease phenotype at diagnosis was similar in the three cohorts (extensive colitis: 24.2% / 24.3% / 34.9% in cohorts A/B/C). Overall immunosuppressive therapy use was increasing in the cohorts (11.3% / 20.9% / 34.4%), as well as the probability of biological therapy initiation within 5 years of diagnosis ($0.0\pm 0\%$ / $3.3\pm 0.7\%$ / $13.9\pm 1.8\%$).

There were no statistically significant differences in the cumulative probability of colectomies between cohorts A/B/C: $1.7\pm 0.7\%$ / $2.2\pm 0.6\%$ / $3.7\pm 1.0\%$ after 5 years; $3.5\pm 1.0\%$ / $3.9\pm 0.8\%$ / $4.5\pm 1.2\%$ after 10 years; and $6.9\pm 1.4\%$ / $5.3\pm 1.0\%$ (cohorts A/B) after 20 years [Log Rank=0.447].

Conclusion: No differences in colectomy risk have been observed in incident UC patients over the 40 years of this population-based study, despite the increasing use of immunosuppressive and biological therapies.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel disease (IBD) may be associated with other immune-mediated conditions, both as a consequence of medical treatment and because of complex etiologic interactions. Diabetes Mellitus (DM) may occur in patients with IBD and influence the disease progression.

Aims & Methods: The aim of this study was to compare the course and outcomes of treatment in IBD patients with and without DM.

This is a PRISMA- and MOOSE- compliant systematic review with meta-analysis recorded on PROSPERO (ID CRD42022315509). Only studies comparing patients with IBD plus DM with patients with IBD only were included.

Primary endpoints were: need for surgery, IBD-related complications, IBD-related hospitalizations, sepsis, and mortality.

Secondary endpoints were risk of infection, quality of life, and healthcare costs.

Results: Five studies including 71,216 IBD patients, 36,248 patients (50.9%) without vs. 34,968 patients (49.1%) with DM, were included in the meta-analysis. The risk for IBD-related complications (OR=1.12 95%CI 0.52-2.45 P 98% $p=0.77$), mortality (OR=1.52 95%CI 0.61-3.81, P 98% $p=0.37$) and IBD-related surgery (OR=1.20 95%CI 0.88-1.63, P 81% $p=0.26$) did not differ between groups.

The risk of IBD-related hospitalizations (OR=2.52 95%CI 2.17-2.98, I^2 0% $p<0.00001$) and sepsis (OR=1.56 95%CI 1.06-2.29, I^2 88% $p=0.0003$) was higher in the IBD+DM group.

The risk of pneumonia and urinary tract infections (UTIs) was higher in the IBD+DM group (OR=1.72 95%CI 1.38-2.14, P 0% $p<0.00001$ vs OR=1.93 95%CI 1.51-2.47 P 8% $p<0.00001$ respectively), while the risk of *C. Difficile* infection did not differ (OR=1.22 95%CI 0.78-1.90 P 88% $p=0.37$).

The mean Short Inflammatory Bowel Disease Questionnaire (SIBDQ) score was lower in the IBD+DM group than in the IBD group (38.9 vs. 47, respectively $p=0.03$). Mean health care costs per year were \$10,598.2 [IQR 37,808.4] vs \$3,747.3 [IQR 20,182.9] ($p<0.001$).

In order to reduce heterogeneity, a sensitivity analysis has been conducted: for surgical interventions related to IBD an OR of 1.21 was found (95%CI 1.00-1.46, P 0% $p=0.05$), as for sepsis, the OR was 1.92 (95%CI 1.56-2.37, P 0% $p<0.00001$).

Finally, an analysis was conducted on patients with Crohn's disease (CD) that reported an OR on surgery CD-related of 3.03, 95%CI 0.92-9.99, I^2 76% $p=0.07$.

Outcomes	IBD+DM vs IBD				CD+DM vs CD		
	Before sensitivity analysis		After sensitivity analysis				Relative effect (95% CI)
	N of patients (studies)	Relative effect (95% CI)	I^2	N of patients (studies)	Relative effect (95% CI)	I^2	
IBD related hospitalizations	3026 (2)	OR 2.54 (0.52 to 2.45)	0	-	-	-	-
Mortality	70225 (2)	OR 1.52 (0.61 to 3.81)	98%	-	-	-	-
Sepsis	70435 (3)	OR 1.56 (1.06 to 2.29)	88%	2695 (2)	OR 1.92 (1.56-2.37)	0%	-
IBD-related surgery	71006 (4)	OR 1.20 (0.88 to 1.63)	81%	3026 (2)	OR 1.21 (1.00-1.46)	0%	OR 3.03 (0.92 to 9.99)
Pneumonia	2695 (2)	OR 1.71 (1.38 to 2.14)	0%	-	-	-	-
Urinary tract infections	2695 (2)	OR 1.93 (1.51 to 2.47)	8%	-	-	-	-
C. difficile	70225 (2)	OR 1.22 (0.79 to 1.90)	88%	-	-	-	-

Conclusion: DM appears to negatively affect the course of IBD by increasing the risk of hospitalization and infections (pneumonia, UTIs and sepsis), while it does not appear to influence IBD-related complications and mortality.

Contact E-Mail Address: mdegregorio@live.com.au

Introduction: Perianal fistulas are a morbid and often treatment refractory manifestation of Crohn's disease. Combination treatment with biologics and definitive surgical closure have shown the highest rates of sustained fistula healing. Multiple surgical drainage and closure techniques can be used, with variable efficacy. Furthermore, there is a paucity of data evaluating real-world colorectal surgeon practice.

Aims & Methods: In an investigator-initiated cross-sectional study we evaluated the preferred definitive surgery of colorectal surgeons in Australia and New Zealand for managing adults with Crohn's perianal fistulas. Data was collected using an anonymous survey developed by a working group of colorectal surgeons and gastroenterologists specialising in inflammatory bowel disease. Twelve questions covered: surgeon characteristics; preferred definitive surgery in adults with Crohn's perianal fistulas with a seton *in situ* and quiescent disease; and factors influencing decision making.

Questions relating to preferred surgery and influential factors used a 100-point continuous visual analogue scale (0 = *never or not influential*; 100 = *always or extremely influential*). Registered colorectal surgeons with *Colorectal Surgical Society of Australia and New Zealand* membership were invited to participate. Ordinal scale data was presented as a median and

interquartile range (IQR). Correlation between preferred surgery and surgeon characteristics and influential factors was assessed using univariate and multivariable logistic regression analysis; presented as an odds ratio (OR) and 95% confidence interval (CI).

Results: Of the 288 colorectal surgeons invited to participate, 129 completed the survey; 54% were registered as colorectal surgeons for >10 years, 84% practiced in public hospitals, 64% had multi-disciplinary meeting access, and 47% performed ≤ 5 definitive surgeries per year, with only 9% performing >20 cases.

Most surgeons preferred to manage fistulas with setons alone, either long-term placement without removal (median score 65; IQR 50-80) or with removal (median score 50; IQR 22-70). The remaining definitive surgical options had median scores <50, including fistulotomy or fistulectomy, mucosal advancement flap, ligation of intersphincteric fistula tract, biomaterial plug, simple closure of internal opening, fibrin glue, video-assisted anal fistula treatment, fat graft injection, and laser closure.

Previous training and experience were rated as the most influential factors on the choice of definitive surgery performed, followed by guidelines and expert opinions, publications and conferences, and multi-disciplinary meetings. Sepsis control was rated as the most influential factor on the timing of definitive surgery, followed by active proctitis, medical therapy optimisation, patient symptom burden, tract maturation, and gastroenterologist agreement.

On multivariable analysis, preference for placement of a long-term seton positively correlated with prioritisation of active proctitis (OR 3.68; CI 1.07-12.67; $P = .039$). No correlations were identified for preference to perform seton removal only.

Conclusion: Despite evidence supporting combination treatment with biologics and definitive surgical closure techniques for sustained fistula healing in patients with Crohn's disease, long-term seton placement is still the preferred practice by colorectal surgeons. Previous training and experience had the highest influence on the choice of surgery performed. Further studies evaluating why colorectal surgeons prefer long-term seton placement as opposed to fistula closure techniques are needed.

Disclosure: No conflicts of interest to disclose.

HAS BODY IMAGE IMPROVED AMONGST INDIVIDUALS WITH INFLAMMATORY BOWEL DISEASE IN THE MODERN ERA?

S. Madigan¹, I. Prichard², C. Smart¹, C.L. Wang^{3,4}, R. Prosser¹, R. Mountfield¹

¹Southern Adelaide Local Health Network, Department of Gastroenterology, Flinders Medical Centre, Bedford Park, Australia, ²Flinders University, College of Nursing and Health Science, Bedford Park, Australia, ³University of Adelaide, Adelaide Nursing School, Faculty of Health and Medical Sciences, Adelaide, Australia, ⁴Flinders Medical Centre, Surgical and Perioperative Medicine, Bedford Park, Australia

Contact E-Mail Address: shaunamadigan@gmail.com

Introduction: IBD is known to adversely affect patient body image due to negative cosmetic effects of disease and the medical and surgical treatments required.[1] This has historically been associated with female sex, previous IBD surgery, and impaired QoL. [2] The introduction of biologic therapies and modern IBD care in Australia in 2007 has improved disease control and endoscopic outcomes, but it is unclear if body image has improved in parallel with this.

Aims & Methods: To determine whether body image and QoL have improved amongst IBD patients with modern IBD care and to determine the relationship between modern IBD surgery and body image.

Individuals with known history of IBD cared for via SALHN IBD service (a tertiary hospital specialist clinic) were offered inclusion in the study both in 2006 by postal survey (historical era), and in 2021 by electronic survey (modern era).

All participants completed surveys which included demographics and history of IBD surgery. In the historical era body image dissatisfaction (BID) and QoL were assessed using a patient reported yes/no question as no validated IBD tools were available. In the modern era the modified Body Image Scale (BIS) and Short Inflammatory Bowel Disease Questionnaire (SIBDQ) were used. The modified BIS is a validated tool for assessing body image in IBD. [3] A score of greater than 10 was considered BID. The SIBDQ is a validated tool that measures QoL and a score of less than 50 was considered impaired QoL. [4]

Results: The modern era included 135 patients, 59% female, mean age 45.9. The historical era included 215 patients, 66% female and mean age 35.5. Historical era had 40% reporting IBD surgery vs 36% in modern era ($P=0.489$). BID was observed in 67% vs 39% of the historical and modern eras respectively ($p<0.00001$). In both eras females were affected to a greater extent with 75% BID compared with 52% of males in the historical era ($p<0.001$), and 50.5% versus 22% of males in the modern era ($p<0.001$). In the historical era patients reporting surgical intervention for their IBD had higher rates of BID than those without surgery (81% vs 58%, $p<0.001$). Interestingly this association between surgery and BID was not observed in the modern era (47% vs 34.9%, $p=0.168$).

In the historical era 89% patients reported impaired QoL compared with 71% in the modern era ($p<0.001$). Females again demonstrated higher rates of impaired QoL than males in the modern era (68% vs 49%, $p=0.03$). Whilst surgical intervention in the historical era was associated with greater QoL impairment than no surgery (94% vs 85%, $p=0.042$), this association was not observed in the modern era, with surgical and non-surgical patients reporting similar QoL (67% vs 57% $p=0.278$).

In the historical era those with BID were significantly more likely to report impaired QoL (97% vs 71%, $p<0.0001$). This association persisted with time with modern era patients with BID also having higher rates of QoL impairment compared to those without BID (85% vs 45% $p<0.0001$). Comparison of the eras demonstrated significant reduction in QoL impairment over time ($p=0.003$).

Conclusion: Whilst the rate of BID has decreased with modern IBD treatment; it remains a common problem for those with IBD, and is associated with impaired QoL. Whilst females remain disproportionately affected, the historically observed association between IBD surgery and impaired body image was not demonstrated in the modern era. This may reflect improved surgical techniques and biologic down staging prior to surgery. However, body image remains an important Patient Reported Outcome in IBD and warrants further attention.

Introduction: There is growing consensus that ileal Crohn's disease (iCD) should be considered fundamentally distinct from colonic Crohn's. Montreal classification of L1 encompasses ileal disease but does not provide additional descriptors for anatomical distribution. The ileum is about 3 meters, the terminal ileum is accessible via colonoscopy but not the distal or proximal ileum. Proximal and terminal ileum disease would be classified as L1 but could have varied clinical implications.

We aimed to describe our cohort of iCD patients and factors associated with surgery. Our secondary aim was to determine if the anatomical distribution of iCD at diagnosis predicts a higher likelihood of unplanned ileal resection.

Aims & Methods: This was a retrospective, study conducted across 3 large hospitals in Singapore. Patients were identified from a prospectively maintained registry of inflammatory bowel disease (IBD) patients.

We enrolled patients between Jan 2001 to Sep 2021 with endoscopic, histological and cross-sectional imaging at diagnosis and excluded patients with colonic involvement.

Cross-sectional images were reviewed by IBD radiologists. Lengths of discrete diseased segments were measured. We used the following anatomical definitions for different ileal segments:

- Terminal ileum (TI): continuous 15cm segment before the ileocaecal valve
- Distal ileum (DI): mid ileum to proximal end of TI
- Proximal ileum (PI): distal end of jejunum to mid ileum

Analysis was done with SPSS version 23.0

Results: From a period between Jan 2001 to Sep 2021, there were 534 patients with CD. We identified 74 patients with iCD. 59 patients were included for analysis, 15 patients were excluded as index cross-sectional images at diagnosis were not available.

The median time to surgery was 337 days. 15 patients required ileal resection for which the indications were: perforation (n=6), obstruction (n=4), medical failure (n=5); 2 patients had concomitant intra-abdominal abscesses. Of these, 7 had immunomodulator, 1 had biologic monotherapy, 6 had combination therapy and 1 was untreated.

iCD with B3 phenotype (p<0.05) and positive smoking history (p=0.013) were associated with higher risks of surgery. Most of the patients who underwent surgery were in the A2 category of the Montreal classification (ages 17 to 40). Of interest, 11 out of 15 (73.3%) patients who underwent resection had multiple diseased segments.

When stratified into isolated TI involvement vs DI/PI involvement in a survival curve, there was trend to ileal resection in the DI/PI group (Log Rank p=0.145). Of note, while not significant, there was DI involvement in 13 out

of 15 patients who underwent resection (86.7%, p=0.085). Gender, Race, Perianal involvement, treatment exposure, total length of ileal disease involvement were not associated with ileal resection.

Conclusion: In iCD, smoking and B3 phenotype are poor prognostic factors in iCD, with most patients having surgery within the 1st year. Although not statistically significant due to few events, involvement of DI/PI at diagnosis tended towards a higher risk of ileal resection compared to isolated TI involvement. Further studies are required to corroborate our findings.

Contact E-Mail Address: catherine.reenaers@chuliege.be

Introduction: Local injection of adipose tissue-derived mesenchymal stem cells (MSC) is effective in fistulizing perianal Crohn's disease (CD) although it is currently hampered by the cost and the logistics of administration of centrally-produced MSC. Less is known about bone marrow-derived MSC and little is known about predictive factors of response and MRI evolution of the fistulae after MSC injection.

Aims & Methods: Our aims were to evaluate the safety and efficacy of bone marrow-derived MSC injection for perianal fistulizing CD, to evaluate the MRI evolution of the fistulae and to identify factors associated with fistula closure.

A prospective interventional uncontrolled study was performed in the CHU of Liège from October 2019 till October 2021. All CD patients with perianal fistula and appropriate drainage with a seton without abscess at MRI were eligible. Clinical examination, biomarkers and pelvic MRI were performed at weeks 0, 12 and 48. MAGNIFI-CD and Van Assche Index were calculated for each MRI. The evolution of the % of fibrosis of the fistula tract was evaluated.

Efficacy was defined as closure of all treated external openings at clinical examination without abscess at MRI. Super closure was defined as closure without discharge reported by the patient the week before examination and partial closure by the closure of some, but not all, external openings.

Results: Sixteen patients with a median age of 49 years old and a median duration of perianal CD of 8 months were included. At baseline, 10 (62.5%) and 6 patients (37.5%) had 1 and 2 external openings at clinical examination respectively. At week 12 and 48, 9/16 and 8/16 patients had fistula(e) closure respectively, 6/16 patients had super closure at week 12 and 48 whereas 11/16 patients had at least partial closure. Fistula closure at week 12 was predictive of fistula closure at week 48 (p=0.024, OR=21). The MAGNIFI-CD index did not change significantly overtime. At MRI, the degree of fibrosis significantly increased after MSC injection and it was associated with fistula closure at week 48 (p=0.036, OR=4.5). Eighty-six % of patients with >80% of fibrosis of the fistula tract at week 48 had fistula closure.

The enhancement of the part of the fistula close to the external opening significantly decreased at week 48 compared to baseline (p=0.002). Several items of the MAGNIFI-CD and Van Assche index at week 48 were

associated with super closure at week 48: number of fistula tracts, hyperintensity of primary tract on post-contrast T1-weighted images, fistula length, hyperintensity T2-weighted images, hyperintensity on T1 post-contrast.

Conclusion: Open-label injection of bone marrow-derived mesenchymal stem cells was safe and effective in half of the patients in fistulizing perianal CD and induced significant MRI changes associated with favorable clinical outcome.

This study might be a first step to define targets in perianal CD to implement a treat-to-target strategy in perianal CD.

Disclosure: Nothing to disclose.

CZECH EXPERIENCE WITH TREATMENT OF CROHN'S DISEASE PERIANAL FISTULAS BY ALLOGENIC MESENCHYMAL STEM CELLS

Z. Serclová¹, P. Zusková¹, A. Tremerová¹, M. Lengálová¹, L. Hrdlicka¹

¹NH Hospital, Surgical Department, Horovice, Czech Republic

Contact E-Mail Address: sercl@seznam.cz

Introduction: Perianal complex fistulas in Crohn's disease (CD) are difficult to treat by both surgical and conservative methods. Administration of allogenic, adipose-derived mesenchymal stem cells (darvadstrocel) was studied in a prospective randomised trial (PRS) with a success rate of more than 50%¹.

The aim of our study was prospectively evaluate results of commercial treatment of perianal fistulas in CD patients by darvadstrocel in Czech Republic.

Aims & Methods: We prospectively followed 56 consecutive patients treated commercially by darvadstrocel since August 2019 till November 2021. Complete healing was considered as: no secretion from the external opening, no infiltration perianally, no pain; treatment failure: clear perianal secretion, painful infiltration and / or the need for surgery; partial response: anamnestic mild secretion from one external opening, infiltration around the fistula without pain and without the need for surgical intervention.

56 prospectively monitored patients (33F/23M), average age 40,5 years (range; 21-71 years) underwent darvadstrocel treatment in 2 Czech mesenchymal stem cell (MSC) therapy centers (53 pp in NH Hospital, 3 in ISCARE center).

Patients suffered from intestinal CD for an average of 14.5 years (2-43 years), perianal CD for 8 years (2-23 years) and underwent an average of 7.5 (3-25) minor perianal surgeries before the treatment. 41% (23) of patients had anorectal stenosis at the time of the treatment.

Patients were treated on average 19 months (1-120) by stable immunosuppressive and/or biologic therapy. Fistulas characteristic: High transfincteric in 52 (92,8%) pts with 1-3 external openings (EO) (72%; 40 pp had 1 EO) and with 1-2 internal openings (IO) (12.5%; 7 pp had 2 IO).

Results: Median follow-up was 12 months (5-31 months). Complete healing occurred in 78,5% patients (44), partial response in 10.7% (6pp) and treatment failure in 6 patients (10.7%). PDAI before MSC surgery was on average 5.8 (3-13), 3 months after surgery 2.4 (0-13) and 6 months after surgery 2.1 (0-13) in healed and unhealed patients.

Conclusion: The treatment was more successful in real life than in PRS, which may be due to the relatively short follow-up period. Another reason for better outcome could be proper selection of patients with long term stable conservative treatment, which demonstrates stable CD.

In our conditions, this treatment is similarly effective as eradication of the fistula using Advancement Flap, but it can also be used in difficult conditions such as anorectal stenosis or chronic inflammatory changes of rectal mucosa.

MESENCHYMAL STEM CELLS INJECTION INTO COMPLEX PERIANAL FISTULAS IN CROHN'S DISEASE: PRELIMINARY REAL-LIFE RESULTS

N. Fathallah¹, L. Siproudhis², M. Akaffou¹, A. Landemaine², E. Pommaret¹, L. Spindler¹, C. Brochard², G. Bouguen², V. de Parades¹

¹GH Paris St Joseph, Proctology, Paris, France, ²CHU de Rennes, Gastroenterology and Proctology, Rennes, France

Contact E-Mail Address: laurent.siproudhis@gmail.com

Introduction: The available data about expanded allogeneic adipose-derived mesenchymal stem cells (darvadstrocel) in Crohn's disease fistulas are limited.

Aims & Methods: The main objective of this study was to evaluate the real-life clinical and radiological efficacy of darvadstrocel injection.

Secondary objectives were to assess safety and predictors of therapeutic response.

We conducted a prospective study including all consecutive treated patients in two French centers.

Complete clinical response was defined as complete closure of all external openings (EOs) with no discharge on pressure. Partial response was defined as not closure of all EO's but with no discharge and no pain on pressure. Failure was defined as no closure of any of the EO's with persistent spontaneous or on pressure discharge ± occurrence of an abscess.

Complete radiological response (MRI), evaluated at least after 6 months of follow up, was defined as fibrous sequelae with no inflammatory enhancement and no abscess. Partial response was defined as a decrease in inflammatory signal ± length ± diameter of tracts without abscess. Failure was defined by the occurrence of new tracts ± abscess.

Results: Forty-six patients were included (F = 23, mean age = 37 ± 13 years). At the time of the procedure, 12 patients (26%) were active smokers. Mean duration of Crohn's disease and anal fistula(s) were 131 ± 114 and 82 ± 81 months respectively. Fistula tracts were multi-branched in 31 patients (67%) including 16 horseshoe fistulas.

The patients underwent a mean of 4 ± 2 drainage procedures and 15 (32%) failed at least one sphincter-saving technique. The last seton was placed 7 ± 8 months before the injection.

On MRI, the fistulous tracts were inflammatory in 42 (91%) patients.

All patients were on biologic treatment (optimized in 50% of cases) and on combination therapy in 75% of cases. Complete clinical and endoscopic remission has been achieved in 37 patients (80%), the others had signs of mild activity.

After a mean follow-up of 10 ± 5 months, 40 patients (87%) improved and 28 patients (61%) had no more perineal symptoms (pain and discharge). There was a significant improvement in the mean PDAI (2,3 ± 3 vs. 6,4 ± 2,5; p<0.0001).

Finally, 74% of patients responded clinically (50 % completely and 24 % partially).

Concerning the 41 patients/46 who had an MRI, 88 % responded radiologically (39% completely and 49% partially).

No significant adverse events were noted except mild to moderate pain in the days following the injection which was adequately managed with simple analgesics.

In univariate analysis, only young age (< 37 years) ($p = 0.049$) and inflammatory disease phenotype (B1) ($p = 0.046$) were associated with complete clinical response. In multivariate analysis, only the inflammatory phenotype remained significant and independently associated with clinical response ($p = 0.046$).

Conclusion: In our series, darvadstrocel injection resulted in 74% clinical response (50 % completely and 24 % partially) and 88% radiological response (39% completely and 49% partially). The inflammatory disease phenotype was the only independent predictor of clinical success.

Introduction: Studies on prehabilitation strategies (PS) to improve post-operative outcomes of patients with Crohn's disease (CD) are scarce and guidelines lack recommendations on tailored management.

Aims & Methods: This study aimed to explore the implementation of PS prior to ileocolic (re-)resection (ICR) in patients with CD.

Patients with CD who underwent an elective ICR, from 2017 to 2021, with a window from surgery indication to ICR of ≥ 2 weeks were included. Data concerning the preoperative management, surgery-related characteristics and -outcomes were retrospectively collected. Primary endpoint was the implementation of PS in patients with CD prior to ICR on several modifiable domains (e.g., nutrition). In addition, early postoperative complications (<30 days) according to the Clavien-Dindo classification were reported.

Results: In total, 124 patients were included. Median window from surgery indication to ICR comprised 7.9 weeks (IQR: 5.0 – 11.5). Preoperative weight was assessed in 39% of the patients. Active smoking and alcohol consumption were reported in 22% and 28%. Malnutrition was diagnosed in 26% of whom 53% consulted a dietician. Consultation of a dietician, psychologist and physiotherapist were reported in 36%, 7% and 3%. Pre-operative anemia was diagnosed in 42% and corrected in 6%. Exposure to a biological or corticosteroid, at time of ICR, was reported in 41% and 28%. Corticosteroids were weaned off in 3% Hand-grip strength was assessed in none of the patients. Overall early postoperative complications rate comprised 39%.

Window from surgery indication to ICR (in weeks), median (IQR)	7.9 (5.0 – 11.5)
Assessment of pre-operative weight, n(%)	48 (38.7)
Malnutrition, n(%) [*]	32 (25.8)
Preoperative weight loss, n (%)	1 (0.8)
Hypoalbuminemia (<30 g/dL)	3 (2.4)
BMI < 18.5	9 (7.3)
BMI > 30.0	19 (15.3)
Active smoking at time of surgery, n (%)	27 (21.8)
Alcohol consumption, n(%)	35 (28.2)
Dietician consultation, n(%)	45 (36.3)
Nutritional intervention, n(%)	41 (91.1)
Enteral support	33 (80.5)
Parenteral support	0
Exclusive enteral nutrition	6 (14.6)
Total parenteral nutrition	2 (4.9)
Micronutrients supplementation, n(%)	39 (31.5)
Psychologist consultation, n(%)	8 (6.5)
Physiotherapy consultation, n(%)	4 (3.2)
Assessment of hand-grip strength, n (%)	0
Assessment of laboratory values, n(%)	
Albumin level	30 (24.2)
CRP	53 (42.7)
Blood count [*]	65 (52.4)
Hemoglobin	84 (67.7)
Hematocrit	70 (56.5)
Leukocyte count	79 (63.7)
Thrombocyte count	44 (35.5)
Vitamin B12	12 (9.7)
Vitamin D	9 (7.3)

Abbreviations: BMI = body mass index; CRP = C-reactive protein level; ICR = ileocolic resection.

^{*}Combination of multiple causes of malnutrition is possible

^{*}Assessment of blood count includes combination of hemoglobin level, hematocrit level, leukocyte and thrombocyte count

Table 1. Prehabilitation strategies prior to ICR

Conclusion: PS are not routinely applied and not individually tailored in the preoperative setting prior to elective ICR in patients with CD. Since early postoperative complications occur frequently, future research on PS is necessary.

Disclosure: Nothing to disclose.

Contact E-Mail Address: elorzainara@gmail.com

Introduction: Perianal fistulizing Crohn's disease has a negative impact on patients' quality of life and despite advances in medical and surgical treatment, high rates of recurrence are still reported. Mesenchymal stem cell therapy has recently been authorized for the treatment of complex perianal fistulas in adult patients with Crohn's disease, and it may be an

effective and safe option. The aim of this study was to evaluate the results of efficacy, defined as combined clinical and radiological remission, and safety after administration of darvadstrocel in clinical practice.

Aims & Methods: All patients with complex perianal disease treated with darvadstrocel were prospectively evaluated at three centers in Spain. The inclusion criteria and the surgical technique followed the predefined indications from Spanish Ministry of Health.

Follow up visits were performed at baseline, 6 and 12 months after the treatment. All visits included a clinical evaluation of perianal disease activity (digital compression and PDAI). Pelvic MRI was performed at baseline and at 6 months, with some cases undergoing also the examination at month 12.

The response variable to be assessed is combined remission, clinical and radiological, which is defined as clinical closure of all treated fistula (absence of discharge despite gentle finger compression) and absence of abscesses larger than 2 cm confirmed by MRI.

Results: From November 2020 to March 2022, 17 patients (mean age 43 years, IQR, 33-53, 66% males) were treated with darvadstrocel. The most common type of fistulas were transsphincteric (70%), high intersphincteric (24%) and the suprasphincteric (12%), the latter associated with other types of fistulas.

All patients had failed anti-TNF treatment and received concomitant biologic therapy with either anti-TNF (70%), ustekinumab (24%) or vedolizumab (6%). Fourteen patients (82%) have reached the 6-month follow up, 7 (50%) of them achieved combined remission, two patients (14%) had radiologic remission, one patient (7%) was in clinical remission, and four (29%) had no response. Seven patients (41%) have reached the 12-month follow up, five (71%) of them showed clinical remission and two patients (28%) have had no response.

The rate of adverse events related to therapy was 18%: two patients developed a new fistula or abscess, one of them underwent a surgical intervention with seton placement, one patient had rectal bleeding and one patient had anal pain.

CHARACTERISTICS	FREQUENCY (N=17)
Mean age	43 (IQR 33-53)
CD extent (n,%)	
L1	11 (65)
L2	1 (6)
L3	5 (29)
Type of fistula (n%)	
Transsphincteric	12 (70)
High intersphincteric	4 (24)
Suprasphincteric	2 (12)
Concomitant treatment (n, %)	
Anti-TNF	12 (70)
Ustekinumab	4 (24)
Vedolizumab	1 (6)
Previous surgical treatment (n, %)	
Seton placement	14 (82)
Abscess drainage	5 (29)
Fistulotomy	1 (6)

Table.

Conclusion: Mesenchymal stem cell therapy shows promising results in terms of effectiveness and safety in the short term in complex perianal disease. A longer follow-up period is still needed to confirm these promising data.

Introduction: Celiac disease (CeD) is triggered by gluten peptides that escape intestinal digestion and are bound to HLA-DQ2 or -DQ8 in the small intestinal lamina propria. The CeD autoantigen tissue transglutaminase (TG2) converts certain glutamines in these peptides, which improves their binding to both HLAs, enhancing the gluten-specific T cell response, resulting in villous atrophy and intraepithelial (cytotoxic) lymphocytosis (IEL).

Aims & Methods: We developed and tested ZED1227, an oral inhibitor of TG2, in a mouse model of small intestinal inflammation induced by poly-IC and in humanized transgenic CeD mice model (NOD-DQ8 mice) that develop mild features of human CeD.

Therefore mice received intraperitoneal poly-IC together with 50 or 150 mg oral ZED1227/kg vs vehicle 2 h before sacrifice. Gluten-sensitized NOD DQ8 mice fed a gluten-containing or gluten-free diet for 3 weeks received daily oral gavages of ZED1227 vs vehicle for the last week.

Results: ZED1227 completely blocked TG2 activity in the poly:IC model. In NOD-DQ8 mice, ZED1227 prevented gluten-induced villous atrophy, IEL, increases in CD45, CD3, CD8, CD68 and Ki67 positive cells, and decreased pro-inflammatory transcripts and serum levels of CeD specific antibodies.

Conclusion: 1.Oral ZED1227 effectively blocked TG2 activity in vivo and attenuated CeD in our transgenic NOD-DQ8 mouse model.

2.The NOD-DQ8 model predicted therapeutic efficacy of ZED1227 that was later demonstrated in a phase 2a clinical trial of 160 CeD patients in remission who were challenged with gluten (Schuppan et al, NEJM 2021).

Introduction: The use of immune checkpoint inhibitors (ICIs) in cancer immunotherapy has shown increased overall survival in a wide range of cancer types with the associated risk of developing severe gastrointestinal immune-mediated adverse events, mainly colitis.

Aims & Methods: The aim of this position statement is to provide an updated practice advice to the Belgian gastroenterologist and oncologists on the diagnosis and management of ICI-induced colitis. Consensus was reached using a 3-round modified Delphi methodology and approved by the members of the Belgian Inflammatory Bowel Disease Research and Development Group (BIRD), Belgian Society of Medical Oncology (BSGO), Belgian group of Digestive Oncology (BGDO), and BeRS (Belgian Respiratory Society).¹

In total 42 physicians agreed for participation of which 34 completed the questionnaire. The accepted statements were those showing an agreement score from 7 to 10 on a 10-point Likert scale (median [IQR]). The percentage after the score showed at Results illustrates the proportion of agreement among the participants.

Results: It is recommended to discuss patients with a suspicion of ICI-induced colitis in a multidisciplinary meeting at an early phase (8,0 [7,00-9,00]; 85,3%). Early endoscopic evaluation with biopsies (even if endoscopically normal) is recommended in patients with grade ≥2 diarrhea (9,0 [8,00-10,00]; 100,0%), being a total ileocolonoscopy the preferred procedure (8,00 [6,00-10,00]; 73,5%).

The first-line therapy for ICI-induced colitis are systemic corticosteroids such as prednisone 1–2 mg/kg/day or an equivalent (10,0 [9,00-10,00]; 94,1%). Biological agents should be considered, after discussion in a multidisciplinary team, as an escalation therapy in non-responders to corticosteroids, after 3–5 days of high-dose corticosteroids (9,00 [9,00-10,00]; 100,0%) and as an early treatment in patients with high-risk endoscopic findings such as presence of deep ulcerations or extensive colitis (8,00 [6,75-9,25]; 76,5%).²

In patients with partial but not complete response after the first dose of biological agent, the standard induction infusion interval of 0–2–6 weeks might be advisable (8,00 [7,00-9,00]; 92,2%). In patients without response to the first biological agent, and after excluding other complications, a second line treatment with vedolizumab (in case of non-response to in-

fliximab) or infliximab (in case of non-response to vedolizumab) can be considered (8,00 [8,00-9,25]; 91,2%).^{3, 4} Resumption of anti-PD(L)-1 and anti-CTLA-4 therapy was evaluated for the different grades of diarrhea. In patients in clinical remission in which the resumption is being discussed, endoscopy should be considered in order to confirm endoscopic remission (8,00 [7,75-8,00]; 85,3%).

Conclusion: The management of ICI-induced colitis requires an early multidisciplinary approach. Early endoscopic assessment is recommended. Even if corticosteroids are still considered the first-line therapy, biologics are recommended as an escalation therapy and as early treatment in patients with high-risk endoscopic findings.

Introduction: Celiac disease is a disease that develops in genetically predisposed individuals. Despite numerous studies dedicated to the prevalence of disease haplotypes in different countries and regions, we found no data on the prevalence of these haplotypes in Ukraine.

Aims & Methods: To study and compare the prevalence of HLA-DQ2.5 and HLA-DQ8 haplotypes, DQA1*05, DQB1*02, DQA1*03, DRB1*04 alleles in patients with celiac disease (CD), non-celiac gluten sensitivity (NCGS) and healthy people in Ukraine.

We investigated 80 persons with previously established diagnoses of celiac disease or NCGS and 68 healthy volunteers for the prevalence of HLA-DQ2.5 and HLA-DQ8 haplotypes, DQA1*05, DQB1*02, DQA1*03, DRB1*04 alleles, or their absence, using the PCR-SSP method.

Results: Haplotype DQ2.5 appeared to be significantly more prevalent in patients with CD than in NCGS patients (OR = 2.77; 95% CI 1.12-6.87, p = 0.022) and in healthy people (OR = 3.99; 95% CI 1.73-9.20, p = 0.0009). Simultaneously the absence of haplotype DQ2.5 was less frequently detected in CD group than in NCGS group (OR = 0.19; 95% CI 0.066 - 0.55, p = 0.0014) and in CD group comparing to the control group (OR = 0.19; 95% CI 0.068 - 0.49, p = 0.0003), without the significant difference between the NCGS and control groups (p > 0.1). The difference in the prevalence of DQ8 haplotype was statistically insignificant - p = 0.052 when comparing the CD and NCGS groups; there was no difference in the frequency of haplotype DQ8 detection between the groups (p > 0.05).

We obtained a higher prevalence of DQA1*05 allele in CD group patients (OR = 2.40, 95% CI 1.03-5.58, p = 0.031) comparing the control group. Simultaneously DQA1*03 allele was detected significantly more often in CD group than in the NCGS group (OR = 2.87; 95% CI 1.05 - 7.81, p = 0.031).

Conclusion: Among the Ukrainian population, patients with CD have a higher detection rate of DQ2.5. Among NCGS and control, the DQ2.5 and DQ8 haplotypes were absent more frequently than in the CD group. The difference in the prevalence of the DQ8 haplotype did not reach the significance level. The DQA1*05 allele is more prevalent in the CD patients than in the control group, and the DQA1*03 allele is more prevalent in the CD than in the NCGS group.

ISOLATED TERMINAL ILEITIS: THE NATURAL COURSE OF DISEASE

J. Doherty¹, A. O Keeffe², K. Sheehan², R. Geraghty², E. McDermott¹
¹St Vincent's Hospital, Dublin, Ireland, ²St Vincent's University Hospital, Dublin, Ireland

Contact E-Mail Address: jaynedohertie@hotmail.com

Introduction: Isolated terminal ileitis is a frequently encountered clinical conundrum. Existing literature provides limited guidance on management or subsequent development of Crohn's disease (CD).

Aims & Methods: To evaluate the natural course of terminal ileitis and factors predictive of CD.

Retrospective review of patients with confirmed histological diagnosis of ileitis from 2015-2020. Patient's characteristics, endoscopic, markers of inflammation including C-reactive protein (CRP) and faecal calprotectin levels (FCP) and outpatient findings were collected. Patients with a previous diagnosis of IBD were excluded from analysis.

Results: 393 patients had histologically confirmed ileitis. 289 were excluded due to a prior diagnosis of IBD. 104 had isolated terminal ileitis. 52.4% were male. Median age 46 years. Median follow-up was 5years. Reasons for endoscopy were as follows; diarrhoea (26%), abdominal pain (18.3%), diarrhoea and abdominal pain (10.6%), weight loss (3.8%), anaemia (7.7%), other causes (29.8%).

32% (n=34) of patients developed CD over a 5-year period. 56% of patients without a subsequent diagnosis of IBD were booked for follow-up outpatient appointments. Patients who had ulceration in the ileum were more likely to develop CD compared to those without ulceration (54% versus 25%, p = 0.006). Median FCP was significantly higher in patients with a subsequent diagnosis of CD (425µg/mg versus 24µg/mg, p = <0.001) and similar results were seen with CRP (19mg/dL versus 6mg/dL, p = < 0.001). On regression analysis, younger age (p = 0.02) and male gender (p = 0.019) were associated with subsequent development of CD.

Conclusion: Isolated terminal ileitis has a general benign course. Factors associated with subsequent development of CD include younger age, male gender and elevated biomarkers, which could help guide clinical follow-up and avoid unnecessary outpatient follow-up.

Introduction: Functional diarrhea is an invalidant condition affecting many patients referred to Gastroenterology clinics. Available evidences suggest a link between functional diarrhea and dysbiosis. Changes in biodiversity and taxonomy of gut microbiota are associated with impaired gut homeostasis and changes in stool frequency and consistency.

Aims & Methods: Aim of this study was to analyze the gut microbiota composition of 40 out of 153 patients referred for microbiota evaluation who reported diarrhea as the main symptom (30 IBS-D patients and 10 patients with functional diarrhea). Gut microbiota analysis of these patients was compared to that of the remaining 113 patients without diarrhea. Alpha-biodiversity and taxonomy were analyzed using 16S rRNA sequencing. Statistical significance was calculated using the Wilcoxon two-sample test (p<0.05).

Results: Alpha-biodiversity by rarefaction curve demonstrated lower values for patients with diarrhea compared to patients without diarrhea. Bacteroidetes were significantly higher in the diarrhea group (p-value 0.0101), while Firmicutes were lower (p-value 0.0082).

Furthermore, our analysis confirmed a gram negativity gut microbiota composition in patients with chronic diarrhea, with a decreased gram +/- ratio (p-value 0.00191).

Regarding taxa analysis, a reduction in butyrate-acetate producer bacteria was observed. *Eubacterium hallii*, *Eubacterium xylanophilum*, *Lachnospira*, *Ruminococcus* and *Blautia* were significantly decreased, while *R. torques* and *Lachnospiridium* were increased.

Conclusion: These preliminary results suggest a reduction of rarefaction curve, Firmicutes, and grams +/- ratio and a corresponding increase in *R. torques* and *Lachnospiridium* (recognized markers of dysbiosis and gut disease), could constitute a possible marker of functional diarrhea.

A PROBIOTIC FORMULA FOR MODULATION OF COLORECTAL CANCER RISK VIA REDUCING CRC-ASSOCIATED BACTERIA

J.Q. Liang¹, Y. Zeng¹, Z. Xu¹, S.C. Ng¹, F.K.L. Chan¹

¹Faculty of Medicine, The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong, China (SAR)

Contact E-Mail Address: jessieqy@cuhk.edu.hk

Introduction: Gut microbiota dysbiosis with increased pathogenic bacteria and decreased beneficial bacteria is associated with colorectal cancer (CRC) development. Specifically, some pathogenic bacteria, such as *Fusobacterium nucleatum* (Fn), have been shown to play important roles in CRC development.

Therefore, it is anticipated that reducing or eliminating pathogenic bacteria associated with CRC can reduce the risk for CRC development. Whether pathogenic bacteria involved in CRC development can be inhibited by

specific probiotic bacteria and their mechanisms of action have not been investigated. We hypothesize that bacteria associated with CRC development can be altered by microbiota modulation via a targeted probiotic formula.

Aims & Methods: This study aimed to examine the effect of a newly developed probiotic formula in modulating CRC-related bacteria. We developed a probiotic formula (SMT04) containing 3 Bifidobacteria (*B. adolescentis*, *B. longum* and *B. bifidum*) based on the identification of bacterial species that showed significant correlations with CRC-related bacteria, including *Fn*, *Lachnoclostridium* sp. m3, *Clostridium hathewayi* (Ch), and *Bacteroides clarus*(Bc). We co-cultured *Fn* with each Bifidobacterium or the combined formula and examined the growth of *Fn* by qPCR. We further examined the effect of SMT04 in a pilot study of 48 subjects (40 on SMT04; 8 no intervention) for 4 weeks and followed up for another 8 weeks.

We quantified levels of the bifidobacteria in SMT04 and CRC-related markers (*Fn*, m3, Ch and Bc) by qPCR in stool samples before and after the intervention. We also assessed the effect of the intervention on the combined CRC risk score (4Bac; *Fn*, m3, Ch and Bc) as established in our previous study (Liang et al, Gut 2020).

Results: *In vitro* co-culturing of individual bifidobacteria in SMT04 significantly inhibited the growth of *Fn* compared with control treatment (24~65% inhibition; all $P<0.001$). The combination of the 3 Bifidobacteria showed a greater inhibitory effect on *Fn* growth (70% inhibition) than individual bifidobacteria (all $P<0.05$).

Subjects treated with SMT04 showed significantly increased levels of the individual Bifidobacterium species from week 2 to week 5 compared with baseline ($P<0.05$) and dropped to baseline levels after cessation of treatment. There was a significant decrease in levels of CRC-related bacteria (*Fn* and m3) and CRC risk score (4Bac) from week 2 to week 12 compared with baseline levels ($P<0.05$) in the SMT04 intervention group but not the control group.

Conclusion: A novel probiotic formula SMT04 was effective in inhibiting the growth of *Fusobacterium nucleatum* *in vitro* and improved the gut microbial environment against CRC development.

INTRODUCTION OF THE PROBIOTIC STRAIN, E COLI NISSE 1917, REDUCES MICROBIAL DIVERSITY, PARTIALLY MEDIATED BY HOST-ACTIVATED TYPE VI SECRETION SYSTEM

H. Bar-Yoseph^{1,2}, A. Serapio Palacios¹, B.B. Finlay¹

¹University of British Columbia, Michael Smith Laboratories, Vancouver, Canada, ²Rambam Health Care Campus, Gastroenterology, Haifa, Israel

Contact E-Mail Address: haggaiy@gmail.com

Introduction: *Escherichia coli* Nisse 1917 (EcN) has been suggested as a safe probiotic intervention to fight enteric pathogens and treat other intestinal disorders. Still, not much is known regarding the effect EcN bare on the intestinal microbiome. Type VI secretion system (T6SS) has been suggested as crucial bacterial machinery used for inter-bacterial competition.

Although typically described in bacterial pathogens, evidence suggests that commensals utilize this system as well. EcN has a T6SS cluster, but its structure and functionality remain to be elucidated.

Aims & Methods: We aimed to investigate the impact that EcN has on the intestinal microbiome and its use of T6SS in this context.

Results: We first characterized EcN's T6SS *in-silico* and showed that it is functional *in-vitro*. A T6SS deletion mutant strain (Δ tssM) was then constructed. To test the effect of EcN and its T6SS on the murine intestinal microbiota, we treated C57BL/6J mice obtained from Jackson Laboratories with either wild-type EcN (WT-EcN), the T6SS mutant (Δ tssM) or PBS (control) (n=30; 10 mice per group). After the treatment, alpha-diversity indices (Chao1, Simpson and Shannon) in mice treated with EcN were significantly lower compared to baseline ($p<0.001$ for all indices).

Interestingly, this effect was not observed in mice treated with Δ tssM or control ($p=NS$ for all indices). Furthermore, post-intervention alpha diversity was lower in the EcN group compared with the control and Δ tssM groups for Chao1 and Shannon indices ($p=0.07$ and 0.08 , respectively). Significant differences were seen between the samples before and after intervention in the Bray-Curtis index (a beta-diversity metric) in the EcN group ($p<0.001$), but not in the control or Δ tssM groups ($p=NS$).

These findings were confirmed using mice originating from a different vendor (Charles River Laboratories), which harbors a different microbiome community (n=15; 5 mice per group).

To better understand EcN's T6SS effect on the microbiota, we co-cultured human commensal *E. coli* and adherent-invasive *E. coli* (AIEC) strains originating from patients with inflammatory bowel disease with either WT-EcN or Δ tssM.

Surprisingly, there was no difference in the commensals/AIECs' growth between the wild-type and the mutant under different co-culture conditions. Since EcN's T6SS induced microbiota changes with no apparent direct bacterial effect on commensals, we hypothesize that this effect is mediated by the host in the intestinal environment. By using a T6SS reporter EcN strain, we found that the T6SS is preferentially activated under gut-mimicking conditions (lower PH, presence of conjugated bile acids and mucin).

Furthermore, in a co-culture with two different human intestinal cell lines (Caco2/TC7 and HT29), we observed that the direct interaction with host cells or its secretome induced T6SS activation. Lastly, we showed that WT-EcN adheres better to human intestinal cells *in-vitro* and outcompetes the Δ tssM mutant strain in *an in vivo* colonization murine model.

Conclusion: Taken together, our findings suggest that EcN reduces the diversity of the normal intestinal microbiome, an effect that is partially mediated by the T6SS in the context of the host. As a common probiotic prescribed to treat gastrointestinal disorders, our data provide further evidence for the need to cautiously use this probiotic in patients, and the importance of the T6SS in the host-microbiome-probiotic interaction.

Disclosure: Nothing to disclose.

Introduction: Diet is a major modifiable factor that could alter composition and metabolism of the human gut microbiota. However, data regarding certain food types and their impact on the gut microbiota are very limited.

Aims & Methods: The aim of the study was to determine the association between the gut microbiota taxonomic composition and specific food group's consumption of the healthy volunteers. Six food groups – vegetables/fruits, meat/high-protein foods, fatty foods, dairy, bakery products, digestible carbohydrates (sugars) – were identified.

A total of 66 healthy subjects were included into the study, food consumption was assessed using a special questionnaire. Subjects stool samples were analyzed using shotgun metagenomic sequencing technology (SOLiD 5500 Wildfire platform) to identify the gut microbiota composition.

Correlations between specific food groups consumption and the microbiota composition were analyzed using the R “psych” package based on Spearman's rank correlation coefficient, p-values were adjusted with the Benjamini–Hochberg method (p-value<0.05 was considered significant).

Results: Only weak and moderate ($0 < r < 0.5$ or $-0.5 < r < 0$) statistically significant correlations were identified in this study. There were the following positive correlations: dairy and bakery foods intake correlated with relative abundance of *Firmicutes* phyla ($r=0.33$ and $r=0.27$, respectively), meat/high-protein foods –with *Spirochaetes* phyla ($r=0.27$); negative correlations were found between dairy intake and *Bacteroidetes* phyla ($r=-0.34$).

Also some statistically significant correlations were revealed between specific food consumption and relative abundance of bacterial genera: bakery consumption positively correlated with *Methanospaera* (Archaea, $r=0.33$), *Clostridium* (*Firmicutes*, $r=0.37$), *Megasphaera* (*Firmicutes*, $r=0.3$) and negatively correlated with *Bacteroides* (*Bacteroidetes*, $r=-0.33$), *Barnesiella* (*Bacteroidetes*, $r=-0.25$), *Coprobacter* (*Bacteroidetes*, $r=-0.29$), *Oscilibacter* (*Firmicutes*, $r=-0.27$), *Sutterella* (*Proteobacteria*, $r=-0.36$).

Consumption of vegetables/fruits positively correlated with *Weissella* (*Firmicutes*, $r=0.28$), *Butyrivibrio* (*Firmicutes*, $r=0.24$), *Haemophilus* (*Proteobacteria*, $r=0.28$) and *Methanospaera* (Archaea, $r=0.32$) and negatively – with *Alistipes* (*Bacteroidetes*, $r=-0.37$), *Sutterella* (*Proteobacteria*, $r=-0.24$) genera.

Dairy intake positively correlated with *Lactobacillus* (*Firmicutes*, $r=0.255$), *Lactococcus* (*Firmicutes*, $r=0.27$) and negatively – with *Bacteroides* (*Bacteroidetes*, $r=-0.29$) bacterial genera.

Fatty food consumption positively correlated with bacterial genera of *Firmicutes* phyla (*Clostridium* ($r=0.27$), *Peptostreptococcaceae* ($r=0.25$), *Mitsuokella* ($r=0.29$)), with archaea *Methanospaera* ($r=0.35$), *P22likevirus* ($r=0.31$) and negatively with *Barnesiella* (*Bacteroidetes*, $r=-0.33$), *Roseburia* (*Firmicutes*, $r=-0.26$), *Sutterella* (*Proteobacteria*, $r=-0.33$).

Meat/high-protein foods usage positively correlated with *Prevotella* (*Bacteroidetes*, $r=0.38$), *Dorea* (*Firmicutes*, $r=0.32$), *Enterobacter* (*Proteobacteria*, $r=0.26$) and *Haemophilus* (*Proteobacteria*, $r=0.36$) bacteria.

In addition, sugars intake positively correlated with *Haemophilus* genus (*Proteobacteria*, $r=0.25$) and negatively with *Blautia* ($r=-0.34$), *Holdeman* ($r=-0.33$) corresponding to *Firmicutes* phyla.

Conclusion: Thus, some associations between the gut microbiota taxonomic composition and specific food groups consumption were identified. So potentially, specific dietary changes could be implemented in the future to develop personalized therapeutic strategies aimed to modify gut microbiome composition.

BAY3295079 BENEFICIALLY MODULATES HUMAN MICROBIAL COMPOSITION AND ACTIVITY IN VITRO

R.M. Ammar¹, M.R. Pausan², C. Duysburgh³, M. Govaert³, T. Van de Wiele³, L. Van Meulebroek³, L. Verstrepen³, O. Kelber², S. Rabini¹

Contact E-Mail Address: ramy.ammar@bayer.com

Introduction: Stress has become nearly unavoidable in today's world. Chronic stress causes allostatic overload and dysregulation, leading to gastrointestinal problems and digestive discomfort. BAY3295079 is a combination of *Lactobacillus acidophilus*-14, lemon balm extract and vitamin B2 that helps in relaxation and digestive comfort.

Aims & Methods: Since dysbiosis is one of the pathomechanisms proposed for both stress and digestive discomfort, in this study we investigated the impact of BAY3295079 on human gut microbiome composition and function. Low grade inflammation and leaky gut are associated with stress induced digestive discomfort therefore we evaluated the impact of BAY3295079 on gut permeability and its immuno-modulatory effects.

A standardized *in vitro* simulation of the colonic environment of six healthy adult donors was used to assess the impact of BAY3295079 on microbial composition (quantitative deep shotgun sequencing) and microbial metabolic activity (gas chromatography). Moreover, Caco-2/THP1 co-culture assay was used to test the effect of colonic incubates on gut barrier integrity (Trans Epithelial Electrical Resistance) and immune functions (cytokine profiles).

Additionally, to assess the potential metabolic alterations that may occur upon treatment with the test product, a strategy of untargeted metabolic fingerprinting was applied using ultra-high performance liquid-chromatography coupled to high-resolution mass spectrometry to map both the polar and lipid fraction of the metabolome.

Results: BAY3295079 was efficiently fermented by the gut microbiota, in a process that started early within 3h and was paralleled by increased levels of short chain fatty acids (SCFAs), mainly propionate and butyrate. BAY3295079 selectively and consistently increased the abundance of lactate-producing Lactobacillaceae and Streptococcaceae.

Furthermore, levels of the butyrate-producing Lachnospiraceae and propionate-producing Veillonellaceae families slightly increased for most of the donors tested. Fermentation of BAY3295079 exerted a protective effect on inflammation-induced barrier disruption as confirmed by the significant increase in TEER and donor-dependent immuno-modulatory effects.

The most pronounced beneficial effects were the trend to increase the level of the anti-inflammatory cytokine IL-10, and decreased level of pro-inflammatory cytokine IL-6. Upon performing untargeted metabolic fingerprinting, both the polar and lipid fraction of the metabolome were mapped, rendering fingerprints that enclosed, respectively, 8749 and 10,499 compounds. Multivariate analysis of these metabolic data revealed significant alterations that occurred upon treatment with the test product.

Selection and subsequent identification of the discriminating compounds suggested relevant shifts in pyrimidine metabolism (i.e. orotic acid, glutamine, and thymine), phenylalanine metabolism (i.e. phenylpropionic acid, phenyllactic acid, and hydrophenylpropionic acid), protein degradation (i.e. leucylglycine), bile acid metabolism (i.e. lithocholic acid), and methionine metabolism (i.e. methionine sulfoxide and methionine).

Conclusion: The synbiotic potential of BAY3295079 formula combining both probiotic and plant-based prebiotic (lemon balm) has been confirmed in this study by the positive modulation of gut microbiome and the

generation of health-related metabolites. This could justify its positioning in the area of stress relief and digestive comfort via modulating the microbiome and immune pathways of the gut brain axis.

Introduction: Recent investigations have revealed that gut microbiota could be a pharmacological target for herbal medicines. STW 5-II, a combination of 6 herbal extracts, is a clinically proven treatment for functional dyspepsia (FD) and irritable bowel syndrome (IBS).

Aims & Methods: Since dysbiosis is one of the pathomechanisms proposed for both FD and IBS, we aimed to explore the bidirectional interaction between this herbal formula and human gut microbiome as a novel mechanism of action. A standardized *in vitro* simulation of the colonic environment of five healthy donors was used to assess the impact of STW 5-II on microbial composition (quantitative 16S rRNA-based Illumina sequencing), pH, gas production, and microbial metabolic activity (Gas chromatography). Moreover, Caco-2/THP1 co-culture assay was used to test the effect of colonic incubates on gut barrier integrity (Trans Epithelial Electrical Resistance) and immune functions (cytokine profiles). Additionally, the impact of gut microbiome on STW 5-II metabolism was evaluated using an established UHPLC-HRMS method.

Results: STW 5-II was efficiently fermented by the gut microbiota, in a process that started early (within 3h) as evidenced by consistent changes in pH and gas production. Fermentation of STW 5-II was paralleled by increase in the level of short chain fatty acids (SCFAs), acetate, propionate, and butyrate. Most of the major classes of secondary compounds in STW 5-II were fermented by the gut microbiota. UHPLC-HRMS analysis allowed identification of 109 compounds that significantly changed: 62 compounds were identified as STW 5-II constituents that significantly decreased, 22 compounds as intermediate metabolites, and 25 compounds as final metabolites. Major stable metabolites were davidigenin, 18-b-glycyrrhetic acid, and 3-hydroxy-phenylpropionic acid. The majority of metabolic reactions were very similar in the five donor samples, indicating that the microbial functions required for conversion of these constituents were present in all donors' microbiome. STW 5-II selectively and consistently increased the abundance of acetate, lactate, butyrate-producing microorganisms including but not limited to *Bifidobacteriaceae*, *Eggerthellaceae*, *Ruminococcaceae* and specific families belonging to the *Bacteroidetes* phylum. While *E. coli/Shigella sonnei* was inhibited in four of five donors. Fermentation of STW 5-II exerted a protective effect on inflammation-induced barrier disruption as confirmed by the significant increase in TEER and donor-dependent immuno-modulatory effects. The most pronounced beneficial effects were the increased secretion of the anti-inflammatory cytokine IL-10, increased NF- κ B activity, and decreased secretion of MCP-1.

Conclusion: The current study shows the two-way interactions between STW 5-II and human gut microbiome indicating that the human gut microbiome could be a novel extra target for STW 5-II. This could explain, at least in part, the clinically proven efficacy of STW 5-II and provides a new basis for better understanding of the pharmacology of STW 5-II.

CHANGES IN THE GUT MICROBIOME ASSOCIATED WITH MURINE MC38 COLON TUMORS BY ANTI-PD-L1 ANTIBODY AND 17 β -ESTRADIOL TREATMENT

C.-H. Song¹, N. Kim^{1,2}, R.H. Nam¹, S.I. Choi¹, J.Y. Jang¹

¹Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam, Korea (Republic of), ²Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea (Republic of)

Contact E-Mail Address: chinheesong@gmail.com

Introduction: The composition of the gut microbiota is affected by sex hormones, immune checkpoint inhibitor therapies, and colorectal cancer (CRC) development. Previously, we reported that 17 β -estradiol (E2) administration before MC38 cell injection inhibits MC38 tumor growth by downregulating PD-L1 expression and regulating tumor-associated cell populations in male mice. Furthermore, E2 boosted the effect of anti-PD-L1 antibody in the MC38 tumor model.

Aims & Methods: Here, we investigated the gut microbiota as a potential biomarker regulated by E2 and/or anti-PD-L1 antibodies in the MC38 tumor model as a secondary outcome of a previous study. A total of 5 x 10⁵ MC38 cells (passage no. 8) resuspended in 100 μ l DPBS were injected subcutaneously into the right flank of 8-weeks-old C57BL/6 male and female mice. E2 (10 mg/kg) was intraperitoneally administered to male mice three days before injection of MC38 cells for one week. The tumor (50–100 mm³) bearing male and female mice were selected and injected with anti-PD-L1 or isotype control antibodies intraperitoneally at a dose of 10 mg/kg every three days for a total of three injections.

Mice were sacrificed at day 26 after injection of MC38 cells and collected feces were used for 16S rRNA sequencing. The composition of the gut microbiota evaluated by means of 16S rRNA metagenomics sequencing of stool DNA extracted from feces.

Results: Microbial diversity (ACE, Chao1 and Jackknife) was increased in the anti-PD-L1 antibody, E2, and anti-PD-L1+E2 groups compared to the MC38 male controls without statistical significance. Similar to males, MC38 female mice also showed a tendency to increase microbial diversity by anti-PD-L1 treatment compared to the control group.

The change in microbial diversity by anti-PD-L1 treatment was strongly increased in males than in females. At the taxonomic family level, *Muribaculaceae* was enriched only in the MC38 male control group among the male and female groups. As a result of LEfSe analysis at the species level in male mice, the four microorganisms were commonly regulated in all treatment groups including anti-PD-L1, E2, and anti-PD-L1+E2; decrease of PAC001068_g_uc and PAC001070_s (family *Muribaculaceae*) and increase of PAC001716_s and PAC001785_s (family *Ruminococcaceae*).

Interestingly, in the anti-PD-L1 and E2 combination treatment group, a decrease in opportunistic pathogen (*Enterobacteriaceae* group) and increase in commensal bacteria (*Lactobacillus murinus* group and *Parabacteroides goldsteinii*) were observed. Furthermore, the abundance of *Parabacteroides goldsteinii* was commonly increased in the anti-PD-L1 group regardless of sex.

Conclusion: Our results suggest that estrogen may contribute to improving anti-PD-L1 therapeutic efficacy by alleviating the dysbiosis of gut microbiota associated with colon tumors in mice.

Introduction: Sex hormones are known to affect the gut microbiota. Previously, we reported that endogenous and exogenous testosterone are associated with colorectal cancer (CRC) development and submucosal invasion.

Aims & Methods: In the present study, we investigated whether the gut microbiota is affected by orchiectomy (ORX) and testosterone propionate (TP) administration using an azoxymethane/dextran sulfate sodium (AOM/DSS)-induced CRC mouse model. Seven-week-old male and female C57BL/6 mice were used in this study. The orchiectomy (ORX) group of male mice underwent surgical orchiectomy. TP supplementation was initiated on the day of the surgery. Gut microbiota was evaluated by means of 16S rRNA gene sequencing of stool DNA extracted from feces that were obtained at 13 weeks after AOM injection (from 22-weeks old animals) and stored in a gas-generating pouch.

Results: The increase in microbial diversity (Chao1 and Phylogenetic Diversity index) and Firmicutes/Bacteroidetes (F/B) ratio upon AOM/DSS treatment in ORX mice was significantly decreased by TP supplementation. The ratio of commensal bacteria to opportunistic pathogens was lower in the TP-administered females and ORX mice than in the AOM/DSS group. Opportunistic pathogens (*Mucispirillum schaedleri* or *Akkermansia muciniphila*) were identified only in the TP group. In addition, microbial diversity and F/B ratio were higher in male controls than in female and ORX controls. *Flintibacter butyricus*, *Ruminococcus bromii*, and *Romboutsia timonensis* showed similar changes in the male control group as those in the female and ORX controls.

Sex	Group	ACE	Chao1	Jackknife	Shannon	Phylogenetic Diversity
Female	Con (n=4)	1161.93	1068.37	1214.25	1.64	552.25
	AOM/DSS (n=7)	1941.47	1766.54^a	1966.76	1.94	704.86^a
	AOM/DSS+TP (n=4)	1545.72	1473.22	1638.25	1.98	689.75
Male	Con (n=4)	2875.33	2683.75	3063.75	2.63	865.50
	AOM/DSS (n=10)	1700.83^a	1567.51^a	1776.17^a	1.92^a	698.00^a
	AOM/DSS+TP (n=8)	1499.86	1405.00	1581.75	1.84	647.00
ORX	Con (n=4)	1604.73	1502.82	1703.00	1.70	706.75
	AOM/DSS (n=10)	2431.72^a	2299.48^a	2592.70^a	2.41^a	778.70^a
	AOM/DSS+TP (n=6)	1014.46^b	931.09^b	1036.55^b	1.39^b	547.83^b

Data are presented as the medians. *p*-value < 0.05 was considered to be significant and was presented as boldface. Mann-Whitney U-test for comparison difference between independent two groups was performed. ^a*p*-values between Con vs AOM/DSS; ^b *p*-values between AOM/DSS vs AOM/DSS+TP. Con, control; AOM, azoxymethane; DSS, dextran sulfate sodium salt; TP, testosterone propionate; ORX, orchiectomized.

Table 1. Alpha diversity of microbiota from fecal contents.

Conclusion: In conclusion, testosterone determines the dysbiosis of gut microbiota, which suggests that it plays a role in the sex-related differences in colorectal carcinogenesis.

Disclosure: Nothing to disclose.

INHIBITION OF IN VITRO CLOSTRIDIODES DIFFICILE BIOFILM FORMATION BY THE PROBIOTIC YEAST SACCHAROMYCES BOULARDII CNCM I-745 THROUGH MODIFICATION OF THE EXTRACELLULAR MATRIX COMPOSITION

S. Bouttier¹, A. Simons², P.-A. Lacotte¹, J. Malet-Villemagne¹, V. Nicolas³, C. Janoir¹

¹Micalis Institute, Châtenay-Malabry, France, ²Laboratoire Eau, Environnement et Systèmes Urbains, Créteil, France, ³UMS IPSIT Université Paris-Saclay-US 31 INSERM-UAR 3679 CNRS, Châtenay-Malabry, France

Contact E-Mail Address: sylvie.bouttier@universite-paris-saclay.fr

Introduction: *Clostridioides difficile* is a Gram-positive, strictly anaerobic, spore-forming bacillus. In Western countries, *C. difficile* is the leading cause of healthcare-associated intestinal infections in adults, and the number of community *C. difficile* infections (CDI) has been steadily increasing for a couple of years [1].

The CDI's clinical signs range from self-resolutive mild- to severe diarrhea to life-threatening pseudomembranous colitis. Furthermore, rare complications such as fulminant colitis may occur, requiring urgent medico-surgical management. A major challenge encountered with CDI is the occurrence of recurrences, most of them being relapses related to the persistence in the colonic niche of the strain responsible for the initial episode [2].

Multiple recurrences can be considered chronic infections. The role of biofilm formation in CDI recurrences is now widely considered and strategies that hinder *C. difficile* biofilm formation or disrupt pre-formed biofilm may be a promising alternative to fight against CDI and/or recurrent CDI [3].

Aims & Methods: This study aimed to explore if the probiotic yeast *Saccharomyces boulardii* CNCM I-745 (Biocodex, Gentilly, France), already known to exert some antagonistic effects against *C. difficile* diarrhea and colitis [4], could impact the biofilm formation of *C. difficile* *in vitro*.

We compared the quality and integrity of single-species biofilms formed by *C. difficile* alone to dual-species biofilms formed by *C. difficile* in presence of *S. boulardii* after different incubation durations and at different bacteria:yeast ratios, using crystal violet staining, quantification of viable bacterial cells and confocal laser scanning microscopy.

Results: Combining these approaches revealed that live *S. boulardii* exerts an antagonistic effect on the biofilm formation by three different *C. difficile* strains, including the 027 PCR-ribotype R20291 strain. In a time- and yeast-concentration-dependent manner, *S. boulardii* significantly reduced biomass and viable bacteria count. Confocal laser scanning microscopy observation confirmed a weakening and an average thickness reduction of the biofilm structure when *C. difficile* was co-incubated with *S. boulardii*, compared to the single-species biofilm structure. These effects were neither observed with a genetically close yeast, *S. cerevisiae*, nor with the supernatant of *S. boulardii* cultures, suggesting they are specific to the probiotic yeast and require direct contact between the yeast and *C. difficile*. We also analyzed the composition of the extrapolymeric matrix of single- and dual-species biofilms, by quantification of polysaccharides, proteins, and eDNA and showed that the matrix of *C. difficile* biofilm produced in presence of live *S. boulardii* comprised significantly less eDNA, an essential structural component of the *C. difficile* biofilm matrix. This observation was further confirmed by biofilm analysis after DNase treatment.

Conclusion: *S. boulardii* CNCM I-745 exerts an antagonistic effect on the formation of the *C. difficile* biofilm, in terms of the biomass produced, on bacterial viability and architecture of the biofilm structure. A modulation of the matrix composition probably mediated this effect.

This could in part explain the preventive effect of this probiotic yeast in recurrent CDI. Further studies investigating the efficacy of various antibiotics associated with *S. boulardii* CNCM I-745 could provide new insights into the management of patients with recurrent CDI.

Introduction: Key mechanisms of the efficacy of intestinal microbiota transplant (IMT) for recurrent *Clostridioides difficile* infection (rCDI) relate to changes in gut microbiome-related metabolites, and alterations of host serum glycan profile (1).

The gut lipidome may be relevant to rCDI pathogenesis; for instance, the cytotoxic action of toxins in other Clostridial diseases depends upon their binding to sulfatides in mucous membranes. As such, we explored the impact of IMT for rCDI upon the gut lipidome and gut microbiota members related to it.

Aims & Methods: Ultra high performance liquid chromatography (UHPLC-MS) and high-throughput laser desorption-rapid evaporative ionisation mass spectrometry (LD-REIMS) was performed on paired pre-/ post-IMT (>4 weeks post-) for patients successfully treated with IMT for rCDI (n=16) and on samples from an *in vitro* artificial gut model (aka “chemostat” model) of IMT/rCDI to compare lipidomic profiles; univariate and multivariate analysis was performed on identified lipid species. 16S rRNA gene sequencing was performed on chemostat samples; shotgun metagenomic

analysis and a functional sulfatase enzyme assay was performed on donor and serial patient stool samples (collected pre-FMT, and weeks 1, 4 and 12 post-IMT) from a separate cohort of rCDI patients treated successfully with IMT (patients: n=17 for shotgun analysis, n=34 for enzyme assay; donors: n=9).

Results: On lipidomic analysis of stool samples (n=16; mean age 69.8 years, female 69%), 6483 molecular features species were found, of which 1873 were significantly different (false discovery rate (FDR) corrected, $p < 0.01$) between pre- and post-IMT; particularly noteworthy was the finding that all 14 identified sulfatide moieties were significantly reduced in human stool in post-IMT samples compared to pre-IMT.

A comparable pattern was observed on analysis of artificial gut culture samples from an IMT/rCDI model, suggesting that the reduction in sulfatides reflected microbial degradation; relative abundance of the glycan-degrading gut commensal *Bacteroides fragilis* showed a strong negative correlation with that of most sulfatides.

Analysis of stool shotgun metagenomic data of the key microbial arylsulfatase EC:3.1.6.1 demonstrated a significant increase in read counts of this gene at weeks 1 and 12 post-IMT versus pre-IMT ($p < 0.05$, Wilcoxon rank sum). Pre-IMT faecal sulfatase activity was significantly reduced compared to that of donors, and of patients post-IMT at all assessed timepoints up to week 12 ($q < 0.01$, Kruskal-Wallis with Benjamini-Hochberg FDR).

Conclusion: Successful IMT for rCDI is associated with restoration of microbial arylsulfatase gene count and enzyme activity, and degradation of sulfatides. *Bacteroides* members with glycan-degrading ability may be responsible for this activity. Restoration of this functionality by IMT may disrupt *C. difficile* toxin binding and may contribute to established changes in host glycan profile after IMT.

THE PECULIARITIES OF INTESTINAL MICROBIOME IN PATIENTS WITH OSTEOARTHRITIS

O. Gubska¹, A. Kuzminets¹

¹Bogomolets National Medical University, Therapy, Infectious Diseases and Dermatology Postgraduate Education, Kyiv, Ukraine

Contact E-Mail Address: andrewkuzminets@gmail.com

Introduction: Osteoarthritis (OA) requires frequent nonsteroidal anti-inflammatory drugs (NSAIDs), harmful to the gastrointestinal tract. Intestinal microbiome (IM) disturbance can result from NSAID use, amplifying NSAID-enteropathy, but some evidence shows that IM disturbance can relate to OA directly.

Aims & Methods: To study the peculiarities of the intestinal microbiome in patients with OA. We investigated 91 patients with OA of different localizations and degrees divided into three subgroups depending on NSAIDs use and their selectivity. 30 people without OA were recruited as a control group (CG).

We studied major phyla of intestinal bacteria (*Bacteroidetes*, *Firmicutes*, *Actinobacteria*), then calculated the *Firmicutes/Bacteroidetes* (F/B) ratio and content of “other” in feces; PCR-SSP method. Among “others,” we determined the content of *Gamma-proteobacteria* class and *Akkermansia muciniphila* species.

Results: There was a negative correlation between *Firmicutes* content and the stage of OA ($p=0.521$); the *F/B* ratio correlated with the body mass index (BMI) ($p=0.455$) and patient's age ($p=0.562$); a negative correlation in *Actinobacteria* content with the patient's age was found ($p=0.300$); $p<0.05$.

The *Gamma-proteobacteria* content was 1.44% (IQR 0.81-2.03) in "non-NSAIDs", 1.96% (IQR 1.52-2.57) in non-selective NSAIDs ($p<0.01$), and 2.19% (IQR 1.08-2.51) in selective NSAIDs ($p>0.05$). A correlation between the bacteria content and stage of OA ($p=0.526$) and BMI ($p=0.356$), $p<0.05$, was found. *Akkermansia muciniphila* content was, respectively, 2.55% (IQR 1.63-4.30), 1.35% (IQR 1.20-1.64), 1.22% (IQR 0.99-1.50), $p<0.001$ in NSAIDs vs "non-NSAIDs" subgroups. The difference was between NSAIDs-intake and "non-NSAIDs" subgroups ($p<0.001$). Its content correlated with the patient's age ($p=0.402$; $p<0.05$).

Phyla content	OA	OA subgroups			CG
		"non-NSAIDs"	non-selective NSAIDs	selective NSAIDs	
<i>Firmicutes</i>	51.80% (IQR 45.37-58.64) [§]	51.47% (IQR 48.11-56.21) [§]	57.21% (IQR 49.98-69.05) ^{**}	47.83% (IQR 32.24-52.92) [§]	66.66% (IQR 58.57-73.66)
<i>Bacteroidetes</i>	15.86% (IQR 8.25-20.54) [§]	15.08% (8.03-29.21) [§]	18.04% (IQR 9.36-17.75) [§]	13.50% (IQR 9.24-17.75) [§]	6.06% (IQR 3.23-8.57)
<i>F/B</i> ratio	3.32 (IQR 2.18-5.47) [§]	3.33 (IQR 1.79-6.74) [§]	3.27 (IQR 2.65-5.25) [§]	3.65 (IQR 1.63-4.84) [§]	11.60 (IQR 6.56-20.76)
<i>Actinobacteria</i>	9.99% (IQR 6.55-13.61) [*]	8.41% (IQR 5.59-10.02) ^{§§}	7.75% (IQR 5.51-10.56) ^{§§}	13.66% (IQR 13.26-14.56)	12.16% (IQR 8.09-16.54)
"other"	22.33% (IQR 13.39-33.95)	25.04% (IQR 19.51-34.48) [§]	17.00% (IQR 12.54-25.69) [§]	25.02% (IQR 12.85-36.16) [§]	15.12% (IQR 12.10-19.57)

§- a significant difference from CG ($p<0.0001$)

*- a significant difference from CG ($p<0.05$)

§- a significant difference from CG ($p<0.01$)

§- a significant difference from selective NSAIDs ($p<0.01$)

§- a significant difference from selective NSAIDs ($p<0.0001$)

§- a significant difference from "non-NSAIDs" ($p<0.05$)

Table.

Conclusion: There is a significant difference in the IM composition among subjects with OA and without this disease. Patients with OA have higher levels of *Bacteroidetes* and "other" bacteria and lower *Firmicutes* and *Actinobacteria* content. The *F/B* ratio is the most sensitive indicator of the difference. The NSAIDs intake and its selectivity affect some bacterial taxonomical units, but we did not find apparent regularity. The most explicit changes were found in *Akkermansia muciniphila* content: NSAIDs intake decreased it, regardless of NSAID's selectivity.

S. BOULARDII CNCM I-745 STIMULATES IMMUNITY BY INCREASING INTRACELLULAR BACTERICIDAL ACTIVITY AGAINST SALMONELLA TYPHIMURIUM IN MACROPHAGES

D. Czerucka¹, R. Pontier-Bres¹

¹Centre Scientifique de Monaco, Ecosystèmes & Immunité, Monaco, Monaco

Contact E-Mail Address: dczerucka@centrescientifique.mc

Introduction: During bacterial infection, macrophages act as "professional phagocytes". *Salmonella typhimurium* (ST) escape from host immune system innate- and humoral- mediated killing, by being internal-

ized into specialized vacuoles in the macrophage that constitute niches for ST protection and bacterial replication. Thus, enhancing intracellular antimicrobial responses of infected macrophages may be determinant for the outcome of the infection. Nitric oxide (NO) is an antimicrobial effector produced by inducible nitric oxide synthetase (iNOS). iNOS expression is controlled by cytokines: produced upon interferon IFN- γ stimulation and repressed by interleukin IL-10. The probiotic yeast *S. boulardii* CNCM I-745 (Biocodex, Gentilly) has been shown to protect mice from infection by ST via various mechanisms, including promoting the differentiation of monocytes that infiltrate the lamina propria into macrophages, which acquire properties to phagocyte ST (Pontier-Bres R et al. *Frontier in Immunology* 2019).

Aims & Methods: The aim of our study was to investigate the effect of *S. boulardii* on bactericidal activity of macrophages.

This study was conducted on the murine macrophages RAW 264.7 cells. The cells were seeded in six well plate and incubated with *S. boulardii* CNCM I-745 (10^6 CFU/ well) overnight before infection with ST (MOI 10 CFU/ cell). After one hour, non-adherent ST were removed by repeated washes and cells exposed to gentamycin 100 μ g/ml, a membrane-impermeant antibiotic, for one hour followed by gentamycin 10 μ g/ml during 22 hours. The number of adherent bacteria (estimated after one hour of infection) and the number of intracellular bacteria (estimated after 24h of infection) were determined by colony forming units (CFU) enumeration. iNOS-, IFN- γ - and IL-10-mRNA were quantified by qPCR.

Results: In this specific model, *S. boulardii* CNCM I-745 didn't modify the number of adherent bacteria but decreased by 5-fold the number of intracellular ST when compared to unexposed macrophages infected with ST. These data suggest that the yeast induces a bactericidal activity in the macrophage.

This bactericidal action of the yeast was confirmed by the 12-fold increase of iNOS expression in cells exposed to *S. boulardii* CNCM I-745 before infection when compared to unexposed cells infected by ST. Interestingly, this induction of iNOS expression in yeast pretreated cells before infection was correlated with the up-regulation of IFN- γ and downregulation of IL-10 as compared with unexposed cells infected with ST.

Conclusion: This study demonstrates that *S. boulardii* CNCM I-745 stimulates intracellular bactericidal activity of macrophages infected by *Salmonella*. This effect is correlated with a stimulation of the expression of iNOS and changes in the expression of cytokines involved in its induction.

Introduction: Fecal microbial transplantation (FMT) is the delivery of microbes, isolated from a healthy donor's feces, into a patient's gastrointestinal tract. FMT is the most efficient treatment for recurrent *Clostridioides difficile* infection (CDI). During the past decade, FMT is under vast investigation as a potential therapeutic option for various conditions and diseases.

Fecal donors undergo a strict screening process to avoid transmission of infections and microbiome-related disease conditions. This consists of several blood and stool tests, which are performed in a conditional, multi-stage process, which may be very costly and time-consuming.

Aims & Methods: Our aim was to review the process of donor recruitment at our Bacteriotherapy Clinic in the Tel Aviv Medical Center, during the past 5 years. We performed a cost-minimizing analysis to find the optimal order in which the tests should be performed, without jeopardizing results, and yet making the process more cost-effective and efficient, without increasing the number of visits of donors.

Methods: This study reviews the economic and chronologic aspects of screening FMT stool donors, description of the etiology of donor disqualification, the number of donors who were disqualified at each stage and the average cost for each screening failure.

In order to study the most cost-effective order of tests, we allocated the screening tests into 14 groups of tests (chemistry, virology, serology, fecal tests etc.). Performance analysis was implemented, and an algorithm for the order of the tests to minimize the cost was defined and proven mathematically. This algorithm takes into account the cost of each test and the probability for it to be abnormal.

Results: A total of 87 volunteers were screened as potential stool donors for CDI treatment. Of these, 53 were not eligible according to their questionnaire, physical examination, or inability to complete the donation process. Thirty-four potential donors (Age- 31.0±6.6 years, 59 % male, mean BMI 21.9±1.9 kg/m²), were screened by laboratory tests. Ten volunteers were disqualified due to abnormal lab tests. Finally, 24 potential donors were qualified as stool donors.

In the current order of tests, according to our data, the average cost of screening of each of the 34 subjects was \$2290±175, and \$3243 to qualify a single donor.

Applying our algorithm to optimize the order of the group of tests, reduced the average cost for screening a potential donor to \$1,150±1,030 and the average cost to qualify a single donor decreased to \$2,550. This resulted in a potential saving of 49.9% of the cost of screening a potential donor and a 21.3% of the cost to qualify a single donor.

Conclusion: Improving the order and timing of the screening tests of potential FMT stool donors can decrease the costs by about 50% per subject.

Disclosure: Nothing to disclose.

DOT-BLOT HYBRIDIZATION FOR THE RAPID AND SIMULTANEOUS DETECTION OF *CAMPYLOBACTER JEJUNI* AND *CAMPYLOBACTER COLI*

B. Bakhshi¹, S. Shams²

¹Tarbiat Modares University, Medical Bacteriology, Tehran, Iran (Islamic Republic of), ²Qom University of Medical Sciences, Cellular and Molecular Research Center, Qom, Iran (Islamic Republic of)

Contact E-Mail Address: sshamsmed@gmail.com

Introduction: Campylobacteriosis is acute bacterial diarrhea that is mainly caused by the genus *Campylobacter*. These are gram-negative, spiral, microaerophilic bacteria and consist of about 25 species. Among them, *C. jejuni* and *C. coli* are known as the main causes of campylobacteriosis worldwide with 90% and 10% of cases, respectively. The disease is common in developed and developing countries, and in many countries, it is about 2 to 3 times more common than salmonellosis.

These bacteria can colonize asymptotically in the intestinal tract of most mammals and birds. It is estimated that 50 to 70% of human *Campylobacter* infections are due to the consumption of contaminated poultry meat products. Cases of Guillain-Barré syndrome (GBS) and reactive arthritis have been reported following *C. jejuni* infection. Therefore, the importance of this disease, especially in children, is very important.

Aims & Methods: Our aim was to develop a dot-blot technique for detecting both *C. jejuni* and *C. coli* simultaneously. The *cadF* gene of *Campylobacter jejuni* and *Campylobacter coli* was selected as the target gene. The sequences were downloaded from GenBank and multiple alignments were done using CLC Sequence Viewer 7.6 software to determine conserved regions among members of both species. GeneRunner and CLC software were used for designing the probe/primers. Dig Oligonucleotide 3-End Labeling Kit was used to synthesize Dig-Probes. TA cloning was also performed to produce a recombinant plasmid (pTG19-T/*cadF*) as a positive control. Dot blot hybridization was performed according to the instructions on DNAs extracted from *C. jejuni* ATCC 29428 and nine laboratory-confirmed campylobacters, including 7 *C. jejuni* and 2 *C. coli* strains. A limit of detection (LOD) was detected using prepared plasmid and different concentrations of the probe (500, 250, 100, 50, and 5 µg/ml).

To evaluate the specificity, a list of intestinal bacteria such as *E. coli*, *Vibrio cholerae*, *Aeromonas hydrophila*, *Enterobacter cloacae*, *Shigella sonnei*, *C. jejuni*, *C. coli*, and *Salmonella enterica* was also used.

Results: A 95-bp fragment of the *cadF* gene was selected, and bioinformatics analyses showed that this region is conserved among campylobacters, so that, in theory, the designed probe can detect these bacteria simultaneously. Hybridization with recombinant plasmid created a black spot on the nylon membrane, which confirmed that the probes were synthesized correctly.

All standard and clinical strains were also identified by the dot-blot technique. The sensitivity of the test was determined at the concentration of 50 µg/ml and no visible spot with other bacteria (100% specificity) was observed.

Conclusion: The designed assay can be useful for the detection of the target bacteria with high specificity and sensitivity, inexpensive, and rapid detection of both bacteria.

Disclosure: Nothing to disclose.

P0551

CLINICAL CHARACTERISTICS AND OUTCOMES OF CLOSTRIDIODES DIFFICILE INFECTION IN THE INTENSIVE CARE UNIT

J.E. Baek¹, I.H. Choi¹, Y.W. Cho¹, Y.-S. Cho¹

¹Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Department of Internal Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: bje310@naver.com

Introduction: *Clostridioides difficile* infection (CDI) is one of the leading causes of hospital-associated infectious diarrhea. Despite of the growing clinical and economic burden of CDI, data on intensive care unit (ICU) related CDI is lacking in Asia-Pacific region. The purpose of our study was to assess patient characteristics and clinical outcomes of CDI treated in the intensive care unit (ICU).

Aims & Methods: Ninety-eight patients with CDI in intensive care unit of Seoul St. Mary's Hospital from January 2017 to May 2021 were analyzed retrospectively. Backward-stepwise multiple logistic regression model was used to analyze factors influencing response to treatment and mortality.

Results: The median age of patients was 70.5 years (IQR 57.8–78.0) and 36 patients (36.7%) were considered immunocompromised. The mean Charlson Comorbidity Index was 5.40±2.44 (10-year survival rate of 21%), APACHE II 18.87±8.16 (predicted mortality rate of 25%), ATLAS score 5.45±1.59 (predicted cure rate of 75%), and SOFA score 8.66±3.83 (predicted mortality rate of 33%), respectively. According to SHEA/IDSA 2017 guideline, 43 cases (43.9%) were mild to moderate CDI, 22 cases (22.4%) with severe CDI, and 33 cases (33.7%) with fulminant CDI.

Oral metronidazole was the most frequently used regime as first-line treatment (n=36; 36.7%), followed by oral vancomycin (n=23; 23.5%), intravenous metronidazole (n=21; 21.4%) and combination of oral vancomycin and intravenous metronidazole (n=18; 18.3%). However, there were no statistically significant differences in the cure rate and all-cause mortality between different treatment groups.

The cure rate after 10 days was 45.9% and the 30 day recurrence rate was 14.3%. Fulminant CDI (OR 0.164; 95% CI 0.053–0.507; p=0.002), high SOFA score (OR 0.207; 95% CI 0.050–0.866; p=0.031), and increment in APACHE II score (OR 0.844; 95% CI 0.727–0.980; p=0.026) were associated with poorer treatment response.

Overall mortality at 60 days was 43.9%, and CDI related mortality 9.1%. Immunocompromised patients (OR 0.240; 95% CI 0.077–0.744; p=0.013), high APACHE II score (OR 0.222; 95% CI 0.064–0.774; p=0.018), and high ATLAS score (OR 0.717; 95% CI 0.514–1.000; p=0.050) were associated with death.

Conclusion: In this study, high-risk patients in ICU have higher mortality and lower cure rate of CDI. Types of antibiotics do not significantly influence the treatment of CDI in ICU patients. Further research is required to provide more accurate prediction scoring systems and better clinical outcomes of CDI in ICU.

Disclosure: Nothing to disclose.

Contact E-Mail Address: onuma.gimed@gmail.com

Introduction: Colonoscopy with tissue biopsy is the gold standard for diagnosing cytomegalovirus (CMV). However, the invasive nature of this technique limits its use in some patients. An alternative non-invasive test, serum CMV real-time polymerase chain reaction (rt-PCR), has insufficient diagnostic performance. Stool CMV-PCR could be an alternative or complementary.

Aims & Methods: This study aimed to assess the diagnosis performance of stool CMV-PCR. This prospective study included 117 consecutive patients with 122 consecutive colonoscopies who had clinically suspected CMV colitis, and 20 asymptomatic healthy volunteers. All participants underwent colonoscopy with tissue biopsy for both H&E stain and immunohistochemistry for CMV as the definite diagnosis. The number of infected cells was counted. Quantitative stool CMV-PCR (CMV R-gene[®] kit, Biomerieux) and quantitative serum CMV-PCR (Cobas[®] CMV, Roche) were collected within 7 days of colonoscopy. The positive test was defined as the detection of virus. The diagnostic performance of the stool and serum CMV-PCR tests were analyzed.

Results: Of 117 patients, 27 (23.1%) were diagnosed with CMV colitis. The stool and serum CMV-PCR performance are shown in Table 1.

Total test (n=122)	Sensitivity(%) (95% CI)		Specificity(%) (95% CI)		PPV(%) (95% CI)		NPV(%) (95% CI)	
Stool CMV-PCR	70.4 (53 – 87)		91.6 (86 – 97)		70.4 (53 – 87)		91.6 (86 – 97)	
Serum CMV-PCR	66.7 (49 – 84)		94.7 (90 – 99)		78.3 (61 – 95)		90.9 (85 – 96)	
Both stool and serum positive	55.6 (36 – 74)		96.8 (92 – 99)		79 (61 – 97)		88.3 (82 – 94)	
Either stool or serum positive	81.5 (67 – 96)		90.5 (84 – 96)		71 (55 – 87)		94.5 (90 – 99)	
Subgroup analysis	IMT	IMP	IMT	IMP	IMT	IMP	IMT	IMP
Stool CMV-PCR	91 (74 – 100)	56 (32 – 81)	95 (88 – 100)	89 (80 – 97)	83 (62 – 100)	60 (35 – 86)	97 (93 – 100)	87 (78 – 96)
Serum CMV-PCR	82 (59 – 100)	56 (32 – 81)	98 (93 – 100)	93 (86 – 99)	90 (71 – 100)	69 (44 – 94)	95 (89 – 100)	88 (79 – 96)
Both stool and serum positive	73 (46 – 99)	44 (19 – 68)	98 (93 – 100)	94 (88 – 100)	89 (68 – 100)	70 (41 – 98)	93 (85 – 100)	85 (76 – 94)
Either stool or serum positive	100 (100 – 100)	69 (46 – 91)	95 (88 – 100)	87 (78 – 96)	85 (65 – 100)	61 (38 – 84)	100 (100 – 100)	90 (82 – 98)
IMT, Immunocompetent (n=52); IMP, Immunocompromised (n=70)								

IMT, Immunocompetent (n=52); IMP, Immunocompromised (n=70)

Table 1. Diagnostic performance of stool and serum CMV PCR

The sensitivity and specificity was 0.70 and 0.91 for stool CMV-PCR and 0.67 and 0.95 for serum CMV-PCR. No significant difference was observed. When both test results were combined, the specificity of the posi-

tive of both tests was 0.97, significantly higher than the stool test alone ($P=0.045$). Furthermore, the sensitivity of the positive of either test was 0.81, significantly higher than the serum CMV-PCR alone ($P=0.045$). In subgroup analysis, diagnostic performance was better in immunocompetent patients (Table 1).

We found a good and significant correlation between stool CMV-PCR and serum CMV-PCR ($r=0.71$, $p<0.01$), and each test with cytomegalic cell count ($r=0.63$, $p<0.01$ for stool CMV-PCR and 0.68 , $p<0.01$ for serum CMV-PCR). There were no positive results for stool and serum CMV-PCR tests among healthy volunteers.

Conclusion: Stool CMV-PCR had a good diagnostic performance for CMV colitis. Combining stool and serum CMV-PCR could improve diagnostic value. Positive both tests had high specificity and can be used for ruling in, while negative results of both tests can exclude CMV colitis.

Disclosure: Nothing to disclose.

Introduction: Human colonic spirochaetosis (CS) is an infection caused by the *Brachyspira* genus. Although considered as commensal, recent evidence suggests *Brachyspira* are associated with gastrointestinal symptoms and irritable bowel syndrome [1].

Increased eosinophils, mast cells and lymphocyte aggregates have been reported in CS [2,3], however, little is known about immune cell localization or activation status. We aim to characterize the distribution and activation of mucosal immune responses in patients with CS compared to controls.

Aims & Methods: Formalin fixed, paraffin-embedded colonic biopsy samples from 20 CS patients (mean age $\pm$ SEM 44.50 $\pm$ 4.32, 70% male) were examined; 20 age/sex and date of colonoscopy-matched patients (45.65 $\pm$ 4.06, 70% male) who did not have CS were recruited as matched controls. Patient demographic and clinical information were collected and the associations with CS were compared (Fisher exact test with odd ratios (OR) and 95% confidence intervals (CI)). Spirochaete infection was confirmed by cross-reactive *Treponema pallidum* antibody immunohistochemistry (IHC) staining. Intra-epithelial lymphocytes (IEL) /150 colonic enterocytes were identified by H&E staining, eosinophils were identified by Congo-red staining, and mast cells were identified by CD117 IHC staining. Tissue sections were visualised using the Aperio AT2 digital pathology scanner. Peak cell numbers were counted in 3 fields of intra-epithelial, intra-crypt and lamina propria areas.

Results: CS patients had a significantly higher risk of faecal incontinence (OR: 14.37, 95%CI: 0.67 to 307.4) and mucus in the stool (OR: 14.37, 95%CI: 0.67 to 307.4) compared to matched controls. Patients with CS also had an increased likelihood of abdominal pain (OR: 3.75, 95%CI: 0.79 to 15.26), diarrhea (OR: 4.33, 95%CI: 1.00 to 16.74), vomiting (OR: 5.09, 95%CI: 0.19 to 135.5), blood in the stool (OR: 9.00, 95%CI: 1.054 to 114.9), defecation urgency (OR: 9.29, 95%CI: 0.41 to 211.9) and nocturnal defecation (OR: 5.09, 95%CI: 0.19 to 135.5). CS patients had a significantly higher eosinophil count and degranulated eosinophil count in the lamina propria, intra-epithelial and intra-crypt regions compared to matched controls (Table 1).

CS patients had a significantly higher mast cell count and degranulated mast cell count in the lamina propria, intra-epithelial but not in intra-crypt regions compared to matched controls (Table 1). CS patients had significantly higher IELs compared to matched controls (Table 1).

Cell count (Mean $\pm$ SEM)	CS (n=20)	Matched control (n=20)	P value
Lamina propria eosinophils	46.84 $\pm$ 4.78	30.69 $\pm$ 3.29	0.0123
Lamina propria degranulated eosinophils	35.81 $\pm$ 3.70	19.11 $\pm$ 2.30	0.0004
Lamina propria CD117+ mast cells	62.77 $\pm$ 3.24	46.21 $\pm$ 1.97	<0.0001
Lamina propria degranulated CD117+ mast cells	50.74 $\pm$ 3.08	37.08 $\pm$ 1.84	0.0002
Intra-epithelial eosinophils	4.68 $\pm$ 0.55	2.82 $\pm$ 0.33	0.0121
Intra-epithelial degranulated eosinophils	4.44 $\pm$ 0.53	2.47 $\pm$ 0.31	0.0045
Intra-epithelial CD117+ mast cells	3.33 $\pm$ 0.38	1.88 $\pm$ 0.28	0.0032
Intra-epithelial degranulated CD117+ mast cells	2.70 $\pm$ 0.32	1.46 $\pm$ 0.24	0.003
Intra-crypt eosinophils	2.21 $\pm$ 0.32	1.07 $\pm$ 0.22	0.01
Intra-crypt degranulated eosinophils	2.10 $\pm$ 0.32	0.67 $\pm$ 0.18	0.0005
Intra-epithelial lymphocytes	14.38 $\pm$ 1.29	6.71 $\pm$ 0.58	<0.0001

Table 1. Summary of immune cell count comparisons between CS patient and matched controls

Conclusion: Patients with CS had increased eosinophils, mast cells count and activation in the lamina propria and intra-epithelial regions, as well as increased IELs, suggesting these cells that play important roles in anti-bacterial defence may be induced by spirochete infection. CS patients also have a higher risk of GI symptoms. These data suggest that CS infection provokes a mucosal immune response and GI symptoms, and that *Brachyspira* species may be a group of underappreciated intestinal pathogens.

CHANGES OF CLOSTRIDIODES DIFFICILE INFECTION RATE DURING FIRST STAGES OF COVID-19 PANDEMIC ERA -A RETROSPECTIVE STUDY FROM A ROMANIAN TERTIARY CENTER

M. Chirvase¹, O. Mocanu¹, R. Stefan¹, S. Bucurica^{1,2}, F. Ionita-Radu^{1,2}

¹Central University Emergency Military Hospital, Bucharest, Romania, ²'Carol Davila' University of Medicine and Pharmacy, Internal Medicine and Gastroenterology, Bucharest, Romania

Contact E-Mail Address: mirela_chereja@yahoo.com

Introduction: Clostridioides difficile infection (CDI) is generally one of the most frequent health care-associated infections (HAI) all around the world, with variations between different medical systems.

The Covid-19 pandemic radically changed our medical practice, with implications in the healthcare-associated infections (HAI) incidence secondary to the enhancement of the measures meant to reduce SARS-CoV-2 spreading. Gut dismicrobism induced by SARS-COV-2 infection, long hos-

pital stay, empirical antibiotic therapy and immunomodulating agents used as treatment for Covid-19 could change CDI incidence during the pandemic.

Aims & Methods: The aim of this study was to evaluate if there is a change in *Clostridioides difficile* infection rates due to Covid-19 pandemic impact in medical system. In this retrospective study we analyzed the rate of new CDI cases diagnosed in the Central Military Hospital of Bucharest from september 1 2020 to march 31 2021 (6 months) in full pandemic time, using the hospital database system. We included 96 hospitalized patients in this study with established diagnosis of CDI by enzyme immunoassay detection of antigen GDH and toxins A and or by positive *Clostridioides difficile* PCR from stool sample.

Also, we studied the CDI diagnosis and death rates of patients diagnosed with CDI during 6 months of Covid-19 pandemic compared to a non-pandemic 6 months time interval (1 sept 2016- 1march 2017).

Results: In our study group of patients with CDI the mean age at diagnosis was 62.52 years old, 52% of patients being over 65 years old, with small difference between genders (53% males vs 47% females).

Most of the patients suffered from chronic comorbidities (87%) and 59.3% of them presented history of SARS-COV-2 infection.

Regarding risk factors, 89.58% of the patients were exposed to 2 or more risk factors for CDI infection (advanced age, antibiotic therapy, proton pump inhibitor administration and immunosuppressive drugs were the most common CDI risk factors).

The infection with *Clostridioides difficile* was significantly higher in Covid-19 infection patients with RR =12.059 (95% CI – Confidence interval, 8.047 to 18.072)

The mortality rate of patients diagnosed with CDI was 15.6%, four times higher than it was found in the pre-pandemic data regarding *Clostridioides difficile* deaths (4%). The number of new CDI cases diagnosed during 6 months of Covid 19 pandemic was almost twice higher (96 vs 54) compared with 4 years ago in a study conducted in the same hospital.

Conclusion: During the Covid-19 pandemic, not only the incidence, but the death rate of CDI was found to be much higher, patients with comorbidities, exposed to one or more risk factors being most common affected. Coronavirus may contribute to worsening the prognosis of CDI patients through dismicrobism (gut specific receptors for SARS-CoV-2), longer hospitalization, empirical antibiotic therapy and immunomodulating agents used as treatment for Covid-19.

Disclosure: Nothing to disclose.

RISK FACTORS FOR TREATMENT FAILURE AFTER FECAL MICROBIOTA TRANSPLANTATION IN *CLOSTRIDIoidES DIFFICILE* INFECTION

J.-H. Lee¹, S.J. Lee², J. Shin², S.-H. Park², B. Cha², K.S. Kwon², Y.-W. Shin²

Contact E-Mail Address: endlesmile@naver.com

Introduction: Recently, Fecal Microbiota Transplantation (FMT) was introduced as an effective treatment option for *Clostridioides difficile* Infection (CDI). However, risk factors associated with treatment failure of FMT were not well-demonstrated in the previous study, So we aimed to investigate risk factors to affect treatment failure or recurrence after FMT for CDI.

Aims & Methods: In this retrospective study, (140)patients with CDI received FMT at the microbiome center in Inha University Hospital from November 2017 to August 2021. Among them, (124) who could follow up until 8 weeks after FMT for signs or symptoms of CDI were excluded. FMT

Failure was defined as recurrence of diarrhea or a positive stool test. We collected the risk factors of treatment failure including comorbidities using Charlson Comorbidity Index (CCI), antibiotics usage before and after FMT, and the number of CDI episodes before FMT.

Results: Ninety-three patients (93/124, 75 %) experienced an improvement in symptoms after FMT within 1 week. Treatment failure occurred in 40 patients (40/124, 32.3%) related to unresolving symptoms or positive stool tests.

In multivariate analysis, the rate of symptom improvement within 1 week after FMT was marginally lower in the group with male patients (Odd ratio[OR]: 0.43, 95% confidence interval [CI], 0.179-0.996, P=0.049). The group using antibiotics after FMT showed significantly high recurrence or treatment failure within 8 weeks (Odd ratio[OR]: 2.41, 95% confidence interval [CI], 1.08-5.40, P=0.032).

Conclusion: Patients who need to use antibiotics after FMT should be considered for treatment failure of FMT. It should be confirmed by a large and randomized prospective study.

Disclosure: We have no conflict of interest to declare.

Contact E-Mail Address: fran_8_orgaz@hotmail.com

Introduction: *Clostridioides difficile* infection (CDI) is the leading cause of nosocomial diarrhea. In addition, multiple studies have shown recurrence rates (rCDI) of approximately 25% (1). Bezlotoxumab, a monoclonal antibody targeted against toxin B, has demonstrated a 40% decrease in the rate of rCDI at 12-week follow-up when co-administered with conventional therapy in clinical trials (2). However, there are still few data that reflect these response rates in daily clinical practice. The main objective of this study was to describe the rate of rCDI during the 12 weeks after administration of bezlotoxumab in patients with CDI.

Aims & Methods: This retrospective, observational, single-centre study recorded all patients who received bezlotoxumab infusion during the duration of antimicrobial treatment for CDI between January 2019 and September 2021. Demographic, clinical data, number of CDI episodes prior to administration of bezlotoxumab, antibiotic treatments received in each episode and follow-up time were included. Treatment success was defined as the absence of rCDI 12 weeks after bezlotoxumab infusion.

Results: 53 patients were included in the study, 27 (50.9%) were women, the median age was 67 years, with a median follow-up of 64 weeks. The main risk factors for rCDI in our population are shown in Table 1.

13 patients (24.5%) received bezlotoxumab in the first CDI episode, 16 (30.2%) in the first recurrence, and 24 (45.3%) in the second or later recurrences. No patient had adverse events related to bezlotoxumab.

Oral vancomycin was the most frequent antibiotic treatment (38.5%) in the patients who received bezlotoxumab in the first CDI, tapered vancomycin the most frequent (62.5%) in the patients who received it in the first rCDI and extended regimen fidaxomicin (29.2%) the most frequent antibiotic in patients who received bezlotoxumab in the second or subsequent recurrences. 49 of 53 patients had no rCDI in the first 12 weeks after administration of bezlotoxumab, which was equivalent to a

success rate of 92.5%. When analyzing risk factors for rCDI in our cohort, we found a significant difference when comparing the recurrence rate between patients who received bezlotuxumab in the first CDI or in the first rCDI versus recurrence rate in those who received bezlotuxumab in the second or later rCDI ($p=0.03$), with a relative risk of 1.2 (95% confidence interval 1.003-1.435).

	N=53
Age >65	34 (64.2%)
Chronic Kidney Disease	13 (24.5%)
Active Cancer (solid organ and hematologic tumors)	11 (20.8%)
Liver Cirrhosis	6 (11.3%)
Inflammatory Bowel Disease	12 (22.6%)
Immunosuppressed	34 (64.1%)
Solid Organ Transplant	10 (18.9%)
Proton Pump Inhibitor Use	47 (88.7%)
Previous Antibiotic Treatment	42 (79.2%)

Table 1. Risk factors for recurrent *Clostridioides difficile* infection (CDI).

Conclusion: In our study, the rCDI rate was lower (7.5%) than that obtained in the pivotal clinical trial (17%) (2). Furthermore, this study demonstrated that late administration of bezlotuxumab (second or later recurrences) increased the risk of recurrences in our population. These results suggest that bezlotuxumab should be used before multiple recurrence occurs. Also, bezlotuxumab was a safe drug with no adverse events reported. However, given the small sample size and the retrospective nature of the study, future evidence is needed to confirm these findings.

THE EFFICACY AND SAFETY OF HEMOSTATIC POWDER UI-EWD IN PATIENTS WITH LOWER GASTROINTESTINAL BLEEDING

J. Shin¹, B. Cha¹, J.-S. Park¹, K.-S. Kwon¹, H.-K. Kim¹

¹Inha University Hospital, Inha University School of Medicine, Department of Internal Medicine, Incheon, Korea (Republic of)

Contact E-Mail Address: shinjongv@naver.com

Introduction: Acute lower gastrointestinal bleeding (LGIB) is a common cause of hospitalization, and there are many cases of readmission for re-bleeding after endoscopic hemostasis. Recently, endoscopic hemostatic powder (UI-EWD/Nexpowder™ Nextbiomedical, Incheon, South Korea) has been developed and used to manage LGIB.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of UI-EWD in LGIB. We conducted this retrospective cohort study of LGIB at a tertiary center. A total number of consecutive patients with LGIB who were included in our research was 167. UI-EWD was applied as rescue therapy during endoscopic treatment in 55 patients. we evaluated the success rate of hemostasis, the adverse event related with UI-EWD and the rate of re-bleeding.

Results: All hemostasis with UI-EWD was successful. The rebleeding rate within 28 days in the UI-EWD group was 5.5% (3/55), which was significantly lower than that in the conventional treatment group, 17.0% (19/112) (p -value:0.039). There were no adverse events associated with or without UI-EWD application.

Conclusion: Apply of UI-EWD is considered as a very effective method for hemostasis, and prevention of rebleeding in LGIB patients who are difficult to control with conventional treatment. Based on this results, we suggest that considering the use of UI-EWD for hemostasis in LGIB is useful and safe.

Disclosure: Nothing to disclose.

CAN HOSPITAL ADMISSIONS FOR LOWER GASTROINTESTINAL BLEEDING BE REDUCED? IMPLEMENTATION OF TWO SCALES FOR THE PREDICTION OF SAFETY DISCHARGE IN A RETROSPECTIVE COHORT

L. Gonzalez Gonzalez¹, I. Iborra², M. Fortuny³, A. Calm Salvans³, F. Cañete^{1,4}, M. Calafat Sard^{4,1}, M. Mañosa^{1,4}, E. Domenech Morral^{4,1}
¹Hospital Universitari Germans Trias i Pujol, Gastroenterology, Badalona, Spain, ²Hospital Universitari Germans Trias i Pujol, Endoscopy, Badalona, Spain, ³Hospital Universitari Germans Trias i Pujol, Badalona, Spain, ⁴CIBEREHD, Madrid, Spain

Contact E-Mail Address: glaug2@gmail.com

Introduction: The incidence of lower gastrointestinal bleeding (LGIB) is increasing due to the population's aging and causes up to 20-30% of all episodes of gastrointestinal bleeding. Most (80-90%) LGIB episodes follow an uncomplicated course with bleeding control without any haemostatic intervention. Conversely, hospital admission can be a cause of morbidity unrelated to the LGIB itself, particularly in elderly or frail patients. Recently, two scales have been developed to predict a "safe discharge" from the emergency room in patients with LGIB.

Aims & Methods: To evaluate the accuracy of two scales (Oakland and SHA₂PE scores) to predict a safe discharge from the Emergency room in a retrospective cohort of patients admitted for LGIB in a tertiary centre. All patients admitted for LGIB between June 2014 and June 2019 in a tertiary care centre were identified. Patients referred from smaller centres for tertiary care and those in whom the reason for admission was not LGIB, were excluded. "Safe discharge" was defined as meeting all the following criteria:

1. No blood transfusion;
2. No haemostatic treatment (endoscopic, radiological, or surgical);
3. No bleeding recurrence;
4. No medical consultation for LGIB within 28 days after discharge; and
5. No death during admission.

Results: A total of 595 admissions due to LGIB were identified, of which 398 episodes were included. The most frequent aetiology was diverticular disease (53%). Among them, 214 episodes (54%) met the criteria for "safe discharge". Among those not meeting the criteria for safe discharge, 42% required blood transfusion, 8.5% haemostatic treatment, 3% had bleeding recurrence, 15.5% seek for medical advice due to LGIB after discharge and 0.9% died. An Oakland score ≤ 8 points was the one with the highest specificity and positive predictive value (PPV) (both 100%), while the Oakland score of ≤ 10 points (specificity 96.7% and PPV of 45.6%) and the SHA₂PE index (specificity of 94.6% and PPV 89.1%) were less accurate. Nine, 42 and 89 admissions would have been avoided in the study period in case of Oakland score ≤ 8 , Oakland score ≤ 10 points and SHA₂PE ≤ 1 point, respectively. However, using Oakland score ≤ 10 points and SHA₂PE ≤ 1 point, 12% and 11% of patients discharged from the Emergency room would have not met the criteria of safe discharge.

Conclusion: With the current admission criteria, almost half of the patients with LGIB meet the “safe discharge” criteria. Nevertheless, the available prediction indices would only avoid a very small proportion of unnecessary admissions. Further research for more accurate prognostic scores is warranted.

MANAGEMENT AND OUTCOMES OF LOWER GASTROINTESTINAL BLEEDING IN PATIENTS ON ANTICOAGULATION

L. Gonzalez Gonzalez¹, I. Iborra², M. Fortuny³, A. Calm Salvans³, F. Cañete^{1,4}, M. Calafat Sard^{4,1}, M. Mañosa Ciria^{4,1}, E. Domenech Morral^{4,1}

¹Hospital Universitari Germans Trias i Pujol, Gastroenterology, Badalona, Spain, ²Hospital Universitari Germans Trias i Pujol, Endoscopy, Badalona, Spain, ³Hospital Universitari Germans Trias i Pujol, Badalona, Spain, ⁴CIBEREHD, Madrid, Spain

Contact E-Mail Address: glaug2@gmail.com

Introduction: Lower gastrointestinal bleeding (LGIB) is common, and it is increasing in incidence among the elderly and in people on anticoagulant treatment. The impact of anticoagulation and its optimal management during the bleeding episode are not well established.

Aims & Methods: To describe the management and impact of anticoagulation on the clinical outcomes of patients with LGIB.

Retrospective analysis of all episodes of LGIB admitted in a tertiary care hospital from June 2014 to June 2019.

Results: Among a total of 398 episodes of LGIB, 102 (26%) occurred while on anticoagulant treatment (71% with dicumarinics and 14% with direct oral anticoagulants -DOAC-). Patient on anticoagulation were older (77 vs. 74 years; $p=0.032$) and had a higher Charlson score (9 vs. 6; $p<0.001$). Anticoagulation was discontinued upon arrival in 16% of the episodes and re-started after a median of 5 days (1-40). At discharge, 4% required modification of the anticoagulation drug or regimen, as follows: 53% treatment discontinuation, 18% were switched from dicumarinics to DOAC and in 29% the DOAC's dose/type was changed. The patients on anticoagulation had a significantly lower haemoglobin concentration upon arrival (10.5 vs.

11.6g/dL; $p<0.001$) and minimum haemoglobin during admission (9 vs. 9.9g/dL; $p=0.001$), as well as a significantly higher need for blood transfusion (55% vs. 37%; $p=0.001$), endoscopic treatment (10% vs. 4%; $p=0.043$), re-admission for LGIB (13% vs. 5%; $p=0.009$) and haemorrhage rate in other territories (17% vs. 5%; $p<0.001$).

In contrast, haemodynamic instability in the emergency room, colonoscopy (62% vs. 61%; $p=0.96$), recurrence of LGIB or death during admission were similar in the two groups. Thirty-nine per cent of patients on dicumarinics had an INR >3 on arrival at the emergency room, which was associated with a lower haemoglobin concentration on arrival and a greater need for transfusion compared to those with an INR within the therapeutic range.

Conclusion: Currently, one fourth of LGIB episodes occur in patients on anticoagulation. Anticoagulation is associated with a greater need for transfusion, endoscopic treatment, and readmission for LGIB, even more pronounced in case of dicumarinic overdose. Anticoagulant therapy is modified at discharge in a very low proportion of patients.

Disclosure: Nothing to disclose.

SAFETY OF PERFORMING LEFT SIDE COLONOSCOPY VERSUS TOTAL COLONOSCOPY IN PATIENTS LESS THAN 45 YEARS OLD AGE PRESENTED WITH FEATURES SUGGESTIVE OF PERIANAL DISEASE

M. Al-Shekhani¹, S. Shekha^{2,3}

¹Kurdistan Center for GEH, Gastroenterology, Asulaimaniyah, Iraq,

²Kurdistan center for GEH, Gastroenterology, Sulaimanyah, Iraq,

³Sulaimani University, Gastroenterology, Sulaimanyah, Iraq

Contact E-Mail Address: shaikhanimohammad@gmail.com

Introduction: Background: Colonoscopy and flexible sigmoidoscopy are both recommended tools in diagnosing colorectal diseases, but their relative effectiveness is unclear. Direct comparisons of colonoscopy and sigmoidoscopy in the same population would be helpful to inform patients, providers, and policy makers about CRC screening options.

Aims & Methods: Objectives: To evaluate the ability of each of these two modalities (colonoscopy and sigmoidoscopy) to reach the diagnosis in patients presented with features suggestive of perianal disease and to determine Factors that predict safely performing left sided colonoscopy in patients less than forty five years old age presented with features suggestive of perianal disease.

This retrospective and prospective observational study is conducted between 1st of January 2021 and 1st of January 2022 in department of KCGH / Ferkary- hospital, Sulaimaniyah city, Iraq. Five hundred patients presented with features of perianal disease where subjected to sigmoidoscopy and extended to full colonoscopy (first group) and other five 500 patients aged equal and more than 45 years with same presentation taken (second group).

Results: Among five hundred patients who visited KCGH for colonoscopy in Sulaimaniyah city- Iraq, All patient's age were below 45 years old with the mean age of about 33 years. All patients underwent sigmoidoscopy and total colonoscopy with terminal ileal intubation, in colonoscopy group we have 226 (about 45.2%) patients with normal total colonoscopy findings while in sigmoidoscopy group 265 (about 54.8%) cases have normal findings, Thirty nine patients (about 7.8%) have normal finding in sigmoidoscopy but positive findings in colonoscopy.

Conclusion: Colonoscopy and sigmoidoscopy are both important tools in investigating patients presenting with perianal features. While both are sensitive in detecting pathology in the left side of colon our study concluded that although colonoscopy is the ideal procedure in detecting lesions in the whole colon (proximal & distal to splenic flexure), but limited colo-

noscopy up to splenic flexure can be safely carried out in patients less than 45 years old presented with perianal diseases without the fear of missing important proximal colonic lesions.

EFFECT OF LONG-TERM TREATMENT WITH SOMATOSTATIN ANALOGUES IN PATIENTS WITH GASTROINTESTINAL ANGIODYSPLASIA: A SINGLE-CENTER EXPERIENCE

A. Jiménez-Masip¹, A. Palacios¹, L. Alcalá¹, C. Alonso-Cotoner^{1,2,3}
¹Vall d'Hebron University Hospital, Gastroenterology / Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain, ²Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERHED), Madrid, Spain, ³Digestive System Research Unit, Vall d'Hebron Institut de Recerca (VHIR), Laboratory of Neuro-Immuno-Gastroenterology, Barcelona, Spain

Contact E-Mail Address: 94jimenezalba@gmail.com

Introduction: Gastrointestinal bleeding due to angiodysplasia represents up to 10% of gastrointestinal bleeding cases and about 60% of small bowel bleeding. First-line treatment consists of endoscopic argon plasma coagulation, but rebleeding occurs in up to 60% of the patients in the following 2 years.

Somatostatin analogues (SA) have emerged as an attractive medical treatment for those patients with multiple or refractory lesions. However, evidence in literature regarding its effectiveness is scarce.

Aims & Methods: To describe clinical characteristics of patients with gastrointestinal angiodysplasia (GIAD), and to analyze the effect of SA in the course of bleeding GIAD a year after its initiation.

Patients from our center with a history of GIAD-related bleeding with transfusion requirements, who initiated or had initiated SA were included between September 2019 and September 2021.

Clinical data were collected and transfusion requirements (number of packed red blood cells, pRBC), number of hospitalizations and number of endoscopic procedures were recorded in the year after and the year before starting SA. Full responders were defined as those patients with a reduction in the number of pRBC $\geq 50\%$.

Results: A total of 53 patients were included (51% women, median age of 77 $\pm$ 9 years). Among them, 67.9% had cardiac valvular disease and 37.7% chronic kidney disease. Most of the patients were under anti-thrombotic treatment: 52.8% on oral anticoagulants and 41.5% on antiplatelets. GIAD was present in 86.8% of the patients (43% colon, 21% small bowel, 15% multiple locations, 8% stomach), while 13.2% had positive fecal occult blood test with no endoscopic findings.

Up to 50.9% of patients received octreotide and the rest of them, lanreotide. SA treatment was associated with a significant reduction in the number pRBC (9.0 $\pm$ 0.9 vs. 5.5 $\pm$ 1.0; $p=0.001$), number of hospitalizations (3.0 $\pm$ 0.27 vs. 2.0 $\pm$ 0.38; $p=0.002$) and endoscopic procedures (3.6 $\pm$ 0.28 vs. 1.13 $\pm$ 0.26; $p<0.001$) after one year of treatment. Full response was observed in 66% of the patients.

No differences were found regarding the type of SA ($p=0.387$), anticoagulant ($p=0.245$) and/or antiplatelet therapy ($p=0.777$) between full responders and non-responders.

Conclusion: In our cohort, long-term treatment with SA has a beneficial effect in GIAD-related bleeding, significantly decreasing red blood cell transfusion requirements, as well as hospitalization and endoscopic procedures. Further studies are required to properly evaluate the efficacy of SA in GIAD-related bleeding.

CHARACTERISTIC OF THE PATIENTS AND LESIONS WITH DELAYED BLEEDING AFTER COLORECTAL ESD THAT DO NOT REQUIRE HEMOSTASIS

S. Takahashi¹, K. Okimoto¹, T. Matsumura¹, T. Kaneko¹, N. Akizue¹, Y. Ohta¹, T. Taida¹, K. Saito¹, J. Kato¹, N. Kato¹

¹Chiba University, Gastroenterology, Graduate School of Medicine, Chiba, Japan

Contact E-Mail Address: u.satsuki.s.u@gmail.com

Introduction: Delayed Bleeding (DB) with colorectal endoscopic submucosal dissection (ESD) is a relatively frequent complication, and while some patients require hemostasis, others can be followed up without hemostasis. It is important to appropriately determine which cases are amenable to follow-up to avoid unnecessary invasive procedures.

Aims & Methods: The aim of this study was to identify the characteristics of the patients and lesions with DB after colorectal ESD that did not require hemostasis.

Method: Of 603 colorectal ESD cases performed at Chiba university hospital between June 2009 and January 2022, 147 patients and 151 lesions with DB were included (DB group). DB was defined as gross hematochezia (including a small amount of hematochezia) or decreases of Hb 2g/dL or more the day after ESD. DB group was classified into two groups: hemostasis group (H-group; endoscopic hemostasis performed) and follow-up group (FU-group; no endoscopy performed, or endoscopy performed but no hemostasis performed).

The patient/lesion backgrounds, details of ESD and postoperative statuses were analyzed retrospectively.

Results: Of DB group (147 patients, 151 lesions), H-group (34 patients (23.1%), 35 lesions (23.2%)) and FU-group (113 patients (76.9%), 116 lesions (76.8%)).

In univariate analysis, the following factors contributed to follow-up without hemostasis: small amount of hematochezia (definition; recorded in the medical chart as "small quantities hematochezia" or the like), hematochezia once a day, no symptoms of dizziness, hypotension, or abdominal pain, and use of traction method had significantly higher Odds ratio (OR) (5.9/7.9/4.1/8.0) respectively.

The OR was significantly higher for patients with ulcerative colitis as a factor contributing to hemostasis (7.3). Neither age or antithrombotic drug use was not a factor contributing to hemostasis.

Thirty of 151 patients (19.9%) had a decrease in Hb of 2g/dL or more on the day after ESD, but none of them without clinical findings required hemostasis. On multivariate analysis, the small amount of hematochezia was the most important factor contributing to the possibility of follow-up (OR 8.1, 95%CI:2.9-22.7, $p<0.01$).

Conclusion: We should pay attention to the amount and frequency of hematochezia, and DB symptoms after ESD. The use of traction device may have contributed to the follow-up factors, since it improved the visibility

of bleeding and appropriate hemostasis was performed during ESD. In addition, cases with UC complications should be noted because hemostasis may be necessary if DB is detected.

Disclosure: Nothing to disclose.

THE FACTOR ANALYSIS INFLUENCING THE DIAGNOSTIC YIELDS OF CAPSULE ENDOSCOPY IN PATIENTS WITH OBSCURE GI BLEEDING

K. Hong¹, W.-C. Chung¹

¹The Catholic University of Korea, St. Vincents Hospital, Internal Medicine, Suwon, Korea (Republic of)

Contact E-Mail Address: kuwa001@naver.com

Introduction: Small bowel capsule endoscopy (SBCE) is widely used for diagnosing obscure gastrointestinal bleeding (OGIB). In general, SBCE was proven as a diagnostic yield of approximate 50% for OGIB. This study was to identify factors to increase the diagnostic yield of SBCE in OGIB.

Aims & Methods: The patients who complained of melena or hematochezia were admitted at St. Vincent Hospital, Catholic University of Korea. All of them had negative results of esophago-gastroduodenoscopy and colonoscopy. Immediately on the same day or the next day of endoscopic examinations, SBCE was performed. A consecutive series of the patients were enrolled from March 2019 to December 2021.

Patients were categorized into two subgroups: positive (n = 78), and negative results of SBCE (n = 67). We analyzed the factors affecting diagnostic yields of SBCE— clinical characteristics, underlying conditions, process, and preparation of the procedures.

Results: The rate of positive diagnostic yield of SBCE was 44.8% (78/ 174). There were no significant differences of sex, body mass index (kg/ m²), the presence of diabetes, intake of nonsteroidal anti-inflammatory drugs or anti-platelet drugs, initial lowest hemoglobin level, procedure interval time (from episode to procedure), observation of ampulla of Vater, and duration of oral-to duodenum. The degree of bowel preparation affects the diagnostic yield of SBCE (P=0.003), and small bowel transit time was the significantly longer than negative results group (P=0.027).

In positive results group, the mean age of the patients was the older than negative results group (P=0.01), and the positive result rate of patients under age 60 was statistically low compared with those equal or over 60 (P<0.01).

Conclusion: In the relatively young patients (age <60) with OGIB, we should consider the SBCE carefully due to relatively lower diagnostic yield. Bowel preparation should be good. Small bowel transit time would be an important factor affecting diagnostic yield of SBCE in patients with OGIB.

Disclosure: Nothing to disclose.

OUTCOMES OF TRANSCATHETER AORTIC VALVE IMPLANTATION IN GASTROINTESTINAL BLEEDING

I. Latras Cortés¹, S. Díez Ruiz¹, R. González Núñez¹, L. Alcoba Vega¹, D. López Cuesta¹, L. Vaquero Ayala¹, S. Vivas Alegre¹, F. Jorquera Plaza¹, A.B. Domínguez Carbajo¹

¹University Hospital of León, Department of Gastroenterology, León, Spain

Contact E-Mail Address: irenelatrascortes@gmail.com

Introduction: Heyde's syndrome is characterized by a triad of aortic stenosis, angiodysplasia with bleeding and acquired von Willebrand syndrome; it is an uncommon cause of gastrointestinal bleeding and iron deficiency anemia.

Hypothesis: transcatheter aortic valve implantation (TAVI) might reduce the presence of gastrointestinal angiodysplasia and their complications.

Aims & Methods: The aim was to compare the existence of anemia (hemoglobin levels), requirements for blood transfusion, hospitalizations for gastrointestinal bleeding and number of endoscopies performed in patients with aortic stenosis before and after TAVI, and describe the medical treatment offered in the Gastroenterology consultation.

Method: Quasi-experimental study with before-and-after design. Data of TAVI performed from January 2018 to December 2020 were collected, and subjects with prior diagnosis of angiodysplasia were selected (n=10) for further analysis.

Results: Ten of the 146 patients (6.85%) who had a TAVI performed had a prior diagnosis of angiodysplasia.

The mean age of the patients with angiodysplasia at time of the TAVI procedure was 83.27 years (SD 3.77); 60% were males.

Regarding medical treatment, 8 patients (80%) were followed in Gastroenterology Consultation. Apart from endoscopic therapy, iron infusion and blood transfusion, octreotide was administered in three of them (37.5%). The mean level of hemoglobin in the 12 months before TAVI was 10.79 g/dl vs 12.01 in the 12 months after TAVI; with statistically significant difference (p=0.0479). There were also statistically significant differences in the comparison of the mean of hospitalizations, endoscopies and blood transfusions before and after TAVI (Table 1).

	Before TAVI	After TAVI	p value
Hemoglobin (g/dl)	10.79 (SD 1.22)	12.01 (SD 1.15)	0.0479
Hospitalizations for gastrointestinal bleeding	1.40 (SD 2.41)	0 (SD 0)	0.0162
Endoscopies	3.30 (SD 3.30)	0.30 (SD 0.67)	0.0129
Blood transfusions	11.90 (SD 19.65)	2.20 (SD 2.62)	0.0244

Table 1. Comparison of levels of hemoglobin, hospitalizations for gastrointestinal bleeding, number of endoscopies and blood transfusion before and after TAVI (expressed as means, standard deviation and p value).

Conclusion: - TAVI reduces gastrointestinal bleeding and improves anemia, so it decreases blood transfusion requirements.

- Anemia, in selected cases, might constitute a criterion for aortic stenosis intervention in the future.

- A multidisciplinary follow-up in Gastroenterology consultation is necessary in order to prepare the patient to the TAVI procedure, by offering endoscopic and medical treatment with somatostatin analogs when iron infusion and blood transfusion are not enough.

Disclosure: Nothing to disclose.

INTRARECTAL FORMALIN TREATMENT FOR HAEMORRHAGIC RADIATION INDUCED PROCTOPATHY: EFFICACY AND SAFETY

D. Kohoutova¹, C. Gee¹, D. Cunningham¹, A. Wilson¹

¹Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom

Contact E-Mail Address: darina.kohoutova@seznam.cz

Introduction: Radiotherapy is a curative treatment option for localized malignancies, nevertheless it is limited by the dose dependent toxicity to the surrounding organs. From the gastrointestinal tract, rectum is the most frequently affected organ due to:

1. Proximity to the irradiated pelvic organs;
2. Its fixed position within the field of radiation.

Total doses exceeding 60Gy are associated with a higher risk of rectal toxicity and bleeding. Patients with chronic radiation proctopathy (CHRP) have symptoms similar to acute proctitis, however full-thickness bowel ischaemia and fibrotic changes contribute to additional complications: severe rectal bleeding, fistulas, strictures, perforations. Neovascularization and formation of teleangiectasias are responsible for rectal bleeding. If bleeding is severe and/or causes iron-deficiency anaemia, treatment should be offered. Sucralfate enema (if applicable) is the first line treatment. If this fails, argon plasma coagulation (few bleeding teleangiectasias) can be used, or installation of intrarectal formalin (widespread teleangiectasias) is opted.

Aims & Methods: Aim of this retrospective study from a prospective database was to analyze efficacy and safety of intrarectal formalin treatment for haemorrhagic CHRP at the Royal Marsden Hospital. Adult patients were enrolled between March 2018 and October 2021. Contraindications were presence of ulcers, fistulas and strictures. Haemoglobin was evaluated before the first and after the last formalin treatment. Antiplatelet, anticoagulation treatment and administration of transfusion (indication: haemorrhagic CHRP) were recorded. Interval between the completion of radiotherapy and first intrarectal formalin treatment was assessed; dose of radiotherapy was evaluated.

Clinical assessment of frequency and amount of rectal bleeding (rectal bleeding score) was adapted from classification used by Takemoto et al. (Ref 1). Endoscopic classification followed classification used by Chi et al. (Ref 2).

Intrarectal formalin treatment was performed by one operator in an outpatient setting, usually after full bowel preparation and without sedation and/or analgesia. Individual treatment sessions were 6-8 weeks apart. Complications were recorded.

Results: Nineteen patients were enrolled: 13 males (68%) and 6 women. All males received radiotherapy for prostate cancer, two females for endometrial, two for anal, one for cervical and one for rectal cancers. Mean age was 75±9 years.

After exclusion of one outlier, median time between completion of radiotherapy and the first formalin treatment was 20 months, inter-quartile range (IQR): 15. Median dose of radiotherapy was 68 Grey, IQR: 14. Median volume of formalin for a single treatment was 35ml, IQR: 10ml. Median duration of a single formalin treatment was 180s, IQR: 150-180s; (min.: 60s, max.: 180s).

Thirty two procedures were performed (1.7 procedure per patient). In total, 9/19 (47%) patients were receiving anticoagulation and/or antiplatelet medication. Five patients (5/19, 26%) received transfusion. Mean value of haemoglobin before the first treatment was 110±18g/l, after the last treatment 123±16g/l; $p=0.022$. Median of rectal bleeding score before the first treatment was 6 (IQR: 0), after the last treatment 2 (IQR: 1-4); $p<0.001$. Median of endoscopy score on the day of the first treatment was 3 (IQR: 0); on the day of the last treatment 1 (IQR: 1-2); $p<0.001$. Three patients developed ulcers. One patient with a healed ulcer developed a recto-vaginal fistula subsequently.

Conclusion: Treatment with intrarectal formalin in haemorrhagic CHRP is effective and safe.

Introduction: The diagnostic and therapeutic strategy in severe lower gastrointestinal bleeding (LGIB) varies depending on the patient's clinical situation. Actual clinical practice guidelines propose different management strategies.

Aims & Methods: We aim to know the attitude of the gastroenterologists from different hospitalary centers in the management of this entity. For this, we have made a descriptive and observational study using an on-line questionnaire addressed to gastroenterologists in Spain and Latin America in December 2021.

Results: We included 281 anonymous questionnaires of gastroenterologists, 223 associate doctors (79.4%) and 58 medical residents (20.6%), from Spanish hospitalary centers (171, 60.9%) and from 15 Latin American countries (110, 39.1%). Diagnostic and therapeutic management of severe LGIB was heterogeneous among the participants.

Regarding to the first diagnostic modalities they showed variability between performing computed tomography angiography (CTA) (44.5%), gastroscopy (33.1%), colonoscopy (20.6%) and arteriography (1.1%). The therapeutic attitude after a positive CTA varied between performing arteriography (38.1%), colonoscopy (44.1%) or rectosigmoidoscopy if the bleeding location was in left colon (12.8%).

If negative CTA, in the majority of cases a gastroscopy was performed. If the patient needed intensive critical unit (ICU) care and to undergo colonoscopy, most participants performed an urgent colonoscopy (<24 hours) (31% always, 43.4% in most cases); while if the patient did not require ICU admission this percentage was lower (10% always, 33.8% in most cases). Most of the participants (234, 83.3%) gave previous bowel preparation to patients undergoing colonoscopy in the first 8-12 hours.

For bowel preparation, 149 (53%) used polyethylene glycol, 37 (13.2%) sodium picosulfate, 4 (1.4%) enema and 74 of them (26.3%) depending on the case. A total of 115 participants admitted having doubts about the management of this patients. The need for thase creation of an action protocol was considered from 276 of the participants (98.2%) and 170 of them (60.5%) answered that they did not have any available at their center.

Conclusion: There is a high interhospitalary variability on the management of severe lower gastrointestinal bleeding among gastroenterologists and most of them have doubts about its management. It is necessary to create and spread an action protocol for diagnosis and treatment of this pathology.

Disclosure: Nothing to disclose.

HYDRAULIC LOCAL INFUSION OF EPINEPHRINE-CONTAINING SALINE IS EFFECTIVE IN PREVENTING POSTOPERATIVE BLEEDING IN COLD SNARE POLYPECTOMY UNDER ANTICOAGULATION THERAPY

M. Yasuda^{1,2}, Y. Naito²

¹Uji-Tokushukai Medical Center, Dept. of Gastroenterology and Hepatology, Uji City, Japan, ²Kyoto Pref University of Medicine Gastroenterology, Dept. of Gastroenterology, Kyoto, Japan

Contact E-Mail Address: koutoku7@fa2.so-net.ne.jp

Introduction: Cold snare polypectomy has been reported to be useful in the treatment of colorectal polyps in recent years, and has become popular worldwide. For HSP (Hot Snare Polypectomy) using radiofrequency devices, CSP is recognized as having a low risk of post-polypectomy bleeding and a low risk of post-polypectomy bleeding complications, which is a post-polypectomy syndrome, because CSP does not coagulate with heat, although bleeding occurs immediately after polyp removal. In recent years, however, due to the development of anticoagulants, antithrombotic agents such as NOAC and aspirin have been administered to a large number of patients for the purpose of preventing cardiovascular diseases, and in the case of colorectal polypectomy, antithrombotic agents have been administered in an increasing number of patients.

Therefore, it is necessary to pay attention to the prevention of bleeding after CSP. In general, physiological saline infusion using the Water Jet mechanism is used to prevent bleeding after CSP. We examined whether adding a small amount of epinephrine to the saline helps prevent postoperative bleeding.

Aims & Methods: From January 2018 to March 2019, 200 patients who underwent CSP with antithrombotic agents in our hospital were prospectively enrolled and randomly assigned to receive hydraulic local infusion of either normal saline (NS group) or epinephrine saline (ES group). The concentration of epinephrine was 0.1%, 2 ml/1A dissolved in 200 ml of physiological saline as a 100-fold dilution. In the NS group, saline was hydraulically injected to the polypectomy wound after CSP, and in the ES group, epinephrine-added saline was hydraulically injected to the polypectomy wound after CSP. The procedure of CSP and equipment such as snare were all the same. The post-CSP fluid infusion was terminated in both groups when the ablated surface bulged, and hemostasis was achieved using Olympus OFP-2 as a Water Jet pump device.

Postoperative bleeding events were defined as the occurrence of anal bleeding from the day following polypectomy. In the CSP, all cases were examined with magnifying endoscopy, and only those diagnosed as adenoma by the diagnosis of JNET TYPE 2A by the magnifying observation of NBI or BLI were examined.

Results: There were no significant differences in age, sex, polyp size, polyp shape, location, mean number of resected polyps, or polyp histology between the NS and ES groups. There was no difference in antithrombotic therapy between the two groups. However, there was a difference in the frequency of postoperative bleeding between the two groups. Postoperative bleeding occurred in 2/100 of patients in the NS group.

Postoperative bleeding occurred in 0/100 patients in the ES group. There was a significant difference in the incidence of postoperative bleeding events between the NS and ES groups.

Conclusion: Hydraulic local infusion of epinephrine-containing saline is effective in preventing postoperative bleeding in cold snare polypectomy under anticoagulation therapy.

Disclosure: Nothing to disclose.

Contact E-Mail Address: tauqeershek@live.com

Introduction: Colorectal cancer (CRC) is the third most common cancer worldwide. CRC death is largely preventable if detected early. Barriers and willingness for CRC screening are not studied previously in Pakistan.

Aims & Methods: To evaluate barriers to CRC screening in the Pakistani population aged > 40 years.

A cross-sectional, questionnaire-based study was conducted among the general population from all provinces of Pakistan. Data were analyzed by using IBM SPSS Statistics v27.

Results: It is an ongoing study where 4877 participants were included with a mean age of 46.05 ± 14.65 years. Out of these, 3365 (69%) were males. The results showed that 3822 (78.4%) participants were unaware of CRC disease. Furthermore, 3518 (72.1%) participants had no intention to get screened in the future.

The main barriers were, lack of knowledge/awareness of CRC screening test 70.5% (p<0.0001), cost and lack of government-funded screening program 84.4% (p<0.0001), shame of getting screened and absence of preferred gender doctor for colonoscopy 59.9% (p<0.0001).

Ineffectiveness of screening tests and doubt about the safety of colonoscopy 50.4% (p<0.0001), fear of getting abnormal results 57.6% (p<0.0001), and lack of doctor's recommendation for CRC screening 75.1% (p<0.000) was also found to be a significant barrier.

Conclusion: In our ongoing survey, we found multiple colorectal cancer screening barriers among the general Pakistani population. A majority of participants were unaware of CRC disease. An extensive government-led awareness campaign must be launched and doctors should discuss CRC screening with their patients. Moreover, the availability of preferred gender endoscopists must be ensured to increase compliance.

Disclosure: Nothing to disclose.

Contact E-Mail Address: Zohar.levi.gastroenterology@gmail.com

Introduction: Subjects from the low socioeconomic state (SES) and racial or ethnic minorities have lower colorectal cancer (CRC) screening rates worldwide due to educational gaps and disparity in health care resources. **Aims & Methods:** We aimed to compare the rate and trend of being updated with screening and colonoscopy completion rate after a positive fecal occult blood test (FOBT) before and during the COVID-19 pandemic among subjects with low SES and minorities compared with others.

This is a retrospective analysis of all insured subjects aged 50-75 years within the Clalit health services in 2019-2021. Up to date with screening was defined as having a colonoscopy within ten years or an FOBT within one year; colonoscopy completion rate was defined as having a colonoscopy within six months of a positive FOBT.

Results: In 2019, out of 918,135 subjects, a total of 61.3% were up to date with screening; 65.9% for high-SES (referent), 60.1% for medium-SES [Odds Ratio (OR) 0.81, 95%CI 0.80-0.82] and 59.0% for low-SES (OR 0.75, 95%CI 0.74-0.75); 61.9% for Jews (referent), 59.7% for Arabs (OR 0.91, 95%CI 0.90-0.92), and 51.7% for Ultraorthodox Jews (OR 0.77, 95%CI 0.75-0.78). Out of 21,308 with a positive FOBT, the colonoscopy completion rate was 51.8%; 59.8% for high-SES (referent), 54.1% for medium-SES (OR 0.79, 95%CI, 0.73-0.86), and 45.5% for low-SES (OR 0.60, 95%CI 0.56-0.65); 54.7% for Jews (referent), 51.4% for Ultraorthodox Jews (OR 0.91, 95%CI 0.90-0.92) and 44.7% for Arabs (OR 0.77, 95%CI 0.75-0.78).

In 2020-2021 there was a slight drop in the rate of being up to date with screening (up to Δ -1.8%) and the colonoscopy completion rate (up to Δ -1.3%), while the of the discrepancies were kept or slightly increased with time (Δ SES 7.9% vs. 6.9% for being up to date with screening; 14.0% vs. 12.5% for colonoscopy completion rate; Jews-Ultraorthodox Jews: Δ 8.4% vs. 6.5% for being up to date with screening; Δ 7.6% vs. 3.3% for colonoscopy completion rate; Δ Jews-Arabs 4.2% vs. 2.2% for being up to date with screening; 10.9% vs. 10.0% for colonoscopy completion rate), P for interaction with time <0.001 for most measures.

Conclusion: In this population-based study, we report that in 2019, about 61% of the target population were up to date with screening, and the colonoscopy completion rate was 52%, with significant socioeconomic and ethnic disparities.

In 2020-2021 there was only a slight drop in both screening measures, while the disparities were kept or slightly increased. These findings should direct health policymakers to build specific programs to improve the screening measures for subjects from low SES and ethnic minorities.

Disclosure: Nothing to disclose.

IMPACT OF THE COVID-19 PANDEMIC ON THE COLORECTAL CANCER SCREENING PROCEDURES IN THE CZECH REPUBLIC

S. Suchanek^{1,2}, T. Grega^{1,2}, K. Hejzmanova^{3,4}, O. Ngo^{3,4}, O. Májek^{3,4}, M. Zavoral^{1,2}

¹Military University Hospital, Department of Medicine, Prague, Czech Republic, ²Military University Hospital, Department of Gastrointestinal Oncology, Prague, Czech Republic, ³Faculty of Medicine, Masaryk University, Institute of Biostatistics and Analyses, Brno, Czech Republic, ⁴Institute of Health Information and Statistics of the Czech Republic, Prague, Czech Republic

Contact E-Mail Address: stepan.suchanek@uvn.cz

Introduction: The organized, population-based National Colorectal Cancer (CRC) Screening Program in the Czech Republic is focused on asymptomatic individuals. Since age 50, the immunochemical fecal occult blood test (FIT) is offered annually at age 50 – 54 and biennially at age ≥ 55 , followed by FIT+ colonoscopy, if positive. As an alternative, there is a choice of screening colonoscopy from age 50, in 10 years interval.

Aims & Methods: Evaluation of FITs and screening colonoscopies performed in the years 2021 (data from January to September) and 2020 (all year), both compared to the same period in the year 2019. The analysis was performed using the database of the National Registry of Reimbursed Health Services in the Czech Republic.

Results: Comparing years 2020 and 2019, there was decrease of the FITs (-16.9 %) with maximum in April (-75.6 %) and screening colonoscopies (-12.0 %), maximum in April (-58.1 %). In comparison between the years 2021 and 2019, the numbers of FITs have dropped by 4.1 % (maximum in January, -20,6 %) and the number of screening colonoscopies has risen by 3.1%.

Despite the decrease of FITs and screening colonoscopies in the year 2020, the number of FIT-positive colonoscopies has risen (from 22.137 to 27.234 procedures), and 1.797 adenomas and 49 colorectal cancers were diagnosed more compared to the year 2019. This phenomenon was caused by the increase of the FIT positivity from 6.8% in the year 2019 to 10.1% in the year 2020.

Conclusion: Despite the reduction of FIT and screening colonoscopies during the COVID-19 pandemic up to now, the number of colorectal adenomas and cancers have risen in the year 2020 thank to the increase in FIT positivity and therefore the number of FIT-positive colonoscopies performed.

SERINE, AN AMINO-ACID INVOLVED IN PRO-CARCINOGENIC EFFECTS OF COLIBACTIN-PRODUCING *ESCHERICHIA COLI* IN THE COLON

A. Devaux¹, R. Villéger¹, B. Diémé², M. Lagrée², M. Rodrigues¹, G. Roche¹, N. Barnich¹, C. Jousse², M. Bonnet¹

¹Université Clermont Auvergne, M2iSH Microbes, Intestin, Inflammation & Host Susceptibility, Clermont-Ferrand, France, ²Université Clermont Auvergne / INRAé, Plateforme d'Exploration du Métabolisme MetaboHUB, Clermont-Ferrand, France

Contact E-Mail Address: amandine.devaux@uca.fr

Introduction: The colonic tissues are abnormally colonized by colibactin-producing *Escherichia coli* (CoPEC) in colorectal cancer (CRC) patients. Colibactin is a genotoxin produced by enzymes encoded by the *pks* genomic island. The pro-carcinogenic effects of CoPEC and colibactin have

been demonstrated using various animal models. Metabolomic studies have shown that CoPEC infection results in reprogramming of intestinal epithelial cell metabolism, leading to a decrease of serine concentration (intracellular and extracellular levels).

The aim of this study is to investigate whether serine allows CoPEC to better persist in the gastrointestinal tract and/or exert their pro-carcinogenic functions.

Aims & Methods: Human colorectal carcinoma T84 cells were infected with a reference CoPEC strain (11G5) isolated from a human CRC sample, its colibactin-negative mutant (11G5- Δ pks) or a commensal strain of *Escherichia coli* (K12C600). Expression of genes coding for the serine utilization and biosynthesis operon was evaluated by RT-qPCR 3h following infection. The impact of a serine- and glycine- depleted diet (SD) on the persistence and genotoxic effects (γ H2Ax immunolabeling) of CoPEC was studied using wild-type animals and APC^{min/+} mouse model of CRC.

Results: Three hours post-infection, we have shown *in vitro* that the CoPEC 11G5 strain uses serine from the enterocyte, via activation of serine-utilization-genes, which provides to CoPEC a competitive growth advantage over a commensal strain or its mutant (11G5- Δ pks). To highlight the specific role of serine on CoPEC colonization and genotoxic effect, APC^{min/+} mice were fed with a SD diet.

As control, we measured a decrease of the serine level in the serum by liquid chromatography–mass spectrometry in SD diet mice compared to control diet mice. SD diet induced an early and transient decrease in CoPEC 11G5 bacterial colonization associated with a decrease of its genotoxic properties, and lower DNA damages induced by infection. Experiments are in progress with the 11G5- Δ tdcA mutant, unable to metabolize serine, to validate the impact of serine utilization on CoPEC virulence.

Conclusion: Altogether, the present study demonstrates that serine could be a metabolite of interest, used by CoPEC to colonize the digestive tract and to exert its genotoxic properties. This work allows us to elucidate the mechanisms of action of CoPEC in colonic carcinogenesis and could identify novel therapeutic targets.

SLC26A9 PROMOTES COLORECTAL TUMORIGENESIS VIA WNT/ β -CATENIN SIGNALING

M. Zhang¹, Z. Ma¹, B. Tuo¹, T. Li², X. Liu¹

¹Department of Gastroenterology, Affiliated Hospital of Zunyi Medical University, Zunyi, China, ²Department of General Surgery, Affiliated Hospital of Zunyi Medical University, Zunyi, China

Contact E-Mail Address: anhuimazhiyuan@163.com

Introduction: Colorectal cancer (CRC) is a common malignant tumor and a major health threat worldwide. SLC26A9 (solute carrier family 26 member 9) is a member of SLC26A family of multifunctional anion transporters, which functions as Cl⁻ channel.¹

Our previous study showed that SLC26A9 deficiency results in gastric tumorigenesis in mice, which demonstrated that its role in the carcinogenesis for the first time.² However, what's the role of SLC26A9 in the CRC onset is not clear and never reported.

Aims & Methods: We utilized a large patient cohort and mouse models of CRC as well as CRC cells to determine the role of SLC26A9 and associated mechanism in CRC.

Results: SLC26A9 was expressed low levels in the cytoplasm of normal colorectal epithelium, polyps and adenomas, but significantly increased in the colorectal adenocarcinoma and translocated to the nucleus. Moreover, increased levels of SLC26A9 associated with high-risk of the disease and poor prognosis.

Compared with normal colon cell line (NCM460), SLC26A9 was significantly upregulated in the all CRC cell lines, with highest expression in cell line COLO201, but the lowest expression in cell line SW48. The shRNA silencing of SLC26A9 expression in COLO201 induced cell cycle arrest and apoptosis, but inhibited cell proliferation and xenograft-tumor growth both *in vitro* and *in vivo*.

Mechanistic analysis revealed showed that SLC26A9 was co-localized with β -catenin in the nucleus of CRC, translocation of these two proteins from cytoplasm to the nucleus reflected the activation of WNT signaling, the key signaling pathway implicated in colorectal carcinogenesis, and promoted the transcription of downstream target proteins including C-myc/pC-myc, CyclinD1, snail, BCL2 and BAX expressions, but inhibited expression of cytochrome C (Cyt-C), Caspase9, Caspase3, apoptosis-inducing factor (AIF) and endonuclease G (Endo G), indicating that the suppression of caspase dependent and independent apoptosis.

Accompanying with alteration of epithelial mesenchymal transition (EMT) markers, including downregulation of E-cadherin, but increasement of N-cadherin, as well as EMT induced cancer stem cell (CSC) phenotypes including upregulation of CD44, CD133, Lgr5, OCT4 and Nanog.

Conclusion: Upregulation and translocation of SLC26A9 to the nucleus reflected the activation of WNT/ β -catenin signaling pathway, resulted in the development and progression of CRC. SLC26A9 might be a novel candidate oncogene of CRC.

TRIGLYCERIDE GLUCOSE INDEX (TYG INDEX) AND RISK OF COLORECTAL ADENOMATOUS POLYPS

D.S. Kim¹, K.-C. Huh¹, H.S. Koo¹

¹Konyang University College of Medicine, Gastroenterology and Hepatology, Daejeon, Korea (Republic of)

Contact E-Mail Address: hornkim0404@gmail.com

Introduction: Insulin resistance is associated with the risk of colorectal adenomatous polyp. Insulin resistance has been constantly associated with high triglyceride. Triglyceride glucose index (TyG index) is a useful indicator of insulin resistance. We investigated the association of TyG index with the risk of colorectal adenomatous polyps.

Aims & Methods: This study was performed on 163 subjects who underwent colonoscopy at university hospital from March to December 2021. TyG index was calculated as formula: $\ln$ [fasting triglycerides (mg/dL) $\times$ fasting plasma glucose (mg/dL)/2]. Variables were investigated using chi-squared test, t-test and Mann-Whitney U test, as appropriate. Logistic regression model was used to investigate the relationship between the risk of colorectal adenomatous polyp and TyG index.

Results: The mean of fasting glucose, fasting triglyceride, and TyG index were all significantly higher in the group with colorectal adenomatous polyps ($p < 0.01$; $p = 0.012$; $p = 0.002$, respectively). Logistic regression analysis showed that fasting triglyceride (TG) [adjusted odds ratio (OR), 1.005; 95% Confidence interval (CI), 1.001–1.009; $p = 0.028$] and TyG index [adjusted odds ratio (OR), 2.049; 95% Confidence interval (CI), 1.121–3.745; $p = 0.020$] were positively associated with an adenomatous polyp detection. The subjects were divided into four groups according to the quartile of each parameter, and the adjusted odds ratios for the 4th quartile group of fasting TG and TyG index were statistically significant.

		Adjusted OR (95% CI)*	P
Fasting TG (mg/dl)	Q1 (38–70)	1	
	Q2 (71–103)	1.231 (0.415–3.654)	0.707
	Q3 (104–166)	1.358 (0.467–3.951)	0.575
	Q4 (167–548)	3.055 (1.064–8.771)	0.038
TyG index	Q1 (7.37–8.14)	1	
	Q2 (8.15–8.62)	1.810 (0.603–5.430)	0.290
	Q3 (8.63–9.08)	1.777 (0.590–5.358)	0.307
	Q4 (9.09–10.44)	3.465 (1.167–10.287)	0.025

* adjusted for age and sex

Table. The risk for colorectal adenoma by quartiles of parameters of insulin resistance

Conclusion: TyG index may predict the presence of colorectal adenomatous polyps, which is particularly pronounced in the group with a high TyG index. Therefore, screening colonoscopy should be recommended for people with a high TyG index. In addition, further studies are needed to establish an appropriate cut-off value.

COLORECTAL CANCER IN PATIENTS WITH SERRATED POLYPOSIS SYNDROME: THE CONTRIBUTION OF THE ADENOMA CARCINOMA PATHWAY

J. Ijspeert¹, D. van Toledo¹, H. Boersma¹, A. Bleijenberg¹, A. Musler², E. Dekker¹, C. van Noesel²

Introduction: Patients with serrated polyposis syndrome (SPS) have an increased risk to develop colorectal cancer (CRC). Because of the large numbers of serrated polyps (SPs) in these patients, CRC is assumed to arise mainly through the serrated neoplasia pathway rather than the adenoma-carcinoma pathway. SPS patients, however, also harbour significant num-

bers of adenomas, and about half of all CRCs occur in the distal colon, the preferential location of adenomas. This suggests that adenomas may also play a role in CRC development in these patients. We aimed to study the contribution of the adenoma-carcinoma pathway to CRC development in SPS patients.

Aims & Methods: We collected a cohort of SPS patients with CRCs at our expertise center. Data regarding polyps and CRCs were retrieved from endoscopy and pathology reports. All CRCs were immunohistochemically stained for expression of MLH1, BRAF^{V600E} and p53. CRCs were divided into ‘serrated-CRC’ and ‘adenoma-CRC’ based on the presence or absence of BRAF^{V600E} expression. CRC characteristics (location, MLH1 expression) were compared between serrated-CRCs and adenoma-CRCs. The proximal colon was defined as proximal from the descending colon.

Primary outcome measure was the proportion of serrated-CRC vs. adenoma-CRC. Statistical comparison between serrated-CRC and adenoma-CRC was performed with Chi-square statistics for categorical variables and Mann-Whitney U statistics for continuous variables.

Results: A total of 43 CRCs from 35 SPS patients were included in the study. Patients had a median age at time of diagnosis of 63 years (IQR, 59–69) and 68.6% (24/35) were female. Twenty-one (49%) CRCs were serrated-CRCs and 22 (51%) were adenoma-CRCs. Loss of MLH1 expression was observed in 10 (48%) serrated-CRCs and in none of adenoma-CRCs. In total, 17 (81%) serrated-CRCs and 5 (23%) adenoma-CRCs were located in the proximal colon (p<0.001).

	Total	Serrated-CRC	Adenoma-CRC	p-value
Total cohort size; n (%)	43 (100)	21 (49)	22 (51)	
CRC location; n (%)				<0.001
Proximal	22 (51)	17 (81)	5 (23)	
Distal	21 (49)	4 (19)	17 (77)	
Loss of MLH1 expression; n (%)	10 (23)	10 (48)	0	<0.001

Table 1: Colorectal cancer characteristics comparing serrated-CRCs and adenoma-CRCs.

Conclusion: Although SPS patients have an abundance of serrated polyps, still half of their CRCs evolve via the non-serrated pathway, i.e. from conventional adenomas. This finding is important in understanding carcinogenesis in SPS patients and underlines the clinical importance of conventional adenomas in these patients.

Introduction: Improving clinical management of early-stage colorectal cancers (T1CRCs) requires a better understanding of their underlying biology. Accumulating evidence shows that cancer-associated fibroblasts (CAFs) are important determinants of tumour biology in advanced colorectal cancer (CRC), but their role in early stages of CRC tumorigenesis is unknown.

Aims & Methods: The aim of our study was to characterize CAFs in T1CRCs (T1CAFs) and to investigate their role in early cancer progression. Primary T1CAFs and patient-matched normal fibroblasts (NFs) were isolated from endoscopic biopsies of histologically confirmed T1CRCs and normal mucosa, respectively. The impact of T1CAFs and NFs on tumour behaviour was studied using 3D co-culture systems with primary T1CRC organoids and extracellular matrix (ECM) remodelling assays. Whole transcriptome sequencing and gene silencing were used to pinpoint mediators of T1CAF functions.

Results: In 3D co-cultures, matrix invasion of T1CRC organoids was induced by T1CAFs, but not by NFs. T1CAFs also exhibited enhanced ECM remodelling capacity as compared to NFs. RNA sequencing of 10 NF-T1CAF pairs revealed 404 differentially expressed genes, with significant enrichment for ECM-related pathways in T1CAFs. Cathepsin H, a cysteine-type protease that was specifically upregulated in T1CAFs but not in tumour fibroblasts from pre-malignant or advanced CRC stages, was identified as a key factor driving matrix remodelling by T1CAFs. Finally, we validated the relative abundance of Cathepsin H-expressing T1CAFs on primary T1CRC tissue sections, highlighting the translational potential of our findings.

Conclusion: Already in early CRC stages, tumour progression is importantly determined by CAFs via direct interactions with tumour cells and stage-specific, Cathepsin H-dependent matrix remodelling.

Introduction: Wnt signaling and the p53 signaling pathway play key roles in carcinogenesis of colorectal cancer (CRC). Truncations and inactivating mutations of the APC gene, a negative regulator of Wnt/ β -catenin signaling, as well as mutations in the tumor suppressor gene TP53 can be observed in the majority of CRCs. In CRC, p53 has been shown to induce Wnt3

transcription and thereby activate Wnt/ β -catenin signaling. Thus, we hypothesized that the p53 and the Wnt signaling pathways interact in CRC. To this end, we developed an innovative method to further investigate the crosstalk between these central pathways for cancer initiation, progression, and drug resistance.

Aims & Methods: To gain insight into CRC biology and facilitate further study of this cancer, we established a CRISPR-Cas9 ribonucleoprotein (RNP) based genome editing tool for arrayed phenotypic screening as well as a fluorophore-based reporter system to monitor transcriptional pathway activity.

Utilizing RNPs for genome editing and mutating specific target genes in an arrayed screening approach allows for faster and more precise editing when compared with traditional plasmid-based methods or lentiviral transduction. In addition, there are less off-target effects. We employed single guide RNA (sgRNA) generated by *in vitro* transcription. In our screening approach, we used two different sgRNAs for each target gene to achieve a high editing efficiency while also limiting cellular toxicity caused by DNA cleavage.

As a readout, we developed a fluorophore-based reporter system coupled to DNA transcription factor binding sites of p53 and Transcription Factor 7 Like 2 (TCF7L2), a downstream transcription factor in the Wnt/ β -catenin signaling pathway. Experiments were conducted in HCT116 cells. After cell fixation and staining of nucleus and cell body, we used fluorescence microscopy images for cell segmentation *in silico*. This allowed us to then analyze transcriptional activity in p53 and Wnt/ β -catenin signaling as well as cell morphology on a single cell basis.

Results: We succeeded in establishing an easy-to-scale 384-well CRISPR/Cas9 transfection platform to generate high-efficiency gene knockouts (KO). Depending on the individual sgRNA used, we were able to achieve a genome editing efficiency of 40-60% 48 hours after transfection without the need for cytostatic selection. This is a major advantage in comparison with established plasmid-based editing methods that require cytostatic selection.

As a proof of concept, we were able to show that our specifically designed reporter system has a high sensitivity for changes in transcriptional activity for both pathways using pharmacological treatments with Chiron, a GSK3 inhibitor that activates Wnt/ β -catenin signaling and Nutlin3a, a MDM2 inhibitor that increases p53 signaling. Combining this readout with our high-efficiency KOs, we demonstrated upregulation of Wnt signaling after KO of APC, as well as GSK3. We are currently extending this approach to CRC organoids.

Conclusion: Here we report an innovative arrayed CRISPR-Cas9 RNP screening method and its application in CRC that allows to investigate p53 and Wnt/ β -catenin signaling activity. This approach is easily scalable to any other cancer gene or signaling pathway of interest. Our method is particularly valuable for screening for pathway activation/deactivation after gene KO in CRC. Furthermore, it can be applied for genetic interaction screening and drug sensitivity screening.

Introduction: Fecal Occult Blood Test (FOBT) is the first line test in organized Colorectal Cancer screening settings in several countries. Adenoma miss rate is still a concerning issue during colonoscopy, related to an increased risk of interval colorectal cancer. Artificial Intelligence (AI) is a technology potentially able to improve diagnostic performance of colonoscopy and to reduce inter- and intra-operator variability.

Aims & Methods: The aim of this study was to compare the diagnostic yield of AI-assisted colonoscopy with that of standard colonoscopy (SC). This is a single-center RCT evaluating consecutive patients undergoing colonoscopy in a FOBT based organized screening population program. Patients were randomly assigned to SC or AI. Subjects with < 6 score at Boston Bowel Preparation Scale were excluded from analysis.

Polyp Detection Rate (PDR), Adenoma Detection Rate (ADR), Serrated Detection Rate (SDR), patients with advanced adenomas (i.e. villous histology, high-grade dysplasia or low-grade dysplasia > 1cm) and patients with at least 3 precancerous lesions were compared between the groups using χ^2 -test. At two-tailed test, $P < 0.05$ was considered statistically significant.

Results: Data about 464 patients were collected, of whom 231 were assigned to AI, while 233 to SC arm. Due to inadequate bowel cleansing, 22 patients (10 AI and 12 SC group) were excluded. PDR and ADR were both significantly higher in the AI group compared to SC group (respectively 81.9% [181/221] vs 71.5% [158/221]; $p = 0.01$ and 69.2% [153/221] vs 60.2% [133/221]; $p = 0.04$).

Patients with advanced adenomas and with at least 3 precancerous lesions were increased in the AI group (respectively 25.3% [56/221] vs 24.4% [54/221]; $p = 0.82$ and 30.8% [68/221] vs 22.6% [50/221]; $p = 0.05$). SDR was slightly increased in the SC arm (14.9% [33/221] vs 16.2% [36/221]; $p = 0.69$).

	AI	SC	p-value
ADR	81.9% [181/221]	71.5% [158/221]	0.01
PDR	69.2% [153/221]	60.2% [133/221]	0.04
SDR	14.9% [33/221]	16.2% [36/221]	0.69
ADVANCED ADENOMAS	25.3% [56/221]	24.4% [54/221]	0.82
≥ 3 ADENOMAS	30.8% [68/221]	22.6% [50/221]	0.05

Conclusion: AI improves ADR and PDR in a screening FOBT based setting. The impact of a AI supported colonoscopy in surveillance intervals needs to be further evaluated.

Disclosure: Nothing to disclose.

Contact E-Mail Address: y_takashina2011@yahoo.co.jp

Introduction: The risk of lymph node metastasis in T1 colorectal cancer is known to be about 10%, and preoperative prediction is essential for determining a treatment strategy. Several histopathological values and scoring systems for predicting lymph node metastasis have been reported. However, interobserver variability for histologic diagnosis remains a major problem. Therefore, we developed a novel artificial intelligence (AI) system using whole-slide images (WSI) to predict lymph node metastasis in T1 colorectal cancer.

Aims & Methods: A retrospective single-center study was conducted analyzing 714 colorectal lesions resected from April 2001 to August 2021. Hematoxylin and eosin stained, formalin fixed, all slide images scanned by NanoZoomer (Hamamatsu Photonics, Japan) were collected for analysis. 614 of these slides were used for training the AI system and 100 (T1 cancer) for validation, which were consecutive cases from January 2019. A deep convolutional neural network was used, and in addition to the slide images, the gender and age of the patient and the tumor location were added as factors. Surgical specimens were used as the gold standard for the presence of lymph node metastases, and the area under the receiver operating characteristic curve (AUC) was calculated for the AI system's performance in identifying patients with lymph node metastases.

Results: A total of 714 colorectal lesions (adenoma: 150 lesions, lymph node positive T1: 60 lesions, lymph node negative T1: 124 lesions, lymph node positive T2: 140 lesions, lymph node negative T2: 140 lesions) were included for study. Of the lesions excluding adenomas, 242 were male and 48 had lesions located in the rectum. The median age was 65.4±11.6 years, and the median number of lymph nodes removed was 18.7±12.5. A total of 100 T1 colorectal cancers were used for validation, and the percentage of lymph node metastases was 15%. The AUCs for the AI system and guidelines in the test cases were 0.68 (95% confidence interval, 0.53-0.88) and 0.52 (95% confidence interval, 0.50 - 0.55), respectively. With a sensitivity of 100%, the specificity was 21.2%.

Conclusion: It is suggested that a lymph node metastasis prediction system based on AI analysis using WSI may contribute to the decision for additional surgical resection after endoscopic treatment of T1 colorectal cancer.

Disclosure: Nothing to disclose.

Contact E-Mail Address: haorancheng@gmail.com

Introduction: Colorectal cancer (CRC) is the third most common cancer worldwide and poses an important healthcare issue with significant morbidity, mortality, and economic impact.¹

CRC can be prevented if precursor lesions are identified and removed endoscopically.² National bowel cancer screening programs have been implemented which significantly reduced CRC related morbidity and mortality.³

These programs often use the fecal immunochemical test (FIT) and when tested positive subsequent colonoscopy. However, FIT suffers from a high number of false positives resulting in many unnecessary colonoscopies (*i.e.* no colorectal neoplasia detected) and is insensitive for detecting clinically relevant advanced adenomas (AA).⁴

Therefore, more accurate, non-invasive screening tools are needed.

Aims & Methods: In this multicenter prospective study, the utility of analyzing volatile organic compounds (VOC) in exhaled breath in a FIT positive population to detect the presence of colorectal neoplasia was studied. Breath samples were collected from FIT positive patients with subsequent colonoscopy participating in the national Dutch bowel screening program. Breath sampling was performed prior to colonoscopy.

One room was assigned for breath collection in each study center. Subjects were asked to inflate a 3 L Tedlar bag and its contents were transferred onto carbon-filled stainless-steel desorption tubes. Exhaled VOCs were analyzed using Thermal Desorption - Gas Chromatography - Mass Spectrometry (TD-GC-MS) and the data was pre-processed and analyzed using machine-learning techniques. Three predictive models were created: CRC vs. controls, AA vs. controls, and non-AA vs. AA vs. controls.

Results: 382 FIT positive subjects (n=84 negative controls, n=130 non-AA, n=138 AA, and n=30 CRC) with breath, colonoscopy, and histopathology data were included between July 2016 and January 2018. Using ten discriminatory VOCs AA could be distinguished from negative controls with a sensitivity and specificity of 79% and 70%, respectively.

The discrimination of CRC from negative controls yielded a sensitivity and specificity of 67% and 70%, respectively. CRC sample size was insufficient for biomarker selection. Using the five most important VOCs from the AA vs. controls model, CRC and CRC/AA combined could be discriminated from controls with sensitivities of 80% and 70%, respectively, and a specificity of 70% (see Table 1). Lastly, the feasibility to discriminate non-AA from controls as well as AA was assessed (data not shown).

Group	Sensitivity	Specificity	AUC	Biomarkers
CRC vs. controls	67%	70%	0.73	N/A
AA vs. controls	79%	70%	0.79	10 VOCs
- CRC vs. controls	80%	70%	0.76	5 VOCs*
- CRC and AA vs. controls	77%	70%	0.75	5 VOCs*

* Five most important VOCs from AA vs. controls model.

Table 1: sensitivity, specificity, and AUC ROC of analyzed groups.

CRC: colorectal cancer, AA: advanced adenoma, AUC: area under the curve, VOC: volatile organic compound

Conclusion: In this proof of principle study, VOCs in exhaled breath can detect the presence of CRC and AA in a CRC screening population. Breath based analysis could be used in combination with FIT or as a standalone screening test and may improve CRC screening in the future.

LOWER HEALTHCARE COSTS ASSOCIATED WITH COLORECTAL CANCER TREATMENT FOLLOWING SCREEN DETECTION

J. Dressler¹, L. Sopina², M. Rasmussen¹, L. Nannestad Jørgensen¹

¹Bispebjerg Hospital, Digestive Disease Center, København NV, Denmark, ²University of Southern Denmark, Danish Center for Health Economics, Odense, Denmark

Contact E-Mail Address: jannie.dressler@regionh.dk

Introduction: Colorectal cancer (CRC) is the 3rd most common type of malignancy. With an approximate 1 million deaths in 2020, CRC is a major burden for public health care systems.⁽¹⁾ In 2014 a national colorectal cancer screening (CRCS) program was implemented in Denmark. Although the implementation and operation of a CRCS program is costly, little is known about its potential financial benefits.

Aims & Methods: This retrospective cohort study based on national databases aimed to evaluate the differences in total healthcare costs between patients with screen-detected colorectal cancer (SD-CRC) and non-screen-detected colorectal cancer (NSD-CRC). The SD-CRC group was defined as patients receiving a CRC diagnosis within 6 months of participating in

CRCS from 2014 to 2018. The NSD-CRC group included patients receiving a CRC diagnosis after non-participation in the CRCS or not attending the follow-up colonoscopy after a positive screening test. All patients with post-colonoscopy- and interval cancers were excluded to avoid length bias. For each group mean quarterly costs were calculated from two years before until two years after the date of diagnosis. Hereafter, we estimated the differences in healthcare costs, using a quasi-experimental difference-in-difference analysis.

Results: Healthcare costs were primarily driven by hospital costs. During the two years before receiving their diagnosis, the mean healthcare costs for the SD-CRC and the NSD-CRC groups were not statistically different. In the two years following the CRC diagnosis, the mean healthcare costs in each quarter were significantly higher in the NSD-CRC group.

Conclusion: This study suggests that NSD-CRC is more costly to treat and surveille than SD-CRC. Funds should be redirected to improve recruitment to CRCS – thus enhancing treatment and prognosis for patients with CRC.

Introduction: Colorectal cancer (CRC) is a major healthcare problem all over the world and screening is effective in reducing mortality and increasing survival.

Since colonoscopy has a central role in faecal immunochemical test (FIT)-based CRC screening and surveillance, consistent quality measures are es-

sential to ensure quality and outcomes. Nevertheless, screening modalities in clinical practice may differ according to the centers experience and the local availability of instrumentation and devices.

Aims & Methods: To assess the quality of endoscopic screening for CRC and adherence to international guidelines across Gastroenterology Departments in Italy.

All members of the Italian Society of Gastroenterology (SIGE) were invited to answer a web-based survey.

Results: Data from 64 hospitals from 17 Italian regions were analyzed. Overall, 32/64 (50.0%) were from northern, 12/64 (18.75%) from central and 20/64 (31.25%) from southern Italy. Half of the centers (57.8%) were non-academic public hospitals, while the others were academic (29.7%) or private hospitals (12.5%).

Surveyed centers perform a median of 4600 (IQR 2500-7750) endoscopic examinations per year and a median of 600 (IQR 300-1000) screening colonoscopies per year.

Each center is equipped with a median of 5.0 (IQR 3.5-7.0) endoscopists involved in CRC screening, 71.4% of which are gastroenterologists.

After a positive FIT, most centers (93.8%) schedule a colonoscopy within 3 months. High-definition video endoscopy is routinely performed in 68.8% and chromoendoscopy in 53.1% of centers. Withdrawal time is ≥ 6 minutes in 79.9% and cecal intubation rate is $\geq 90\%$ in 94.4% of departments.

Moreover, in 92.7% of centers adenoma detection rate (ADR) overcome the minimum standard of 25%. Analyzing the data by regional areas, a significant higher number of median endoscopic examinations/year (6500 vs 4000 and 3000 respectively, $p=0.024$) and of endoscopists per center (6.5 vs 5.0 and 3.5 respectively, $p<0.001$) has been registered in the northern compared to central-southern centers.

Finally, in most of the surveyed centers (62.5%), a program aimed at training young endoscopists to perform quality screening for CRC is absent.

Conclusion: Data from this survey show adequacy and good quality of endoscopic screening for CRC in Italy, highlighting, at the same time, relevant deficiencies and a discrepancy in procedural attitudes between the different centers.

These findings call for urgent action to overcome the shortcomings, refine and homogenize the behaviour of all screening centers in the national territory and improve the outcomes.

CHANGE IN COLONOSCOPY RECEIVING RATE FOR POSITIVE FECAL IMMUNOCHEMICAL TEST AND A DELAY OF COLORECTAL CANCER DETECTION UNDER THE COVID-19 PANDEMIC

F. Ishibashi¹, S. Suzuki¹, D. Shida², M. Nagai¹, K. Mochida¹, T. Morishita¹

¹International University of Health and Welfare Ichikawa Hospital, Department of Gastroenterology, Chiba, Japan, ²Institute of Medical Science, University of Tokyo, Division of Frontier Surgery, Tokyo, Japan

Contact E-Mail Address: f.jazzmaster@gmail.com

Introduction: There is concern that the COVID-19 pandemic may cause people to refrain from undergoing examination resulting in delayed detection of colorectal cancer (CRC).

Aims & Methods: The purpose of this study was to investigate whether there was a delay in CRC detection due to withholding of screening. As a longitudinal cohort study, we selected cases who underwent fecal immunochemical test (FIT) (twofold method) as a cancer screening program supported by Tama District administration in Japan every year from 2019 to 2021.

Among recipients of initial screening by FIT, changes over time in the receiving rate of colonoscopy under scrutiny for positive FIT recipients and the detection rate of CRC. Furthermore, the stages of CRC cases detected as a result of positive FIT in each year were compared.

Results: A total of 30,172 patients were initially screened by FIT over a 3-year period. The number (rate) of FIT positives was 420 (4.6%) in 2019, 453 (4.9%) in 2020, and 504 (4.3%) in 2021, with no difference, but the number (rate) of colonoscopy secondary scrutiny visits was 160 (38.1%) in 2019, 117 (25.8%) in 2020, and 286 (56.7%) in 2021 with a decrease in 2020 and an increase in 2021. The number (rate) of CRC detected among colonoscopy recipients was 7 (4.4%) in 2019, 6 (5.1%) in 2020, and 23 (8.0%) in 2021. The advanced adenoma detection rate increased from 11.1% in 2020 to 15.7% in 2021. Stage 1 or higher accounted for 42.9% (3/7) of CRCs detected in 2019, 50.0% (3/6) in 2020, and 69.6% (16/23) in 2021. Among the CRC cases detected each year, 1 (14.3%), 1 (16.7%), and 10 (43.5%) did not undergo colonoscopy despite positive FIT results in the previous year.

Year	2019	2020	2021
Patients who received FITs	9,156	9,255	11,760
Patients with positive FITs (%)	420 (4.6%)	453 (4.9%)	504 (4.3%)
Patients who underwent colonoscopy (%)	160 (38.1%)	117 (25.8%)	286 (56.7%)
Colorectal cancers detected (%)	7 (4.4%)	6 (5.1%)	23 (8.0%)
Stage 0	4	3	7
Stage 1,2	2	2	10
Stage 3,4	1	1	6
Advanced adenomas detected (%)	21 (13.1%)	13 (11.1%)	45 (15.7%)

Conclusion: In 2020 under COVID-19 pandemic, the colonoscopy receiving rate for FIT-positive recipients decreased, but in 2021, the colonoscopy receiving rate and the number of CRC found increased perhaps with the lifting of behavioral restrictions by COVID-19 pandemic. Many of the CRC cases detected in 2021 were stage 1 or higher, suggesting a delay in diagnosis due to the previous year's refraining from examinations. One of the challenges of FIT-based CRC screening is that under conditions such as the COVID-19 pandemic, behavioral changes in recipients are likely to result in changes in the inspection rate, even if the receiving rate of primary screening by FIT remains unchanged. As a result, the accuracy of the cancer screening may decline.

Disclosure: Nothing to disclose.

ROUTINE IMMUNOHISTOCHEMICAL ANALYSIS OF MISMATCH REPAIR PROTEINS IN COLORECTAL CANCER - A PROSPECTIVE ANALYSIS

J. Lemos Garcia¹, I. Rosa², S. Saraiva¹, I. Marques¹, R. Fonseca³, P. Lage², I. Claro²

¹Instituto Português de Oncologia de Lisboa Francisco Gentil, Gastroenterology, Lisboa, Portugal, ²Instituto Português de Oncologia de Lisboa Francisco Gentil, Gastroenterology, Familiar Cancer Clinic, Lisboa, Portugal, ³Instituto Português de Oncologia de Lisboa Francisco Gentil, Pathology, Lisbon, Portugal

Contact E-Mail Address: joanalemosgarcia@gmail.com

Introduction: Colorectal cancer (CRC) is the third most common cancer type. Recognition of an hereditary CRC syndrome is of paramount importance and Lynch Syndrome (LS) is the most frequent. The diagnosis can be suspected by using the Amsterdam criteria (AC) and the revised Bethesda guidelines (BC), but both lack sensitivity and specificity. International guidelines recommend universal tumour screening for mismatch repair proteins (MMR) deficiency.

Aims & Methods: The goal of this study was to confirm the importance of routine immunohistochemistry (IHC) screening in CRC patients.

An unicentric cohort study was conducted in a central Oncological Hospital, which integrates a Familiar Risk Clinic. All patients under 70 years-old admitted due to CRC during 07/2017-06/2019 were included.

Data collected included demographic information, tumour characteristics, relevant family history, MMR protein status, genetic diagnosis when available and outcome.

Results: 292 patients were included; 56.0% males; median age 61.0 (IQR 54.0-65.0); stage IV CRC 5.8%; located in the right colon 21.8%, left 28.0% and rectum 50.2% (synchronous CRC in 5 patients). Histological analysis revealed high grade (G3) adenocarcinoma in n=23 (8.4%); mucinous and/or signet ring differentiation n=31 (11.3%); lymphocyte infiltrate n=82 (29.8%). AC and BC were fulfilled in n=11 and n=74 patients, respectively (simultaneously in 6). IHC revealed loss of expression of MMR in n=24 (8.7%) – MLH1 and PMS2 n=15; PMS2 n=4; MSH2 and MSH6 n=1; MSH2 n=1; MSH6 n=2; MLH1, PMS2 and MSH6 n=1. Among these, 0 patients fulfilled AC and 13 fulfilled BC. BRAF mutation was found in n=3 and MLH1 promoter hypermethylation in n=3.

Overall, genetic diagnosis was performed in 51 patients, LS was diagnosed in 3, in whom only BC were present in n=2, which means that one patient would not have been investigated without routine IHC screening. 2 patients had MSH2 and MSH6 mutations with uncertain pathogenicity. 2 patients have their genetic study results pending.

Conclusion: These results strengthen the important role of universal IHC screening for MMR proteins loss of expression in CRC.

Contact E-Mail Address: a.hann@posteo.de

Introduction: The ability of artificial intelligence to recognize specific pattern lead to a wide area of applications in the medical field. In colonoscopy, it is used to detect polyps. Resection of adenomatous polyps correlates with the decrease of colorectal cancer risk.

In various randomized controlled studies, computer-aided polyp detection systems (CADE) increased the adenoma detection rate. Anyhow, most studies are limited by being monocentric and the systems work solely on one processor type. Furthermore, most systems are purely focused on detection.

Aims & Methods: We developed the for research purpose publicly available CADE system EndoMind. Besides its ability of real time polyp detection, it offers the opportunity of end-to-end data acquisition. We aim to evaluate the practical value of EndoMind in a prospective multicenter study in three outpatient practices and one community based hospital in Germany.

To specify the performance of EndoMind, colonoscopies were analyzed regarding diagnosed polyps, adenoma detection rate (ADR) and time to first detection of a polyp.

A questionnaire containing the System Usability Scale was used to examine the usability of EndoMind.

Results: Overall 41 colonoscopies were performed in 4 study centers with 4 different endoscopy processor types. EndoMind detected 66 of 66 polyps and 29 of 29 adenomas with a median time to first detection of 130 ms (95%-CI, 80 – 200 ms). EndoMind maintained a median false positive rate of 2.2 % (95%-CI, 1.7 - 2.8 %), while the ADR for these examinations was 41.5%. EndoMind reached a median System Usability Score of 96.3 (95%-CI, 70 - 100), which ranges above average.

Conclusion: EndoMind proved its practical value in clinical practice and for research with its high usability, sensitive real time predictions and ability of data acquisition. A prospective randomized multicenter study has to determine the clinical benefit of EndoMind regarding ADR.

Disclosure: The authors declare no conflicts of interest.

Introduction: Colorectal cancer (CRC) is a very heterogeneous disease, with special features due to the different location of the tumour. It has been suggested that the risk of colorectal cancer differs for tumours located in the proximal and distal segments, due to the different influence of environmental and genetic factors [1].

There is conflicting information about the effect of fatty acids (FAs) on the risk of developing CRC in different locations, and about FAs' levels associated with tumour localisation in different segments of the colon [2-4].

Aims & Methods: The purpose of the research: To study the characteristics of erythrocyte membrane FAs' composition in patients with different tumour localisation in CRC, including the early stages of the disease.

Materials and methods: Using a gas chromatography-mass spectrometric system (GC/MS) based on three Agilent 7000B quadrupoles (USA), the composition of the FAs' membranes of erythrocytes (Er) of 129 patients with CRC has been studied: (average age 63.2±9.4 years, 68 of them men and 61 women; 25 – with proximal, 98 – with distal localisation of the tumour) and 35 people of the comparison group.

According to the TNM classification, 65 patients have been diagnosed with stages I-II of the disease, 64 have been found to have advanced stages of colorectal cancer - III-IV.

Results: There was a greater degree of reduction in levels of saturated, monounsaturated fatty acids (SFAs, MUFAs) ($p=0.015-0.0001$), and, in contrast, an increase in polyunsaturated fatty acid (PUFAs) levels ($p=0.002-0.00001$) in patients with distal tumour localisation compared to healthy controls than the same ratio in the proximal CRC tumour – healthy controls pair ($p=0.034-0.002$).

There was a greater degree of increase in omega-3 PUFAs than omega-6, which was reflected in the n-6/n-3 ratio, which was significantly lower in cancer patients, more so in distal tumour localisation ($OR=0.589$, $p=0.004$). The most relevant for distinguishing between tumours localised in different parts of the colon were as follows: saturated fatty acids - myristic C14:0 ($p<0.001$) and pentadecanoic C15:0 ($p=0.012$), α -linolenic acid n-3 (C18:3 n-3) ($p=0.02$), whose levels were significantly higher and, in contrast, most omega-6 PUFAs (C18:2 n-6, C20:3 n-6, C20:4 n-6) and one omega-3 PUFA, C22:6 n-3 ($p<0.05$), whose levels were significantly lower in the proximal than in the distal tumour.

A study of the associations between FAs' levels and tumour localisation in early-stage CRC identified the biomarkers most relevant for distinguishing between proximal and distal tumours (Volcano plot method): serum FAs - C18:3 n-3 (FC 0.659, $\log_2$ (FC) -0.602, $p=0.02$), C22:6 n-3 (FC 0.749, $\log_2$ (FC) -0.46, $p=0.03$), erythrocyte membrane FAs - C18:3 n-3 (FC 0.36, $\log_2$ (FC) -1.44, $p=0.00007$), C15:0 (FC 0.64, $\log_2$ (FC) -0.64, $p=0.02$), C14:0 (FC 0.71, $\log_2$ (FC) -0.48, $p=0.05$), C20:2 n-6 (FC 0.76, $\log_2$ (FC) -0.39, $p=0.05$).

Conclusion: The results obtained indicate the importance of taking into account the localization of the tumor in patients with CRC when conducting studies of metabolic profiles. The revealed differences in FAs' levels in the early stages of CRC of different localisations may be useful for the development of new diagnostic markers of this disease.

Introduction: Computer-aided characterization (CADx) may be used to implement optical biopsy strategies into colonoscopy practice; however, the impact of CADx on endoscopic diagnosis remains unknown.

Aims & Methods: We aimed to evaluate the comprehensive performance of endoscopists using CADx for the assessment of colorectal polyps. This was a single-center, prospective study conducted between July 2021 and September 2021. We developed CADx for narrow-band imaging colonoscopy (NBI-CAD) with three potential pathological predictions: adenoma, sessile serrated lesion (SSL), and hyperplastic polyp.

We enrolled patients who underwent colonoscopy using real-time NBI-CAD, and participating endoscopists then predicted the pathology of the polyps considering the NBI-CAD output.

The primary outcome was the diagnostic sensitivity for diminutive (≤ 5 mm) neoplasms with high confidence predictions, based on pathology as the gold standard.

In this study, SSLs were treated as neoplasms and the latest WHO criteria was used for pathological diagnosis. The surveillance interval agreement between the endoscopist's diagnosis and pathology-based interval and the negative predictive value (NPV) for rectosigmoid neoplasms were also calculated.

Results: A total of 397 patients were enrolled and 395 diminutive polyps from 181 eligible patients were analyzed, including 259 adenomas (65.6%) and 25 SSLs (6.3%). The high-confidence diagnosis rate was 92.7% (366/395). The sensitivity for diminutive neoplasms diagnosed with high confidence was 95.8% (95% confidence interval [CI]: 92.7%–97.9%). The surveillance interval agreement with American guidelines was 90.1% (84.7%–94.0%) and the NPV for rectosigmoid neoplasms diagnosed with high confidence was 94.1% (83.8%–98.8%).

Conclusion: In conclusion, we developed a CADx for colorectal polyps and prospectively evaluated its performance in a real-world setting. The developed CADx showed diagnostic competence that allowed the implementation of optical biopsy strategies into clinical practice.

Contact E-Mail Address: linda.anarkulova@gmail.com

Introduction: The incidence of colorectal cancer (CRC) is increasing worldwide and is one of the main causes of cancer-related deaths. The mortality rate of CRC is high when it is detected in advanced stages, which requires effective screening methods to detect it early. Although there are screening modalities for CRC, there is still room for improvement. The analysis of exhaled breath by sensors that detect volatile organic compounds (VOCs) is a unique and progressive method of detecting CRC and could become a promising screening method.

Aims & Methods: The aim of the study was to evaluate the ability of a modular multi-sensor VOC analyser to distinguish between the breaths of CRC patients and healthy individuals' breaths.

Altogether 53 patients were enrolled in the study: 23 patients with CRC (histologically confirmed CRC) and 30 healthy individuals (histologically without CRC). Their breath was measured with a modular multi-sensor VOC analyser. The device included 48 repeated gold nanoparticle sensors (GNP) for improved robustness (6 sets of 8 different sensors), 11 analogue metal oxide sensors (MOX), and 12 digital MOX sensors. The signal of

each sensor was normalized against sensors response to ambient air and smoothed to remove noise using moving median approach. The sensor responses were analysed using the mean signal at the end of the measurement after the sensor readings were stabilized. These values were used to build a decision tree classifier, evaluation was carried out using leave-one-out approach.

Results: The classification model that was built on sensor data showed 79.25% overall accuracy. The sensitivity (correctly recognized cancer cases) was 69.6% and specificity (correctly recognized control cases) was 86.7%.

Conclusion: The results demonstrate that the proposed approach (device and machine learning model) is promising and could effectively distinguish CRC specific breath from controls. The study will be continued to build and evaluate more specific detection models in larger patient groups.

Introduction: Colorectal cancer is the third most common cancer worldwide and the second cancer death cause. Nowadays, extracellular vesicles have become an important diagnostic strategy. These extracellular vesicles have a different cargo according to the cell of origin and participate in a varied kind of functions, such as cellular communication, proliferation, and migration, among others. The different omics techniques, as mRNA array, allow to generate a huge amount of data that can be used as screening to find new biomarkers.

Aims & Methods: Our aim was to characterize the extracellular vesicles obtained of the bowel lavage fluid of colorectal cancer patients and realize a mRNA array to achieve the differential gene expression in the different type of patients.

Bowel lavage fluid samples were collected during colonoscopy, stored at -80°C, and divided according to pathology: without pathology, with polyps (divided into low- and high-risk of suffering from neoproliferative processes according to their number and size) and with neoproliferative processes. Subsequently, extracellular vesicles were extracted from the intestinal lumen aspirate by the differential ultracentrifugation method.

For the characterization of the extracellular vesicles, these were observed in the atomic force microscope on a mica surface and dried with nitrogen. RNA from these extracellular vesicles was extracted with TRI Reagent LS® and divided into 3 pools of 6 samples each without pathology, 3 pools of 5 low-risk samples each, 3 pools of 6 high-risk samples each, and 3 pools of 3 cancer samples each to be analyzed in a Clariom S Human mRNA array. The array results were studied by gene set enrichment and the gene differentially expressed by the package limma, Bioconductor.

Results: The atomic force microscope revealed that the extracellular vesicles diameter in all samples was between 40-100 nm. The analysis of the mRNA array demonstrated the presence of some mRNAs differentially

expressed between samples (34 mRNA differentially expressed between control and low-risk, of these, only 2 mRNA were differentially expressed between control and high-risk and, of these, only 1 mRNA was differentially expressed between control and cancer) and the altered biological functions, some of them belonging to mitochondria.

Conclusion: The analysis of the extracellular vesicles obtained from the bowel lavage fluid could increase the knowledge of colorectal cancer and could be an improvement in the diagnostic of the disease because of the possible biomarkers that extracellular vesicles could carry on inside.

Disclosure: Nothing to disclose.

Introduction: Several development concepts have been proposed for colorectal neoplasms in the carcinogenesis of colorectal cancer. One is “adenoma-carcinoma sequence”. In this concept, polypoid adenoma develops into early polypoid cancer and finally develops to advanced cancer. One is “serrated-pathway”. In this concept, serrated lesion develops into early cancer.

The other is “de novo” pathway. In this concept, early cancers develop without preexisting adenoma. We investigated clinicopathological characteristics of depressed-type colorectal carcinomas considered as “de novo” pathway.

Aims & Methods: A total of 43679 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our center from April 2001 to February 2022 at our center. Of these, 1384 lesions were T1 cancers. According to the developmental morphology classification, they were divided into 3 types: 303 lesions (21.9%) were depressed-type, 497 lesions (35.9%) were flat-type and 584 lesions (42.2%) were protruded-type. We analyzed the pathological difference of these types.

Results: The average tumor size were 15mm, 30mm, and 19mm in depressed-type, flat-type and protruded-type lesions, respectively. The rates of vessel invasion were 48%, 23% and 22%, that of poorly differentiated or mucinous adenocarcinoma were 17%, 11% and 15% in depressed-type, flat-type and protruded-type lesions, respectively.

The rates of these pathological factors were significantly higher in depressed-type lesions than other types. On the other hand, the rates of adenomatous component were 6%, 56% and 53%, and the rates of polypoid growth were 15%, 56% and 97%, respectively.

These rates were significantly lower in depressed-type lesions than other types, suggesting that they emerge directly from normal epithelium without going through the adenomatous stage. The rate of distant metastasis or recurrence was observed in 0.9% (13/1384). Among these 13 cases, 7 cases were depressed-type lesions among which one showed a para-aortic lymph node metastasis and five showed a lung metastasis.

Conclusion: Depressed-type colorectal carcinomas had significantly lower adenomatous components and smaller size than flat-types or protruded-types, and they also contained worth pathological features than other types. So, depressed colorectal carcinoma can be the important lesions for clinical diagnosis.

Therefore, during routine colonoscopy, we should give a greater attention to the morphological features of the depressed-type colorectal carcinomas.

Disclosure: Nothing to disclose.

WHICH IS THE BETTER PREDICTOR OF LYMPH NODE METASTASIS IN T1 COLORECTAL CANCER, LEAST OR PREDOMINANT DIFFERENTIATION? A SINGLE-CENTER STUDY OF 853 LESIONS

O. Shiina¹, S. Kudo¹, K. Ichimasa^{1,2}, Y. Kouyama¹, K. Mochizuki¹, Y. Takashina¹, Y. Morita¹, T. Kuroki¹, S. Kato¹, Y. Mori^{1,3}, M. Misawa¹, T. Kudo¹, K. Wakamura¹, T. Hayashi¹, N. Sawada¹, T. Nemoto⁴, T. Baba¹, F. Ishida¹, H. Miyachi¹

Introduction: Several guidelines such as US, European and Japanese include “tumor differentiation” as a risk factor for lymph node metastasis in T1 colorectal cancer. Surgical resection with lymph node dissection is recommended as an additional treatment, if poorly differentiated adenocarcinoma, signet-ring cell carcinoma or mucinous carcinoma are observed during histological findings of the endoscopically resected specimens. However, the way to diagnose the tumor differentiation is different among these guidelines (least differentiation in US guidelines, predominant differentiation in Japanese guidelines).

Aims & Methods: The aim is to determine which is more reliable method in risk stratification of lymph node metastasis, least or predominant differentiation analysis. We initially evaluated the consecutive 853 patients with T1 colorectal cancer who underwent initial or additional surgical resection with lymph node dissection from 2001 to 2019 at our institution, for inclusion in this retrospective study. We then excluded those who had (a) metachronous or synchronous advanced cancer, (b) invasion to the muscularis propria or deeper in surgical specimens, (c) Lynch syndrome, familial adenomatous polyposis or ulcerative colitis, (d) preoperative chemotherapy or radiotherapy, or (e) missing data.

Finally, we enrolled 805 patients in this study. We evaluated tumor differentiation in two methods (least or predominant) and divided into low-risk (well or moderately differentiated adenocarcinoma, or papillary adenocarcinoma) and high-risk (poorly differentiated adenocarcinoma, signet-ring cell carcinoma or mucinous carcinoma) in each method. The correlation between two patterns of differentiation analysis (least or predominant) and the rate of lymph node metastasis was investigated. Operative specimens were used as the gold standard for the presence of lymph node metastasis.

Results: Lymph node metastasis was found in 9.7% (78/805). Mean number of dissected lymph nodes were 15±10. Rates of high-risk cases in least and predominant analysis were 16.3% (131/805) and 0.7% (6/805), respectively. Sensitivity, specificity, and area under the receiver operating characteristics curve for lymph node metastasis in least and predominant analysis were 28.2%, 85.0%, 0.56 and 2.6%, 99.4%, 0.50, respectively.

Conclusion: Least differentiation analysis would be more effective in predicting the risk of lymph node metastasis in T1 colorectal cancer than predominant differentiation analysis.

Disclosure: Nothing to disclose.

IS A NEGATIVE FIT FALSELY REASSURING?: A RETROSPECTIVE EVALUATION

S. Manning¹, D. Maxfield¹, R. Bragg¹, H. Gillott¹, M. Clarkson-Cox¹, I. Malik¹, C.J. Rees², L.J. Neilson³

¹South Tyneside District Hospital, South Tyneside, United Kingdom, ²South Tyneside General Hospital South Tyneside NHS Trust, Dept. of Gastroenterology, South Tyneside, United Kingdom, ³South Tyneside and Sunderland NHS Foundation Trust, Gastroenterology, South Shields, United Kingdom

Contact E-Mail Address: s.h.manning@outlook.com

Introduction: FIT (faecal immunochemical test) is recommended by NICE in the assessment of symptomatic patients who do not meet criteria for an urgent suspected cancer referral. It can be a useful tool, in patients where there is a lower suspicion of cancer and may avoid unnecessary colonoscopies in select cases. However, previous studies have reported a cancer miss rate of 7-13% [1,2]. The aim of this audit was to identify the number of FIT-negative new colorectal cancer (CRC) cases in a single centre.

Aims & Methods: This was a single centre, retrospective audit. New CRC cases between June and December 2021 were identified. UK Bowel Cancer Screening Programme (BCSP) patients were excluded, as all of these patients, by default, have a positive FIT. Where histology was available, adenocarcinomas and polyps with high grade dysplasia were included. If only a radiological diagnosis was available, patients were included if the diagnosis was presumed to be CRC. Neuroendocrine tumours, cancers of non-colorectal primary, lymphomas and anal squamous cell carcinomas were excluded. Data was collected on symptoms, tumour location, histology, metastases and FIT level. A FIT cut off of <10ug/g was used as recommended by NICE.

Results: 122 patients were identified and included in the audit. 67 of these patients had FIT tests prior to their diagnosis, of which 5 were negative (7.5%). Of the FIT negative cases, patient age ranged from 56-82 years and cancer location varied (rectum, splenic flexure, hepatic flexure, ascending colon and caecum). Two of these patients had presented with iron deficiency anaemia, one with rectal bleeding, one with weight loss and diarrhoea and a further patient with weight loss alone.

Conclusion: 7.5% of CRC cases had a negative FIT, which is a false negative rate consistent with previous literature. This adds to the existing body of evidence that a negative FIT does not rule out CRC in symptomatic patients and urgent referral should be offered if red flag features are present. In our series, one patient did not meet NICE criteria for suspected CRC and therefore referral would not have been indicated based on FIT alone. Clinicians must consequently bear this in mind, thoroughly assess risk factors and use clinical judgement on an individual patient basis when considering whether to refer for investigation.

This was a small, single centre audit and further studies and therefore, larger data sets would be recommended and required to accurately assess FIT's sensitivity and specificity, on a larger scale.

COLONIC POLYPS: SMALL IN SIZE, BIG IN IMPACT?

C. Chia¹, S. Tsao², S. Thrumurthy²

¹Tan Tock Seng Hospital, Gastroenterology & Hepatology, Novena, Singapore, ²Tan Tock Seng Hospital, Gastroenterology & Hepatology, Singapore, Singapore

Contact E-Mail Address: tzechris@gmail.com

Introduction: Removal of colonic adenomas is proven to reduce incidence of colorectal cancer (CRC) and mortality. The current practice of routinely resecting all diminutive (1-5mm) and small (6-9mm) colonic polyps and submitting them for histopathologic assessment has several disadvantages in terms of cost-effectiveness and risks from repeated colonoscopies. The resect-and-discard (RD) strategy has been proposed to reduce retrieval of diminutive polyps (1-5mm) for histology which has been deemed not to have advanced histologic features. RD strategy for small polyps (6-9mm) are still controversial. The prevalence of advanced histologic features in the diminutive and small polyp category remains small but not clearly defined.

Aims & Methods: In this cross-sectional study, we aim to find the prevalence of small & diminutive polyps resected that shows advanced histologic features such as high grade dysplasia(HGD) or villous histologic features to determine if RD policy is feasible in the local Asian tertiary setting. Data was retrieved over 2 years with assistance from the Pathology Department to identify all submitted colonic polyp specimens. Each patient also had their colonoscopy report and detailed histology report reviewed by 2 separate colleagues within the team to ensure data consistency. The variables captured include age, gender, ethnicity, total polyp number, polyp distribution in the colon, histology, polyp size and respective number in each histology subtype and concurrent CRC. Data was analysed using SPSS v.20.

Results: There were a total 1482 colonic polyps retrieved for histology from 871 patients. 88% of the cases with colonic polyps were ≥50 years with male gender making up 60% of total cases and the major ethnic group being Chinese, comprising 88%. The colonic distribution of the polyps was 45.4% right-sided and 54.6% left-sided, including 8.5% rectal. There were 844 diminutive polyps (1-5mm), 447 small polyps(6-9mm) and 191 large polyps(≥10mm).

The proportion of HGD seen in each of these groups were 18.7%, 37.6% and 56.5% respectively (p<0.001). This was relatively high and significant compared to figures in published literature. The proportion of polyps containing villous histology was 3.0% for diminutive polyps and 12.5% for small polyps(p=0.041). There were no concurrent malignancy seen in all the polyps.

Polyp size	Diminutive (1-5mm)	Small (6-9mm)	Large (≥10mm)
Total number (1482)	844 (57.0%)	447 (30.1%)	191(12.9%)
Proportion with HGD	18.7%	37.6%	56.5%
Proportion with villous histology	3.0%	12.5%	37.1%
O'Brien et al. Gastroenterology 1990	1.0%	5.0%	21.0 %

Table.

Conclusion: These findings showed that a significant proportion of diminutive polyps(18.7%) and small polyps(37.6%) harboured features of HGD, which is significantly higher than previous findings of 1% for diminutive polyps and 5% for small polyps in some literature.

Based on size alone without the aid of narrow band imaging (NBI) or other forms of image enhanced endoscopy(IEE), we find that RD strategy for diminutive or small polyps may miss a significant group of patients with advanced neoplastic histology who needs earlier colonoscopic surveillance.

There may be merits in the RD approach but this would require incorporation of other real-time endoscopic modalities such as IEE and more robust evaluation.

Introduction: The standard therapy for rectal cancer patients is neoadjuvant therapy (NT), including chemotherapy and radiotherapy followed by surgery. Immune biomarkers are potential predictors of the response to NT, however, none of them have achieved an application in clinical practice.

Aims & Methods: The aim of this study is to evaluate predictive role of biopsy-based biomarkers including tumor-infiltrating lymphocytes (TILs) and immune checkpoints in rectal cancer patients.

To identify relevant studies, the search was conducted in PubMed, Ovid MEDLINE and EMBASE databases. Two independent researchers selected studies followed by data extraction, quality assessment and data analysis.

Results: From the total of 321 studies identified between May 1979 and October 2021, 36 were included in qualitative synthesis, while 17 were eligible for meta-analysis.

The final results have shown that high levels of total CD8+ TILs (OR 2.25, 95% CI 1.64 to 3.08; participants = 690; $P < 0.00001$) as well as its stromal (OR 1.52, 95% CI 1.05 to 2.18; participants = 542, $P = 0.03$) and intraepithelial (OR 3.43, 95% CI 2.56 to 4.62; participants = 961, $P < 0.00001$) compartments individually, CD4+ TILs (OR 2.26, 95% CI 1.30 to 3.94; participants = 239, $P = 0.004$), CD3+ TILs (OR 1.78, 95% CI 1.08 to 2.95; participants = 267, $P = 0.02$) and high levels of tumoral and immune cell expression of PD-L1 (OR 2.21, 95% CI 1.17 to 4.16; patients = 182; $P = 0.01$ significantly predict good pathological response to NT.

On the contrary, high levels of intraepithelial CD4+ TILs (OR 0.35, 95% CI 0.15 to 0.84; participants = 275, $P = 0.02$) were correlated with poor pathological response. Furthermore, FoxP3 TILs, tumoral PD-L1, CTLA-4 were not predictive biomarkers for the treatment response.

Conclusion: Collectively, our meta-analysis demonstrated that high density tumor inflammatory infiltrate is associated to improved pathological response in patients that underwent NT for the rectal cancer and could assist to predict the good response. To further verify the predictive role of PD-L1 and the possibility of distinct role of CD4+ TILs depending on the site of infiltration, more studies with fractionated CD4+ TILs levels and fractionated tumoral and TILs expression of PD-L1 are required.

Contact E-Mail Address: HAN_SO@yuhs.ac

Introduction: There was limited data regarding endoscopic features for predicting invasion depth of colorectal cancer. We aimed to develop simple scoring model for selection of colorectal cancer amenable to endoscopic resection.

Aims & Methods: From March, 2009 to September, 2019, a total of 854 patients who underwent colonoscopy and diagnosed with colorectal cancer invaded mucosa (Tis), submucosa (T1), and muscularis propria (T2) were enrolled at two tertiary medical center. All the cases are biopsy confirmed by endoscopic resection or surgery.

Development model was designed with significant endoscopic features that were selected through chi-square analysis and multiple regression model. Thereafter, this scoring model was examined with validation model to evaluate its power to predict invasion depth.

Results: Then we randomly selected two-thirds of cases (n=570) to establish development model. Six meaningful endoscopic morphological features were selected by Chi-square tests, multiple logistic regression model and simplified risk predicting model was designed in consideration of odds ratios.

The numerical formula is as below; size (0: under 20mm; 1: over 20mm) x1 + fold convergence (0: no fold convergence; 1: fold convergence)x1 + crumple (0: no crumple; 1: crumple)x1 + demarcated depression (0: no demarcated depression; 1: demarcated depression)x1 + nonstructural pit pattern (0: regular pit pattern; 1: pit pattern with VI, VN)x2 + surface ulceration (0: no ulceration; 1: ulceration)x3.

Validation model with remained 284 cases were tested to evaluate efficacy of this simple model. Area under curve (AUC) for development model was 0.763 (0.724-0.801) and 0.819 (0.768-0.870) for validation model, respectively.

Conclusion: A simple predicting model composed of six endoscopic morphological features might guide to differentiate early colorectal cancer that is amenable to endoscopic resection.

Disclosure: none.

P0595

RISK OF ADVANCED LESIONS AT SURVEILLANCE COLONOSCOPY COMPARING PATIENTS WITH SERRATED LESIONS AND HIGH-GRADE DYSPLASTIC ADENOMAS

E. Medawar¹, R. Djinbachian¹, M. Taghiakbari¹, T. Khoury¹,

A. Zoughlami², M. Zarandi-Nowroozi¹, D. von Renteln¹

Introduction: Patients with serrated lesions (SL = sessile serrated lesions (SSL) and traditional serrated adenomas (TSA)) or high-grade dysplastic adenomas (HGD) are at risk to develop advanced colorectal adenomas (AA) or colorectal cancer (CRC).

However, studies evaluating the risk of developing total metachronous advanced neoplasia (TMAN) for patients diagnosed with HGD or SL, and comparing this risk, are lacking.

Aims & Methods: Study aim was to compare the incidence of TMAN in surveillance colonoscopies of patients diagnosed with SL <10 mm, SL ≥10 mm or HGD at index colonoscopy. A cohort study was conducted. Through pathology database search, we identified 1529 patients with HGD and 2428 patients with SL diagnosed between 2010 and 2019 at the University of Montreal Hospital Center.

We excluded patients under 45 or over 75 years of age, with inflammatory bowel disease, hereditary CRC syndromes, previous or synchronous CRC, first surveillance <12 months after complete index, or concomitant SL and HGD at index. Patient files were reviewed for demographic data and findings at index and follow-up colonoscopies. Follow-up was continued until the outcome of interest or the last colonoscopy within 10 years.

The primary outcome was TMAN (=either advanced neoplasia (AN), which combines AA and CRC, or advanced serrated lesion (ASL), defined as SSL ≥10 mm or with dysplasia, TSA or hyperplastic polyp (HP) ≥10 mm). The secondary outcomes were AN, ASL, [TMAN or ≥5 SSLs or ≥5 adenomas] and [TMAN or ≥3 SSLs or ≥3 adenomas].

Continuous and categorical variables were compared between the three groups using 1-way ANOVA and the Pearson chi-squared test, respectively, followed by post-hoc tests. For the outcomes, we performed univariate and multivariate Cox regressions and present hazard rate ratios (HR) with their 95% confidence intervals.

Results: A total of 585 patients were eligible (55% male; mean age 63 years). The mean duration of follow-up was 3.67 years (range 0.94 – 9.88 years). There were 226 patients in the SL <10 mm group (216 SSL and 10 TSA), 204 patients in the SL ≥10 mm group (198 SSL and 6 TSA) and 155 patients in the HGD group.

Compared to SL <10 mm (reference group), SL ≥10 mm resulted in a higher rate of TMAN (HR=2.08 (1.38-3.15)), a similar rate of AN (HR=1.45 (0.81-2.77)), and a higher rate of ASL (HR=2.53 (1.50-4.25)), [TMAN or ≥5 SSLs or ≥5 adenomas] (HR=1.87 (1.25-2.78)) and [TMAN or ≥3 SSLs or ≥3 adenomas] (HR=1.64 (1.14-2.37)), after adjusting for age, sex, family history of CRC, proximal location of HGD or SL, tubulovillous or villous adenomas (TVA/VA), adenomas ≥10 mm and ≥3 adenomas.

Compared to SL <10 mm, HGD resulted in a similar rate of TMAN (HR=0.87 (0.62-1.20)) and AN (HR=1.08 (0.74-1.57)), a lower rate of ASL (HR=0.40 (0.19-0.85)), and a similar rate of [TMAN or ≥5 SSLs or ≥5 adenomas] (HR=0.84 (0.62 – 1.16)) and [TMAN or ≥3 SSLs or ≥3 adenomas] (HR=0.87 (0.65-1.17)), after adjusting for the same covariates.

A significant univariate effect of HGD was observed on TMAN and AN, but adjusting for either adenomas ≥10 mm, TVA, VA or ≥3 adenomas was sufficient to lose this effect. Compared to all SLs, HGD had a similar rate of TMAN and AN, and a lower rate of ASL.

Conclusion: Patients with a SL ≥10 mm at index colonoscopy have the highest risk of developing TMAN compared to patients with HGD and to patients with SL <10 mm. HGD does not increase the risk of TMAN compared to SL <10 mm.

The apparently increased risk of TMAN in the HGD group compared to SL <10 mm was explained by the multiple synchronous high-risk adenomas found with HGD or that HGD was in, and not by HGD itself.

THE EFFECT OF EDIBLE SEAWEED CONSUMPTION ON RISK OF COLORECTAL CANCER: A SYSTEMATIC REVIEW

M.L. Adnan¹, R. Rahmawati²

¹Universitas Islam Indonesia, Sleman, Indonesia, ²Universitas Islam Indonesia, Pharmacology, Sleman, Indonesia

Contact E-Mail Address: luthfiadnan35@yahoo.co.id

Introduction: Colorectal cancer is one of the most common malignancies in the world after lung and breast cancer. Diet is known to affect the risk of colorectal cancer incidence. Consumption of seaweed is common to use in Asian culinary. However, the relationship between seaweed consumption and the risk of colorectal cancer is still unclear because there is limited evidence. The aim of this study is to discuss the relation of seaweed consumption to the risk of colorectal cancer incidence.

Aims & Methods: The aim of this study is to discuss the relation of seaweed consumption to the risk of colorectal cancer incidence. The preparation of this systematic review was conducted according to PRISMA guidelines. Literature searches were conducted from February-May 2021 with the search engines PubMed, Google Scholar, and ScienceDirect with limited publication between 1990-2021. The keywords used were "colorectal cancer", "seaweed", "incidence", "risk factor", and "diet". The inclusion criteria used were nonrandomized controlled trials (RCTs) such

as observational studies, case-control, and cohort studies with full text in English. The exclusion criteria used were a review, systematic review, or meta-analysis, studies that were not conducted in humans.

Results: Six studies, 4 case-control and 2 cohort studies meet the criteria. Based on the comparison of case and control groups, seaweed consumption is significantly associated with a lower risk of colorectal cancer. A recent cohort study from Minami *et al*(2020) showed there is frequent seaweed intake was inversely associated with the risk of all-cause death among patients with colon cancer (Ptrend = 0.03).

Rectal cancer patients who had frequently consumed seaweed tended to have a lower risk of rectal cancer death (Ptrend = 0.02). Some confounding can affect are age, sex, family history, nutritional status, comorbidities, occupation, and history of treatment.

Conclusion: Seaweed consumption has been associated with a lower incidence and mortality of colorectal cancer.

Disclosure: There is no conflict of interest between the author.

MODIFIED UNDERWATER ENDOSCOPIC MUCOSAL RESECTION FOR INTERMEDIATE-SIZE SESSILE COLORECTAL POLYPS

D.H. Kim¹, H. Kim², S.-Y. Park¹, H.S. You¹, S.Y. Cho¹

Introduction: The European Society of Gastrointestinal Endoscopy (ESGE) guideline recommends cold snare polypectomy (CSP) for 6–9 mm sized sessile polyps. Hot snare polypectomy (with or without submucosal injection) is suggested for the removal of sessile polyps 10–19 mm in size.[1] According to a recent paper, the rate of complete resection was higher with underwater endoscopic mucosal resection (UEMR) than with conventional endoscopic mucosal resection (CEMR) for the polyps 10–20 mm in size.[2]

In general, UEMR is performed after infusing about 200–1000 mL of water. [2–4] However, some intestinal lumens cannot be easily filled with water. Therefore, sometimes, an excessive amount of water fills the lumen,; the procedure takes a long time, causing abdominal discomfort; and there is a concern of hypernatremia or hyponatremia depending on the nature of the water.[5] Moreover, when performing UEMR, the lumen decreases after filling with water, making visualization difficult.

Hence, the authors devised a modified version of UEMR that compensates for the shortcomings of conventional UEMR. We aimed to elucidate the effectiveness and safety of this modified UEMR method.

Aims & Methods: This prospective, observational, single-center study included consecutive patients with intermediate-sized (10–20 mm) sessile colorectal polyps. The modified UEMR method was used to initially snare the lesion without injection or water infusion.

Thereafter, water was infused until the lesion was submerged, then it was resected using electrocautery. We also evaluated the rates of complete resection and procedure-related complications.

Results: Forty-two patients with 47 polyps were enrolled in the study. The median procedure time and fluid infusions were 71 s (42–607) and 50 mL (30–130), respectively. The rates of R0 resection and *en bloc* resection were 80.9% and 97.9%, respectively, with 100% technical success. R0 resection was observed in 42.9% of polyps sized ≥15 mm and 87.5% sized <15 mm (*p* <0.01). Muscle entrapment was found in 71.4% of patients with polyps sized ≥15 mm and 10% <15 mm (*p* <0.01).

	Total (n=47)	Polyp size ≥15 mm (n = 7)	Polyp size <15 mm (n = 40)	p value
Ro resection rate, n(%)	38 (80.9)	3 (42.9)	35 (87.5)	<0.01
Muscle entrapment, n(%)	9 (19.1)	5 (71.4)	4 (10.0)	<0.01
<i>En bloc</i> resection rate, n (%)	46 (97.9)	6 (85.7)	40 (100)	0.15
Piecemeal resection rate, n (%)	1 (2.1)	1 (14.3)	0	
Technical success, n (%)	47 (100)	7 (100)	40 (100)	
Median procedure time, seconds (range)	71 (42–607)	110 (69–379)	68 (42–607)	0.16
Fluid infusion (mL), median (range)	50 (30–130)	70 (40–130)	50 (30–120)	<0.01
Snare tip ablation, n (%)	13 (27.7)	3 (42.9)	10 (25.0)	0.38
Coagrasper use, n (%)	3 (6.4)	2 (28.6)	1 (2.5)	0.054

Table 1. Procedure-related Outcomes

Immediate bleeding occurred in 12.8% of cases and was controlled using a snare tip or coagrasper. Snare-tip ablation and coagrasper ablation were performed in 27.7% and 6.4% of patients, respectively. No delayed bleeding, perforation, or any other complications were reported.

Conclusion: Modified UEMR can be used in cases in which securing visibility or performing the existing UEMR is challenging. Careful treatment is required when removing polyps >15 mm in size.

Introduction: The importance of cancer stem cells (CSCs) on tumor formation, invasion, and resistance to therapy in colorectal cancer (CRC) is currently widely accepted.

Aims & Methods: Here, we explored the anti-CSC potential of a novel curcumin analog – MVC12 – identified in a compound screening campaign based on a tumorsphere forming assay.

Human CRC cell lines HT29, HCT116, and SW620, and AML12 immortalized murine hepatocytes were incubated with MVC12 under tumorsphere forming (3D) and adherent (2D) conditions, and dose-response curves were built. The impact of MVC12 on tumorsphere formation and stemness regulation was assessed by qRT-PCR and immunoblotting.

Flow cytometry analysis of cell death markers, caspase-3/7 activity assays, and Hoechst staining were used to evaluate apoptotic cell death. MVC12 anti-tumor effectiveness was evaluated *in vivo* using xenografted HT29 subcutaneous tumors in Foxn1^{nu/nu} athymic mice treated with 10 mg/kg intraperitoneal administrations every two days. Potential molecular targets were evaluated *in silico*, *in vitro*, and *in vivo*.

Results: MVC12 presented equal or better efficacy than salinomycin (CSC-targeting agent) and 5-fluorouracil (5-Fu, traditional chemotherapy agent) in reducing cell viability in 3D and 2D cell cultures and was up to four times less toxic in AML12 cells. MVC12 decreased tumorsphere size and number. Further, MVC12 decreased stemness markers and increased differentia-

tion markers as well as apoptosis in both 3D and 2D cell cultures. MVC12 significantly reduced tumor burden *in vivo*, accompanied by increased differentiation and apoptosis in tumors. *In silico* screening and molecular docking analysis revealed NF- κ B and STAT3 as putative molecular targets of MVC12. Experimental validation confirmed reduced NF- κ B and STAT3 activity after MVC12 treatment *in vitro* and *in vivo*.

Conclusion: In conclusion, we describe a novel curcumin analog that targets colorectal CSCs and efficiently reduces tumor burden *in vivo* by inducing apoptosis and modulating stemness. Functional assays will further validate MVC12 putative targets and mechanisms of action in future studies.

RATES OF SYNCHRONOUS ADVANCED NEOPLASIA AND COLORECTAL CANCER IN PATIENTS WITH COLONIC SERRATED LESIONS

R. Djinbachian¹, M.-L. Lafontaine¹, T. Dufault¹, M. Boivin¹, M. Bouin¹, D. von Renteln¹

¹Centre Hospitalier de l'Université de Montreal (CHUM), Montreal, Canada

Contact E-Mail Address: rdjinbachian@gmail.com

Introduction: Serrated lesions (SL) have been associated with significant risks of developing colorectal cancer (CRC). There is little data on synchronous findings after detection of SLs during colonoscopy.

Aims & Methods: Our study aim was to evaluate the rate of synchronous advanced neoplasia (S-AN) and synchronous CRC (S-CRC) in colonoscopies where SLs were detected. We conducted a retrospective study of screening aged patients 45-74y with a colorectal SL (sessile serrated polyp [SSP] or traditional serrated adenoma [TSA]) detected during a screening, surveillance, or diagnostic colonoscopy. Exclusion criteria were: inflammatory bowel disease; hereditary CRC syndromes; personal history of CRC; serrated polyposis syndrome; patients referred for CRC or resection of large adenomas.

Primary outcome was risk of S-AN in patients with SL. Secondary outcomes included risk of S-AN or S-CRC stratified by SL characteristics. Multivariate logistic regression was performed and adjusted for colonoscopy indication; sex; bowel preparation quality.

Results: The study included 1262 patients with 1649 SLs (1214 with SSPs and 48 with TSAs). 47.2% were female and 22.9% of exams were screening colonoscopies, 48.2% surveillance, 28.9% diagnostic. The overall rates of S-AN and S-CRC were 15.1% and 1.7% respectively. Presence of SSPs ≥ 10 mm was associated with higher rates of S-AN, (18.1 vs 12.2%, Odds Ratio [OR]=1.61 [95% Confidence Interval [CI]1.17-2.23], $p=0.004$). SSP dysplasia was predictive of both S-AN, (30.3 vs 14.1%, OR=2.68 [95%CI 1.24-5.78], $p=0.012$) and S-CRC, (12.1 vs 1.3%, OR=9.79 [95%CI 3.03-31.62], $p<0.001$). SSP number (≥ 3) was not a predictor of S-AN, (17.8 vs 14.4%, OR=1.13 [95%CI 0.67-2.15]) or S-CRC, (2.4 vs 1.5%, OR=1.60 [95%CI 0.36-7.08]). SSP location (proximal) was not a predictor of S-AN, (14.5 vs 16.5%, OR=0.85 [95%CI 0.50-1.46]) or S-CRC, (1.2 vs 3.7%, OR=0.37 [95%CI 0.12-1.12]).

Conclusion: Patients with SLs are at significant risk of S-AN and S-CRC. Findings of SSPs ≥ 10 mm are associated with significant risk of S-AN, and SSP dysplasia is associated with significant risks of both S-AN and S-CRC. Endoscopists should exercise heightened vigilance for synchronous findings when SLs are detected, especially SSPs ≥ 10 mm or when bowel preparation is suboptimal. Expedited repeat colonoscopy is warranted after detection of SSPs with dysplasia to rule out advanced lesions and CRC.

Introduction: In cases of positive or indefinite margin status after cold snare polypectomy (CSP) for high-grade dysplasia (HGD) or cancers, the risk of post-colonoscopy colorectal cancer should be considered and managed appropriately. Nonetheless, the management after CSP for HGD or cancers has not been fully investigated, and varies depending on the institution's policy.

The limited number of these cases contaminates the data on the recurrence pattern of HGDs or cancers after CSP, and the lack of evidence makes it difficult to decide on the appropriate management strategy.

Aims & Methods: The present study aimed to investigate the recurrence pattern of colorectal HGDs or cancers after CSP and the appropriate management strategy. This nationwide multicentre retrospective exploratory cohort study was conducted at 22 secondary or tertiary care centres in Japan. The study was approved by the institutional review board of each participating centre and registered with the University Hospital Medical Information Network (UMIN) Clinical Trials Registry as UMIN000043670. The data of patients over 20 years of age who underwent CSP for colorectal HGD or cancer between January 2014 and December 2020 and had undergone one or more follow-up colonoscopies at the participating 22 centres were retrospectively analysed.

We divided the curability of CSP into three categories: curative, borderline, or non-curative resection. The pathological diagnosis was based on the Japanese classification of colorectal, appendiceal, and anal carcinomas, to which we included the presence of intramucosal carcinoma. In the present study, intramucosal carcinomas were classified as having HGD. The lesion where the tumour invaded the submucosa was classified as cancerous. We investigated the detection rate of CSP scars, local recurrence rate (LRR), risk factors for local recurrence, and the follow-up strategy.

Results: The study included 155 patients with 156 lesions. The median tumour size was 6 mm (range: 2–18 mm), and the most frequent macroscopic type was protruded (70.5%). CSP scars were identified in 22 (31.4%), 41 (54.7%), and 10 (90.9%) patients with curative, borderline, and non-curative resection, respectively. Of them, the residual tumours were observed in one (4.5%), six (14.6%), and three (30.0%) cases, respectively.

The total LRR was 13.7% (95% confidence interval, 6.8–23.8). R1 resection cases (either horizontal or vertical margins positive for tumour) were associated with local recurrence ($p = 0.031$). Salvage endoscopic resection or surgery was performed on 21 and 10 patients, respectively. Of them, the proportion of endoscopically suspected residual tumours was significantly higher ($p < 0.001$) in the residual tumour positive (100%) than in the negative group (28.6%).

All residual tumours were diagnosed at first surveillance colonoscopy. The median observation period after CSP was 12.7 months (range: 0.6–77.1). The median number of times of colonoscopic surveillance was two (range: 1–7). Although three patients died due to duodenal cancer, cerebral infarction, and an unknown cause, none of them died due to colorectal cancer.

Conclusion: Identification of CSP scars is sometimes difficult; the LRR after CSP for HGDs or cancers is 13.7% based on scar-identified cases. Salvage endoscopic or surgical resection should be performed according to the curability of the lesions and the endoscopic findings during surveillance endoscopy. Further long-term follow-up studies including cases with unidentified CSP scars are necessary.

Disclosure: Nothing to disclose.

A PILOT CONSEQUENCES OF COLORECTAL CANCER VIRTUAL CLINIC IN LINCOLNSHIRE DURING THE COVID-19 PANDEMIC

D. Fernandes¹, J. Andreyev^{1,2}

¹Lincoln County Hospital, Gastroenterology, Lincoln, United Kingdom, ²University of Nottingham, The Biomedical Research Centre, Nottingham Digestive Diseases Centre, School of Medicine, Nottingham, United Kingdom

Contact E-Mail Address: dcrfernandes@gmail.com

Introduction: Recent reductions in cancer mortality rates are the result of better screening and the use of improved treatments. Whilst there has been a longstanding awareness of the psychological and social impact of cancer therapy, there has been little emphasis on dealing with the physical symptoms that are a frequent complication of treatment. This can include living with chronic and debilitating bowel symptoms as well as problems with sexual and urinary function.

At the United Lincolnshire Hospitals Trust, over 400 patients are diagnosed and treated for colorectal cancer annually. We therefore sought to develop a unique virtual service to help patients who have developed gastrointestinal symptoms following treatment.

Aims & Methods: A virtual telephone clinic was set up during the COVID-19 pandemic. Patients in need of specialist gastroenterology input were identified by colorectal cancer nurse specialists, colorectal surgeons or oncology specialists in their follow up clinics. Patients were then reviewed by a gastroenterology research fellow via a telephone consultation. Investigations requested included blood tests, faecal elastase, faecal calprotectin, SeHCAT scan, abdominal x-ray and breath test.

Results: 38 patients (18 male, 20 female) were reviewed between October 2020 to October 2021. The median age was 71 (range 44 to 86) and the average duration of symptoms was 38 months (range 8 to 86). All had been diagnosed with colorectal cancer and received treatment that included surgery, chemotherapy, radiotherapy either alone or in combination with one another. Symptoms included loose stool, bloating, increased frequency and incontinence with diagnoses made shown in Table 1.

Constipation	8
Bile Acid Malabsorption	6
Pancreatic Insufficiency	5
Small Intestinal Bacterial Overgrowth	4
Radiation Proctopathy	2
Reoccurrence	2
Excessive Alcohol Intake	2
Fistula	2
Excess Fibre	2
Possible Colitis	1

Table 1

Patients' symptoms pre-referral and post treatment were assessed objectively using the gastrointestinal symptoms rating scale (GSRs), with an average GSRs on referral of 29.5, improving to 16.2 following investigation and treatment.

Conclusion: In most patients referred to our specialist clinic, we have been able to identify one or more cause for their problems. Treatment, that may include laxatives, bile acid sequestrants, antibiotics and dietary changes may lead to a dramatic improvement in symptoms. Future recommendations include earlier recognition of patients in need of specialist referral

through the use of symptom questionnaires, improved funding for this neglected field in post cancer treatment and the development of similar consequences of cancer clinics in trusts nationwide.

Disclosure: No conflict of interest.

Contact E-Mail Address: kenrunaway@yahoo.co.jp

Introduction: Both underwater endoscopic mucosal resection (UEMR) and endoscopic submucosal resection (ESD) are effective procedures for removing colorectal polyps. Currently, there are no prospective studies evaluating the short-term outcomes of UEMR and ESD for relatively large colorectal polyps. Thus, the aim of this phase 2 randomized controlled trial was to evaluate the short-term outcomes of UEMR and ESD for colonic polyps (21–30 mm).

Aims & Methods: We conducted a single center randomized controlled trial at Chiba University Hospital, Japan. This study was performed in accordance with the Declaration of Helsinki. The study protocol was reviewed and approved by the Chiba University Graduate School of Medicine Ethics Review Committee (registration no. G2020032) on January 21, 2021. The study protocol was not changed after trial commencement. All patients provided written informed consent. The study was registered in the Japan Registry of Clinical Trial as jRCT1030210015.

Patients diagnosed with suspected colorectal intramucosal carcinoma (diameter from 21–30 mm and adaptable for both UEMR and ESD) were randomly assigned in a 1:1 ratio to UEMR and ESD group. Only one polyp per one patient was enrolled. In total, 11 polyps in the UEMR group and 11 polyps in the ESD group were analyzed.

The primary endpoint was whether the lower limit of 95% confidence interval (CI) for the R0 resection rate (The polyp in the resected specimen is negative for horizontal and vertical margin) exceeds the set threshold. For UEMR, the threshold for R0 resection rate was set at 30%, and for ESD, the threshold for R0 resection rate was set at 40%.

Results: The R0 resection rate (%) (95% CI) was 36 (11-69)/ 100 (72-100) for UEMR and ESD respectively with significant difference (p=0.002, Welch Two Sample t-test). The lower limit of 95% CI for ESD exceeded the threshold of 40%, while the lower limit of 95% CI for UEMR did not exceed the threshold of 30%. En bloc resection rates (%) were 82 (48-97)/ 100 (72-100), respectively, and were not significantly different (p=0.167, Welch Two Sample t-test). There were no intraoperative/ delayed perforation nor delayed bleeding in both groups. Treatment time (min) mean ± standard deviation was 8 ± 6/ 48 ± 29, which was significantly shorter for UEMR (p=0.001, Welch Two Sample t-test). UEMR was performed in all cases as an outpatient and ESD was performed in all cases as an inpatient.

Conclusion: The R0 resection rate of UEMR did not exceed the set threshold, while that of ESD was preferable and superior. On the other hand, the en bloc resection rate was comparable between UEMR and ESD. UEMR may be beneficial with less burden on the patient in that it requires shorter procedure time compared to ESD, and can be performed on a outpatient basis.

Disclosure: There are no Conflict of Interest.

Introduction: Many countries have implemented fecal immunochemical test (FIT) -based colorectal cancer (CRC) screening programs. However, little is known about the effectiveness of FIT-based screening on CRC incidence and mortality.

The aim of this study was to evaluate this impact.

Aims & Methods: Before implementing a national screening program, a population-based cohort study was performed in The Netherlands. The screened individuals, aged 50-75 years, participated in a biennial FIT screening program between 2006-2014, with a follow-up until December 31st 2018. All Dutch inhabitants aged 50-75 years on January 1st 2006 - same time period as the screening cohort started - were used as reference cohort.

Since an organized nationwide CRC screening program was gradually implemented from 2014 onwards, persons in the reference cohort needed to be censored when they were eligible to participate in the national CRC screening program, resulting in a shorter follow-up time.

To enable analyses with a longer time horizon, we additionally included all Dutch inhabitants aged 50-75 years at January 1st 2001. They were eligible to participate in the nationwide CRC screening after at least 13-years and could therefore be followed until December 31st 2013. The Kaplan Meier method and Cox regression analysis were performed to evaluate the association between FIT screening and CRC incidence or mortality.

Results: In total, 15,397 individuals (mean age: 59.0 years; 52.6% female) participated at least once in the screening program ("screenees") and were compared to the cohort of non-screened individuals starting in 2001 (n=4,292,731) and the cohort starting in 2006 (n=4,682,982). The proportional hazards assumption of the Cox regression models was violated for age and year.

Therefore, analyses were performed by stratifying the follow-up time. Over 13-years of follow-up, screenees had a significantly lower CRC incidence (hazard ratio (HR) 0.78; 95%CI 0.68-0.90; p=0.001) compared to the non-screened individuals. In the first five years of screening an initial increase in cumulative CRC risk was found, followed by a subsequently decrease after seven years.

Screenees had a significantly lower CRC-related mortality (HR 0.39; 95%CI 0.29-0.53; p<0.001) compared to the non-screened individuals. Female gender was associated with a lower CRC-related mortality (HR 0.65; 95%

CI: 0.64-0.66, $p < 0.001$). Age was associated with an increased CRC-related mortality (HR 1.11 per year increase in the first two years of follow-up, which slightly decreased over time (HR 1.07 after 6 years).

Conclusion: Biennial FIT-based CRC screening is associated with lower CRC incidence and CRC-related mortality. However, healthy screenee bias cannot be ruled out. These results further encourage the implementation of FIT-based CRC screening programs.

Introduction: Endoscopic management is preferred to surgical management for large superficial colorectal lesions. However, the optimal endoscopic resection strategy (piecemeal endoscopic mucosal resection [pEMR] or endoscopic submucosal dissection [ESD]) is still debated from an economical point of view. To date, in France and other European countries, there is no Health Insurance reimbursement rate for either the procedure or the hospital stays related to ESD.

We searched to estimate the global cost of colorectal ESD and to define the most cost-effectiveness endoscopic strategy according to the resection strategy used and the results of optical diagnosis.

Aims & Methods: Since 1 January 2017, all superficial colorectal lesions larger than 20 mm have been removed by ESD with double clip traction (DCT-ESD) in our two centers. We searched to know what would have been the medical and economic outcomes if all those same lesions had been treated by a selective ESD or an exclusive pEMR strategies.

A model was created to compare the cost-effectiveness of ESD and pEMR according to optical diagnosis results using several classifications (Japan NBI Expert Team [JNET], laterally spreading tumour [LST], CONECCT) in real time before the procedure. We distinguished three groups from the same multicentre colorectal ESD cohort and compared the medical and economic outcomes. We also compared our real-life DCT-ESD data to modelled selective ESD and exclusive pEMR strategies.

We distinguished and analysed three groups from the same cohort.

1. Universal ESD strategy (U-ESD): actual strategy applied to the French multicentre cohort. All lesions were removed by DCT-ESD.
2. Selective ESD strategy (S-ESD): DCT-ESD was reserved for lesions considered at risk of submucosal cancer according to endoscopic classification (JNET IIb or CONECCT IIc or LST G with macronodule > 1cm or LST NG)
3. Universal pEMR strategy (U-EMR): removal of all lesions by pEMR.

Results: The en-bloc, R0, and curative resection rates were 97.5%, 86.5%, and 82.6%, respectively in the real life French ESD cohort of 833 colorectal lesions.

U-ESD was the least-expensive strategy, with a global cost of 2,858,048.17 €, i.e. 3,431.03 €/patient and was also the most effective strategy because it avoided 774 surgeries, which was more than any other strategy. It outperformed S-ESD CONECCT (global cost = 2,951,411.44 €, and 3,543.11 €/patient, 765 surgeries avoided, S-ESD LST (global cost = 3,055,951.53 €, and 3,668.61 €/patient, 749 surgeries avoided), and S-ESD JNET (global cost = 3,547,426.97 € and 4,258.62 €/patient, 704 surgeries avoided) and U-EMR (global cost = 4,060,547.62 € and 4,874.61 €/patient, 620 surgeries avoided). Even though a model which optimized pEMR results (0% technical failure, 0% primary surgery), U-EMR strategy remained the most expansive strategy and the one that avoided the least surgeries. Only the CONECCT classification referred to ESD whole submucosal cancer, contrary to LST and JNET classifications that missed 24% and 27% of those lesions by orienting them to pEMR.

Conclusion: In the era of clip-and-rubber-band countertraction, ESD for all large LSTs is more cost-effective than pEMR, and can be superior to a S-ESD depending on the reimbursement scheme.

The CONECCT classification, which combines overt and covert signs of carcinoma, is preferable to select lesions that will most benefit from an ESD. Data from the randomised French trial, RESECT-COLON (NCT03962868) are coming and may improve the management of patients with large colorectal LSTs.

Introduction: Around 40% of colonoscopies performed in colorectal cancer (CRC) screening programmes are normal. New strategies are needed to reduce non-pathologic endoscopies in this setting. Bleeding associated with colonic lesions is intermittent, therefore, the positivity of the quantitative faecal immunochemical test (FIT) can be variable in different samples. Repeating FIT could be a useful strategy to reduce unnecessary colonoscopies.

Aims & Methods: Consecutive patients referred for colonoscopy in the CRC screening program were included. Patients were asked to perform a second FIT prior to the colonoscopy using the same test as the first FIT. We analyzed positive and negative predictive values (PPV and NPV), sensitivity (Se) and specificity (Sp).

The aim is to explore whether in those patients with a first FIT with a low positive determination ($\leq 35 \mu\text{gHb/g}$), a negative second FIT ($\leq 20 \mu\text{gHb/g}$) is associated with a low probability of CRC or those lesions that require endoscopic follow-up, according to ESGE 2020.

Results: 508 patients were included. In 220 (43.3%), the colonoscopy was normal. 20 cases of CRC (3.9%) and 133 (26.2%) of adenomas that require follow-up were diagnosed. In 347 (68.3%), the second FIT were negative. Considering patients with a low positive first FIT (132), the second was negative in 105 (79.5%). Diagnostic accuracy for all patients and for patients with a first low positive FIT is summarized in Table 1.

With a low positive first FIT ($\leq 35 \mu\text{gHb/g}$) and a negative second test, the probability of significant pathology (adjusted by sex and age) was 80% lower than in the other possible results in first FIT (high positive result, $> 35 \mu\text{gHb/g}$) and second FIT (positive result) (OR 0.2, 95% CI, 0.1-0.4). Nevertheless, with a positive first and second FIT, the probability of significant pathology is 4 times higher than in the other possible results (OR 4.8, 95% CI, 3.1-7.4).

		Se	Sp	PPV	NPV
All patients included (n= 508)	CRC (n=20)	75%	70.08%	9.32%	98.56%
	CRC + sessions that require follow-up (n= 153)	56.86%	79.15%	54.04%	80.98%
Patients with a first FIT $\leq 35 \mu\text{gHb/g}$ (n= 132)	CRC (n=3)	100%	81.4%	11.11%	100%
	CRC + sessions that require follow-up (n= 23)	52.17%	86.24%	44.44%	89.92%

Table 1.

Conclusion: In our CRC screening cohort, nearly 80% with a low positive ($\leq 35 \mu\text{gHb/g}$) first FIT had a negative second FIT, with a 90% NPV for CRC and lesions that require follow-up.

This strategy allows to reduce more than 20% of normal colonoscopies.

3D COMPUTED TOMOGRAPHY IN PREOPERATIVE ANALYSIS OF VASCULAR ANATOMY OF PATIENTS WITH RIGHT SIDED COLON CANCER

A. Bedeniuk¹, I. Dzyubanovsky¹, S. Grytsenko¹, I. Hrytsenko²

¹Ternopil National Medical University, Department of Surgery with Urology №1 by L.Ya. Kovalchuk, Ternopil, Ukraine, ²Medical center "Omega", Kyiv, Ukraine

Contact E-Mail Address: stepan_grytsenko@ukr.net

Introduction: In modern science it is difficult, if not impossible, to say anything new in surgical vascular anatomy, but with widely used in clinical practice contrast-enhanced computed tomography (CT) has made it possible to reach a qualitatively new level in preoperative diagnosis and determination of treatment tactics for patients with colorectal cancer (CRC).

Aims & Methods: The aim of this study is to analyze the clinical and radiological aspects that usually need to be discussed before surgery by a multidisciplinary team in patients with right-sided colon cancer. Carry out a comparative analysis of 3DCT angiography data with intraoperative data. 103 patients with CRC who underwent preoperative 3D CT at Ternopil Regional Hospital between 2016 and 2021. We set the following objectives: determine the type of superior mesenteric artery (SMA); determine the distance from the root of the SMA to the root of the middle colic artery (MCA); the distance from the root of the MCA to the root of the ileocolic artery (ICA); variant structure of the right colic artery (RCA); the relationship between MCA and gastroduodenal trunk of Henle (TH); explore different variants of TH confluence.

Results: All patients underwent radical right hemicolectomy with complete mesocolic excision with central vascular ligation; the median quantity of removal lymph nodes were $24,71 \pm 10,04$ (range 13-58). Positive lymph nodes were revealed in 38,7 % cases. The incidence of metastatic lymph nodes in D1 zone was 38.7%, D2 zone - 3,2% and the zone D3 - 9,7%. Mean operative time was 82 minutes (range 63 -130 min).

Postoperative complications were developed in 7 patients. Anastomotic leakage was diagnosed in 1 patient. We have identified 8 types of SMA that are most common in practice: type A - MCA, RCA and ICA deviate classically independently of each other from the main SMA trunk; type B - RCA is absent; type C - RCA deviate from ICA; type D - RCA deviate from the right branch of the MCA or the main trunk of the MCA; type E - classical type A + the presence of additional MCA (AMCA); type F - right and left MCA branches deviate separately from the main SMA trunk; type G - MCA and ICA have a common trunk and RCA is absent; type H - RCA deviate from ICA + AMCA.

Our analysis showed that type A was detected in 27 (25.9%) patients, type B in 22 (21.4%) patients, type C in 20 (19.2%) patients, type D in 12 (11.6%) patients, type E in 9 (8.7%) patients, type F in 9 (8.7%) patients, type G in 3 (2.9%) patients and type H in 1 (0.9%) patients. In 64 (62,1 %) the ileocolic artery (ICA) crossed the superior mesenteric vein on the anterior surface and in 39 (37,9 %) on the posterior surface. In 58 (56.3%) patients RCA was either absent or was a non-independent branch of SMA. The distance from the root of the SMA to the root of the middle colic artery (MCA) was 37.8 ± 12.8 mm; from the root of the MCA to the root of the ICA was 29.5 ± 15.7 mm. In 66 (64.1%) patients trunk of Henle (TH) was above the root of the MCA, in 16 (15.5%) TH was at the same level with the MCA and in 18 (17.5%) TH was below the MCA.

Conclusion: Preoperative 3D-CT angiography is a key pattern in assessment of vascular anatomy and can potentially reduce intraoperative time for identifying key landmarks and reduce the risk of anastomotic leakage.

Introduction: Various methods have been developed to decrease complications associated with endoscopic resection (ER) for colorectal lesions. ER with bipolar snare, in which the electric current only passes through the tissue between the two electrodes of the device, is the one of prominent methods to potentially prevent perforation due to electricity.

In addition to the effect of reducing electronic damage to tissues, ER with bipolar snare has advantages over conventional monopolar snare in terms of safety and convenience, as it has less risk of burns even if any metal such as a pacemaker is present inside patients' body and doesn't require the attachment of a counter electrode.¹ In ex vivo porcine model, we recently reported that hot snare polypectomy (HSP) with bipolar snare for 10-15 mm lesions didn't cause thermal damage to the muscularis propria, whereas perforation was seen in HSP with monopolar snare.²

Furthermore, we found that such the thermal damage was not seen in bipolar HSP regardless of whether submucosal injection prior to resection is performed.

Therefore, ER with bipolar snare for 10-15 mm colorectal lesions is expected to have good treatment outcomes with high safety even without submucosal injection, but there are no reports comparing treatment outcomes with and without submucosal injection in clinical.

Aims & Methods: The aim of this study is to compare the outcomes of ER with bipolar snare for 10-15 mm colorectal lesions between HSP, which is the bipolar resection without submucosal injection, and endoscopic mucosal resection (EMR), which is the bipolar resection with submucosal injection.

We retrospectively enrolled all non-pedunculated colorectal lesions sized 10-15 mm which were diagnosed as JNET Type 2A by magnifying endoscopy and subsequently resected by either HSP or EMR at the National Cancer Center Hospital East between January 2018 and June 2021. We divided all polyps into two groups based on the treatment method, HSP and EMR group, respectively, and performed propensity score matching using age, gender, antithrombotic medication, lesion size, localization, morphology, and endoscopist experience as covariates.

And we compared en bloc resection rate, R0 resection rate, and the adverse events including delayed bleeding and perforation between HSP and EMR in the score matched cohort.

Results: Of the enrolled 565 polyps in 463 patients, 440 polyps in 346 patients were resected by HSP and 125 polyps in 117 patients were resected by EMR. After propensity score matching, 117 polyps in HSP group and 117 polyps in EMR group were finally selected, and almost all baseline characteristics became balanced (standardized differences < 0.1 between HSP and EMR). In the matched cohort, the en bloc resection rate was comparable in HSP group and EMR group (93.2% [109/117] vs 92.3% [108/117], chi-square test P=0.80).

There was no significant difference between HSP group and EMR group in the R0 resection rate (77.8% [91/117] vs 80.3% [94/117], P=0.63). The incidence of delayed bleeding was similar in the both groups, at 1.7% [2/117]. Perforation did not appear in the HSP group, but appeared in the EMR at 0.9% [1/117] (P=0.32).

Conclusion: There was no difference in treatment outcome between bipolar HSP and EMR. With bipolar snares, an effective and safe endoscopic resection may be achieved without submucosal injection for colorectal lesions sized 10-15 mm.

Introduction: Cancer stem cells (CSCs) are implied in tumour formation, metastasis and recurrence. Here, we aimed to optimize and apply a phenotypic high-throughput screening (HTS) platform to identify novel molecules from diverse compound libraries that specifically impact on colorectal CSC phenotype.

Aims & Methods: Cell viability of HT-29, SW-620 and HCT116 cell lines plated at low density, in undifferentiated medium, in ultra-low attachment conditions for sphere formation was assessed upon incubation with compounds from in-house and external libraries for 7 days. Hit efficacy was validated *in vivo* in a HT-29 xenograft model at 10 mg/kg i.p., 3 days/week. The *in vivo* extreme limiting dilution assay was further used to determine the impact of the lead in colorectal CSCs. Target deconvolution was performed by machine learning, and molecular docking further applied to specific targets. The viability of CSC-enriched tumorspheres treated with the hit in the presence or absence of chemical inhibitors of distinct cell death modalities was assessed.

Results: The primary screening tested ~1500 compounds at 1 µM in HT-29-derived tumorspheres, leading to a 10% hit rate for the full library. Dose-response curves were built, and 69 compounds showed a half-maximal inhibitory concentration (IC₅₀) ≤ 2 µM. Twenty-four compounds were further selected based on their structural diversity and predicted drug-like properties and 17 compounds displayed an IC₅₀ ≤ 2 µM in HCT116 and SW-620 spheroids. From those, 7 compounds at the IC₅₀ dose robustly decreased the number and/or area of spheres *in vitro*.

Finally, 5 compounds were well tolerated in mice and prevented tumour growth in subcutaneous xenografts, accompanied by a reduction of stemness and increased differentiation markers. From those, 2 hits were tested *in vivo* extreme limiting dilution assay, showing the ability to reduce the colorectal cancer-initiating cell frequency.

Computational tools identified Bcl-2 as the putative target more prevalent in actives, while differentiation, iron homeostasis and ferroptosis are signalling pathways commonly modulated. The docking score and ligand efficiency, two readouts produced by molecular docking, further validated Bcl-2 as a potential target of a novel chemical scaffold. Curiously, although Bcl-2 is low expressed in HT-29 cells, the hit induced apoptosis, necroptosis and ferroptosis in both HT-29- and HCT116-derived CSC-enriched tu-

morspheres, concomitant with an increased extracellular release of ATP, a well-established damage associated molecular pattern. Future work will further validate the induction of immunogenic cell death by the hit, and dissect the contribution of Bcl-2 for its effect.

Conclusion: In conclusion, an HTS platform to test a wide range of candidate compounds targeting CSCs was developed, allowing the identification of novel colon cancer stem cell inhibitors that may grasp the tumor biological space and this therapeutic arena. In particular, a novel chemical scaffold was identified as an inhibitor of both bulk colon tumor cells and CSCs by triggering multiple types of regulated cell death with potential immunogenicity.

Introduction: Non-right-sided obstructive colon cancer (NROCC) is an emergency situation causing high morbidity and mortality in the short term. Although emergency surgery is regarded as standard therapy for NROCC, one-stage surgery without colostomy is occasionally difficult in this emergency setting. Trans-anal colorectal tube (TCT) and self-expanding metallic stent (SEMS) are alternatives to conventional surgery for NROCC, enabling one-stage surgery without colostomy. We have previously shown that TCT can achieve safe one-stage surgery with laparoscopy-assisted colectomy¹ and equivalent long-term outcomes to emergency surgery for stage II/III NROCC².

SEMS is another alternative treatment for NROCC used worldwide; however, it remains controversial which one can achieve better short-term outcomes. Hence, we conducted a multicenter retrospective case-control study to analyze TCT and SEMS for NROCC, focusing on short-term outcomes.

Aims & Methods: Data from consecutive stage II/III NROCC patients who underwent surgery between January 2010 and December 2019 were retrospectively reviewed using the computerized databases at eight Japanese affiliate hospitals with the mutual exchange of endoscopists. NROCC was defined as obstructive colon cancer located in the transverse to the sigmoid colon. Propensity score (PS) matching was used to adjust baseline characteristics between the TCT and the SEMS groups.

Results: Among the 239 patients with stage II/III NROCC (TCT group 163 cases, SEMS group 76 cases), the PS matching identified 115 cases in the TCT group and 65 cases in the SEMS group. Baseline characteristics were well balanced between the two groups.

No significant differences were found in the technical success rate (TCT vs. SEMS, 98.3% vs. 98.5%, $p > 0.999$), clinical success rate (TCT vs. SEMS, 89.6% vs. 95.4%, $p = 0.175$), decompression-related perforation (TCT vs. SEMS, 7.0% vs. 4.6%, $p = 0.748$), and postoperative complications ($\geq$ grade 3) (TCT vs. SEMS, 10.4% vs. 7.7%, $p = 0.546$) between the TCT and SEMS groups. There were no deaths within 30 days of decompression in both the TCT and SEMS groups.

The primary resection/anastomosis rate in the SEMS group was significantly higher than in the TCT group (TCT vs. SEMS, 77.4% vs. 90.8%, $p < 0.001$), and overall stoma rates were significantly lower in the SEMS group than in the TCT group (TCT vs. SEMS, 22.6% vs. 9.2%, $p < 0.001$). The SEMS group achieved a significantly higher laparoscopic surgery rate than the TCT group (TCT vs. SEMS, 43.5% vs. 64.6%, $p < 0.001$).

Furthermore, the technical decompression time was significantly shorter in the SEMS group than in the TCT group (TCT vs. SEMS, 26 minutes vs. 21 minutes, $p = 0.046$).

Conclusion: Although both SEMS and TCT achieved similar technical and clinical success rates, SEMS placement enabled more primary resection/anastomosis and laparoscopic surgery than TCT for stage II/III NROCC patients, with shorter decompression times.

Introduction: Malignant colorectal polyps (MPs) are polyps in which histology confirms the presence of carcinoma invading into the submucosa. A dilemma is evident after diagnosis of a MP: is surgery necessary to warrant complete clearance of disease or is polypectomy enough? The risks of major resectional surgery when no remaining disease is present versus recurrent/residual disease not properly treated are clear.

Aims & Methods: This was a single center, retrospective study, involving a cohort of patients referred to a multidisciplinary team (MDT) after endoscopic resection of MP between 2015-2021.

The primary aim was to assess the overall management of MPs in our center, the level of histological reporting of MPs and oncologic outcomes. Clinical, endoscopic and histopathological features were collected. High risk malignant polyp was considered if at least 1 high risk feature (HRF) was present; piecemeal resection; invasion depth > 1 mm (Haggitt 4: pedunculated tumours; Kikuchi 2/3: non pedunculated tumours); lymphovascular invasion; tumour budding; poor differentiation; positive resection margins/cannot be assessed.

Results: 72 patients were included, with 65% ($n=47$) being males and a median age of 69 (34-90) years. The median size of lesions was 20 mm (8-60) and most were located at sigmoid colon 61,1% ($n=44$). A polypoid morphology was present in 84,7%.

Piecemeal resection was performed in 27,8% (n=20); invasion depth > 1 mm in 30,6% (n=22) and not quantified in 58,3% (n=42); positive, indeterminate, or < 1 mm vertical margin in 62,5% (n=45); lymphatic invasion in 6,9% (n=5) and not reported in 16,7% (n=12); vascular invasion in 2,8 % (n=2) and not reported in 12,5% (n=9); poor differentiation in 2,8% (n=2) and degree not differentiated in 11,1% (n=8); tumour budding was present in 23,6% (n=37) and not reported in 66,7% (n=48); Haggitt 4 in none and Kikuchi 2/3 in 9,7% (n=7).

Overall, 75% (n=54) of patients had at least one HRF. The median follow-up was approximately 26 months (6-52).

Surgery with lymph node dissection was proposed to 38 patients, but 3 patients refused. Laparoscopic surgery was the preferred approach (n = 26). Two anastomotic colorectal leakages occurred after sigmoidectomy, one case after open surgery and the other after laparoscopic approach.

One patient had prohibitive factors for surgery and was proposed for chemoradiotherapy and posterior 'watchful waiting' approach and is doing well.

A total of 36 (50%) patients were managed with surveillance.

Residual lesion in lymph nodes was found in 3 (8,6%) patients submitted to surgery (n=35), and no residual disease was found in bowel wall. Distant metastasis at follow-up were found in 2 patients in surveillance: one had recurrent cancer (rectum, piecemeal resection) with hepatic and pulmonary metastases and another patient died from hepatic metastases (rectum, piecemeal resection).

4 patients died of other causes, without evidence of local or metastatic disease at last follow-up.

Conclusion: Metastatic lymph nodes were identified in 8,6%, a value in accordance with the literature (7,0-13,0%) (1,2). Those managed with bowel resection had no residual invasive disease in the resection specimen, meaning many patients undergoing bowel resection gained no additional benefit from major surgery with its associated risks.

Our findings point out that variables such as tumour budding and depth of submucosal invasion are between the less reported in real-world clinical practice. Hence, we highlight the importance of achieving complete histological reports to better refine risk stratification.

Introduction: To prevent colorectal cancer, patients with familial adenomatous polyposis (FAP) undergo colectomy at a young age. In most patients an ileorectal/ileosigmoidal anastomosis (IRA/ISA) or ileal pouch-

anal anastomosis (IPAA) is created. We aimed to compare the quality of life and functional outcomes after IRA/ISA versus IPAA and after open versus laparoscopic surgery.

Aims & Methods: We performed a cross-sectional questionnaire study including FAP patients with IRA/ISA and IPAA. Quality of life was assessed using the Short Form-36 (SF-36) health survey. Functional outcomes included bowel function, urological function and sexual function and those were assessed using the Vaizey score (including stool frequency), International Prostate Symptom Score (IPSS) for both men and women, International Index of Erectile Dysfunction (IIEF) and the Female Sexual Function Index (FSFI).

The primary aim was to compare IRA/ISA to IPAA and in sub-analysis we compared open versus laparoscopic surgery, primary versus secondary IPAA (after previous IRA/ISA), handsewn versus stapled IPAA and IRA versus ISA. Moreover, we studied the relation between bowel function and quality of life.

Results: Questionnaires were sent to 115 patients and returned by 92: 25 IRA/ISA patients, 67 IPAA patients (response rate 80%). We only included patients who filled in the questionnaires over 50%. No difference in quality of life, urological function or sexual function were observed between the groups. Although the stool frequency was significantly higher in the IPAA group (7.3 ± 3.8 versus 4.8 ± 2.3 , $p = 0.002$), no difference in incontinence was observed.

Sexual function was significantly better in patients who underwent laparoscopic IPAA vs open IPAA and a non-significant trend towards a better bowel and urological function after laparoscopic IPAA was observed. These differences were not seen when comparing open to laparoscopic IRA/ISA. Patients with primary IPAA had a significantly better urological function compared to patients with secondary IPAA ($p=0.011$) and almost significantly better incontinence score ($p=0.065$).

Comparing patients with IRA vs ISA and handsewn vs stapled IPAA did not show any differences. Patients with a stool frequency of 8 or higher and patients with higher fecal incontinence score (Vaizey score >12) had a significantly lower quality of life.

Conclusion: FAP patients with IRA/ISA and IPAA reported equal outcomes on quality of life, urological and sexual function. Bowel function was worse after IPAA and since bowel function was related to quality of life, IRA/ISA seems the preferred type of operation, if safe in terms of rectal polyp burden.

For IPAA, laparoscopic surgery results in better functional outcomes, and IPAA after previous IRA/ISA has worse functional outcomes compared to primary IPAA. These findings inform surgical counseling. However, larger studies are needed to confirm our findings.

Introduction: In the current guidelines around the world, the indication of surgical resection (SR) with lymph node dissection for T1 colorectal cancers (CRCs) is based merely on the risk of simultaneous lymph node metastasis, with no consideration of metachronous recurrence or overall survival (OS). It is also unclear whether SR can prolong OS by reducing recurrence. Moreover, there is no clear guidances on whether the indication criteria for additional SR in elderly patients should be the same as in non-elderly ones.

Aims & Methods: The aim of this study is to reconsider the indication for additional SR after ER for T1 CRC patients, taking into account recurrence and age. Of the 1359 patients with T1 CRCs endoscopically or surgically resected at our center from April 2001 to March 2019, 1271 patients (excluding complications of advanced cancer or hereditary colorectal cancer and so on) were retrospectively reviewed.

The 1271 subjects were divided into endoscopic treatment alone (ER) and surgical resection (SR) groups, and the effects of SR on distant recurrence and overall survival (OS) were examined. The OS was also compared focusing on the target population of 80 years of age and older.

Results: The mean observation period was 73.5 months. No recurrence was observed in the 287 patients who had no factors for additional SR according to the JSCCR guidelines. Among the 984 patients for whom additional SR should be recommended, 6 (3.33%) of the 180 patients in the ER alone group recurred and 4 (2.22%) died, while 9 (1.12%) of the 804 patients in the SR group recurred and 4 (0.50%) died.

Among the overall 1271 patients, the OS was significantly shorter in the ER alone group than in the SR group ($p=0.0017$). In those ≤ 80 years old, that was also shorter in the ER alone group ($p=0.047$), while in those >80 years, no significant difference was found in the OS ($p=0.49$) after propensity-score matching analysis.

Conclusion: For the overall T1 CRC patients, SR with lymph node dissection would reduce recurrence and prolong their OS, however, the effect on OS might disappear for the patients >80 years of age.

Introduction: Colorectal Cancer (CRC) is the third most common cancer diagnosed worldwide with an increasing incidence. In addition to traditional prognostic factors (high histologic grade, lymph node status, involved margins, tumor size) the identification of new clinical markers is the goal of ongoing research to improve the therapeutic management. In this context, there is growing awareness of the relationship between sarcopenia and outcomes in cancer including CRC, as sarcopenia patients may present impaired nutritional and immunological factors suggesting lower response to consecutive anti-tumor treatments.

Aims & Methods: The aim of our study was to determine the prevalence and to assess the impact of sarcopenia in CRC patients. we conducted a retrospective single-center study including patients diagnosed with CRC in between 2014 and 2021.

We collected anthropometric measurements, clinical, biological, histological data and outcomes. Total psoas muscle area (TPA) was determined by analyzing the tomographic total cross-sectional area of left and right psoas muscle at the level of lumbar 3rd vertebra at initial staging computed tomography. Then, the total psoas area index (TPAI) was calculated using the equation: $TPAI = TPA (mm^2) / height (m^2)$. The TPAI cut-offs used to define sarcopenia were $385 mm^2/m^2$ for female patients and $545 mm^2/m^2$ for male patients. We investigated the associated factors to sarcopenia. The Kaplan Meier method was used to analyse the influence of sarcopenia on overall survival (OS).

Results: Sixty-one patients were included. The mean age was 60.69 years (extremes: 32-88 years) and sex-ratio M/F of 2.05. The tumor was located in the right colon in 21 patients (34%), in the left colon in 22 patients (36%) and in the rectum in 18 patients (30%). Lieberkuhnien adenocarcinoma was the most frequent histological type (78.3%).

According to TNM classification, patients were mainly classified in stage II and stage III. Regarding treatment, 17 patients received neoadjuvant chemotherapy (27.9%), 10 patients received neoadjuvant radiotherapy (6.1%) and 51 patients underwent surgery (83.6%) divided between primary curative surgery (72%), urgent surgery (23%) and palliative surgery (5%). Adjuvant chemotherapy was indicated in 30 patients (62.5%).

The mean TPA was $555.95 \pm 222.12 mm^2$ (range 187.24-1718.24 mm^2). The overall incidence of sarcopenia was 42% (N=21) according to sex-adjusted cutoff. The mean survival was 27.35 months. The overall survival at 1 year and 3 years was of 76% and 67% respectively.

On univariate analysis, sarcopenia was significantly associated with elder age ≥ 65 years ($p=0.015$), male gender ($p=0.007$), bowel obstruction revealing CRC ($p=0.041$), lymphopenia ($p=0.015$), right-sided cancer ($p=0.036$), vascular emboli and perineural invasion ($p=0.03$). In terms of survival, sarcopenia was predictive of lower survival with statistically significant difference between the two Kaplan-Meier curves of sarcopenic versus non-sarcopenic patients (log rank test $p=0.008$).

Conclusion: In our study, pre-treatment sarcopenia negatively impacts the overall survival. Total psoas area index is valuable to assess sarcopenia which should be routinely screened in every patients with CRC at first presentation and considered in therapeutic management.

ENDOSCOPIC SUBMUCOSAL DISSECTION IS SAFE AND EFFECTIVE FOR LESIONS LOCATED AT THE ANO-RECTAL JUNCTION: ANALYSIS FROM TWO REFERRAL EUROPEAN CENTRES

M. Figueiredo Ferreira¹, J. Santos-Antunes², M. Marques², R. Morais², A. Lemmers¹, G. Macedo²

²Centro Hospitalar São João, Gastroenterology Department, Porto, Portugal

Contact E-Mail Address: mariana.fig.ferreira@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is well-established resection technique for colorectal superficial tumours. However, evidence of its efficacy in anorectal junctions is still scarce. We aimed to evaluate the feasibility, safety and efficacy of ESD for anorectal junction lesions (<20 mm from the dentate line) in comparison to more proximal rectal lesions.

Aims & Methods: Retrospective analysis of prospectively collected registries from two European referral centers, from 2015 to 2021.

Results: Two hundred and fifty-two lesions were included. From them, 60 (24%) were located in the anorectal junction, and the remaining 192 were located elsewhere in the rectum. Technical success was achieved in 248 procedures (98%), and it was similar in both locations ($p=0.246$). Most of them had high-grade dysplasia/ Tis adenocarcinoma (54%); 36 (15%) had submucosal adenocarcinoma, being 16 deeply invasive (>SM1 T1 cancers).

We found no differences between anorectal junction and rectal lesions regarding en bloc resection (100%vs96%, $p=0.204$), R0 resection (76%vs75%, $p=0.531$), curative resection (70%vs70%, $p=0.920$), duration of ESD (median 120min vs 90min, $p=0.072$), ESD velocity (14vs12 mm²/min, $p=0.415$) or histopathology result ($p=0.053$), as well as the need of surgery due to a non-curative ESD (5%vs3%, $p=0.739$).

Also, delayed bleeding (7%vs8%, $p=0.709$), perforation (0%vs5%, $p=0.075$) and the need of late admission due to adverse events (2% vs 2%, $p=0.939$) was similar. Ano-rectal stenosis ($p=0.003$) and anorectal pain ($p=0.002$) were more frequent in anorectal junction lesions.

Conclusion: ESD is a safe and efficient resection technique for the treatment of rectal lesions located in the anorectal junction.

Introduction: Large >2cm colorectal mucosal neoplasms can be resected using endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR). Enbloc resection is desirable to provide accurate post-resection histological assessment; and to minimize risk of recurrence. EMR for larger lesions often requires piecemeal resection (EMR-p) and ESD has superior enbloc resection rates.

Colorectal ESD, however, is technically difficult, time consuming, and is associated with a steep learning curve. There is limited data evaluating predictors associated with difficult colorectal ESD. The current single center clinical audit of colorectal ESD identifies factors predicting difficulty to perform colorectal ESD and those increasing risk of failure of enbloc resection; and calculates the learning curve to achieve competency to perform colorectal ESD for large (>2cm) colorectal mucosal neoplasms.

Aims & Methods: Single center retrospective evaluation of a prospectively maintained database. Study duration – 10 years (2012 – 2021). Data of 149 consecutive patients with large >2cm colorectal mucosal neoplasms undergoing ESD was abstracted. Parameters studied included colonic segment (rectum, left, right, anastomotic site), prior resection attempt, dissection speed (S), adverse events (AE), enbloc and R0 resection rates. Primary outcome was to identify factors predicting difficulty while performing ESD. Secondary outcomes were to identify risk factors for failure of enbloc resection and to assess the learning curve based on enbloc resection rate, S and AE.

Results: N = 149; mean age – 61.36 years, 101 males (67.8%). Mean size of colorectal neoplasm –46.62mm (±25.46), Median 40mm (IQR 30-60, Range 20-125). Successful enbloc resection – 141/149 (94.6%), (EMR-p = 7, failure – 1) and successful R0 resection – 132/142 (92.9%). AEs = 6 (4%) – Bleeding – 1 (Endotherapy), deep muscle injury – 2 (Endotherapy – 1, Surgery – 1), Others-3 (unrelated, treated conservatively). Mean S for cohort was 9.03 ± 7.94 mm²/min. Speed was fastest for rectum – 10.9 and slowest for right colon – 4.22 with sigmoid – 5.72, anastomotic site – 4.72 being in between. Mean procedure time was significantly prolonged in patients with previous resection attempt (298.44 min ±161.1) compared to naïve lesions (209.77 min ±146.44) ($p<0.009$).

Increase in procedure time showed a significant positive correlation with increase in area of the lesion ($\rho = 0.64$, $p = <0.001$); with procedure time increasing by a mean 3min for every 100mm² increase in area of the lesion. ROC curve analysis estimated lesion size of ≤ 68 (mm) as a predictor for enbloc resection (PPV 95.8%, OR 14.06, $p<0.001$). Univariate regression analysis identified size of the lesion as the single independent predictive factor for enbloc resection (OR 0.96; 0.95–0.98; $p < 0.001$).

Tumor location and prior resection attempt were associated with dissection speed and AEs, but not with enbloc resection. Learning curve analysis revealed a minimum 47 procedures to attain competency in colorectal ESD.

Conclusion: This clinical audit of colorectal ESD from a non-endemic population for lower GI polyps and mucosal cancers revealed that lesion size was the single most important determinant of success for enbloc resection. Lesions in the right colon, anastomotic site and patients with history of previous resection attempts were associated with longer procedure times. The learning curve to attain competency in ESD was approximately 47 procedures.

Disclosure: Nothing to disclose.

Introduction: Although self-expandable metal stent (SEMS) insertion has been shown to be an effective therapy for palliation of obstruction from pancreatobiliary malignancy, Studies on comparative clinical outcomes to bypass surgery is limited.

Aims & Methods: This is a retrospective, single tertiary-center study that involved all consecutive patients with pancreatic cancer or biliary tract cancer who were treated with SEMS (n=58) or emergency surgery (n=5) for palliation of malignant colorectal obstruction between January 2005 and December 2021. Time to recurrent obstruction requiring additional intervention and stent patency was analyzed by Kaplan-Meier analysis. Factors related to clinical outcomes were analyzed by log-rank test and Cox regression analysis.

Results: The types of cancer included were 48 patients (82.8.2%) with pancreatic cancer, 3 patients (5.2%) with biliary cancer, and Gallbladder cancer is 7 (12.1%). The technical succession rate of the SEMS group and emergency surgery group was 98.1% (52/53) and 100%(5/5), and the clinical success rate was 91.4%(53/45) and 100%(5/5), respectively. There was no significant statistical difference between SEMS and the bypass operation group (p=0.349). Regarding the time to recurrent obstruction required additional intervention, there was no marginally improved longer duration of time to recurrent obstruction in the bypass operation group. (p=0.101)

When we analyzed in a subgroup of the stent population, palliative chemotherapy after stenting was associated with increased duration of stent patency(p=0.019, Log-rank).

Conclusion: In patients with colorectal obstruction due to pancreatobiliary malignancy, the short-term clinical outcomes of the bypass surgery group were comparable to the stent group. However, the surgery group showed a trend for favorable long-term outcomes in terms of reintervention-free survival. Palliative chemotherapy was associated with an increased duration of stent patency.

THE ENGLISH BOWEL CANCER SCREENING PROGRAMME: DESIGNED FOR AN ASYMPTOMATIC POPULATION, BUT IS THIS THE CASE?

S. Serna¹, R. Granville¹, T. Baldwin¹, A.M. Verma¹

¹Kettering General Hospital, Department of Digestive Diseases, Kettering, United Kingdom

Contact E-Mail Address: ajay.verma@nhs.net

Introduction: The English Bowel Cancer Screening Programme(BCSP) was designed to screen an asymptomatic middle-aged population for pre-malignant colonic adenomas and early colorectal cancer (CRC). Whilst the programme is considered a success, ~40% of those diagnosed with CRC are still having adverse outcomes with advanced disease which is non-curable.¹ When informing patients of a CRC diagnosis at colonoscopy, it is not uncommon to hear that they have had suggestive symptoms for many months. We aim to evaluate the proportion of patients diagnosed with CRC at BCSP, who have suggestive symptoms.

Aims & Methods: Data from the BCSP reporting database on symptoms recorded by the specialist screening nurse practitioners at pre-endoscopy assessments for patients diagnosed with CRC were analysed. Symptoms were classified as red flag(based on urgent cancer pathway referral criteria in England); change in bowel habit, rectal bleeding, weight loss, abdominal pain, and other; chronic diarrhoea, constipation, mucous discharge, urgency of defecation, rectal irritation.

Results: Data were analysed on symptoms recorded pre-endoscopy from 316 patients diagnosed with CRC in BCSP 2015-2021 (7 years) in the Northamptonshire County BCSP.

- 180 males (57.0%) / 132 female (41.8%) / 4 unrecorded (1.3%)
- Mean / median age = 68.0 / 68.7 years
- 69 patients were asymptomatic (21.8%)
- 247 patients were symptomatic (78.2%), **HR 3.58** (95% CI 2.63-4.88; **p <0.0001**)
- 166 had red flag symptoms (52.5%), **HR 2.41** (95% CI 1.75-3.32; **p <0.0001**)
- The most common reported symptom reported by patients was urgency of defecation (49.9%)
- The most common reported "red flag" symptom was change in bowel habit (45.8%)

Conclusion: This analysis significantly shows that the vast majority of patients diagnosed with CRC in the English BCSP were symptomatic, with over half having red flag symptoms. Those patients should have ideally been managed on symptomatic pathways (especially those with "red flag" symptoms) in a timely manner.

Despite the BCSP in England being aimed at an asymptomatic population, it is possibly acting as a safety net for those with suggestive symptoms for weeks or months. It is sobering to contemplate that without a BCSP colonoscopy diagnosing CRC, some of these patients may have presented later as an emergency with a severe complication such as bowel obstruction or metastatic disease.

The English population awareness about symptoms of CRC, and the effectiveness of symptomatic pathways in identifying symptoms and managing patients with CRC needs to improve.

Contact E-Mail Address: denysenko.natalia@gmail.com

Introduction: Colorectal cancer (CRC) is the third most common malignancy and the second most deadly cancer worldwide. This makes the search of promising drugs be an actual objective for biomedical sciences. Management of malignancies is frequently accompanied with activation of free radical oxidation. On the one hand this effect provides efficiency of chemotherapy, on the other hand – the side effects.

Aims & Methods: The aim of this research was to investigate the changes of free radical oxidation in colon mucosa (CM) of rats with CRC after the action of compounds with anticancer properties (Les-6485, Les-5303). Male Wistar rats were divided into 4 groups: 1 – control, 2 – CRC, 3 – CRC + Les-6485, 4 – CRC + Les-5303. CRC was induced by administration of dimethylhydrazine in a dose 20 mg/kg/week for 20 weeks.

The experimental compounds are the derivatives of 4-thiazolidinone, were tested for their anticancer activity *in vitro* and showed a selective effect on the growth of several colon cancer cell lines, especially COLO-205, HCC-2998, HCT-116, HCT-15, HT29, KM12, SW-620. It is assumed that mechanism of anticancer properties of tested compounds involves activation of caspase 3 and Nrf2-Keap1 pathway.

After euthanasia specimens of colon for histological investigation were taken. Homogenates of CM were used for determination of superoxide dismutase (SOD), glutathione peroxidase (GPO), myeloperoxidase (MPO) activity, concentration of reduced glutathione (GSH), TBA-active products and products of proteins oxidation (aldehydes and ketones).

Results: CRC caused threefold increase of MPO activity whereas activity of both GPO and SOD decreased by 25% compared to control group. Concentration of GSH was reduced by 12%, both MDA and neutral ketones content raised by 14%, concentration of basic aldehydes – by 24% compared to control group.

Dimethylhydrazine model of CRC is based on inflammation, which stimulates the activity of MPO and thus cause the oxidative stress. Compound Les-6485 increased the level of GSH by 13% which might raise the antioxidant capacity.

This lowered the accumulation of products of proteins oxidation, mainly basic aldehydes by 21% compared with CRC group. Compound Les-5303 augmented SOD activity by 34% compared with CRC group. Nevertheless, higher SOD activity in Les-5303 group was not enough to normalize the rest indices.

Conclusion: Considering the obtained data, we suppose that compound Les-6485 might have more potent antioxidant properties due to its structure which included extra group with anticancer properties. Being a Michael acceptor, compound Les-5303 can bind sulfhydryl groups including GSH and have less pronounced antioxidant properties.

Disclosure: Nothing to disclose.

Introduction: Irritable bowel syndrome (IBS) has been described as a disorder of the microbiome-gut-brain axis, associated with both gastrointestinal (GI) and psychosocial symptoms¹. The gut microbiota may differ between people with IBS and those without², and may be a potential therapeutic target. Clinical trials have demonstrated improvements in GI symptoms, depression, anxiety, and quality of life following supplementation with *Bifidobacterium longum* 35624 and 1714 individually and in combination³⁻⁵, however real-world evidence is limited.

Aims & Methods: This real-world experience programme aimed to evaluate GI and psychosocial symptoms of people with IBS who received a supplement containing *Bifidobacterium longum* 35624 and 1714 (Dual Strain). Participants were referred to the 12-week programme by UK registered dietitians, to receive Dual Strain (1x10⁹ colony-forming units, once-daily). Abdominal pain, distension, bowel habit dissatisfaction (frequency and ease), stress, fatigue, mood and impact to daily life over the previous 2 weeks were assessed at baseline and 4-week intervals by 10-point Likert scale in an online survey. Interim statistical analysis compared data from baseline and week 4 using Wilcoxon signed-rank test.

Participants prescribed antibiotics during the programme were excluded from the primary analysis but included in a sensitivity analysis. Results are presented as percentage of participants, mean±SD scores, and calculated percentage change over time.

Results: 63 participants (75% female, 24% male, 1% other; 55% aged <34y, 22% 35-54y, 23% ≥55y) completed surveys at baseline and week 4, of whom 8 (13%) were prescribed antibiotics during the programme and excluded from primary analysis.

Outcome	Baseline	Week 4	Mean percentage change	p-value
Abdominal distension	6.15±2.80	4.67±2.44	24%	p=0.0002
Abdominal pain	5.42±2.53	4.04±2.28	25%	p<0.0001
Bowel habit dissatisfaction	6.38±2.06	4.82±2.33	24%	p<0.0001
Stress	6.49±2.28	5.78±2.42	11%	p=0.02
Fatigue	7.24±2.10	6.35±2.24	12%	p=0.01
Mood*	4.85±1.84	5.82±1.99	20%	p=0.005
Impact to daily life	6.36±2.15	4.51±2.29	29%	p<0.0001

*For all outcomes except 'mood', lower Likert scale scores indicate positive outcomes, whilst higher scores indicate negative outcomes (e.g. abdominal pain 0=no pain, 10=severe pain). For 'mood', scores were inverted (0=low mood, 10=good mood).

Table. Mean±SD 10-point Likert scale symptom scores before and 4 weeks after supplementation with Dual Strain.

All participants (n=55, 100%) reported being affected by GI symptoms (abdominal distension 85%; abdominal pain 73%; diarrhoea 65%; constipation 45%); 85% also reported psychosocial symptoms (stress from con-

dition 67%; fatigue 65%; anxiety/low mood 49%; sleep disruption 45%). At week 4, significant improvements ($p \leq 0.02$) were observed for all symptoms, including abdominal pain (1.38 ± 2.51), distension (1.47 ± 2.59), bowel habit dissatisfaction (1.56 ± 2.55), stress (0.71 ± 2.39), fatigue (0.89 ± 2.44), mood (0.96 ± 2.36), and impact to daily life (1.85 ± 2.36) (Table).

Overall, the mean percentage improvement for all symptoms was 21% (range 11–29%), with impact to daily life improving by the greatest increment. Results of the sensitivity analysis ($n=63$), including those prescribed antibiotics, were similar and remained statistically significant.

Conclusion: These real-world data are consistent with clinical research findings that supplementation with *Bifidobacterium longum* 35624 and 1714 may produce strain-specific clinical benefits in people with IBS. Further research investigating the mode of action of these combined probiotic strains is warranted.

Introduction: Hypermobility spectrum disorders (HSD), previously known as joint hypermobility syndrome, have been associated with disorders of gut brain interaction (DGBIs) such as irritable bowel syndrome (IBS). HSD encompasses a spectrum of disorders – on the one end there is symptomatic generalized joint hypermobility (gJHM)(i.e. the capability of a joint to move beyond normal limits) –hypermobile Ehlers Danlos Syndrome

(hEDS) on the other. Joint hypermobility is the key characteristic of all subjects along the entire spectrum. Disordered autonomic regulation has been suggested as a possible underlying mechanism in symptom genesis in hypermobile patients with DGBIs, but the exact mechanisms behind these overlapping syndromes still need to be unraveled.

Aims & Methods: The aim of this study was to determine the prevalence of generalized joint hypermobility and HSD in an IBS population, and to evaluate differences in clinical presentation between subjects with and without gJHM or HSD. 258 (Rome III) IBS patients were included.

Patients included prior to 2015 were screened retrospectively for gJHM and HSD using a validated questionnaire (JHM Questionnaire) and subsequently assessed by physical examination, using the Beighton score and Brighton criteria. Those included after 2015 were assessed prospectively by physical examination.

Subjects were categorized as non-hypermobile, gJHM, or HSD. Subjects also completed the Gastrointestinal Symptom Rating Scale for gastrointestinal symptom severity, Hospital Anxiety and Depression Scale to screen for (subclinical) depression and anxiety, and RAND 36-item Short-Form Health Survey for quality of life.

Results: Of the 258 subjects, 195 were screened using the JHM questionnaire, and 63 subjects were directly assessed by physical examination. In the questionnaire group, 58 subjects (29.7%) scored positive and in total 35 subjects (15.6%) had gJHM. In the prospective group, 20 subjects (31.7%) had HSD. Hypermobile subjects were more often female and significantly younger than non-hypermobile subjects, but these differences were not found for HSDvs.no HSD. No differences could be demonstrated in gastrointestinal symptom severity, subclinical anxiety/depression, or quality of life when comparing gJHM/HSD tonon-hypermobile/non-HSD counterparts.

Conclusion: gJHM and in particular HSDs are present in substantial numbers (~30%) in a heterogeneous group of IBS patients. However, when comparing IBS patients with gJHM or HSD to their non-hypermobile/non-HSD counterparts, no apparent differences in gastrointestinal symptoms, depression, anxiety, and quality of life were found.

Future studies should focus on differences in additional somatic symptoms (including overlapping DGBIs), autonomic symptoms, and somatization scores, in order to unravel the question of whether IBS patients with a comorbid diagnosis of joint hypermobility or HSD represent a specific subgroup within the IBS population.

NETWORK MODELLING IN CHRONIC CONSTIPATION: DELINEATING DISEASE PHENOTYPES

R. Rajiah¹, C.E. Ng², R.L. Embleton², Y. Yiannakou², J. Ruffle³

¹Brighton & Sussex Medical School, Brighton, United Kingdom,

²County Durham and Darlington NHS Foundation Trust, Durham, United Kingdom, ³Queen Square Institute of Neurology, University College London, London, United Kingdom

Introduction: Chronic constipation (CC) is a common condition affecting 14% of adults worldwide. Attributed to a complex and multifactorial underpinning pathophysiology, CC remains both incompletely understood and difficult to treat. Patients with CC experience an array of debilitating symptoms, which may interact to worsen quality of life. Yet, the impact on a patient's overall health and quality of life caused by interacting symptoms is unknown. To address this, we applied graphical modelling to characterise these symptom interactions and better interrogate the disease process. By treating this complex heterogeneity in clinical features as a network, we aimed to delineate the core connective features in CC symptomology and outline the structure of the underlying symptom constellations such that key links may be revealed and constituent disease phenotypes better understood.

Aims & Methods: Objective: To characterise the network constellation of symptoms afflicting patients with CC and identify constituent disease phenotypes.

Methods: Patient assessment of constipation symptoms (PAC-SYM) and quality of life (PAC-QOL) questionnaires were collected in 786 CC patients prospectively from a tertiary centre over 7 years. We investigated the interplay between symptoms and quality of life (QOL) domains in a graphical domain, utilising weighted undirected graphical networks, quantifying centrality metrics and applying Bayesian inference to derive the community structure of underpinning symptom and QOL domains.

Results: Statistically significant positive correlations were found between many common CC features, including abdominal discomfort and eating less ($r>0.42$), painful bowel movements and rectal burning ($r>0.53$), and stress with decreased self-confidence ($r>0.70$) (all $p<0.0001$). Features with the greatest eigenvector centrality comprised factors relating to mental wellbeing, including the presence of stress, irritability, sadness, decreased self-confidence and worry over lack of bowel movements. Use of the Bayesian generative stochastic block model revealed six distinct phenotypic symptom/QOL clusters spanning the following domains: abdominal symptom burden, rectal symptom burden, treatment dissatisfaction, mental health impact, and impact upon daily life.

Conclusion: Network modelling reveals the associations between symptoms and quality of life disruptors in an unprecedented sample size of patients afflicted with chronic constipation. The results yield an improved understanding of this patient population, wherein stratification of symptom and QOL impacts is apparent across distinct domains.

Future work should evaluate if these graphical representations can be used to facilitate personalised medicine, with treatment allocation based upon targeted therapies to a given symptom cluster.

Introduction: The pathophysiology of irritable bowel syndrome (IBS) is not completely understood; however, dysregulation of the brain-gut axis is believed to lead to IBS. Various central and peripheral mechanisms are indicated to be involved, such as altered GI motility, visceral hypersensitivity, alteration of the intestinal microbiota, low-grade immune activation, and intestinal inflammation, which may be linked to enhanced exposure to antigens due to increased intestinal permeability. Fecal calprotectin (FC) is a marker of intraluminal intestinal inflammation that could have a clinical utility in identifying IBS patients with more inflammation.

Aims & Methods: Aims: To explore the levels of FC in IBS-diarrhea (IBS-d) patients and healthy controls (HC) and to correlate the levels of FC with clinical characteristics and inflammatory and anti-inflammatory cytokines.

Material and methods: We included 129 patients aged over 18 years referred to tertiary hospital outpatient with Rome IV criteria for IBS-d, in whom normal colonoscopy and appropriate tests had excluded organic disease, and 53 HC (mainly patients relatives) with no history of gastrointestinal disorders and no bowel-related symptoms. None of the subjects included in the study was taking any medications known to affect the gastrointestinal tract or the immune system.

Clinical, laboratory data, blood and stool samples were collected. FC was measured quantitatively using a commercially available enzyme immunoassay ((Bühlmann Laboratories, Shönenbuch, Switzerland). 27- pro and anti-inflammatory cytokines (Bio-Plex Pro™, Bio- Rad) were measured in serum. IBS-d patients completed the Bristol scale and IBS severity score. FC levels adjusted for age, sex, and BMI among patients with IBS-d and HC were analyzed by linear regression. Correlations between IBS severity, levels of cytokines and FC were analyzed through the Spearman correlation coefficient.

Results: IBS-d patients has a mean age of 56 ± 16 , ($F=79\%$). HC 52 ± 7 , ($F=60\%$). Compared with HC, IBS-d patients had significantly higher median FC levels after adjusting for age, sex, and BMI ($63 \mu\text{g/g}$ [IQR 40-127] vs $33 \mu\text{g/g}$ [IQR 22-49], $p=0.000$). 29 (22%) patients with IBS-d had calprotectin values greater than $150 \mu\text{g/g}$.

In IBS-d patients, no significant correlation was observed between IBS severity and FC levels. Neither between the number of bowel movements per day and FC levels. There was a positive correlation between FC levels and the levels of IL-8 ($\text{Rho } 0.27$, $p=0.007$), IL-10 ($\text{Rho } 0.28$, $p=0.005$) and IP-10 ($\text{Rho } 0.21$, $p=0.04$).

There was a negative correlation between FC levels and distension Likert scale ($\text{Rho } -0.25$, $p=0.01$)

Conclusion: The FC level was significantly higher in patients with IBS-d than in HCs, regardless age, sex, and BMI. In IBS-d patients, no positive correlation was observed between FC levels and IBS severity or the number of bowel movements. FC levels was positive correlated with the levels of some serum cytokines, supporting the notion that IBS is a type of low-grade bowel inflammation.

BENIGN JOINT HYPERMOBILITY SYNDROME IN IRRITABLE BOWEL SYNDROME

I. Midenfjord¹, A. Polster¹, S. Lindholm¹, H. Törnblom¹, M. Simrén^{1,2}
¹Institute of Medicine, Department of Molecular and Clinical Medicine, Gothenburg, Sweden, ²Centre for Functional GI and Motility Disorders, University of North Carolina, Chapel Hill, NC, United States

Contact E-Mail Address: irina.midenfjord@gu.se

Introduction: Previous literature suggests a higher prevalence of irritable bowel syndrome (IBS) in hypermobility disorders (Beckers et al 2017), but few studies exist evaluating the prevalence of benign joint hypermobility syndrome (BJHS) in IBS. Hence, our aim was to assess the prevalence of BJHS in IBS and to characterize IBS patients with and without BJHS.

Aims & Methods: Patients with a prior IBS diagnosis and actively seeking health care for IBS (N= 68), and subjects without documented or self-reported chronic diseases volunteering for participation in research (N=124) were included 2015-2020 and completed the Rome III diagnostic questionnaire. They were divided into groups with or without IBS according to the Rome III criteria for the subsequent analyses.

The presence of BJHS was assessed through the revised Brighton criteria (Grahame et al 2000). The subjects also completed questionnaires to assess severity of IBS symptoms (IBS-SSS), anxiety (HAD-A), depression (HAD-D), somatic non-GI symptoms (PHQ12), GI-specific anxiety (VSI) and pain catastrophizing (PCS).

Results: In total, 99 subjects with IBS and 93 without IBS were included. The participants with IBS were older and more likely female than the subjects without IBS, and reported more severe GI and non-GI symptoms overall (table). A trend towards a higher prevalence of BJHS in the IBS group was seen (p=0.06), and the IBS subjects more often had hypermobile backs (58% vs. 41%, p=0.04) and arthralgia in 1-3 joints (36% vs. 17%, p=0.07) or in 4 or more joints (9% vs. 1%, p=0.02). Subjects with IBS and BJHS were not clearly different from subjects with IBS alone regarding GI and non-GI symptoms (table). A numerical difference, although not reaching statistical significance, was seen in the IBS subtype distribution comparing those with and without BJHS.

Conclusion: Benign joint hypermobility syndrome is relatively common among subjects with IBS, and they frequently report hypermobile backs and arthralgia. However, clear differences in other symptoms were not evident in subjects with IBS with or without joint hypermobility. Acknowledging the presence of joint symptoms in patients with IBS seem to be one important aspect of the holistic management approach recommended in this patient group.

	Subjects with IBS (N=99)	Subjects without IBS (N=93)	P-value	Subjects with IBS alone (N=63)	Subjects with IBS and BJHS (N=36)	P-value

Introduction: Antibody reactivity to gluten has been suggested to be linked to symptoms of patients with irritable bowel syndrome (IBS) (Uhde et al. *Gastroenterology*, 2020).

Aims & Methods: We aimed to assess the prevalence of serum antigliadin (AGA) specific Immunoglobulin-G (IgG) antibodies in IBS, and to identify associations between AGA IgG, including subclasses, and gastrointestinal symptoms in IBS.

IBS patients (n=506; 78% females; all with negative tissue transglutaminase IgA antibody tests) provided serum samples as well as recordings of gastrointestinal symptoms (GSRS-IBS), bowel habits (BSF), and psychological distress (HADS). Demographics included sex, age, and body mass index (BMI). Levels of total AGA IgG and subclasses (IgG1-4) were assessed by Gliadin IgG ELISA (IBL International Hamburg, Germany). IgG subclass

profiles were assessed in those with a positive AGA IgG test (>14.0 U/mL) and in a set of IBS patients with negative AGA IgG test (n=11). The IgG values were normalized by the mean of the negative controls. AGA IgG1–4 tests were considered as positive when the concentrations were at least two standard deviations higher than the mean concentrations of the negative controls.

Associations between AGA IgG, IgG1–4 and demographics/IBS symptoms/psychological distress were assessed with Mann Whitney U tests and followed by false discovery rate (FDR) correction (q<.05). Data are presented as medians with interquartile range.

Results: In total, 11% (n=54) of the IBS patients had a positive AGA IgG test. Demographics, IBS symptoms and psychological distress did not differ between patients with a positive versus negative AGA IgG test. A lower BMI was associated with a positive AGA IgG test (Table). Among IgG subclasses, a positive test was observed in 8% (n=43) for AGA IgG1, 10% (n=51) for AGA IgG2, 1.6% (n=8) for AGA IgG3, and 9% (n=48) for AGA IgG4. No associations were observed between gastrointestinal symptoms and positive AGA IgG1–4 tests.

Table	AGA IgG total		P
	Positive (n=54) (≥14.0 U/mL)	Negative (n=452) (<14.0 U/mL)	
Female sex, %	77	76	.80
Age, years	21 (26–47)	35 (27–47)	.37
BMI, kg/m ²	22 (21–24)	24 (21–27)	<.01#
IBS-C/D/nonCnonD), %	37/26/37	35/35/30	.63
Stool frequency/day	1.6 (1.2–2.2)	1.7 (1.3–2.4)	.38
Stool consistency (BSF)	3.7 (2.6–4.4)	3.8 (2.8–4.8)	.39
GSRS-IBS total	3.8 (3.4–4.2)	3.8 (3.4–4.4)	.68
Abdominal pain	4.5 (3.5–5.0)	4.0 (3.5–5.0)	.78
Abdominal bloating	4.7 (3.7–5.3)	5.0 (4.0–5.7)	.13
Diarrhea	3.8 (2.9–4.0)	3.5 (2.8–4.5)	.76
Constipation	3.0 (1.5–4.5)	3.0 (1.5–4.6)	.78
Satiety	3.5 (2.0–4.0)	2.5 (1.5–4.0)	.28
Psychological distress (HADS)	10 (7–15)	11 (7–16)	.85

AGA, antigliadin antibodies; BSF, Bristol stool form; BMI, body mass index; GSRS-IBS, Gastrointestinal Symptom Rating Scale – IBS version; HADS, hospital anxiety and depression scale; IgG, immunoglobulin-G; IBS, irritable bowel syndrome; IBS-C, IBS with predominant constipation; IBS-D, IBS with predominant diarrhea; IBS-nonCnonD; IBS with mixed bowel habits or unspecified IBS. Significant results are shown in bold. # q<.05 after false discovery rate correction

Table.

Conclusion: A positive AGA IgG test, including IgG subclasses, does not have a clear association to common gastrointestinal symptoms in IBS. Follow-up studies are needed to understand the relevance of IgG antibody responses to gliadin for symptom generation in IBS.

Disclosure: Nothing to disclose.

Introduction: The pathophysiology of Irritable bowel syndrome (IBS) is multifactorial and includes alterations in intestinal permeability contributing to symptom generation. The present study aimed to assess: intestinal permeability of the gastrointestinal tract in a well-characterized IBS-D cohort and asymptomatic controls (AC); the correlations between intestinal permeability alterations and abdominal symptoms, psychological functioning and general health; the diagnostic accuracy of sugar test in discriminating between IBS-D and AC.

Aims & Methods: Eighteenand 31 patients with IBS-D have been enrolled. Rome IV criteria, Bowel disease questionnaire, Short Form 36, Hospital Anxiety Depression Scale were used to phenotype patients. Mannitol, lactulose, sucralose, and sucrose urinary excretion was assessed by HPLC-MS. The lactulose/mannitol ratio (L/M ratio) was calculated. Correlation analyses were performed between demographic and laboratory data. Receiver operating characteristic (ROC) curve analyses were used to evaluate the accuracy of sugar test in discriminating between IBS-D and AC.

Results: Compared to AC, lactulose (P<0.05), sucralose (P<0.01), sucrose (P<0.01) excretion and the L/M ratio (P<0.01) were significantly increased in IBS-D patients. Abdominal pain and bloating scores correlated with the excretion of all sugars. Anxiety score correlated with sucrose (P=0.026; rs:0.324) and lactulose (P=0.022; rs:0.333) excretion and with L/M ratio (P=0.001; rs:0.462). Depression score correlated with L/M ratio (P<0.0001; rs:0.552), sucrose (P=0.033; rs:0.311), lactulose (P=0.003; rs:0.420) and sucralose (P=0.039; rs:0.303) excretion.

Physical and mental health-related quality of life inversely correlated with L/M ratio, sucrose, lactulose and sucralose excretion. L/M ratio had the highest diagnostic accuracy in discriminating IBS-D from AC (AUROC: 0.773).

Conclusion: Intestinal permeability is increased along the entire gastrointestinal tract and correlates with abdominal and psychological symptoms and with health related quality of life. L/M ratio has the highest diagnostic accuracy in discriminating IBS-D from AC.

Disclosure: Nothing to disclose.

GASTROINTESTINAL SYMPTOMS AND AUTONOMIC DYSFUNCTION IN HEREDITARY TRANSTHYRETIN AMYLOIDOSIS: EARLY DETECTION AND MONITORING THROUGH THE COMPASS 31 SCORE

D. Brinch¹, V. Di Stefano^{2,3,2}, S. Muscarella¹, M. Saladino¹, F. Brighina³, M. Cappello¹

³Unit of Neurophysiopathology, Department of Biomedicine, Neuroscience and advanced Diagnostic (BIND), Palermo, Italy

Contact E-Mail Address: danielebrinch@gmail.com

Introduction: Hereditary transthyretin amyloidosis (hATTR) is a rare multisystemic hereditary disease which manifests mostly as sensorimotor polyneuropathy but can involve also the heart, the kidney and the eye and the gastrointestinal (GI) system. hATTR is a progressive and fatal disease, death occurs within ten years from the onset but novel gene silencing therapies are potentially able to arrest progression and prevent disability if used in early stages.

Data on the prevalence of GI disturbances are discrepant, they are common (56-69 %) but often misleading being non-specific: they can be the presenting symptoms and their underrecognition can cause diagnostic delay.

The aim of our study was to assess the prevalence and burden of GI involvement in a ethnically homogeneous cohort of patients with hATTR.

Aims & Methods: The aim of our study was to assess the prevalence and burden of GI involvement in a ethnically homogeneous cohort of patients with hATTR. We studied a cohort of sicilian patients with hATTR, diagnosed at our referral center for rare neuromuscular disease, focusing From January 2019 to December 2021 on the GI involvement and analysing distribution of symptoms and age of onset in relation to the age of diagnosis and to the onset of neurological disturbances. The burden of GI symptoms related to autonomic dysfunction was objectively assessed by the Compass 31 score, in particular 12 to 23 item were evaluated.

Results: 21 sicilian patients with hATTR were studied. All received genetic testing and 16 (76,2%) have the Phe84Leu mutation. 13/21 (62%) patients present GI symptoms (diarrhea 38 %), unintentional weight loss (38 %), constipation (23 %) and nausea (30%). GI involvement appeared before the diagnosis in 11/13 (85%) of patients (mean diagnostic delay 22 months); 9/11 (75 %) had also neurological symptoms (mostly bilateral carpal tunnel) suggestive of ATTR amyloidosis: mean global and GI COMPASS-31 score, evaluated at diagnosis, was 20 and 10, respectively.

Conclusion: Our experience confirm that GI involvement in hATTR is frequent (62%) but often underrecognized in spite of the presence of neurological red flags, thus leading to a diagnostic delay than can blunt the effectiveness of the new therapies. The Compass score for GI items confirms that autonomic dysfunction is the main pathogenetic mechanism and will be an effective monitoring toll for follow up.

Awareness of this rare disease must increase among gastroenterologists, who should be able to recognize the red flags that raise clinical suspicion. Their role in a multidisciplinary team could be relevant also in providing supportive measures to improve symptoms.

Disclosure: Nothing to disclose.

Introduction: Disturbance of the bidirectional brain-gut axis is increasingly recognized as a conceptual model of IBS pathophysiology, involving abnormal function in the enteric, autonomic and/or central nervous systems. Chronic stress is one of the confounding factors for gut brain miscommunication and pathogenesis of disorders of gut-brain interaction (DGBI) such as irritable bowel syndrome. Stress stimulates the HPA axis and then triggers the release of corticotropin-releasing factor (CRF) and cortisol, which directly or indirectly affect gut function, influences the composition and the growth of microbiota, and also stimulates the sympathetic nervous system. CRF enhances the release of mast cell mediators such as pro-inflammatory cytokines by acting on CRF receptors on the mucosal mast cells in the gastrointestinal tract.

These mediators act on intestinal epithelium to increase permeability and induce visceral hypersensitivity, representing two major pathophysiological features of IBS. STW 5-II, a combination of 6 herbal extracts, is a clinically proven treatment option for IBS and functional dyspepsia.

Aims & Methods: In this study we aimed to establish an organoid-based IBS-like model. This model has been used to investigate the molecular mechanisms of STW 5-II on CRF and stress-related inflammatory parameters in stress-induced IBS-like model.

Mouse intestinal organoids were cultured in Matrigel domes. The organoids were pretreated with increasing concentrations of STW 5-II (10, 20, 30 µg/ml) for 24 h followed by treatment with CRF (100 nM) for 48 h. Afterward, the effects of CRF and STW 5-II were studied using several *in vitro* and *in silico* approaches. We have investigated the expression of many pro-inflammatory mediators and cytokines such as NF-κB, TLR4, MYD88, IL-6, IL-1β, and TNFα using quantitative real-time PCR and microarrays analyses. The expression of NF-κB was additionally assessed via whole-mount immunofluorescence staining.

Moreover, the expression of the tight junction protein claudin-2 has been evaluated. ELISA was performed to study the activity of STW 5-II on CRF-mediated elevation of serotonin. Such activity towards CRF signaling was further confirmed by PyRx screening and molecular docking of the major 52 constituents in STW 5-II against both CRF receptors, CRFR1 and CRFR2.

Results: Stress-induced IBS-like model was successfully established in rat organoids.

Exposure to CRF has induced inflammation, as evidenced by the increased expression of the inflammatory mediators TLR4, MYD88, IL-1β, IL-6, TNFα, and NF-κB. STW 5-II was able to reverse these effects in a dose-dependent manner. STW 5-II was able to reduce CRF-mediated claudin-2 upregulation that could play a role in leaky gut. Moreover, STW 5-II inhibited CRF-mediated serotonin secretion in a dose-dependent manner.

Conclusion: STW 5-II counteracted stress-induced inflammation and tight junction disruption, one of the major predisposing factors for the development of DGBIs such as IBS. These multi-targets activities could substantiate and explain the clinically proven efficacy of STW 5-II in IBS.

IMPORTANCE OF BOWEL HABITS AS A RISK FACTOR OF INADEQUATE BOWEL PREPARATION IN COLONOSCOPY: A PROSPECTIVE QUESTIONNAIRE-BASED OBSERVATIONAL STUDY

N. Maeda^{1,2}, A. Higashimori¹, M. Nakatani², Y. Nakamura², A. Hashimoto², K. Morimoto², T. Fukuda², Y. Fujiwara¹
¹Osaka Metropolitan University Graduate School of Medicine, Gastroenterology, Osaka, Japan, ²Minami Osaka Hospital, Gastroenterology, Osaka, Japan

Contact E-Mail Address: natsu072407@yahoo.co.jp

Introduction: Inadequate bowel preparation (IBP) negatively affects the efficacy and quality of colonoscopy. Although constipation has already been reported as one of the most important predictors of IBP, there is limited information about the relation of IBP to bowel habit factors including symptoms, medications, and severity of constipation.

Aims & Methods: We aimed to investigate predictors of IBP focusing on symptoms, medications, and severity of constipation. This was a questionnaire-based prospective observational study in single institution. Between March and December 2019, 1157 consecutive outpatients underwent afternoon colonoscopy.

All patients received low-volume polyethylene glycol solution with ascorbate (Moviprep®) on the same day as the examination. Bowel preparation cleansing was evaluated using Boston Bowel Preparation Scale (BBPS). IBP was defined by BBPS<2 per each segment. Chronic constipation was diagnosed by ROME 4 criteria, which includes six questions regarding constipation-related symptoms. Severity of constipation was scored by Constipation Scoring System (CSS; range 0-30). Chronic use of laxatives was defined as uses more than 3 days per week for at least 3 months.

The potential predictors for IBP were age, male sex, high body mass index (BMI), abdominal/pelvic surgery, constipation, tricyclic antidepressant use, diabetes mellitus, stroke, Parkinson's disease, and cirrhosis. Exclusion criteria were incomplete total colonoscopy, colectomy, and active inflammatory bowel disease.

Results: A total 1049 patients were included. Their average patient age and BMI were 63.8±12.8 years old and 23.5±4.9 kg/m². IBP was found in 104 patients (10%) and chronic constipation was found in 290 patients (28%). At multivariate analysis, age, chronic constipation, and diabetes mellitus were independent risk factors for IBP. By dividing patients into 3 equal groups by CSS score (mild [CSS: 0-2], moderate [CSS: 3-8], and severe constipation [CSS: >9]), IBP rate was 15% in mild group, 18% in moderate group, and 23% in severe constipation group and IBP increased with CSS score (P for trend=0.01).

Among constipation-related symptoms, straining during defecations was a significant predictor of IBP (odds ratio (OR)=1.62, 95% confidence interval [CI] 1.03-3.36) after adjusting cofounders. Furthermore, chronic use of stimulant laxatives is an independent predictor of IBP (OR=2.57, 95% CI 1.59-4.17), whereas chronic use of non-stimulant laxatives was not related to IBP.

Conclusion: Chronic constipation was a risk factor of IBP, as expected. The risk of IBP increased with the severity of constipation. Straining and chronic use of stimulant laxatives were significant predictor of IBP. For severe constipated patients with straining and chronic use of stimulant laxatives, an intensified preparation regimen should be especially considered.

Disclosure: Nothing to disclose.

P0630

STUDY OF THE DIAGNOSTIC ABILITY OF ULTRASONOGRAPHY COMPARED TO CT FOR FECES IN THE RECTUM

N. Misawa¹, S. Tamura¹, T. Kessoku¹, T. Higurashi¹, A. Nakajima¹
¹Yokohama City University School of Medicine, Department of Gastroenterology and Hepatology, Yokohama, Japan

Contact E-Mail Address: nobomisa@yokohama-cu.ac.jp

Introduction: Chronic constipation is a common functional gastrointestinal disorder in older adults, and it is very important to manage chronic constipation. Computed tomography (CT) has been used to evaluate fecal masses in the rectum, but there are problems such as radiation exposure, cost, and the inability to evaluate at facilities where CT cannot be performed.

Ultrasonography (US) can be broadly applied in clinical practice because of its low cost, high safety, high speed and use of non-ionising radiation, and it is known that US observation of colonic faecal retention is useful for diagnosing constipation and evaluating the effectiveness of treatment. However, it is not yet known whether feces in the rectum can be accurately assessed by US.

Aims & Methods: In this study, we investigated the evaluation of fecal mass retention in the rectum using US. US was performed within 1 hour before and after CT in patients scheduled to undergo CT. Background information (age, gender, BMI), history (presence of chronic constipation, presence of diabetes mellitus), and findings of rectal stool (US and CT) were evaluated. Stool findings in the rectum were evaluated on three levels: no stool (R1), presence of stool (R2), and hard stool filling (R3), and the degree of agreement between CT and US findings was evaluated.

Results: A total of 96 cases (52 males and 44 females) were included in the study, of which 47 cases were constipated. 79 cases (R1: 45 cases, R2: 26 cases, R3: 8 cases) were matched with CT and US findings, and 17 cases were not matched, showing high statistical agreement (kappa coefficient 0.711, P<0.001). When evaluated in the constipation group and non-constipation group, all cases with R3 were found in the constipation group, while more than half of the cases with R1 were found in the non-constipation group. CT and US findings showed high agreement in both constipation and non-constipation groups (constipation group: kappa coefficient 0.717, P<0.001; non-constipation group: kappa coefficient 0.651, P<0.001). Cases that did not match were considered to have low urine volume or high gas.

Conclusion: CT and US showed a high degree of agreement in the evaluation of fecal mass retention in the rectum, indicating that US may be a substitute for CT.

In addition, many cases in the non-constipation group showed no stool in the rectum, whereas many cases in the constipation group showed stool accumulation findings. US was considered to be a simple, bedside, and objective method of diagnosing rectal fecal conditions without radiation exposure or other invasive procedures.

Disclosure: Nothing to disclose.

PREVALENCE AND PATHOPHYSIOLOGY OF FECAL CONSISTENCY DISORDERS AND THEIR IMPACT ON CLINICAL SEVERITY AND QUALITY OF LIFE IN PATIENTS WITH FECAL INCONTINENCE

A. Raventós¹, S. Carrión Bolorino¹, P. Clavé^{1,2}, L. Mundet^{1,2}

¹Hospital de Mataró (Consorci Sanitari del Maresme), GI Motility Unit, Mataró, Spain, ²Centro de Investigación Biomédica En Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain

Contact E-Mail Address: alba.ravens92@gmail.com

Introduction: Fecal incontinence (FI) affects up to 24% of middle-aged and older women, seriously impacting their health and quality of life (QoL). Pathophysiological studies have focused more on sphincter and anorectal dysfunctions than on the role of changes in fecal consistency.

Aims & Methods: To compare the impact of sphincter dysfunctions with changes in fecal consistency on pathophysiology, clinical severity and QoL in women with FI.

Cross-sectional observational study. We evaluated sociodemographics, medical history, anorectal physiology (HR anorectal manometry, endo-anal ultrasound, neurophysiology with pudendal nerve terminal motor latency (PNTML)) and fecal consistency (Bristol Scale). In patients with stools on Bristol Scale ≥ 5 we performed: a) breath-test to detect lactose, fructose/sorbitol malabsorption, bacterial overgrowth (SIBO), and an empirical test using cholestyramine (4g/12h for 2 weeks) to assess the presence of bile salt malabsorption. We compared anorectal physiology, clinical severity (Wexner/St.Mark's) and QoL (EQ5D/FIQL) of the group with Bristol ≥ 5 vs the rest.

Results: We studied 74 women with FI (St.Mark's 13 ± 3.59 /Wexner 10.82 ± 3.44), mean age 64.81 ± 11.96 . A total of 64.38% had emergency FI, 15.06% passive FI and 19.18% both. Up to 56.2% had soft stool consistency (Bristol ≥ 5) associated with: 20.5% bile acid malabsorption, 17.9% lactose intolerance, 14.3% fructose/sorbitol malabsorption, and 14.3% SIBO.

The sphincter dysfunction of the patients was homogeneous regardless of fecal consistency. A 66.6% had insufficiency of the external anal sphincter, 38.8% internal and 27.7% both, 37.5% had altered Valsalva reflex and 25.45% delayed PNTML. A 17.5% showed rectal hypersensitivity and 8.9% showed hyposensitivity.

Clinical severity (St. Mark's) worsened with Bristol ≥ 5 (14.2 ± 3 vs 12.3 ± 3.6 $p < 0.05$) as did QoL in the FIQL dimensions of lifestyle, coping, depression/self-perception ($2.7 \pm 0.8/2.2 \pm 0.8/2.6 \pm 0.7$ vs $3.3 \pm 0.6/2.8 \pm 0.7/3.1 \pm 0.5$ $p < 0.05$) and in the anxiety/depression dimension of the EQ5D (51.6% vs 24.7% $p < 0.05$).

Conclusion: More than 50% of patients with FI have excessively soft stools (Bristol ≥ 5). Sphincter dysfunction is severe and similar in patients with or without loose stools, but their presence worsens clinical severity and QoL significantly, requiring a specific diagnostic and therapeutic approach.

Disclosure: Nothing to disclose.

P0633

EFFECTIVE DIAGNOSIS OF DYSSYNERGIC DEFECATION IN REFRACTORY CONSTIPATION BY MINIMALLY INVASIVE PROTOCOL

G. Chiarioni¹, C. Lambiase², W.E. Whitehead³, R. Morganti⁴, S.L. Popa⁵, M. Bellini²

¹Division of Gastroenterology B, AOUI Verona, Verona, Italy and UNC Center for Functional GI and Motility Disorders, University of North Carolina at Chapel Hill, USA, Gastroenterology, Verona, Italy, ²Gastrointestinal Unit, Department of Translational Sciences and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, ³UNC Center for Functional GI and Motility Disorders, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ⁴Clinical Trial Statistical Support Unit, Azienda Ospedaliero Universitaria Pisana, Pisa, Italy, ⁵2nd Medical Department, Iuliu Hațieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania

Contact E-Mail Address: christian.lambiase93@gmail.com

Introduction: Dyssynergic Defecation (DD) is prevalent etiology of refractory Chronic Constipation (CC) which can be managed successfully by biofeedback therapy. DD diagnosis requires focused anorectal physiology testing not available outside specialized Center thus delaying effective management. Easy-to-perform tools would be key to improve referral of CC patients.

Aims & Methods: Aim of this study was to evaluate the accuracy and Odds Ratio (OR) of a minimally invasive protocol consisting of a:

1. Straining questionnaire (SQ),
2. Digital rectal examination on straining (DRE) and
3. Balloon Expulsion Test (BET) on predicting a Rome III DD diagnosis in refractory CC patients.

Two hundred and thirty-eight CC patients (Rome III) failing fiber/laxatives for 4 weeks were enrolled. A SQ (What muscles do you mainly use when you push to defecate?) was administered to patients before entering the study (T0) and after the 30-day fiber/laxative trial (T30). The possible answers were: "belly muscles"; "anal muscles"; "both muscles"; "Prefer not to answer/I don't know".

DRE and BET were again performed at T0 and at T30.

At T30, all patients underwent anorectal manometry (ARM).

OR, sensitivity, specificity, positive and negative predictive values (PPV and NPV) were calculated for the SQ, DRE and BET in predicting a DD, alone and in combination.

Sixty healthy volunteers underwent SQ and BET, but not DRE.

Results: One hundred nine patients (45.8%) showed features of DD according to Rome III criteria: paradoxical contraction or failure to relax pelvic floor muscles on straining at physiology and failed BET.

The most significant response to the SQ in predicting a DD was "anal muscles" (SQ+). At T30, the OR of this response in predicting a DD was 32.6 ($p < 0.001$). This response had sensitivity:72.1%, specificity:92.7%, PPV:92.1%, and NPV:73.7% in diagnosing DD.

The most significant DRE pattern in predicting a DD was failure of anal relaxation during push (DRE+). At T0, the OR of this pattern in predicting a DD was 15.6 ($p < 0.001$). This pattern had sensitivity:83.72%, specificity:75.23%, PPV:80%, and NPV:79.61% in diagnosing DD.

The most significant outcome on BET in predicting a DD was a failed balloon expulsion within 2 minutes. The OR of this response in predicting a DD was 3.5 ($p < 0.001$). This response had sensitivity:72.87%, specificity:56.88%, PPV:66.67%, and NPV:63.93% in diagnosing DD.

Cohen's Kappa was calculated to establish the concordance at T0 and T30 for the SQ (0.97), DRE (0.517), and BET (1).

When considering the combination, the most significant in predicting a DD are summarized in the table.

Combination	Sensitivity	Specificity	PPV	NPV	OR	p-value
SQ+,DRE+,BET+	53.12%	95.41%	93.15%	72.57%	38	<0.001
SQ+,DRE+,BET-	15.62%	99.08%	95.24%	50%	23	<0.001

Table.

Interestingly, combinations where pathological outcomes do not appear are not associated with DD: SQ-,DRE+,BET+ has an OR of 0.24 ($p=0.004$) in predicting DD; SQ-,DRE-,BET- has an OR of 0.04 ($p<0.001$) in predicting DD. All 60 HC could evacuate the rectal balloon. Only one of them had SQ+.

Conclusion: In our sample of 238 refractory CC patients, 45.8% showed features of DD according to Rome III criteria. Our data support screening CC patients for DD at any level of care by SQ, DRE and BET to improve management and facilitate the referral to anorectal physiology testing.

Moreover, our protocol may offer an opportunity to consider biofeedback treatment in the community without additional physiology testing. It is intriguing to speculate DD patients are conscious of their maladaptive behavior thus suggesting faulty learning as potential disorder etiology.

Disclosure: Nothing to disclose.

P0634

CHARACTERIZATION OF DEFECATION DISORDERS FROM A STRUCTURAL AND A FUNCTIONAL PERSPECTIVE IN A COHORT OF 588 PATIENTS

L. Mundet^{1,2}, A. Raventós¹, S. Carrión Bolorino¹, C. Bascompte Jurado¹, P. Clavé^{1,2}

¹Hospital de Mataró (Consorci Sanitari del Maresme), GI Motility Unit, Mataró, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Instituto Carlos III, Madrid, Spain

Contact E-Mail Address: lluismundetp@gmail.com

Introduction: Evacuation disorders are the result of sphincter dysfunction and/or structural alterations of the rectal ampulla during evacuation. They are studied with anorectal manometry (ARM) and evacuation defecography (ED), which allow the assessment of defecation from a dual perspective: pressure dynamics and dynamic imaging of the posterior compartment.

Aims & Methods: Characterize functional (FDD) and structural (SDD) defecation disorders with ARM and ED, along with clinical manifestations of obstructive defecation.

Retrospective study with 588 patients with obstructive defecation who underwent ED (2012-2020). Diagnosis, pelvic dynamics during defecation (anorectal angle (ARA)) and perineal descent (PD) were collected and quantified; in a subsample of 294 patients, anorectal function was evaluated with ARM, and clinical manifestations were collected.

Results: Five hundred and eighty-eight patients (90.3% women) were evaluated, with a mean age of 58.39 ± 13.11 .

Structural study.

Mean age was 58.5 ± 12.4 , mostly women (90.1%). Most had some SDD (76.5% rectocele (43.7% significant), 45.3% some type of prolapse, 19.3% enterocele, and 8.5% megarectum). The percentage of women with rectocele was significantly higher than in men (78.4%—21.1%, respectively; $p<0.001$), and the same was true for prolapse (48.9%—12.3%; $p<0.001$), and enterocele (20.2%—8.9%; $p=0.041$). Megarectum was more prevalent in men (7.7%—15.8%; $p=0.038$).

Functional study.

ED: The ARA was not rectified in 66.3% of the patients (64.7% of women and 80.7% of men; $p=0.015$). PD was poor in 31.6% of the patients (30.7% of women—40.9% of men; ns), and excessive in 32.2%.

ARM: From the 294 patients evaluated with ARM, 40.4% showed hyper-tonicity of internal anal sphincter, 21.2% abnormal RAIR (19.1% of wom-

en—36.7% for men; $p=0.027$), 33.3% rectal hyposensitivity (30.5% women—54.3% men; $p=0.020$). PD was poor in 57.5% of women and 62.9% of men (ns).

Overall, 16.3% of the patients had FDD (women—men) (12.3%—54.5%), 46.4% SDD (48.2%—29.1%) and 37.3% both (39.5%—16.4%); $p<0.001$.

Symptoms.

The most frequent symptoms were straining (86.8%), sense of incomplete defecation (84.8%), anal blockage (58.3%), and hard stools (38.9%). Digitation was present in 35.8% of them. More than 20 years with symptoms was reported by 44.8% of the patients.

Expulsive capacity was impaired in 66.2% of SDD, 71.3% of FDD and in 78% of patients with both ($p=0.017$).

Conclusion: Coexistence of SDD and FDD is common. Isolated SDD is much more common in females, with rectocele being the most prevalent disorder. Pure FDD is more prevalent in men, and is manifested primarily by high MRP, rectal hyposensitivity and dyssynergic defecation. It is very common that expulsive difficulty is accompanied by an incomplete evacuation, especially in those patients in whom SDD coexist with FDD, followed by those who present Isolated FDD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: takahashi1700pk9@gmail.com

Introduction: Chronic intestinal pseudo-obstruction (CIPO) is a rare and intractable disease of the gastrointestinal tract that presents with abdominal symptoms such as abdominal pain, abdominal bloating, and pathological dilation of the intestinal tract without any organic obstruction. Many patients have difficulty in controlling their symptoms, so our challenge is to improve the symptoms and quality of life (QOL). In this study, we assessed QOL before and after the treatment intervention.

Aims & Methods: 41 patients with CIPO diagnosed by cine-MRI (1) and treated with treatment intervention were included in this study. Therapeutic interventions were defined as dietary restriction, intestinal sterilization, and decompression therapy such as percutaneous endoscopic gastro-jejunostomy (PEG-J) (2).

Patient background, treatment, desire for palliative care intervention, numerical rating scale (NRS) for abdominal pain/abdominal bloating, Japanese version of the Patient Assessment of Constipation QOL (JAPC-QOL) and Short Form (SF)-36 were prospectively sampled and collected. JAPC-QOL subscales were categorized into physical, mental, anxiety and satisfaction. SF-36 was classified into Physical component summary (PCS), Mental component summary (MCS) and Role/Social component summary (RCS).

Results: The mean age of onset of the target patients was 42 years, 29 were female (71%), and 30 were willing to undergo palliative care intervention (73%). Effective treatment included intestinal sterilization in 18 patients, decompression therapy with PEG-J in 8 patients, dietary restriction in 5 patients, and others in 11 patients. The mean NRS for abdominal distention was 8.7 before treatment, but improved to 2.7 after treatment, and the mean NRS for abdominal pain improved from 7.6 to 2.2 ($P<0.0001$).

SF-36 showed a change from an average of 30.1 to 38.1 for PCS ($P=0.0231$), an average of 42.0 to 47.9 for MCS ($P=0.0073$), and an average of 28.7 to 39.0 for RCS ($P=0.0079$). JPAC-QOL subscales showed a change from 2.6 to 1.2 for physical ($p<0.0001$), 1.9 to 1.4 for mental ($p=0.0022$), 2.1 to 1.5 for anxiety ($p<0.0001$), and 3.0 to 1.6 for satisfaction ($P<0.0001$).

Conclusion: The majority of CIPO patients were those who requested palliative care intervention, and were suffering from holistic distress that combined physical, mental, and social aspect.

This study suggested that appropriate treatment intervention for CIPO not only reduced physical suffering, but also improved mental and financial quality. In the future, it will be necessary to standardize treatment strategies for CIPO by searching for the invasiveness of treatment of CIPO and the effectiveness of different treatments.

Introduction: Low anterior resection syndrome (LARS) is a very common pathology among patients that had a sphincter-preserving surgery for rectal cancer. The most frequent complication is fecal incontinence (FI), which can be found in up to 95% of patients, with a huge impact on patients quality of life. This syndrome has a multifactorial origin, and thus, there are no clear manometric patterns so far.

Aims & Methods: Our aim was to assess and describe the anorectal manometric parameters found in patients who suffered FI following a low anterior resection (LAR) surgery.

Observational and cross-sectional study in 19 patients consecutively studied for FI after LAR. Epidemiological, clinical, and severity data were obtained with structured medical history followed by a high-resolution anorectal manometry (HRAM) (Manoscan®, Medtronic). Severity of FI was graded according to the Wexner score, establishing a moderate-severe disease when it was ≥ 9 . Severity of LARS was quantified with the LARS score, describing severe disease values ≥ 30 .

Results: 19 patients were included, of which 13 (68.4%) were male. Mean age and BMI were 63.2 (57.8-68.5) and 27 (24.8-29.2) respectively. Most of them suffered comorbidities 12 (63.2%), most frequently diabetes 7 (31.6%). Self-reported bowel habit was altered in 16 (84.2%) patients with more than 3 stools per day, and 13 (68.4%) had loose stools (Bristol scale ≥ 5). FI was frequently passive in 13 (72.2%) and on a daily basis in 14 (82.4%) patients. Seventeen (94.4%) had a Wexner score of ≥ 9 , and 14 (73.7%) had a LARS score ≥ 30 . Within parameters related to surgery, the anastomosis mean distance was 8.5 cm (6.5-10.5) and the mean time until surgical reconstruction was 17.5 months (7.7-27.4). All of them had received radiotherapy before the intervention.

As for the manometric parameters (Table 1), internal anal sphincter (IAS) was hypotensive in 14 (73.7%), with spontaneous relaxations of the anal canal in 15 (78.9%) of them. External anal sphincter (EAS) was hypoten-

sive in 4 (21.1%) patients, and 4 (21.1%) had hypotensive sphincter with shorten squeeze duration. Rectal volume tolerability (first sensation, urge to defaecate and discomfort volume) were reduced in 16 (84.2%) of them. Cough reflex was normal in 11 (57.9%) patients and RAIR was present in 17 (89.5%). Simulated defecation was normal in all of them except in one patient that was not studied.

Characteristic anal canal spontaneous relaxation was correlated with lower anal canal pressures ($p=0.028$). No other parameters studied included the anastomosis distance and the time until surgical reconstruction were associated with them. No other correlations were found with the anastomosis distance and the time until surgical reconstruction.

PARAMETER	MEAN VALUE	CI 95%
Anal canal length	4.7	1.3-7.9
Mean Resting pressure (mmHg)	44.9	33.2-56.7
Maximum Resting pressure (mmHg)	63.6	50.1-77.2
Maximum Squeeze pressure (mmHg)	162.1	128.6-195.6
Pressive increase (%)	77.8	46.5-119.2
Squeeze duration (seconds)	13.2	9.5-16.9
First sensation	14	8.9-19
Urge	35.3	29.1-41.6
Discomfort	48.7	40.9-56.5

Table.

Conclusion: Severe and daily FI is one of the most devastating problems in patients suffering LARS. HRAM is very useful to understand the anorectal function in these with the most common pattern being hypotensive IAS with spontaneous relaxations of the anal canal that explain passive FI. Decreased rectal volume tolerability is also very frequently found.

PROSPECTIVE ASSESSMENT OF ANAL DISTENSIBILITY USING ENDOFLIP IN HEALTHY VOLUNTEERS

A. Rasijeff¹, C.H. Knowles¹, S.M. Scott¹

¹Queen Mary University of London, Blizard Institute, London, United Kingdom

Contact E-Mail Address: a.rasijeff@qmul.ac.uk

Introduction: Only a proportion of patients with faecal incontinence (FI) have abnormal anal tone (Rasijeff, Colorectal Dis 2022). Anal distensibility, measured by EndoFLIP, has been proposed as a viable alternative to manometry for assessing anal sphincter competence. A lower distensibility index (DI) has been observed in FI patients compared with healthy volunteers (HV) previously (Gourcerol, Neurogastroenterol Motil 2016; Zifan, Neurogastroenterol Motil 2012).

Aims & Methods: Aim: to describe distensibility of the anal canal using EndoFLIP in HV, and to define normal ranges for opening pressure, opening volume and DI, as well as to compare the results of manual data processing with data from commercially available software (EndoVizX [Motilityviz, California]). In total, 51 normal subjects without bowel symptoms underwent EndoFLIP at the Wingate Institute of Neurogastroenterology,

London, UK, as previously described (Alqudah, Neurogastroenterol Motil 2012). Opening (or yield) pressure (the pressure at which the diameter of the most narrow region of the anal canal first began to increase continuously during constant inflation of the EndoFLIP bag from 0 – 50 ml at a rate of 40 ml/minute), opening volume (the bag volume at opening pressure), opening DI (the narrowest CSA at opening, divided by the opening pressure), and DI at rest (median CSA at the narrowest anal canal location at rest, divided by the median pressure over the same time period) were calculated. Results were compared between sexes and according to female parity, and the impact of age and BMI was also assessed.

Results: Distensibility parameters were analysed in 46 subjects (35 F; mean age 38.5). At 50 ml, no significant differences in opening pressure (mean 49 mmHg, 95% CI: 45–54, $p=0.270$), opening volume (38 ml, 95% CI: 37–40, $p=0.232$), opening DI (0.49, 95% CI 0.4–0.6, $p=0.313$), or DI at rest (2.1, 95% CI: 1.7–2.6, $p=0.244$) were observed between men ($n=11$), nulliparous women ($n=19$), and parous women ($n=16$). There was no statistically significant linear association between distensibility parameters during inflation and age ($p=0.15$, $R^2=4.9\%$, 95% CI= -0.001 to 0.009) or BMI ($p=0.823$, $R^2=1.2\%$, 95% CI= -0.02 to 0.01). DI at rest increased by 0.4 units (95% CI 0.1–0.7) for every 10 year increase in age. Normal ranges are presented in Table 1. Statistically significant ($p<0.001$) linear relationships were observed between the results of manual data processing and results analysed using EndovizX software.

	Median	5 th percentile	95 th percentile
Opening pressure (mmHg) during inflation	47	22	75
Opening volume (ml) during inflation	38	30	45
Opening DI (cm ² /mmHg) during inflation	0.5	0.4	0.6
Distensibility index (cm ² /mmHg) at rest	1.9	0.8	4.8

Table.

Conclusion: Evaluation of the biomechanical properties of gastrointestinal sphincters using EndoFLIP technology to delineate function is gaining popularity. This study describes anal canal resistance to opening (during inflation) and DI at rest in a group of 46 HV - the largest HV cohort, including both sexes, studied to date. Normal cut-offs were defined based on 5th and 95th percentiles in health.

Introduction: Constipation is a common and occasionally disabling digestive problem with an estimated prevalence ranging from 2% to 28% in adults. In previous reports, short chain fatty acids(SCFAs) has been decreased in constipated patients (1).

SCFAs enhance colonic fluid and sodium absorption and thus may aggravate the symptoms of constipation; however, the effect of SCFAs on colonic contractility, motility, and transit time remains unclear. *Bifidobacterium bifidum G9-1 (BBG9-1)* is a probiotic that has been used as an intestinal medicine for decades and has been shown to be effective for treating constipation in animal and human study (2,3).

Furthermore, few studies that have assessed the effect of probiotics on SCFAs in patients with constipation are available.

Aims & Methods: In our report, we showed that *BBG9-1* is effective for constipation, and we investigated whether one of the mechanisms is the alteration of SCFAs. This was a prospective, multicenter, observational study. Chronic constipation with patients diagnosed as Rome IV criteria were enrolled from the 4 institutions from July 2018 to February 2022. After baseline period, patients received 72 mg daily of *BBG9-1* for 8 weeks. We evaluated the effects on bowel function, changes in fecal SCFAs concentrations before and after *BBG9-1* administration.

Results: In the 87 patients analyzed, the frequency of pre- and post-treatment bowel movements per fortnight was 7 and 10 ($P < 0.001$), respectively. Not only bowel movement but also sense of incomplete evacuation, straining and stool form were significantly improved before and after *BBG9-1* administration.

The pre-treatment fecal n-butyrate concentration increased significantly from 0.76 to 1.03 mg/g stool post-treatment ($P < 0.0001$), with a significant increase in fecal iso-butyrate (pre-treatment 0.18 mg/g stool to post-treatment 0.21 mg/g stool, $P = 0.003$) and in acetic acid (pre-treatment 2.9 mg/g stool to post-treatment 3.2 mg/g stool, $P = 0.008$).

Conclusion: 8-week treatment with *BBG9-1* increased the concentrations of n-butyrate, iso-butyrate and acetic acid.

VALIDATION OF THE RAPID BAROSTAT BAG (RBB) PUMP AND COMPARISON WITH CONVENTIONAL ELECTROMECHANICAL BAROSTAT

A. Rasijeff¹, A. Choudhary², R. Fried³, C.H. Knowles¹, S.M. Scott¹

¹Queen Mary University of London, Blizard Institute, London, United Kingdom, ²Queen Mary University, Wingate Institute of Neurogastroenterology, London, United Kingdom, ³University Hospital Zurich, Klinik für Gastroenterologie und Hepatologie, Zurich, Switzerland

Contact E-Mail Address: a.rasijeff@qmul.ac.uk

Introduction: Awareness of rectal filling is critical to normal bowel function. A tenth of women and 1 in 4 men with FI exhibit abnormal sensory thresholds to balloon distension (Rasijeff, Colorectal Dis 2022), however balloon distension alone cannot determine the *cause* of abnormal thresholds. While the electromechanical barostat is the gold-standard method for assessing rectal sensorimotor function, the Rapid Barostat Bag pump (Mui Scientific) seeks to enable accurate and consistent measurement of rectal capacity, compliance and sensory thresholds in a more timely fashion, using a portable device.

Aims & Methods: Aim: to compare measures of rectal sensorimotor function in health using the RBB pump against the standard electromechanical barostat (G&J Electronics). Healthy volunteers (n=19, mean age 37 [sd: 13], 13 F) were recruited prospectively to undergo standard barostat and RBB assessment on the same day in randomised order. Each method incorporated an infinitely compliant rectal barostat bag (600 ml for standard barostat, 700 ml for RBB). Compliance was defined as the slope of the line of best fit of the steepest part of a pressure-volume curve plotted using raw data from each method. Capacity (volume at 40 mmHg or maximum tolerable volume) and sensory threshold volumes for first sensation, urge and maximum tolerable volume (MTV) were also obtained. Bland and Altman plots were generated to assess agreement between methods and assess inter- and intra-rater agreement.

Results: Data on sensory thresholds, capacity and compliance for standard and rapid barostat are summarised in Table 1.

		Mean difference (SD)	95% CI	Limits of agreement		Outer Confidence Limits of LoA	Inner Confidence Limits of LoA
				Lower limit	Upper limit		
Standard barostat vs RBB	First sensation (ml)	-38.7 (47.6)	-65.1 - (-12.4)	-133.9	56.3	-191.5 - 113.8	-108.7 - 31.1
	Urge (ml)	-19.5 (63.5)	-54.6 - 15.7	-146.5	107.5	-223.1 - 184.1	-112.7 - 73.7
	MTV (ml)	-10.2 (46.2)	-35.8 - 15.4	-102.5	82.3	-158.3 - 138.1	-77.9 - 57.7
	Compliance	-2.4 (5.1)	-5.3 - 0.4	-12.7	7.8	-18.8 - 14.0	-9.9 - 5.1
	Capacity	-10.9 (40.5)	-33.4 - 11.5	-91.8	70.2	-140.7 - 119.1	-70.3 - 48.7
RBB vs RBB	Intra-observer	0.1 (2.7)	-1.2 - 1.4	-5.3	5.5	-8.0 - 8.1	-4.0 - 4.1
	Inter-observer	2.6 (4.6)	0.4 - 4.8	-6.5	11.7	-11.0 - 16.2	-4.3 - 9.5

Table 1.

Sensory threshold volumes measured by RBB were significantly higher for first sensation (112 ml vs 74 ml; $p=0.007$), but similar for other thresholds (urge: 221 ml vs 202 ml; MTV: 345 ml vs 335 ml). Mean compliance (17.9 ml/mmHg, 95% CI: 14.7-21.1 for RBB, and 16.8 ml/mmHg, 95% CI: 14.7-19.0 for standard barostat) and mean capacity (312 ml for RBB vs 301 ml) were also similar between methods. Although mean differences were clinically insignificant, the wide Limits of agreement (LoA) suggest-

ed poor agreement between the two methods (Table 1). Generally, the wider the inner and outer limits of LoA, the more inaccurate either (or both) methods are.

Conclusion: The RBB pump has been developed to facilitate routine measurement of compliance, capacity, and rectal sensation. Despite clinically insignificant differences between mean measurements by standard barostat and RBB pump, wide limits of agreement suggest that the two methods do not provide entirely comparable measures of rectal compliance (i.e. elasticity). The RBB pump showed excellent intra- and inter-rater agreement for compliance. However, while the RBB may be clinically useful as an alternative to balloon distension or conventional barostat, these data preview the need for the development for a larger normative RBB dataset.

TSH RECEPTOR ANTIBODIES (TRAB) – A POTENTIAL NEW BIOMARKER TO DIFFER BETWEEN IRRITABLE BOWEL SYNDROME AND ENDOMETRIOSIS

B. Ohlsson¹, B. Roth¹, A. Svensson¹

¹Skanes Universitetssjukhus, Department of Clinical Sciences, Malmö, Sweden

Contact E-Mail Address: Bodil.Ohlsson@med.lu.se

Introduction: Irritable bowel syndrome (IBS) is common in the society, especially in young women. Before the diagnosis is set, other organic diseases have to be excluded. Endometriosis is defined by endometrial cells and stroma growing outside of the uterus. The disease affects 5–10% of women in reproductive age; thus affecting the same group which suffer from IBS. Endometriosis is causing symptoms such as pelvic pain, gastrointestinal symptoms and infertility.

The prevalence of gastrointestinal symptoms is as common as other symptoms, and was present in 85% during the last year (Ek et al. 2015). One-third of endometriosis patients also suffer from IBS (Ek et al. 2021). It is a great challenge for the clinicians, to differ between IBS and endometriosis. Endometriosis demands ultrasound examination or laparoscopy for diagnosis, and the disease demands quite a different treatment compared with IBS.

Thus, it is very important for the clinicians to have access to biomarkers that can differ the two conditions, and suggest more examinations in one or the other direction. Several autoimmune diseases, including thyroid dysfunction, has been reported to be increased in patients with endometriosis, which has not been observed in IBS. Upregulated thyroid-stimulating hormone (TSH) receptors in ectopic endometrium and elevated serum titers of TSH receptor antibodies (TRAb) IgG in endometriosis patients indicates an overlap in pathophysiology (Ek et al. 2018).

Aims & Methods: The objective of this study was to compare the expression of autoantibodies in women with endometriosis, IBS and controls to evaluate the potential of TRAb IgG as a diagnostic marker to exclude endometriosis at a Department of Gastroenterology or in primary care. This cross sectional study was carried out in 172 women with surgically confirmed endometriosis and two control groups consisting of 50 healthy

female blood donors and 114 women from the general population with known IBS prevalence, respectively. Serum levels of TRAb IgG antibodies, TSH and thyroid hormones were analyzed by standardized methods at the Division of Clinical Chemistry, whereas serum levels of IgM were evaluated by in-house enzyme-linked immunosorbent assays (ELISA).

The endometriosis patients and controls from the general population answered a questionnaire and estimated their gastrointestinal symptoms using the Visual Analogue Scale for Irritable Bowel Syndrome (Bengtsson et al. 2007).

Results: There was no difference in TRAb titers between population-based controls who had IBS (N=25, 21.9%; p=0.655) or reported gastrointestinal symptoms in the past two week (N=30, 26.3%; p=0.885) compared to those without symptoms. Of the endometriosis patients, 29.1% had TRAb IgG above the present detection limit of 1.0 IE/L compared to 2.6% of the population-based controls (p<0.001) and 94.5% had levels of TRAb over the previous detection limit 0.3 IE/L compared to 7.9% of the controls (p<0.001).

Titers of both TRAb IgG and IgM were increased in patients compared to population-based controls and healthy controls (p<0.001). TRAb titers did not correlate with age, disease duration, TSH, thyroid hormones or gastrointestinal symptoms. The prevalence of TRAb IgG as defined as grey-zone (1.2-1.7) and positive (>1.7 IE/L) was higher in endometriosis than controls (p<0.001), whereas positive for IgM did not differ (p=0.162) between endometriosis and controls.

Conclusion: TRAb IgG and IgM are slightly elevated in patients with endometriosis, but not in IBS. The results indicate that TRAb is truly elevated in endometriosis and thereby has the potential to support the diagnosis. Thus, TRAb could be used to help the clinician to exclude endometriosis in women with gastrointestinal symptoms. Very low levels of TRAb support the diagnosis of IBS.

Introduction: Disorders of gut-brain interaction (DGBI) are characterized by symptoms clusters emanating from the gastrointestinal (GI) tract in the absence of explanatory organic findings on routine examination. The diagnostic Rome IV criteria, mainly validated in Western countries, classify DGBI based on the anatomical section of the GI tract where the predominant symptoms originate from.

However, a study in Eastern patients using an Enhanced Asian Rome III questionnaire (EAR3Q) identified symptom clusters involving more than one anatomical section:

1. Meal-related bowel symptom cluster,
2. Upper abdominal pain with constipation cluster, and
3. Bloating, fullness, belching, and flatulence cluster (1).

Our aim was to compare Eastern and Western DGBI patients and investigate if these three symptom clusters were reproducible in a Western cohort.

Aims & Methods: We conducted descriptive analyses on the first data of an ongoing international survey study comparing symptom patterns and clusters in both Eastern and Western participating centers. We included consecutive adult patients who were diagnosed with a DGBI by their treating physician. In addition to a primary DGBI diagnosis, the physician identified potential overlapping symptoms of other DGBI based on the Rome IV classification (secondary diagnosis). Patients completed the Adult Diagnostic Rome IV questionnaire supplemented with questions from the EAR3Q that identified the aforementioned three symptom clusters. Patients were appointed to symptom clusters if they reported presence of the respective GI symptoms in the Rome IV and EAR3Q for more than six months. The subjects' quality of life (QoL) (mental and physical health) was measured with the validated PROMIS Global-10 questionnaire.

Results: We included 375 Eastern and 89 Western DGBI patients from respectively 3 and 5 centers (Western: 75% female, age: 39±14 years, BMI: 23±4 kg/m² and Eastern: 55% female, age: 43±13 years, BMI: 22±4 kg/m²).

In both the Western and Eastern cohort, the most prominent DGBI diagnoses were functional dyspepsia (34% vs. 37%), irritable bowel syndrome (33% vs. 29%), functional constipation (6% vs. 10%), and functional diarrhea (2% vs. 8%).

The most common secondary diagnoses in the Western and Eastern cohort included functional dyspepsia (18% vs. 3%), irritable bowel syndrome (14% vs. 2%), functional bloating (7% vs. 4%), and functional constipation (6% vs. 4%). The proportion of patients without overlapping symptoms was 21% vs. 67% in the Western and Eastern cohort, respectively. The Western cohort reported better physical QoL (Western physical QoL: 12±3 vs. Eastern physical QoL: 10±2, $p<0.001$). In total, 83% vs. 33% of the Western and Eastern patients could be appointed to one of the three previously reported Eastern symptom clusters.

Within the three symptom clusters outside the current Rome IV consensus, the largest proportion of both Eastern and Western patients reported symptoms representing cluster 1 (Table). Patients could also be appointed to more than 1 symptom cluster with the largest overlap between clusters 1 and 3.

	Cluster 1	Cluster 2	Cluster 3	Overlap cluster 1 and 2	Overlap cluster 1 and 3	Overlap cluster 2 and 3
Western cohort (n=87)	76%	27%	33%	24%	29%	11%
Eastern cohort (n=468)	31%	5%	4%	4%	4%	2%

Table.

Conclusion: The previously found Eastern GI symptom clusters involving more than one anatomical section are also present in a Western DGBI cohort. The anatomical basis for disorder classification as used in the Rome IV consensus may not cover the full symptom spectrum of patients with DGBI.

COMPARISON OF THE HABITUAL DIETARY INTAKE AND DIET QUALITY IN PATIENTS WITH IRRITABLE BOWEL SYNDROME AND THE GENERAL POPULATION

E. Colomier^{1,2}, S. Nybacka¹, S. Störsrud¹, J. Tack^{1,2}, H. Törnblom¹, M. Simré^{1,3}

¹Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Molecular and Clinical Medicine, Gothenburg, Sweden, ²Translational Research Center for Gastrointestinal Disorders (TARGID), Chronic Diseases, Metabolism and Aging (CHROMETA), KU Leuven, Leuven, Belgium, ³Center for Functional GI and Motility Disorders, University of North Carolina-Chapel Hill, Chapel Hill, United States

Contact E-Mail Address: esther.colomier@kuleuven.be

Introduction: Food hypersensitivity is of importance in the pathophysiology of irritable bowel syndrome (IBS). To improve gastrointestinal symptoms, patients with IBS tend to avoid triggering foods, which might influence their habitual dietary intakes and diet quality. Therefore, we aimed to determine and compare the habitual diet quality and dietary intake of IBS patients and controls.

Aims & Methods: We used baseline data of patients with IBS who were recruited for a dietary intervention study or a study investigating pathophysiological factors. For the age and gender-matched control sample, we used data from a Swedish population-based study that collected data during the same period, the Riksmaten study (2010-2015).

The habitual dietary intake was assessed with consecutive 4-day food diaries, during Wednesday-Saturday in the patient cohort, and with an equal distribution of weekdays and weekend days in the control group. A dedicated software (DIETIST XP V.3.1) was used to calculate the mean daily energy, macronutrient, and fiber intake.

The food group categorization was based on the classification of the Swedish National Food Administration. Diet quality was assessed using a diet quality index (DQI) based on adherence to the Swedish nutrition recommendations and dietary guidelines (1).

The index considered the intake of saturated and polyunsaturated fatty acids, fish, fiber, fruit and vegetables, and sucrose. Per component, adherence vs. non-adherence to the recommendations resulted in a score of 1 vs. 0, leading to a sum score ranging from 0-6.

Results: We included 197 patients with IBS and 197 controls (both cohorts: 77% female, age: 37±14 years, BMI: 24±4 kg/m²). Controls had a significantly lower total energy intake compared to patients with IBS (1858±616 kcal vs. 2127±550 kcal, $p<0.001$), including a higher intake of carbohydrates (43±7 E% vs. 40±8 E%, $p=0.003$) and lower intake of protein (16±4 E% vs. 17±4 E%, $p=0.01$) and fat (38±8 E% vs. 36±7 E%, $p=0.003$). In both patients and controls the intake of carbohydrates was lower than the recommendations, i.e. 45-60 E%. The intake of other macronutrients adhered to the Swedish national nutrition recommendations.

Patients had a higher cereal, egg, fish, meat, nuts and seeds intake, and a lower coffee, and mixed dishes intake compared with controls. Reported intake of alcohol, dairy, fruits, and vegetables did not differ between patients and controls.

The mean DQI did not differ between the patients and controls (2.8±1.3 vs. 2.8±1.3, $p>0.99$), but the proportion of patients adhering to the recommended cut-offs of DQI components fish and dietary fiber differed from the proportion of controls adhering to these recommendations (37% vs. 26%, $p=0.02$ and 46% vs. 62%, $p=0.001$, respectively) (Table).

Description of DQI	Adherence			
	Index component	Cut-off	IBS patients	Controls p-value
Short-chain fatty acids (non-alcohol Energy %)	≤14	43%	44%	>0.99
Polyunsaturated fatty acids (non-alcohol Energy %)	5-10	68%	68%	>0.99
Fish (gram/week)	≥300	37%	26%	0.02
Dietary fiber (gram/Megajoule)	2.2	46%	62%	0.001
Fruit and vegetables (gram/day)	≥400	14%	13%	>0.99
Sucrose (non-alcohol Energy %)	≤10	73%	68%	0.26

Table.

Conclusion: The reported habitual dietary intake in patients with IBS included a higher energy intake with slight differences in macronutrient composition compared with a population-based control group. More patients adhered to the recommended fish intake, but less patients adhered to the recommended dietary fiber intake compared to controls. Habitual dietary intakes should be monitored in clinical practice to assure healthy eating habits.

P0643

IDENTIFYING DIFFERENT IRRITABLE BOWEL SYNDROME SUBGROUPS BASED ON BOWEL HABITS AND PSYCHOLOGICAL COMORBIDITY: A REPLICATION STUDY USING MIXTURE MODELLING

I.A. Trindade¹, I. Midenfjord¹, E. Colomier¹, J. Hreinsson², S. Störsrud², H. Törnblom¹, M. Simrén^{1,3}

¹University of Gothenburg, Department of Molecular and Clinical Medicine, Institute of Medicine, Sahlgrenska Academy, Gothenburg, Sweden, ²Sahlgrenska University Hospital, Department of Molecular and Clinical Medicine, Gothenburg, Sweden, ³University of North Carolina-Chapel Hill, Center for Functional GI and Motility Disorders, Chapel Hill, North Carolina, United States

Contact E-Mail Address: ines.trindade@gu.se

Introduction: Previous studies have identified subgroups of irritable bowel syndrome (IBS) patients based on bowel habits, and comorbid extraintestinal and psychological symptoms [1]. Different group profiles regarding combinations of bowel habits and low/high comorbidities were identified. This study aims to replicate these findings while also considering additional relevant aspects.

Aims & Methods: IBS patients completed self-report questionnaires as measures of gastrointestinal symptom severity (GSRS-IBS), stool consistency and frequency (BSF), anxiety and depression (HADS), extraintestinal somatic symptoms (PHQ-12), GI-specific anxiety (VSI), trait anxiety (STAI-T), stress (PSS), sexual and physical abuse (Leserman et al. [2]), fatigue (MFI), and pain catastrophizing (PCS). A mixture model analysis was performed to identify latent classes based on questionnaire scores. The subgroups were then compared regarding demographic variables, other disease diagnoses, IBS severity (IBS-SSS), post-traumatic stress (SQ-PTSD), and work absenteeism and impairment (WPAI), using analysis of variance, chi-squared tests, or Fisher's exact tests.

Results: We included 181 IBS patients; 70.7% female; mean age 35.9 (range 19-66) years. Five latent subgroups were identified and characterized by:

- constipation with low level of severity of somatic/psychological comorbidities;
- constipation with high comorbidities;
- diarrhea with low comorbidities;
- diarrhea with high comorbidities, high pain catastrophizing, and history of sexual and/or physical abuse; and,
- mild symptoms with low comorbidities.

The high comorbidities groups had a higher proportion of females ($p < .001$) and higher IBS severity ($p < .001$), work absenteeism ($p = .008$), impairment while working ($p < .001$), and general activity impairment ($p < .001$). Post-traumatic stress was more prevalent in the diarrhea with high comorbidities group ($p = .041$), and chronic fatigue was more prevalent in constipation with high comorbidities ($p < .001$). No differences were found between subgroups regarding age ($p = .215$), duration of symptoms ($p = .061$), fibromyalgia ($p = .603$), and overall work impairment ($p = .054$).

Conclusion: This study confirms previous findings of latent IBS subgroups based on bowel habits combined with somatic/psychological comorbidity and the association of these subgroups to other important clinical, demographic, and outcome parameters. This study also contributes with novel findings by considering variables such as abuse history, pain catastrophizing, and fatigue to identify these subgroups.

KOMBUCHA-BASED SPECIALIZED FOOD PRODUCT FOR TREATMENT OF CONSTIPATION

V. Pilipenko¹, S. Morozov², V. Isakov²

¹Federal Research Centre of Nutrition, Gastroenterology and Hepatology, Moscow, Russian Federation, ²Federal Research Center of Nutrition and Biotechnology, Gastroenterology & Hepatology, Moscow, Russian Federation

Contact E-Mail Address: pilipenkovork@rambler.ru

Introduction: Aim: To assess the efficacy of kombucha-based specialized food product, enriched with inulin in patients with constipation-predominant irritable bowel syndrome.

Aims & Methods: The study (NCT05164861) was approved by LEC and enrolled subjects with constipation-predominant irritable bowel syndrome (according to ROME IV). The subjects were randomized to receive either 220 ml of a non-alcoholic drink, based on pasteurized kombucha (KG), enriched with inulin (1.15 g/100ml) or 220 ml water (control group, CG), for 10 days.

Except study product, subjects were advised to follow their usual diet. Standard examination included evaluation of stool frequency (bowel movements per day), stool form (with the Bristol stool scale) and evaluation of concomitant symptoms (abdominal pain/discomfort, abdominal fullness, bloating, and feeling of incomplete bowel emptying) with the use of 5-point Likert scale before (BL) and 10 days after the start of intervention (EOT).

Results: The complete data of 40 subjects were available for the analysis. Significant increase of stool frequency was found at the EOT compared to BL in KG ($n = 20$), Mean $\pm$ SD: 0.60 ± 0.31 to 0.85 ± 0.19 times/day; $p = 0.004$, while there was no change in CG ($n = 20$): 0.63 ± 0.33 vs 0.72 ± 0.28 , $p > 0.05$. Mean values of stool scale form increased in KG (2.95 ± 1.15 to 4.4 ± 0.97 ; $p = 0.001$), while remained unchanged in CG (2.94 ± 1.2 vs 3.4 ± 1.2 , $p = 0.6$). Mean values of the Bristol stool scale in KG and CG differed significantly at EOT ($p = 0.018$).

Significant decrease in mean values of incomplete bowel emptying feeling was found in KG (1.88 ± 0.78 at BL vs 1.41 ± 0.56 points at EOT, $p = 0.015$), but not in the control group. There was no difference in patient's reports for other symptoms between KG and CG.

Conclusion: New specialized kombucha-based drink enriched with inulin is well-tolerated and increases stool frequency and consistency in patients with constipation-predominant irritable bowel syndrome.

NON-COELIAC GLUTEN SENSITIVITY APPEARS TO BE THE MAJOR PRESENTING AETIOLOGY BEHIND IBS

T. Su^{1a}, J. Ye², C. Montoya^{3,4}, D. Luo⁵, K. Rostami²

¹University of Otago, Christchurch, New Zealand, ²MidCentral DHB Palmerston North Hospital, Department of Gastroenterology, Palmerston North, New Zealand, ³AgResearch Limited, Smart Foods and Bioproducts Innovation Centre of Excellence, Palmerston North, New Zealand, ⁴Massey University, Riddet Institute, Palmerston North, New Zealand, ⁵AgResearch Limited, Ruakura Research Centre, Hamilton, New Zealand

Contact E-Mail Address: suata871@student.otago.ac.nz

Introduction: Non-coeliac gluten sensitivity diagnosis has improved the therapy approach for many patients diagnosed with irritable bowel syndrome (IBS). The polymorphisms of gluten and other food antigens implicated in the modern lifestyle could act as strong epigenetic factors with a spectrum of different severity. Identifying and addressing food sensitivities in patients presenting with IBS like symptoms are currently underemphasised in clinical guidelines. Yet have the potential to provide major benefits for patients.

Aims & Methods: This observational study aimed at assessing the efficacy of targeted interventions addressing common food sensitivities and lifestyle factors that commonly contribute to the presentation of gastrointestinal symptoms identified as IBS.

Information was collected from the medical records of patients that were referred to the Gastroenterology Unit of Palmerston North DHB with unexplained gastrointestinal (GI) symptoms with or without other GI comorbidities between September 2018 and November 2021. A diagnosis of coeliac disease was excluded. The main management option offered to the 121 patients included in this study, was a trial of 6 weeks, eliminating gluten according to Salerno expert criteria and lactose exclusion from the diet and/or lifestyle adjustment recommendations.

Results: The most prevalent symptoms were abdominal pain (79%), and diarrhoea (69%), followed by bloating and constipation. Seventy-eight patients had the outcomes of their improvement available. A total of 42 out of 78 patients (54%) were treated exclusively with a gluten and lactose-free diet, in this group of patients 86% (36/42) reported a significant improvement in their symptoms with a score in the range of 40-100%.

Conclusion: The improvement score between 40-100% of symptoms following gluten elimination advocates that gluten represents a major pathogenic factor behind IBS presentation. But the disunity and variability of the response indicate that gluten might not be the only noxious factor implicated in these patients' conditions.

Nevertheless, gluten elimination for treating IBS patients' symptoms is non-toxic and highly effective in achieving optimal outcomes and improving many of these patients' quality of life.

Introduction: The pathophysiology of Irritable Bowel Syndrome (IBS) has not been clearly understood but diet and intestinal dysbiosis appear to be involved. The aim of the present pilot study was to observe the interaction between Mediterranean diet (MD), gastrointestinal (GI) symptoms and gut microbiota changes in prevalent constipation IBS (IBS-C) patients.

Aims & Methods: 15 IBS-C were underwent to a targeted nutritional protocol for 4 weeks, filling a food diary and an IBS symptoms questionnaire 2 weeks before and at the end of the nutritional intervention.

Moreover a fecal sample was collected 2 weeks before and at the end of the nutritional protocol performing the microbiota analysis by 16S rRNA targeted-metagenomics.

The control group, composed by 17 healthy subjects, received a food diary and a symptoms questionnaire to exclude gastrointestinal disorders. The nutritional protocol was elaborated respecting the macronutrient percentage and the quantity of fiber indicated by LARN 2014 guidelines (Reference Levels of Nutrients and Energy Intake for the Italian population). MD adherence was calculated using the MDSS score.

Results: MDSS index was significantly reduced in IBS patients compared to controls ($p > 0.0001$). The analysis of food diaries at T0 showed a significant increase of protein intake ($p = 0.0229$) in IBS patients compared to controls as well as a less intake of carbohydrates and fiber without a significant difference.

After the nutritional intervention, the MDSS index was significantly increased in IBS patients, showing a better adherence to MD ($p < 0.0001$). The percentage of proteins, lipids, carbohydrates, simple sugars and grams of fibers intake were checked before and after the nutritional protocol. Up to these five items checked a significant improvement from T0 to the endpoint was observed ($p = 0.0199$).

Gut microbiota analysis showed, at phylum level, an increase of *Bacteroidetes* and a decrease of *Firmicutes* in IBS patients after the nutritional protocol (T1) with an increase of *Bacteroidaceae* and a decrease of *Ruminococcaceae*, *Lachnospiraceae*, *Clostridiales* and *Prevotellaceae* at the family level.

A significant reduction in pre-evacuation abdominal pain ($p = 0.0004$), in the daily frequency of abdominal pain ($p = 0.0020$) and in the abdominal pain during the evacuation ($p < 0.0001$) was observed in IBS patients following the nutritional intervention.

Conclusion: These preliminary results show a significant role of a right dietary lifestyle in controlling IBS symptoms; further investigations, increasing the number of patients, are needed to confirm these data.

Disclosure: Nothing to disclose.

GENERAL LIFE SATISFACTION IN IBS PATIENTS IS ASSOCIATED WITH PSYCHOLOGICAL SYMPTOM BURDEN AND QUALITY OF LIFE, RATHER THAN GASTROINTESTINAL SYMPTOM SEVERITY

J.T.W. Snijkers^{1,2}, B. Winkens³, Z.Z.R.M. Weerts^{1,2}, L. Vork^{1,2}, Z. Mujagic^{1,2}, M.A.M. Hesselink^{1,2}, C. Leue^{4,5}, J.W. Kruimel^{1,2}, J.W.M. Muris⁶, D.M.A.E. Jonkers^{1,2}, A.A. Masclee^{1,2}, D. Keszthelyi^{1,2}

Introduction: Irritable bowel syndrome (IBS) is a disorder of gut-brain interaction. IBS symptoms have major impact on a person's emotional, social, and professional life. Previous research showed the high disease burden in IBS patients, but studies on general life satisfaction in IBS populations are lacking.

Aims & Methods: The current study aims to evaluate general life satisfaction in IBS patients and to determine which factors are associated with higher life satisfaction. IBS patients (n=195, median age 53 years (interquartile range 29 years), 73.8% female) recruited from primary and secondary/tertiary care completed questionnaires regarding gastrointestinal symptoms (Gastrointestinal Symptom Rating Scale-IBS), quality of life (36-item Short-Form Health Survey, physical and mental composite score), psychological factors (Hospital Anxiety and Depression Scale), gastrointestinal-specific anxiety (Visceral Sensitivity Index), and life satisfaction. Life satisfaction was measured by the Satisfaction With Life Scale (SWLS, 5 items, range 5-35). This instrument assesses the judgement of one's life as a whole and does not measure satisfaction in specific life domains. Multivariable linear regression was used to identify variables associated with life satisfaction.

Results: Overall, 76.4% of the patients had a SWLS-score ≥ 20 , corresponding with a neutral score or higher on life satisfaction. When a cut-off of SWLS-score ≥ 21 was used, corresponding with scores between slightly satisfied and extremely satisfied, 71.3% of the patients scored satisfied about their life.

The mean of the SWLS-score was 23.9 (standard deviation 6.4). Female gender (B (unstandardized coefficient)=1.926, $p=0.025$), higher physical quality of life (B=0.229, $p<0.001$), higher mental quality of life (B=0.216, $p<0.001$), and fewer general anxiety symptoms (B=-0.334, $p=0.032$) were associated with higher life satisfaction. No significant association was found between gastrointestinal symptom severity and life satisfaction.

Conclusion: Higher quality of life and less anxiety symptoms, but not gastrointestinal symptom severity, were associated with higher general life satisfaction in IBS. These findings support the clinical need in IBS treatment to take psychological factors and quality of life into account in order to enhance life satisfaction.

IRRITABLE BOWEL SYNDROME SYMPTOM SEVERITY AND ASSOCIATION WITH SHORT-CHAIN FERMENTABLE CARBOHYDRATES CONSUMPTION AFTER BARIATRIC SURGERY: AN OBSERVATIONAL PROSPECTIVE STUDY

P. Van Ouytsel^{1,2}, A. Szalai², K. Buedts², M. Barea², V. Huberty¹, J. Closset³, P. Loi³, H. Piessevaux⁴, H. Louis¹
¹Hopital Erasme, Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Bruxelles, Belgium, ²Hopital Erasme, Dietetic, Bruxelles, Belgium, ³Hopital Erasme, Digestive Surgery, Bruxelles, Belgium, ⁴Cliniques Universitaires Saint-Luc, Department of Hepato-Gastroenterology, Brussels, Belgium

Contact E-Mail Address: pauline.vanouytsel@gmail.com

Introduction: Irritable Bowel Syndrome (IBS)-like symptoms such as diarrhoea, constipation, bloating, and gas are frequent following bariatric surgery. Since short-chain fermentable carbohydrates (FODMAPs) can trigger symptoms in IBS, we aimed to prospectively evaluate the frequency of IBS symptoms severity before and after bariatric surgery and their link with FODMAPs consumption.

Aims & Methods: The primary outcome was to evaluate the IBS symptom severity in a cohort of obese patients before, 6 and 12 months after bariatric surgery by validated questionnaires and tools (Irritable Bowel Syndrome Severity Scoring System (IBS SSS), Bristol Stool Scale (BSS), Quality of Life Short-Form-12 (SF-12), Hospital Anxiety and Depression scale (HAD)).

The secondary outcome was to evaluate the FODMAPs consumption and its association with IBS symptom severity, using a food frequency questionnaire focused on high-FODMAPs food consumption.

Results: Fifty-one patients were included (41 female; mean age 41 years (SD: 12) ; 10 with a previous bariatric surgery), 84% benefited from a sleeve gastrectomy, and 16% from a Roux-en-Y gastric bypass. IBS SSS score was not significantly different before, 6 and 12 months after surgery (83.5 ± 81.6 vs 105.8 ± 91.3 vs 83.3 ± 95.0 ; NS).

Nevertheless, compared to pre-surgery score, IBS symptoms severity increased in one third of the patients 6 months following surgery, and in one quarter of the patients at 12 months.

According to the IBS SSS score, no severe IBS was diagnosed before surgery, but was observed in 5 % of the patients at 6 and 12 months. Forty-three percent of the patients had a mild to moderate IBS before surgery, compared to 53 % and 29% of the operated patients after 6 and 12 months respectively.

In a multivariate model, a significant association was found between the IBS SSS score and lactose consumption at 6 months ($\beta = + 58, 1; p = 0.03$), and with polyols consumption at 12 months ($\beta = + 112, 6; p = 0.01$).

Conclusion: Mild to moderate IBS symptoms are frequent in obese patients before bariatric surgery. Despite anatomical and physiological alterations induced by surgical procedures, IBS symptom severity does not seem to increase significantly after surgery.

However, a significant association between lactose and polyols consumption after operation and IBS SSS score was observed after bariatric surgery suggesting a potential link between the severity of IBS symptoms and some specific FODMAPs consumption, such as lactose and polyols.

Disclosure: Nothing to disclose.

P0649

EFFECT OF IBEROGAST (STW5) ON TOLERANCE TO COLONIC GAS IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

A. Aguilar^{1,2}, B. Benslaiman¹, J. Serra²

¹University Hospital Germans Trias i Pujol, Motility Unit, Badalona, Spain, ²University Hospital Vall d'Hebron, Digestive System Research Unit, Barcelona, Spain

Contact E-Mail Address: ariadna.agca@gmail.com

Introduction: Patients with irritable bowel syndrome (IBS) have a poor tolerance to colonic gas that has been related to visceral hypersensitivity. STW5 is a medicinal product composed of 9 herbal extracts that has shown clinical efficacy in relieving symptoms in IBS patients, including abdominal pain and sensation of tension and fullness¹.

Further, STW 5 promotes changes in gastric tone, gastrointestinal motility, intestinal inflammation and visceral sensitivity. The effect of STW5 on tolerance to colonic gas in IBS has never been studied.

Aims & Methods: The aim of the present study is to determine the effect of STW5 on tolerance to colonic gas in patients with IBS. In 10 IBS patients (1 IBS-C; 7 IBS-D and 2 IBS-M) with bloating (8 female and 2 male, age range 22-61 yrs), we designed a controlled, randomized, double blind, cross-over study. On separate days, two gas challenge tests were performed in each patient: a) after two weeks on STW5 20 drops t.i.d. and b) after 2 weeks on placebo.

The gas challenge test consisted in an infusion period, with continuous infusion of a mixture of gases into rectum at 24 mL/min for 60 minutes, followed by a 30-min period of free rectal gas evacuation period. Gas evacuation was recorded by means of a barostat, abdominal symptoms were scored using a 0-6 perception questionnaire and abdominal distension was measured using a tape measure.

Results: Colonic gas infusion was associated to a progressive and significant increment in abdominal symptom perception, which was significantly greater when gas infusion was performed on placebo than when gas was infused on STW5.

At the end of the infusion period, when 1440 ml of gas were infused into the colon, abdominal perception score had increased by 4.0 ± 0.3 in the studies performed on placebo, and by 3.2 ± 0.4 when gas infusion was performed on STW5 ($p=0.034$).

In parallel, gas infusion was also associated to a progressive abdominal distension, that was similar at the end of the infusion period in the studies performed on placebo (2.3 ± 0.4 cm) and on STW5 (2.2 ± 0.3 cm; $p=0.434$).

During the evacuation period, opening of the rectal cannula was followed by a massive gas evacuation, and after 30 min of free gas evacuation only 408 ± 99 ml and 359 ± 70 ml of gas were still retained into the colon (placebo and STW5, respectively; $p=0.309$). Gas evacuation was associated to a rapid decrease in symptom perception and abdominal distension, which was faster when patients were on STW5 than on placebo.

Hence, at the end of the evacuation period, abdominal perception (score increment 0.5 ± 0.3 ; $p=0.048$ vs basal) and distension (girth increment 0.8 ± 0.3 mm; $p=0.016$ vs basal) remained significantly greater when compared to basal levels in the studies performed on placebo, whereas both had returned to basal levels in the studies performed on STW5 (perception score increment -0.1 ± 0.4 ; $p=0.399$ vs basal, and girth increment 0.3 ± 0.2 cm vs basal; $p=0.112$).

Conclusion: STW5 improves tolerance to increments in colonic gas in patients with IBS. This medicinal product may be beneficial for management of gas-related symptoms, like bloating, in patients with IBS. EudraCT: 2019-003976-38.

INTESTINAL METHANOGEN OVERGROWTH IN AN IRISH COHORT - A CHALLENGING PROBLEM

L. Barry¹, D. Houlihan^{2,3}, W. Stack^{2,3}, L. Jackson^{2,3},

A.M. Keane McCarthy³

¹Bon Secours Hospital, GI Physiology Laboratory & Dept. of Gastroenterology, Cork, Ireland, ²Bon Secours Hospital, Dept. of Gastroenterology, Cork, Ireland, ³University College Cork, Department of Medicine, Cork, Ireland

Contact E-Mail Address: 119301866@umail.ucc.ie

Introduction: Small Intestinal Bacterial Overgrowth (SIBO) & Intestinal Methanogen Overgrowth (IMO) are recognized but poorly defined conditions which are increasingly recognized to play a role in the clinical manifestations of IBS. Recent meta-analysis² data shows high prevalence of SIBO/IMO in 31% IBS patients. Recent AGA Clinical Practice update acknowledges that there is limited data to guide clinicians on optimum treatment of SIBO/IMO¹. Data has suggested that a combination of Rifaximin and Neomycin was effective treatment strategy in those with Intestinal Methanogen Overgrowth.³

Aims & Methods: To assess the efficacy of recommended antibiotic treatment strategies for the eradication of IMO in an Irish cohort. Retrospective review of results of Glucose Breath Tests & medical records of 201 consecutive patients (153F, 48M), who attended our unit between Feb'21 & Feb'22 was undertaken.

Results: 58/201 (28.8%) patients (46F, 12M) referred with IBS symptoms were found to have abnormal Hydrogen (7/58 -12%) and Methane (51/58-87.9%) Breath Tests. All patient identified with intestinal methanogenic overgrowth (the presence of methane levels of >10 ppm CH₄ any time during the breath test) were prescribed antibiotic therapy. The importance of addressing the constipation was reiterated. All of the treated IMO patients were scheduled follow up glucose Breath Test to confirm "eradication" ~12 weeks post cessation of treatment. 26/51 patients with IMO have returned for repeat breath testing to date. 17/26 (65.4%) of returning IMO patients were treated with dual antibiotic therapy (Rifaximin & neomycin), 5/26 (19.2%) were treated with single agent Rifaximin and 4 with metronidazole (15.4%)

Remission was observed in 8/26 (30.7%) patients who returned for repeat breath test post antibiotic treatment. There was no significant difference between remission in dual vs single agent antibiotic therapies (35.2% vs. 22.2%, $p=0.66$).

Conclusion: We have demonstrated high prevalence of IMO/SIBO in an Irish population similar to that reported in large meta-analysis². This represents a high burden of care. Treatment with current recommended therapies resulted in sustained eradication in only 30.7% of those treated to date. This is significantly lower than previously reported³. With increasing mindfulness of need for antibiotic stewardship urgent further studies are required to determine better therapeutic strategies for this cohort

IMPACT OF INTEGRATED MULTIDISCIPLINARY MANAGEMENT ON SUBSEQUENT HEALTH CARE UTILISATION BY COMPLEX PATIENTS WITH DISORDERS OF BRAIN-GUT INTERACTION: A PROSPECTIVE 12-MONTH CONTROL COHORT STUDY

B. McKillen¹, N. Moy², C.-y. Chao³, A. Ahmadvand¹, A. Taylor¹, A. Shah¹, G.J. Holtmann¹, N. Talley⁴, M. Jones⁵

Contact E-Mail Address: benjamin.mckillen@hotmail.com

Introduction: An integrated approach for the management of patients with functional gastrointestinal disorders (FGID) has recently been shown to result in superior reductions in both symptom burden and psychological morbidity compared to standard care.⁽¹⁾ It is not clear, however, whether this results in a subsequent reduction in healthcare utilisation.

Aims & Methods: **Aims:** To assess the impact of a 3 month structured treatment in a dedicated integrated care clinic (ICC) versus standard care on subsequent healthcare utilisation among patients with functional gastrointestinal disorders (FGID) who had failed to respond to conventional treatment modalities available in the outpatient setting.

Methods: A cohort of 100 consecutive patients with FGID were matched with 200 FGID control patients according to age, gender, FGID diagnosis and symptom severity at a large tertiary hospital. ICC patients received 3 months of a highly structured treatment program provided by a multidisciplinary team of gastroenterologists, general practitioners, dietitians, psychologists, and exercise physiologists. Historic controls (before the ICC program commenced) received standard care at the same facility meeting established clinical guidelines with access to allied health interventions but no standardised multidisciplinary approach.

Healthcare utilisation including hospital admissions, emergency department presentations, outpatient clinic attendances, procedures, imaging studies and allied health reviews were assessed by review of the statewide integrated electronic medical record (iEMR), capturing service events 12 months before and after the ICC intervention or standard care in the case of the controls.

Healthcare utilisation by each group was compared by category (hospital admissions, emergency department presentations, outpatient visits, allied health reviews, diagnostic and therapeutic procedures and imaging) and the overall cost of healthcare utilisation was estimated using Australian costing (MBS) data.

Results: Healthcare utilisation by ICC patients decreased by a mean of 2.4 service occasions per patient compared to controls, resulting in a cost delta of approximately \$2,600 for the 12 months after the intervention. This change was driven by a statistically significant decrease in OPD attendances, allied health reviews and a reduced number of imaging studies in the ICC group.

	ICC Patients	Controls
Mean age (years)	45.8	43.2
Gender (percentage female)	81	81
Gastrointestinal Symptom Score (SAGIS) prior to ICC or standard care	30.3	31.2
Mean service encounters in 12 months post intervention	3.02	5.385

Conclusion: This matched cohort study demonstrates that an intensive 3 month integrated treatment program results in a significant reduction in healthcare utilisation when compared to a standard model of care in patients with treatment resistant FGID.

THE LOW FODMAP DIET IS EFFECTIVE IN IBS-C TERTIARY CARE NORMAL CLINICAL PRACTICE AND DOES NOT INCREASE CONSTIPATION

L.D. Martin¹, N. Canga², A. Alolyan²

¹University College London Hospital, Nutrition & Dietetics, London, United Kingdom, ²University College London, London, United Kingdom

Contact E-Mail Address: lee.martin1@nhs.net

Introduction: The low fermentable oligosaccharides, disaccharides, monosaccharides and polyols (FODMAP) diet is an effective treatment for irritable bowel syndrome (IBS). However the majority of randomised controlled trials have focused on those with a diarrhoea predominant subtype (IBS-D) and efficacy in IBS with constipation (IBS-C) still requires further evaluation¹.

Additionally there are concerns the diet could increase (or not improve) constipation symptoms² and taken together these factors may cause trepidation in offering a low FODMAP diet to IBS-C in clinical practice.

Aims & Methods: This study utilised a relatively large IBS data set from normal clinical practice and aimed (1) to evaluate the effectiveness of FODMAP Restriction across the range of IBS sub-types and (2) to describe the impact of diet had on stool patterns in IBS-C and how this related to diet effectiveness.

An observational, prospective study of patients with IBS (n=272) aged 18 to 86 years (44.6 ± 15.5), 226 females (83%). All patients attended FODMAP Restriction (baseline) and FODMAP Reintroduction (follow up) dietetic-led group education sessions.

Primary outcome of effectiveness was assessed using the global symptom question (GSQ)³ measuring 'satisfactory relief of gut symptoms'. Secondary outcomes assessed changes in stool consistency and related IBS sub-type using Bristol Stool Form Scale (BSFS)⁴.

To determine any differences in satisfactory relief at baseline and follow up across IBS sub-types a Bonferroni Mann Whitney U test was applied. Descriptive analyses identified changes in IBS sub-type at follow up while satisfactory relief at follow up was compared using Chi-squared.

Results: In the entire cohort (n=272), IBS-C represented 23%. Both IBS-C (n=63) and IBS-D (n=98) achieved similar satisfactory relief from FODMAP Restriction (p=NS). IBS-U (n=83) were more likely to have satisfactory relief at baseline compared to IBS-D (p=0.012) and IBS-C (p=0.011) but similar relief at follow up (p=NS). IBS-M (n=28) experience significantly less satisfactory relief compared to IBS-C (p=0.006) and IBS-U (p=0.008) but not IBS-D (p=0.073).

Following FODMAP Restriction in patients with IBS-C 51% (n=32) remained IBS-C while 44% (n=28) changed to IBS-U, the remaining 5% changed to IBS-M (n=2) or IBS-D (n=1).

Satisfactory relief was achieved in 50% (n=16) of 'IBS-C to IBS-C' but in 71% (n=20) of 'IBS-C to IBS-U' although this did not reach significance (p=0.091).

Conclusion: Overall 60% of IBS-C achieved satisfactory relief of symptoms following FODMAP Restriction. 44% changed stool pattern from abnormal (IBS-C) to normal (IBS-U) consistency, highlighting FODMAP Restriction does not necessarily increase constipation in IBS-C.

Higher rates of satisfactory relief were achieved in those who improved stool consistency. In tertiary care clinical practice patients with IBS-C should be offered the low FODMAP dietary treatment.

13C-BUTYRATE AND 13C-GLUCOSE BREATH TESTING TO DETECT MESENTERIC ISCHEMIA, A PROOF OF PRINCIPAL STUDY IN HEALTHY VOLUNTEERS

D. Harmankaya¹, L. Terlouw¹, D. Leemreis- van Noord², A. Moelker³, M.J. Bruno¹, M.P. Peppelenbosch¹

Introduction: Chronic mesenteric ischemia (CMI) is an incapacitating disease that can progress to potentially fatal acute mesenteric ischemia. A gold standard diagnostic test to diagnose CMI is currently lacking, causing both undertreatment and overtreatment of patients.

Since CMI is accompanied by a switch of the intestinal epithelium from butyrate-dependent oxidative phosphorylation to anaerobic glucose metabolism and oxygen is needed to absorb and metabolize butyrate and glucose in the enterocyte, a labelled-butyrate and labelled-glucose breath test could theoretically quantify mucosal oxygen content and thereby detect ischemia.

Aims & Methods: This study is a multi-center randomized interventional proof of principal study, conducted in healthy volunteers without gastrointestinal complaints and with an unremarkable medical history. Two control groups and two intervention groups each consisting of five volunteers received either 13C-butyrate or 13C-glucose.

The control groups performed breath tests without performing any physical exercise. The intervention groups performed a 30 minute standardized bicycle ergometer exercise test, which has been proven to elicit mesenteric ischemia. Breath samples of expired 13CO₂ were collected during a period of 4 hours.

Results: A total of twenty volunteers were included in this study. In the control and intervention group butyrate reached the peak concentration of expired 13CO₂ faster than glucose (65 min. vs. 130 min). Compared to the control group butyrate and glucose were metabolized less in the intervention group (T30 min p=0.0043, T60 min p=0.0171, T75 min p=0.0360).

Conclusion: Glucose/butyrate breath testing can identify exercise-induced mesenteric ischemia by measuring mucosal oxygen consumption. This holds great promise for the development of a new diagnostic tool to detect and quantify mesenteric ischemia.

AGE-ADJUSTED CHARLSON COMORBIDITY INDEX PREDICTS COLONIC DIVERTICULAR REBLEEDING

H. You¹, D.H. Kim¹, S.-Y. Park¹, H. Kim¹

¹Chonnam National University Hospital and Medical School, Department of Gastroenterology and Hepatology, Gwangju, Korea (Republic of)

Contact E-Mail Address: go6003@naver.com

Introduction: Colonic diverticular bleeding (CDB) is a common cause of acute lower gastrointestinal bleeding.¹ Patients with CDB are at increased risk for recurrence.²⁻⁵ Its reported risk factors are similar but inconsistent, as previous studies included a small number of patients, and related clinical situations at each period may be different.

Here, we aimed to evaluate the clinical course of patients with CDB and identify risk factors, including the age-adjusted Charlson comorbidity index (ACCI), for recurrent CDB (rCDB).

Aims & Methods: We retrospectively included patients who were hospitalized at the Chonnam National University Hospital for management of CDB between January 2005 and March 2020, and data on the underlying disease, drug history, treatment method, post-discharge rCDB, and death were checked.

The primary and secondary outcomes were rCDB and mortality after diverticular bleeding, respectively. Rebleeding free days were calculated from the date of first bleeding to the date of recurrence or death using the Kaplan-Meier method.

Results: Among 221 investigated patients (mean age, 68.1 years; 56 females), 56 and 165 had definite and presumptive CDB, respectively, 122 (55.2%) had a right-sided CDB, and 51 (23.3%) experienced rCDB throughout a median period of 339 days (range, 3-4817 days).

Variables	cHR	95% CI	p-value	aHR	95% CI	p-value
Male sex	1.73	0.96-3.10	0.07			
ACCI ≥ 7	2.11	1.05-4.22	0.04	2.76	1.30-5.88	0.03
Number of antithrombotics	1.00	0.71-1.43	0.99			
Steroids	0.31	0.07-1.38	0.12			
NSAIDs	0.81	0.29-2.26	0.69			
Hemostasis	1.03	0.55-1.90	0.94			
Location of bleeding	0.80	0.33-1.91	0.61			

Table 1. Univariate and multivariate analyses of the risk factors for increase in diverticular rebleeding using Cox regression.

The most common comorbidities were hypertension (62.4%) and diabetes (33.5%). The median length of hospitalization was 5 days (range, 2-119 days). The CDB-related mortality rate was 0.9% at first admission. The cumulative incidence rates of rCDB after 1, 6, 12, 24 months were

4.6%, 9.1%, 12.3%, and 16.9%, respectively. In Cox regression analysis, rCDB more frequently occurred in patients with ACCI ≥ 7 than in patients with ACCI < 7 (adjusted hazard ratio, 2.76; 95% confidence interval, 1.30–5.88; $p = 0.03$).

Conclusion: This study presented the clinical course of 221 patients with CDB over 13 years in a tertiary referral center. The recurrence rate was as high as 23%. rCDB occurred frequently at any time in patients with previous CDB. ACCI was effective for predicting rCDB. ACCI ≥ 7 was found to be significantly associated with an increased risk of rCDB. Clinicians need to consider possible rCDB for patients with high ACCIs.

CURRENT TREATMENT AND MANAGEMENT OF DIVERTICULAR DISEASE IN GERMANY: CHALLENGING DIAGNOSIS AND SUCCESSFUL PROBIOTIC THERAPY

M. Gross¹, U. Beckenbauer²

¹Internistisches Klinikum München Süd, Klinik für Allgemeine Innere Medizin und Gastroenterologie, Munich, Germany,

²Internistische Praxisgemeinschaft & Zentrum f. Präventivmedizin, Munich, Germany

Contact E-Mail Address: gross@muellerklinik.de

Introduction: The symptomatic uncomplicated diverticular disease (SUDD) is the most common type of diverticular disease, but guidelines provide only a few treatment options.

Aims & Methods: The aim of the present German-wide survey was to evaluate the current medical care situation for patients with diverticula in primary care and to record the grade of satisfaction with available therapeutic options. A questionnaire was sent to 13,790 German general physicians (GP). It contained questions concerning the diagnosis and medical care of patients with diverticula, the evaluation of available treatment options, and the challenges for the daily medical routine.

Results: In total, 526 questionnaires were sent back for analysis. The biggest challenge for GPs handling patients with chronic diverticular disease (SUDD) is making an accurate diagnosis (37%), including difficulties with the clear demarcation to the irritable bowel syndrome (22%). In line with that, only 6% of the medical practitioners feel themselves sufficiently informed about SUDD, despite the high prevalence of this disease.

The support for GPs by medical specialist such as gastroenterologists is relatively limited: After referring a patient with suspected acute diverticulitis or SUDD, the GP sometimes receive a therapy plan (27%), infrequently

advice for diverticulitis relapse prevention (18%), and rarely assisting information for patient education (4%). For primary prevention of symptoms in asymptomatic patients with diverticula, 41% of the GPs give nutritional advice, 37% recommend lifestyle changes and 18% recommend probiotics.

After an acute diverticulitis, 42% recommend lifestyle changes and nutritional measures, 26% probiotics. In agreement with the German guideline that does not recommend the use of mesalazine or rifaximin in this situation, these drugs are only recommended by 7% and 3%, respectively.

The most popular treatment options used by GPs for SUDD, are lifestyle and diet modification (45%) as well as the use of probiotics (30%). Mesalazine (8%) and rifaximin (2%) are seldom prescribed for SUDD.

Of the GPs who answered the survey, 72% and 74% are satisfied or very satisfied with the effect of lifestyle recommendations and dietary measures, respectively. 62% of the physicians are satisfied or very satisfied with the therapeutic effect of probiotics for SUDD. 47% of the participating GPs use probiotics to treat SUDD often or always.

Another 15% stated that they have not yet used probiotics to treat SUDD. The reasons given were the lack of reimbursability for probiotics by German health insurances (31%), the poor adherence of patients to therapy because of the delayed onset of the therapeutic effect (20%) and the difficulty of selecting an appropriate evidence-based probiotic (16%).

Conclusion: In daily medical routine, the accurate diagnosis of SUDD is a major challenge for GPs and supporting information provided by gastroenterologists is limited. Lifestyle and diet recommendations, as well as probiotics, are common and satisfying interventions in SUDD.

After acute diverticulitis, many GPs also give lifestyle and diet recommendations and around every fourth recommends probiotics after acute diverticulitis.

Disclosure: The study was supported by Microbiotica GmbH.

P0655

PRIOR ABDOMINAL SURGERY: A POTENTIAL RISK FACTOR FOR COLONIC DIVERTICULOSIS OR DIVERTICULITIS

E. Ariam¹, H. Shirin¹, A. Bermont¹, D.E. Cohen¹, V. Richter¹, Y. Sandler²

¹Shamir (Assaf Harofeh) Medical Center, Gastroenterology, Zerifin, Israel, ²Shamir (Assaf Harofeh) Medical Center, Surgery, Zerifin, Israel

Contact E-Mail Address: haimsh@shamir.gov.il

Introduction: Abnormal colonic pressure profiles have been associated with an increased risk of colonic diverticulosis. A surgical history is a known risk factor for abdominal adhesions, and these may lead to increased intraluminal colonic pressure. We assessed whether previous abdominal surgery is associated with colonic diverticulosis or diverticulitis.

Aims & Methods: We analyzed data from a prospective study of patients undergoing colonoscopy for different indications from 2020 through 2021. Patients completed a structured questionnaire concerning previous abdominal surgeries, dietary and lifestyle exposures including smoking and alcohol use, and co-morbidities.

Results: 359 patients were included in the study. The mean age was 67.6 and 46% were females. Diabetes mellitus, hypertension, ischemic heart disease, chronic obstructive pulmonary disease, chronic renal failure, and BMI were similar in the diverticulosis and control groups.

The overall prevalence of colonic diverticulosis was 25% (91/359) and 48% of the patients had previous abdominal surgery. As expected, the prevalence of diverticulosis increased with age. There was no difference in the rate of previous abdominal surgery between patients with or without diverticulosis (49% vs 47%, $p=0.78$).

In regards to specific surgeries, inguinal hernia repair was significantly associated with diverticulosis (52% vs 20%, $p=0.001$), but not diverticulitis. In contrast, appendectomy was found to have a protective effect for diverticulosis (6% vs 14%, $p=0.048$).

Conclusion: These findings suggest that post-operative abdominal adhesions inducing high colonic intraluminal pressures do not appear to be the mechanism for diverticula formation. Rather, inguinal hernia and diverticulosis probably share similar connective tissue pathologies with no causative relationship between them.

Contact E-Mail Address: mike.jones@mq.edu.au

Introduction: Diverticulosis is common in the general population and is generally a benign disease although diverticulitis can be complicated. As the exact prevalence of diverticular disease in the general population is largely unknown, the association with future health care use in non-health care seekers is uncertain. Here, we investigate if diverticulosis is associated with future health care use (HCU) in a population-based colonoscopy study.

Aims & Methods: This study is based on the PopCol study¹ in which 745 individuals from the general population had an ileocolonoscopy for research purposes. 130 individuals (55% women, mean age 61 years) had diverticulosis at the time of the investigation, and they were older than the individuals without diverticulosis (58% women, mean age 49 years). The study was later linked with registry data on health care use over the sub-

sequent 10 years. Health care use was classified based on ICD-10 codes for the health encounter. Since many patients do not seek some categories of health care, the association between diverticulosis and HCU was modelled using a zero-inflated negative binomial model which simultaneously estimates the association of any HCU (reported as log-odds ratio [ln-OR]) as well as the quantum of HCU (reported as incidence rate ratio [IRR]).

Results: Diverticulosis was associated with increased future extra-GI health care use, so that those that had sought care had more encounters, both in outpatient and tertiary care, but not GI or psychiatric health care (Table 1).

	IRR (SE) p-value	ln-OR (SE) p-value
Outpatient Extra-GI	1.25 (0.11) p = .02	-
Outpatient Psych	1.23 (0.44) p = .54	-1.19 (2.30) p = .61
Outpatient GI	1.42 (0.32) p = .15	-16.95 (7631.25) p = .99
In-patient Extra-GI	1.21 (0.11) p = .04	0.05 (22851.55) p = .99
In-patient GI	1.22 (0.48) p = .61	-1.16 (1.00) p = .25
In-patient Psychiatric	2.55 (5.31) p = .65	0.34 (1.68) p = .84

Table 1. Association between diverticular disease and future health care use, adjusted for age and gender

Conclusion: These novel data suggest extra-GI health care use was more common among those with diverticulosis than those without. The reasons remain to be clarified but the association between diverticulosis and extra-GI health care use will be further investigated in relation to extra GI symptom burden.

Contact E-Mail Address: dr.dancarter@gmail.com

Introduction: Fecal incontinence (FI) is a common chronic debilitating condition, diagnosed both in men and women. FI is often underreported and underestimated in men.

Aims & Methods: Our aim was to clarify the causes and the physiologic characteristics of FI in men and to compare these factors to those of women diagnosed with FI.

The study cohort encompassed 200 men and 200 women who were evaluated for FI in a tertiary referral center specializing in pelvic floor disorders. All patients underwent endoanal ultrasound and anorectal manometry. Demographic, medical, anatomic and physiologic parameters were compared between the 2 study groups.

Results: Urge incontinence was the most frequent type of FI both in men and women. Diagnosis of anal fistulas and history of anal surgeries, rectal tumors and pelvic radiotherapy were more common in men while

history of pelvic surgeries was more common in women. Associated urinary incontinence was reported more frequently by women. External anal sphincter defects, usually anterior, were more common in women (M:1.5%, W:24%, $p<0.0001$). Decreased resting and squeeze pressures were more common in women (M:29%, W:46%, $p<0.0001$: M:44%, W:66%, $p<0.0001$).

The incidence of rectal hyposensitivity was higher in men (M:33%, W:18%, $p<0.0001$), while rectal hypersensitivity was higher in women (M:29%, W:49%, $p<0.0001$). Anorectal dyssynergia was more common in men (M:66%, W:37%, $p<0.0001$). Ninety-one percent of patients had decreased maximal tolerance volume without significant difference between genders.

	Women	Men	p value
Age (years), median (IQR)	66 (55-72)	63(52-73)	0.8000
Anal surgery, n(%)	20 (10.9)	47 (25)	<0.0001
Pelvic surgery, n(%)	49 (26.5)	28 (14.9)	0.0060
EAS defect, n (%)	49 (24.5)	3 (1.5)	<0.0001
Resting pressure (mmHg), median (IQR)	52.9 (39.0-72.9)	62.5 (45.6-83.4)	0.004
Squeeze pressure (mmHg), median (IQR)	90.4 (69.5-123.2)	125.1 (96-162)	0.001
First sensation volume (ml), median (IQR)	30 (20-40)	40 (30-50)	<0.0001
Desire to defecate (ml), median (IQR)	80 (60-110)	100 (70-145)	<0.0001
Anismus, n (%)	74 (37.0)	132 (66.3)	<0.0001

Conclusion: FI in men has different etiologic factors and physiologic characteristics when compared with women. Acknowledging these differences is significant and may yield better treatment options.

Introduction: Hemorrhoidal disease (HD) therapy comprises office-based treatments as well as surgery.(1,2) This pilot study aimed to compare the efficacy and safety of polidocanol foam sclerotherapy (SP) with the surgical technique doppler-guided hemorrhoidal artery ligation with recto-anal repair (HAL-RAR).

Aims & Methods: Prospective, randomized, single centre study including patients with HD grades II and III. Participants were randomly assigned (1:1) into one of two groups (SP or HAL-RAR), stratified according to Goligher classification, during a recruitment period of six months. Therapeutic success, using Sodergren's score and a bleeding score, was the primary efficacy outcome. Primary and secondary safety outcomes evaluated complications and implication in professional life, respectively.

Results: A total of 46 eligible patients were allocated either to SP (n=22; 47.8%) or HAL-RAR (n=24; 52.2%). Most patients achieved therapeutic success (SP 100% vs. HAL-RAR 90.9%, $p=0.131$). However, complete success was higher in SP group (91.7% vs. 68.2%, $p=0.045$). SP treated patients had less complications (25%), when compared to HAL-RAR (68.2%) ($p=0.003$). Additionally, HAL-RAR revealed a higher rate of mild complications ($p=0.003$). HAL-RAR had a greater negative impact in patients' work activity, measured in days of absence from work (SP 0.6 ± 0.2 vs. HAL-RAR 9.5 ± 10.1 , $p\leq0.001$).

Conclusion: SP was more effective when considering complete success, and had fewer complications than HAL-RAR. Patients undergoing SP had less impact on their work activity.

CELL SHAPE CHARACTERISTICS OF HUMAN SKELETAL MUSCLE CELLS AS A PREDICTOR OF MYOGENIC COMPETENCY: A NEW PARADIGM TOWARDS PRECISION CELL THERAPY FOR INCONTINENCE

C. Desprez¹, D. Danovi², C.H. Knowles³, R. Day¹

¹Centre for Precision Healthcare, UCL Division of Medicine, University College London, London, United Kingdom,

²Centre for Gene Therapy and Regenerative Medicine, King's College London, London, United Kingdom, ³Queen Mary University of London School of Medicine NCBRSI, NBRC, London, United Kingdom

Contact E-Mail Address: charlotte-desprez@orange.fr

Introduction: Skeletal muscle derived cells (SMDC) hold tremendous potential for replenishing dysfunctional muscle associated with incontinence. Autologous SMDC-based therapy for faecal incontinence (FI) is reported to be safe, but the level of efficacy reported in previous studies suggests that heterogeneity in the proposed therapy may contribute to inconsistent clinical outcomes.

Improved methods for patient stratification to identify patients who are (un)likely to respond well to regenerative therapies are advocated to ensure the potential benefits of cell-based regenerative medicine can be fully exploited.

Aims & Methods: Here, we report on the development of a novel SMDC profiling tool to examine populations of cells *in vitro* derived from different donors.

The primary aim of the study was to evaluate the applicability of multi-parametric imaging-based phenotypic characterization to distinguish myogenic potency of SMDC. Heterogeneity in the formation of myotubes from different donors was correlated with cell shape descriptors.

Commercially available human SMDC (Cook MyoSite) consisting of non-differentiated primary human muscle cells were derived from 14 individual human donors. Image acquisition of SMDC growth was performed using a CytoSMART Lux2 microscope. Images were acquired every 5 minutes over a period of 72 hours.

CellProfiler software was used to create an image analysis pipeline for analysis of different cell shape characteristics during 2 hours of tracking at 12- and 24-hours post-culture. The Konstanz Information Miner (KNIME; open-source data analytics) software was used to calculate the mean and SD of the characteristic for all the objects identified in one image.

These data were then used for statistical correlation with the fusion index calculated from myotube formation assays established in the same cultures after 5 days of subsequent incubation in differentiation medium. The fusion index was calculated as the ratio of nuclei number in myocytes with 2 or more nuclei divided by the total number of nuclei. Correlation studies used the Spearman test with $r < -0.5$ or $> +0.5$ indicating correlation.

Results: Several early cell shape characteristics were found to negatively correlate with the fusion index. Images collected at 12 hours after initiating culture revealed that 5 cell shape characteristics negatively correlated with the fusion index, including the total area occupied by cells ($r = -0.815$, $p = 0.001$), area shape ($r = -0.631$; $p = 0.028$), bounding box area ($r = -0.576$; $p = 0.049$), minimum ferret diameter ($r = -0.589$; $p = 0.044$) and minor axis length ($r = -0.614$; $p = 0.034$). Images collected at 24 hours after initiating culture revealed 8 cell shape characteristics that negatively correlated with the fusion index.

These included: total area occupied by cells ($r = -0.686$; $p = 0.007$), area shape ($r = -0.709$; $p = 0.005$), bounding box area ($r = -0.563$; $p = 0.036$), compactness ($r = -0.534$; $p = 0.049$), equivalent diameter ($r = -0.576$; $p = 0.031$), minimum ferret diameter ($r = -0.620$; $p = 0.018$), minor axis length ($r = -0.590$; $p = 0.026$) and perimeter ($r = -0.654$; $p = 0.011$). There was a high correlation between all these characteristics at 24 hours of imaging after initiating culture.

Conclusion: Results indicate that monitoring of cell shape during the early stages of bioprocessing using real-time imaging could be used to predict cellular competency necessary for differentiation and myofibre formation *in vivo*.

Further studies could establish whether selection of either patients or cell populations on this basis have a higher probability of yielding better outcomes in cell-based therapy for incontinence.

A SYSTEMATIC REVIEW OF OUTCOMES ASSOCIATED WITH SETON PLACEMENT AND OTHER NON-INVASIVE TECHNIQUES FOR COMPLEX CRYPTOGLANDULAR FISTULA

D. Bennett^{1,2}, X. Zhang^{3,4}, M.D. Kappelman⁴, K. Iglay³, M. Aldridge³, C. Karki¹, S.F. Cook³

¹Takeda Pharmaceuticals USA, Inc., Cambridge, United States,

²University of Pennsylvania Perelman School of Medicine, Philadelphia, United States, ³CERobs Consultancy LLC, Chapel Hill, United States, ⁴University of North Carolina, Chapel Hill, United States

Contact E-Mail Address: dimitri.bennett@takeda.com

Introduction: Complex cryptoglandular fistulas (CCFs) are abnormal passages arising from inflammation of the proctodaeal glands in the intersphincteric space, which can be associated with substantial disease burden in affected patients. Treatment options include surgical and non-surgical interventions. Regardless of treatment strategy, seton placement is used to facilitate fistula drainage, promote fistula healing and prevent recurrent abscess formation.

Aims & Methods: The aim of this systematic literature review (PROSPERO registration: CRD42020177732) was to assess treatment outcomes of interest (fistula healing, recurrence, faecal incontinence and pain) associated with seton placement, selected biomaterial approaches (plug, collagen paste and plasma) and non-operative techniques (laser ablation, video-assisted anal fistula treatment and over-the-scope clip) in patients with CCF. Embase and PubMed were searched for CCF observational studies published between 1 January 2015 and 25 March 2020 reporting the outcomes of interest.

Articles were screened for inclusion by two trained reviewers using PI-COTS criteria and data on outcomes of interest were extracted from included articles. Articles were assessed for risk of bias using the Risk of Bias in Non-randomized Studies – of Interventions (ROBINS-I) tool. Data were summarized using descriptive statistics.

Results: After screening, 18 studies were included (Table). In total, 17 articles reported rates of fistula healing or success, with notable heterogeneous or absent outcome definitions. Healing/success rates were intervention-dependent (Table), ranging from 39% to 98% with mean and median follow-up times ranging from 6 months to 9.4 years. Recurrence/treatment failure was reported in 14 articles (Table).

Rates of recurrence/treatment failure were also variable and dependent on intervention type (range: 3%–44%; Table), with the same follow-up times as for healing. Rates of faecal incontinence were reported in 16 articles using a variety of faecal incontinence scales.

Overall, faecal incontinence was minimal during post-operative follow-up (range: 6–24 months) regardless of intervention. Few studies (n = 8) reported pain as a clinical outcome. The majority used a mix of clinician- and patient-reported scales with limited evidence of long-term post-operative pain (follow-up range: 6–24 months). Most articles (89%) included had a moderate risk of bias.

Intervention	Overall number of articles included in the systematic literature review (n)	Rate of healing/success ^a (range, % [number of articles, n])	Rate of recurrence/treatment failure ^b (range, % [number of articles, n])
Seton use	2	90–98 (2)	7–10 (2)
Biomaterial approaches	9	41–70 (8)	3–44 (7)
Non-operative techniques	7	39–90 (7)	10–40 (5)

^aHealing was generally defined as closure of the fistula opening or lack of fistula drainage
^bRecurrence/treatment failure was generally defined as persistence or reappearance of fistula with or without symptoms such as pain or purulent discharge

Table: Rates of healing and recurrence in patients with complex cryptoglandular fistula by intervention

Conclusion: Rates of healing/success and recurrence/treatment failure in patients with CCF varied widely among and within most interventions. The variability observed is potentially due to the heterogeneous outcome definitions, follow-up duration, patient characteristics and study designs, which highlight a need for consistent approaches to study CCF and produce comparable outcomes.

Despite limited evidence, the low to modest rates of recurrence and rare reports of long-term post-operative incontinence or pain suggest non-invasive procedures may help to relieve the substantial burden of CCF.

Contact E-Mail Address: charlotte-desprez@orange.fr

Introduction: Faecal incontinence (FI) subtypes (urge, passive, mixed) are linked to the physiopathological mechanism of FI. Previous studies have failed to demonstrate a consistent relationship between FI subtypes and anal sphincter dysfunctions. Our aim was to evaluate the relationship between anal sphincter function assessed using the new EndoFLIP® technology and FI subtypes.

Aims & Methods: Patients referred for FI were prospectively enrolled between October 2015 and May 2021 in a registry, and data were retrospectively examined. Each patient underwent a clinical assessment as well as 3D-high resolution or water-perfused anorectal manometry, anal EndoFLIP®, anorectal electrophysiological, and endoanal ultrasound tests. The results of the investigations were compared across FI subtypes.

Results: The cohort included 133 patients, 54 (41%) meeting the criteria for urge FI, 40 (30%) for passive FI, and 39 (29%) for mixed FI. The resting anal distensibility index (DI) at 50 mL of distension was significantly lower in patients with urge FI than in patients with passive FI (p=0.04). At rest, a DI at 50 mL of distension ≥7.3 mm².mmHg⁻¹ and a DI at 40 mL of distension <1.3 mm².mmHg⁻¹ were associated with the passive and urge FI subtypes, respectively, with poor discriminatory power (accuracy of 0.49 compared to 0.33 for random assignment).

There were no differences in anorectal manometry, endoanal ultrasound, electrophysiologic test results among the urge, passive, and mixed FI subgroups (all p>0.05).

Conclusion: The anal sphincter DI using the EndoFLIP® system displayed poor predictive performance in distinguishing among FI subtypes. The EndoFLIP® system can distinguish among FI subtypes in some extreme cases but is not powerful enough to be used alone to diagnose an FI subtype.

THE EFFECTIVENESS OF PERSONALIZED COLORECTAL CANCER SCREENING BASED ON PRIOR FECAL HEMOGLOBIN CONCENTRATION: PERFECT-FIT STUDY PROTOCOL

E. Toes-Zoutendijk¹, E. Brekvelde¹, L. de Jonge¹, M.C.W. Spaander², A. van Vuuren², F. van Kemenade³, C. Ramakers⁴, E. Dekker⁵, I.D. Nagtegaal⁶, M. van Leerdam⁷, I. Lansdorp-Vogelaar¹

Contact E-Mail Address: e.toes-zoutendijk@erasmusmc.nl

Introduction: In 2014, a national population-based colorectal cancer (CRC) screening program was implemented in the Netherlands, using biennial fecal immunochemical testing (FIT) at a cut-off of 47 µg haemoglobin (Hb)/g feces. The CRC screening program has been successful; high participation rates and yield of screening resulting in a decrease in overall and advanced-stage CRC incidence (1-3).

However, the vast majority of people screened will never develop cancer and thus will not benefit from CRC screening. Now that the program has reached its steady state, there is potential to further optimize the program. Previous studies showed that prior fecal Hb concentration just below the FIT cut-off (<47 µg Hb/g feces) is associated with a higher risk for detection of CRC or advanced adenomas (AA) at subsequent screening rounds (2). Therefore, individuals with a prior negative FIT, but with higher prior fecal Hb concentrations below the FIT cut-off, may benefit from a shorter invitation interval, whereas individuals with unmeasurable fecal Hb concentrations could benefit from longer invitation intervals. In this study, we aim to improve the yield and effectiveness of the Dutch CRC screening program by using a personalized screening strategy based on prior fecal Hb concentrations.

Aims & Methods: This mixed-method study will consist of three parts: 1) a randomized controlled trial (RCT), 2) decision modelling, 3) and focus groups. The RCT will be conducted within the national CRC screening program among individuals with a negative FIT in the previous screening round.

Individuals in the intervention arm will receive a new invitation after one, two, or three years after their last invitation, depending on their prior fecal Hb concentration. Individuals in the control arm will receive an invitation after 2 years according to current practice.

The fecal Hb concentration thresholds for the intervention arm are >15-47 µg Hb/g feces (one-year interval), >0-15 µg Hb/g feces (two-year interval), and 0 µg Hb/g feces (three-year interval), respectively. Primary study outcome is the yield of CRC and AA per screened individual in the intervention arm compared to the control arm. Secondary study outcomes are acceptability of and adherence to personalized screening.

Results of the RCT will be incorporated into the MISCAN-Colon decision model to determine long-term benefits, harms, and costs of personalized versus uniform screening. Focus group will be organized to gain insight in the information need about personalized screening and to evaluate experiences with receiving an adjusted screening interval based on personal risk.

Results: We anticipate that with a personalized screening strategy with adjusted intervals based on prior fecal Hb concentration of individuals with a negative FIT, will result in higher yield of CRC and AA detection per screened individual, anticipating on an increase in detection rate from 1.5% to 2.0%. In the long-term, personalized screening will require fewer FITs and colonoscopies than uniform screening for the same level of benefit for the total target population.

Conclusion: In the proposed study, we aim to prove superiority of a personalized CRC screening strategy in terms of harms-benefits ratio, by using an already registered risk factor, for which no additional resources are required.

Furthermore, we aim to prove the feasibility and acceptability of personalized screening within a national population-based CRC screening program making use of the current screening infrastructure.

DIAGNOSTIC VALUE OF BIOPSY FOR LESIONS FOUND IN THE TERMINAL ILEUM DURING COLONOSCOPY

D.S. Kim¹, H.S. Koo¹, K.-C. Huh¹

¹Konyang University College of Medicine, Gastroenterology and Hepatology, Daejeon, Korea (Republic of)

Contact E-Mail Address: hornkim0404@gmail.com

Introduction: Despite the development of enteroscopy, it is not easy to diagnose small bowel diseases. In many cases, it is possible to obtain clues about small bowel diseases by observing the terminal ileum during colonoscopy.

However, in many cases, even if a lesion is found, it is more likely to be a nonspecific finding rather than to help diagnose a specific disease. The diagnostic value of ileoscopy is not well established and the routine practice of ileal intubation is controversial.

Aims & Methods: This study was performed retrospectively in patients who had biopsy on abnormal lesions in the terminal ileum during colonoscopy from 2000 to 2019. Positive diagnosis for significant disease was defined as a case in which a specific disease was suspected or confirmed in the biopsy results, requiring additional examination or treatment for the disease. These included inflammatory bowel diseases (IBD) such as Crohn's disease, intestinal tuberculosis, infectious diseases, neoplastic diseases, and Behcet's disease.

Results: 854 biopsies were obtained from macroscopically abnormal lesions of the terminal ileum. The number of positive diagnosis for significant diseases were 75(8.8%). The rate of positive diagnosis was statistically significant in patients with anemia, clinically suspected IBD, right lower quadrant (RLQ) pain or abnormal radiologic finding on the terminal ileum. The incidence of specific diseases was higher when the lesion found in the

terminal ileum was an ulcer or when there were accompanying abnormalities in the ileocecal valve (ICV), in that case, the rate of Crohn's disease was particularly high.

	Number of cases	Positive diagnosis, n (%)	OR (95% CI)	P
Colonoscopy Indications				
Suspected IBD	28	13 (46.4)	10.680 (4.864–23.449)	<0.01
Anemia	21	7 (33.3)	5.625 (2.196–14.408)	<0.01
RLQ pain	16	4 (25)	3.601 (1.132–11.457)	0.03
Radiologic abnormality in the terminal ileum	50	15 (30)	5.314 (2.748–10.278)	<0.01
Macroscopic findings				
Ulcer	243	40 (16.5)	3.243 (2.005–5.246)	<0.01
Abnormal finding in ICV	107	15 (14)	1.867 (1.018–3.423)	0.04
Mass or polyp	63	20 (31.7)	6.224 (3.426–11.308)	<0.01

OR, Odds ratio; IBD, inflammatory bowel disease; RLQ, right lower quadrant; ICV, ileocecal valve

Table. The diagnostic yield of terminal ileum biopsy according to the indication of endoscopy and the macroscopic finding of the terminal ileum

Conclusion: Terminal ileum intubation is required if the patient has anemia, clinically suspected IBD, or has radiological abnormalities in the terminal ileum. If the lesion observed in the terminal ileum is an ulcer, polyp, or mass, and if there are accompanying abnormal findings in the ICV, a biopsy should also be performed. Crohn's disease should be considered, especially in cases of anemia, suspected IBD patients, gross ulcers on the terminal ileum, or abnormal findings in the ICV.

Introduction: Although the split dose regimen is recommended as bowel preparation in patients underwent to morning colonoscopy, its use in daily practice remains limited. Conversely, the classic day before regimen account for up to 35% of inadequate bowel cleansing.

Aims & Methods: On this context, the Italian Society of Digestive Endoscopy (SIED) promoted a prospective multicentric randomised non inferiority study to compare two different regimen of low volume (PEG/citrate/symeticone) bowel preparation in patient that undergo to early morning colonoscopy

Tree hundred and twenty patients (mean 58 years old, 165 female) were equally randomised in group A to assume both dose of preparation from 8pm to midnight (*the day before late group*) and group B in which the second dose was taken 4 hours before the examination (*split dose group*).

The primary endpoint was to evaluate bowel cleansing adopting Boston Bowel Preparation Score. Secondary endpoints were the evaluation of compliance and tolerability, safety, Intraluminal boubles score, polyp detection rate.

Results: Efficacy measured using Chi-square test showed 86,1% (CI 95%, 79,7-90,7) good or optimal bowel cleansing for patients in group A and 96,8% (CI 95% 92,5-98,7) in group B (p-value <0,001). Propensity to repeat the same regimen at the next colonoscopy was significantly in favour of the *day before late group* (89,5% vs 80.8% - p value 0.034). Twenty-two patients in the group A and 40 in the group B referred fear of incontinence during the journey to the hospital (p value=0.01). Compliance and tolerability didn't show differences among the two groups.

Conclusion: Although the split dose regimen remains the standard, in some specific settings, the use of the *day before late regimen* represents an acceptable alternative that guarantees an adequate intestinal cleansing and better patients acceptability for early morning colonoscopy.

Introduction: Wnt/ β -catenin signaling plays a key role in hepatocyte regeneration in homeostasis and after liver injury. R-spondins (RSPO) amplify the signal of Wnt ligands by stabilizing and increasing the amount of Wnt receptors on the cell surface.

We previously showed that our hepatocyte-targeted RSPO mimetic, SZN-043, specifically induced Wnt target gene expression in the liver and promoted hepatocyte proliferation in mice. This study aims to evaluate the kinetics and the overall effects of SZN-043 induced hepatocyte proliferation in a 2-week daily SZN-043 dosing schedule.

Aims & Methods: In a 14-day period, SZN-043 treatments were administered intraperitoneally daily to NOD.CB17-Prkdcscid (SCID) mice. The control anti-GFP was administered intraperitoneally twice weekly. The nucleoside analog 5-ethynyl-2'-deoxyuridine (EdU), which labels DNA during S phase of proliferation, was included in the drinking water at 1 mg/mL throughout the 14 days of the study. Livers were collected daily of the first week and every other day of the second week. Liver sections were co-stained for EdU, Ki67, HNF4A and DAPI. At each time point, the hepatocyte proliferation index (number of Ki67+HNF4A+DAPI+ nuclei) and the accumulated number of hepatocytes that had gone through at least one round of proliferation (EdU+HNF4A+DAPI+ nuclei) were quantified with an ImageJ macro.

Results: Significant hepatocyte proliferation was observed 48 hours after the first dose of SZN-043, as shown by quantifying the Ki67+HNF4A+DAPI+ co-labeled nuclei, reaching a peak at Day 4, followed by a rapid decline to near baseline level at Day 6. This observation was supported by quantification of the EdU-labeled hepatocytes (EdU+HNF4A+DAPI+) in the study.

The percent of hepatocyte nuclei that were EdU-positive reached a plateau after Day 5, suggesting most hepatocytes stopped proliferating or incorporating EdU after this timepoint, with close to 60% of all hepatocytes in the SZN-043-treated group being EDU+ from day 6 to the end of the study.

Liver mRNA expression of *Axin2* was significantly increased with SZN-043 treatment compared to anti-GFP throughout the 14-day study, indicating that continuous daily dosing of SZN-043 maintained β -catenin signaling induction despite the much-reduced level of hepatocyte proliferation after day 5.

Significant non-hepatocyte (HNF4A-negative) cell proliferation was also observed with SZN-043 treatment. Histological evaluation suggested the Ki67-positive non-hepatocytes consisted mostly of Kupffer cells/macrophages and some endothelial cells.

Conclusion: Hepatocytes responded quickly to SZN-043 treatments and underwent a limited number of proliferation cycles, despite the continued exposure to SZN-043 and β -catenin signaling induction for up to 14 days. The proliferation observed in the HNF4A-negative cells in this study was

likely due to the tissue responding to the large number of proliferating hepatocytes, as we have previously shown that SZN-043 has no direct impact on cells other than hepatocytes (Surrozen data presented previously).

INHIBITION OF BCL-2 AND MCL-1 EFFECTIVELY INDUCES CELL DEATH IN HEPATOCELLULAR CARCINOMA (HCC) CELL LINES

F. Walz¹, M. Michalski¹, M. Bauer¹, M. Müller-Schilling¹, K. Gülow¹

¹University Hospital Regensburg, Internal Medicine I, Regensburg, Germany

Contact E-Mail Address: franziska1.walz@stud.uni-regensburg.de

Introduction: Hepatocellular carcinoma (HCC) is the sixth most common cancer type and the third most common cancer related cause of death worldwide. Especially in advanced stages, prognosis is still poor. Therefore, HCC is a major health issue with urgent need of new therapeutical options.

BH3-mimetics have become an emerging class of drugs during the last years. These small molecules inhibit anti-apoptotic Bcl-2 molecules, which are frequently overexpressed in cancer, including HCC. Intrinsic apoptosis can be induced by pro-apoptotic proteins Bax and Bak, which form pores in the outer mitochondrial membrane, resulting in the release of cytochrome c and the activation of caspases. Anti-apoptotic Bcl-2 proteins such as Bcl-2 and Mcl-1 exert their function by inhibiting this apoptotic process via blockage of Bax and Bak. Thus, inhibition of anti-apoptotic Bcl-2 proteins might restore apoptosis susceptibility of cancer cells.

ABT-199, a specific inhibitor of Bcl-2, is already approved for hematologic malignancies including CLL (chronic lymphocytic leukemia). MIK665 inhibits Mcl-1 and is currently in clinical trials for hematologic malignancies. BH3-mimetics have also proven preclinical efficacy in solid tumors.

Aims & Methods: We investigated whether the two described drugs could be repurposed for the treatment of HCC.

The three HCC cell lines Hep3B, HepG2 and Huh7 were treated with up to 5 μ M ABT and up to 6 μ M MIK, either alone or in combination. After 24 and 48h, cell death was assessed using flow cytometry after staining with DAPI and Annexin V. To characterize the underlying cell death mechanism, we measured the activity of caspases 3/7 in a luminescence based assay after 4 to 24h. Cleavage of caspase 3 and its substrate PARP was assessed by Western Blot after 4h.

Results: Single application of both drugs had only minor effects on cell death of all three cell lines. 5 μ M ABT induced up to 13%, 6 μ M MIK up to 20% cell death after 48h. In contrast, the combination of both drugs in these concentrations resulted in strong effects of up to 85% cell death after 48h, suggesting a synergistic effect. The most pronounced effect was observed in HepG2. Next, we analyzed the underlying cell death mechanism in more detail.

We detected a strong time and dose dependent increase in activity of caspases 3/7 after 4 to 24h treatment with the combination of ABT and MIK. Cleavage of caspase 3 and PARP was detected in Western Blot 4h after treatment with 5 μ M ABT and 6 μ M MIK. This indicates apoptosis as underlying cell death mechanism.

Conclusion: BH3-mimetics directly target resistance to apoptosis as one of the hallmarks of cancer. They have already proven beneficial in hematologic and some solid cancers. We now provide evidence that a combination of the BH3-mimetics ABT-199 and MIK665 effectively induces cell death in HCC cell lines. Drug combinations such as the ABT199/MIK665 presented here will therefore expand the therapeutic repertoire in the management of HCC and other tumor diseases in the future.

THEROLE AND MECHANISM OF IRBITIN HYPOXIA INDUCED ACTIVATION OF HEPATIC STELLATE CELLS

Z. Jin¹, J. Xu¹, R. Xie¹

¹Affiliated Hospital of Zunyi Medical University, Department of Gastroenterology, Zunyi, China

Contact E-Mail Address: jinzhe8725@163.com

Introduction: Studies have found that that hypoxia stress and hypoxia effector molecule.

HIF-1α are involved in the whole process of activation of hepatic stellate cells (HSCs) and development of hepatic fibrosis, inhibition of HIF-1α can effectively block the continuous activation of HSCs, but the regulatory mechanism of HIF-1α in the process of liver fibrosis is not clear.

In our previous experiments, we found that the increase of intracellular calcium concentration was accompanied by the stimulation of hypoxia inducer CoCl₂, suggesting that calcium signal may participate in its regulation mechanism. IRBIT, as a binding protein of IP3 receptor, can regulate the activities of many calcium channels on the membrane and affect the calcium transport inside and outside the membrane.

The purpose of this study is to explore the role and mechanism of IRBIT and its coupled calcium channels in hypoxia induced activation of hepatic stellate cells, so as to seek new drug targets for the treatment of liver cancer.

Aims & Methods: The expression of IRBIT was detected by Western blot and immunohistochemistry. CCK8 proliferation assay was used to detect the proliferation of hepatic

stellate cells stimulated by silencing IRBIT and CoCl₂. The expression of IRBIT, α-SMA, HIF-1α and related signal pathway proteins were detected by Western blot. The changes of intracellular calcium in hepatic stellate cells

stimulated by CoCl₂ were detected by Ca²⁺ imaging. The intracellular calcium channels regulated by IRBIT were screened by agonists and blockers, and

ShRNA lentiviral vector was constructed and transfected into the cells to silence the expression of IRBIT.

Results:

1. Immunohistochemistry showed that the expression of IRBIT, α-SMA and HIF-1α in liver fibrosis group was higher than that in normal liver tissue.
2. Western blot showed that TGF-β1 could induce the expression of α-SMA in HSC-T6 and LX-2 cells, but the expression of IRBIT was increased, which had statistical significance ($P < 0.05$).
3. Western blot showed that IRBIT, HIF-1α and α-SMA were increased after CoCl₂ stimulated hepatic stellate cells. ($P < 0.05$).
4. After silencing IRBIT in hepatic stellate cells LX2, the expression of HIF-1α and α-SMA induced by CoCl₂ was significantly reversed, suggesting that IRBIT may affect the occurrence and development of hepatic fibrosis by affecting hypoxia response pathway.
5. High speed calcium imaging showed that the intracellular Ca²⁺ concentration of LX-2 cells was significantly increased after CoCl₂ stimulation. When IRBIT expression of LX-2 cells was silenced by lentivirus, the increase

of intracellular Ca²⁺ induced by CoCl₂ was significantly blocked, which proved that IRBIT may promote the occurrence and development of liver fibrosis by regulating intracellular Ca²⁺ level under hypoxia stress.

Conclusion: Hypoxia stress can stimulate the up regulation of IRBIT expression in hepatic stellate cells, increase IRBIT movement to open corresponding calcium channels on the cell membrane, mediate the intracellular Ca²⁺ remodeling, promote the continuous activation of HSCs cells and the development of liver fibrosis. The results of this study have found a new way to affect the activation mechanism of HSC, which provides theoretical basis for targeted treatment of liver fibrosis targeting IRBIT.

Disclosure: The authors declare that they have no conflict of interest.

CASR AS AN IMPORTANT PROTECTIVE FACTOR COMBINED TO THE REGULATION OF HEPATIC STELLATE CELL ACTIVATION

J. Lou¹, X. Jingyu², R. Xie², XR-TEAM Study Group

¹Affiliated Hospital of Zunyi Medical University, Zunyi, China,

²Affiliated Hospital of Zunyi Medical University, Department of Gastroenterology, Zunyi, China

Contact E-Mail Address: lj29860431@126.com

Introduction: Clinical literature shows that patients from chronic hepatitis to cirrhosis show a gradual decrease in blood calcium concentration as the disease worsens. Therefore, calcium-sensitive receptors (CASR), which can sense changes in calcium in the blood, are particularly critical in liver fibrosis. Our previous experiments showed that as the index of liver fibrosis (α-SMA) was up-regulated in liver fibrotic tissue, the expression of CASR was down-regulated. Apoptosis increased significantly during the activation of HSCs stimulated by CaCl₂. CASR may be a new protective factor to inhibit the occurrence of liver fibrosis.

Aims & Methods: Immunohistochemistry, Western blot, high-speed calcium imaging and CCK8 were used to reveal the role of CaSR in liver fibrosis

Results: 1) In clinical data, the blood calcium concentration of patients with liver cirrhosis is significantly lower than normal.

2) In human tissue specimens, with the up-regulation of liver fibrosis index (α-SMA) in liver fibrosis tissue, the expression of CASR is down-regulated, and the two are negatively correlated.

3) Before and after the activated HSCs, pre-treatment with the CASR agonist CaCl₂, it was found that the protein expression of α-SMA decreased.

4) After adding CaCl₂ stimulation to activated HSCs, it was found that the proliferation ability of activated HSCs was significantly reversed.

5) Before and after the activation of HSCs, CaCl₂ and spermine stimulation can significantly induce changes in intracellular calcium.

6) CaCl₂ can significantly promote the apoptosis of activated HSCs.

7) In the activation of HSCs by high calcium stimulation, the expression of BAX increased and the expression of Bcl2 decreased significantly.

Conclusion: The calcium signal mediated by CaSR plays an important role in regulating the activation of hepatic stellate cells. CaSR may be used as a new target therapeutic mechanism, providing a novel and effective treatment for liver fibrosis.

RELATIONSHIP BETWEEN THE RATIO OF THE MAIN PHYLOTYPES OF THE GUT MICROBIOTA AND BODY COMPOSITION IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

G. Fadieienko¹, O. Gridnyev¹, N. Chereliuk¹

¹Government Institution „L.T.Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine“; Division for the Study of the Digestive Diseases and its Comorbidity with Noncommunicable Diseases, Kharkiv, Ukraine

Contact E-Mail Address: nat.chereliyk@gmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is one of the most common liver diseases worldwide and its development are closely related to the lifestyle of the population (especially nutrition and physical activity), especially in developed countries.

Aims & Methods: To analyse the relationship between the main phylotypes of gut microbiota (GM) and body composition in patients with NAFLD. 120 patients with NAFLD were examined: among them were 59 men (49.2%) and 61 (50.8%) women, the average age of patients was 47 years. All patients were divided into groups according to body mass index (BMI). The first group included 85 patients with NAFLD with BMI - 36.50 [32.00; 40.60] kg / m² (i.e. with obesity), and the second group included 35 patients with NAFLD with BMI - 28.00 (27.10; 29.35] kg / m² (i.e. with overweight). The control group consisted of 20 healthy volunteers: 8 men (40%) and 12 women (60%), whose average age was 43 years and BMI of 23.50 [21, 35; 24.78] kg / m². The study of GM composition at the level of basic phylotypes was performed by identifying total bacterial DNA and DNA of *Bacteroidetes* (*B*), *Firmicutes* (*F*), as well as the ratio of *F* / *B* by quantitative polymerase chain reaction in real time using universal primers for 16S rRNA and taxon specific primers. Determination of body composition was performed using bioimpedancemetry. Interpretation of the results of measuring the content of adipose tissue (AT) in the body, the percentage of visceral fat (VF) and skeletal muscle (SM) was performed according to the tables of the OMRON device. Statistical processing was performed using the Statistica 13.1 package. Data are given in the form of Me [LQ; UQ], where Me is the median, LQ and UQ are the lower and upper quartiles, respectively.

Results: In patients of the first group the relative content of *F* was - 52.12 [39, 94; 67.03]%, in patients of the second group - 51.49 [39.26; 62.88]%, which is almost 2 times higher than the corresponding indicator of the control group. The opposite dynamics was observed with respect to the relative content of *B* - in patients of the first group it acquired minimal values - 15.97 [8,10; 27.52]%, and was slightly higher in patients of the second group - 18.83 [7.96; 32.35]%, but in the control group it was probably higher. The *F* / *B* ratio in patients of the first group exceeded that of the control group by 5.7 times, and in patients of the second group by 4.3 times. Perhaps the resulting changes in the composition of GM may be associated with excessive development of AT: increase in the relative content of *F* in patients of both groups correlated with % of VF (*r* = + 0.74, *p* = 0.01 and *r* = + 0.70, *p* = 0, 01, respectively) and accordingly % SM (in patients from the second subgroup *r* = -0.47, *p* = 0.03); in turn, the decrease in the relative content of *B* in patients of both groups had reverse connection with % of VF (I- *r* = -0.48, *p* = 0.01 and II- *r* = -0.49, *p* = 0.003, respectively).

Conclusion: In patients of both groups there was an increase in the relative amount of *F* and the ratio of *F* / *B* against the background of the decrease in the relative content of *B*. These changes were statistically significantly more pronounced in patients with NAFLD in the presence of obesity. This allowed us to suggest the relationship between GM and the presence of NAFLD in patients of both groups, but this requires additional verification on the larger number of observations and is important for deepening the

understanding of the pathophysiological mechanisms of the development of ectopic fat depots, in particular in the liver.

DOPAMINE REGULATES AUTOPHAGY DURING TGF- β 1-INDUCED ACTIVATION OF HEPATIC STELLATE CELLS

X. Yang¹, X. Jingyu², R. Xie²

¹Affiliated Hospital of Zunyi Medical University, Zunyi, China,

²Affiliated Hospital of Zunyi Medical University, Department of Gastroenterology, Zunyi, China

Contact E-Mail Address: yangxiaoxu90@126.com

Introduction: The activation of hepatic stellate cells (HSCs) is the key factor in the pathogenesis of liver fibrosis. Studies have confirmed that autophagy is involved in the activation of HSCs, but the regulatory mechanism of autophagy is unclear. With the development of brain gut axis and neurotransmitters in the study of digestive system diseases, our preliminary results show that neurotransmitter dopamine (DA) can significantly inhibit the expression of autophagy gene and liver fibrosis marker α -SMA during the activation of HSCs.

Further studies suggest that DA stimulates the activation of TRPV1 calcium channel on the cell membrane of HSCs, which leads to intracellular calcium remodeling, and then inhibits autophagy and activation of HSCs, and finally plays an anti-fibrosis role.

This project aims to clarify the role and mechanism of DA in the autophagy of HSCs activation from animal experiments in vivo and cell experiments in vitro, that provides a theoretical basis for the targeted therapy of autophagy during the process of liver fibrosis.

Aims & Methods: The expression of α -SMA, autophagy gene and TRPV1 in human and liver fibrosis model mice were detected by immunohistochemistry. The effect of DA on the expression of α - SMA and autophagy gene before and after activation of HSCs was detected by Western-blot. The inhibition and construction of TRPV1 interference and overexpression plasmids were transfected into HSCs to observe the effect of DA on the expression of autophagy gene Flux variation. Calcium imaging was used to detect the changes of intracellular Ca²⁺ during DA stimulation on HSCs.

Results:

1. Compared with normal liver tissue, the expression of α -SMA and autophagy gene LC3 in liver fibrosis tissue increased, while the expression of TRPV1 decreased. Compared with the normal group, the expression of α - SMA increased and TRPV1 decreased in the liver fibrosis model group, which was reversed after DA treatment
2. Compared with activated HSCs, DA can significantly reduce the proliferation of HSCs (stimulated by TGF- β 1). Flow cytometry showed that DA had no significant effect on the apoptosis of HSCs.
3. Western-blot showed that DA and capsaicin could significantly reduce the expression of α - SMA, autophagy gene LC3 protein and autophagy flow in activated HSCs, which were eliminated by TRPV1 inhibitor sb-705498 or by interfering with the function of TRPV1. Overexpression of TRPV1 could enhance the effect of DA. It is suggested that DA may play a protective role by activating TRPV1.
4. Through calcium imaging experiments, it was found that DA stimulation was accompanied by the increase of intracellular Ca²⁺ in HSCs. At the same time, the intracellular Ca²⁺ in HSCs stimulated by capsaicin was increased, while using the intracellular Ca²⁺ chelators BAPTA-AM, sb-705498 and calcium free environment could not induce the change of Ca²⁺ in HSCs.
5. Mechanism studies confirmed that DA significantly inhibited the expression of p-smad3 protein in activated HSCs, and this effect disappeared after inhibition and interference of TRPV1.

Conclusion: Dopamine may act as a protective factor in the process of liver fibrosis. Dopamine may activate TRPV1 calcium channel on cell membrane to mediate extracellular calcium influx, leading to intracellular calcium remodeling, and then inhibit the autophagy and activation of HSCs mediated by TGF- β 1/Smad3 signaling pathway, and finally play an anti-fibrosis role.

Disclosure: no conflict interest.

Introduction: Hepatic encephalopathy (HE) remains one of the most debilitating complications of liver cirrhosis. Changes in gut microbiome composition have been linked to liver diseases and its complications including HE, while direct or indirect gut microbiome modulation remains standard of care treatment in HE. Fecal microbiota transplantation (FMT) has shown great success in the treatment of recurrent *Cl. Difficile* infection which led to further studies assessing FMT's efficacy in other diseases associated with dysbiosis including cirrhosis.

Recent randomized controlled trial showed FMT to be safe and effective in HE treatment, however transferring unidentified live bacteria could cause various complications, including infections, especially in immunocompromised patients. In 2017 a pilot study developed a special device with bacterial filters to produce sterile fecal filtrate (FFT), which maintained efficacy in treating *Cl. Difficile* infection while avoiding potential risks associated with bacterial transfer.

Aims & Methods: **Aims:** We have aimed to investigate safety and efficacy of sterile fecal filtrate in the treatment of hepatic encephalopathy

Methods: The study was conducted in Lithuanian University of Health Sciences, Kaunas Clinics, Department of Gastroenterology. Sterile fecal filtrate from a healthy tested donor stools was prepared following the methods described by Ott SJ¹. Seven patients with hepatitis C virus or alcohol induced cirrhosis and HE have been enrolled in the study and received sterile fecal filtrate through the nasojejunal tube. Patients were monitored for a month after a procedure. Standard blood tests reflecting liver function in addition to stool samples were collected prior to the procedure, a week and a month after the procedure.

Psychometric HE score tests were used to monitor hepatic encephalopathy during the control visits. Micorbial DNA was isolated from stool samples and 16S rRNA sequencing was performed using V1-V2 primers to determine fecal microbiome composition.

Results: Sterile fecal filtrate transfer was well tolerated, no adverse events were registered. Cirrhosis patients showed reduced alpha diversity prior to the procedure as compared to the donor. Significant shifts in stool microbiome composition were observed in 3/7 patients, as there was an increase in Shannon alpha diversity index, reduction in abundance of *Proteobacteria* phylum and a shift towards donors' microbial composition as assessed by Bray-Curtis dissimilarity analysis. Despite compositional changes - we have not observed any significant clinical effects of the pro-

cedure. Liver function biochemical tests, psychometric HE score tests did not reveal any significant improvement over the observational period. One of the patients who received FFT died shortly after the observational period. The death was unrelated to the FFT procedure. The patient did not show significant shifts in microbiome composition after the FFT procedure, on the contrast - there was a gradual reduction in alpha diversity metrics during the control visits.

Conclusion: Sterile fecal filtrate transfer resulted in significant shifts in stool microbiota composition for a portion of the patients. Despite the effect on the microbiota composition, we have not witnessed any additional clinical benefits for these patients.

Introduction: Non-invasive ultrasound-based techniques for liver stiffness assessment (LSM) were developed as an alternative to liver biopsy. Transient Elastography (TE) is the first method validated by several guidelines and recently other new methods were developed. The aim of this study was to evaluate the performance of two point Shear Waves Elastography (pSWE) techniques implemented in the same ultrasound system for liver stiffness assessment, using TE as reference.

Aims & Methods: A prospective study was conducted, in which 271 consecutive patients with or without previously diagnosed liver disease were included.

LSM was evaluated by point Shear Wave Elastography (pSWE and Auto pSWE) implemented on a Siemens ACUSON Sequoia system (Deep Abdominal Transducer-DAX) and by TE, using a FibroScan Compact M 530 system (M and XL probes).

For Auto pSWE, 15 measurements/values are automatically obtained in a single evaluation and the median and IQR are displayed. For p-SWE and TE, reliable measurements were defined as the median value of 10 measurements and IQR/M<0.3 for all probes. For significant fibrosis, a cut-off value by TE of 7 kPa was used, and for liver cirrhosis 12 kPa [1].

Results: Valid LSM were obtained in all 271 (100%) patients using both elastographic methods. A very good positive correlation was found between the LS values obtained by TE and both Auto pSWE and pSWE: $r=0.78$, $p<0.0001$; and between Auto pSWE and pSWE: $r=0.92$, $p<0.0001$.

The best pSWE and Auto pSWE cut-off value for significant fibrosis ($F\geq 2$) was 5.1 kPa (p-SWE: AUC- 0.81; Se-58.3%; Sp-94.6%; PPV-83.1%; NPV-83.5%; Auto pSWE: AUC- 0.82; Se-63.1%; Sp-90.4%; PPV-76.8%; NPV-84.4%) and for liver cirrhosis (F4) was 6.7 kPa (p-SWE: AUC- 0.92; Se-73.8%; Sp-94.3%; PPV-83.8%; NPV-95.3%; Auto pSWE: AUC- 0.93; Se-78.5%; Sp-97.8%; PPV-86.8%; NPV-96.1%).

Conclusion: The two techniques, *pSWE* and *Auto pSWE* have very good correlations with TE and similar performance for predicting significant fibrosis and liver cirrhosis in a mixed cohort of patients.

Introduction: The neutrophil-to-lymphocyte (NLR) ratio is a marker of systemic inflammatory response, which has been studied as an interesting prognostic biomarker in various tumor types. This ratio incorporates two immune systems: neutrophils which exemplify the continual inflammation and lymphocytes which exemplify the regulatory pathway.

Aims & Methods: The aim of our study was to establish the correlation between NLR, the severity of cirrhosis and the occurrence of complications. This is a retrospective descriptive study including all patients followed for cirrhosis between January 2015 and January 2021.

Results: 60 patients were collected during the study period. The mean age at the time of diagnosis was 52 ± 14.88 (26-87) years. Fifty-three patients (53.3%) were female. Etiologies found for cirrhosis were: hepatitis B virus infection in 30% of cases, primary biliary cholangitis in 16.7%, non-alcoholic steatohepatitis in 11.7%, hepatitis C virus infection in 8.3 % of cases and alcohol intake in 1.7% of cases.

The aetiological assessment was negative in 28.3% of cases. The average MELD score at admission was 42 points (9-80). Cirrhosis was classified as CHILD A in 19 cases, CHILD B in 31 cases and CHILD C in 10 cases. Endoscopic signs of portal hypertension were present in 95% of cases at the time of diagnosis, of which 33% were represented by grade 1 esophageal varices, 35% by grade 2 esophageal varices and 3.3% by grade 3 esophageal varices. 11.7% of the patients had gastric varices and 48% of the patients had hypertensive gastropathy.

Ascites was the main complication present in 66.7%. The other complications of cirrhosis were upper gastrointestinal bleeding by rupture of esophageal varices in 28.3% of cases, hepatic encephalopathy in 16.7% of cases and hepatocellular carcinoma in 11.7% of cases. The average NLR score was 4.4 (0.82-22.7).

The analytical study had shown that the RNL ratio was positively correlated with the MELD score with ($p = 0.03$); as well as with the occurrence of cirrhosis complications ($p=0.05$). However, there was no correlation between NLR and CHILD score ($p=0.29$).

Conclusion: In our study, the neutrophil-to-lymphocyte (NLR) ratio was significantly correlated with the MELD score and the occurrence of complications and can thus be used to assess the prognosis of cirrhotic patients.

Disclosure: Nothing to disclose.

THE POSITIVE EFFECTS OF SYMBIOTICS ON LIVER STEATOSIS BY IMPROVING GUT MICROBIOLOGY- RANDOMIZED CONTROLLED TRIAL

M. Mitrović¹, M. Pantelic¹, D. Zlatković¹, P. Svorcan^{2,1}

¹Kbc Zvezdara, Gastroenterology and Hepatology, Belgrade, Serbia, ²School of Medicine Belgrade, Belgrade, Serbia

Contact E-Mail Address: miloskbcz18@gmail.com

Introduction: Treatment options for non-alcoholic fatty liver disease (NAFLD) are currently limited. No pharmaceutical intervention is approved, and the focus is on lifestyle modification. Altering dysbiotic gut flora through synbiotic supplementation has recently been recognized as a potential treatment strategy to reduce the production of microbial endotoxins, decrease local and systemic inflammation, and liver steatosis. Assessing the efficacy and safety of this potential strategy has been the main goal of our randomized, double-blind, placebo-controlled trial.

Aims & Methods: A total of 21 NAFLD patients aged 18-80 years with the ability to provide informed consent, were included in the study. NAFLD was defined by a baseline attenuation (ATT) coefficient score measured by shear-wave (SW) elastography of 0.63 dB/cm/MHz or higher and a baseline ALT of more than 40 IU/L for males and 35 IU/L for females.

The exclusion criteria were alcohol use (consuming > 40 g alcohol/day for men and > 20 g/day for women in the preceding 12 months), chronic viral hepatitis, the presence of hepatic carcinoma, biliary disease, drug use, and hypothyroidism associated with fatty liver.

Patients were randomized either to an intervention group ($n = 11$) receiving synbiotics (*Lactobacillus acidophilus*, *Lactobacillus casei*, and *Bifidobacterium lactis*, 32 billion colony forming units per day plus 3.2 g of inulin) or control group ($n = 10$) receiving placebo for 3 months.

The impact of treatment on the dynamic of ALT and SW elastography parameters was defined as the primary outcome of the study. Secondary outcomes included changes in the stool microbiome, serum interleukin-6 levels, high sensitivity C-reactive protein (hsCRP), diet, and safety. A correlation substudy between microbiome composition and clinical parameters was also performed. Stool microbiome analysis was performed through 16S rRNA gene sequencing.

Results: Synbiotic treatment significantly modified the gut microbiome with *Bifidobacteria* ($p = 0.11$) and *Faecalibacterium* ($p = 0.016$) genera enrichment and consequently significantly reduced serum ALT levels (Δ ALT -4.2 vs 0.6 IU/L, $p = 0.024$). The effect of synbiotics on SW elastography parameters was less pronounced.

Although both groups of patients showed a tendency towards ATT decrease, the effect of synbiotics was of larger magnitude, but fell short of statistical significance (Δ ATT -0.062 vs -0.058, $p=0.063$). An inverted correlation between *Bifidobacterium* abundance and hsCRP levels was noted ($\rho = -0.446$, $p = 0.033$). No safety issues were noted.

Conclusion: Synbiotics could be available, safe, and an effective therapeutic strategy that we could use in daily practice as a complementary treatment for NAFLD patients. Further studies on the subject are needed.

Disclosure: Nothing to disclose.

Introduction: Metabolic-associated fatty liver disease (MAFLD) is related to deviations in various serological and hematological markers. Nevertheless, looking for new laboratory parameters with a good diagnostic accuracy in its course constitutes an essential direction in hepatology all the time.

Aims & Methods: The purpose of our survey was to evaluate a diagnostic accuracy of cytokeratins [apoptosis-associated caspase-cleaved keratin 18 (CCK18) and keratin 18 (K18)] and Golgi protein 73 (GP73) together with relationships between them and selected hematological indices [red cell distribution width-to-platelet ratio (RPR), neutrophil-to-lymphocyte ratio (NLR) and red cell distribution width-to-lymphocyte ratio (RLR)], direct and indirect markers of liver fibrosis and microRNAs (miRNAs), in the course of MAFLD.

One hundred ninety six persons were enrolled to the study: 96 with MAFLD and 100 healthy volunteers in control group. Serological expression of cytokeratins (CCK18 and K18), GP73, procollagen I carboxyterminal propeptide (PICP), procollagen III aminoterminal propeptide (PIIINP), platelet-derived growth factor AB (PDGF-AB), transforming growth factor- α (TGF- α), laminin, miR-126-3p, miR-197-3p and miR-1-3p was evaluated in all examined patients. We measured AAR, APRI, FIB-4 and GPR in examined patients, too. RPR, NLR and RLR were obtained, as well. Then we looked for correlations between investigated cytokeratins, GP73 and the rest of assessed parameters.

Additionally, a diagnostic value of cytokeratins (CCK18 and K18) and GP73 together with proposed cut-off in research group were measured with area under the curve (AUC).

Results: The concentration of CCK18 and K18 together with GP73 was significantly greater in MAFLD group compared to controls ($p < 0.0001$). Moreover, MAFLD patients with BARD score ≥ 2 had significantly higher results of CCK18 and GP73 ($p < 0.05$) in comparison to persons with BARD score < 2 . K18 correlated positively with PICP, miR-126-3p, GPR, APRI and RLR ($p < 0.05$).

We did not find any dependences between cytokeratins, GP73, indirect markers of liver fibrosis and hematological scales. AUC and the cut-offs for CCK18, K18 and GP73 in MAFLD group were: 0.780, >74.56 U/L $p < 0.001$; 0.764, >64.13 U/L, $p < 0.001$ and 0.767, >323.32 ng/ml, $p < 0.001$, respectively.

Conclusion: Presented relationships seem to be the kind of novelty in the group of MAFLD patients. Noticed dependences between cytokeratins and miRNAs together with serological markers of liver fibrosis and hematological indices, should be explored as a potential new diagnostic pathway in the course of MAFLD.

Contact E-Mail Address: frederikcold422@hotmail.com

Introduction: In Nature Duan et al. recently reported how the mortality rate in patients hospitalized with alcoholic hepatitis is highly correlated with the presence of cytolysin-producing *Enterococcus (E) faecalis*.¹

The mortality 180 days after diagnosis of alcoholic hepatitis was 89% in patients hosting this bacteria in their gut microbiome compared to only 3.8% in patients without this bacteria.

Further, transfer of the bacteria to mice reproduced the liver damage and treatment with bacteriophages targeting cytolysin-producing *E. faecalis* was able to counteract this liver damage.

Aims & Methods: The first aim of the BATTLE project is to: Confirm the correlation between cytolysin-positive *E. faecalis* in the gut microbiota and poor disease outcome in patients with alcoholic hepatitis. The second aim of the BATTLE project is to: Find, test, purify and produce phages targeting cytolysin-producing *E. faecalis*.

The BATTLE-study has been approved by the regional scientific committee and will begin recruiting participants May 2022. Thirty patients with alcoholic hepatitis hospitalized at Copenhagen University Hospital Hvidovre or Herlev will be followed for one year following hospital admission. Within the first seven days following hospital admission faecal samples are collected and analysed for the presence and quantity of cytolysin producing *E. faecalis* through 16S rRNA gene sequencing using primers targeting cytolysin-producing *E. faecalis*.

Lytic bacteriophages with the potential to eliminate cytolysin-producing *E. faecalis* will be isolated from sewage water and characterised.² Bacteriophages with the ability to eliminate the disease-causing *E. faecalis* will be produced, stored, and tested according to current international standards, so they are ready for potential application in human trials or as a last-resort treatment.

Results: Primary outcome: Survival 180 days after hospital admission with alcoholic hepatitis in patients with and without cytolysin-positive *E. faecalis* in their faecal samples.

Secondary outcomes: 1) Survival 30-, 90- and 365-days following hospital admission with alcoholic hepatitis in patients with and without cytolysin producing *E. faecalis* in their faecal samples. 2) Correlation between quantity of cytolysin producing *E. faecalis* in faecal samples and survival 180 days following hospital admission. 3) Correlation between faecal bacterial alpha-diversity and survival 180 days following hospital admission.

Conclusion: The goal of the BATTLE project is to improve the prognosis for patients with alcoholic hepatitis by offering an innovative antimicrobial targeted-treatment that seeks to directly address a possibly major contributing factor leading to liver damage.

Introduction: There is evidence of a strong association between non-alcoholic fatty liver disease (NAFLD) and obesity and intestinal dysbiosis (ID) in a number of clinical studies. However, there are still many open questions.

Aims & Methods: The study of the state of the intestinal microbiota (IM) in patients with NAFLD and the determination of changes in its composition at the level of the main phylotypes, depending on the amount and activity of visceral adipose tissue (VAT).

108 patients with NAFLD with metabolic disorders and 30 people in the control group were examined. The mean age of the examined NAFLD patients was (56.46 ± 10.4) years. The assessment of anthropometric parameters included the calculation of body mass index (BMI), the percentage of visceral adipose tissue (VAT).

To determine the dysfunction of the VAT, the visceral obesity index (VOI) was calculated according to the method of Amato M.S. The composition of IMs at the level of the main phylotypes was determined by detecting total bacterial DNA and DNA of Bacteroidetes, Firmicutes, and Actinobacteria by real-time quantitative polymerase chain reaction (PCR) using universal primers for the 16S rRNA gene and the App taxon system.

Results: In patients with NAFLD, there was a probable increase in the content of Firmicutes bacteria with a simultaneous decrease in the number of Bacteroidetes and a slight increase in the content of Actinobacteria. In addition, significant changes were observed in the value of the Firmicutes: Bacteroidetes index. In patients with NAFLD, this indicator was significantly higher than in the control group ($p < 0.05$) and amounted to 6.48 and 1.28, respectively.

The study of the relative quantitative composition of IM in the study groups revealed significant differences in NAFLD patients with overweight and varying degrees of obesity compared with the control group and the group of NAFLD patients with normal BMI. In patients with varying degrees of obesity, there was a significant decrease in Bacteroidetes to 16.8 [8.7; 24.2]%, with moderate obesity and up to 11.2 [6.2; 19.8]% in morbid obesity with a simultaneous increase in the Firmicutes/Bacteroidetes ratio to 3.7 [1.8; 6.7] and 5.2 [2.9; 7.5] respectively.

It has been established that as the weight increases, deeper changes in the ratio of the main bacterial phyla of IM occur. Later, we studied the dependence of changes in MI on the amount and activity of VAT. In patients with NAFLD, as the percentage of VAT increased, the content of IM was redistributed towards an increase in Firmicutes compared with the control group and patients with NAFLD with a normal amount of VAT.

At the same time, in the NAFLD group with visceral obesity, the number of Bacteroidetes decreased, while the content of Actinobacteria did not change significantly. A similar relationship was obtained between the distribution of the main IM filets and the activity of VAT.

Thus, in patients with high VOI, an increase in the content of Firmicutes bacteria is likely; on the contrary, in these patients, the number of Bacteroidetes has decreased. In the group of NAFLD patients with a low level of VOI, a high variability in the composition of Firmicutes bacteria was revealed, although in the whole group there was a tendency to an increase in the content of bacteria of this class.

Conclusion: Changes in the composition of IM indicate the likely involvement of bacteria of the genus Firmicutes in the formation of VOI, an increase in the activity of VAT, and in the further development and progression of NAFLD.

Disclosure: No Conflict of Interest.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is currently known as a risk factor for chronic kidney disease (CKD and gut microbiota dysbiosis could be a driver for both entities.

Aims & Methods: Aim of this study was to assess whether gut microbiota dysbiosis (DB) may associate more severe forms of both NAFLD and CKD.

Patients and Methods: 80 patients with NAFLD, 40% women, 60% men, average age 42 to 85 years joined this observational study.

Patients were divided in two groups based on the presence or absence of CKD: 40 patients without CKD and 40 patients with early stages of CKD (stage 1=13 patients and stage 2=27 patients). Renal obstructive pathology, lithiasis, cirrhosis and other etiologies of liver diseases were ruled out.

Biochemistry of blood and urine and microbiology of urine and stool, fatty liver index (FLI), estimated glomerular filtration rate (e-GFR) as well as abdominal Duplex/ computer tomography examination, liver point shear wave elastography were performed in all research participants.

Next generation sequencing of stool's samples from dysbiotic patients was also performed. NAFLD was classified as mild, moderate, severe and consecutively scored between 1 to 3 points.

Results: Significant differences were noted between severity of NAFLD in group without CKD :1.3±0.48 vs. group with CKD: 2.13±0.76($p=0.002$). DB range was significantly higher in patients with CKD 1.69± 0.9vs.0.7±0.67 in patients without CKD($p=0.0019$.) Decrease of H index of biodiversity of gut microbiota was observed in 20% in patients with no CKD vs.62.5% in those with CKD($p=0.0001$).

Stool's functional bacteria assessment showed significant differences related to increase of lipopolysaccharide (LPS) positive bacteria and decrease of Akkermansia muciniphila spp. in favor of patients with CKD ($p<0.001$). Good positive correlations were observed between DB range, microproteinuria, NAFLD score and FLI in patients with CKD.

Conclusion: Higher range of gut DB and particular fingerprint of functional stool's bacteria were associated to more severe forms of NAFLD and CKD.

Introduction: The liver is a unique organ that has an extraordinary regenerative capacity. Liver regeneration (LR) is a complex process involving different molecules, signaling pathways and cellular responses.

However, genome-wide expression changes during LR have not been investigated thoroughly; thus, it is urgent to elucidate the underlying molecular mechanisms associated with LR.

Aims & Methods: RNA sequencing was performed to investigate temporal changes in transcription after partial hepatectomy (PH) in male C57BL/6 mice. Differentially expressed genes (DEGs) were identified using DESeq2. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses were performed to explore the functions of DEGs. The protein-protein interaction (PPI) network of DEGs was established, and hub genes were screened by Cytoscape.

Results: In total, 2348 and 3534 DEGs were found at 4 h and 12 h after PH, respectively. Enrichment analysis showed that these DEGs were significantly related to LR-associated pathways, such transcription factor activity, the MAPK signaling pathway, cytokine-cytokine receptor interactions, and ribosome biogenesis. Then, the protein-protein interaction network and key modules were constructed by Cytoscape, and four hub genes were identified, including ATF3, GNL3, CEBPA, and DDIT3.

Conclusion: This study presented a comprehensive transcriptomic profiling of LR and investigated the temporal variations in gene expression patterns. Furthermore, the hub genes identified by us may become key regulators of LR. Our study may provide further insights into the comprehension of LR.

Disclosure: Nothing to disclose.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is one of the leading causes of chronic liver diseases. NAFLD spectrum begins from simple steatosis to non-alcoholic steatohepatitis (NASH), progressive fibrosis, cirrhosis, and even hepatocellular carcinoma. Although most NAFLD patients are overweight and obese, 30% are lean. We analyzed lean and non-lean NAFLD patients' liver biopsies for cytokeratin 8/18 immunohistochemical staining differences.

Aims & Methods: Thirty biopsy-proven NAFLD patients (15 patients with BMI ≤ 25 kg/m², 15 patients with BMI > 25 kg/m²) were included in the study. Demographic, biochemical, and histologic features of the patients were recorded. Biopsy specimens from our archive were re-stained with cytokeratin 8/18 marker and were re-evaluated by a single expert hepatopathologist according to Brunt's classification, the NASH Clinical Research Network (NASH-CRN) scoring system, and fatty liver inhibition of progression (FLIP) algorithm.

Results: The presence of pathological granular staining with cytokeratin 8/18 marker in hepatocytes positively correlated with ballooning degeneration (r=0.461, p=0.027), the grade of lobular inflammation according to the FLIP algorithm (r=0.461, p=0.027), the grade of lobular inflammation according to the NAFLD activity score (r=0.545, p=0.007), presence of portal inflammation (r=0.525, p=0.010), age (r=0.534, p=0.009), gender (r=0.464, p=0.026), serum glucose value (r=0.537, p=0.008), direct bilirubin (r=0.523, p=0.022) and HbA1c (r=0.758, p=0.029) levels, and negatively correlated with hemoglobin (r=-0.473, p=0.030) and hematocrit (r=-0.437, p=0.047) levels.

	Lean (n:15)	Non-Lean (n:15)	p value
Age (Years, mean±SD)	38.27±13.6	50.73±12.8	0.016
BMI (kg.m ⁻² , mean±SD)	23.4±1.8	34.7±4.9	0.001
Presence of hepatic steatosis (%)	24.1	33.6	0.217
Hepatic cytokeratin 8/18 staining positivity (%)	75.0	93.3	0.427
Hepatic pathological granular cytokeratin 8/18 staining positivity (%)	33.3	35.7	0.926
Presence of ballooning degeneration (%)	66.7	100.0	0.028
AST (U/L, mean±SD)	52.5±45.9	39.8±22.4	0.482
ALT (U/L, mean±SD)	101.0±118.4	47.6±32.4	0.031
Triglycerides (mg/dL, mean±SD)	131.7±129.9	171.9±56.2	0.003*

BMI: Body mass index, AST: Aspartate aminotransferase, ALT: Alanine aminotransferase

Table: Characteristics of the patient groups.

There was no significant difference in the presence or staining pattern of cytokeratin 8/18 marker between the two groups. In the lean NAFLD group, liver damage was milder, serum triglyceride levels were lower ($p=0.003$) and ALT values were higher ($p=0.031$) compared to the non-lean group.

Conclusion: Although the presence of cytokeratin 8/18 immune marker staining has no role in the differential diagnosis of lean and non-lean NAFLD, the presence of granular staining may be an indicator of progression.

Contact E-Mail Address: marioromeo@virgilio.it

Introduction: In the last decades, the Metabolic-(dysfunction)-Associated-Fatty-Liver-Disease (MAFLD) has rapidly become the most common cause of chronic liver damage and hepatocellular carcinoma (HCC) worldwide. An unhealthy lifestyle has been identified as a key element fueling its genesis and worsening.

Given the scant evidence existing, we aimed to evaluate the effects of related-confinement lifestyle changes experienced during the Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV-2) pandemic on MAFLD evolution.

Aims & Methods: A cohort of 122 MAFLD patients, including individuals with simple steatosis (SS), histological steatohepatitis (NASH), and liver cirrhosis (LC), was enrolled and followed during the last four years: two

years pre- and two years during the pandemic. For each patient, biochemical, fibrosis non-invasive, nutritional, and body composition data were collected, before and during the pandemic.

Results: The cohort (SS:28, NASH:45, LC:49) showed a relevant worsening in the insulin levels, liver-stiffness, controlled-attenuation-parameter (CAP), and NAFLD-fibrosis-score (NFS) during the pandemic period (Pre vs during, insulin levels: 22.01 ± 11.44 vs 24.39 ± 12.64 U/ml, $p:0.0003$; stiffness: 9.965 ± 4.816 vs 11.77 ± 5.837 kPa, $p<0.0001$; CAP: 290.9 ± 32.89 vs 335.9 ± 39.49 dB/m, $p<0.0001$; NFS: -0.75 ± 0.97 vs -0.2312 ± 1.05 , $p<0.0001$). A significant increase in daily calorie intake and a specular decrease in physical activity was also observed (Pre vs during, daily calorie intake: 2307 ± 411.5 vs 3056 ± 521.3 Kcal, $p<0.0001$; physical activity: 6.1 ± 1.3 vs 4.2 ± 1.4 hours/week, $p<0.0001$).

Body composition analysis highlighted a reduction of Free-Fat-Mass (FFM), Body-Cell-Mass (BCM), and an increase in Fat Mass (FM) (Pre vs during, FFM%: 79.6 ± 4.10 vs 73.31 ± 5.625 , $p<0.0001$ BCM%: 40.3 ± 3.1 vs 37.4 ± 3.4 , $p<0.0001$; FM%: 20.4 ± 4.1 vs 26.69 ± 5.6 , $p<0.0001$).

The Kaplan-Meier Log-Rank Test analysis on overall HCC occurrence and HCC Milan-out criteria occurrence revealed HR:2.29, 95% CI:1.1-4.6, $p:0.02$ and HR:7.7, 95% CI:2.6-22.7, $p:0.02$ respectively. The logistic regression for HCC occurrence revealed the event's independence from the stiffness threshold of 10 kPa (RR:5.06, 95% CI:7.14-3.16, $p:0.08$) and the significant impact of body composition modifications (Δ =pre-during) on the first [Δ FM (kg)= $p<0.0001$, RR 1.878, C.I. 95% 1.322-2.668; Δ FM (%) = $p<0.0001$, RR 1.704, C.I. 95% 1.248-2.327] and second [Δ FM (kg)= $p:0.007$, RR 1.478, C.I. 95% 1.111-1.967; Δ FM (%) = $p:0.006$, RR 1.469, C.I. 95% 1.114-1.937] outcome.

Variables	Pre-SARS-CoV-2 % (M±SD)	During SARS-CoV-2 % (M±SD)	p-value (Pre vs during)	Pre-SARS-CoV-2 Kg (M±SD)	During SARS-CoV-2 Kg (M±SD)	p-value (Pre vs during)
FM	20.40±4.104	26.69±5.625	<0.0001	16.23±3.726	23.12±5.900	<0.0001
FFM	79.60±4.104	73.31±5.625	<0.0001	63.37±8.139	63.51±10.04	0.9848
BCM	40.33±3.088	37.41±3.995	<0.0001	32.03±3.848	32.37±5.565	0.7994

FM: Fat mass; FFM: Free fat mass; BCM: Body cellular mass; M: mean; SD: standard deviation

Table 1. Body composition data before vs during SARS-CoV2-Pandemic.

Conclusion: The lifestyle changes imposed by the pandemic restrictions impacted MAFLD evolution promoting body compositions modifications negatively influencing the overall HCC and HCC Milan-out criteria occurrence.

IMPACT OF RENAMING NAFLD TO MAFLD IN A SINGLE ITALIAN CENTER

V. Cossiga¹, M.R. Attanasio¹, M. Capasso¹, L. Pignata¹, F.M. Cutolo¹, R. Lieto¹, M. Guarino¹, F. Morisco¹

¹University of Naples Federico II, Department of Clinical Medicine and Surgery, Gastroenterology and Hepatology Unit, Napoli, Italy

Contact E-Mail Address: valentina.cossiga@gmail.com

Introduction: Metabolic Associated Fatty Liver Disease (MAFLD) is the novel definition and the new paradigm of NAFLD introduced in 2020, but its clinical and health public implications remain under evaluation.

Aims & Methods: The aims of this study are to analyze the prevalence of MAFLD and NAFLD and compare them in a well-defined cohort of patients with liver steatosis.

A cross-sectional study was conducted in a single Liver Unit in Italy. Clinical, laboratory and imaging data were collected. NAFLD and MAFLD were defined according to international expert consensus.

Results: A total of 404 patients with ultrasound steatosis were included. The mean age was 61.6±13.4 years (61.8% male). The mean body mass index (BMI) was 29.2±5.2 kg/m². Most of them (84.1%) were overweight/obese, 216 (53.4%) had arterial hypertension, 86 (21.2%) had type 2 diabetes and 178 (44%) had dyslipidemia. MAFLD was present in 340 (84.1%) patients, while NAFLD in 138 (34.1%) of them. The increased prevalence of MAFLD in this cohort was driven by dual etiology of liver disease (29.1% of previous HCV infection; 30.2% of virologically suppressed HBV patients). All participants classified as NAFLD met the new definition of MAFLD. Compared with NAFLD subjects, MAFLD patients had higher ALT (p=0.01), AST (p=0.009), GGT (0.0038) and FIB-4 (p=0.02) values.

No significant differences in the others non-invasive markers of fibrosis or steatosis (liver stiffness, NAFLD score, Controlled Attenuation Parameter) were observed.

Conclusion: Metabolic-associated fatty liver disease is a highly prevalent condition in this well-defined cohort. Application of these new criteria for MAFLD definition will increase the prevalence of fatty liver due to the inclusion of patients with dual etiology of liver disease.

WILSON'S DISEASE DIAGNOSIS IN PAEDIATRIC AGE

D. Araújo¹, H. Antunes^{1,2,3}

¹Hospital de Braga, Paediatric Gastroenterology Hepatology and Nutrition Unit, Braga, Portugal, ²Hospital de Braga, Academic Clinical Centre (2CA Braga), Braga, Portugal, ³Universidade do Minho, Life Sciences and Health Institute (ICVS), ICVS/3B's Associated Laboratory and School of Medicine, Braga, Portugal

Contact E-Mail Address: da.nielamatos@hotmail.com

Introduction: Wilson's Disease (WD) is a rare autosomal recessive disease. The prevalence of DW in Minho's region in Portugal is 1:37 000. In children, presentation is usually of hepatic involvement.

Aims & Methods: Our aim is to characterize the patients diagnosed with WD in a Paediatric Gastroenterology, Hepatology and Nutrition Unit of a central hospital in Portugal.

Methods: A descriptive retrospective observational study of the patients diagnosed with WD in this Unit between 1996 and 2021 was performed. Data related to the diagnosis and treatment were analysed.

Results: Twelve patients were diagnosed with WD, the majority being male (n=8). Median age at diagnosis was 8 years (IQR 5-13,8 years; minimum 3 and maximum 17 years). Four patients were diagnosed before the age of 5. The majority of patients (n=11) was referred to the Unit for

hepatic enzymes' elevation; one had neurological symptoms and Kaiser-Fletcher rings. At the time of diagnosis, renal involvement was present in one patient.

All patients had high urinary copper levels. Mutations in the ATP7B gene were found in all patients. One patient had normal levels of ceruloplasmin levels. The median time between the first observation and hepatic biopsy was 7 days (IQR 3-17 days; minimum 2 and maximum 82 days).

At the time of diagnosis, all patients initiated penicillamine and pyridoxine. During follow-up, therapy was changed to trientine and zinc sulfate in 4 patients, the majority for adverse events.

Clinical evolution was favourable in 10 of the patients.

Conclusion: We present 12 cases of WD diagnosed in children by the same paediatric gastroenterologist.

Four out of 12 patients presented symptoms before the age of 5 years, reinforcing the need to consider WD in children aged over 12 months with suggestive symptoms and/or analytic abnormalities.

As expected, hepatic involvement was the predominant form of presentation. As WD is a treatable cause of elevated liver enzymes, it is important to consider this diagnosis in the presence of elevated liver enzymes. In the presence of high clinical suspicion, normal levels of ceruloplasmin should not preclude considering WD in the differential diagnosis.

RESISTANT STARCH SUPPRESSES HIGH-FAT DIET-INDUCED STEATOSIS

R. Yoshida¹, Y. Yano¹, N. Hoshi¹, N. Asaji¹, A. Yamamoto¹, E. Yasutomi¹, A. Minami¹, Y. Ueda¹, Y. Kodama¹

Introduction: Obesity and related diseases, such as type 2 diabetes and hypertension, have been common problems worldwide. And non-alcoholic fatty liver disease (NAFLD) is the liver's expression of an obesity-related disease.

It has been reported that the gut microbiota in patients with obesity and NAFLD is altered from that of healthy individuals, and the changes in the gut microbiota can cause various obesity-related diseases and make steatosis worse.

Resistant starch (RS) is a type of starch that is not easily digested or absorbed in the small intestine. RS is a starch, but like dietary fiber, it is decomposed by the gut microflora into short chain fatty acids (SCFA). Many studies have reported inhibitory effect of RS on obesity and steatosis, but most of studies evaluating the effects of RS on suppressing fatty liver are using type 2 resistant starch (RS2). Therefore, in this study, we examined the inhibitory effects of type 4 resistant starch (RS4) on fatty liver using a murine high-fat-diet (HFD) induced fatty liver model.

Aims & Methods: We evaluated the effect of RS4 on fatty liver inhibition using HFD-fed mice. The changes in gut microbiota and SCFA after feeding RS were also investigated.

We prepared HFD, HFD+RS (high-fat-diet with resistant starch), and control diets. Seven-week-old male B6 mice were divided into three groups, and each group was fed HFD, HFD+RS, and control. Body weight changes were monitored weekly until 22 weeks of age. We also measured body weight, white adipose tissue weight, and liver weight, and collected plasma, liver tissue, and cecal feces for analysis.

Results: The HFD group showed marked weight gain, while the HFD+RS group showed less weight gain than the HFD group. In addition, body weight, liver weight, and white fat cell weight were all suppressed in the HFD+RS group compared to the HFD group. Furthermore, fatty liver, which was observed in the HFD group, was not observed in the HFD+RS and Control groups.

When we evaluated the liver tissue, there was no difference in the expression of fatty acid synthesis-related genes and fat accumulation-related genes between the HFD and HFD+RS groups.

Interestingly, *Bifidobacterium* and *Lactobacillus* in the feces were significantly increased in the HFD+RS group compared to the HFD group. In addition, the SCFA, acetic acid and propionic acid, were significantly increased in the HFD+RS group compared to the HFD group.

Conclusion: Our data suggests that dietary RS4 improved the gut environment in terms of the components of gut microbiota and levels of SCFA; which might have played a role to prevent weight gain and development of fatty liver in our setting. In general, SCFA receptors, such as GPR41 and GPR43, are involved for SCFA to function in the host, further studies using SCFA receptor deficient animals will be required to confirm the mechanisms.

Introduction: Fatty liver disease (FLD) is a heterogeneous group of diseases, differing significantly in a set of etiopathogenetic factors, progression rate and prognosis [1].

An important criterion for distinguishing non-alcoholic fatty liver disease (NAFLD) from alcoholic fatty liver disease (AFLD) is that patients do not drink alcohol at hepatotoxic doses. Primary NAFLD is associated with metabolic syndrome (MS) in most patients [2].

In the pathogenesis of AFLD and NAFLD with metabolic syndrome, a coincidence of most of the metabolic pathways has been noted, which creates difficulties in diagnosis [3, 4].

Aims & Methods: The aim was to investigate the fatty acid composition of erythrocyte (Er) membranes and blood serum (BS) in patients with fatty liver disease of alcoholic and non-alcoholic genesis for possible use in differential diagnosis.

Materials and methods. 45 men (51,8±3,9 years old) with WBC (F0-1) of alcoholic (n=14), non-alcoholic (n=16), mixed genesis (alcohol + metabolic factors) (n=15) and 16 conditionally healthy subjects have been screened. The study of the composition of fatty acids (FAs) of Er and BS has been performed using a gas chromatography-mass spectrometry (GC/MS) system based on the Agilent 7000B Triple Quadrupole (USA).

Results: The serum and erythrocyte membranes of patients with FLD have been dominated by saturated FAs (p<0.02), especially C16:0 (p<0.02), C18:0 (p<0.01), saturated/unsaturated FAs ratio (p<0.02) with a significant decrease in unsaturated (p<0.02), especially C18:2 n6 (p<0.01) and polyunsaturated (p<0.05) compared to healthy subjects.

AFLD is associated with decreases in linolenic, arachidonic acid (p<0.01), omega-6/omega-3 polyunsaturated FAs (p<0.001) in erythrocytes, which is probably due to chronic exposure to a universal membranotropic factor - ethanol. With NAFLD, an increase of C20:0 has been detected (p<0.01) and a decrease in C20:3 n6 (p<0.02) associated with shifts in metabolic syndrome compared to healthy controls.

In the group with fatty liver disease of mixed genesis at the background of an increase in the level of saturated FAs (p<0.04), the contents of monounsaturated (p<0.03), especially C18:1 and unsaturated (p<0.04) have been reduced both in erythrocytes and in blood serum.

A panel consisting of serum fatty acids (C14:0, 15:0, 20:0, 20:4 n6, sum of monounsaturated fatty acids, sum of PUFAs, sum of omega-6 PUFAs) and a list of red cell membrane FAs (C18:0, 22:6 n3, saturated/unsaturated FAs, saturated/polyunsaturated FAs) it allowed to differentiate patients with AFLD from NAFLD with AUC 0.790, sensitivity 0.73, specificity 0.78.

Correlations of FAs' levels in erythrocyte membranes and blood serum with manifestations of metabolic syndrome in patients with NAFLD, alcohol consumption in patients with AFLD have been revealed. In patients with NAFLD, waist circumference correlated with the amount of PUFAs in erythrocyte membranes (r=-0.48, p<0.001), HOMA-IR index - with C22:6/C20:5 n6 (r=-0.44, p<0.001). Patients with AFLD have showed associations of frequency of alcohol consumption with C20:5 n3 in erythrocyte membranes (r=-0.42, p<0.01), weekly dose of ethanol consumed with erythrocyte membrane ethyl esters level (r=0.46, p=0.002) and GGT activity with C18:2 n6 level (r=-0.43, p=0.003).

Conclusion: Peculiarities of fatty acid composition of Er and BS membranes in fatty liver disease of alcoholic, non-alcoholic and mixed genesis seem to be promising for the purposes of differential diagnosis.

Introduction: Due to invasive diagnostics used, the prevalence of pediatric fatty liver disease is scarcely studied. A recently introduced concept of metabolic-associated fatty liver disease (MAFLD) enables to establish the diagnosis in children with excess adiposity and alanine aminotransferase (ALT) twice the upper limit of normal.

Aims & Methods: We investigated the prevalence, risk factors and metabolic co-morbidities of MAFLD in overweight and obese Finnish children and adolescents. Comprehensive medical data of 703 consecutive children and adolescents aged 2-16 years examined due to overweight in primary and tertiary healthcare in 2002-2020 was collected. Patients with and without MAFLD were compared, and subgroup analyses were conducted among boys and girls.

Results: The median age of the participants was 11.5 years, and 43% were girls. All were overweight, 89% obese and 47% severely obese, and the median body mass index (BMI) Z-score was 2.5. The prevalence of MAFLD was 15% (boys 18%, girls 11%, $p=0.018$). The prevalence increased in boys by age and during puberty, whereas in girls it peaked at early puberty. There was no significant change in the prevalence during the study period. Risk factors for MAFLD in boys were type 2 diabetes (T2D) (OR 7.55, 95% CI 1.23-46.2), a postpubertal stage (5.39, 2.26-12.8), hyperinsulinemia (3.20, 1.44-7.10), hypertriglyceridemia (2.97, 1.67-5.30), hyperglycemia (2.88, 1.64-5.07), low high-density lipoprotein cholesterol (HDL) (2.16, 1.18-3.99) and higher BMI (1.01, 1.05-1.15), and in girls T2D (18.1, 3.16-103), hypertriglyceridemia (4.28, 1.99-9.21), low HDL (4.06, 1.87-8.79). Overall, dyslipidemia were present in 51%, hypertension in 48%, signs of abnormal glucose metabolism in 44% and T2D in 2%.

Conclusion: The prevalence of MAFLD in overweight and obese children and adolescents was 15%, with no significant increase in the 2000s. The condition was associated with male sex, higher age in boys, puberty stage and disturbances in glucose and lipid metabolism.

Disclosure: No Conflict of Interest.

RARE DISEASES MIMICKING BILIARY ATRESIA: GENETIC ANALYSIS IS THE KEY

P.R. Tripathi¹, S. Oruganty^{2,2}, V.V. Ramaswamy²

¹Ankura Hospital for Women and Children, Pediatric Gastroenterology, Hyderabad, India, ²Ankura Hospital for Women and Children, Neonatology, Hyderabad, India

Contact E-Mail Address: parijattripathi1986@gmail.com

Introduction: A timely confirmative diagnosis of Neonatal cholestasis (NC) is vital for its management as well as prognostication. We are presenting a series of four infants with NC with classical symptoms and histo-biochemical features of extrahepatic biliary atresia (EHBA), but with few atypical signs.

Aims & Methods: Clinical, biochemical-histological and genetic data were prospectively collected.

Results: Two infants had a diagnosis of Niemann-Pick type C (NPC, C1 and C2) and the other two mitochondrial DNA depletion syndrome type-3 (MDDS-3) with clinical exome sequencing. While all four had jaundice with high colored urine in early infancy, three had pale stools and all of them were clinically suspected to have EHBA. NPC infants had splenohepatomegaly, an uncommon finding in EHBA. Of the MDDS-3 infants, one had failure to thrive (FTT) alone and the other had horizontal nystagmus along with FTT, both of which are uncommon with EHBA. Liver biopsy indicated EHBA features and GGT levels were high in all infants. (Table 1)

In view of these atypical clinical features, an earlier genetic test was done. While three infants died with progressive liver disease and coagulopathy, one with NPC2 survived with normalization of liver functions and neurological parameters till last follow-up.

Clinical presentation	Case 1: Conjugated hyperbilirubinemia with splenohepatomegaly since day 10 of life	Case 2: Conjugated hyperbilirubinemia with pale stool, splenohepatomegaly since day 30 of life	Case 3: Conjugated hyperbilirubinemia with pale stool since birth, failure to thrive, horizontal nystagmus hepatomegaly	Case 4: Conjugated hyperbilirubinemia since day 45 with pale stool, failure to thrive, ascites and hepatomegaly
Age at 1 st presentation	63 days	70 days	5 months	3 months
consanguinity	No	Yes (3rd degree consanguinity)	No	No
TB/DB (mg/dl)	17/12	11.9/9.7	8.7/6.2	16.8/14.3
AST/ALT (0-35 IU/L)	551/107	221/50	307/139	388/208
ALP (150-300 IU/L)/ GGT(0-30IU/L)	718/198	662/293	252/86	720/247
INR	1.2	1.02	1.35	2.9 (increased to 6.2)
Other test	S.GALT-normal,, AFP-168900IU/ml, HIDA -Excretory	S.GALT-Normal,, AFP-36,300 IU/ml, HIDA-Excretory	HIDA-Excretory	AFP >1000 IU/mL, HIDA -Excretory
Liver biopsy	Mild bile ductular proliferation with focal bridging fibrosis with early nodule formation	Mild bile ductular proliferation, periportal inflammation and mild portal fibrosis with extensive hepatocyte ballooning.	Bile ductular proliferation with with fibrosis with gaint cells and nodule formation	Not done (due to ascites and coagulopathy)
Genetic diagnosis And follow-up	NPC type C1 (NPC1 gene mutation) Died at 7 months of age with sepsis and GI/pulmonary bleed	NPC type C2(NPC2 gene mutation) Jaundice resolved over 8 month age, after that lost to follow-up	Hepatocerebral type of MDDS-3(DGUOK gene mutation) Died with bleeding manifestation at 10 month age (pulmonary)	MDDS-3(DGUOK gene mutation) Died at 4 month of age with bleeding manifestation (Pulmonary)

Table 1: Characteristics of the included infants.

Conclusion: Genetic analysis should be performed early in cases of NC with a suspicion of EHBA where atypical clinical features are present. Even if the prognosis in most of the aforementioned cases is poor, a confirmed genetic diagnosis could prevent futile surgical exploration and liver transplantation as well as future recurrence with genetic counselling and antenatal surveillance.

Disclosure: Nothing to disclose.

THE ROLE AND MECHANISM OF S100A6 IN PROMOTING NON-ALCOHOLIC FATTY LIVER DISEASE BY NEGATIVELY REGULATING LIPOPHAGY SIGNALING PATHWAY

Q. Du¹, J. Xu², R. Xie², B. Tuo², X. Ma³

¹Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China, ²Affiliated Hospital of Zunyi Medical University, Department of Gastroenterology, Zunyi, China, ³Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Division of Gastroenterology and Hepatology, Shanghai, China

Contact E-Mail Address: duqianL5@163.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) has become a major chronic metabolic disease that seriously threatens human health, but the exact pathogenesis of NAFLD has not been fully clarified. We previously screened that the expression of S100A6 was up-regulated in NAFLD through animal models, cell models and transcriptomics, but its role in NAFLD was unclear.

Therefore, this study will explore the mechanism of S100A6 in the development of NAFLD from the clinical, animal and cellular levels, so as to provide new ideas and strategies for the diagnosis and treatment of NAFLD.

Aims & Methods: Overexpression/knockdown of S100A6 cell models constructed by lentivirus, overexpression/knockout of S100A6 mice models by adeno-associated virus (AAV), RFP-GFP-LC3 adenovirus, BODIPY 493/503 staining, autophagy activator and inhibition, HE, immunohistochemistry, Western Blot, qPCR and other methods gradually confirmed the regulation of S100A6 on lipid metabolism, autophagy pathway, lipid droplets, and lipophagy pathway in hepatocytes, and finally confirmed that S100A6 promotes hepatic lipid metabolism disorder by inducing lipophagy injury in hepatocytes.

Results: 1. The GEO database analysis showed that S100A6 was highly expressed in each NAFLD model. Consistent with the GEO data, the S100A6 expression was significantly increased in the two NAFLD models we established, high-fat high-cholesterol (HFHC) and high-fat-diet (HFD) induced. On the other hand, the expression of S100A6 showed a concentration-dependent up-regulation in Liver-02 cells and HepLi5 cells after stimulation with different concentrations of palmitic acid (PA)/Oleic acid (OA). These results suggest that S100A6 is highly expressed in NAFLD, which may act as a novel key factor promoting lipid metabolism disorders.

2. In the NAFLD cell models, compared with normal Liver-02/HepLi5 hepatocytes, overexpression of S100A6 aggravated the accumulation of PA/OA-stimulated intracellular lipids and induced lipid metabolism-related gene expression. After knockdown of S100A6, the lipid accumulation induced by PA/OA stimulation was alleviated, and lipid metabolism-related genes expression was reversed. The above results suggest that S100A6 may promote lipid accumulation in hepatocytes in vitro by regulating the expression of lipid metabolism-related genes.

3. In the NAFLD animal models, the tail vein injection of adenovirus-associated virus was used to overexpress/knock down the hepatic S100A6 expression in vivo, and it was found that overexpression of S100A6 could significantly increase the fat accumulation, glucose tolerance and insulin

resistance induced by HFHC. Knockdown of hepatic S100A6 expression can significantly reverse this process, reduce liver weight and serum triglyceride and low-density lipoprotein levels.

4. In the mechanistic study, we found that PA/OA stimulation significantly decreased the expression of LC3II and up-regulated the expression of P62, and inhibited autophagic flux in S100A6-overexpressing cells. Autophagy-related genes ATG5, ATG7, and ATG12 mRNA and ATG2, which is involved in lipid transport to promote autophagosome formation were significantly downregulated than those in the PA/OA-stimulated control group. At the same time, CD36 mRNA was also up-regulated and PPARα mRNA was down-regulated. All of which were reversed by knockdown of S100A6.

Conclusion: S100A6 may be a key target to promote the development of NAFLD. HFHC-induced S100A6 to negatively regulate the process of lipophagy, resulting in autophagy damage, which leads to lipid accumulation in the liver and ultimately promotes the development of NAFLD.

Introduction: Intestinal microbiota alteration, microbial diversity reduction, and intestinal permeability impairment which promote inflammation and insulin resistance are the cutting edges of the non-alcoholic fatty liver (NAFLD) pathophysiology.

Aims & Methods: The aim of our study was to investigate insulin resistance markers and their association with fecal short-chain fatty acids (SCFA) content in obese children with NAFLD.

104 obese NAFLD children aged from 10 to 17 years (average age was 12.15±2.51 years) were included in the study. The presence of NAFLD was determined by transient elastometry (Fibroscan®502touch, Echosence, France) with controlled attenuation parameter measurement.

Patients were divided into 3 groups according to the Homeostasis Model Assessment of Insulin Resistance (HOMA-IR) level: the I group included 23 children with the normal HOMA-IR level (up to 75 percentile according to age and sex), II group included 46 children with a moderate increase (HOMA-IR up to 6.0) and III group included 35 children with a significant increase (HOMA-IR greater than 6.0). The control group consisted of 10 children with normal weight, and normal HOMA-IR levels without liver steatosis.

Serum insulin levels were determined by enzyme immunoassay (DRG International, Inc., Germany). Assessment of insulin resistance was carried out with HOMA-IR calculation. Glycosylated hemoglobin was determined by a Lachema kit (Czech Republic). Chromatography of fecal SCFA was performed by gas chromatograph Chromatec-Crystal 5000.

Results: Children of the III group had significantly higher liver stiffness (6.6±0.9 kPa, p<0.05) compared to other groups. An increase in the HOMA-IR level in children of the studied groups was accompanied by an increase in the glycosylated hemoglobin level.

The highest content of glycosylated hemoglobin reached 4.09 (3.32; 4.91) μM fructose/gHb was observed in the III group of children. The median level of fecal acetic acid was increased in the I, II, and III groups, while the median level of fecal butyric acid was decreased. Children of the III group

had a 2-fold lower propionic acid level ($p < 0.05$), and a 1.5-fold lower total SCFA level ($p < 0.05$) compared to patients of the II group. A negative correlation was found between fecal butyric acid content, insulin levels ($r = -0.228$; $p = 0.02$), and the HOMA-IR ($r = -0.229$; $p = 0.019$), positive correlation between HOMA-IR and liver stiffness ($r = 0.37$, $p < 0.05$).

Conclusion: Progression of insulin resistance in obese NAFLD children is accompanied by an increase in glycosylated hemoglobin level, an increase in fecal acetic acid content, and a significant decrease in total SCFA content due to propionic and butyric acids reduction, which may contribute to NAFLD progression in obese children.

Introduction: The global epidemic of nonalcoholic fatty liver disease (NAFLD) occurs in parallel with other dysmetabolic diseases such as obesity and type 2 diabetes, which is reflected in the introduction of a new term «diabesity». Insulin resistance markers are promising markers for noninvasive assessment of hepatocyte damage and metabolic risk in NAFLD children so can be used to select pediatric patients at risk of disease progression.

Aims & Methods: The aim of our study was to investigate the association of insulin resistance markers with liver fibrosis in obese children with NAFLD. 40 obese children with NAFLD aged from 10 to 17 years (average age was 12.15 ± 2.51 years) were examined. Obesity was established by body mass index (BMI) calculation and comparison with the sigma deviations of BMI values according to age and sex. The presence of liver fibrosis and steatosis was established by transient elastography (Fibroscan[®]502touch, France). Children were divided into 4 groups according to transient elastography and BMI: I group - 13 children with NAFLD and liver fibrosis, II group - 13 children with NAFLD without fibrosis, and group III - 14 obese children without NAFLD and fibrosis. The control group consisted of 10 children with normal weight without NAFLD and fibrosis.

Serum insulin levels were determined by enzyme immunoassay (DRG International, Inc., Germany). Assessment of insulin resistance was carried out with a homeostasis model with the calculation of the HOMA-IR.

Results: A significant increase in median insulin level (3.1 times, $p < 0.05$) and HOMA-IR level (3.3 times, $p < 0.05$) in children of the I group was observed compared to the control group.

Moreover, the median insulin and HOMA-IR levels in children of the I group also differed significantly from children of the II group (1.5 times, $p < 0.05$ and 1.6 times, $p < 0.05$, respectively) as well as from children of the III group (2.0 times, $p < 0.05$ and 2.4 times, $p < 0.05$, respectively).

Children of the II group had 2.1 times higher median insulin and HOMA-IR levels ($p < 0.05$), and children of the III group had 1.5 times ($p < 0.05$) and 1.4 times ($p < 0.05$), respectively, higher levels compared to the control group. It was found a positive correlation between HOMA-IR and the liver fibrosis degree ($r = 0.373$; $p = 0.019$).

Conclusion: The development of liver fibrosis in NAFLD children is accompanied by a significant increase in insulin and HOMA-IR levels, indicating insulin resistance progression in these patients.

HEART RATE VARIABILITY IN CHILDREN WITH NON-ALCOHOLIC FATTY LIVER DISEASE DEPENDING ON INTESTINAL MICROBIOTA COMPOSITION

N. Zavhorodnia¹, E. Zygalo², N. Zhigir¹, O. Petishko³

¹SI "Institute Gastroenterology of NAMS of Ukraine", Pediatric Gastroenterology Department, Dnipro, Ukraine, ²SI "Institute Gastroenterology of NAMS of Ukraine", Mini-Invasive Endoscopic Interventions and Instrumental Diagnostics Department, Dnipro, Ukraine, ³SI "Institute Gastroenterology of NAMS of Ukraine", Research Department, Dnipro, Ukraine

Contact E-Mail Address: nzavgorodni75@gmail.com

Introduction: Heart rate variability (HRV) provides information about the adaptive potential of the patients and has an important prognostic and diagnostic value in non-alcoholic fatty liver disease (NAFLD).

Aims & Methods: The aim of our study was to investigate HRV in NAFLD children depending on the presence of small intestine bacterial overgrowth (SIBO).

64 obese patients with NAFLD aged from 10 to 17 years (average age was 12.15 ± 2.51 years) were included in the study. Obesity was established by body mass index (BMI) calculation and comparison with the sigma deviations of BMI values according to age and sex. The presence of liver steatosis was evaluated by transient elastography (Fibroscan[®]502touch, France). The presence of SIBO was determined with the hydrogen breath test (HBT) with glucose loading using a Gastrolyzer from Bedfont Scientific Ltd (UK). HRV assessment was performed based on the cloud technology of automated interpretation on the AMAZON web service with calculation ratio of low-frequency to high-frequency bands (HF/LF), root mean square of successive RR interval differences (RMSSD).

Children were divided into 3 groups according to transient elastography, HBT, and BMI data: 1 group - 28 NAFLD children with SIBO, 2 group - 36 NAFLD children without SIBO, 3 group (control) - 10 normal-weight children without NAFLD and SIBO.

Results: In 42.9% of NAFLD children with SIBO 2.5-fold increase ($p < 0.05$) in LF / HF ratio was found compared to the NAFLD patients without SIBO which reflects an increase in sympathetic nervous system influences. Moreover, in 60.7% of NAFLD patients with SIBO a decrease of RMSSD 4.59 times ($p < 0.05$) compared to the control group was observed while in NAFLD patients without SIBO only 38.9% of patients demonstrated a decrease of RMSSD in 1.5 times ($p < 0.05$).

Also, positive correlation between presence of SIBO and LF/HF ratio ($r = + 0.492$, $p < 0.05$) as well as negative correlation with RMSSD ($r = -0.65$, $p < 0.05$) were found.

Conclusion: The presence of SIBO in NAFLD children is accompanied by adaptive mechanisms impairment and changes in autonomic balance towards sympathicotonia.

Disclosure: Nothing to disclose.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disorder, which is a major cause of illness and mortality. Liver biopsy remains the best tool for its diagnosis, but it is an invasive procedure. Adiponectin and chemerin can be noninvasive diagnostic tools.

Aims & Methods: We aimed to study the levels of serum adiponectin and chemerin in patients with NAFLD and their diagnostic role.

Methods: This prospective study was carried out from March 2020 to October 2021 on 90 subjects including 60 patients with NAFLD and 30 age and gender-matched healthy individuals as control group. History was taken from all subjects, complete medical examination, thorough laboratory and radiological data were collected. Serum adiponectin and chemerin were assessed by enzyme linked immunosorbent assay (ELISA) technique and liver stiffness (LS) was assessed by point shear wave elastography (pSWE).

Results: There was a high statistically significant elevation of serum chemerin values and pSWE measurements in NAFLD patients than control. High statistically significant decrease of serum adiponectin values in patients with NAFLD than control. At cutoff point more than 280 ng/ml, serum chemerin value can predict NAFLD with 97% sensitivity, 90% specificity, while, at cutoff point less than 9 ug/ml, adiponectin level can predict NAFLD at 95% sensitivity, 97% specificity and at cutoff point more than 6.10 kpa and pSWE can predict NAFLD at 80% sensitivity, 100% specificity.

Introduction: Polycystic liver disease (PLD) is a rare heritable disease characterized by growth of hepatic cysts and can lead to hepatomegaly. It is diagnosed in the presence of > 10 hepatic cysts and can occur as an isolated disease (autosomal dominant polycystic liver disease, ADPLD) or in combination with renal cysts (autosomal dominant polycystic kidney disease, ADPKD). Disease severity is determined using total liver volume (TLV) which is measured from computed tomography (CT) or magnetic resonant imaging (MRI) scans.

The current gold standard, manual segmentation, is time-consuming, labor-intensive and requires expert knowledge of the anatomy. This warrants the need for novel fast and reliable TLV measurement tools.

Aims & Methods: This study aims to validate a semi-automatic liver segmentation technique for CT scans of patients with PLD. Adult PLD patients were recruited from two tertiary referral centers.

We used two CT scans from each included patient. Manual contouring was performed with software programs called Pinnacle and Analyze. Both measure liver volume by manually delineating liver contours on axial CT slices.

Manual contouring was compared with a semi-automatic segmentation technique (Volume), in which the liver is contoured on every 4th axial CT slice. The program interpolates between contours and removes non-cystic and non-liver tissue based on their Hounsfield unit density.

We assessed the correlation between the two techniques using intraclass correlation coefficients (ICC) and Bland-Altman analyses. We determined the performance of the semi-automatic segmentation technique cross-

sectionally and longitudinally. Bias was defined as the mean difference between manual and semi-automatic measurements; precision as the corresponding standard deviation.

Results: We included 60 patients in this study of which 85.0% (n=51) were female, the median age was 51.3 years (interquartile range (IQR) 44.7–59.2) and median TLV was 5293 ml (IQR 3141–7840 ml). The underlying diagnosis was ADPKD with PLD for 35 patients, ADPKD without PLD in 2 patients and ADPLD in 23 patients.

Manual segmentation lasted 73.2 (standard deviation SD 45.3) minutes per scan, whereas automatic segmentation lasted only 22.2 (SD 8.4) minutes (p=0.001). Cross-sectional analysis of the first CT scan showed that manual and semi-automatic measurements correlated highly with an ICC of 0.996, and a bias and precision of 1.9% and 3.4% respectively.

Comparable results were observed in sensitivity analyses consisting of 1) CT scans without contrast (n=28, bias 1.7%, precision 4.6%), 2) ADPKD patients with PLD (n=35, bias 1.2%, precision 2.4%), and 3) patients that underwent invasive treatment before the cross-sectional CT (n=18, bias 2.2 %, precision 4.6%).

The longitudinal analysis including data from 45 patients with two CTs obtained at least 1 year apart demonstrated that percentual liver growth can be accurately determined using the semi-automatic approach with a bias of 0.0% and precision of 4.8%. Results were robust across various subgroups defined by patient characteristics.

Conclusion: Semi-automatic liver segmentation is a fast and accurate method to determine TLV in PLD patients, and has sufficient accuracy and precision to be used in clinical care as well as trials to determine change in TLV.

IMPAIRED QUALITY OF LIFE MAY HINDER THE ACHIEVEMENT OF THERAPY GOALS IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE

Y. Golubeva¹, A. Sheptulina¹, A. Yafarova¹, E. Mamutova¹, O. Drapkina¹

¹National Medical Research Center for Therapy and Preventive Medicine, Moscow, Russian Federation

Contact E-Mail Address: yu_golubeva@mail.ru

Introduction: Nonalcoholic fatty liver disease (NAFLD) is often considered to be clinically asymptomatic. However, a large number of NAFLD patients complain of fatigue and decreased mood, which may affect their quality of life (QoL). This, in turn, may become a barrier to weight loss and, therefore, hinder the achievement of NAFLD therapy goals.

Aims & Methods: Present study aimed to evaluate the QoL in patients with NAFLD vs. healthy volunteers and to determine possible influencing factors. In total, 95 outpatients with NAFLD and 37 healthy volunteers were recruited. Fatty liver was diagnosed based on ultrasonographic findings. 36-Item Short Form Survey (SF-36) was used to assess the QoL.

Anxiety and depression were evaluated by the Hospital Anxiety and Depression Scale (HADS), to measure fatigue, we used the Fatigue Assessment Score (FAS).

Results: Median age was 50 years (interquartile range (IQR)=43-58) in NAFLD patients and 45.5 (IQR=36-51) for healthy volunteers; the majority of patients in this study were women: 62.1% and 78.4% in NAFLD and control groups respectively; 60.6% of NAFLD patients and 2.6% of controls had body mass index >30 kg/m².

Physical component summary score was significantly lower in NAFLD patients compared to the healthy volunteers (Mann-Whitney U-criteria, p<0.001). Fatigue was more common in NAFLD patients (χ², p<0.045), and

there was a trend towards an increased prevalence in depression in NAFLD group (U-criteria, p<0.014), compared to controls. Impaired QoL was significantly associated with fatigue (FAS score ≥22, p<0.001) and depression (HADS-D ≥8, p<0.001).

Conclusion: Adults with NAFLD had a significantly poorer QoL compared to healthy volunteers, in particular with regard to the physical component of health. Impaired QoL seems to be associated with fatigue and depression, and together they may militate against the increased physical activity and lifestyle modifications in NAFLD patients.

Disclosure: Nothing to disclose.

METABOLIC ASSOCIATED FATTY LIVER DISEASE (MAFLD) AND COVID-19: AN INTERPLAY LEADING TO POOR PATIENT OUTCOME?

V. Milivojević¹, I. Babić², J. Bogdanović³, I. Ranković¹, A. Pavlovic Marković¹, M. Krstić¹, T. Milosavljević⁴

¹University Clinical Centre of Serbia, University of Belgrade, Clinic for Gastroenterology and Hepatology, Belgrade, Serbia, ²University Clinical Centre of Serbia, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia, ³University Clinical Centre of Serbia, University of Belgrade, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia, ⁴Euromedic, General Hospital, Gastroenterology, Belgrade, Serbia

Contact E-Mail Address: dotorevlada@gmail.com

Introduction: Metabolic associated fatty liver disease (MAFLD) is a novel term that represents a spectrum of chronic liver disease phenotypes with systemic metabolic dysfunction. The SARS-CoV2 virus has been proven to cause innate and adaptive immunity impairment leading to abrupt systemic metabolic alterations. The question arises as to what extent does the bidirectional MAFLD/COVID-19 relationship affect patient outcome.

Aims & Methods: Our aim was to assess the influence of MAFLD on COVID-19 severity and its outcome. A retrospective study was conducted, including 130 patients, divided into two groups, group A (MAFLD) and group B (non-MAFLD). MAFLD diagnosis was made using criteria set by an International Consensus Panel.

Detailed demographic, anthropometric, biochemical analysis, comorbidities, and vital parameters were recorded. COVID-19 severity and liver fibrosis were assessed using NEWS2 and FIB-4 score (respectively). COVID-19 outcome was regarded as discharged patients, mechanical ventilation (MV) need and non-survivors.

Results: MAFLD prevalence was 42%, mortality rate was 14%, 67% of patients were discharged, and 19% needed MV. MAFLD patients were significantly younger (53.5±4.5ys vs 62.3±4.2yr, p<0.001), had higher body mass index (BMI, 28.5 kg/m²±2.8 vs 24.8±3.1 kg/m², p<0.05), respiratory rate (RR, 19.2±1.9 vs 16.0±1.4, p<0.05) and higher systolic blood pressure (SBP, 142.5±10.1mmHg vs 130.4±7.9mmHg, p<0.05) than nonMAFLD patients. When it came to metabolic syndrome and inflammatory parameters: group A had significantly higher glycemia at admission (8.4±1.2mmol/l vs 7.1±2.6mmol/l, p=0.008), lower HDL-c (0.7±0.1mmol/l vs 1.0±0.4mmol/l, p<0.01), higher triglycerides (Tg, 3.4±0.9mmol/l vs 2.8±1.0mmol/l, p<0.01), higher CRP (29.5±11.0mg/l vs 21.2±7.9mg/l, p<0.001), IL-6 (56.5±5.1pg/ml vs 54.2±4.1pg/ml, p<0.05) and ferritin (331.2±31.0µg/l vs 256.2±28.5µg/l, p<0.05) than group B.

MAFLD was associated with more prevalent type 2 diabetes (p=0.035) and hypertension (p<0.05). NEWS2 score was significantly higher among MAFLD patients (6.5±0.5 vs 3±1.0, p<0.05). MAFLD presence was associated with lower patient discharge (p<0.01), increased need for MV (p=0.024) and presence of advanced liver fibrosis (p<0.05). Multiple regression analysis showed that BMI (OR 2.3 (95% CI) 1.7-3.1, p=0.045), IL-6 (OR 2.1 (95% CI)

1.2-2.0, $p=0.03$), and MAFLD (OR 3.4 (95% (CI) 3.0-6.3, $p<0.05$)) are independent risk factors for poor COVID-19 infection outcome. MAFLD patients are at increased risk for poor outcome (RR 2.1 95% (CI) 1.2-3.8, $p<0.001$) as compared to nonMAFLD patients.

Conclusion: Our results imply that MAFLD poses a risk for poor COVID-19 infection outcome. In that sense, it is important to put an emphasis on MAFLD as one of the modifiable risk factors for severe COVID-19 infection in order to ameliorate MAFLD-related inflammatory state that contributes to poor COVID-19 outcome.

Contact E-Mail Address: julianaserrazina@gmail.com

Introduction: A terminology-change from nonalcoholic fatty liver disease (NAFLD) to metabolic associated fatty liver disease (MAFLD) has recently been proposed. MAFLD is a novel concept based on “positive criteria” that accurately reflects metabolic dysfunction, regardless of alcohol consumption or concomitant diseases. We aim to evaluate the importance of the novel MAFLD classification, by reclassifying our study cohort according to MAFLD and NAFLD definition.

Aims & Methods: This study was conducted at the outpatient Hepatology Clinic of a tertiary University hospital, where patients were followed due to fatty liver disease, by a multidisciplinary team.

Results: Amongst overall population ($n=157$), there were 92 males (58.6%), with a mean age of 54.2 $\pm$ 14.4 years at diagnosis. Mean body mass index (BMI) was 32.25 $\pm$ 6.49 Kg/m². 101 patients met diagnostic criteria for NAFLD (64.3%) while 154 (98.1%) fulfil MAFLD criteria. Only 3/157 were non-MAFLD patients. Analysing MAFLD-patients who were excluded from NAFLD definition ($n=56$), 51 (91.1%) had significant alcohol consumption (20 g/per day in women and 30 g in men), and 5/56 (8.9%) had another aetiology for liver disease. We further analyse non-NAFLD patients ($n=56$) according to metabolic risk factors and we did not find any significant difference in prevalence of arterial hypertension ($p=0.517$), dyslipidemia ($p=0.516$), diabetes mellitus ($p=0.741$) and overweight (BMI > 25 kg/m²) ($p=0.833$). From our total cohort, 17.3% had advanced fibrosis, from which 55.6% were non-NAFLD patients. The non-NAFLD group more frequently had advanced fibrosis ($F4 > 10.4$ kPa), (26.8 vs 12%, $p=0.019$). Evaluating the degree of hepatic steatosis with controlled attenuation parameter (CAP), no statistical difference between the groups was found ($p=0.989$).

Conclusion: Patients with fatty liver disease frequently fulfil MAFLD criteria, with is a substantial overlap between NAFLD and MAFLD. A significant proportion of MAFLD patients not fulfilling NAFLD criteria, had advanced fibrosis, thus emphasising the importance of MAFLD concept.

Introduction: The prevalence of non-alcoholic fatty liver disease (NAFLD) is increasing in patients with type 2 diabetes (T2D), as a result, a systematic screening in this population should be performed.

Aims & Methods: The aim of this study was to identify risk factors associated with moderate steatosis and advanced fibrosis and to develop a score that could be used in daily practice.

A prospective study on 534 patients with T2D was conducted using Vibration Controlled Transient Elastography (VCTE). We stratified our cohort into study cohort (348 patients) and validation cohort (186 patients). We aimed for 10 valid Controlled Attenuation Parameter (CAP) and liver stiffness measurements (LSM) with an IQR/Median $<30\%$. A cut-off value of 290 dB/m was used to define moderate steatosis (S2) while for advanced fibrosis ($F\geq 3$) a cut-off of 9.7 kPa [1]. For developing a score for stratifying the risk of moderate steatosis, and of advanced fibrosis, we used univariate and multivariate logistic regression analysis.

Results: Out of 534 patients, 62.7% had at least moderate steatosis and 19.2% had at least advanced fibrosis by VCTE. In univariate analysis, BMI ($p<0.0001$), waist circumference -WC ($p<0.0001$), elevated levels of ALT ($p=0.001$), total cholesterol ($p=0.03$), triglycerides ($p=0.01$), blood glucose ($p=0.004$) and presence of hypertension ($p=0.04$) were associated with at least moderate steatosis. The steatosis score is composed of: 0.5 points for high BMI (>32.1 kg/m²), cholesterol (> 235 mg/dl), triglycerides (> 165 mg/dl), glycemia (> 200 mg/dl), ALT (> 40 U/L) and WC (> 100 cm) and 1 point for the presence of hypertension. The maximum score can be 4 points. In univariate analysis, BMI ($p<0.0001$), WC ($p<0.0001$), elevated levels of AST ($p=0.001$), liver steatosis ($p=0.03$) were associated with at least advanced fibrosis. The fibrosis score is composed of: 0.5 points for high BMI (>32.4 kg/m²), AST (> 42 U/L), WC (> 110 cm) and for the presence of steatosis. The maximum score can be 2 points. The derived steatosis and fibrosis cut-offs for identifying patients with T2D were for steatosis $\geq S2$ (2 points) with an AUROC of 0.72 (42.4% Se, 96.7% Sp, 45.2% PPV, 90.9% NPV) and for fibrosis $\geq F3$ (1 point) with an AUROC of 0.68 (77.3% Se, 56.4% Sp, 37.8% PPV, 90.1% NPV). When we validate both scores, we obtained an accuracy of 83.9% for identifying at least moderate steatosis and 84.1% for advanced fibrosis.

Conclusion: Both steatosis and fibrosis score can be used in clinical setting for identifying patients with T2D at risk for developing at least moderate and advanced fibrosis.

ESTIMATION OF THE PREVALENCE OF NON-ALCOHOLIC FATTY LIVER DISEASE DURING OBSTRUCTIVE SLEEP APNEA SYNDROME

A. Ben Mohamed¹, M. Yakoubi¹, A. Khsiba¹, M. Mahmoudi¹, M. Medhioub¹, M.L. Hamzaoui¹, M.M. Azzouz¹

¹Department of Gastroenterology, Mohame Taher Maamouri Hospital, Gastroenterology, Nabeul, Tunisia

Contact E-Mail Address: asmabenmed2014@gmail.com

Introduction: The non-alcoholic fatty liver disease (NAFLD) is emerging as an important public health problem across the globe due to the increase of the prevalence of obesity and metabolic syndrome. Recent data have shown a frequent association between this liver disease and obstructive sleep apnea syndrome (OSAS).

Aims & Methods: The aim of our study was to estimate the prevalence of non-alcoholic fatty liver disease in patients with confirmed OSAS with daily alcohol consumption <20 g / day in women and <30 g / day in men. **Methods:** This is a prospective, comparative study over a period of 6 months, through which we tried to compare the prevalence of NAFLD between two groups of patients: the first comprising patients with confirmed OSAS and followed up in the department of pneumology, the second was a control group of patients followed for irritable bowel syndrome (IBS) at the outpatient clinic. The two groups were comparable for age, sex and co-morbidities.

Results: We collected 60 patients followed for OSAS. The mean age was 55.25 ± 11.14 years [23-75]. The sex ratio (M / F) was 0.5. Obesity, defined by a body mass index (BMI) > 30 kg / m², was noted in 76.6% and overweight (25 < BMI < 30 kg / m²) was present in 26.6% of the population. The average waist circumference was 112.34 ± 14.61 cm [90-150] and the average neck circumference was 37.17 ± 5.58 cm [28-58]. Type 2 diabetes was present in 25% of cases and high blood pressure in 41.6% of cases. An abdominal ultrasound, performed in all patients, showed a steatotic liver in 51.66% of cases (31/60) whereas this prevalence was lower in the control group (8% (4/50) with a statistically significant difference (p < 0.001). In univariate analysis, waist circumference > 115 cm was associated with hepatic steatosis (p < 0.001) which is the same for type 2 diabetes (p = 0.003). In multivariate analysis, the only independent variable associated with hepatic steatosis was a waist circumference > 115 cm.

Conclusion: The prevalence of non-alcoholic fatty liver disease is higher in patients with obstructive sleep apnea syndrome. Screening for this pathology in these patients would help in managing them and monitoring of the liver complications.

Disclosure: Nothing to disclose.

EFFECTIVENESS OF THE FIBROSCAN-ASAT (FAST) SCORE IN IDENTIFYING NON-ALCOHOLIC STEATOHEPATITIS (NASH) PATIENTS WITH SIGNIFICANT ACTIVITY AND FIBROSIS: A PROSPECTIVE STUDY

K. Amalou¹, R. Rekab¹, F. Belghane¹

¹HCA, Gastroenterology, Algiers, Algeria

Contact E-Mail Address: amalou_kh@yahoo.fr

Introduction: The prevalence of non-alcoholic fatty liver disease (NAFLD) is increasing worldwide. A major priority is to identify patients with non-alcoholic steatohepatitis (NASH) who are at higher risk of progression to cirrhosis, and who will be candidates for clinical trials and new emerging drug therapies.

Aims & Methods: We sought to investigate the effectiveness of the FAST score in identifying patients with NASH, high NAFLD activity score (NAS ≥ 4) and advanced fibrosis (fibrosis stage ≥ 2).

This prospective study included a cohort of patients aged 18 years or older, scheduled to undergo liver biopsy for suspected NAFLD at a tertiary care centre in Algeria. The measurement of liver elasticity (LSM) by transient vibration-controlled elastography and the controlled attenuation parameter (CAP) measured by the FibroScan device were combined with aspartate aminotransferase (ASAT), alanine aminotransferase (ALAT) or AST/ALT ratio. To identify patients with NASH, elevated NAS and significant fibrosis. **Results:** Between March 1, 2019 and January 21, 2019, 220 patients suspected of having NAFLD. The most predictive model combined LSM, CAP and AST, and was designated FAST (FibroScan-AST). The performance was satisfactory in the derivation data set (C-statistic 0-80, 95% CI 0.78-0.87) and was well calibrated. The cut-off was 0-38 for a sensitivity of 0-90 or greater and 0.67 for a specificity of 0.90 or greater in the derivation cohort, leading to a positive predictive value (PPV) of 0.85 (86/101) and a negative predictive value (NPV) of 0.88 (94/110).

Conclusion: The FAST score offers an effective means of non-invasively identifying patients at risk of progressive NASH for clinical trials or treatments when they become available, and thus reducing unnecessary liver biopsies in patients unlikely to have significant disease

Disclosure: Nothing to disclose

Introduction: Alcohol biomarkers are divided into direct ones, which are formed only during the ethanol metabolism (e.g. phosphatidylethanol, Peth), and indirect ones – enzymes that can change in response to alcohol consumption (e.g. alanine transaminase, ALT; aspartate aminotransferase, AST; gamma-glutamyltransferase, GGT). A direct alcohol biomarker Peth is formed only in the presence of alcohol, while liver enzymes can be elevated due to a number of causes. To protect against false positives, Peth is considered to be an indicator of purposeful alcohol consumption at values >20 ng/mL. The detection time of Peth can be maintained up to 2-3 weeks. Indirect markers have found the most widespread use in clinical practice, they are used to determine the etiology, severity and prognosis of liver cirrhosis. While direct markers are considered mainly only as a means of establishing the fact and nature of alcohol consumption. In our study, we evaluated alcohol biomarkers as a prognostic factor in patients with alcohol-related liver cirrhosis (ARC).

Aims & Methods: We aimed to assess the risk of readmission and fatal outcome in patients with ARC based on the alcohol biomarkers level. We performed a prospective observational cohort study involved 112 patients with history of ARC. All patients underwent clinical and laboratory examination on the first day of hospitalization, including quantitative LC/MS/MS determination of the Peth level and the liver cirrhosis severity on the Child-Pugh scale. Repeated contact to determine the outcomes (the pres-

ence of re-admission or fatal outcome) was appointed a year after the initial examination. Depending on the outcome, the patients were divided into groups: favorable outcome (n=74) - patients without re-admissions or fatal outcome; unfavorable outcome (n=38) - patients with re-admissions (n=36) and/or with fatal outcome (n=18). A ROC analysis of the relationship between the level of alcohol biomarkers and the course of liver cirrhosis was performed.

Results: The average level of Peth was higher in patients with fatal outcome and re-admission compared with patients with a favorable outcome of cirrhosis (468.7 ng/ml, 392.7 ng/ml and 249.8 ng/ml, respectively), a similar situation is typical for the GGT level (390.1 U/l, 270.7 U/l and 137.7 U/l, respectively) and alkaline phosphatase (ALP) (388.3 U/l, 331.3 U/l and 240.6 U/l, respectively).

The difference between the levels of albumin, ALT, AST, total and direct bilirubin, creatinine, INR values and the severity of liver cirrhosis on the Child-Pugh scale between the groups had no statistical significance. The indicators for which a statistically significant difference was obtained were used for ROC analysis. Re-admission was significantly associated with the level of Peth ($p=0.004$), GGT ($p=0.028$), and ALP ($p=0.05$), no significant relationship was obtained for platelet, leukocyte and Maddrey score values. The fatal outcome was significantly associated with the Peth level ($p=0.001$). Based on the ROC analysis results, the odds ratio (OR) of re-admission and fatal outcome in patients with ARC for 1 year were calculated. For lethality, a significant value of OR was observed with an increase of Peth more than 340 ng/ml (OR =3.8 (1.0-14.01); $p=0.04$). For re-admission, a significant OR value was noted with an increase in Peth > 340 ng/ml (OR 4.86 (2.0-11.8); $p=0.0005$).

Conclusion: Alcohol consumption is one of the factors influencing the prognosis of ARC. The Peth level >340 ng/ml is associated with an increased risk of re-admission and fatal outcome in patients with alcohol-related liver cirrhosis.

SZN-043, AN R-SPONDIN MIMETIC IN DEVELOPMENT FOR THE TREATMENT OF LIVER DISEASE, DEMONSTRATES A STRONG SAFETY PROFILE IN NONCLINICAL TOXICOLOGY STUDIES

J. Tibbitts¹, M. Newman¹, P. Stathis², A. Diep¹, G.F. Vanhove²

¹Surrozen Inc, Nonclinical Development, South San Francisco, United States, ²Surrozen Inc, South San Francisco, United States

Contact E-Mail Address: jtibbitts@surrozen.com

Introduction: Wnt signaling plays a central role in hepatocyte expansion during development and tissue repair. R-spondins (RSPOs) amplify Wnt signaling via stabilization of Frizzled and Lipoprotein receptor related protein co-receptors. SZN-043 is a hepatocyte-targeted antibody-based R-spondin mimetic shown to stimulate hepatocyte proliferation and improve hepatic function in preclinical models of liver injury.

Toxicology studies are essential to the development of potential therapeutic agents. For SZN-043 the mouse and cynomolgus monkey nonhuman primate (NHP) are relevant species based on their similarities in the binding and cellular function of SZN-043 to humans.

Aims & Methods: To support dosing in humans for up to one month, 4-week Good Laboratory Practice (GLP) compliant toxicology studies were conducted in mice and NHPs.

The purpose of these studies was to evaluate the toxicology and toxicokinetics (TK) of SZN-043. Normal mice (C57BL/6) or NHPs received 0, 12.5, 37.5, or 125 mg/kg SZN-043 intravenously (IV) (slow bolus) twice weekly for 28 days. A cohort of animals was terminated one day after the last dose and the remaining animals were terminated 28 days later.

Standard toxicologic analyses were included such as clinical and anatomic pathology, physical and other organ system evaluations, and toxicokinetic and antidrug antibody assessment.

Results: There were no SZN-043-related effects on body weights, food consumption, physical examinations, vital signs, ECGs, neurologic examinations, ophthalmology, hematology, coagulation, urinalysis, macroscopic examinations and histopathology.

Mice and NHPs receiving SZN-043 showed minimally to markedly increased alkaline phosphatase (ALP) levels during the dosing period which returned to baseline following cessation of dosing. The increase in serum ALP levels was not accompanied by changes in other hepatic, nor was there any evidence of hepatic injury by histopathology. This change was not considered adverse as increases in ALP are an expected pharmacologic effect of SZN-043 related to binding to the hepatocyte-specific protein ASGR1 preventing the elimination of ALP from serum. In mice but not NHP, a minimal decrease in serum albumin and total protein were observed with partial recovery following dosing.

An increase in liver weight was observed in male and female mice, and in female NHPs, receiving SZN-043 with no microscopic correlate. Liver weight returned to baseline during recovery and was not considered adverse. This is an expected pharmacologic effect of SZN-043 related to a transient increase in hepatocyte proliferation. In mice, other SZN-043-related changes in organ weights at the terminal necropsy included minimally higher adrenal and pituitary gland weights in some male animals at the higher doses; which was reversible and nonadverse, with no microscopic correlate.

Serum concentrations of SZN-043 were consistent with the dose and route of administration. Area under the curve increased greater than proportional to dose; consistent with the binding of SZN-043 to ASGR1.

Conclusion: Administration of SZN-043 was well-tolerated up to 125 mg/kg twice weekly. SZN-043-related changes were considered nonadverse and limited to clinical chemistry and organ weight changes. All observations showed evidence of recovery. There were no macroscopic or microscopic SZN-043-related observations. Serum exposure was consistent with the nature of SZN-043 and its dosing regimen. Based on the results of these studies, the no-observed-adverse-effect level was the highest dose of 125 mg/kg.

Disclosure: Nothing to disclose.

INTESTINAL ENDOTOXEMIA IS ONE OF THE FACTORS OF METABOLIC DISORDERS AND PROGRESSION OF NON-ALCOHOLIC FATTY LIVER DISEASE

G. Fadieienco¹, I. Kushnir¹, V. Chernova¹, T. Solomentseva¹, Y. Nikiforova¹, O. Kurinna¹

¹Government Institution L.T. Malaya Therapy National Institute of the National Academy of Medical S, Department of the Study of Diseases of the Digestive System and their Comorbidity with the Noncommunicable Diseases, Kharkov, Ukraine

Contact E-Mail Address: dr.jana@email.ua

Introduction: The progression of non-alcoholic fatty liver disease (NAFLD) is based on multiple parallel mechanisms that explain the complex molecular pathogenesis of NAFLD. One of the mechanisms of influence on the development of NAFLD is a violation of the intestinal microbiota (IM) and the production of endotoxin (ET) - lipopolysaccharide of the outer part of the cell membrane of gram-negative microorganisms.

Aims & Methods: To study the level of ET and evaluate the relationship between endotoxemia, metabolic parameters and the degree of hepatic steatosis in patients with NAFLD.

Materials and methods: The 86 patients with NAFLD with various metabolic disorders and 30 individuals in the control group were examined. All patients underwent an assessment of anthropometric parameters, a study of body composition with the determination of the percentage of visceral adipose tissue (VAT). VAT dysfunction was calculated by the visceral obesity index (VOI) according to the M.C. Amato method. Staging of steatosis according to the results of ultrasound CM was performed on the scale of the parameter of controlled attenuation (PCA), which corresponded to the morphological scale of fat activity NAS (Non-Alcoholic Steatosis). Serum ET concentration was determined using the LAL Chromogenic End-point Assay kit (Hycult Biotech, Netherlands).

Results: The levels of bacterial ET in the peripheral blood of the examined patients were almost three times higher than in the control group and amounted to 1.68 ± 0.19 U ET/ml and 0.43 ± 0.05 U ET/ml, respectively ($p < 0.05$). The relationship between the level of endotoxemia and the degree of nutritional status of patients with NAFLD was determined. In patients with overweight (BMI 25-30 kg/m²) and obesity (BMI >30 kg/m²), higher levels of ET were determined - 0.81 ± 0.09 U ET/ml and 1.84 ± 0.12 U ET/ml, respectively, compared with NAFLD patients with normal weight - 0.51 ± 0.05 ET units/ml ($p < 0.05$). In the examined patients, a direct correlation was determined between ET indices and parameters of abdominal obesity, namely, waist circumference (WC) ($r = +0.42$), the ratio of WC to hip circumference - ($r = +0.37$) and visceral obesity (VAT) ($r = +0.43$).

In the group of patients with high activity of VAT, the maximum levels of ET were recorded, which statistically significantly differed from those in patients with low and medium VOI ($p < 0.05$). In patients with steatosis of the 2nd and 3rd degree, the level of endotoxemia was higher, the difference in indicators in the control group and in the group with steatosis of the 1st degree was statistically significant ($p < 0.05$).

Conclusion: The data obtained suggest that bacterial metabolites of the IM, namely endotoxemia, make a significant contribution to the formation and maintenance of one of the components of the metabolic syndrome, namely visceral obesity with subsequent formation of fatty liver infiltration.

Introduction: Alcoholic liver disease (ALD) and Non-alcoholic fatty liver disease (NAFLD) are becoming the most common causes of chronic liver diseases and the leading causes of liver transplantation. Developing non-invasive methods for liver fibrosis and steatosis assessment are needed in these patients.

In addition to Transient Elastography (TE), new methods were developed. The aim was to evaluate and compare the performance of two point shear wave elastography techniques (pSWE and Auto pSWE) for the assessment of fibrosis and of Ultrasound Derived Fat Fraction (UDFF) for the assessment of steatosis, in patients with NAFLD and ALD using TE with Controlled Attenuation Parameter (CAP) as a reference methods.

Aims & Methods: A prospective study was conducted in which 166 consecutive patients with previously diagnosed ALD and NAFLD were included. All were evaluated in the same session by pSWE, Auto pSWE and UDFF, implemented in a Siemens ACUSON Sequoia system, using a Deep Abdominal Transducer (DAX), and by TE with CAP, implemented in a FibroScan Compact M 530 system (M and XL probes). Reliable measurements were defined as the median value of 10 measurements with an IQR/M < 0.3. The following TE cut-off values were used: for significant fibrosis ($F \geq 2$) - 9 kPa for ALD and 8.2 kPa for NAFLD. For mild (S1) steatosis, the following CAP cut-off values were used: 268 dB/m for ALD and 294 dB/m for NAFLD [1,2,3].

Results: Fibrosis distribution was the following: in the ALD group $F \geq 2$ - 10% (5/48) patients and $F 4$ - 25% (12/48) patients; in the NAFLD group, $F \geq 2$ - 4.2% (5/118) patients and $F 4$ - 6% (7/118) patients. In the ALD group 50% (24/48) had severe steatosis and in the NAFLD 39% (46/118), with no significant differences between the two groups, p -values > 0.05.

The best cut-off values for identifying significant fibrosis ($F \geq 2$) with pSWE and Auto pSWE in ALD patients were: >7 kPa, with AUCs (0.94 and 0.90), Se (83.3% and 41.6%), Sp (83.3% and 100%); in NAFLD patients: >5.2 kPa, AUCs (0.71 and 0.75), Se (40% and 60%), Sp (100% and 96.2%); For the presence of at least mild steatosis, UDFF cut-off value in ALD patients was >5%, AUC=0.94, Se=96.6%, Sp=83.3% and in NAFLD patients was >12%, AUC=0.87, Se=78.5%, Sp=84.2%.

Conclusion: The cut-off values by pSWE and Auto pSWE for identifying significant fibrosis were >7 kPa in ALD patients and > 5.2 kPa in NAFLD patients. The cut-off values for UDFF in diagnosing at least mild steatosis were >5% in ALD patients and >12% in NAFLD patients.

Introduction: Alcoholic hepatitis (AH) is one of the most severe forms of alcohol induced liver disease, especially severe alcoholic hepatitis (sAH), defined by a modified discriminant function (MDF) >32, being associated with 1 month mortality of 30%. Infections complicates AH and is the main cause of death in these group of patients, even in those who benefit from corticotherapy.

Aim: to evaluate the frequency of infections in patients with AH and the outcome of these patients.

Methods: A retrospective study was performed including 150 patients with AH over a period of 6 years in a tertiary Department of Gastroenterology and Hepatology. Systematic screening of infections was performed at admission, including chest x-ray, blood, urinary and ascites cultures. Severe AH was defined by a MDF score >32, response to corticotherapy was evaluated by Lille score at 7 days. Univariate regression was used to determine independent factors related to mortality.

Results: One hundred and fifty subjects were included in the final analysis, 84% male, mean age 55.5 ± 9.42. All patients were previously diagnosed with liver cirrhosis. 39.3% (59/150) presented infections at admission and 37.3% of the subjects with infections (22/59) died during admission, while only 19.7% (18/91) of those without infections, died (p=0.0283). 72.7% (109/150) of the included subjects had MDF>32 and received corticosteroid therapy and 42.2% of these (46/109) had an associated infection. In the group of those who received corticosteroid therapy, 35/109 (32.1%) deaths were recorded, 18/35 of them in patients with an associated infection (51.4%). Lille-7 was calculated in 90/109 subjects. 75.2% (82/109) of the subjects who received corticosteroid therapy were not responsive at 7 days and 31.7% of them (26/82) died, while 25% (2/8) of the responders died (p=0.9926).

In univariate regression analysis the presence of infections at admission was found to be an independent predictor for mortality (p=0.027).

Conclusion: AH is associated with a high risk of infection and infection screening is mandatory in these patients. The presence of infections at admission was found to be an independent predictor for mortality.

ROLE OF OSTEOPONTIN AS A POTENTIAL SERUM MARKER OF HCV RELATED HEPATOCELLULAR CARCINOMA

E. Abdelatti¹, A. Ezz¹, R. Elkholy², K. Elsayed¹

¹Faculty of Medicine, Menoufia University, Gastroenterology and Hepatology, Alexandria, Egypt, ²Faculty of Medicine, Menoufia University, Clinical Pathology, Menoufia, Egypt

Contact E-Mail Address: ehab_abdelatty@hotmail.com

Introduction: Hepatocellular Carcinoma (HCC) is a major type of primary liver cancer and one of the most frequent human malignant neoplasm. Owing to the lack of reliable clinical HCC markers, fewer than 20% of patients are diagnosed at a stage where curative treatment can be performed.

The poor outcome of patients with HCC is related to the late detection with more than two-thirds of patients diagnosed at advanced stages of disease. Osteopontin is an important tumor marker. It presents as an immobilized extracellular matrix molecule in addition to present as a secreted form in body fluids involving plasma.

Aims & Methods: The aim is to evaluate the role of plasma Osteopontin (OPN) level as potential serum marker of HCC among HCV related liver cirrhosis.

The study was carried out on 80 Egyptian patients with HCV related liver disease (chronic hepatitis (CH) group: 30 patients with HCV positive chronic hepatitis, Liver cirrhosis (LC) group: 20 patients with HCV positive liver cirrhosis without HCC and HCC group: 20 patients with HCV positive liver cirrhosis and HCC) and 20 healthy volunteers as controls from Menoufia University Hospitals (Egypt).

They underwent history taking, physical examination and laboratory investigations (CBC, liver profile {ALT, AST, albumin, bilirubin, PT}, urea, creatinine, AFP, HBsAg, HCV Ab and serum Osteopontin).

Child-Pugh score was calculated for all patients. Abdominal ultrasonography was done for all patients and controls. HCC is further confirmed by triphasic CT. Patients with extrahepatic malignancy, having any bony lesions or chronic liver disease other than HCV were excluded from the study.

Results: Osteopontin level was significantly higher in HCC group (232.1±59.7) ng/ml than LC (92.9±18.5) ng/ml, CH (27.8±13.8) ng/ml and control group (33.1±16.4) ng/ml (P=0.001 for all). Also OPN level was significantly higher in LC group than CH and control group (P=0.001 for both) but there was no significant difference between CH and controls (P=0.8). AFP level was significantly higher in HCC group (639±2226.8) ng/ml than LC (24.8±25.9) ng/ml, CH (8.1±2.8) ng/ml and control group (4.6±2.4) ng/ml (P<0.05).

Also AFP level was significantly higher in LC group than CH and control group (P=0.03 for both) but there was no significant difference between CH and controls (P=0.06). In LC group, one patient (3%) was Child A, 15 patients (50%) were Child B and 14(49%) patients were Child C. In HCC group, 26 patients (86.7%) were Child A, 4 patients (13.3%) were Child B. In HCC group, size of HCC ranges from 1.4 to 9 cm. 90% of the patients (n=27) have single lesion, 2 patients (n=2) have 2 lesions and only one patient have 3 lesions.

Three patients (10%) have portal vein thrombosis. In HCC group, there was a significant positive correlation between OPN level and age (r=+0.5, P=0.001) and AFP (+0.56, P=0.001). In HCC group, there was a negative correlation between OPN and WBC (r=-0.2, P=0.03), platelet count (r=-0.54, P=0.001), PT (r=-.45, P=0.001) and albumin (r=-.45, P=0.001). In HCC group, there was no correlation between OPN level and blood urea, serum creatinine, AST, ALT, bilirubin, size of HCC and number of HCC (P>0.05). OPN at cutoff level >164.5 ng/ml have 96.7% sensitivity and 98.6% specificity for detection of HCC. AFP at cutoff level >6.5 ng/ml have 80% sensitivity and 96% specificity for detection of HCC.

Conclusion: Osteopontin has a higher sensitivity and specificity than AFP for detection of HCC. Therefore Osteopontin could be used for detection of HCC.

QUALITY OF LIFE WITH THE USE OF PERITONEAL CATHETER IN TERMINAL PATIENTS WITH REFRACTORY ASCITIS AT HOSPITAL REGIONAL LIC. ADOLFO LOPEZ MATEOS

A. Chávez Santiago¹

¹Hospital Regional Lic. Adolfo López Mateos ISSSTE, Department of Gastroenterology, Ciudad De México, Mexico

Contact E-Mail Address: alejandrogastro140517@gmail.com

Introduction: In patients with a terminal disease state who develop ascites,* intractable with medical management, require repeated evacuating paracentesis; but it must be taken into account that this treatment method causes a great psychological and economic waste, both for the patient and for their main caregiver.

The literature reports that the placement of the peritoneal catheter as a palliative procedure attracts certain anticipated complications, not only because of the discomfort that the procedure itself entails, but because of the comorbidities that these patients present. Therefore, the cost-benefit of using this procedure should be evaluated, depending on the diagnosis of each patient and the etiology.

However, this research considers that any approach that contributes to mitigating the secondary symptoms of ascites and, therefore, to a better quality of life for the patient, is worth performing as part of the treatment provided by our hospital institution, after evaluation their status and their informed consent.

However, it is necessary to carry out studies with a more representative population of patients with the aforementioned characteristics of peritoneal catheter carriers, in order to weigh the positive effects of this procedure on their quality of life and that of their main caregivers.

Aims & Methods: A total of 12 patients participated in the study who were admitted with a diagnosis of intractable ascites of any etiology to the Regional Hospital "Lic. Adolfo López Mateos" in the period from March 2019 to February 2020, which also met the inclusion criteria of the protocol. A Tenckhoff catheter was placed in 6 patients in the experimental group, while said catheter was not placed in the remaining 6 patients in the control group.

The SF-36 Questionnaire was applied twice to all the patients in the control group: the first time at the start of their hospital admission and the second time 3 months later, while in the same lapse the respective caregivers were given the Zarit abbreviated scale. Likewise, in equal time and form, the SF-36 Questionnaire was applied twice to all the patients in the

experimental group: the first time at the start of their hospital admission and the second three months after the Tenckhoff catheter was placed, while in the same lapse the Zarit abbreviated Scale was applied to their respective caregivers.

Finally, the results of the questionnaires were compared with each other, in order to have a reliable clinical parameter that would allow the hypothesis to be verified or not.

Results: No statistically significant difference was found before and after placement of the Tenckhoff catheter on the quality of life of the patient ($p = 0.29$) and the burden of the main caregiver ($p = 0.65$). On the other hand, compared to the control group of patients, there was also no statistically significant difference on the quality of life of the patients ($p = 0.67$), so the hypothesis was null.

Conclusion: The results obtained in this study do not suggest significant differences in the quality of life of the patient and the main caregiver after the placement of the Tenckhoff catheter, having made an evaluation three months after the placement of this device.

Introduction: Hepatic Antigen Presenting Cells (hAPCs), mainly Liver Sinusoidal Endothelial Cells (LSECs) and Kupffer Cells (KCs), express C-type lectin receptors, like LSECTin. This protein is known for its interaction with effector T-cell ligands and its consequent role in inflammatory response control during liver damage (1).

Previous studies from our laboratory showed a negative transcriptional regulation of LSECTin in models of experimentally induced cirrhosis that resulted in a proinflammatory T-cell expansion (2).

Aims & Methods: Our aim in this study is to investigate whether LSEctin expression can be restored via an external intervention in hAPC from cirrhotic mice. For that objective, progressive liver damage was induced in mice by oral administration of carbon tetrachloride (CCl₄). Laparotomies were performed at week 12 in pools of control and treated mice (n = 6). Liver cirrhosis was assessed by qPCR and IHC staining of different proinflammatory and profibrogenic markers. LSEctin expression in whole livers was studied by qPCR, WB and IHC. FACS-isolated hAPCs were treated with and without combinations of anti-inflammatory cytokines (IL-4, IL-13, IL-10 and TGFβ1) for 48 hours. LSEctin expression was assessed in primary cultures by flow cytometry and qPCR.

Results: Livers from treated mice exhibited a strong expression of proinflammatory and profibrogenic markers indicating the onset of cirrhosis. A reduction of LSEctin expression during fibrosis progression was confirmed in our model, not only transcriptionally, but also at the protein level by IHC, WB and flow cytometry. LSEctin gene expression was induced in primary cultures of LSECS and KCs from control and fibrotic mice in the presence of anti-inflammatory cytokines (Table 1). Although IL-10 and IL-13 stood out individually, the combination of all four anti-inflammatory cytokines exhibited a synergistic upregulatory effect on LSEctin expression.

	KCs		LSECS	
IL-4	1.60	0.84	1.17	0.58
IL-10	1.53	0.99	1.68	1.18
IL-13	2.34	0.10	1.88	0.45
TGF-B	1.65	0.41	1.44	0.59
IL-4+IL-10	2.07	0.73	0.95	0.37
IL-4+TGF-B	2.11	0.33	0.94	0.15
IL-10+TGF-B	1.28	0.27	1.34	0.27
IL-4+IL-10+TGF-B	1.01	0.44	1.43	0.48
IL-4+IL-10+IL-13+TGF-B	1.93	0.12	3.05	1.72

Table 1. LSEctin Relative Expression induced by cytokine treatment (10 ng/mL). Relative expression values indicated as mean ± SD (untreated: 1.00 ± 0.00).

Conclusion: LSEctin expression can be exogenously induced in cirrhotic hAPCs by the generation of a tolerogenic microenvironment. Cytokine-induced LSEctin restoration may constitute a new tool in the control of liver inflammatory response in advanced liver disease.

CONTRIBUTION OF THE NEW PROGNOSTIC SCORE LIVER-RENAL-RISK (LIRER) IN PREDICTING SURVIVAL IN CIRRHOTIC PATIENTS

M. Mtir¹, D. Cherif¹, H. Garraoui¹, H. Hassine¹, H. Kechir¹, N. Maamouri¹

¹La Rabta Hospital, Department of Gastroenterology B, Tunis, Tunisia

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: The Model for End stage Liver Disease (MELD) score has been widely used in the selection of cirrhotic candidates for liver transplantation (LT) by prioritising them on the waiting list. For patients with a relatively low score (below 18), the MELD may underestimate the severity of the disease. For this reason, several scores have been proposed to improve its predictive value, including the MELD-Na. More recently, the liver-renal-risk score (LIRER) has been developed to resolve this problem.

Aims & Methods: The aim of this study was to evaluate the reliability of the LIRER score in predicting survival in cirrhotic patients compared to standard scores.

We conducted a monocentric retrospective study collecting all cirrhotic patients over an 8-year period (2008-2015). Clinical, biological, morphological and evolutionary data were collected.

The LIRER score was calculated for all patients according to the formula :
LIRER= [Natremia (mEq/L) x -0.09] + [Bilirubinemia (mg/dl) x 0.27] + [Albuminemia (g/dl) x -1.16] + [GFR-MDRD (ml/min) x -0.01] + Presence of ascites (1.2 if yes; 0 if no) +30 (constant)

Moreover, the glomerular filtration rate (GFR) was calculated according to the formula :

$$\text{MDRD} = 186 \times (\text{creatinine } (\mu\text{mol/l}) / 88.4)^{-1.154} \times \text{age}^{-0.203} \times (0.742 \text{ if female}) \times (1.212 \text{ if black})$$

A cut-off of 15.9 for the LIRER score was identified as a factor in rapid disease progression.

The performance of this score was compared with that of the Child And Pugh (CP), MELD and MELD-Na for 1 year, 3 years and 5 years survival using the area under the ROC curve (AUROC) with 95% confidence.

Results: We included 120 cirrhotic patients with an M/F sex ratio equal to 0.5. The mean age was 57 years [14-85]. The most frequent aetiology of cirrhosis were viral C (49%) and viral B (31%). Eighty-eight patients were in the complication stage, and the remaining 22 were still in the compensated stage. The mean overall survival was approximately 6 years after diagnosis. The mean scores were: CP 7.6 (stage B), MELD 17.54, MELD-Na 17.47 and LIRER 14.46 [range 1.1 - 19.9].

By analysing the areas under the ROC curves, the prognostic performances for 1 year, 3 years and 5 years survival were respectively:

	AUROC survival at 1 year	AUROC survival at 3 years	AUROC survival at 5 years
Child And Pugh	0.692	0.658	0.662
MELD	0.569	0.582	0.553
MELD-Na	0.547	0.578	0.577
LIRER	0.634	0.616	0.619

Furthermore, among the 71 patients with a low MELD score (below 18), 11 patients (9.1%) had a LIRER score above 15.9 constituting the group of patients underestimated by the MELD but with a high risk of unfavourable evolution. The LIRER score allowed us to reclassify this group of cirrhotics who can thus join the waiting list as potential candidates for TH.

Conclusion: At the end of this study, our results suggest that the LIRER score is a new reliable prognostic tool, with performances comparable to the usual scores, notably CP, MELD and MELD-Na, in predicting survival in

cirrhotics. Its use as an auxiliary prognostic tool in patients with a MELD of less than 18 could broaden the criteria for inclusion in the liver transplant waiting list.

LIVER-RENAL-RISK (LIRER): PERFORMANCE AND RELIABILITY IN PREDICTING THE OCCURRENCE OF HEPATORENAL SYNDROME IN CIRRHOTICS

M. Mtir¹, D. Cherif¹, H. Garraoui¹, H. Hassine¹, H. Kechir¹, N. Maamouri¹

¹La Rabta Hospital, Department of Gastroenterology B, Tunis, Tunisia

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Cirrhosis is a frequent pathology whose evolution can be marked by the occurrence of multiple complications that condition the prognosis.

Thus, the use of simple and reproducible prognostic scores could considerably improve its management. For this purpose, several scores have been developed, including the liver-renal-risk (LIRER) score, which has been proposed by certain authors in order to assess the severity of cirrhosis and thus allow the stratification of patients by order of priority for receiving a liver transplant.

Among these complications, renal dysfunction remains one of the most dreaded, namely the hepatorenal syndrome (HRS), often fatal in the absence of a liver transplant.

Therefore, we were interested in evaluating the performance of the LIRER score in predicting the occurrence of HRS and its reliability compared to the usual scores.

Aims & Methods: We conducted a monocentric retrospective study collecting all cirrhotic patients over an 8-year period (2008-2015). Clinical, biological, morphological and evolutionary data were collected.

The LIRER score was calculated for all patients according to the formula:

$$\text{LIRER} = [\text{Natreemia (mEq/L)} \times -0.09] + [\text{Bilirubinemia (mg/dl)} \times 0.27] + [\text{Albuminemia (g/dl)} \times -1.16] + [\text{GFR-MDRD (ml/min)} \times -0.01] + \text{Presence of ascites (1.2 if yes; 0 if no)} + 30 \text{ (constant)}$$

Moreover, the glomerular filtration rate (GFR) was calculated according to the formula :

$$\text{MDRD} = 186 \times (\text{creatinine } (\mu\text{mol/l}) / 88.4)^{-1.154} \times \text{age}^{-0.203} \times (0.742 \text{ if female}) \times (1.212 \text{ if black})$$

A cut-off of 15.9 for the LIRER score was identified as a factor for rapid disease progression.

The performance of this score was compared with that of the Child and Pugh (CP), MELD (Model for End stage Liver Disease), and MELD-Na regarding HRS occurrence using the area under the ROC curve (AUROC) with 95% confidence.

Results: We included 120 cirrhotic patients with an M/F sex ratio equal to 0.5. The mean age was 57 years [14 - 85]. The most frequent aetiology of cirrhosis were viral C (49%) and viral B (31%).

The mean serum creatinine was 10.23 mg/l [5 - 52], and the GFR calculated by MDRD was 85.9 ml/min/1.73m². The latter was below the threshold value in 55% of cirrhotics.

The mean scores were : CP 7.6 (stage B), MELD 17.54, MELD-Na 17.47 and LIRER 14.46 [1.1 - 19.9].

Thirty-five patients (29.1%) developed HRS and almost half of them were in refractory ascites stage (n=18). HRS was more frequent in patients classified as Child B and C by 37.1% and 51.4% respectively.

The mean LIRER score in patients who developed HRS was 16.07 [11.7 - 19.9] and that in cirrhotic patients without HRS complication was 13.78 [1.1 - 17.2].

The cut-off of the LIRER score in the occurrence of HRS in our population was 14.85 with a sensitivity of 80% and a specificity of 77,6%.

In univariate study and using the Chi-square test, the predictive factors for the occurrence of HRS were : an infectious episode apart from ascites fluid infection (AFI) with p= 0.0001, AFI (p= 0.002), ascitic decompensation (p= 0.0001), hyponatremia of less than 136 mmol/l (p= 0.005) and a CP stage C (p= 0.0001).

Furthermore, by analyzing the areas under the ROC curves, the prognostic performances regarding the occurrence of HRS of the CP, MELD, MELD-Na and LIRER scores were respectively:

	Child And Pugh	MELD	MELD-Na	LIRER
AUROC in predicting the occurrence of HRS	0.800	0.660	0.692	0.841

Conclusion: Our results suggest that the new prognostic score "LIRER" is a reliable and powerful tool in predicting the occurrence of renal dysfunction including hepatorenal syndrome.

PREDICTION MODEL OF 30-DAY INPATIENT MORTALITY FOR ALCOHOLIC HEPATITIS

H. Ali¹, R. Pamarthy¹

¹East Carolina University, Greenville, United States

Contact E-Mail Address: alih20@ecu.edu

Introduction: Alcoholic hepatitis (AH) is associated with morbidity and mortality depending upon the disease severity. Studies estimate that 30% of chronic alcohol drinkers will develop AH. Early recognition of high-risk patients can help improve mortality outcomes during AH hospitalizations.

Aims & Methods: We aimed to devise a mortality scoring system for risk stratification for AH hospitalizations. National Inpatient Sample (NIS) database from January 1st, 2019 to December 31st, 2019 was used to identify AH hospitalizations for the derivation cohort in the United States population. A mortality scoring system was derived using multivariable cox regression and validated using receiver operating characteristic curves in the NIS database 2018.

Results: Independent predictors for 30-day all-cause mortality included anemia [Adjusted Hazard Ratio (aHR):1.45, 95% CI:1.18–1.78, p < 0.001], Age > 60 years [aHR:1.75, 95% CI:1.51–2.03, p < 0.001], Female gender [aHR:1.16, 95% CI:1.01–1.33, p < 0.001], Mechanical Ventilation [aHR:2.8, 95% CI:2.4–3.3, p < 0.001], Vasopressor [aHR:2.3, 95% CI:1.82–2.8, p < 0.001], Hepatorenal syndrome [aHR:1.73, 95% CI:1.45–2.04 p < 0.001], Spontaneous bacterial Peritonitis [aHR:1.37, 95% CI:1.1–1.72, p < 0.001] Acute Renal failure [aHR:4.9, 95% CI:4.1–6.1, p < 0.001] and Coagulopathy [aHR:1.76, 95% CI:1.51–2.1, p < 0.001]. These were used to develop the predictive scoring system for inpatient 30-day inpatient mortality (Table

1). The cut-off was 4 points using Liu index (Sensitivity 78.38%, Specificity 92.98%) for 30-day mortality based on the highest sensitivity and specificity values from the ROC curves. The Area under curve (AUC) of the derivation cohort was 0.8766 (95% CI, 0.865–0.888). The validation cohort had an AUC of 0.862 (95% CI, 0.855–0.868).

Score	30-Day Mortality Rate (%)
1	0.29%
2	8.01%
3	4.1%
4	14.7%
5	33.1%
6	51.1%
7	69.6%
≥ 8	99%

Table 1: Risk Score system for 30-day inpatient mortality for AH hospitalizations using the US population

Conclusion: This system can be used as an objective method for predicting 30-day all-cause mortality for AH hospitalizations.

Disclosure: Nothing to disclose.

RELATION OF PROTEIN S AND PORTAL VEIN THROMBOSIS IN EGYPTIAN PATIENTS WITH HCV RELATED LIVER CIRRHOSIS

E.A. Abdelatti¹, R. Elkholy², A. Talkhan¹, A. Ezz¹

¹Faculty of Medicine, Menoufia University, Gastroenterology and Hepatology, Alexandria, Egypt, ²Faculty of Medicine, Menoufia University, Clinical Pathology, Menoufia, Egypt

Contact E-Mail Address: ehab_abdelatty@hotmail.com

Introduction: Portal vein thrombosis (PVT) is common in cirrhotic patients with a risk related to the severity of the disease. The prevalence ranges from 1%, at earlier stages to 30% in candidates for liver transplantation. PVT causes portal hypertension with development of esophageal varices, and if severe, can cause variceal hemorrhage and ischemic bowel disease. Protein S (PS) is natural anticoagulant protein produced by hepatocytes and decreased in setting of liver cirrhosis. Patients with PS deficiency are at increased risk for venous thromboembolic disease, arterial thrombosis and PVT. The pathogenesis of PVT has not been identified clearly, but it can be related to systemic causes such as protein S deficiency.

Aims & Methods: The aim was to investigate the relation of serum protein S level and pathogenesis of PVT in patients with HCV related liver cirrhosis. The study was carried out on 70 Egyptian patients with HCV related liver cirrhosis (LC) (LC group: 36 cirrhotic patient without PVT and LC+PVT group: 34 cirrhotic patient with cirrhosis and PVT) and 20 healthy volunteers as controls from Menoufia University Hospitals (Egypt). The study was conducted in the period from June 2020 and July 2021. They underwent history taking, physical examination and laboratory investigations (CBC, liver profile [ALT, AST, serum albumin, bilirubin, PT %], urea, creatinine, HBsAg, HCV Ab and PS assay). Abdominal ultrasound with Doppler of portal vein (PV) was done for all patients and controls. Triphasic CT of the liver was done for patients with PVT to exclude hepatocellular carcinoma (HCC). Child-Pugh score, AST/Platelet ratio index (APRI score) and FIB-4 were calculated for all patients. Patients on anticoagulant therapy, age less than 18 years, inflammatory or bleeding events in previous 2 months,

history of personal unprovoked thromboembolism (familial in first-degree relatives), diabetes mellitus, and HCC are excluded from the study.

Results: Protein S level was significantly lower in LC+PVT group (2.1 ± 1.9) than in LC (12.6 ± 12.9) and control group (20.8 ± 12.3) ($P=0.0001$ for both). Also PS level was significantly lower in LC group than in control group ($P=0.01$). PV diameter was significantly higher in LC+PVT group (14.3 ± 1.3) than in LC group (12.1 ± 1.3) ($P=0.001$). FIB-4 was significantly higher in LC group (6.56 ± 3.04) than in LC+PVT group (4.93 ± 1.77) ($P=0.02$).

There was no significant difference between LC+PVT group and LC group as regard, history of encephalopathy, history of gastrointestinal bleeding, presence of ascites, CBC, liver profile (ALT, AST, serum albumin, bilirubin, PT%), Child-Pugh score, APRI score, renal function (urea, creatinine), liver size and spleen size ($P>0.05$).

There was a significant positive correlation between PS level and PT%, APRI score, FIB-4, in LC+PVT group ($P=0.03$, 0.03 and 0.04 respectively). There was no correlation between PS level and age, platelet count, serum albumin, AST, ALT, serum bilirubin, blood urea, serum creatinine and spleen size ($P>0.05$). PS at cutoff level 3.2 ng/ml have 91% sensitivity and 98% specificity for prediction of PVT. In LC+PVT group, 82% have partial PVT (grade I) ($n=28$), 12% complete PVT (grade II) ($n=4$) and 6% complete PVT with superior mesenteric extension (grade III) ($n=2$).

Conclusion: Low protein S concentration is associated with pathogenesis of PVT in liver cirrhosis. Protein S concentration is potential biochemical marker in diagnostic strategy of PVT in patients with cirrhosis. Protein S below 3.2 is highly indicator of PVT in cirrhotic patients with high sensitivity and specificity.

BAVENO VII CRITERIA AS NON-INVASIVE PREDICTORS OF ESOPHAGEAL VARICES AND RISK OF DECOMPENSATION

E. Afecto¹, S. Sousa-Fernandes¹, J.P. Laranjeira Correia¹, M.M. Estevinho¹, A.P. Silva¹, T. Freitas¹

¹Centro Hospitalar de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal

Contact E-Mail Address: joaopaulo_laranjeira@hotmail.com

Introduction: The presence of clinically significant portal hypertension (CSPH) is an important prognostic marker in chronic liver disease (CLD). The recent Baveno VII consensus proposes non-invasive diagnostic methods for this condition, using transient elastography (TE) and platelet count. This work aims to evaluate these criteria and their influence on long-term prognosis.

Aims & Methods: We retrospectively included patients with compensated CLD, submitted to TE between 2013 and 2015, who had an analytical study (within 3 months from TE) and upper digestive endoscopy (within 1 year from TE). Patients with decompensated CLD were excluded. CSPH was defined as liver stiffness ≥ 25 kPa and absence of CSPH as liver stiffness ≤ 15 kPa + platelets ≥ 150000 , per Baveno criteria. The prediction accuracy of the Baveno criteria for CSPH was compared with the presence of varices in endoscopy.

Results: 104 patients were included, 69.2% men, mean age 56.8 years. Hepatitis C (79.8%) and alcohol (11.5%) were the main causes of CLD in our cohort. Esophageal varices were present in 26 patients, 9 of which were considered high risk. The Baveno criteria significantly predicted the presence of esophageal varices ($p < 0.001$), with sensitivity, specificity, positive and negative predictive value of 95%, 82%, 67%, and 98%, respectively. Additionally, over a mean follow-up of 56 months, the patients classified as CSPH under Baveno criteria had increased risk of bleeding, death, or transplantation (HR 9.9).

Conclusion: This study demonstrates the ability of the Baveno criteria to non-invasively identify patients with CSPH immediately and their risk of gastrointestinal bleeding, death or transplantation over a long period of follow-up, which highlights its usefulness in clinical practice.

Disclosure: Nothing to disclose.

THE IMPACT OF COVID-19 PANDEMIC IN LIVER CIRRHOSIS HOSPITAL ADMISSIONS

V. Martins^{1,2}, R. Oliveira^{1,2}, J. Roseira^{1,2}, A.M. Vieira^{1,2}

¹Centro Hospitalar Universitário do Algarve, Portimão, Portugal,

²Algarve Biomedical Centre, Faro, Portugal

Contact E-Mail Address: viviana.s.martins@hotmail.com

Introduction: The impact of COVID-19 pandemic in cirrhotic patients' management is yet to be determined. Whether the unavoidable clinical practice modifications resulted in worse outcomes remains unanswered.

Aims & Methods: We aimed to compare hospital admissions due to cirrhosis acute decompensations or complications before and during the pandemic.

Methods: Retrospective unicentric cohort study considering all hospital admissions due to cirrhosis acute decompensations or complications between April-September 2019 (pre-pandemic), 2020 (early pandemic in Portugal) and 2021 (1 year post pandemic start).

Patients' sociodemographic, clinical and biochemistry data at admission were reviewed. Hospital 30-day readmission and mortality (at hospital; post discharge: 30, 90 days, 1 year), were the outcomes of interest.

Statistics: descriptive statistics, chi-square, Mann-Whitney and Kruskal-Wallis tests.

Results: We evaluated 127 admissions of 96 patients, mean age 60.1 $\pm$ 11.0 years, mostly male (84.4%), with alcohol related liver cirrhosis (59.4%), and no previous hepatocarcinoma diagnosis (87.5%).

Overall, patients' clinical status before and during the pandemic (including both periods) was similar, regarding causes of admission, biochemistry data, prognostic scores, and outcomes (all $p > 0.050$).

Most patients presented severe disease at admission (median Child Pugh, 10; median MELD, 22). Ascites (68.5%) and hyponatremia (53.5%) were the most common clinical features detected. As for admission causes, hydropic decompensation and hepatic encephalopathy were the main findings irrespective of the study's timepoints (before 40.0% and 17.5%, during 37.9% and 17.2%, respectively). Interestingly, patients were discharged sooner during the pandemic (median 9 vs 14 days, $p < 0.049$).

Conclusion: Unlike empirical belief, this study showed that disease severity and decompensation of cirrhotic patients admitted to the hospital during the last 3 years, were similar, irrespective of COVID-19 pandemic, suggesting the contingency plans did not negatively impact these patients. Larger studies may further confirm these results. Whether cirrhotic patients delayed discharges before pandemic were modified due to contingency plans or social causes remains unaddressed.

Disclosure: Nothing to disclose.

Introduction: End-stage liver disease is a major cause of death worldwide. It usually evolves over several years from compensated to decompensated cirrhosis, which is identified by the onset of acute decompensation (AD) with the development of hepatic encephalopathy (HE), ascites, and variceal hemorrhage (VH). Further decompensation frequently leads to the terminal stage of cirrhosis characterized by occurrence of acute-on-chronic liver failure (ACLF). Patients with either AD or ACLF usually require admission to the intensive care unit (ICU). Several ICU and liver-specific scores have been used to predict outcomes of critically ill patients with cirrhosis. The most often used ICU scores is Sequential Organ Failure Assessment (SOFA) scores.

Aims & Methods: This study was conducted to evaluate the performance of prognostic scores, including Chronic Liver Failure Consortium (CLIF-C) SOFA, CLIF-C OF and CLIF-C ACLF scores, in predicting mortality of cirrhotic patients admitted to the gastroenterology ICU.

Cirrhotic patients admitted in the Gastroenterology Department for the management of an acute decompensation of cirrhosis between January 2019 and January 2022 were retrospectively included. All prognostic scores were calculated in the first 24 hours of admission. Their ability to predict mortality was measured using the analysis of the area under the receiver operating characteristic curve (AUC).

Results: A total of 62 consecutive patients (sex-ratio M/F: 1.58, mean age 64.82 $\pm$ 13.51 years) were admitted due to AD of cirrhosis ($n=46$) or ACLF ($n=16$). At the time of the study, cirrhosis had progressed for a mean of 5.9 $\pm$ 4.56 years. Most of cirrhosis was due to viral hepatitis C (28%). The average MELD score was 16 $\pm$ 7 [range 7-31].

The AD/ ACLF occurred on average 31 [0-154] months after the diagnosis of cirrhosis. The main clinical features of those individuals were bacterial infections with or without sepsis or septic shock (30%), HE (10%) and VH (23%). Among the patients, 39 had concurrent ascites (63%).

The average (CLIF-C) SOFA, CLIF-C OF and CLIF-C ACLF scores were respectively 5.22 $\pm$ 3.47, 7.63 $\pm$ 2.17 and 51.56 $\pm$ 8.37. According to CLIF-C criteria, 16 patients (26%) had ACLF classified grade I ($n=8$), grade II ($n=7$), or grade III ($n=1$).

The mean length of hospital stay was 8 $\pm$ 6 days. Mortality was observed in 18 patients (29%). Analysis of AUC revealed that CLIF-C OF (0.880) and CLIF-SOFA (0.942) had the best ability to predict mortality in all patients. CLIF-SOFA, and CLIF-C OF had the highest AUC values in patients with ACLF, with no statistical difference ($p: 0.875$).

Conclusion: When compared to other general or liver-specific prognostic scores, CLIF-C OF, CLIF-SOFA, and CLIF-C AD have good accuracy to predict mortality in critically ill patients with cirrhosis and patients with AD. According to the clinical scenario, different scores should be used to provide prognosis to patients with cirrhosis in the ICU.

Introduction: Acute variceal bleeding is a major cause of death in patients with liver cirrhosis. The aim of this study was to investigate mortality predictors and develop a simplified prognostic model in patients with acute variceal bleeding.

Aims & Methods: We conducted a retrospective monocentric study in a cohort of cirrhotic patients with acute variceal bleeding between January 2010 and December 2021.

Results: A total of 131 patients were included, the majority male (80.2%), with a median age of 59 years old (IQR 50-65). Alcoholic liver disease was the leading cause of liver cirrhosis (77.8%). Twenty-six patients (19.8%) had concomitant hepatocellular carcinoma. Eleven (8.4%) patients were taking antiplatelet agents and six (4.6%) anticoagulants. Esophageal and gastric varices were the cause of bleeding in 123 (93.9%) and 8 (6.1%) patients, respectively. All patients received endoscopic therapy at the time of initial endoscopy. Band ligation was performed in 114 patients (87.0%), sclerotherapy in 17 (13.0%) and cyanoacrylate injection in 9 (6.9%). The 90-day overall mortality rate was 16.0%. The value of aspartate aminotransferase ($p < 0.001$), albumin ($p = 0.006$), sodium ($p = 0.001$) and rebleeding within five days of endoscopy ($p = 0.010$) were independent predictors of mortality after the acute variceal hemorrhage episode. A new logistic model using these variables was developed: $0.716 * \text{Albumin} + 1.022 * \text{aspartate aminotransferase} + 0.694 * \text{sodium} + 42.169 * \text{rebleeding within five days of endoscopy}$. This model's AUROC was 0.841 (CI 95% 0.726-0.956, $p < 0.001$), which was significantly higher than that of MELD (0.723, CI 95% 0.555-0.891, $p = 0.007$) or Child-Pugh scores (0.789 CI 95% 0.653-0.924, $p = 0.001$).

Conclusion: Our new simplified model accurately and consistently predicted 90-day mortality in patients with acute variceal bleeding. Our system can be used to identify high-risk cirrhotic patients.

Disclosure: Nothing to disclose.

SPLENIC ARTERY ANEURYSMS AND PORTAL HYPERTENSION: CAUSE OR CONSEQUENCE

S. hmimass¹, I. Khalif¹, M. Borahma¹, M. Kadiri¹, I. Benelbarhdadi¹, F.z. Ajana¹

¹University Mohammed V, Medicine C-Hepatogastroenterology, Rabat, Morocco

Contact E-Mail Address: hmimass19@gmail.com

Introduction: Splenic artery aneurysms (SAAs) are rare, asymptomatic and incidentally discovered. The majority of SAAs are medium-sized, measuring 3 cm at diagnosis. Associations with portal hypertension (PH) have been frequently reported.

Recently, attention has been drawn to chronic liver disease requiring liver transplantation as risk factors. The risk of rupture of true aneurysms appears to be negligible, below a size of 2 cm.

Aims & Methods: This was a retrospective study conducted in a hepatogastroenterology department. Splenic artery aneurysms were discovered incidentally by performing an angiography scan in our patients followed for portal hypertension. The aim of our work was to identify risk factors for the occurrence of ASA in patients with PH.

Results: We registered 5 patients with splenic artery aneurysms over a period of 2 years (2021-2022). The mean age of the patients was 44.4 years with extremes ranging from 36 to 59 years, with a male predominance (sex ratio of 1.5). The circumstances of discovery were variable, all patients presented an anemic syndrome, upper GI hemorrhage was found in 60% of cases, abdominal pain at the left upper quadrant with weight loss, homogeneous abdominal distension and chronic malabsorption diarrhea encountered in 20% of cases each.

Clinical examination revealed splenomegaly (SMG) in 80% of the patients, signs of hepatocellular insufficiency, conjunctival jaundice, and stage I hepatic encephalopathy in 2 patients each; collateral venous circulation (CVC) in both flanks and basithoracic in 20% of the patients, and in only one patient ascites grade III.

The clinical examination of the liver revealed an overloaded liver in 40%, a dysmorphic liver with a cirrhotic appearance in 20%, and hepatomegaly in only one case. Liver function tests showed chronic hepatocellular failure in 60% of the cases, cytotoxicity in 2 patients, and no patient had cholestasis, with elevated total bilirubin in 2 patients. Abdominopelvic ultrasound with Doppler examination showed an inhomogeneous dysmorphic liver in 2 patients, a normal liver in 40%, and heterogeneous hepatomegaly with irregular contours in 20% and portal cavernoma in 20% of cases.

All our patients had PH with portosystemic shunts. An abdominal angiography scan was performed as part of the monitoring and etiological work-up of our patients who were all asymptomatic; and objectified a single splenic artery aneurysm in 80%, with an aneurysm size greater than 2 cm in 50% of the patients and less than 2 cm in 2 patients; and 3 splenic artery aneurysms were found in only one patient. A partial atheromatous plaque was found in only one patient. Splenic artery aneurysms were found on angiography scan at the time of diagnosis of PH in 3 patients, after 9 years in one case and after 5 years in another case.

In terms of the etiology of PH, autoimmune hepatitis at the stage of cirrhosis was diagnosed in 2 cases, of which one case was associated with celiac disease, hepatic sarcoidosis at the F1 stage was associated with celiac disease in one case, and PH caused by portal cavernoma and Portosinusoidal vascular disease (PSVD) in one case each. Therapeutically only one patient was splenectomized with good outcomes, 2 patients needed clinical +/- radiological monitoring, one patient will be scheduled for surgical treatment and only one patient refused treatment.

Conclusion: Splenic artery aneurysm is a rare and often asymptomatic complication of portal hypertension. In our series, 3 patients had advanced PH in the setting of chronic liver disease and in 2 cases was developed after more than 5 years of evolution.

Disclosure: Nothing to disclose.

USEFULNESS OF MELD AND MELD-NA FOR PREDICTING MORTALITY IN CIRRHOTIC PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS

C. Coxeter-Smith¹, A. Al-Adhami², L. Alrubaiy²

¹Imperial College, School of Medicine, London, United Kingdom,

²St Mark's Hospital, Gastroenterology, Harrow, United Kingdom

Contact E-Mail Address: dr.amsk82@yahoo.com

Introduction: Spontaneous bacterial peritonitis (SBP) is defined as a bacterial infection of the ascitic fluid that occurs in the absence of any surgically treatable intra-abdominal sources of infection [1]. SBP is common in patients with cirrhosis and ascites [2,3] as a result of increased bacterial translocation from the gastrointestinal tract to mesenteric lymph nodes and other extraintestinal sites [4]. Due to impaired local [5] and systemic [6] immune defences, these microorganisms, most commonly gram-negative enteric bacteria [7], may not be killed effectively and therefore can colo-

nise the ascitic fluid [4]. Presentation with SBP varies; some patients are asymptomatic and are diagnosed incidentally during large volume paracentesis [8], whereas others present with severe sepsis and multiorgan failure [9,10]. Despite vast improvements in the early diagnosis and treatment of SBP [11], the short-term prognosis is poor; in-hospital and 90-day mortality is 36% and 45% respectively [12].

The model for end-stage liver disease (MELD) is a widely used prognostic score in patients with cirrhosis. Originally designed to predict short-term survival following elective transjugular intrahepatic portosystemic shunt (TIPS) placement [13], it subsequently showed excellent ability to predict 90-day mortality in patients on the liver transplant waiting list in the United States [14,15]. Therefore, in 2002, MELD replaced Child-Turcotte-Pugh as the basis for prioritising donor livers to patients on the waiting list with the poorest short-term prognosis [16].

Outside of the context of donor liver allocation, MELD has also been validated as a prognostic score in multiple other cohorts: for example, to predict short-term mortality in cirrhotic patients undergoing elective and emergency surgery [17] and in alcoholic hepatitis [18].

Currently, the accuracy of the model for end-stage liver disease (MELD) and MELD-sodium (MELD-Na) as prognostic scores in cirrhotic patients with SBP is unclear.

Aims & Methods: This study aimed to evaluate and compare the accuracy of MELD and MELD-Na for predicting 90-day mortality and determine whether the mortality risk estimates they provide accurately reflect the poor prognosis of SBP patients. Cirrhotic patients with SBP were retrospectively identified from ascitic fluid samples sent for microscopy, culture and sensitivity analysis (1/1/18-31/12/20) and a previous audit. MELD and MELD-Na scores at diagnosis were calculated and associations with 90-day mortality were assessed using univariate analysis. Receiver operator characteristic curves were compared, and standardised mortality ratios (SMRs) were calculated by comparing the number of deaths observed to the number predicted by MELD and MELD-Na.

Results: Of the 567 patients identified, 15 cirrhotic patients with SBP were included. 90-day mortality was 66.7% (10/15). Only concurrent hyponatremia (<135mmol/L) was associated with mortality (6/10 non-survivors vs 0/5 survivors, $p=0.04$). The difference in MELD and MELD-Na's c-statistic was not significant: 0.66 (95% CI: 0.35-0.98) vs 0.74 (95% CI: 0.47-1.0) respectively ($p=0.72$). Patients with a MELD-Na >18.5 had significantly higher 90-day mortality than patients with MELD-Na ≤18.5 (88.9% (8/9) vs. 33.3% (2/6), $p=0.05$). The SMR (95% CI) for each MELD decile evaluated was 33.3 (0-79.5), 11.1 (0.2-22.0) and 3.4 (0-7.0) for scores ≤9, 10-19 and 20-29 respectively. For each MELD-Na tertile these were: 25 (0-59.6), 5.2 (0.1-10.3) and 2.7 (0.1-8.1) for scores <17, 17-26, ≥27 respectively.

Conclusion: In a small cohort of cirrhotic patients with SBP, the MELD's accuracy in predicting 90-day mortality was limited. MELD-Na's accuracy was higher but not significantly. Both scores consistently underestimated participants' mortality, therefore future studies could evaluate the accuracy of alternative prognostic scores in this patient group.

TREATMENT AND OUTCOMES OF POST-BANDING ULCER BLEEDING AFTER PROPHYLACTIC ENDOSCOPIC BAND LIGATION

R. Medas¹, R. Liberal¹, R. Coelho¹, H. Cardoso¹, G. Macedo¹

¹Centro Hospitalar Universitário São João, Gastroenterology, Porto, Portugal

Contact E-Mail Address: renatogmedas@gmail.com

Introduction: Post-banding ulcer bleeding (PBUB) is a potential complication after endoscopic band ligation (EBL), with a reported incidence between 2-8%. Several endoscopic treatments have been described to manage PBUB, however, optimal management strategy remains undefined.

Aims & Methods: We aim to describe the management and outcome of patients presenting with PBUB after prophylactic EBL, defined as upper gastrointestinal bleeding within 30 days after EBL. All EBL procedures performed in a tertiary center, between 2015 and 2021, were analyzed retrospectively. Patients with noncirrhotic portal hypertension or submitted to EBL for treatment of acute variceal haemorrhage were excluded.

Results: 871 prophylactic EBL, performed in 281 patients, were included. PBUB occurred in 20 cases (2.3% of procedures; 18 patients) within a median time of 11 days (IQR 8-17). Most patients were male (94.4%) and median age was 58 years (IQR 50-69). 77.8% patients were Child-Pugh B.

Most PBUB occurred after primary prophylaxis (70.0%) and of those, 52.9% occurred after first EBL session. Endoscopic plus medical treatment (sucralfate plus pump proton inhibitors) was performed when high-risk stigmata were present (clot=6, visible vessel=2, active bleeding=3). Polidocanol was the preferred treatment (63.6%).

Despite a technical success of 100%, re-bleeding occurred in 5 cases (45.5%). The remaining cases received only medical therapy (clean base=9). Re-bleeding occurred in 33.3% of these patients. 4 patients (22.2%) died before home discharge for causes related to bleeding episode. 6 and 12-month mortality rate were 44.4% and 72.2%, respectively. Portal hypertensive bleeding and hepatocellular carcinoma were the main causes of death (38.9% and 22.2%, respectively).

Conclusion: Most cases of PBUB occurred in primary prophylaxis and after first EBL session. Re-bleeding was a frequent event, even after adequate endoscopic treatment, posing PBUB as a life-threatening complication. Our results reinforce the role of beta-blockers as the preferred method for variceal bleeding primary prophylaxis.

Disclosure: Nothing to disclose.

Introduction: Advanced chronic liver disease (ACLD)/cirrhosis is often only diagnosed after the development of complications, when therapeutic options are generally limited. In our study we assessed clinical characteristics at first diagnosis of cirrhosis and its further course during etiologic and/or portal hypertension treatment.

Aims & Methods: Charts of patients presenting at a large, non-liver transplant center were reviewed for presence of esophageal varices in endoscopy, liver stiffness ≥ 15 kPa in elastography, or undergoing paracentesis for ascites to define the date of diagnosis of cirrhosis (at our center). Clinical, laboratory, and imaging data were collected at diagnosis (DG) and last follow-up (FU). The observation period was 01/2015 until 03/2020.

Results: 477 patients were included, 345 (72.3%) were male, and median age at diagnosis was 55 years. Most common etiologies were alcohol-related liver disease (ALD; n=211, 44.2%) and viral hepatitis (n=163, 34.2%). 105 patients (22.0%) presented with Child-Pugh C and 160 (33.5%) with MELD >15 ; 239 patients (50.1%) presented with at least one decompensation event (ascites, bleeding, encephalopathy) at DG. Median follow-up was 12 months (range 6-26 months).

In ALD patients, we observed an improvement in MELD (mean 17.4 to 11.6, $p<0.001$) and Child-Pugh score (CPS; mean 8.6 to 7.7, $p<0.001$), while in viral hepatitis patients overall there were no significant improvements during FU for MELD (mean 10.2 to 10.0, $p=0.26$) and for CPS (mean CPS 5.9 to 5.9, $p=0.35$). However, in patients with hepatitis C virus cirrhosis achieving virological cure (n=109/147, 74.1%), we observed significant improvements in liver stiffness (26.2 to 17.7 kPa, $p<0.001$) and in platelet count (147 to 169 G/L, $p<0.001$).

Overall, 17 patients (3.6%) were diagnosed with hepatocellular carcinoma at DG and 6 (1.3%) during FU. Eight patients received locally ablative therapy, and 3 received systemic therapies. Fourteen patients (2.9%) presented with portal vein thrombosis at DG and 7 (1.5%) developed PVT at a later date. Overall, 115 patients (24.1%) died during FU.

Conclusion: At a large non-liver transplant center, about 50% patients diagnosed with cirrhosis presented with decompensation at baseline. Liver cancer was mostly diagnosed in advanced stage without curative treatment options. This calls for action in terms of developing strategies for screening and early diagnosis of liver disease.

Disclosure: Michael Schwarz received speaking honoraria from BMS and travel support from BMS, AbbVie, MSD and Gilead.

Introduction: Cirrhosis is believed to be associated with frailty and depression, and is often unrecognized. The relationship between frailty and depression in cirrhosis is poorly understood.

Quantifying disease burden for cognitive disorders and frailty is an important measure for predicting functional decline and adverse outcomes in cirrhosis.

Aims & Methods: The aim of this study is to assess the relationship between frailty and depression in cirrhotic patients, and other factors associated with the disease. This is a cross sectional study that included 57 cirrhotic patients over 18 years of age, enrolled from April 2020 to December 2021. These patients were hospitalized, seen in the endoscopy service for routine or therapeutic interventions, or seen in the clinics for follow up. Patients with neurological or psychiatric disease, severe cardiac or renal insufficiency, were excluded from the study.

The patients filled out a questionnaire containing the demographic and anthropometric characteristics (body mass index, circumference of the neck and the calf, age, sex), the etiology and complications of the cirrhosis (ascites, encephalopathy, Child Pugh score and the MELD Na), and the latest blood test (creatinine, albumin, bilirubin, Na, INR).

The presence of depression was assessed using the PHQ9 score. The frailty status was determined by using the frailty scale risk assessment score. One point was assigned for each component of the score: fatigue, resistance, ambulation, illness and loss of weight.

The presence of minimal hepatic encephalopathy was assessed using the animal naming test (ANT). Patients having a score ≥ 3 were classified as frail. All data collected from the questionnaires were introduced in a table and analyzed using statistical package for social science (SPSS) software. A level of $\alpha = 0.05$ was used to denote statistical significance. In order to establish the correlation between different variables, the Pearson correlation coefficient was used.

Results: We identified 15 (26.7%) frail patients. Compared with non-frail patients, the frail patients were older (68 in frail versus 59 in not frail, $p=0.038$), had higher neck circumference (39.7 in frail versus 35 in not frail, $p=0.025$), higher serum creatinine level (114 in frail versus 69 in not frail, $p=0.015$), and lower blood levels of sodium (134.8 in frail versus 137.1 in not frail, $p=0.032$) and albumin (31.4 in frail versus 35.8 in not frail, $p=0.038$).

Moreover, frail patients had higher MELD Na score (17.9 in frail versus 13.9 in not frail, $p=0.022$), higher Child Pugh score (66.7% of frail patients Child B or C versus 35.7% of not frail, $p=0.038$), and higher prevalence of ascites (73.3% of frail patients versus 14% of not frail, $p=0.007$).

Frailty score was strongly correlated with the PHQ9 score using the Pearson correlation ($r=0.725$, $p<0.001$), and moderately correlated with the MELD Na score ($r=0.449$, $p=0.002$). Severe depression was noted in 80% of the frail patients, versus 19.4% of the non-frail patients ($p<0.001$). Therefore, the frailty was strongly associated with the depression with an odds ratio of 16.57 (confidence interval 3.67-75).

In multivariate analysis, frailty was independently associated with the PHQ9 score ($\text{Exp}(\beta)=1.408$, $p=0.003$, confidence interval 1.125-1.763), and with the ANT ($\text{Exp}(\beta)=0.74$, $p=0.040$, confidence interval 0.555-0.987).

Conclusion: To sum up, frailty and depression are common in cirrhotic patients. Frailty in cirrhosis is independently associated with the depression and the minimal hepatic encephalopathy.

Disclosure: Nothing to disclose.

Introduction: Physical frailty is highly prevalent in patients with end stage liver disease and has been associated with poor outcomes. Liver Frailty Index (LFI) is a standardized tool to assess frailty in patients with cirrhosis on liver transplant waiting list. However there is a paucity of data on the prognostic value of LFI in patients hospitalized for acute decompensation (AD) of cirrhosis.

Aims & Methods: We evaluated LFI in patients hospitalized for AD and the association of LFI with complications occurred during hospitalization and 90-day survival. We enrolled 117 consecutive patients admitted for AD of cirrhosis from 2019 to 2021. LFI was performed at the time of hospital admission. Occurrence of complications (hepatic encephalopathy [HE], sepsis, organ failures, ACLF) during hospitalization was recorded. Patients were followed up until death, liver transplant or 90 days.

Results: mean age and MELD-Na were 64 ± 10 and 20 ± 7 , respectively. The majority of patients were male (71%) and had alcohol-related cirrhosis (56%). Median LFI was 6.1 (IQR 5.0 – 6.5). LFI showed a weak, but significant, correlation with age ($r=0.202$; $p=0.029$), MELD-Na ($r=0.292$; $p=0.001$) and parameters of systemic inflammation such as C-Reactive Protein ($r=0.235$; $p=0.014$) and white blood cell (WBC) count ($r=0.207$; $p=0.025$). LFI was significantly higher in patients developing hepatic encephalopathy, sepsis, renal failure, circulatory failure, respiratory failure and ACLF than in those who did not. Patients transferred to the ICU had significantly higher LFI than those who did not.

LFI was significantly higher in patients who died than in those who survived during hospitalization (median=6.5 [IQR=6.0-6.7] vs 6.0 [IQR 4.8-6.5]; $p=0.006$) and at 90 days (6.45, IQR 6-6.64 vs 5.87, IQR 4.81-6.37; $p=0.001$). In multivariate analysis LFI was an independent risk factor of 90-day mortality (HR=1.88, 95% CI 1.07-3.32; $p=0.028$), as well as MELD-Na (HR=1.11, 95% CI 1.04-1.18; $p=0.01$) and WBC(HR=1.08, 95% CI 1.00-1.17, $p=0.046$).

Conclusion: In patients with cirrhosis hospitalized for AD, LFI identifies patients at higher risk of worse outcomes and can be used for the assessment of frailty in these patients.

Introduction: Serum electrolyte disturbances are common in cirrhosis. Hyponatremia has profound prognostic implications, and thus, has been incorporated in the 2016 update of the UNOS MELD. Changes in serum chloride (Cl) are thought to be interrelated, however, are less well studied in the context of cirrhosis.

Aims & Methods: We investigated the prognostic utility of Na- and Cl-changes on hepatic decompensation/liver-related mortality in patients with stable cirrhosis as well as on ICU mortality in critically ill patients with cirrhosis.

Therefore, 891 patients with stable cirrhosis managed at the Vienna General Hospital between 2003-2020 were included in *cohort I*. 181 critically ill patients with cirrhosis admitted to ICUs at the Vienna General Hospital between 2004-2007 were recruited for *cohort II*. Hypo-/hyper-Na (normal range: 136-145mmol/L) and hypo-/hyper-Cl (normal range: 98-107mmol/L) were assessed.

Results: *Cohort I:* 68% male patients with a median UNOS MELD of 11 (9-17) were included (Child-Pugh-stages A/B/C: 46%/38%/16%). Na and Cl levels were significantly interrelated (Pearson's $r=0.63$, $p<0.001$).

Hypo-/hyper-Na were present in 29%/0% and hypo-/hyper-Cl in 15%/9%. The median follow-up was 59.9 months during which 445 patients (50%) experienced hepatic decompensation/liver-related death. Cl showed a linear association with hepatic decompensation/liver-related mortality on multivariable Cox regression analysis adjusting for age, HVP, albumin, MELD (adjusted average hazard ratio [HR] per mmol/L: 0.972, 95% confidence interval, [95%CI]: 0.949-0.996, $p=0.022$). In line, hypo-Cl was significantly associated with hepatic decompensation/liver-related mortality (adjusted average HR: 1.553, 95%CI: 1.149-2.098, $p=0.004$).

Cohort II: 70% male patients had a median MELD of 31 (22-39) at ICU admission (92% with Child-Pugh-stage C). Again, Na and Cl levels were strongly correlated (Pearson's $r=0.82$, $p<0.001$).

Hypo-/hyper-Na was present in 47%/7% and hypo-/hyper-Cl in 30%/25%. ICU-mortality was 50% after a median of 6 (5-7) days. While the effect of Na on ICU mortality was U-shaped in restricted cubic spline analyses, it seemed to be rather linear for Cl with a worse prognosis in patients with hypo-Cl.

In univariable logistic regression analyses, patients with hypo-Cl (odds ratio [OR]: 3.039, 95%CI: 1.569-6.075, $p=0.001$), but not hypo-Na had a significantly worse ICU survival, which was confirmed after adjusting for hypo-/hyper-Na and MELD (aOR CI: 1.267-7.659, $p=0.014$).

Conclusion: Even though Na and Cl levels are strongly interrelated in cirrhosis, the presence and severity of hypochloremia provides incremental prognostic information – especially in critically ill patients with cirrhosis.

Introduction: Early diagnosis of spontaneous bacterial peritonitis (SBP) especially in asymptomatic patients is based on a high index of suspicion and associated with a better outcome. Although the gold standard for diagnosis is based on polymorphonuclear leukocyte count $\geq 250/\text{mm}^3$ in ascitic fluid with or without positive ascitic culture, we still need rapid and reliable inflammatory markers for diagnosis of SBP.

Aims & Methods: The aim of the study was to evaluate serum c-reactive protein (CRP), ascitic procalcitonin (PCT) and monocyte chemotactic protein-1(MCP-1) in the diagnosis of spontaneous bacterial peritonitis (SBP) in cirrhotic patients. A cross-sectional analytic study that included 199 patients with decompensated cirrhosis (101 with SBP and 98 without SBP). Patients were classified according to Child-Pugh criteria. Ascitic PCT and MCP-1 were measured by enzyme-linked immunosorbent assay. Serum CRP, liver and renal functions were assessed.

Results: The three markers are significantly elevated in SBP patients than those without ascites. Using the ROC curve at AUC 0.883 and a cut-off value of $>186 \text{ ng/ml}$, the diagnostic performance of ascitic MCP-1 level was higher than CRP (AUC 0.562) and ascitic fluid procalcitonin (AUC 0.751) in the diagnosis of SBP. The sensitivity and specificity were 86.15% and 79.59 % at the cutoff of 186 ng/ml for MCP-1, 65.4 and 75.5 at $\geq 1 \text{ ng/ml}$ for PCT, and 52.5 and 64.3, at 11.2 mg/dl for CRP respectively.

Conclusion: Ascitic MCP-1 has a better diagnostic value with higher sensitivity and specificity in SBP diagnosis compared to CRP and procalcitonin which has higher diagnostic accuracy than CRP.

Further studies with a large number will be necessary to evaluate the usefulness of these markers in diagnosis, follow-up and relation to morbidity and mortality of SBP patients.

CLINICAL OUTCOMES OF CRYPTOGENIC COMPARED WITH VIRAL CIRRHOSIS

Z. Benzarti¹, B. Bouchabou¹, M. Kefi¹, S. Chtioui¹, A. Nakhli¹, N. Hemdani¹, R. Ennaifer¹

Introduction: Cryptogenic cirrhosis (CC) is the end stage of a chronic liver disease in which its underlying etiology remains unknown after extensive clinical, serological, and pathological evaluations. Since identification of non alcoholic steato-hepatitis (NASH), many CC have been reclassified to post-NASH cirrhosis.

Models of the natural history of cirrhosis are based on findings in individuals with viral or alcoholic cirrhosis and the outcome of CC is far less characterized than cirrhosis with a definite etiology.

Aims & Methods: To characterize natural history of cryptogenic cirrhosis (CC) and compare its clinical features and outcomes to those of viral related cirrhosis.

Between 2019 and 2020, we identified all patients with a diagnosis of cryptogenic or viral cirrhosis. The criteria for the exclusion of diagnosis of CC were: cases with histological clear-cut features of fatty changes and cirrhosis with definite etiology such as: excessive alcohol consumption, HCV antibody positivity, hepatitis B surface antigen positivity, autoimmune hepatitis, primary biliary cirrhosis, primary sclerosing cholangitis or genetic liver diseases.

The following outcomes were assessed: severity of liver disease at the time of first diagnosis; liver decompensation (*i.e.*, at least 1 episode of ascites, encephalopathy, or variceal bleeding either at presentation or during follow-up); HCC diagnosed according to current guidelines and death. Cardiovascular events, particularly the presence of coronary artery disease, were recorded. SPSS version 26.0 was used for the descriptive and comparative analysis.

Results: A total of 77 patients with cirrhosis were enrolled (cryptogenic $n = 35$; viral $n = 42$). Compared with viral cirrhosis, patients with CC were older (mean age 63 vs 59 years, $p = 0,04$) and had a significantly higher prevalence of overweight/obesity, hypertension, dyslipidemia and gallstone disease ($p = 0,04$; $p = 0,028$; $p = 0,004$ and $p = 0,01$ respectively). Over a median period of 19 months of follow up, hepatocellular carcinoma development was more observed in viral cirrhosis group (74 % vs 29% in CC patients, $p < 0,001$).

On the other hand, there was no significant difference in terms of liver decompensation ($p = 0,96$). Patients with CC exhibited a significantly higher prevalence of cardiovascular events ($p = 0,02$). Kaplan Meier survival analysis showed no significant differences in survival between both types of cirrhosis for all grades of severity.

Conclusion: Comparatively to viral cirrhosis, patients with CC have more frequently features of metabolic syndrome and a higher risk of developing cardiovascular events and thus a poor prognosis owing to non liver-related morbidity. Our study confirms that CC likely results from the progression of unrecognised NASH in a large proportion of cases.

P0732

MALNUTRITION IN PATIENTS WITH CHRONIC LIVER DISEASE UNDERGOING INPATIENT LIVER TRANSPLANT EVALUATION

K. Cooper¹, D. Devuni²

¹University of Massachusetts Medical School, Worcester, United States, ²University of Massachusetts Medical School, Gastroenterology and Hepatology, Worcester, United States

Contact E-Mail Address: katherine.cooper@umassmed.edu

Introduction: Malnutrition is a known complication of cirrhosis and a predictor of post-operative mortality in liver transplantation. We aimed to identify predictors of malnutrition in patients with chronic liver disease (CLD) undergoing inpatient liver transplant evaluation (LTE) and assess the effect of malnutrition on outcomes in the liver transplantation evaluation outcomes.

Aims & Methods: Medical records for all patients undergoing ILTE between 10/15/2017 and 8/3/2021 were reviewed. Those patients with CLD undergoing inpatient LTE for first transplant were included in the study; patients with a history of liver transplant or in fulminant liver failure were excluded. Demographics, past medical history, and transplant evaluation details were collected using RedCAP. Patients were categorized by nutritional status as determined by the transplant nutritionist at the time inpatient LTE (Malnutrition vs. No Malnutrition). Issues with skin integrity included pressure ulcers and moisture associated skin damage. Outcomes included: 1) Overall outcome [Dead, Transplanted and 32) Listing outcome [listed at some point vs. never listed]. Variables were compared using Fisher's exact test and student's T-tests. Predictors for malnutrition were assessed using multivariable linear regression. Significance was evaluated at $p=0.05$ given low participant number in the malnourished group.

Results: One hundred and fifty-nine patients, mean age 57.7 were included and one in three were diagnosed with malnutrition (33.9%). There were no differences in age, gender, disease etiology, or MELD-Na between groups. Patients without malnutrition tended to have ACLF grade higher than Grade 2 more often (42.9% vs. 29.6%, $p=0.10$) and had higher BMI (33.2±9.9 vs. 27.6±7.1, $p<0.001$). Overall outcome did not differ by malnutrition status, but patients with malnutrition tended to be listed for liver transplant less often than those without malnutrition (86.4% vs. 95.3%). Patients with malnourishment were more likely to have issues skin integrity (33.1% vs. 17.1%, $p=0.02$) and a recent significant weight loss (51.9% vs. 17.1%, $p<0.0001$). In a model including age, gender, disease etiology, BMI, history of low albumin and previous hepatic decompensations, the following were predictors of being diagnosed with malnutrition during inpatient LTE: BMI ($p=0.05$), a prior episode of spontaneous bacterial peritonitis ($p=0.03$), and having known varices by imaging or EGD ($p=.03$)

		Malnutrition (n=54)	No Malnutrition (n=105)
Outcomes	Dead	24.1%	34.3%
	Transplant	44.4%	35.2%
	Listed at any point	86.4%	95.3
Demographics	Gender (%Male)	63%	55.20%
	BMI	27.6	33.2
	MELD-Na (Points)	28.22	26.57
	ACLF Grade ≥ 2	70.4%	57.1%
	Alcohol associated liver disease	57.4 %	43.8 %

Table.

Conclusion: Malnutrition may impact likelihood to be listed for transplant in patients with CLD who require inpatient LT evaluation. However, once approved, malnutrition may not negatively impact transplant rate in this

population. Of the hepatic decompensations, patients with a history of spontaneous bacterial peritonitis may be at increased risk for malnutrition, which may reflect the impact that malnutrition has on immune regulation.

Disclosure: Nothing to disclose.

Contact E-Mail Address: zallatzallat@gmail.com

Introduction: Hepatitis C virus (HCV) infection is a significant cause of morbidity and mortality worldwide. HCV infection inflames the liver which, if untreated, will inevitably result in fibrosis and then progress to cirrhosis which has many co-morbid complications such as hepatocellular carcinoma (HCC). Cancer stem cells (CSCs) are a small subpopulation in cancer, have been proposed to be cancer-initiating cells, and be responsible for chemotherapy resistance and cancer recurrence.

The identification of CSC subpopulations inside a tumor presents a new understanding of cancer development because it implies that tumors can only be eradicated by targeting CSCs.

Aims & Methods: This study was conducted to assess the use of miRNA 203 in circulating liver CSCs as non-invasive predictive and early diagnostic markers in genotype 4 HCV-induced HCC. 150 patients with chronic hepatitis C (CHC) were participated in this study and divided into 3 groups: 1) HCV group: 50 patients infected with HCV without cirrhosis, 2) Liver cirrhosis group: 50 patients infected with HCV with liver cirrhosis, 3) HCC group 50 patients infected with HCV and cirrhosis. 50 normal controls were also included in the current study.

Peripheral blood mononuclear cells were separated by the gradient density separation method and assessed for the presence of EpCAM/CD44 as markers for CSCs. Total RNA was extracted from these cells and miRNA 203 was relatively quantified by real-time PCR. The receiver operating characteristics curve (ROC) and confidence interval (CI) of miRNA 203 were established to discriminate HCV-induced HCC from CHC.

Results: Our results showed that the relative expression of miRNA 203 was significantly decreased ($p<0.001$) in the HCC group when compared to the liver cirrhosis group and the HCV group. miRNA 203 had a sensitivity of 100%, specificity of 97.5%, and AUC of 0.987 (95% CI: 0.88 – 1.0), suggesting that measuring miRNA 203 level could be a promising non-invasive predictive early diagnostic marker for HCC development in patients with CHC.

Conclusion: miRNA 203 could be used as a predictive marker for HCC in Egyptian people with CHC.

HIGH SERO-PREVALENCE OF HEPATITIS E VIRUS AMONG HEALTHY ASYMPTOMATIC BLOOD DONORS IN PAKISTAN: CAN THE RISK OF TRANSFUSION DEPENDENT TRANSMISSION BE IGNORED?

A. Rahat¹, L. Kamani¹

¹Liaquat National Hospital, Gastroenterology and Hepatology Department, Karachi, Pakistan

Contact E-Mail Address: adeelrahat@gmail.com

Introduction: Hepatitis E Virus (HEV) is now recognized as a major public health issue, causing over 20 million infections every year worldwide and accounting for approximately 70,000 deaths^[1].

HEV-RNA prevalence in blood donors was reported at one per 600 to 800 donations in Germany and The Netherlands^[2,3]; and seroprevalence, documenting prior exposure, as high as 52 percent in Southwestern France^[4,5]. It has been estimated that the mortality rates for HEV infections in pregnant women and young people are about 20% and 3%, respectively^[6]. Transfusion of blood products (cellular and plasma) is a frequent, potentially life-saving medical treatment. The safety of blood products has been a concern. Subsequently, testing for HIV, HBV and HCV has been implemented in Pakistan.

There is emerging evidence that HEV can be transmitted by transfusion of different types of blood-derived products. Immunosuppressed individuals, organ transplant recipients, hemodialysis patients, and pregnant women are at a high risk of developing life-threatening diseases, including chronic hepatitis and acute liver failure, after infection with HEV^[7,8].

Chronic hepatitis E can progress to chronicity, resulting in liver failure with life-threatening complications. Till the availability of vaccine, HEV-RNA testing is the only effective mitigation to prevent transfusion-transmission. Immunosuppressed individuals and pregnant women are at higher risk of developing acute liver failure and chronic hepatitis secondary to HEV. HEV is endemic in Pakistan and routine screening of blood donors for HEV has not yet been implemented in Pakistan and other endemic South Asian countries. There is dearth of literature regarding the sero-prevalence and viremia of HEV among healthy blood donors.

Aims & Methods: A cross-sectional study was conducted at Liaquat National Hospital, Karachi, Pakistan to assess sero-prevalence and viremia of HEV among healthy blood donors in a tertiary care set-up. Blood samples were obtained for HBsAg, Anti-HCV Antibody, Anti-HIV Antibody, Syphilis, Malaria, ALT and HEV antibodies (IgG and IgM by ELISA kits (Novalisa by Novatec immundiagnostica GmbH)) after written informed consent. Positive samples for anti-HEV IgM were subjected to detect HEV-RNA by real-time reverse transcription polymerase chain reaction assay (RealStar® HEVRT-PCR Kit 2.0 by Altona Diagnostics).

Results: Total of 515 adult participants were enrolled with a mean age of 30.08 ± 7.56 years. Mean ALT levels of 43.05 ± 32.45 IU/L were observed. Anti HEV IgG was positive in 365 participants (70.9%) with ALT levels of 43.61±34.03. 31 participants (6%) were positive for Anti HEV IgM with ALT levels of 44.06±69.21. All IgM positive were subjected to PCR testing which came out negative (PCR detection limit >18 copies/mL). Patients who tested positive for HBsAg, Anti-HCV Ab, Syphilis and HIV were 11 (2.1%), 9 (1.7%), 9 (1.7%) and 0 (0%) respectively.

Serology	Results (Total number of participants : 515)
Anti HEV IgM	31 (6%)
Anti HEV IgG	365 (70.9%)
HBsAg	11 (2.1%)
Anti-HCV Ab	9 (1.7%)
Syphilis	9 (1.7%)
Anti HIV Ab	0 (0%)

Conclusion: High sero-prevalence of Anti HEV IgM among healthy blood donors emphasizes the need for further studies and robust measures of routine screening for HEV of all blood products in endemic countries to prevent transfusion dependent transmission with special consideration when the recipients are either immunocompromised or pregnant.

Introduction: Oral Direct-acting antivirals (DAAs) are safe, highly effective altering disease burden and prognosis in hepatitis C patients. Sustained virologic response (SVR) is achieved nowadays in more than 90% of the treated patients and related to the improvements in functions of the liver, fibrosis plus survival. Furthermore, portal hypertension is thought to be improved with achievement of virological response, parallel to the improvements in hepatic inflammation and fibrosis.

Aims & Methods: We aimed to assess the recurrence rate of oesophageal varices by long-term follow-up in patients treated with different DAAs regimens who had achieved SVR. We studied 176 Child A cirrhotic HCV pa-

tients who achieved SVR after DAAs treatment and had a history of endoscopic oesophageal varices obliteration and were on maximum tolerated propranolol dose. They were subjected to follow-up upper gastrointestinal endoscopy repeated every 6 months for 4 years.

Results: Fifty-two patients (29.5%) had recurrence of oesophageal varices observed during the 4-years follow-up upper GIT endoscopy. On multivariate analysis, platelet count was the only significant variable, P-value = .007*. HbA1C, HOMA IR, BMI 1 and BMI 2 showed non-significant differences between the studied groups.

By ROC analysis, we identified baseline platelet count of 96 000/ μ L with 100% sensitivity (95% confidence interval [CI] [91%-100%]) and 74% specificity (95% CI [65%-81%]). Spearman correlation showed a positive correlation between AFP, age, AST, Bilirubin, creatinine, INR.

Exp (B)	P-Value	Df	Wald	S.E.	B	
1.918	0.336	1	0.924	0.678	0.651	Sex
1.000	0.007*	1	4.275	0.000	0.000	Platelet count

AST: aspartate aminotransferase TLC: Total leucocytic count
INR: International normalized ratio

Table 1. Multivariate regression analysis for predicting recurrence of esophageal varices.

Conclusion: Patients who achieved SVR post DAAs showed a significant decrease in oesophageal varices recurrence post endoscopic obliteration. Baseline platelet count was found to be a strong independent predictor for oesophageal varices recurrence.

CLINICAL SPECTRUM AND OUTCOMES OF PATIENTS WITH SEVERE SPONTANEOUS HEPATITIS B FLARES AND REACTIVATION

A. Jindal¹

¹Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India

Contact E-Mail Address: ankur.jindal3@gmail.com

Introduction: Reactivation of hepatitis B presenting as acute hepatic flare can have variable outcomes; acute hepatic insult (serum bilirubin > 5 mg/dl and INR >1.5) alone (*pre-ACLF*) or with the development of new ascites or hepatic encephalopathy (HE) within 4 weeks (*ACLF-B*), which connotes high mortality. The clinical outcome of hepatitis B flare in decompensated cirrhosis is largely unknown.

Aims & Methods: Patients with pre-ACLF, ACLF-B and hepatitis B flares in decompensated cirrhotics (DC flare) were compared for clinical, biochemical, serological and virological parameters. Patients with hepatitis B related acute liver failures were excluded. All patients received potent antivirals and standard medical therapy; none underwent liver transplantation.

Results: 827 consecutive patients (Mean age – 47.1 + 16 years; Male: Female – 4:1) with acute hepatic insult presented with pre-ACLF, ACLF-B and DC flare – 23.9%, 53.3% and 22.7% respectively.

Almost 15% patients with ACLF-B had superimposed hepatic insults [alcoholic hepatitis (n=23), drug-induced liver injury (n=31) and hepatitis E superinfection (n=14)]. Baseline mean HBV DNA (Log 5.4 IU/ml), HbsAg (Log 3.6 IU/ml) levels and positive HBeAg rates (49.5%) were comparable among the groups and did not independently predict mortality.

Patients with pre-ACLF compared to ACLF-B had higher baseline ALT (median - 850 IU/L vs. 140 IU/L; p<0.01) with higher rates of HBeAg (34.6% vs. 7.7%; p<0.01) and HbsAg seroconversion (11.6% vs. 1.1%, p<0.05) at 6 month. In comparison to DC flare, ACLF-B had higher baseline HVP (19.4 + 2.6 vs. 15.2 + 2.4 mm Hg; p<0.007) and liver related complications including HE (42.4% vs. 18.1%, p<0.01), acute kidney injury (32.9% vs. 18.6%, p<0.01) and sepsis (51.2% vs. 22.9%, p<0.01).

Mortality at 3-month was highest in ACLF-B group (45.1%) than in DC flare (18.6%) and pre-ACLF (1%), p<0.05. Presence of sepsis (HR-6.4) and HE (HR-2.7) were independent predictors of mortality.

Conclusion: More than one-half of symptomatic hepatitis B flares have ACLF. Hepatitis B DNA or HBeAg at baseline or follow-up did not predict clinical outcomes. Hepatitis B flares in decompensated cirrhosis are different from ACLF-B. Presence of ACLF-B warrants careful monitoring and need for early liver transplantation. New-onset HE and sepsis were independently associated with high mortality.

Disclosure: Nothing to disclose.

P0737

CLINICAL COURSE AND PREDICTORS OF OUTCOME OF SEVERE HEPATITIS B REACTIVATION PRESENTING WITH NEW-ONSET ASCITES

A. Jindal¹

¹Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India

Contact E-Mail Address: ankur.jindal3@gmail.com

Introduction: Reactivation of hepatitis B (HBVr) presenting as acute icteric flare can have variable presentations. New-onset ascites in patients with HBVr might predispose to bacterial infections, hepatic encephalopathy (HE) and acute kidney injury (AKI). Predictors and outcomes of HBVr with ascites are largely unknown.

Aims & Methods: Icteric HBVr patients, with or without new-onset ascites were enrolled. HBVr was diagnosed based on AASLD 2018 recommendations. All patients received potent antivirals, and were followed for further complications and outcomes.

Results: Of 347 patients (mean age- 49.2±14.7 years; M: F- 4:1; mean HBV-DNA- 4.2 Log₁₀ IU/ml, 48.5% HBeAg +), 242 (69.7%) had ascites at presentation. Despite comparable baseline HBV DNA and quantitative HBsAg levels, patients with new onset ascites compared to no ascites were older and had more frequent large esophageal varices (13.3% vs. 2%; p-0.001), higher baseline HVPg (15.3 ± 5.9 mmHg vs. 9.9 ± 4.7 mmHg; p-0.001) and MELD score (27.5 ± 6.9 vs. 22.3 ± 5.2; p-0.02).

None of the patients without ascites had cirrhosis on biopsy. HVPg ≥12 mmHg alone was independently associated with ascites (area under ROC: 0.78; 95% CI: 0.66-0.89). Each 1 mmHg change in HVPg increased the probability for ascites by 30% (p-0.002; 95% CI: 1.09-1.52).

Patients with HBVr and ascites had more complications during hospital course (Hepatic encephalopathy- 37.6% vs. 6.7%, pneumonia- 11.2% vs. 1.9%, acute kidney injury- 38.4% vs.12.4% and variceal bleed- 8.7% vs. 1%; all p<0.01) as well as higher mortality (40.1% vs. 8.6%; p-0.001). Presence of HE (OR: 4.7, p-0.001), pneumonia (OR: 10.3, P-0.003), MELD ≥26.5 (OR: 1.12, p-0.01) and total leucocyte count ≥9.9x10³ per cu.mm (OR: 1.09, p-0.04) were independent predictors of mortality.

Among those who survived, 26 (7.5%) patients lost HBsAg by 12 months. Despite higher ALT flare in patients without ascites (762 U/L (227-1554) vs. 138 U/L (74-295); p<0.01), loss of HBV DNA at the end of 4 week was unrelated to presence of ascites (70.1% vs. 63.3%; p-0.2) and outcomes.

Conclusion: Acute rise in portal pressure following hepatocellular necrosis is associated with development of ascites in patients with severe reactivation of hepatitis B. Early recognition of these "high risk" patients who have underlying chronic liver disease or cirrhosis (acute-on-chronic liver failure) is important to prevent organ failure, development of complications and list them for liver transplantation.

Disclosure: Nothing to disclose.

Introduction: Hepatitis C virus (HCV) is a common viral infection affecting over 180 million persons all over the world. DAAs (Direct acting antivirals) may improve thrombocytopenia after achieving sustained virologic re-

sponse (SVR), but some patients may be manifested with thrombocytopenia after SVR. The aim of our study was to evaluate the presence of OCI in the peripheral blood mononuclear cells (PBMCs) in thrombocytopenic patients after achieving SVR with DAAs.

Aims & Methods: This cross-sectional study included 32 thrombocytopenic patients who achieved SVR with DAAs and 32 HCV-infected patients who achieved SVR with DAAs without thrombocytopenia as a control group. All patients were investigated for HCV-ribonucleic acid (RNA) in PBMCs (peripheral blood mononuclear cells), hepatitis C virus core antigen (HCV cAg), platelet autoantibodies, and serum thrombopoietin.

Results: Among thrombocytopenic, non-thrombocytopenic, and both groups, HCV-RNA in PBMCs were detected in 40.63, 6.25, and 23.44%, respectively, although HCVcAg was detected in 31.25, 3.13, and 17.19%, respectively. The comparisons between thrombocytopenic and nonthrombocytopenic patients regarding HCV-RNA in PBMCs and HCVcAg were statistically significant.

Conclusion: Our study is the first to provide insights into the relationship between occult hepatitis C and thrombocytopenia in patients with chronic hepatitis C virus infection after achieving sustained virologic response with direct-acting antivirals. The association between occult hepatitis C and thrombocytopenia may be explained by auto-immune mechanism due to the development of platelet auto-antibodies.

A complete eradication of HCV after SVR seems to be doubtful in spite of significantly improvement in DAAs efficacy due to occult C occurrence in other body compartments. Consequently, we recommend testing for occult C infection by HCV-RNA in PBMCs and/or HCVcAg in addition to serum HCV-RNA testing at the end of DAAs therapy before confirmation of SVR.

Disclosure: Nothing to disclose.

Introduction: The elimination of hepatitis C virus (HCV) was declared a global public health goal by the world health organization (WHO). Here, we present an interim analysis of an Austrian macro-elimination project, aiming to link patients with a positive HCV PCR result at the last available HCV test to care and provide antiviral treatment.

Aims & Methods: Patients who were last tested positive via HCV-RNA PCR between 2010 and 2020 at one of the 8 participating HCV treatment centers in Eastern Austria (Burgenland, Lower Austria and Vienna) were identified. We describe the demographics and report the preliminary results of the systematic recall, direct-acting antiviral (DAA) treatment-uptake, as well as the sustained virological response (SVR) rates of these persons.

Results: Among 22682 persons tested during the study period, 11216 were HCV-RNA PCR positive at any time, while 6223 tested positive at the last available test (i.e. indicating potential persisting HCV viremia). At the time of abstract submission, 2252/6223 (36.2%) persons have been evaluated: Finally, 215 (9.6%) could be linked to hepatological care, active viremia

was confirmed in 82 (38.1%), and 56 (26.0%) initiated DAA treatment, of which 38 (67.9%) already achieved SVR. The major obstacles in linking patients to care through this project were the lack of valid contact data in n=687 (30.5%) or pre-treatment death in n=429 (19.0%), while n=497 (22.1%) had already reached SVR before contact through this project.

Conclusion: 6223 persons with potential persisting HCV viremia could be identified through the ELIMINATE project so far. Among the 2252 persons evaluated, lack of valid contact data (30.5%) and pre-treatment mortality (19.0%) were the most common obstacles in linkage to care through the ELIMINATE project. Nevertheless, 215 persons were already linked to hepatological care and 56 started DAA therapy.

Disclosure: This project is financially supported by Gilead.

Introduction: Direct-acting antivirals (DAAs) have improved the treatment of chronic hepatitis C allowing high rates of sustained virological response (SVR) and better outcomes. However, data concerning the risk of de novo intrahepatic (IHT) and extrahepatic tumors (EHT) following DAAs remains controversial (1-3).

Aims & Methods: We aimed at assessing whether the exposure to DAAs as compared to IFN-based therapy, taking into account SVR, is associated with the occurrence and recurrence of intrahepatic- (IHT), and extrahepatic tumors (EHT) in Switzerland. We performed a retrospective analysis of patients prospectively included in the Swiss Hepatitis C cohort, from September 2000 to September 2018 in 7 centers in Switzerland.

We collected data on age, sex, presence of cirrhosis, HCV genotype, type, number and date of antiviral therapies, SVR, presence of concomitant HBV and HIV infections, liver stiffness, body mass index, alcohol consumption, presence of diabetes type 2, previous history of IHT and EHT, occurrence and recurrence of IHT and EHT, death. IHT/EHT occurrence, recurrence and death were evaluated by Kaplan-Meier curves.

A semiparametric competing risk proportional hazards regression model was performed to evaluate the risk of IHT/EHT according to the exposure to DAAs, IFN or no exposure.

Results: 4082 patients (male 62.2%, median age 45 IQR [37-53] years; 48.5% genotype 1; 16.4% with cirrhosis) were included. 997 patients were treated exclusively with IFN-based regimens and 1085 only with DAAs, and 80 treated *ab initio* with both IFN-based therapy and DAAs were excluded. 1660 patients remained untreated until the last follow-up.

SVR was obtained in 652 (65.4%) of patients treated with IFN and in 933 patients (86%) with DAAs. In a median follow-up of 7.8 years (3.8-11.9), IHT developed in 179 (4.4%) patients, while EHT in 168 (4.1%). At the end of follow-up, 613 patients (15.3%) had died.

Of these 85 had a diagnosis of IHT (13.9%) and 74 (12%) of EHT. The 5-year cumulative incidence of IHT was 1.55% (95% CI 0.96-2.48) for IFN-based regimens, 4.27% (95% CI 2.93-6.2) for DAA and 0.89% (95% CI 0.4-1.99) for untreated patients. In patients with cirrhosis the 5-year cumulative incidence was higher, 4.95% (95% CI 2.78-8.81), 12.45% (95% CI 8.08-19.18) and 4.54% (95% CI 1.39-14.82), respectively.

We found no significant difference in risk of IHC (HR = 1.34; 95% CI = [0.70; 2.58]; $p = 0.380$) and death (HR = 0.66; 95% CI = [0.43; 1.03]; $p = 0.066$) between patients treated with DAAs and those treated with IFN.

After adjusting for covariates, the hazard for developing IHT was higher in patients treated with DAAs as their first line of treatment compared to patients who remained untreated (HR = 2.01; 95% CI = [1.10; 3.67], $p = 0.023$). However, the hazard for death was lower in patients treated with DAAs vs. those who remained untreated (HR = 0.49; 95% CI = [0.33; 0.72], $p < 0.001$).

Conclusion: Antiviral therapy with DAAs was not associated with an increased risk of EHT, and the risk of IHT in patients exposed to DAAs is comparable to that observed in patients exposed to IFN-based therapy.

We observed an increased risk of IHT in subjects treated with DAAs as compared to untreated patients with chronic hepatitis C; further studies should clarify this aspect. In agreement with previous data, DAAs were associated with a lower risk of death in the population of the study.

HEPATITIS B VIRUS SCREENING AND PROPHYLAXIS THERAPY IN PATIENTS WITH SOLID TUMORS TREATED WITH ANTICANCER THERAPIES

Introduction: Hepatitis B virus (HBV) reactivation is defined as a rise in viral replication diagnosed by laboratory tests, sometimes resulting in hepatocellular injury. Reactivation can occur in any patient with anti-hepatitis B core (Hbc) antibodies, regardless of HBsAg status. Immunosuppression may lead to viral reactivation, and the risk is dependent on the viral status and type of immunosuppression agent used, with the highest risk documented in patients treated with anti-CD20 regimens and in hematopoietic stem-cell or solid organ transplant recipients. HBV reactivation may also occur in patients with solid tumors treated with chemotherapy. Recently the American Society for clinical Oncology (ASCO) followed suite with EASL and AASLD and suggested universal screening for all patients receiving anti-cancer therapies.

Aims & Methods: Our study aim was to find the rates of HBV reactivation in patients treated systemically for solid organ tumors.

Methods: We conducted a retrospective single-center study of 404 patients with solid tumors treated with chemotherapy and screened for HBV infection in the Tel Aviv Sourasky Medical Center between January 2014 and April 2021. Demographics, clinical and laboratory data were extracted from medical records.

Adult patients diagnosed with solid tumors and treated with chemotherapy with positive serology of anti-Hbc antibodies were included. We examined patient's reactivation of HBV, defined as seroconversion of HBsAg or increase in HBV PCR after chemotherapy treatment.

Results: Out of 404 patients diagnosed with solid tumors screened for anti-Hbc antibodies, 66 patients had positive serology and were included. Thirty-eight were males (57.6%), median age at cancer diagnosis was 66 years (range 48-88), 23 were of Russian origin (34.8%), 37 patients were smokers (56.1%), and three (4.5%) had history of alcohol consumption. The most common tumors were breast, lung and colon cancer (15 (22.7%), 11(16.6%), 10(15.1%), respectively) and 50 patients had metastatic disease (75.8%).

Seven patients had a positive HbsAg (10.6%) and most of them were treated with nucleoside analogues, none of the patients had co-infection with HDV. Among patients with negative HbsAg (59), only 5 received prophylaxis therapy.

Only one patient was diagnosed with reactivation of HBV infection (1.5%). This patient was diagnosed as chronic HBV carrier (HBsAg+/anti Hbc+ and undetected HBV PCR) before she was treated with chemotherapy (Adriamycin and Taxol). The patient did not receive prophylactic anti-viral therapy and two years after initiation of chemotherapy she had elevated liver enzymes and a positive HBV-PCR. Entecavir was started and the patient recovered without further liver related complications.

Conclusion: The rate of HBV reactivation followed chemotherapy for solid tumor is low. Nevertheless, since reactivation can be fatal it is not negligible. Further prospective controlled studies are needed to help guide the appropriate screening regimen in high-risk populations.

Disclosure: There is no conflict of interest.

PREVALENCE OF INFECTIVE AND NON-INFECTIVE HEPATITIS AND JAUNDICE IN A TERTIARY FEVER HOSPITAL: ALEXANDRIA GOVERNORATE, EGYPT

A. Aboelfetouh¹, M.A. Amin²

¹A FH Alexandria, Liver and GIT, Alexandria, Egypt, ²University of Cairo, Dept. of Internal Medicine, Cairo, Egypt

Contact E-Mail Address: amrohosny65@gmail.com

Introduction: In a developing country like Egypt, the importance of estimating the prevalence of each illness is pivotal to minimize occurrence of complications, time waste and costs of investigations and treatment. Patients with biochemical liver impairment are commonly admitted to Alexandria Fever Hospital (AFH) with a multitude of causes that might be difficult to distinguish. Every year, about one thousand patients with jaundice and hepatitis are admitted to AFH. About 15-20% (150-200 patients / year) of those patients have negative viral markers for hepatotropic viruses A, B and C, namely HAV-IgM, HBs-Ag and HCV-Ab.

Aims & Methods: The present study aims at assessing the diversity of infective and non-infective causes responsible for hepatitis with or without jaundice in AFH.

Study design, period and setting:

A hospital-based cross sectional study was conducted at AFH, a tertiary hospital in Alexandria governorate, Egypt. The Liver Investigations unit (LIU) was responsible for setting the protocol of investigations and management. The study took place over a period of 12 months from January to December 2016.

Study sample:

Admitted to AFH, a total of 111 patients of acute hepatitis and chronic liver disease with negative markers for hepatitis A, B and C.

Criteria of acute patients:

1. High serum Bilirubin.
2. ALT & AST > 3folds.
3. Negative viral markers (A, B, C).
4. No signs of biliary obstruction in abdominal U/S

Acute patient investigations protocol:

1. HEV-IgM
2. HBc-IgM (Ab)
3. Leptospira-IgM
4. Non-hepatotropic viral markers: CMV-IgM, EB-IgM, Herpes S. -IgM
5. Autoimmune markers: ANA, ASMA, Anti-Actin, LKM-AB, AMA, Ig-G, Ig-M, ANCA

If all found to be negative the following investigations were proceeded:

6. PCR for HCV (Acute HCV)
7. If +ve HBc-IgM → PCR for HBV

If these two were negative the following investigations were proceeded:

8. Metabolic markers: S.Iron, Ferritin, transferrin saturation, ceruloplasmin, urine copper, a1-antitrypsin.

Criteria of chronic patients:

Undiagnosed jaundice, chronic liver disease, or liver cirrhosis with negative markers for hepatitis A, B or C.

chronic patient investigations protocol:

1. Autoimmune markers
2. Metabolic markers
3. HBc-IgM (Ab) – (Occult HBV) → PCR for HBV

If all found to be negative the following investigations were proceeded:

4. Liver biopsy
5. Other investigations: CT, Triphasic CT, MRI, MRCP.

Results: Acute HCV was 3 patients (pts), acute HDV on chronic HBV 1 pt, alcoholic steato-hepatitis 1 pt, autoimmune hepatitis 29 pts, bacterial (septicemia, liver abscess) 2 pts, Bilharziasis 4 pts, cardiac cirrhosis 2 pts, CMV acute hepatitis 1 pt, Cryptogenic 16 pts, EBV acute hepatitis 2 pts, Gilbert Disease 3 pts, Hemochromatosis 6 pts, ischemic 1 pt, Leptospirosis 7 pts, NASH 13 pts, occult HBV 2 pts, pregnancy induced cholestasis 2 pts, primary biliary cirrhosis 1 pt, primary sclerosing cholangitis 1 pt, toxic hepatitis (Drug induced) 11 pts, Wilson disease 3 pts.

The most common causes were autoimmune hepatitis (25.2%) followed by cryptogenic (14.4%).

Most patients with toxic hepatitis (Drug induced) (81.8%), autoimmune hepatitis (72.4%), acute HCV (66.7%) were females while most cases with leptospirosis (85.7%), hemochromatosis (83.3%), Bilharziasis (75%) were males.

Conclusion: In acute hepatitis patients, autoimmune hepatitis was the most common cause followed by toxic hepatitis. In chronic hepatitis patients, nonalcoholic steatohepatitis (NASH) was the most common cause followed by metabolic causes.

Introduction: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease. In PBC patients, hyperlipidemia is common and it is due to an altered cholesterol metabolism as consequence of cholestasis. The hypercholesterolemia itself is not associated to an increased cardiovascular risk, but, if associated to other metabolic conditions, the risk is increased.

Aims & Methods: The aim of this study was to evaluate eating habits and physical activity in PBC patients and compare them to a control group. This is a prospective and multicenter study evaluating lifestyle in PBC patients. A group of 54 healthy subjects without liver disease, matched by age and sex, served as controls. Eating habits were evaluated with a food frequency questionnaire (FFQ) consisting of 100 different food items most consumed by Italian population. The adherence to Mediterranean diet was evaluated with the aMED (alternate Mediterranean diet) score. Physical activity was assessed with a short pre-validated questionnaire.

Results: Overall, 107 PBC patients were enrolled (92.5% female, median age 61 years). Sixty-one (57%) patients had metabolic comorbidities (58.8% with overweight/obesity, 54% with arterial hypertension, 37.8% with dyslipidemia and 8.2% with diabetes mellitus). The total fat and cholesterol intakes were higher in controls than in PBC (respectively $p=0.004$ and $p=0.015$), but above the national recommendation in both groups. Moreover, in PBC patients monounsaturated fat (MUFA) and polyunsaturated fatty acid (PUFA) intakes were lower than in the control group (respectively, $p<0.001$ and $p=0.005$). The adherence to Mediterranean diet was low in 75.7% of PBC patients. Regarding physical activity, PBC subject had a sedentary behavior, spent many hours/day sit and exercise <200 min/week, similar to controls (respectively $p=0.845$ and $p=0.115$).

Conclusion: The eating habits and lifestyle of PBC patients are unhealthy and at high risk of developing metabolic conditions and MAFLD (metabolic associated fatty liver disease). Therefore, hepatologists should pay attention to the presence of metabolic comorbidities in PBC patients, evaluate eating habits and physical activity and promote a lifestyle change to reduce liver disease progression and hepatocellular carcinoma risks.

Introduction: COVID-19 associated secondary sclerosing cholangitis (SSC) is a recently described cholestatic liver disease that seems to be a variant of SSC in critically ill patients (SSC-CIP). About 30 cases were described in the literature so far. In this disease, the direct cytopathic effect on cholangiocytes, the cytokine storm and hypercoagulability state add up to the mechanisms identified for SSC-CIP, such as ischemic cholangiopathy caused by invasive mechanical ventilation and hemodynamic instability, bile toxicity, biliary infection and drug-induced liver injury.

Aims & Methods: We present a case series of 4 patients who developed SSC complicating the course of severe COVID-19. These cases are illustrated by detailed iconography.

Results: Clinical cases of 63 and 64-years-old female patients and 56 and 78-years-old male patients are described. None of the individuals had a previously known liver disease. However, we documented previous hepatitis B virus (HBV) infection in one patient and chronic HBeAg negative HBV infection, with low DNA level, in another one.

All patients had long stays in the intensive care unit (ICU) with invasive mechanical ventilation (high positive end-expiratory pressure [PEEP], periods of prone positioning, difficult ventilator weaning), need for vasopressors and multiple other drugs, including various antibiotics and high dose steroid therapy. Initially, a significant raise in aminotransferases (aspartate aminotransferase 13-17x upper limit of normal [ULN] and alanine aminotransferase 20-34x ULN) was observed, with subsequent improvement, followed by marked cholestasis (alkaline phosphatase 17-23x ULN and gamma-glutamyl transpeptidase 40-99x ULN) and jaundice (total bilirubin 3-7x ULN), in spite of clinical improvement.

Magnetic resonance cholangiopancreatography (MRCP) showed similar aspects in different patients - prominence, thickening or irregularity of intra-hepatic biliary ducts (all patients), strictures and cystic dilations with a typical beaded appearance (three patients) and liver abscesses (two patients). In one patient, endoscopic retrograde cholangiopancreatography (ERCP) was performed, confirming rarefaction and focal dilations of intra-hepatic ducts and a biliary cast was extracted. The liver biopsy performed in three patients revealed significant edema and mixed inflammatory infiltrate of portal spaces, ductulitis, proliferation of the bile duct epithelia, intra-hepatic cholestasis and inflammatory aspects of a small-medium size vessel. All patients were started on ursodeoxycholic acid. None of them reached normalization of liver enzymes and at least one patient progressed to liver cirrhosis (follow-up time of 4-15 months). Two patients were referred to a liver transplant center.

Conclusion: COVID-19 associated SSC is a rare late complication of severe SARS-CoV-2 infection. These patients exhibit a spectrum of similar laboratory, cholangiographic and histological features. The prognosis is dismal with rapid progression to advanced chronic liver disease. Since effective medical treatment is lacking, early referral for liver transplantation should be considered.

Disclosure: Nothing to disclose.

Introduction: Primary Sclerosing Cholangitis (PSC) is a hepatobiliary disease closely related to ulcerative colitis (UC). Genetics, dysregulation of bile mediated by dysbiosis of the gut, and the gut-lymphocyte homing theory all contribute to explanatory models of PSC pathogenesis. However, neither microbiome- nor immune modulating therapies have yet convincingly shown to affect the progression of disease. In PSC patients, colectomy has been shown to be associated with a better outcome, and a lower incidence of recurrent PSC following liver transplantation. These findings speak in favor for an involvement of the gut liver axis in the origin of PSC.

Aims & Methods: The aim of this study was to evaluate if colectomy in UC-patients is associated with decreased risk of development of PSC. Nationwide registers were used to identify all adult Swedish patients with ulcerative colitis (UC) in 1990-2018. Information regarding colectomy and diagnosis of PSC was retrieved.

Within the cohort of UC-patients, colectomized patients were matched to those with no colectomy, by sex, age at UC-onset (± 5 years), year of UC onset (± 3 years) and presence of proctitis at time of colectomy. Incidence rates of PSC per 1000-person year were calculated, as well as survival analyses calculating the risk of PSC using the Kaplan Meier method and Cox proportional hazard regression model.

Results: From the cohort of 61 993 UC-patients, 5 577 colectomized patients (median age 44y, 41% women) were matched to 15 078 patients with colon in situ (median age 45y, 41% women). During follow-up, 3.4% of the colectomized patients developed PSC compared with 3.0% among the comparators, yielding incidence rates/1000 person years of 2.6 and 2.4, respectively. There was no overall difference in incidence of PSC in colectomized UC-patients vs UC comparators (Hazard Ratio [HR] 1.07 [95%CI 0.90-1.28]).

Conclusion: Colectomy was not associated with a lower incidence of PSC in patients with UC, speaking against a protective effect of colectomy for the development of PSC.

Introduction: Primary sclerosing cholangitis (PSC) is a rare cholestatic liver disease characterised by inflammatory and fibrosing involvement of the bile ducts. It is often associated with chronic inflammatory bowel diseases.

Aims & Methods: The purpose of this work is the study of the different-clinical, morphological, therapeutic and outcomes of this association. This is a retrospective and descriptive study covering a period of 18 years from January 2003 to April 2022, including all cases of PSC. The diagnosis of PSC was based on biological, radiological and histological arguments. The diagnosis of IBD was based on a combination of clinical, endoscopic, histological and radiological evidence.

Results: Twenty-eight cases of PSC were collected. 12 were women and 16 were men. The average age was 48.9 $\pm$ 16.77 years. Out of 1590 IBD patients, PSC was detected in 1% of patients (1.27% in Crohn's disease and 0.52% in UC) and out of 28 PSC cases, IBD was noted in 57.1% of cases. The association of PSC and IBD was found in 16 patients (n=16). The association with Crohn's disease was found in 13 patients (46.42%) and with ulcerative colitis (UC) in 3 patients (10.71%).

Crohn's disease was colonic in 8 patients, ileocolic in 5 patients, UC was rectosigmoid in 2 patients and pancolic in one case.

Crohn's disease and ulcerative colitis were diagnosed on all clinical, morphological, endoscopic and histological arguments. As for PSC, it was evoked by an troubled liver test during IBD monitoring, showing cholestasis in 66.6% of cases, hyperbilirubinemia in 20.8% of cases and moderate cytotoxicity in 41.6% of cases. The cholangio-MRI was performed for each patient showing an aspect of primary sclerosing cholangitis. Cholangio-MRI showed moniliform dilatation of the intrahepatic bile ducts in 9 cases, segmental stenosis-dilatation of the intrahepatic bile ducts in 3 cases and stenosis-dilatation of the bile duct in 1 patient and was normal in 4 patients.

Liver biopsy was performed first in the 4 patients with a normal CP-MRI and then in 6 other patients (n=10), showing PSC of the small ducts in 4 patients, cirrhosis in 2 patients, portal fibrosis with rare septa in 2 patients. Colonoscopy with histological study was normal in 3 patients with UC and 4 patients with Crohn's disease as part of colorectal cancer screening.

Two patients with Crohn's disease underwent surgery for obstruction and received ileo-caecal resection and were put on combiotherapy (adalimumab+azathioprine) to avoid post-operative recurrence, the other patients were on immunosuppressive therapy. The 3 patients with UC were put on salicylates.

Treatment with urso-desoxy-cholic acid was started in all our patients. Seven of our patients were lost to follow-up. Two of our patients died (one from sepsis in the setting of stage C cirrhosis and the other from enteromesenteric ischemia) and two did not respond to treatment (One of the non-respondents progressed to cholangiocarcinoma with hepatic metastases) and five progressed well clinically and biologically.

Conclusion: Primary sclerosing cholangitis is a rare condition. Our work showed particularly that the association of PSC with Crohn's disease is higher than that of UC which is different from the literature series. These data require confirmation through more extensive prospective studies.

Disclosure: Nothing to disclose.

Introduction: The presence of sarcopenia is a well-validated prognostic tool in chronic liver disease (CLD) to predict morbidity and mortality. Further investigation on its value for patients with primary sclerosing cholangitis (PSC), a specific and rare form of cholestatic CLD, is lacking.

Aims & Methods: This retrospective, cross-sectional study includes 91 patients with PSC from a tertiary german liver center. Skeletal muscle index (SMI) was assessed using cross-sectional images at the third lumbar vertebra (L3) to determine sarcopenia, according to previously published cut-off values. The primary endpoint of this study was transplant-free survival at 2 and 5 years following cross-sectional imaging.

Results: Sarcopenia, assessed by SMI, is significantly associated with impaired transplant-free survival and was identified as an independent risk factor via multivariate Cox-regression analysis ($P=0.005$, B 3.129, 95%-CI 1.423-6.880).

The 2-year and 5-year transplant-free survival is significantly lower if sarcopenia is present (2-year transplant-free survival: 78.6% vs. 51.4%, $p=0.001$, log-rank test; 5-year transplant-free survival: 69.9% vs. 35.7%, $p=0.001$, log-rank test).

Conclusion: This study provides first evidence to establish imaging-based diagnosis of sarcopenia as an independent risk factor in PSC patients. Further prospective studies are required to improve diagnostic accuracy and integrate sarcopenia in future scoring systems for PSC patients.

KLF14 ALLEVIATES IMMUNE LIVER INJURY IN MICE VIA NF- κ B SIGNALING PATHWAY

X. Chen¹, W. Shi¹, P. Liu¹

¹First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China

Contact E-Mail Address: chenxiaoyan_wow@163.com

Introduction: To date, immunopathogenic mechanisms of autoimmune hepatitis (AIH) have not been well elucidated yet. Previous studies showed macrophages were involved in the development of autoimmune hepatitis. At the same time, KLF14 was reported to moderate AIH. Thus, we attempt to study whether KLF14 could alleviate AIH through influencing the function of macrophage in liver.

Aims & Methods: At first, we identified the hepatic expression of KLF14 in human and murine AIH. Immune-mediated hepatitis was induced by concanavalin A (Con A). A KLF14 recombinant adenoviruses plasmid (Ad-KLF14) was constructed and injected into mice. Expressing of KLF14 in mechanisms were detected by immunofluorescence, inflammatory cytokines were tested by qRT-PCR. In vitro, we stimulated the KLF14/vector plasmids-transfect RAW264.7 cells with IFN- γ and examined the expression of inflammatory factors. Then we took luciferase reporter assay and co-immunoprecipitation assay to identify whether KLF14 regulated macrophage through NF- κ B.

Results: Expression of KLF14 was suppressed in liver tissues of human and murine AIH. KLF14-overexpressed mouse revealed lower degree of inflammation and pathological injury in liver compare with normal controls. In vitro, after the administration of INF- γ , the expression of inflammatory factors was down-regulated in Ad-KLF14 RAW264.7 cells. Meanwhile, the result of luciferase reporter assay and Co-IP showed KLF14 covalently bind to NF- κ B and directly inhibited it.

Conclusion: KLF14 could alleviate immune liver injury and inflammation induced by Concanavalin A in mice via blocking the NF- κ B signaling pathway. Collectively, our results point to a novel gene regulating AIH within the pathogenic, pro-inflammatory macrophage activation in the setting of liver inflammation.

Introduction: Vaccination against SARS-Cov-2 infection has significantly reduced the incidence of severe cases. However, safety concerns have increased as possibly related side effects have been described. It is postulated that vaccination could induce different autoimmune diseases, probably due to cross-reactivity between SARS-Cov-2 proteins and human proteins. To date, more than 20 cases of post-vaccination autoimmune hepatitis (AIH) have been described in the literature.

Aims & Methods: The aim of this study was to collect cases of AIH that were detected after vaccination for SARS-Cov-2 in our hospital, and to analyse their characteristics and the possible causality of the vaccine. Cases of probable or definitive autoimmune hepatitis according to the simplified criteria of the International Autoimmune Hepatitis Group that presented less than 90 days after COVID-19 vaccination were collected. All cases had to have a compatible liver biopsy and response to corticosteroids in order to be included.

The following data were collected: age, sex, type of vaccine, latency, transaminase and bilirubin (BT) levels at diagnosis, liver biopsy, autoantibodies and IgG, predisposing HLA and treatment received.

Results: Since the start of vaccination, 5 cases of altered liver biochemistry after vaccination have been detected (Table 1).

Patient	Sex	Age (years)	Vaccine	Latency (days)	GPT (U/L)	GOT (U/L)	Total bilirubin (mg/dl)	ANA +	IgG (mg/dl)	Compatible biopsy	HLA	IAIHG simplified score
1	Female	47	AstraZeneca	24	353	241	0.4	1/160	2016	Yes	HLA-DRB1 *03:01,*04:03	8
2	Male	72	Pfizer	46	248	204	12.3	1/320	1670	Yes	HLA-DRB1*04	7
3	Female	62	AstraZeneca	4	655	498	2.5	1/160	1684	Yes	HLA-DRB1 *03:01 *07:01	8
4	Female	72	Pfizer	46	866	570	2.3	1/320	1916	Yes	HLA-DRB1 *03:01 *07:01	8
5	Female	59	AstraZeneca	9	1799	1292	1.3	1/640	1978	Not performed	HLA-DRB1 *01:03, *11:04	/

Table 1.

Four patients were female and one male, with a mean age of 62 years. Sixty percent received Pfizer and 40% AstraZeneca. The mean time from vaccination to detection of laboratory abnormalities was 26 days. No patients showed evidence of liver failure, although there was one case of severe acute hepatitis. ANAs were positive together with elevated IgG levels in all patients. Liver biopsy was performed in 4 cases, which were compatible with AIH. Four patients were treated with systemic corticosteroids with good outcome, and three of them were prescribed azathioprine as maintenance therapy (in one patient it was contraindicated due to a concomitant diagnosis of endometrial neoplasia). Four of the patients had HLA susceptibility for IAH. The score was calculated based on the simplified diagnostic criteria of the International Autoimmune Hepatitis Group, with all patients who underwent biopsy scoring ≥ 7 points (definite autoimmune hepatitis).

Four of the patients received a new dose of the vaccine at a later date. The second patient had a slight worsening of transaminases, which was related to the concomitant suspension of azathioprine due to digestive intolerance, with an improvement in blood tests when a new course of corticosteroids was started.

Conclusion: In all of the cases presented, there is a temporal relationship with onset of the alterations less than 90 days after vaccination. Although controversial, it is postulated that vaccination could be the cause of autoimmunity, or rather play a role as a trigger for latent disease.

At least 20 cases of probable AIH following vaccination have been reported in the literature, with characteristics similar to the cases presented in this study. However, at present, it is not possible to say with certainty whether the vaccine is the cause of the debut of IAH or whether it is a casual association in predisposed patients.

Contact E-Mail Address: marcello.dallio@gmail.com

Introduction: Trained Immunity (TI) represents a novel concept of the immunological reaction involving the innate immune cells, triggered by a second antigenic contact, gaining a long-term reversible pro-inflammatory phenotype. In liver cirrhosis, immune dysfunction impacts the onset of chronic local and systemic inflammation, the disease worsening, and the development of its complications.

Aims & Methods: The aim was to highlight TI response impairment along with the progression of chronic liver disease and to estimate its implications on the cirrhosis outcome.

Healthy subjects, patients with chronic hepatitis (CH) (alcoholic and non-alcoholic fatty liver disease ones), and liver cirrhosis (LC) were enrolled. For each patient, medical history and a peripheral venous blood sample were collected (20 ml). After a per gradient isolation, monocytes were sequentially stimulated with β -glucan for 24 h (1 μ g/mL) and lipopolysaccharide (LPS) (10 ng/mL) for 24 hours in order to assess the pro-inflammatory [tumor necrosis factor (TNF)- α , interleukin (IL)-6] and anti-inflammatory response (IL-10) (at day 3 and 6 respectively). Evaluation of blood levels of LPS, IL-6, and TNF- α was also performed.

Results: Regarding TNF- α and IL-6, the maintenance of TI was highlighted in healthy subjects (n.10) and CH (n.15) as well but not in LC patients (n.38) (TNF- α controls, LPS:2800 $\pm$ 628.8, β -glucan+LPS:5046 $\pm$ 136.2 pg/ml, p:0.008, IL-6 controls, LPS:2487 $\pm$ 562.4, β -glucan+LPS:4556 $\pm$ 190.2 pg/ml, p:0.008; TNF- α CH, LPS:1839 $\pm$ 70.7, β -glucan+LPS:4445 $\pm$ 162.6 pg/ml, p:0.007, IL-6 CH, LPS:2576 $\pm$ 177.9, β -glucan+LPS:3865 $\pm$ 332.3 pg/ml, p:0.008). IL-10 levels showed a typical TI trend only in healthy subjects (LPS:2797 $\pm$ 518.9, β -glucan+LPS:6001 $\pm$ 1523 pg/ml p: 0.001). In cirrhotic group, the bivariate analysis revealed an inverse correlation between circulating LPS, IL-6 (R = -2.511; p = 0.01) and TNF- α (R: -1.887; p = 0.02).

The Kaplan-Meier Log-Rank test analysis (24 LC patients with inefficient and 14 with efficient TI response) on not SARS-CoV-2 infections development and liver-related hospitalizations (HR 4.09, 95% CI: 1.57-10.61, p = 0.01; HR: 4.66, 95% CI: 1.5-14.47, p = 0.02 respectively) revealed lower risk for patients with efficient TI response.

	Tumor Necrosis Factor - α					Interleukin-6				
Healthy subjects (n.10)	Controls	β -glucan	LPS	β -glucan + LPS	P-value (LPS vs β -glucan + LPS)	Controls	β -glucan	LPS	β -glucan + LPS	P-value (LPS vs β -glucan + LPS)

LSP: lipopolysaccharide.

Table. Trained immune response in healthy subjects, chronic hepatitis, and liver cirrhosis patients.

Conclusion: The worsening of chronic liver disease appears related to the progressive impairment of the TI response whose maintenance seems to be associated with a lower risk of unfavorable clinical events in cirrhotic patients.

INTERDISCIPLINARY APPROACH IS ESSENTIAL FOR SUFFICIENT DIAGNOSIS AND THERAPY IN IGG4-RELATED DISEASE INVOLVING MULTIPLE ORGANS

S. Christoph¹, G. Gerken², H. Schmidt¹, A. Kahraman³

¹University Hospital Essen, Clinic for Gastroenterology, Hepatology and Transplant Medicine, Essen, Germany, ²Helios Clinic Niederberg, Clinic for Gastroenterology, Hepatology and Palliative Medicine, Velbert, Germany, ³Max Grundig Clinic GmbH, Clinic for Gastroenterology, Hepatology and Infectiology, Bühl, Germany

Contact E-Mail Address: drsandra.christoph@gmail.com

Introduction: IgG4-related disease (IgG4-RD) is a systemic, chronic inflammatory syndrome, with enlargement of involved organs, elevated serum levels of IgG4, dense lymphoplasmocytic infiltrates, rich in IgG4-positive plasma cells, and fibrosis in involved organs. The most frequently involved organs are the pancreato-hepatobiliary tract, salivary and lacrimal glands, the retroperitoneum, kidneys, lungs, and aorta. Often multiple organ systems are involved. As an initial treatment, glucocorticoids are recommended. In patients with relapse along with glucocorticoid dose reduction, various immunosuppressive agents have been reported.

Aims & Methods: We reviewed 98 patients (2019-now) who were treated in the special outpatient unit for IgG4-RD at the University Hospital of Essen and identified 10 patients with IgG4-RD involving multiple organ systems.

Results: The first patient is a 65-year-old male diagnosed with an IgG4-RD involving parotitis, lymphadenitis, sialadenitis with orbitopathy and elevated IgG4 serum level (7400 mg/l). Clinically response to therapy with steroids was documented.

The second patient is a 63-year-old man with an IgG4-positive pancreatitis, sialadenitis, lymphadenopathy, and elevated IgG4 serum level (3960 mg/l). Immunosuppression with tacrolimus led to clinical benefit.

As the third patient, we report a 48-year-old man with IgG4-related inflammatory condition in pancreas and kidneys with high IgG4 serum levels. The patient was successfully treated with azathioprine and prednisolone. As the fourth patient, we demonstrate a 34-year-old man with IgG4-related autoimmune hepatitis, lymphadenitis, and pancreatitis. After treatment with tacrolimus in combination with rituximab, a significant decrease of IgG4-level was detected.

The fifth patient, a 65-year-old man, was diagnosed with IgG4-related fibro-inflammatory pseudotumors in the liver, esophagitis, and lymphadenopathy combined with high serum levels of IgG4 (12000 mg/l). Clinically response to therapy with steroids and azathioprine was reported.

As the sixth patient we demonstrate a 29-year-old male with IgG4-related lymphadenopathy, recurrent myocarditis, and pancreatitis.

The patient has symptom-free episodes under low-dose prednisolone. We also found an IgG4-RD with multiple organ involvement in our seventh patient. A 54-year-old man with IgG4-related cholangitis, pancreatitis, prostatitis, and very high serum level of IgG4 (26700 mg/l) were treated with steroids and azathioprine.

As our eight case, we present a 23-year-old man with congenital hepatic fibrosis, after living-donor liver transplantation, who developed an IgG4-related disease with high IgG4 serum levels (45300 mg/l) after infection

with SARS-CoV-2. Pathologically enlarged lymph nodes were detected. In a biopsy of retroperitoneal lymph nodes, IgG4-positive plasma cells were detectable. Intestinal biopsies have shown numerous positive plasma cells in the IgG4-staining (40 IgG4 positive plasma cells/HPF). Treatment with rituximab is planned.

The ninth patient is a 56-year-old woman with lymphadenitis and cholangitis, who clinically responded to a treatment with budesonide. As the last patient we present a 59-year-old man with an IgG4-related aortitis, cardiac fibrosis, cholangitis, hepatitis, exocrine pancreatic insufficiency and Hashimoto's thyroiditis responding very sufficient to rituximab.

Conclusion: An interdisciplinary approach is essential for a sufficient diagnosis and therapy in IgG4-RD involving multiple organs. This collective is extremely heterogeneous, and treatment is often based on individual concepts.

INCIDENTAL M2-AMA POSITIVITY BY IMMUNOBLOT IS A STRONG INDICATOR OF PRIMARY BILIARY CHOLANGITIS

I. ergenc¹, B. Gözaydınlioğlu², Ç. Keklikkiran³, Y. Yilmaz⁴
¹Marmara University, Gastroenterology, Istanbul, Turkey, ²Marmara University School of Medicine, Istanbul, Turkey, ³Marmara University School of Medicine, Gastroenterology, Istanbul, Turkey, ⁴Marmara University, School of Medicine, Gastroenterology, Istanbul, Turkey

Contact E-Mail Address: ergencilkay@gmail.com

Introduction: Anti-mitochondrial antibodies (AMA) are the typical biomarkers of primary biliary cholangitis (PBC). Anti-mitochondrial M2 antibody (M2-AMA), formed against the E2 subunit of pyruvate dehydrogenase complex, is the most specific AMA subtype for PBC¹.

AMA antibodies might become positive years before the development of PBC². Furthermore, the M2-AMA dot-blot is more specific to PBC than indirect immunofluorescence based AMA (IIF-AMA).

Aims & Methods: This study aims to investigate the natural evolution of incidental AMA-M2 positivity by immunoblot test to PBC diagnosis with or without IIF-AMA positivity. The Extractable Nuclear Antibodies (ENA) Im-

munoblot (IB) panel tests (Euroimmun, Germany) including M2-AMA requested by rheumatology, endocrinology, neurology and general internal medicine to investigate autoimmune disorders were screened (n=11459) and patients with positive M2-AMA (n=120) were identified. Patients with a definite or provisional diagnosis of PBC (n=21) at the time of the ENA panel test were excluded.

Ninety-nine M2-AMA positive patients who underwent ENA panel test for suspected autoimmune disorders were invited to the study. Patients who agreed to participate in the study were tested for AMA and Antinuclear antibody (ANA) by indirect immunofluorescence method (IIF) (Euroimmun, Germany). Serum alkaline phosphatase (ALP) activity was tested and previous ALP results were noted. European Association for the Study of the Liver (EASL) criteria were used for PBC diagnosis.

Results: Among 11459 samples tested for the ENA panel, 0.1% (n=99) were M2-AMA positive by IB. A total of 99 patients were eligible for the study and 48 patients agreed to participate. The mean age was 48.5±4 and 93.75% (n=45) were female. 64.5% (n=31) of patients were followed-up in rheumatology clinic, 23% (n=11) in internal medicine clinic and 12.5% (n=6) in neurology clinic.

The median follow-up period after M2-AMA positivity was 27 months. Twenty-eight (58.5%) were ANA positive (Table 1), 21 (43.5%) were IFA-AMA positive and 31.2% were diagnosed with PBC. Thirteen out of these 21 AMA positive patients had elevated ALP levels and were eventually diagnosed with PBC.

In addition, two of AMA negative patients had persistently increased ALP levels and were diagnosed with PBC. Twelve of 15 newly diagnosed PBC patients had autoimmune disorders. Of these, 4 were diagnosed with rheumatoid arthritis, 3 with connective tissue disease, 3 with ankylosing spondylitis, 1 with Hashimoto's thyroiditis and 1 with Familial Mediterranean Fever. While six newly diagnosed PBC patients had a history of increased serum ALP levels at the time of first M2-AMA positivity, nine of them developed an increase in ALP during the follow-up.

	AMA (+) (n= 21)	AMA (-) (n=27)	Total
PBC Diagnosis	13	2	15(%31,2)
ANA positivity	12	16	28(%58,3)
Accompanying autoimmune disorders	12	19	31(%64,5)

AMA: Anti-mitochondrial antibody, PBC: Primary Biliary Cholangitis, ANA: Antinuclear antibody

Table 1: Antibody positivity and PBC diagnosis rates.

Conclusion: Immunoblot AMA M2 positivity was only 0.1% in the suspected autoimmune disorders patients. Two-thirds of M2-AMA positive patients were diagnosed with PBC, 6 of these patients were missed the diagnosis although they met the EASL criteria at test day, remaining 9 patients were diagnosed in a median follow-up of 27 months. This study demonstrates that M2-AMA positivity in patients with autoimmune disorders is extremely valuable and should alert the physicians for current and future diagnosis of PBC.

ANTI-MITOCHONDRIAL ANTIBODY-NEGATIVE PRIMARY BILIARY CHOLANGITIS: EPIDEMIOLOGICAL, CLINICAL, BIOLOGICAL, HISTOLOGICAL AND EVOLUTIONARY CHARACTERISTICS

R. Ayadi¹, D. Cherif², H. Debbabi¹, H. Yacoub¹, H. Hajer³, H. Kchir¹, N. Maamouri⁴

¹La Rabta University Hospital, Gastroenterology Department B of La Rabta Hospital in Tunis, Tunisia, ²Rabta, Gastroenterology, Tunisia, ³La Rabta University Hospital, Gastroenterology, Ben Arous, Tunisia, ⁴La Rabta Hospital, Tunisia

Contact E-Mail Address: ayadirahmaa018@gmail.com

Introduction: Primary biliary cholangitis (PBC) is a chronic inflammatory liver disease with an autoimmune mechanism. Its diagnosis is based on the presence of biological cholestasis, positive anti-mitochondrial antibodies (AMA) type 2 and suggestive histological lesions. AMA- negative PBC represents a rare form of PBC with misleading signs that can lead to misdiagnosis.

The main objective of this study was to determine the epidemiological, clinical, biological, histological and evolutionary characteristics of this particular form compared to the seropositive form.

Aims & Methods: A retrospective, descriptive, comparative, mono-centric study was carried out at the gastroenterology B department of La Rabta hospital in Tunis over a period of 23 years. Medical records of 108 patients admitted for PBC during the study period were collected. The diagnosis of seronegative PBC was made when biological cholestasis was associated with characteristic histological signs in the absence of anti-mitochondrial antibodies (AMA).

Results: Among the 108 patients followed for PBC, we collected 11 cases of seronegative PBC (11,88%). The mean age was 51 years with a predominance of women (75%). PBC was asymptomatic in 45% of cases and was most often discovered incidentally in an abnormal liver blood test (36%). Immunologically, only anti-nuclear antibodies (ANA) were positive (63%). Liver biopsy confirmed the diagnosis in all patients. Histologically, lymphocytic destructive cholangitis was the most frequent lesion (63%) as well as Scheuer stage 4 (36%). At least one associated autoimmune disease was present in 45% of patients. All patients received ursodeoxycholic acid (UDCA) at a dose of 12-15 mg/Kg/d. Three patients with overlap syndrome received corticosteroids in combination with UDCA. The mean follow-up was 60 months (0-200 months).

A complete response was noted in 5 cases. Four patients were lost to follow-up. Only one patient had a relapse due to poor compliance with treatment. An hepatocellular carcinoma was observed in only one case during the course of the disease. No significant differences were found between seropositive and seronegative groups for any of the studied characteristics of the disease.

Conclusion: Although AMA-negative PBC is a rare form of PBC, it is associated with similar rates of complications as the seropositive form. Only the early initiation of UDCA can control the progression of the disease. However, its misleading signs can delay the diagnosis and the management of patients.

Therefore, AMA- negative PBC should be considered in the presence of any hepatic cholestasis and the treatment with UDCA must be provided at an early stage to improve the prognosis of the disease.

Introduction: Reported prevalence of hepatitis E virus (HEV) in patients with autoimmune hepatitis (AIH) varies markedly (8 - 40%). A recent study in non-alcoholic fatty liver disease (*Paternostro et al. Hepatol Res. 2021*) showed a relationship between HEV seropositivity and more advanced liver fibrosis and cirrhosis. This aspect has not yet been evaluated in AIH.

Aims & Methods: Here we assessed the prevalence of HEV seropositivity in patients with AIH and its impact on disease course. A group of 398 non-transplant adult patients (female 68%, mean age 38 ± 16 years, liver cirrhosis 38%), including 270 (68%) with AIH and 128 (32%) with its variants (AIH-PSC and AIH-PBC) was enrolled.

The serum concentration of HEV IgG and IgM antibodies was measured by enzyme-linked immunosorbent assay (ELISA). Liver cirrhosis was diagnosed by liver biopsy or imaging studies.

Moreover, in patients with AIH in remission, liver fibrosis was assessed as liver stiffness measurement (LSM) by 2D-Shear Wave Elastography (Aixplorer, SuperSonic), used to measure spleen stiffness as well.

Results: In total, 59 (15%) patients were HEV IgG positive, and 5 (1%) were HEV IgM positive. This proportion was lower than previously reported (Grabarczyk et al. Transfusion 2018) in Polish blood donors (43%; $p < 0.001$). The HEV IgG-positive patients were older both at the study time (45.6 vs 36.7 years, $p < 0.001$) and at the diagnosis of their disease (39.0 vs 30.6 years, $p < 0.001$), as compared to IgG-negative patients. They also had higher BMI (25.0 vs 23.7 kg/m², $p = 0.031$), liver stiffness (17.2 vs 14.7 kPa, $p = 0.014$) and spleen stiffness (29.7 vs. 26.8 kPa, $p = 0.043$).

In patients with AIH in biochemical remission ($n = 198$), the multivariate analysis revealed that the risk of liver cirrhosis (LSM > 16.1 kPa) was increased by HEV seropositive status (OR 2.46, CI 95% 1.03 - 5.87) and older age (OR 1.03, CI 95% 1.01-1.06).

However, there was no impact of HEV seropositivity or age in the entire cohort on the clinically diagnosed liver cirrhosis. There was no difference between patients with AIH and with or without HEV IgG positive regarding biochemistry at the time of diagnosis (i.e. ALT, bilirubin, IgG) or the enrolment in the study and treatment regime.

Conclusion: Despite a lower prevalence of HEV IgG in patients with AIH than in the general population, these patients might be more prone to have advanced liver fibrosis. Nevertheless, the impact of HEV infection on the disease course of AIH needs to be fully elucidated in prospective studies.

Introduction: Liver transplantation (LT) provides life-saving therapy for children with end-stage liver disease and liver-based metabolic defects. Over the last decades important advances have been made both from the surgical and clinical point of view making LT an effective and widely available treatment in children ensuring notable results in terms of patient and graft survival rates [1-3].

Since LT in pediatric age is a relatively recent reality, there is still limited knowledge about its long-term impact in terms of quality of life and chronic immunosuppression long-term effects [4-5].

Aims & Methods: This study aimed to describe long-term outcomes in LT children followed-up for more than two decades, with particular interest to late post-transplant complications and patient survival rates.

We conducted a single-center retrospective study including all pediatric patients who underwent LT from 1987 to 2011 and followed-up until 2021 at the "Federico II" University Hospital of Naples.

Results: A total of 119 patients have been enrolled, 62 males and 57 females, with a median age at the time of enrollment of 24.3 years (25th-75th percentile: 18.7-32.4). The median age at the time of LT was 1.71 years (25th-75th percentile: 0.73-6.14) with a median follow-up time of 21.6 years (25th-75th percentile: 15.7-25.7).

The main indication for LT was biliary atresia (63%), followed by liver-based metabolic defects (10.1%), autoimmune liver diseases (7.6%), progressive familial intrahepatic cholestasis (5.9%) and Alagille syndrome (3.4%). Immunosuppressive regimens undertaken in the immediate post-transplant period were in all patients based on calcineurin inhibitors (119/119). Tacrolimus-based regimens were used in 85 patients (71.4%), in the majority as monotherapy (75 patients).

During the post-LT follow-up in 34 patients (28.6%) a therapeutic switch was necessary, mostly due to chronic rejection (16 cases). Twenty-two re-transplantations were performed in 13 patients with a 20-year graft survival rate of 81.56%. Vascular complications represented the most frequent cause of graft failure (8/22). The most common comorbidities were allergic ones (29.4%). Long-term immunosuppression-related complications included metabolic bone diseases (12.6%), arterial hypertension (10.1%) and chronic kidney dysfunction (10.1%). De novo malignancies occurred in 20 patients (16.8%), mostly represented by lymphoproliferative disorders (18/20). No skin neoplasms were reported. Six deaths (5.04%) have been registered (for malignancies in 2 cases, for sepsis in 2 cases and for cirrhosis in 2 cases) with a 20-year survival rate of 94.96%.

Conclusion: The present study shows a significant increase in survival of LT pediatric patients and grafts and confirms the less frequent onset of complications compared to the adult setting but also highlights the emerging and still unresolved issues.

ELASTOGRAPHY BY FIBROSCAN AND POINT SHEAR WAVE FOR ANALYSIS OF LIVER STIFFNESS: A PROSPECTIVE STUDY

G. Losurdo¹, I. Dittonno¹, D. Novielli¹, N. Ranaldo¹, E.G. Ierardi¹, M. Rendina¹, A. Di Leo¹

¹Section of Gastroenterology, DETO, University of Bari, Bari, Italy

Contact E-Mail Address: ilaria.dittonno@gmail.com

Introduction: Liver stiffness measurement (LSM) by fibroscan is the most used non invasive method to assess the fibrosis of the liver. Recently, point shear wave elastography (pSWE) has been introduced as a simple alternative non invasive test. Therefore, we aimed to compare the results of these two techniques.

Aims & Methods: Consecutive patients attending our ultrasound facility in our outpatient clinic in the period January-December 2021 were recruited. For each patient, LSM was performed by both Fibroscan (Echosens, Paris, France) and pSWE (Esaote Mylab Xpro80, Genova, Italy).

At least 10 measurements were performed, and results were expressed as median with interquartile range. Staging of fibrosis was assigned according to Metavir classification. Statistical analysis was conducted by Pearson's test for correlation and linear regression. Bland-Altman graphs were drawn.

Results: Sixty-three patients (35 males, 28 females, mean age 56.7 ± 13.0) were recruited. The most common indications to perform LSM were chronic viral hepatitis (14.3%), unexplained hypertransaminasemia (36.5%), non alcoholic steatohepatitis (14.3%), and autoimmune liver diseases (6.3%). LSM measurements of pSWE and Fibroscan showed a poor correlation (r=0.56, p<0.001) and linear regression (b=0.93 ± 0.03, p<0.0001). Bland-Altman graph found only 4 outliers.

The best correlation was observed in patients with non alcoholic steatohepatitis (r=0.81), while those with unexplained hypertransaminasemia had r=0.76.

Overall, Fibroscan classified one patient as F4, one as F3, three as F1 and 13 as F0. Concordance with pSWE for F staging was observed in 16 (84.2%) patients. A full concordance in fibrosis Metavir staging was recorded in 47 cases (74.6%), while in 9 patients (14.3%) SWE overestimated and in 7 (11.1%) underestimated fibrosis.

Conclusion: In most of cases, pSWE shows LSM estimation in agreement with Fibroscan, and the best concordance was observed for non alcoholic steatohepatitis. A slight trend of stiffness overestimation by pSWE was observed, despite only for mild, non significant fibrosis.

Disclosure: Nothing to disclose.

Introduction: Liver fibrosis is a progressive process leading to liver cirrhosis. Several non-invasive elastography techniques were developed for liver stiffness measurements (LS) as a marker of liver fibrosis.

The aim of this study was to evaluate the performance and feasibility of 2D-Shear Wave Elastography (2D-SWE) for liver fibrosis (LF) assessment using Transient Elastography (TE) as the reference method.

Aims & Methods: 67 subjects were included, 65% (44/67) male, mean age 55.6 ± 13.2 , in which LS was evaluated in the same session by TE (FibroScan Compact M 530) and 2D-SWE (Samsung-Medison RS85). Reliable LS measurements were defined for TE the median value of 10 measurements with an IQR/M $\leq 30\%$, while for 2D-SWE the median value of 10 measurements, with a reliability measurement index (RMI) ≥ 0.5 and IQR/M $\leq 30\%$. For classification of LF severity we used TE as reference method with cut-off value ≥ 7 kPa for at least significant liver fibrosis (1).

Results: Reliable measurements by TE and 2D-SWE were obtained in all 67 cases. A strong correlation was found between 2D-SWE and TE, $r=0.83$. The best cut-off value for 2D-SWE in identifying at least significant fibrosis ($F \geq 2$) was >7 kPa [AUROC=0.91, 95% CI (0.82;0.97), $p<0.0001$, Se=81.8%, Sp=80.0%, PPV=66.7%, NPV=90.0%].

Conclusion: 2D-SWE is a feasible method for assessing liver fibrosis, that strongly correlates with TE results.

Introduction: Hepatocellular carcinoma (HCC) is the most frequent subtype of primary liver cancer and one of the leading causes of cancer-related mortality worldwide. Emerging evidence has recently suggested that long noncoding RNAs (lncRNAs) have tumor-suppressive roles in cancers. LINC01018 can inhibit the proliferation of tumor cells and promote cell differentiation in HCC.

Aims & Methods: In this study, a new therapeutic modality using lncRNA LINC01018 was designed to control HCC progression. sixty mice were included and categorized into 3 groups. The 1st group acted as a normal control group whereas the 2nd group acted as a pathological control group and was injected with N-Nitrosodiethylamine (DEN) weekly for 16 weeks. The 3rd Group was injected intrahepatically with lncRNA LINC01018 once/week for four weeks starting from the 12th week after initiating DEN injection. After 16 weeks, animals were euthanized, and liver specimens and blood samples were collected for pathological, biochemical, and assessment.

Results: Our results showed that lncRNA LINC01018 administration leads to inhibition of cell proliferation of HCC. It was observed that there was an improvement in histopathology in the 3rd group when compared to the pathological control group. The levels of AFP, VEGF, TNF- α , PD-EGF, and EpCAM decreased significantly ($P<0.001$) and the Relative expression of hepatic B-Catenin and SENP was significantly down-regulated ($P<0.001$) after LINC01018 administration.

Conclusion: lncRNA LINC01018 can be considered a new target for therapeutic intervention in HCC.

Introduction: Hepatocellular carcinoma (HCC) arises from a liver cirrhosis in more than 80% of cases and this condition could determine the beginning and/or maintenance of the HCC treatment. In addition, comorbidities and frailty of the patients may induce a treatment stage migration or even be the reason to leave them without specific treatment for the HCC.

Aims & Methods: The aim of our study is to assess the characteristics and survival of patients with HCC in natural history in our setting.

Unicentric retrospective cohort study with the inclusion of all consecutive HCC patients diagnosed at our Unit between Jan 27th 2015 and Dec 27th 2021. The main inclusion criterion was the selection of “non treatment” as first and sole therapy for HCC. Baseline clinical variables, reason of non-treatment and period from diagnosis to death/end of follow-up were systematically recorded.

Results: A hundred eighty-one patients from 685 met our inclusion criterion: 82% were men, median age 71 years, 93% with cirrhosis, 55% alcohol related vs 34% viral, 54% with previous decompensation (73% ascites). After a median follow-up of 9.98 months, 84% had died.

There were statistical differences in median survival according to 1) tumor-related symptoms [ECOG PS-0: 13 months, ECOG PS-1: 6 months, ECOG PS $\geq$ 2: 2 months; $p < 0.001$], 2) tumor stage [BCLC 0-A: 13 months, BCLC-B: 12 months, BCLC-C: 4 months, BCLC-D: 2 months; $p < 0.001$], 3) baseline AFP [AFP < 200 ng/mL: 9 months vs AFP ≥ 200 : 3 months; $p < 0.001$] and 4) baseline Child-Pugh [A: 8 months vs B: 4 months vs C: 6 months; $p = 0.003$].

The most common reasons for non-treatment were: cirrhotic decompensation / BCLC-D stage (51%), frailty/advanced age (25%), comorbidity (16%) and patient refusal (8%). Baseline factors independently associated with survival were the absence of previous decompensation (HR 0.492, IC 95% 0.331-0.733, $p < 0.001$), BCLC stage (HR 0.389 IC 95% 0.183-0.813, $p = 0.012$) and diagnosis during screening program (HR 1.614, IC 95% 1.058-2.463, $p = 0.026$).

Conclusion: Twenty-six percent of HCC patients remain in their natural history without HCC-specific therapy at our center. The main reasons were liver impairment/BCLC-D stage, followed by frailty/old age and extrahepatic comorbidity. Baseline BCLC stage, absence of prior cirrhosis decompensation and diagnosis during the screening program were independently associated with increased survival.

IMPACT OF THE COVID-19 PANDEMIC IN THE DIAGNOSIS AND THERAPY OF SINGLE HEPATOCELLULAR CARCINOMA LESS THAN 3 CM IN A WESTERN COUNTRY

M. Garcia-Calonge¹, L. Martinez Cambor¹, H. González Sánchez¹, D. Muiño Domínguez¹, M. Celada Sendino¹, P. Flórez-Díez¹, A. Castaño¹, C. Alvarez Navascues¹, M.L. Gonzalez Dieguez¹, V. Cadahia Rodrigo¹, M. Rodriguez Garcia¹, M. Varela¹

Introduction: The aim of a cancer screening program is to reduce cancer-related mortality. For that reason patients with liver cirrhosis are enrolled into surveillance through biannual ultrasonography plus AFP to detect single hepatocellular carcinomas (HCC) less than 3 cm, best candidates to apply therapies with curative intent.

This study evaluates the impact of the COVID-19 pandemic in the time between detection, diagnosis, and treatment in patients with uninodular HCC ≤ 3 cm. The secondary objective is to assess the number and sequence of tests needed to achieve the final diagnosis.

Aims & Methods: Retrospective inclusion of consecutive patients with final diagnosis of single HCC ≤ 3 cm at our centre. Baseline clinical and analytical variables, date of detection, diagnosis, treatment / entry on the transplant waiting list and the sequence of tests performed (CT, MRI, biopsy) were recorded. Time to diagnosis (period from detection to diagnosis), time to treatment (from diagnosis to date of treatment/entry on the waiting list) and overall time (the sum of the above) were defined. The results were analyzed globally and divided into two periods: pre-COVID (Jan-15 to Feb-2020) and COVID (Mar-20 to the present).

Results: From Jan 27th 2015 to Dec 27th 2021, 128 patients of 685 had a final diagnosis of single HCC ≤ 3 cm, 18% in the pre-COVID era and 22% in the COVID era. Baseline characteristics: median age 64 years old, 84% males, aetiology: alcohol 46%, hepatitis C 39%, fatty liver disease 5%. Child-Pugh class A 86%, BCLC-0 29%, BCLC-A 71%. Median size 20.5 mm, median AFP 5 ng/mL. Only 74% were diagnosed within the screening program. Thermal ablation was applied in 58 patients, liver transplantation in 29, surgical resection in 21 and intraarterial therapy in 16. Twelve patients were left in natural history.

Diagnosis was reached by non-invasive criteria (imaging) in 112 patients and by biopsy in 16. The tests performed are shown in the TABLE 1. No statistically significant differences were found in the diagnostic capacity between multiphasic CT (67.6%) and dynamic MRI (73.3%), p -value 0.113. There were no differences in the diagnostic method (imaging versus biopsy) according to the size of the nodule (21.43 mm vs. 21.13 mm), p -value 0.199; nor in the number of studies performed according to the sequence (CT-MR-Biopsy vs MR-CT-Biopsy vs others), p -value 0.746.

There were no significant differences neither in the proportion of tumors diagnosed between 10-20 mm and 21-30 mm on the pre-COVID vs COVID era, p -value 0.80, nor in the therapy applied (surgical versus loco-regional, p -value 0.639).

Time to diagnosis, time to treatment, and overall time are shown in TABLE 2. Significant differences were found in the time to treatment between the pre-COVID and COVID eras: 8 weeks vs 11 weeks, p -value 0.038.

Conclusion: The COVID pandemic did not affect the proportion of single HCC ≤ 3 cm diagnosed, but it increased the median time from diagnosis to treatment.

Contact E-Mail Address: daniel.muinho@gmail.com

Introduction: Abstinence from alcohol is associated with a lower risk of hepatocellular carcinoma (HCC) in patients with compensated cirrhosis. However, the evolution of HCC in relation to the maintenance of alcohol abstinence is unknown.

Aims & Methods: Firstly, to determine the prevalence of alcohol consumption (AC) in HCC patients regardless of its etiology, presence of cirrhosis and previous AC. Secondly, to assess the usefulness of the AUDIT-C to detect any AC in HCC patients. Thirdly, to compare AUDIT-C with other commonly used methods (CAGE and biological markers). Alcohol was measured in standard alcohol units (1 containing 10 g of pure alcohol). Cross-sectional study including 100 consecutive HCC patients who attend the outpatient clinic. Exclusion criteria: hepatic encephalopathy at the moment of the interview, patients with HCC in the waiting list/ followed after liver transplantation. Clinical and sociodemographic variables were collected. AUDIT-C, CAGE questionnaire and collection of AC through a semi-structured survey were performed. Alcohol-free beer consumption was also registered, because this is associated with a higher rate of abstinence in patients without alcohol cessation.

Results: One hundred and two HCC patients were prospectively included. The average time to complete the interviews and questionnaires was 6 min per patient. No patient refused to enter the study. The median time from HCC diagnosis to the date of the study was 25 months (mean 33 months, range 1-72).

Alcohol was the underlying cause of HCC in 60 (58.8%) patients, alone or associated with hepatitis C, metabolic syndrome, hemochromatosis, etc. The prevalence of AC was 35.29% (n=36). The prevalence of alcohol-free beer consumption was 49.02% (n=50). Only 10 patients (9.8%) drank > = 10 standard alcohol units per week.

There were no differences in AC regarding age, educational level, concomitant medications (benzodiazepines, antipsychotic, antidepressant). However, those who lived in urban areas had a higher AC than those who lived in rural areas (p-value 0.04) and those who never smoked drank significantly less than smokers/ex-smokers (p-value 0.002).

AC was not different regarding the presence of underlying cirrhosis (p-value 0.35), alcohol aetiology (p-value 0.66) or in patients with active treatment vs those under surveillance of HCC relapse (p-value 0.32).

In contrast, AC was significantly higher in males (p-value <0.001), in patients diagnosed more than 1 year ago vs newly diagnosed (p-value 0.01), and in patients with early/very early BCLC stages vs others (p-value 0.05).

Regarding alcohol-free beer consumption, patients with alcohol etiology drank more than patients with other etiologies (p-value 0.0001), without differences regarding the HCC BCLC-stage (p-value 0.95).

The AUDIT-C score = > 3 (AUROC 0.849) predicts any AC with a sensitivity of 75% (95% CI 59.47-90.53) and a specificity of 84% (95% CI 74.70-94.05). Instead, the CAGE questionnaire and the analytical values [mean corpuscular volume, gamma-glutamyl transpeptidase] have a low sensitivity and specificity to discriminate against any AC in this population. CAGE > 1 [AUROC 0.626] sensitivity 72.22 (56.20-88.24) specificity 53.03 (40.23-65.83); CAGE > 2 [AUROC 0.615] sensitivity 47.22 (29.53-64.92) specificity 75.76 (64.66-86.85); MCV > 85 fL (AUROC 0.509) sensitivity 0.81 (68.94-96.08) specificity 21.2% (6.2-26.5); GGT > 40 IU/L (AUROC 0.487) sensitivity 75% (62.81-92.75) specificity 33% (18.46-42.15).

Conclusion: One third of HCC patients consume alcohol, however less than 10% consume more than 10 standard alcohol units per week. This consumption is higher in urban area, males, smokers/ex-smokers, in HCC patients diagnosed more than 1 year ago and in patients with early/very early staged tumors.

Patients with alcohol-related HCC consume more alcohol-free beer. The AUDIT-C score >= 3 discriminates against any alcohol consumption with a sensitivity of 75% and a specificity of 84% in this population.

WHAT CHANGED IN HEPATOCELLULAR CARCINOMA PRESENTATION IN THE LAST ELEVEN YEARS? COMPARISON OF TWO SEQUENTIAL TIME SERIES FROM A TERTIARY HOSPITAL

D. Conceição¹, J. Serrazina², I. Coelho Rodrigues², A. Craciun², J. Lemos Garcia¹, M. Moura², C. Freitas², S. Carvalhana², R. Tato Marinho², H. Cortez Pinto^{2,3}

Contact E-Mail Address: dgc1990@gmail.com

Introduction: Hepatocellular carcinoma (HCC) is the sixth most common cancer and the second leading cause of cancer mortality worldwide. Hepatitis B virus (HBV) and hepatitis C (HVC) remain, at present, the most important worldwide risk factors for HCC. Nevertheless, universal HBV vaccination of new-borns and effective treatments for chronic HCV infection, will likely decrease the rates of viral-associated HCC.

Aims & Methods: Our main aim was to analyse the changes in demographics and risk factors for HCC in the last 11 years.

Retrospective single-centre study, including all patients with HCC diagnosis between 2011 and 2021 who have been referred to the multidisciplinary hepatic tumours team, in a Portuguese tertiary hospital.

We compared two subgroups, according to the diagnosis date: Group 1 from 01/2011 to 06/2016; Group 2 from 07/2016 to 12/2021. We analysed the patients' demographics, the presence of liver cirrhosis aetiology of liver disease, Child-Pugh score, ECOG score; alcohol abstinence, ALBI score, the presence of portal vein thrombosis and the imaging appearance of HCC. We performed a T-test to analyse the mean difference between the two different groups.

Results: From the total of 173 patients included, 141 were males, with a mean age of 66 years at diagnosis. Liver cirrhosis was present in 96% of patients with alcohol as main aetiology (50%), followed by HCV infection (25%), HBV (10%) and non-alcoholic fatty liver (8%).

Comparing the two series (Table), during the same length of time, the more recent one had more patients referred, patients had a worst performance status and there were more patients non-Child A. In what regards aetiology there was a percentual increase in NASH and alcohol-related cases, and a decrease in HBV and HCV related cases, although it did not reach statistical significance.

	Total (173)	Group 1(64) 01/2011 to 06/2016	Group 2 (109) 07/2016 to 12/2021	p-value
Age at diagnosis (mean)	66	67	66	0,798
Gender				
Male	141 (82%)	47 (73%)	94 (86%)	0,036
ECOG 0	130	58 (90%)	72 (66%)	0,001
Liver cirrhosis	167	62 (96%)	105 (98%)	0,848
Child-Pugh score A	135	57 (89%)	78 (72%)	0,003
Liver cirrhosis main etiology				
alcohol	86	26 (41%)	60 (55%)	0,587
HCV	43	21 (33%)	22 (25%)	
HBV	17	8 (13%)	17 (10%)	
NASH	13	3 (4%)	10 (8%)	

Table.

Conclusion: There seems to a trend for a change of HCC aetiology, as expected, with a relative increase in fatty liver disease, either alcohol or non-alcohol related. The observation that patients are referred even with decompensated liver disease, and without a good performance status, may indicate that consideration is now given to the management of HCC even in more advanced states, since there is a large array of options, that that may include active palliative care.

CLINICAL CHARACTERISTICS AND RISK FACTORS OF EXTRAHEPATIC RECURRENCE AFTER HEPATECTOMY OF HEPATOCELLULAR CARCINOMA WITHOUT INTRAHEPATIC HEPATOCELLULAR CARCINOMA: A MULTI-INSTITUTIONAL 15-YEAR OBSERVATIONAL STUDY

W.R. Kang¹, J.H. Yoon¹, S.B. Cho¹, J.-Y. Hong¹, Y.S. Ko¹, S.K. Choi¹

¹Chonnam National University Hospital and Medical School, Department of Gastroenterology, Gwangju, Korea (Republic of)

Contact E-Mail Address: kwoorim89@hanmail.net

Introduction: Extrahepatic recurrence (EHR) is a well-known poor prognostic factor regarding hepatocellular carcinoma (HCC). Although EHR after hepatectomy of HCC may occur in high risk group of patients, little is known about EHR when there are no intrahepatic HCC. We investigated the clinical features and risk factors regarding EHR without remnant intrahepatic HCC at the time of EHR diagnosis.

Aims & Methods: This retrospective study included 1,069 treatment-naive patients who underwent curative hepatectomy for HCC at four tertiary academic hospitals from January 2004 to December 2019. Multivariate analysis via Cox-regression was performed to identify the variables associated with EHR.

Results: One hundred and sixty five patients developed EHR after hepatectomy of EHR during median follow-up duration of 4.01 years. Among patients with EHR, 58 patients (35.2%) had no viable intrahepatic HCC at EHR diagnosis. There was no significant difference in time to initial HCC recurrence and EHR development between patients group with intrahepatic HCC and without intrahepatic HCC at EHR diagnosis; 18.16 vs. 19.79 months, and 37.14 vs. 28.43 months (p=0.337), respectively.

Compared to patients with intrahepatic HCC at EHR, patients without intrahepatic HCC at EHR showed higher portion of worst Edmondson Steiner grade ≥ 3 (74.8 vs. 89.7, p=0.022), mUICC stage ($\geq III$) at 1st recurrence (45.8 vs. 74.1, p<0.001) and with lower mUICC T stage ($\geq III$) at 1st recurrence (34.6 vs. 13.8, p=0.004).

On multivariate analysis, presence of metastatic lymph nodes at pathologic examination, tumor necrosis, micro-/macro-vascular invasion, and HCC stage beyond Milan criteria was closely associated with EHR without intrahepatic HCC.

Conclusion: EHR without remnant viable HCC may occur in considerable number of patients after hepatectomy for HCC. Close monitoring for EHR is warranted in high risk group of patients despite of no HCC in liver.

Disclosure: Nothing to disclose.

P0764

EARLY EXTRAHEPATIC RECURRENCE AFTER HEPATECTOMY FOR HEPATOCELLULAR CARCINOMA SIGNIFICANTLY REDUCES SURVIVAL: A 15-YEAR OBSERVATIONAL STUDY

W.R. Kang¹, J.H. Yoon¹, S.B. Cho¹, Y.S. Ko¹, S.K. Choi¹

¹Chonnam National University Hospital and Medical School, Department of Gastroenterology, Gwangju, Korea (Republic of)

Contact E-Mail Address: kwoorim89@hanmail.net

Introduction: Extrahepatic recurrence (EHR) after curative hepatectomy for hepatocellular carcinoma (HCC) is closely associated with a poor prognosis. We investigated the features and mortality regarding early EHR and identified the predictive factors and its association with survival.

Aims & Methods: This retrospective study included 779 treatment-naive patients who underwent curative hepatectomy for HCC at two tertiary academic hospitals from January 2004 to December 2019. Multivariate analysis via Cox-regression was performed to identify the variables associated with EHR. Early EHR was defined as EHR development within 2 years after curative hepatectomy.

Results: Early EHR was diagnosed in 74 patients (9.4%) over a median follow-up period of 14.3 years, most commonly in the lungs (36.5%) followed by lymph nodes (32.4%), bone (20.3%), peritoneum (13.5%), and adrenal gland (13.5%). The median time to EHR was 0.73 year in early EHR group and 4.87 years in non-early EHR group.

The median survival duration of early EHR group, non-early EHR group, and non-EHR group was 3.05, 6.62 and 11.53 years, respectively (p<0.001) and early EHR was significantly associated with survival duration (Exp(B)=7.897, p<0.001).

On multivariate analysis, serum albumin < 4.0g/dL, serum alkaline phosphatase > 100U/L, surgical margin involvement, venous and/or lymphatic involvement, satellite nodule, tumor necrosis at pathology, sum of tumor size ≥ 7 , and macrovascular invasion at diagnosis were predictive of early EHR.

As the numbers of the risk factors increased, the probability of early EHR and the overall mortality rate inclined exponentially. (Probability of early EHR; 0/1/2/3/4/5≥ risk factors, 4.1/5.0/13.2/21.1/42.5/44.6%, respectively, median survival duration; 0/1/2/3/4/5≥ risk factors, 12.1, 11.5, 8.4, 7.0, 5.0, 2.7 years, respectively).

Conclusion: Early EHR significantly deteriorates the prognosis of HCC patients and our risk factors clarifies the clinical course of EHR and could improve the follow-up strategy to improve outcomes in high risk patients.

Disclosure: None.

Introduction: It has been clinically shown that molecular targeted agents (MTAs) targeting vascular endothelial growth factor (VEGF) and other molecules can significantly reduce tumor blood flow on CT images. The modified response evaluation criteria in solid tumors (mRECIST) have been developed to overcome the limitations of standard RECIST criteria in assessing the response to therapy of HCC, including evaluation of tumor blood flow.

Currently, mRECIST has become the standard tool for the measurement of radiological endpoints in the early/intermediate stages of HCC. The mRECIST has been proven to capture higher objective response rates in tumors treated with molecular therapies, and these responses have been shown to be independently associated with better survival.

Although evaluation using mRECIST is an excellent tool, it is not clear whether the site of decreased “early enhancement” in the tumor (suggestive of a complete response (CR) or partial response (PR) by mRECIST evaluation) after MTA treatment is pathologically necrotic or viable.

Moreover, the future course of HCC patients with CR according to mRECIST following MTA therapy is uncertain. In terms of continuing MTA treatment or predicting the course of treatment, it is clinically important to determine whether the area in the HCC with a CR after MTA treatment according to mRECIST pathologically consists of necrotic or viable tissue.

Furthermore, it is significant to determine the criteria that might predict subsequent tumor progression following a diagnosis of CR with MTA therapy.

Aims & Methods: In this study, we attempted to identify CTav that can be used to identify necrosis in HCC tumors after lenvatinib treatment (N-CTav), and to clarify the association between the tumor N-CTav occupancy rate and maintenance of CR following lenvatinib treatment.

We compared CTav in arterial phase CT images with postoperative histopathology in four patients who underwent HCC resection after lenvatinib treatment, to determine CTav thresholds indicative of histological necrosis (N-CTav). Next, we confirmed the accuracy of the determined N-CTav in 15 cases with histopathologically proven necrosis in surgical specimens. Furthermore, the percentage of the tumor with N-CTav, i.e. the N-CTav occupancy rate, assessed using Image J software in 30 tumors in 12 patients with CR out of 571 HCC patients treated with lenvatinib, and its correlation with local recurrence following CR were examined.

Results: Receiver operating characteristic (ROC) curve analysis revealed an optimal cut-off value of CTav of 30.2 HU, with 90.0% specificity and 65.0% sensitivity in discriminating between pathologically identified necrosis and degeneration, with a CTav of less than 30.2 HU indicating necrosis after lenvatinib treatment (N30-CTav).

Furthermore, the optimal cut-off value of 30.6% for the N30-CTav occupancy rate by ROC analysis was a significant indicator of local recurrence following CR with 76.9% specificity and sensitivity (area under the ROC curve; 0.939), with the CR group with high N30-CTav occupancy (≥ 30.6%) after lenvatinib treatment showing significantly lower local recurrence (8.3% at 1 year) compared with the low (< 30.6%) N30-CTav group (P<0.001, 61.5% at 1 year).

Conclusion: The cut-off value of 30.2 HU for CTav (N30-CTav) might be appropriate for identifying post-lenvatinib necrosis in HCC, and an N30-CTav occupancy rate of >30.6% might be a predictor of maintenance of CR. Use of these indicators have the potential to impact systemic chemotherapy for HCC.

Introduction: Hepatocellular carcinoma (HCC) is one of the most common malignancies and a leading cause of cancer-related death worldwide. Indeed, we need a novel tumor marker other than AFP for early detection and to improve the outcome. Serum thioredoxin is a promising protein involved in the pathogenesis of many malignancies.

Aims & Methods: The study aims to evaluate serum thioredoxin and its gene polymorphism in HCC in cirrhotic patients due to HCV infection. Three hundred fifty patients with HCC, 350 patients with chronic liver diseases, and 300 healthy controls were enrolled in our study. Serum thioredoxin level was measured by ELISA and a molecular study of thioredoxin domain-containing 5 (TXNDC5) gene polymorphism (rs1225943) polymorphism using real-time PCR by Taqman allele discrimination was done for all subjects.

Results: Our study revealed a significant increase in serum thioredoxin levels in patients with HCC compared to chronic liver diseases and healthy controls. Using the receiver operating characteristic (ROC) curve at the area under the curve (AUC) 0.917 and a cut-off value of >14.6 U/ml, our overall sensitivity and specificity for the HCC group over the other groups

were 86 % and 92.15%, respectively with 92.2% positive predictive value and 54.9% negative predictive value. The molecular study of TXNDC5 gene polymorphism (rs1225943) polymorphism revealed no significant difference between the studied groups.

Conclusion: Serum thioredoxin may be used as a promising tumor marker for HCC. Future researches are needed to assess its use as a single or combined with other markers in the diagnosis and follow-up of the patients after interventions.

Disclosure: Nothing to disclose.

Contact E-Mail Address: dr.ibtissamkhalif@gmail.com

Introduction: Paroxysmal nocturnal hemoglobinuria (PNH) is a genetic pathology due to a clonal acquired somatic mutation of the PIGA gene in one or more hematopoietic stem cells, responsible for a partial or complete deficiency of glycosylphosphatidylinositol (GPI) anchor synthesis. The prognosis of this pathology is particularly related to thromboembolic complications.

The aim of our work was to specify the prevalence of this pathology in patients with vascular liver diseases (VLD) and specifying their epidemiological, clinical, therapeutic profiles, and outcomes.

Aims & Methods: It was a retrospective and descriptive study conducted over 19 years, from 2003 to march 2022, including all patients followed for vascular liver diseases, and having the presence of a positive PNH clone. The PNH clone was searched by flow cytometry to demonstrate a deficiency in GPI-linked markers on a maximum of two distinct bloodlines, in addition to an exhaustive thrombosis work-up (thrombophilia test, antiphospholipid syndrome, JAK2 mutation, neoplasia...)

Results: Out of 119 patients with vascular liver diseases, six patients had the presence of an erythrocytic and granular PNH clone, which represented a prevalence of 5.04%, including 2.5% for Porto-sinusoidal vascular disease (PSVD), 1.7% for portal cavernoma, and 0.84% for Budd Chiari syndrome (BCS).

The mean age was 42.8 years (24-65 years), and all were female.

The circumstances of discovery were variable, the pain of the left hypochondria in 66% of the cases (n=4), an upper digestive hemorrhage in 50% of the cases (n=3), and one only patient had abdominal distension (16.6%). Clinical examination revealed an enlarged spleen in 83.4%, collateral venous circulation in both flanks in 50%, and the thorax in 16.6%, and one patient only had ascites grade II. Clinical examination of the liver revealed a firm liver in 50%, a cirrhotic-looking liver in 33.4%, and a clinically normal liver in 16.6%.

Abdominal ultrasound coupled with Doppler showed a heterogeneous liver with irregular contours in 50% of cases, chronic portal thrombosis with portal cavernoma in 33.4% of cases, and BCS in 16.6% of cases.

All our patients (n=6) had portal hypertension (PH). The upper endoscopy showed endoscopic signs of PH (esophageal varices with red signs) in all patients.

Liver function tests were normal in 67% of cases, and in 33% of cases, they showed isolated anicteric cholestasis. Liver biopsy showed obliterative portal venopathy in 33% (n=2) and sinusoidal dilatation in 17% (n=1).

The etiological workup revealed an isolated PNH clone in three patients, associated with a combined protein S and C deficiency in two patients, and associated with an antiphospholipid syndrome in one patient.

The treatment was symptomatic (beta-blockers and esophageal varicose vein ligation) for all patients, AVK anticoagulation in 33% of patients (n=2); however, due to lack of resources, none of the patients was put on the specific treatment Eculizumab.

The patients were monitored every six months, with good evolution, marked by the absence of AVK-related hemorrhagic events, and eradication of esophageal varices in all patients (100%).

Conclusion: The presence of the PNH clone is a rare cause of vascular liver disease, in our small series the prevalence was 5.04%, dominated by intrahepatic block (PSVD) in 2.5% of cases.

In the setting of thrombosis, the search for PNH clone should be systematic, and the main treatment relay on Eculizumab, because anticoagulant treatment alone does not reduce the thrombotic risk in patients with PNH.

Disclosure: Nothing to disclose.

P0768

LIVER VASCULAR DISEASE AND MYELOPROLIFERATIVE SYNDROMES

Z. Amzal¹, M. Borahma², M. Kadiri³, F. Chabib⁴, N. Lagdali¹, C. Berhili¹, I. Benelbarhdadi¹, F.Z. Ajana⁴

¹Mohammed V University, Department of Hepatogastroenterology, Medecine C, CHU Ibn Sina, Rabat, Morocco, ²Mohammed V University, Ibn Sina Hospital, Department of Gastroenterology C, Rabat, Morocco, ³Ibn Sina Hospital, Rabat, Rabat, Morocco, ⁴CHU Ibn Sina, SMMAD, Moroccan Society of Digestif Diseases, Rabat, Morocco

Contact E-Mail Address: Zinebamzal199@gmail.com

Introduction: Myeloproliferative disorders are a group of diseases characterized by clonal and malignant proliferation of one or more myeloid cell lines. The platelet and leukocyte changes characteristic of these syndromes facilitate the formation of Platelet-leukocyte aggregates and therefore the development of venous and arterial thrombosis. it may involve Hepatic venous and the entire splanchnic system (portal vein, intrahepatic vessels, hepatic vein).

Our work aimed to report the epidemiological, clinical, etiological, therapeutic profiles, and outcomes of our patients.

Aims & Methods: This was a retrospective, descriptive study over 9 years, from 2013 to March 2022, and including all patients with portal hypertension (PH) by suprahepatic block (Budd Chiari), intrahepatic in the context of Liver vascular diseases (LVD), and infrahepatic (portal thrombosis).

Results: Out of 119 patients followed for liver vascular disease, 17 patients had a myeloproliferative syndrome, which represented a prevalence of 14. The average age was 44.5 years, with extremes ranging from 20 to 74 years, with a sex ratio F/H = 1.83% with a clear female predominance of 65% (n=11), the circumstances of discovery were variable: digestive hemorrhage and abdominal pain in 59%(n=10), jaundice in 24%(n=4), ascites in 18%, the clinical examination revealed the presence of splenomegaly in 94%(n=16), collateral venous circulation in 47%(n=8). Forty-seven percent (n=8) of our patients had an overloaded liver, 35% (n=6) normal liver, and 6% liver with a cirrhotic appearance.

Ultrasound coupled with Doppler showed chronic portal thrombosis with portal cavernoma in 35% (n=6), acute thrombosis in 29% (n=5), and Budd Chiari syndrome in 24% (n=4). The liver was heterogeneous in 47% (n=8),

dysmorphic in 29% (n=5) and normal in 24% (n=4). All our patients were in the stages of the PH, and the block 47% (n=8) was infrahepatic, 29% (n=5) intrahepatic and 24% (n=4) suprahepatic.

Liver biopsy confirmed intrahepatic origin (Porto-sinusoidal vascular disease (PSVD)) in 24%. The Upper endoscopy showed signs of PH esophageal varices in 95%, gastroesophageal in 59% (n=10) and isolated gastric varices in 53% (n=9). The workup showed cholestasis in 47% of cases (of which 3 patients had icteric cholestasis), cytolytic in 35%, anemia in 88%, polycythemia in 12%, hyperleukocytosis in 59% and thrombocytosis in 24%. The etiological workup (bone marrow biopsy, and JACK 2 mutation) were performed in all our patients. The bone marrow biopsy revealed the presence of primary myelofibrosis in 41% (n=7), chronic myeloid splenomegaly, and essential thrombocythemia in 18% (n=3), and Polycythemia vera in 12% (n=2).

The JAK2 gene mutation was positive in 53% (n=9). The treatment was mainly based on symptomatic treatment (beta-blockers, esophageal varices ligation if red signs, anticoagulation treatment in 77% (n=13), specific treatment of myeloproliferative syndrome based on hydroxyurea capsules in 47% (n=8).

The evolution was marked by the death of 2 patients before treatment (one patient by bleeding and another by acute myeloid leukemia at the stage of acutisation) and 1 patient after the beginning of the treatment (following an acute hepatocellular insufficiency), the rest of the patients were followed up twice a year with good clinical and biological evolution.

Conclusion: In our series, the prevalence of myeloproliferative syndrome was 14.28%. Primary myelofibrosis was the most dominant etiology. The outcomes of our patients were favorable under symptomatic and specific treatment.

Disclosure: Nothing to disclose.

Introduction: Biological abnormalities exposed to thrombotic risk are multiple, the most commonly explored are constitutional coagulation inhibitor deficiencies. Our study aimed to determine the prevalence of constitutional coagulation inhibitor deficiencies in liver vascular diseases (LVD) and the different sites of these thromboses.

Aims & Methods: This was a retrospective, descriptive, single-center study conducted over 29 years from 2010 to April 2022, including 119 patients followed in our department. All our patients benefited from an abdominal echography completed by an abdominal CT angiography.

Results: A total of 119 patients followed for LVD, the prevalence of constitutional coagulation inhibitor deficiencies was 40.35% (n=46). The average age of our patients was 39.86 ± 12.69 years with a sex ratio F/H of 2.8. Two patients had a personal history of thrombosis, the first one had a femoral and cerebral thrombosis, and the second one had a deep vein thrombosis (DVT).

Abdominal pain was present in 56.5% (n=26) followed by digestive bleeding in 54% of cases (n=25). The clinical examination showed signs of Portal hypertension including splenomegaly in 85% (n=39), CVCs in 45.6% (n=21)

and ascites in 13% (n=6). The liver was normal in 64% (n=44), and cirrhotic in 8.7% (n=4). CT angiography showed portal thrombosis in 32.7% of cases, all of which were in the portal cavernoma stage, and Budd Chiari syndrome in 26% of cases.

Liver biopsy showed Porto-sinusoidal vascular disease (PSVD) in 41.3% of cases (n=19), five of which were complicated by portal cavernoma (10.8%). An upper endoscopy was performed for all patients and showed hypertensive gastropathy in 50% (n=23), esophageal varices grade I in 13%, grade II in 34.4%, grade III in 37%, and Gastric varices in 47.7%.

The thrombophilia etiology workup revealed a protein S (PS) deficiency in 82.6% of cases (n=38), a protein C (PC) deficiency in 69.5% of cases (n=32), antithrombin (AT) deficiency in 19.5% of cases (n=9) and a Factor V mutation in 4.3% of cases (n=2) complicated to SBC and PSVD.

A combined deficiency was found in 71.7% of cases (n=33). Half of the cases (n=23) were deficient in PC and PS, PS and AT in 4.3% of cases (n=2), and deficient in PC and AT was found in 8.7% of cases (n=4).

Three factors (PS, PC, and AT) were found in 8.7% of cases (n=4). In our series, 37% of the cases (n=17) received anticoagulant treatment, 17.5% of which were on oral anticoagulation (n=8) and 19.5% were on vitamin K antagonists (VKAs) (n=9). No cases of re-permeabilization were found, but no cases of thrombosis extension were noted under treatment. Hemorrhagic decompensation was noted in 6.5% of cases (n=3), two of which died.

Conclusion: Constitutional coagulation inhibitor deficiencies are frequent causes of vascular liver disease. In our series, they had a prevalence rate of 40.35%.

Disclosure: Nothing to disclose.

ORAL MUCOSAL HEALTH IN LIVER TRANSPLANT RECIPIENTS

A. Santonicola¹, S. Camera¹, M. Mercurio¹, F. Spirito¹, L. Sisalli¹, M. Amato¹

¹University of Salerno, Department of Medicine, Surgery and Dentistry, Scuola Medica Salernitana, Salerno, Italy

Contact E-Mail Address: antonellasantonicola83@gmail.com

Introduction: Liver transplantation (LT) is the therapeutic option of choice for acute and chronic end-stage liver disease. However, chronic immunosuppressive treatment may impact the oral health of LT recipients, although data are limited.

Aims & Methods: To evaluate the prevalence of oral mucosal lesions (OMLs) in a cohort of LT patients.

We recruited 68 LT recipients (79.4% men, mean age 64.54±10.1 years, mean BMI= 26.88±6.48 Kg/m²) from the Liver Transplant Follow-up Center of the University of Salerno. We collected demographic characteristics (gender, age, smoking habits), anthropometric data (weight, height, and BMI), the prevalence of comorbidities (hypertension, dyslipidemia, type II diabetes mellitus, chronic kidney disease, osteoporosis), LT data, and type of immunosuppressive therapy.

All patients underwent a clinical oral examination and laboratory tests. We compared data obtained with those of 34 controls, similar in age, sex, and smoking habits, recruited from the Odontostomatology clinic.

Results: 62/68 (91.2%) LT patients showed oral mucosal lesions (OMLs), in particular 40(58.8%) patients parodontopathy; 25(36.8%) Candidiasis; 20(29.4%) reduced salivary flow; 15 (22.1%) atrophic tongue, 13(19.1%) recurrent aphthous stomatitis; 10(14.7%) fissured tongue; 5(7.4%) angular cheilitis, 3(4.4%) keratotic lesions, and 1(1.5%) lichen planus-like lesions. The prevalence of OMLs was statistically higher in LT patients than in the controls (91.2% vs. 61.8%, p<0.001). In particular, LT patients showed a significantly higher prevalence of recurrent aphthous stomatitis, hypostomia, and plicated tongue than controls (p<0.05 in all cases).

The prevalence of OMLs was not significantly different in LT patients on treatment with calcineurin inhibitors (cyclosporine A and tacrolimus) compared to mTOR inhibitors (everolimus) ($p=0.33$). There was no correlation between LT time and the prevalence of OMLs ($p=0.75$). Non-smoker LT patients showed a significantly higher prevalence of recurrent aphthous stomatitis than smokers (25% vs. 0%, $p=0.026$).

Conclusion: There is a high prevalence of OMLs in LT recipients. In particular, parodontopathy is the most frequently diagnosed lesion. LT patients showed a significantly higher prevalence of OMLs than controls, probably due to chronic immunosuppressive therapy. However, the type of immunosuppressive drugs and the time from LT do not influence the prevalence of OMLs. A regular oral examination should be recommended in all LT patients.

Disclosure: Nothing to disclose.

P0771

THE ASSOCIATION BETWEEN COFFEE CONSUMPTION AND NON-ALCOHOLIC FATTY LIVER DISEASE: A CASE-CONTROL STUDY

N. Anass¹, O. Zineb¹, M. Meryem², F. Rouibaa³

¹Faculty of Medicine, Mohammed VI University of Health Sciences, Gastroenterology, Casablanca, Morocco, ²Faculty of Medicine, Mohammed VI University of Health Sciences, Casablanca, Morocco, ³Military Hospital Mohamed V-Souissi University, Rabat, Morocco

Contact E-Mail Address: anas21nadi@gmail.com

Introduction: Non-alcoholic steatotic liver disease (NAFLD) is the most common chronic liver disease worldwide. No pharmacological treatment is approved for the treatment of this disease, and all therapeutic recommendations are based on compliance with hygienic-dietary rules, weight loss, and physical activity.

Coffee is the most consumed beverage in the world and its consumption is said to reduce mortality and the risk of metabolic syndrome and type 2 diabetes. Several studies have suggested a protective role for coffee against chronic liver disease, hepatic fibrosis, and hepatocellular carcinoma; however, this finding comes from observational studies and remains controversial, particularly in the presence of confounding factors such as diabetes and low alcohol consumption.

Aims & Methods: This study aims to assess the association between coffee consumption and the prevalence and severity of NAFLD in a non-diabetic population who has never consumed alcohol. Secondly we aimed to study the other factors associated with NAFLD.

This case-control study was conducted from December 2020 to December 2021 at Cheikh Khalifa International University Hospital, Casablanca, Morocco. The target population included 157 participants seeking care in the outpatient and inpatient units of the gastroenterology and internal medicine department. Cases were defined by the presence of steatosis on liver ultrasound, the severity of which was assessed by the Bright Liver Steatosis Score. Controls were defined by the absence of steatosis on liver ultrasound. All patients with cytotoxicity and/or cholestasis had an etiological investigation (serologic testing for HBV and HCV infection, autoimmune investigation). All participants underwent liver ultrasound, clinical assessment (blood pressure, waist circumference and BMI), and biological assessment (blood count, lipid profile test, liver function tests, FBG). Dietary assessment was conducted using a food frequency questionnaire, coffee consumption was dichotomized into present or absent and then categorized according to the number of cups consumed per day.

Results: The study included 94 NAFLD and 63 controls, the two groups were comparable in demographic characteristics. The means of SBP, BMI, waist circumference, AST, ALT, Gamma-GT, Alkaline Phosphatase, and FBG were significantly higher in the NAFLD group.

The study of the association between coffee consumption and NAFLD showed a significant decrease in the risk of its occurrence ($OR=0.39$) and its severity ($OR=0.32$) in coffee consumers, mainly in those consuming 3 or more cups. In multivariate analysis, the following factors were associated with increased prevalence of NAFLD: metabolic syndrome, high mean levels of Alkaline phosphatase, Gamma-GT, ALT, FBG, BMI, and waist circumference. However, Green tea consumption was not associated with either prevalence or severity of NAFLD ($OR=1.02$, $p=0.82$).

Conclusion: The relationship between coffee and steatotic liver disease is not fully understood, and the results of studies are disparate. Our work suggests that coffee plays a protective role against the prevalence and severity of NAFLD. As coffee is an accessible and relatively inexpensive beverage, it could be included in dietary rules for a healthier diet and implemented as a preventative strategy if future studies were to confirm our data. Further prospective studies are needed to establish a cause-effect relationship between coffee and NAFLD.

Contact E-Mail Address: drmerveeren@gmail.com

Introduction: Hepatitis C virus (HCV) infection is a major public health problem. According to 2015 data, approximately 71 million people have chronic HCV viremia globally. It is one of the leading causes of liver-related morbidity and mortality in the world. The seroprevalence of anti-HCV in our country has been detected 0.5-1%. Due to its silent progress many patients may be unaware of the situation.

Aims & Methods: In our study, we aimed to determine the rate of the anti-HCV positive patients who were able to achieve viral elimination and also the number of the patients who were possibly under-diagnosed or lost to follow-up. Subjects who had anti-HCV positivity between 2014-2019 and older than 18 have been reviewed retrospectively.

The data of the patients were recorded and patients referred for further evaluation and accessed to the treatment and the ones who achieved sustained viral response after twelve weeks from the end of the therapy (SVR12) were identified.

Results: There were 7260 anti-HCV positive patients in 5-years period. 5685 of them were tested for HCV viremia (78.3 %). HCV-RNA was positive in 1620 of them (22.3 %), corresponding to 28.4 % of the patients who have been tested for HCV-RNA. Among the patients with HCV-RNA positivity, 1288 of them were tested for HCV genotype (17.7 %). Only 848 of them could access to treatment (11.6 %). The patients were treated with either an interferon-based regimen (n= 143, 16.9 %) or direct acting antivirals (n= 705, 83.1%). Only 607 of the patients were tested for SVR12 and 568 of them could achieve viral clearance.

Conclusion: The World Health Organization has been set international targets for the elimination of HCV infection by 2030, which is a public health threat. According to our study, there are significant deficiencies in several stages of the treatment cascade, which is consistent with world data. Recently, highly efficient oral direct acting antivirals have made the treatment of HCV infection more practical. Both improving patients' awareness and knowledge of all physicians is essential to prevent losses and delays in the diagnosis and treatment of HCV infection.

Disclosure: Nothing to disclose.

INCREASING OF GUT BACTERIAL BILE SALT HYDROLASE ACTIVITY BY PROBIOTIC LACTOBACILLUS PLANTARUM IN PATIENTS WITH DYSLIPIDEMIA: A RANDOMIZED STUDY

A. Neverovsky¹

¹Bogomolets National Medical University, Internal Medicine #1 with a course of Gastroenterology, Kyiv, Ukraine

Contact E-Mail Address: artemneverovskiy@gmail.com

Introduction: Supplementation with probiotic bacteria may be effective in the treatment of hypercholesterolemia due to different mechanisms. One of them is a modification of bile acid metabolism by gut bacterial bile salt hydrolase (BSH).

Aims & Methods: Aim of study was to assess the effectiveness of additional supplementation with probiotic Lactobacillus plantarum (LP) in modification of gut bacterial BSH relative activity (RA) in patients with dyslipidemia. The trial included 77 patients aged 40-74 years with dyslipidemia that were randomly divided in two groups: case group (n=41) that were treated with combination of simvastatin 20 mg once daily and probiotic LP in the amount of 2×10^9 CFU once daily and control group (n=36) that were treated with simvastatin monotherapy 20 mg once daily during 12 weeks.

Fecal samples were collected for assessment of RA of gut bacterial BSH using the ultra-performance liquid chromatography-mass spectrometry (UPLC-MS) method. For determining the differences between groups, the unpaired, paired t-tests, Wilcoxon signed-rank and matched pairs tests were used.

Results: The baseline demographic and clinical characteristics were not different between trial's groups. It was shown that baseline levels of RA of gut bacterial BSH were not significantly different between case group (0,1 (0,06-0,14) U/ml) and control group (0,086 (0,05-0,13) U/ml), p=0,4. But after 12 weeks of treatment it was revealed that RA of gut bacterial BSH: in case group began significantly higher ($0,2 \pm 0,07$ U/ml) comparing with baseline levels, p<0,001; in control group there was no difference between baseline levels and after 12 weeks of investigation (0,085 (0,05-0,14) U/ml), p=0,53. RA of gut bacterial BSH after 12 weeks of trial was significantly higher in case group comparing to control group, p<0,001.

Conclusion: Additional supplementation with probiotic Lactobacillus plantarum during 12 weeks was effective in increasing of relative activity of gut bacterial BSH in patients with dyslipidemia.

EFFECT OF ANTIBIOTICS AND ERCP STENT PLACEMENT IN THE BILIARY MICROBIOME IN THE CHOLEDOCHOLITHIASIS PATIENTS WITH ACUTE BILIARY INFECTION

Y.-C. Chen¹, T.-K. Fang¹, X.-H. Huang¹, T.-Y. Chiang¹, Y.-N. Huang¹, Y.-B. Lu¹, Y.-C. Weng¹

¹Xiamen Chang Gung Hospital, Department of Digestive Disease, Xiamen City, China

Contact E-Mail Address: yuchieh.j.weng@gmail.com

Introduction: It is generally believed that endoscopic retrograde cholangiopancreatography (ERCP) is the vital treatment for those choledocholithiasis patients with acute biliary infection. However, administration of antibiotics before ERCP treatment is usually the clinical routine medicine therapy for acute biliary infection.

In addition, endoscopic sphincterotomy in ERCP is common procedure prior to the retrieval of common bile duct stones. Some studies indicated that endoscopic sphincterotomy (EST) damaged the function of sphincter

of Oddi, leading to further regurgitation of the duodenal contents and gut bacteria into the bile duct, biliary tract infection due to biliary microbiome alteration and choledocholithiasis recurrence.

However, there is lacking of study to prove the effect of antibiotic agents and ERCP biliary plastic placement procedure whether affect the variety of biliary microbiome. Therefore, in this study, we try to investigate whether ERCP biliary plastic stent placement and usage of antibiotics affect the characteristic of biliary microbiome.

Aims & Methods: 10 choledocholithiasis patients with acute biliary infection, diagnosed basing on Tokyo guideline 2018(TG18), were recruited at Xiamen Chang Gung Hospital from 2019 to 2021. At beginning of admission, all patients were administrated antibiotic agents (3rd generation ciprofloxacin or quinolone) for the medical therapy of acute biliary infection. The bile samples were collected during the 1st time ERCP treatment. And we all preformed EST for stone retrieval and biliary plastic stent was placed to avoid the complication of biliary obstruction related to blood clot and the complication of post-ERCP cholangitis.

The 2nd time ERCP was executed to remove the biliary plastic stent and collect the bile samples in these same patients without usage of antibiotics at least over 21 days. The method of DNA extraction and 16s rRNA gene sequencing of bile samples was used to analyze and compare the biliary microbiome composition between 1st and 2nd time ERCP group.

Results: The result revealed that Firmicutes (44.7%), Actinobacteriota (15.9%), Bacteroidota (13.5%) and Proteobacteria (11.2%) were the most dominant phyla in these 20 bile samples. The beta-diversities of bile juice from 2nd time ERCP group were significantly different to 1st time ERCP group (Anosim; R= 0.2037; p=0.001), but the alpha-diversities were comparable (Chao1; p=0.2899). LefSe results showed that 1st time ERCP group had higher abundance in Streptococcus (LDA=4.02; p=0.028) and Cyanobacteria (LDA=4.38; p=0.049), while the 2nd time ERCP group had higher levels of Blautia(LDA=4.08; p=0.018)and Gammaproteobacteria (LDA=4.16; p=0.049).PICRUST2 analysis revealed that KEGG Level 2 of 1sttime ERCP group was significantly difference to 2nd time ERCP group(Anosim; R=0.1867; p=0.012).

Conclusion: Our study showed that under the treatment of antibiotics and ERCP plastic stent placement, the choledocholithiasis patients with acute biliary infection demonstrated microbial dysbiosis with a significant reduction in microbial beta-diversity in bile of 1st time ERCP group comparing to the 2nd time ERCP group. In addition, the Streptococcus and Cyanobacteria were abundant in the 1st ERCP group; microbiota functional capacities with significant differences between 1st and 2nd time ERCP group which suggested that they can be used as predictive indicators for acute biliary infection in choledocholithiasis patients.

EFFECTS OF BILE ACIDS ON METABOLIC PROFILE IN OBESE ANIMAL MODEL

C.H. An¹, K.H. Ryu¹, H.Y. Chon¹, D.S. Kim¹, S.H. Lee¹, Y.W. Choi¹
¹Konyang University College of Medicine, Gastroenterology, Daejeon, Korea (Republic of)

Contact E-Mail Address: anchy92@naver.com

Introduction: Microbiotas in the body affect metabolism. Some studies show that sterile laen mouse receiving intestinal microbiota from obese mouse gained more weight. Bile acids are inhibitor of intestinal microorganisms. Each of bile acids have a varying degree of hydrophobicity and pH, so the influence on microbiotas also varies.

Therefore, the administration of bile acids are expected to change the microbial environment in the intestine microbiota and would affect metabolic indicators including body weight.

Aims & Methods: The first study was conducted for 8 weeks by comparing the weight change of three groups: control, high fat diet (HFD) and HFD + ursodeoxycholic acid (farenoid X receptor[FXR] antagonist; UDCA).

The second study compared the two groups of HFD, HFD + UDCA for 5 weeks to confirm reproducibility, and as another control, HFD + obeticholic acid(FXR agonist; Ocaliva®) was added. In the study, serum metabolic indices were evaluated and homeostatic model assessment for insulin resistance(HOMA-IR) were also measured.

Results: Compared to the control group, the weight gain rate of the HFD group was significantly increased, but the increase was slowed in the group receiving the UDCA together. In the second experiment, although the rate of weight gain was slowed in the group treated with obeticholic acid, it was less than that of UDCA.

Compared to the high-fat diet alone group, liver enzymes were significantly decreased in the UDCA group. There was no statistically significant difference in blood glucose in the UDCA group, but significantly decreased in the obeticholic acid group. HOMA-IR also decreased in the UDCA group, but more significantly in the obeticholic acid group.

Both UDCA and obeticholic acid co-administration with high-fat diet group showed an increased Firmicutes/Bacteroidetes ratio in the intestinal microbiota, more clearly observed in the obeticholic acid group.

Conclusion: Coadministration of obeticholic acid slowed weight gain but was less potent than UDCA. In high-fat diets, UDCA administration had a positive effect on values reflecting hepatobiliary inflammation. UDCA did not have a positive effect on blood glucose or lipid level but reduced insulin resistance. Obeticholic acid administration had a strong positive effect on blood sugar, lipid levels, and insulin resistance in high-fat diets than UDCA. The experimental results showed that the intestinal Firmicutes/Bacteroidetes ratio increased in the UDCA and obeticholic acid co-administration group, Contrary to past reports.

This result is paradoxical to the slowing of weight gain by bile acid administration. In conclusion, weight gain due to high fat diet may be slowed down by bile acids. However, It is not likely to be due to microbial changes in the intestinal tract but is likely to be involved in the direct effect of body metabolism of bile acids.

DELAYED VERSUS EARLY LAPAROSCOPIC CHOLECYSTECTOMY POST PERCUTANEOUS CHOLECYSTOSTOMY. DOES IT MATTER?

K. Abdelsaid¹, M. Hassan¹, B. Jayasanakar¹, Y. Abdul Aal¹

¹Maidstone and Tunbridge Wells NHS trust, General Surgery, Tunbridge Wells, United Kingdom

Contact E-Mail Address: Kirolos.Abdelsaid@nhs.net

Introduction: Percutaneous cholecystostomy (PC) is an effective option for high risk and delayed presented Acute cholecystitis (AC). However, the optimal timing for subsequent laparoscopic cholecystectomy (LC) as a definitive treatment remains controversial.

Aims & Methods: This study includes 41 patients who underwent LC following PC for severe AC. We compared the length of tube insertion, the period from PC till LC and the period from PC removal till LC against comorbidities, another attack of AC, subsequent pancreatitis/jaundice and operative difficulties in terms of intraoperative adhesions, drain insertion, conversion to open, length of operation.

To compare the effectiveness, possible advantages, and complications of early cholecystectomy versus delayed cholecystectomy following Percutaneous Cholecystostomy in patients with Acute Cholecystitis.

Results: The median time of the length of tube insertion was 36 days (range 5-208), while the median time of PC insertion till LC was 144 days (range 31-744), and for the period from PC removal till LC was 78 days (range 0-714).

In addition, patients with prolonged tube insertion (more than a month) showed a higher risk of developing subsequent pancreatitis and jaundice ($P=0.04$). At the same time, intraoperative adhesions were associated with prolonged time from tube insertion to operation (more than four months). However, there was no significant association between the length of tube insertion, period from PC insertion till LC, period from PC removal till LC, and other studied parameters.

Conclusion: Prolonged time of PC insertion and prolonged time from PC insertion till LC in patients with AC have a higher risk of pancreatitis and surgical difficulties. Further studies, including a more significant number of patients sample, are warranted to confirm the outcomes and determine the optimal time of LC following PC in those patients.

RISK FACTORS ASSOCIATED WITH HEMORRHAGIC AND THROMBOEMBOLIC COMPLICATIONS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP)

J. Castro Rodríguez¹, R.M. Alejandro Altamirano¹,

M. Pleguezuelo Navarro¹, F.J. Serrano Ruiz¹, A.J. Hervás Molina¹

¹Hospital Universitario Reina Sofía, Department of Gastroenterology, Córdoba, Spain

Contact E-Mail Address: jcastorodriguez01@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is a growing procedure in the diagnosis and treatment of biliary and pancreatic obstructive pathologies. Among its complications are: pancreatitis (the most frequent 1.3-9.7%), hemorrhage (0.76-2.3%) and others such as perforation and cholangitis. Thrombotic complications have been less studied.

Aims & Methods: The aim of the study was to identify risk factors associated with the occurrence of hemorrhagic complications and thromboembolic events in the 30 days post-ERCP.

We conducted an observational study that included a total of 644 therapeutic ERCPs performed on 544 patients at the Hospital Universitario Reina Sofia in Cordoba (Spain) in 2019, with prospective follow-up within 30 days after the procedure.

Results: A total of 51.6% of ERCPs were performed in men, with a mean age of 72 ± 15.1 years. There were history of hypertension (64.9%), diabetes (26.4%), stroke (8.9%), ischemic heart disease (9%), atrial fibrillation (15.5%) and thromboembolic event (2.8%). The most frequent indication for ERCP was the presence of choledocholithiasis (73.3%), with malignant stenosis accounting for 15.2%. Prior anticoagulant and antiplatelet medication was present in 17.4% and 24.2% of procedures, respectively.

Bleeding occurred in 9.8% of procedures. The only variable associated with an increased risk of bleeding was the performance of sphincterotomy, with biliary prosthesis placement after sphincterotomy being a protective factor (Table 1), both of them in univariate and multivariate logistic regression.

Six thromboembolic events were identified in the 30 days after ERCP (0.93%): 3 strokes, 2 deep venous thromboses of the lower limbs and 1 portal thrombosis. The variables associated with an increased thrombotic risk were: atrial fibrillation, recurrent thromboembolism (TE) and rheumatic valve disease (Table 1).

The recurrent TE maintains statistical significance in multivariate analysis. The incidence of thrombosis was also higher in patients taking apixaban and heparin compared to other anticoagulants ($X^2: 81.19$ $p < 0.001$, $R^2: 1.96$). Correct or inadequate discontinuation and/or reintroduction of anticoagulant and/or antiaggregant drugs was not associated with an increased risk of thromboembolic or hemorrhagic events.

	X ²	p	OR (IC95%)	p
Sphincterotomy	92,1% vs 7,9% X ² :14,11	0,001	4,56 (1,86-11,2)	0,001
Biliary prosthesis	11,85% vs 5,07% X ² :7,12	0,006	0,17 (0,07-0,39)	0,013
Atrial fibrillation	50% vs 15,2% X ² :10,91	0,05	5,57 (1,14-27,23)	0,037
Recurrent thromboembolism	16,7% vs 0,15% X ² :52,34	0,001	64,10 (12,45-329,78)	0,001
Rheumatic valve disease	16,7% vs 0,2% X ² :6,58	0,037	9,71 (1,21-77,36)	0,039

Table 1.

Conclusion: The occurrence of bleeding and thrombosis after ERCP or other endoscopic procedures has been well established in several studies. Identifying predisposing risk factors allows close monitoring of the most

vulnerable patients to prevent the appearance of these complications or to detect them early. Although in our study inadequate periprocedural management of antithrombotic therapy was not associated with a significant increase in the incidence of hemorrhagic or thromboembolic events 30 days after ERCP, it is advisable to follow the recommendations of the different clinical practice guidelines, since this relationship has been established in other studies.

THE IMPACT OF HOSPITAL LEVEL OF CARE ON THE MANAGEMENT OF ACUTE CHOLECYSTITIS: A POPULATION-BASED STUDY

L. Lindqvist¹, A. Andersson¹, J. Österberg^{2,3}, G. Sandblom⁴, O. Hemmingsson¹, P. Nordin¹, L. Enochsson¹

¹Umeå University, Department of Surgical and Perioperative Sciences, Surgery, Umeå, Sweden, ²Karolinska Institutet, Department of Clinical Sciences, Intervention and Technology (CLINTEC), Stockholm, Sweden, ³Mora Hospital, Department of Surgery, Mora, Sweden, ⁴Karolinska Institutet, Department of Clinical Science and Education, Södersjukhuset, Stockholm, Sweden

Contact E-Mail Address: lars.enochsson@umu.se

Introduction: Acute cholecystitis (AC) is the most common complication of gallstone disease, affecting about 20% of patients admitted for biliary tract disease (1,2). Several studies have shown that early cholecystectomy performed within the first week decreases overall morbidity and the total length of stay compared to delayed operation (3,4). The organisation of healthcare might also have an impact on when patients with AC are treated which in turn may affect the outcome.

Aims & Methods: The aim of this study was to analyse how patients with AC are treated in relation to the number of hospital beds as well as level of care at the respective hospital. Data were collected from the Swedish Register for Gallstone Surgery and ERCP (GallRiks). Cholecystectomies between 2010 and 2019 were included. The inclusion criterion was acute cholecystectomy in patients with ongoing AC.

Results: Of 120 655 cholecystectomies, 24 194 (20%) met the inclusion criterion. There was a positive correlation between number of hospital beds at the surgical clinics and number of days between admission and surgery ($R^2=0.132$; $p=0.0075$).

Furthermore, the time between admission and surgery was significantly extended at Tertiary Referral Centres (TRC) compared to regional hospitals (2.2 ± 1.7 days vs. 1.6 ± 1.4 days, mean $\pm$ SD; $p<0.0001$). However, there was no correlation between time of cholecystectomy and intra- and/or postoperative complications at the respective hospital levels ($R^2=0.002$; $p=0.7618$).

Conclusion: An increased number of surgical hospital beds did not shorten the time to acute cholecystectomy on patients with AC. However, the time to cholecystectomy was significantly longer at TRCs compared to regional hospitals. Although it is not certain that these findings can be generalised to healthcare organisations outside Sweden, these results indicate that logistic differences as well as different levels of hospital care may affect the management of patients with AC.

EFFECTIVENESS AND FACTORS AFFECTING TECHNICAL SUCCESS OF AN ENDOSCOPIC SPHINCTEROTOMY IN PATIENTS WITH LARGE STONES AND COMMON BILE DUCT EMPYREMENT

B. Aourarh¹, A. Benhamdane¹, T. Addajou¹, K. Boualiten¹, E. ilham¹, F. Rouibaa¹, A. Benkirane¹, H. Seddik¹

¹Mohamed V Military Hospital, Gastroenterology II, Rabat, Morocco

Contact E-Mail Address: benayad.aourarh@gmail.com

Introduction: Biliary endoscopic sphincterotomy stands as a gold-standard in the treatment of the common bile duct (CBD) stones. Its efficiency can be nevertheless limited by the presence of large stones or CBD empyrement.

The aim of our study is to evaluate the effectiveness of biliary endoscopic sphincterotomy (EST) in patients with large stones (more than 15mm), patients with one or two stones and patients with a CBD empyrement; and also, to identify the factors affecting technical success of endoscopic drainage and its complications in the management of large bile duct stones.

Aims & Methods: In this monocentric study, conducted in the gastroenterology department, 1011 patients with CBD stones treated by EST were included retrospectively over a period of 19 years between April 2002 and September 2021.

The common bile duct empyrement was defined by the presence of multiple stones (more than 3) while the large stone was defined by a stone with a size >15mm.

Our patients were divided in two groups:

Group 1. (n=143): Patients with a large stone

Group 2. (n=868): Patients with one or two stones; or a CBD empyrement.

All the demographic, clinic, endoscopic and therapeutic data was collected, and entered then analyzed on the program JAMOV 2.0 using the logistic regression model in univariate and multivariate analyses.

Results: Patients in group 1 represented 14.1% of the patients included whereas the group 2 included 85.9% of the patients.

Success rate after one catheterization was 55.2% in group 1 versus 81% in group 2 ($p < 0.001$).

An endoscopic revision was noted in 14.7% of the patients in group 1 versus 8% in group 2 ($p = 0.009$). Complementary maneuvers were performed in 46.2% of cases in group I versus 16.1% in group II.

Global success rate after the endoscopic revision and/or complementary maneuvers was of 88.7% in group 1 versus 10.5% in group 2 ($p = 0.125$).

The overall rate of early complications was 10.5% in group 1 versus 5.1% in group 2 with a statistically significant difference between the two groups ($p = 0.017$).

In univariate analysis, the factors that reduce significantly the overall success of endoscopic treatment were: age, a cholangitis, a stenosis or an important dilation ($> 15\text{mm}$) of the CBD.

In a multivariate analysis and by adjusting the parameters studied, namely age, sex, surgical treatments, acute pancreatitis, cholangitis, perampullary diverticulum, CBD diameter and a CBD stenosis; only the presence of a cholangitis (OR: 0,295 IC 95%: [0,164 – 0,532] $p < 0.001$) and the presence of a CBD stenosis (OR: 0,53 IC 95%: [0,922 – 1,051] $p: 0.001$) were statistically significantly associated with the reduction of the overall success of endoscopic treatment.

Conclusion: Our study showed that there was no significant statistical difference of effectiveness in the endoscopic treatment between patients with a large stone and those with a simple stone.

The presence of a cholangitis and a CBD stenosis seem to be factors affecting the decrease of the overall success of an endoscopic treatment.

Disclosure: Nothing to disclose.

LOW-PHOSPHOLIPID-ASSOCIATED CHOLELITHIASIS (LPAC) SYNDROME - CLINICAL, RADIOLOGICAL AND GENETIC ASPECTS OF A CASE SERIES

F. Bordalo Ferreira¹, L. Martins Figueiredo¹, M. Cardoso¹, J. Carvalho e Branco¹, L. Carvalho Lourenço¹, D. Horta¹

¹Hospital Professor Doutor Fernando Fonseca, Gastroenterology, Amadora, Portugal

Contact E-Mail Address: filipamvpbferreira@gmail.com

Introduction:

LPAC (low-phospholipid-associated cholelithiasis) syndrome is a genetic condition associated with increased incidence of gallstone disease. This disorder is caused by mutations in ABCB4 and related genes, which reduce the biliary concentration of phosphatidylcholine, contributing to lithogenic bile and biliary epithelium lesion.

This diagnosis should be suspected when at least two clinical criteria are present: age less than 40 years at onset of biliary symptoms, recurrence of biliary symptoms after cholecystectomy or intrahepatic hyperechogenic foci detected by ultrasound suggestive of intrahepatic sludge or stones. Clinical suspicion should be raised by personal history of intrahepatic cholestasis of pregnancy or by first degree family history of gallstones. Treatment with ursodeoxycholic acid is usually effective.

Aims & Methods: We describe a series of 5 patients with an established diagnosis of LPAC syndrome. Patients with at least two clinical criteria and confirmed mutations in ABCB4 and/or ABCB11 genes were included. These cases are illustrated by detailed iconography.

Results: Three male and two female patients were included, with ages at

diagnosis of 38 to 55 years-old. Clinical manifestations and outcomes were variable. The description of cases encompasses personal and family history, clinical presentation, findings of diagnostic and therapeutic exams (abdominal ultrasound, computed tomography, magnetic resonance cholangiopancreatography [MRCP] and endoscopic retrograde cholangiopancreatography [ERCP]), genetic testing and clinical outcomes.

We describe different manifestations, including acute pancreatitis, acute cholangitis and their complications (liver abscesses and portal vein thrombosis), recurrent choledocholithiasis and intrahepatic lithiasis, and chronic complications, namely secondary sclerosing cholangitis and biliary cirrhosis.

Conclusion: This case series alerts to clinical manifestations which should raise suspicion for LPAC syndrome, such as recurrent biliary gallstones, especially after cholecystectomy, and intrahepatic foci of lithiasis. Recognizing this diagnosis has important therapeutic implications and allows for genetic counseling, essential for timely detection of at risk relatives.

Disclosure: Nothing to disclose.

THE RISK FACTORS OF RECURRENT CHOLEDOCHOLITHIASIS IN PATIENTS AFTER GASTRECTOMY

M.K. Jung¹, J. Heo¹, C.-M. Cho², D.W. Lee², J.-K. Lim³

¹Kyungpook National University Hospital, Internal Medicine, Daegu, Korea (Republic of), ²Kyungpook National University Chilgok Hospital, Internal Medicine, Daegu, Korea (Republic of),

³Kyungpook National University Hospital, Radiology, Daegu, Korea (Republic of)

Contact E-Mail Address: hero797@hanmail.net

Introduction: The incidence of cholelithiasis was reported to be higher in patients after gastrectomy than in the general population. However, there is no study for recurrent choledocholithiasis incidence in patients after gastrectomy.

Aims & Methods: The aim of this study is to evaluate the risk factors contributing to the recurrence of choledocholithiasis in patients after gastrectomy. A retrospective analysis was made of the patients after gastrectomy who underwent choledocholithiasis removal between January 2011 and December 2019 in Kyungpook National University Hospital.

Results: The choledocholithiasis was treated by endoscopic retrograde cholangiopancreatography (ERCP) ($n = 41$) or percutaneous transhepatic biliary drainage (PTBD) ($n = 90$). The type of gastrectomy was classified as subtotal gastrectomy with Billroth-I (18.3%), Billroth-II (45.0%), and total gastrectomy with Roux-en-Y (35.1%). The recurrence of choledocholithiasis was found in 18 of 131 patients (13.7%) during mean follow-up period of 31.5 months (range 6-105 months). The recurrent choledocholithiasis was higher in ERCP group (24.4%) than in PTBD group (8.9%). Stone removal modality (ERCP), no use of balloon sphincteroplasty, sphincteroplasty balloon size less than 12 mm, the presence of perampullary diverticulum and common bile duct (CBD) stricture were the significant risk factors for recurrent choledocholithiasis.

On univariate analysis, CBD stricture (HR 5.73, 95% CI: 1.53-21.48) was risk factor for recurrent choledocholithiasis after ERCP stone removal. The balloon sphincteroplasty (HR 0.23, 95% CI: 0.06-0.94) and balloon size larger than 12 mm (HR 0.88, 95% CI: 0.78-1.00) were factors that decrease the recurrent choledocholithiasis after PTBD stone removal.

By multivariate analysis of Cox proportional hazard model, stone removal modality (ERCP) ($P = 0.024$), no use of balloon sphincteroplasty ($P = 0.005$), and sphincteroplasty balloon size less than 12 mm ($P = 0.027$) were associated with recurrent choledocholithiasis after gastrectomy.

Conclusion: This study demonstrates the balloon sphincteroplasty with

balloon size over 12mm could decrease the recurrence of choledocholithiasis following gastrectomy regardless of the stone removal modality.

CAN DI-ISOPROPYL IMINODIACETIC ACID (DISIDA) SCAN PREDICT THE RECURRENT BILIARY EVENTS?

S.J. Hwang¹, W.C. Chung¹

¹St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Department of Internal Medicine, Suwon, Korea (Republic of)

Contact E-Mail Address: niledelta@naver.com

Introduction: A Tc-99m di-isopropyl iminodiacetic acid (DISIDA) scan is a specialized radiology procedure used to assess the function and structure of the gallbladder. We aim to whether DISIDA scan predict the recurrent biliary events after recovers from mild cholecystitis or removal of the common bile duct (CBD) stones.

Aims & Methods: A consecutive series of the patients were undertaken from March. 2010 to March. 2020. A total of 121 patients were enrolled. The mean follow-up period was 58 months (range 6–125 months).

The patients with mild cholecystitis, and those with CBD stone with or without gallbladder stones were enrolled. Due to mild symptoms, all of them did not have cholecystectomy.

After the improvement of symptoms, they underwent DISIDA scan and regular follow-up was done. We checked whether there were recurrent biliary events. Patients were categorized into two subgroups: recurrent biliary events (n = 55), and symptom-free group (n = 66).

Results: In patients having the positive results of non-visualization of the gallbladder or gallbladder ejection fraction (GBEF) <40 %, the risk of cholecystectomy due to event recurrence was significantly higher ($P < 0.01$). In patients with cholecystitis, the patients with positive DISIDA scan had the higher rate of recurrent biliary events regardless of gallbladder stones ($P < 0.01$). In patients with CBD stone, the results of DISIDA scan was a good predictor for recurrent biliary events ($P < 0.01$).

Conclusion: DISIDA scan could be a good tool to predict recurrent biliary events in patients who had cholecystitis or CBD stone.

Disclosure: Nothing to disclose.

CHOLECYSTECTOMY REDUCES THE RISK OF MYOCARDIAL INFARCTION AND CEREBRAL INFARCTION IN PATIENTS WITH GALLSTONE-RELATED INFECTION

S.-M. Park^{1,2}, H.S. Ahn³, H.J. Kim³, S.M. Lee², C. Park², H.B. Kwon²

¹Chungbuk National University College of Medicine, Internal Medicine, Cheongju, Korea (Republic of), ²Chungbuk National University Hospital, Internal Medicine, Cheongju, Korea (Republic of), ³Korea University College of Medicine, Preventive Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: jyoosin@hanmail.net

Introduction: Gallstones are positively associated with myocardial infarction (MI) and cerebral infarction (CI). However, risk changes of MI or CI in the condition of gallstone-related infection (GSI) or by cholecystectomy are still controversial.

Aims & Methods: We compared the risks of MI or CI in patients with GSI or not-GSI and risk changes of them by cholecystectomy. GSI (n=84,467) and non-GSI (n=406,800) patients with age- and sex-matched controls (n=4,912,670) were identified from Korean National Health Insurance and

Korean National Health Screening Exam database. Adjusted hazard ratios (aHRs) of MI or CI were analyzed in both groups treated by cholecystectomy or not.

Subgroup analysis was performed in both sexes and in different ages. Cardio-metabolic risk factors such as blood pressure, pulse pressure, fasting plasma glucose, body mass index, cholesterol, smoking, alcohol drinking and physical activity were adjusted.

Results: Risks of MI or CI were higher in GSI group compared to non-GSI group (aHR of MI; 1.32 vs. 1.07, aHR of CI; 1.24 vs. 1.06, respectively). Risk of MI was reduced by cholecystectomy in GSI group, while it was equivocal in non-GSI group (risk reduction rates by cholecystectomy; 11.4% and 0%, respectively).

Risks of CI were reduced by cholecystectomy in both GSI and non-GSI groups, while its effect was greater in GSI group (16.1% and 4.7%, respectively). Original risks of MI or CI in gallstone patients and risk reduction rates by cholecystectomy were higher in females and in younger patients compared to those in males and in older ones, respectively.

Conclusion: Increased risks of MI or CI and greater risk reduction by cholecystectomy were seen in patients with GSI. Therefore, cholecystectomy is strongly recommended for patients with GSI, especially in females or in young patients.

Disclosure: No conflict of Interest.

THE YIELD OF ENDOSCOPIC ULTRASOUND IN INVESTIGATION OF INCIDENTAL COMMON BILE DUCT DILATATION

T. Khoury¹, A. Shahin², W. Sbeit²

¹Galilee Medical Center, Department of Gastroenterology, Naharia, Israel, ²Galilee Medical Center, Gastroenterology, Naharia, Israel

Contact E-Mail Address: tawfik.khoury.83@gmail.com

Introduction: There are controversies regarding the upper normal diameter of the common bile duct (CBD) but it is accepted to be 7 mm. Dilated bile ducts are usually caused by an obstruction of the biliary tree, which can be due to stone, tumors (usually of either the papilla of Vater or the pancreas), benign strictures (due to chronic pancreatitis or primary sclerosing cholangitis) benign stenosis of the papilla (ie, papillary stenosis), and papillary diverticulum.

Factors like age, height, weight, BMI, previous cholecystectomy, drugs, and type of imaging modality affect CBD diameter, but the duct significantly dilated due to obstructive biliary pathology.

With the widespread use of abdominal imaging, an incidentally found dilated common bile duct (CBD) is a common radiographic finding. Endoscopic ultrasound (EUS) provides high-resolution, real-time imaging of the gastrointestinal tract and surrounding extramural structures.

Aims & Methods: The aim of the study is to explore the yield of EUS in investigation of incidental common bile duct dilatation according to computed tomography (CT) scan. This is a retrospective single-center study with inclusion of all patients who referred for EUS performed for evaluation of incidental CBD dilatation according to CT in the Gastroenterology department at Galilee Medical Center from 2016 till 2020.

Results: Overall, 65 patients were included in the study. All of them were referred for further investigation of dilated CBD according to CT. The average age of the entire cohort was 67.2 ± 16.1 (28-97) years. Twenty-one patients (32.3%) were males.

The rate of smoking, obesity, diabetes mellitus, hypertension, hyperlipidemia, congestive heart failure and alcohol drinking were 15.4%, 27%, 32.3%, 52.3%, 53.8%, 6.2% and 1.54% respectively. Notably, the rate of personal and family history of cancer was 12.3% and 1.54%, respectively. EUS examination was normal in 29 patients (44.6%), while the other

patients had pathological findings. Three patients (4.6%) had hypoechoic mass on EUS (2 in the pancreas and 1 in the CBD). Nineteen patients (29.2%) had gallstone disease (10 patients within the CBD, 5 within the GB and 4 within both the CBD and the gallbladder ((GB)). Ten patients had pancreatic cysts. Three patients had main pancreatic duct dilatation and 1 patient had GB polyp.

Comparing the patients who had normal EUS examination, with those who had abnormal EUS examination, only two parameters showed a trend for significance with abnormal EUS findings including: age and personal history of cancer (69.4 years and 17.5% vs. 63.7 years and 4%, $P=0.08$ and $P=0.05$), respectively.

Conclusion: EUS for investigation of idiopathic CBD dilation showed pathology in more than 50% of cases. Predictors for abnormal findings were including advanced age and personal history of cancer. Further larger studies are needed to better elucidate the role of EUS in this setting.

Disclosure: Nothing to disclose.

P0785

ULTRASOUND-BASED ASSESSMENT OF BILIARY MANIFESTATIONS IN ADULT PATIENTS WITH CYSTIC FIBROSIS. PREVALENCE AND RISK FACTORS

A. Marinero Martínez-Lázaro¹, R.M. Girón Moreno^{2,3}, F. Casals Seoane^{4,3}, Ó. Cano-Valderrama⁵, L. García-Buey^{4,3}
¹Hospital Clínico San Carlos, Department of Gastroenterology, Madrid, Spain, ²Hospital Universitario de La Princesa, Department of Pneumology, Madrid, Spain, ³Universidad Autónoma de Madrid, Instituto de Investigación Sanitaria Princesa (IIS-IP), Madrid, Spain, ⁴Hospital Universitario de La Princesa, Department of Gastroenterology, Madrid, Spain, ⁵Complejo Hospitalario Universitario de Vigo, Department of General and Gastrointestinal Surgery, Vigo, Spain

Contact E-Mail Address: almunenamarinero@hotmail.com

Introduction: Biliary pathology is thought to be highly prevalent in patients with Cystic Fibrosis. However, the published data vary widely regarding its exact frequency and clinical impact, especially in adult patients. More so, to date, the underlying pathophysiological mechanism is not completely understood.

Aims & Methods: The aim of the study was to evaluate the prevalence of biliary manifestations in a cohort of adult Cystic Fibrosis patients in a tertiary referral hospital and to evaluate the possible risk factors that influence its development. Adult patients with Cystic Fibrosis were recruited and laboratory tests and abdominal ultrasound were performed. Clinical characteristics of the patients with biliary disease were collected and possible risk factors for the development of the most frequent manifestations were studied.

Results: Ninety-five patients were included, 48 (50.5%) women, with a mean age of 30.4 (28.6-32.2) years and a mean value of FEV1 of 81.5 (77.9-85). 71 (74.7%) were F508del mutation carriers. 35 (37.2%) of patients presented biliary abnormalities in abdominal ultrasound. The different biliary findings observed are shown in Table 1.

Mean values of the different laboratory parameters were as follows: total bilirubin mean value of 0,5 (0,4-0,5) (mg/dl), a mean value of 21,2 (19,3-23,1) (U/l) for aspartate aminotransferase; 23,7 (20,8-26,6) (U/l) for alanine aminotransferase, 24 (17,2-30,8) (U/l) for gamma glutamyltransferase and 92,7 (84,5-100,9) (U/l) for alkaline phosphatase. 4 (4,4%) of the patients were above the upper normal limit of the laboratory values regarding total bilirubin, 2 (2,2%) regarding aspartate aminotransferase levels and 11 (12,1%) regarding alanine aminotransferase, and 5 (5,5%) and 17 (18,7%) regarding levels of gamma glutamyltransferase and alkaline phosphatase,

respectively. Therapy with Cystic Fibrosis Transmembrane Modulators was a risk factor for the development of cholelithiasis (Odds Ratio 3.53 [1.10-11.44] $p=0.05$).

Body Mass Index was a risk factor for cholecystectomy (Pearson coefficient 0.26 $p=0.05$) but male sex (Odds Ratio 0 [0-0.6] $p=0.02$), pancreatic insufficiency (Odds Ratio 0.12 [0-0.65] $p=0.02$) and having been diagnosed with Cystic Fibrosis in the paediatric age (OR 0.07 [0.01-0.51] $p=0.03$) were protective factors. History of meconium ileus (Odds Ratio 16.87 [5.54-51.33] $p=0.001$) and Bhalla Score (Pearson coefficient -0.25 $p=0.02$) were risk factors for the development of microgallbladder.

Biliary manifestations	Patients (n)	Total prevalence (%)	Relative prevalence within affected individuals (%)
Cholelithiasis/biliary sludge	20	21.3 %	57.1%
Microgallbladder	7	7.4%	20%
Cholecystectomy	6	6.4%	17.1%
Gallbladder agenesis	1	1.1%	2.9%
Cholangiopathy (bile duct dilation)	2	2.1%	5.7%
Gallbladder polyps	1	1.1%	2.9%

Table 1.

Conclusion: Biliary involvement reached a prevalence of 37.2%. Cholelithiasis was the most frequent finding, with a prevalence similar to that described in previous publications, and clearly more prevalent than in general population. The administration of Cystic Fibrosis Transmembrane Modulators was a risk factor for its development. History of meconium ileus and Bhalla score were risk factors for microgallbladder, which was the second most frequent finding.

It seems that a milder phenotype of the disease (regarding mutations, pancreatic function and possibly, lung function) may pose a risk for developing gallbladder complications that require cholecystectomy.

RISK FACTORS FOR GALLSTONES IN PATIENTS WITH LIVER CIRRHOSIS

R. Ennaifer¹, Z. Benzarti¹, B. Bouchabou¹, S. Chtioui¹, A. Nakhli¹, M. Kefi¹, N. Hemdani¹

¹Mongi Slim Hospital, Department of Hepatology, Marsa, Tunisia

Contact E-Mail Address: zeinebbenzarti9@gmail.com

Introduction: Gallstone disease is one of the most prevalent and costly digestive disorders in the world. Recent studies have indicated that cirrhosis is a relevant risk factor for gallstone formation. However, risk factors for lithogenesis in cirrhotic patients are still incompletely elucidated.

Aims & Methods: The aim of this study was to estimate the risk factors for gallstone formation in cirrhotic patients.

A total of 84 patients with liver cirrhosis between 2019 and 2020 were studied. Patients were divided into two groups according to the presence of cholelithiasis evaluated by ultrasonography. Thirty one (36,9%) had gallstones (Group 1) while 53 patients (63,1%) had no gallstone disease (Group 2). The groups were compared in terms of basal characteristics (age, gender, obesity, diabetes meelitus and dyslipidemia) and characteristics of liver cirrhosis (etiology, duration and Child class) to determine risk factors for gallstone formation. SPSS version 26.0 was used for the descriptive and comparative analysis.

Results: The study included 52 males (62%) and 32 females (38%) with a mean age of 61 years. The etiologies of cirrhosis in all patients were as follows: cryptogenic n = 28 (33,3%), viral n = 42 (50%), alcoholic n = 6 (7,2%), autoimmune n = 7 (8,3%) and Wilson n=1 (1,2%). Child score was A in 33 patients, B in 38 patients and C in 13 patients.

Cholecystectomy was performed in 11% of patients of the first group.

Advanced age, female gender, obesity, diabetes, and cryptogenic cirrhosis were significantly associated with gallstone disease by the univariate analysis ($p=0,01$; $p=0,004$; $p<0,001$; $p=0.006$; $p=0.01$ respectively). Alcohol use, cirrhosis duration and the stage of liver disease were not associated to lithogenesis. On multivariate analysis, only obesity was independently associated with cholelithiasis ($p=0,04$; OR = 2,34 CI 95%).

Conclusion: In our study, risk factors for lithogenesis in cirrhotic patients are predominantly related to metabolic syndrome. Further study of the relationship between cirrhosis and gallstones is critical for predicting clinical outcomes in patients with liver disease, as it seems to be associated to a poorer prognosis.

Introduction: Diagnosis of malignant biliary stricture remains a challenge. With regard to low sensitivity of brush cytology (BC), fluorescence in situ hybridization (FISH) has been reported as a useful adjunctive test.

Aims & Methods: We aimed to determine performance characteristics of both BC and FISH alone and in combination (BC+FISH).

This single center prospective study was conducted between April 2019 and January 2021. Consecutive patients with biliary strictures undergoing ERCP were included. Tissue specimens from 2 independent brushings were examined by routine cytology and FISH using the UroVysion probes. Histopathological confirmation after surgery or 12-month follow-up were considered as the reference standards for final diagnosis.

Results: From a total of 109 enrolled patients, 7 were lost to follow-up. In the remaining 102 patients (61% males, median age 67, range 25–92 years), the proportion of benign and malignant strictures was 28 (27.5%) and 74 (72.5%), respectively; the proportion of proximal and distal strictures was 26 (25.5%) and 76 (74.5%), respectively. Performance characteristics for each diagnostic test are shown Table 1.

Study cohort (n=102)	BC	BC + FISH	p-value
Sensitivity (95% CI)	0.361 (0.251–0.483)	0.507 (0.387–0.626)	0.076
Specificity (95% CI)	0.852 (0.663–0.958)	0.741 (0.537–0.889)	0.311

Table 1: Performance characteristics of selected diagnostic tests in diagnosis of biliary strictures (BC – brush cytology, FISH – fluorescence in situ hybridization, 95% CI – 95% confidence interval)

Conclusion: Dual-modality tissue sampling using BC + FISH demonstrated an improving trend in sensitivity for primary diagnosis of biliary strictures when compared with BC alone ($p=0.076$).

KNOCKDOWN OF HSDL2 PROMOTES CELL PROLIFERATION, MIGRATION AND INVASION BY INHIBITING FERROPTOSIS VIA P53PATHWAY IN CHOLANGIOCARCINOMA

Z. Lu¹, D. Zhang¹

¹The First Affiliated Hospital of Bengbu Medical College, Anhui, China

Contact E-Mail Address: zdy527897470@126.com

Introduction: Cholangiocarcinoma (CCA) is a malignant tumor of the bile duct epithelium, including intrahepatic, perihilar, and distal CCA based on anatomical location. However, the precise underlying mechanisms are not yet fully understood. Hydroxysteroid dehydrogenase-like 2 (HSDL2) belongs to the SDR subfamily of oxidoreductases, involved in the development of a variety of cancers. In a previous study, we found that overexpression of HSDL2 suppresses cell proliferation in cholangiocarcinoma.

Aims & Methods: This study aimed to investigate the potential molecular mechanisms of HSDL2 affecting the development of cholangiocarcinoma. The cells knockdown and overexpressed HSDL2 were constructed by a stable lentivirus-mediated transduction strategy, respectively. Transcriptome and proteome sequencing were performed on knockdown and negative control cells, and relevant mRNA and protein expression were determined by qRT-PCR and Western blotting. T

he levels of glutathione and lipid peroxidation were measured using related kits, and changes in reactive oxygen species were detected using flow cytometry. CCK8 assay, colony formation assay and 5-Ethynyl-2-Deoxyuridine(EDU) incorporation assay were used to detect cell proliferation ability, and wound healing assay and transwell assay were used to detect cell migration and invasion ability.

Results: Through the transcriptome and proteome data analysis, we found that differential genes and proteins were significantly enriched in cell proliferation and death, and were closely related to P53 signaling. Knockdown of HSDL2 promotes cell proliferation, migration and invasion, and inhibits ferroptosis.

The reversed assay showed that the overexpression of p53 partially reversed the above phenomenon. However, the inhibition of ferroptosis counteracted the effect of overexpressed p53 on the proliferation, migration and invasion capacity.

Conclusion: The knockdown of HSDL2 inhibits ferroptosis via the p53 pathway to promote cell proliferation, migration and invasion in cholangiocarcinoma.

Introduction: Cholangiocarcinoma (CCA) is the second most common liver cancer. Diabetes is a major risk factor; however, treatment with metformin has been reported to be protective for several cancers, but data on CCA are still sparse and heterogeneous.

Aims & Methods: The aim of this meta-analysis is to investigate the role of metformin as a potential protective factor for CCA.

In this systematic review and meta-analysis, we searched PubMed/MEDLINE and EMBASE databases from the date of inception to May 2021, for studies analyzing the CCA rate in patients taking metformin.

Results: Twenty-eight articles were initially identified, of which three were eligible and included in our systematic review and meta-analysis estimating the relative risk (RR). The rate of CCA was lower for diabetic patients taking metformin than diabetic patients without metformin intake (RR 0.34, 95% CI 0.51-0.35, $p < 0.001$), without significant statistical heterogeneity ($I^2 = 35.08\%$, $P = 0.2143$) among studies.

Conclusion: Our study demonstrated a significant impact of metformin in reducing the risk of CCA by nearly 66% in diabetic patients taking metformin.

Introduction: In patients with inoperable perihilar cholangiocarcinoma (pCCA) uncovered metal stents are preferred over plastic stents because of longer stent patency and fewer re-interventions in the short term.(1-4) However, concerns have risen regarding the number and complexity of re-interventions in the long term.(5)

This is of increasing importance considering the expected improvement in systemic and/or locoregional therapy and subsequent increase in life expectancy.(6)

Aims & Methods: Aim of the study was to assess the long-term efficacy (>6 months) of metal versus plastic stents. This retrospective study was performed at two Dutch tertiary referral hospitals and consisted of patients with inoperable pCCA who underwent biliary drainage between 2001 and 2021 and survived at least 6 months. Patients were divided in two groups; 1. plastic stent placement(s) for the full extent of follow-up and 2. metal stent(s) which had been in situ for at least 6 months.

Primary outcome was the estimated number of re-interventions per patient-year and need for permanent external or internal/external percutaneous drainage catheters. Secondary outcomes included re-interventions between 6 and 12 months in patients with at least 12 months follow-up and time to recurrent biliary obstruction.

Results: A total of 127 patients were found eligible, of whom 40 patients (31%) only underwent plastic stent placement(s) and 87 patients (69%) had metal stent(s) placed. Metal stents were placed at the initial procedure in 7 patients. In the remaining 80 patients, the first metal stent was placed after a median of 2 months (IQR 1-5) and a median of 3 interventions (IQR 1.75-4) in which plastic stent(s) or percutaneous biliary drainage catheter(s) were placed.

Patients in the metal stent group underwent fewer re-interventions compared with the plastic stent group corrected for the length of follow-up (4.8 vs. 3.1 per patient-year; incidence rate ratio (IRR), 0.64; 95% CI, 0.47 to 0.88). When only non-elective re-interventions were included no significant difference between the groups was present (2.8 vs. 2.1 per patient-year; IRR, 0.77; 95% CI, 0.55 to 1.09).

At final follow-up, 7 patients (18%) had a percutaneous drainage catheter in situ in the plastic stent group versus 12 patients (14%) in the metal stent group (risk ratio (RR), 0.79; 95% CI, 0.34 to 1.85).

In patients who had at least 12 months follow-up (n=71) patients in the plastic stent group (n=16) underwent a median of 2 re-interventions (IQR 1-2) between 6 and 12 months versus 1 re-intervention (IQR 0-3) in the metal stent group (n=55; p=0.229).

One-hundred and ten patients (87%) experienced recurrent biliary obstruction during follow-up. The median time to recurrent biliary obstruction was 2 months (IQR 0-7.25) in the plastic stent group versus 6 months (IQR 3-11) in the metal stent group (p=0.001).

Conclusion: This study confirms previous short-term data that the placement of metal stent(s) leads to fewer re-interventions compared with plastic stent(s) in patients with inoperable pCCA. Also in patients who survive beyond 6 months. To confirm this conclusion prospective data with long-term sufficient follow-up is warranted.

ENDOSCOPIC RADIOFREQUENCY ABLATION FOR MALIGNANT BILIARY OBSTRUCTION: RISK FACTORS FOR BILIARY INFECTION

H. Haitao¹, W. Gu¹, H. Khizar², X. Zhang¹, Y. Jianfeng¹

¹Hangzhou First People Hospital, Department of Gastroenterology, Hangzhou, China, ²Zhejiang Chinese Medical University, International Education College, Hangzhou, China

Contact E-Mail Address: yjf3303@zju.edu.cn

Introduction: The aim of this study is to investigate risk factors for early adverse events in endoscopic radiofrequency ablation (RFA) for unresectable malignant biliary obstructions.

Aims & Methods: We performed a retrospective review of 148 patients with malignant biliary obstruction who had undergone endoscopic RFA between January 2012 and January 2022 at a single tertiary care center. Data obtained through the medical records included ERCP indication, patient factors (biliary anatomy, demographics, and comorbidities), stent characteristics (material, length, and design), change in serum bilirubin, rates and etiologies of bacteremia, and the mortality rate.

Results: Adverse events occurred in 34 cases (23.0%), including postoperative biliary infection in 28 cases (acute cholangitis (15.5%, 23/148), acute cholecystitis (3.4%, 5/148)), acute pancreatitis in 4 cases (2.7%), and hemobilia in 2 case (1.4%). There was no perforation. Patients with postoperative biliary infection had a higher proportion of type 2 diabetes, hypoproteinemia (<30g/L), bile duct stenosis length > 2.5 cm, segmented RFA, drainage by single stent was significantly higher than patients without biliary infection ($P < 0.05$). Logistic regression analysis showed the combination of type 2 diabetes, segmented RFA, and single stent drainage were the independent risk factors for biliary infection.

Conclusion: The most common adverse event of endoscopic RFA treatment for unresectable malignant biliary obstruction is biliary infection. History of type 2 diabetes, biliary stricture length > 2.5 cm, single stent drainage were high risk factors for biliary infection.

Disclosure: Nothing to disclose.

Introduction: The indication for endoscopic papillectomy (EP) for duodenal papillary tumors is considered to be benign lesions such as adenomas, but recently the indication has been expanded to include early-stage cancer. However, there is currently no sufficient evidence or consensus regarding the efficacy of EP for papillary carcinoma. In this study, we conducted a retrospective review of the prognosis of cancer patients who underwent EP at our hospital.

Aims & Methods: We included 107 patients who underwent EP for duodenal papillary tumors at our department between 2005 and 2020. The residual rate, recurrence rate, and prognosis of neoplastic lesions (adenocarcinoma) were evaluated. The resection was performed in the endcut mode.

Results: There were 30 cases of adenocarcinoma (17 with localized Tis, 10 with T1a, and 3 with T1b), 8 with hyperplastic changes, 2 with NETs, and 13 with other conditions. Median tumor diameter (range) was 11 (5-25) mm for adenomas, 15 (8-25) mm for Tis-T1a, and 15 (10-21) mm for T1b.

Mean observation time (range) after EP was 43.9 (0.7-185.7) months for adenomas, 41.8 (2.1-139.0) months for Tis-T1a, and 33.5 (0.7-185.7) months for T1b. b: 33.9 (4.7-87.8) months. The post-EP remnant rate of adenocarcinoma was 34.5% (29/84) in 10 cancer cases (Tis-T1a: 7, T1b: 3).

Five patients (Tis-T1a: 3, T1b: 2) underwent additional pancreaticoduodenectomy (PD), and 3 of them (Tis-T1a: 1, T1b: 2) had no malignant findings in the resection specimens, indicating that complete resection had been performed by EP. None of the 10 cancer remnants, including 5 additional untreated cases, progressed or recurred during the observation period. One case of recurrence after adenocarcinoma EP was adenocarcinoma (Tis). The patient with T1a recurrence of adenocarcinoma was treated with PD, and the patient was free of recurrence during the follow-up period.

Conclusion: EP can provide local control not only in Tis-T1a but also in T1b in the majority of cases, suggesting that EP may be an alternative treatment for patients who cannot tolerate surgical resection because of its relatively minimally invasive nature.

Disclosure: Nothing to disclose.

Introduction: The biliary tract cancer (BTC) has very poor prognosis. Some BTC has been shown to respond to pembrolizumab, but there are no known clinical prognostic factors to predict its treatment effects. In this study, we tried to find prognostic factors associated with pembrolizumab as 2nd-line treatment for gemcitabine plus cisplatin refractory BTC.

Aims & Methods: This is a retrospective, single tertiary-center study that involved all consecutive patients with refractory advanced BTC who was treated with pembrolizumab between August 2017 and February 2021. Patients who received pembrolizumab as the first treatment choice were excluded. And prognostic factors affecting overall survival were analyzed through cox regression analysis.

Results: Total 93 patients enrolled in this study according to the inclusion criteria. We found statistically significant factors for overall survival. It contains albumin, ALP, CA19-9, Lymphocyte-Monocyte-Ratio (LMR), Neutrophil-Lymphocyte-Ratio (NLR), and Platelet-Lymphocyte-Ratio (PLR). In multivariate cox regression analysis, albumin and LMR were identified as significant variables associated with overall survival. (adjusted HR=0.358 [95% CI: 0.205-0.627]; $p=0.000$, adjusted HR=0.279 [95% CI: 0.161-0.485]; $p=0.000$) Contrary to expectations, TPS and CPS were not significant variables affecting overall survival. (HR=1.00 [95% CI: 0.992-1.008]; $p=0.937$, HR=0.995 [95% CI: 0.986-1.003]; $p=0.215$).

Conclusion: Higher albumin and LMR were significantly associated with better overall survival. Further studies are needed to find genetic and clinical factors to predict who would be benefited from pembrolizumab as treatment for advanced biliary tract cancer.

IGG4-RELATED SCLEROSING CHOLANGITIS MAY BE A RISK FACTOR FOR BILE DUCT CANCER

Y. Kurita¹, K. Kubota¹, K. Suzuki¹, S. Yagi¹, S. Hasegawa¹, K. Hosono¹, A. Nakajima¹

¹Yokohama City University, Yokohama, Japan

Contact E-Mail Address: kuritay@yokohama-cu.ac.jp

Introduction: The potential risk for bile duct cancer in patients with immunoglobulin 4-related sclerosing cholangitis (IgG4-SC) is unclear.

Aims & Methods: The present study aimed to evaluate the incidence of bile duct cancer in patients with IgG4-SC.

We retrospectively collected clinical data for 121 patients diagnosed with IgG4-SC. We calculated the standardized incidence ratio (SIR) of cancer in IgG4-SC patients based on the national cancer rates. The SIR of bile duct cancer and that of the period after the diagnosis of IgG4-SC were also calculated.

Results: The mean follow-up period was 6.4 years, with 121 IgG4-SC patients. During the follow-up period, 26 patients had cancer, and 29 cancers were diagnosed. Three bile duct cancer cases were diagnosed. The SIR of cancer after the diagnosis of IgG4-SC was 1.90 (95 % confidence interval [CI] 1.67-2.21). The SIR of bile duct cancer was 8.88 (95 % CI 7.81-10.30). The SIR of cancer in <1 year, 1-5 years, and > 5 years after diagnosis of IgG4-SC were 2.58 (95 % CI 2.53-2.64), 1.01 (95 % CI 0.91-1.12), and 2.44 (95 % CI 1.92-3.37), respectively.

Conclusion: IgG4-SC patients have a high risk of cancer. IgG4-SC may be associated with the development of bile duct cancer. The risk of cancer was high less <1 year and >5 years after diagnosis of IgG4-SC. Therefore, IgG4-SC patients may require careful long-term follow-up.

Disclosure: Nothing to disclose.

Introduction: Acute gallstone cholangitis necessitates biliary decompression and stone extraction with endoscopic retrograde cholangiopancreatography (ERCP).

The European Society of Gastrointestinal Endoscopy 2019 guideline¹ stipulates timeframes for ERCP in these patients in accordance with severity of disease, as stratified by the Tokyo 2018 guidelines² (Severe – within 12 hours, moderate – within 72 hours, mild – elective).

Aims & Methods: We aimed to assess current performance and compare outcomes in relation to time to ERCP, in multiple centres with differing hepatobiliary endoscopy services and ERCP availability. A retrospective multicentre audit of patients admitted to four institutions within the Merseyside and Cheshire region, United Kingdom between January 2016 and December 2019, with probable or definite episodes of acute cholangitis (as per Tokyo 2018 criteria) was performed.

Cases were assessed for severity of illness as per Tokyo criteria and time to ERCP, with outcomes including length of hospital stay, procedure-related complications and all-cause 30 day mortality recorded.

Results: In total, 390 patients were included for analysis across the four centres, with one hospital providing an out-of-hours emergency ERCP service. Overall, 283 patients (72.6%) presented within 'normal working hours.' Successful biliary decompression and stone extraction was achieved in 83.6% (n=326) of patients with a median time to ERCP of 5.8 days (range 0.1 – 37.5).

	Mild	Moderate	Severe
Number of pts	174	156	60
Age (range) - Male:Female	68 (19-96) - 65:109	80 (34-98) - 78:78	78 (52-94) - 36:24
ICU admissions (%)	1/174 (0.6)	1/156 (0.6)	15/60 (25)
Median time to ERCP in days (range)	5 (0.1-35.1)	6 (0.1-25)	7.3 (0.5-37.5)
Complete decompression (%)	C - 153 (87.9)	C - 124 (79.4)	C - 49 (81.7)
Partial decompression (%)	P - 12 (6.9)	P - 16 (10.3)	P - 9 (15)
Unsuccessful decompression (%)	U - 9 (5.2)	U - 16 (10.3)	U - 2 (3.3)
Adverse events (%)	6.9	3.2	3.3
Median LOS (range)	7 (1-44)	8 (1-64)	9.5 (1-40)
30 day all-cause mortality (%)	1 (0.6)	2 (1.3)	3 (5)
30 day readmission rates (%)	11 (6.3)	11 (7.1)	4 (6.7)

Table 1 - Summary across four centres (n=390)

When stratified by severity, median time to ERCP was 7.3 days (range 0.5 – 37.5) in severe cases, 6.0 days (range 0.1 – 25) in moderate cases and 5.0 days (range 0.1 – 35.1) in mild cases. 17 of the 390 patients (4.4%) required intensive care (ICU) input, with 25% (15/60) of patients classified as severe having an ICU stay.

There was a higher proportion of those presenting outside of normal working hours requiring ITU admission (37.5%, 6/16), having all been classified as severe at presentation. Those with severe cholangitis also had a longer length of stay (median 9.5 days) compared to 8.0 days for those with moderate disease.

Table One summarises the outcomes assessed across the four participating centres - one centre provided an out-of-hours ERCP service as required.

Conclusion: Median time to ERCP did not differ when stratified by severity of cholangitis and did not meet ESGE recommendations. However, patients with severe disease were able to receive emergency ERCP if clinically indicated. Provisions for emergency ERCP centred at a tertiary institution within a regional network is required.

SILENCING OF *AHR* AND *ELAVL1* GENES INFLUENCES POST-TRANSCRIPTIONAL EXPRESSION OF EACH OTHER AND CHEMORESISTANCE OF PANCREATIC CANCER CELLS, IN VITRO

D. Stukas¹, A. Jasukaitiene¹, J. Matthews², A. Gulbinas¹,
Z. Dambrasukas¹

Introduction: Pancreatic cancer (PC) is a devastating disease that has less than 10 % five-year survival rate [1]. There is an urgent need to find new therapies to treat PC patients. HuR protein (*ELAVL1* gene) expression in cell cytoplasm is positively associated with PC response to gemcitabine which is currently first-line treatment for PC [2].

The aryl hydrocarbon receptor (*AHR*) is a ligand-dependent transcription factor that among other purposes modulates RNA-binding protein *ELAVL1* signaling pathway by blocking HuR protein (*ELAVL1*) translocation from nucleus to cytoplasm which consequently leads to overexpression of cytoprotective, anti-apoptotic proteins and chemoresistance [3].

Overexpression of *AHR* leads to decreased cytoplasmic levels of HuR protein (*ELAVL1*) which in turn might contribute to chemoresistance of PC patients and their survival.

Aims & Methods: The aim of this research was to investigate how *AHR* and *ELAVL1* gene silencing affects the post-transcriptional expression of related genes, each other, and chemoresistance of PC cell lines.

Three PC cell lines were used (T3M4, BxPc3, Su.86.86). *AHR* and *ELAVL1* genes were silenced for 24-hours by lipofectamine mediated siRNA transfection. Afterwards the cells were treated with IC50 of gemcitabine for 48-hours (calculated for each cell line independently). After treatment gene expression was measured by RT-PCR and protein expression by Western Blot assay. Metabolic activity was measured by MTT assay.

Results: The results showed that silencing of *AHR* and/or *ELAVL1* resulted in decreased cell viability and increased sensitivity to gemcitabine in all three PC cell lines. Silencing of *AHR* gene resulted in increase of *ELAVL1* RNA expression, however, HuR protein (*ELAVL1* gene) expression was not affected by silencing of *AHR*. Silencing of *ELAVL1* resulted in reduced *AHR*RNA as well as reduced *AHR* protein expression. Results show that *AHR* could be involved in regulation of *ELAVL1* expression in post-transcriptional level and vice versa. The results of *AHR* and/or *ELAVL1* gene silencing and expression of cytoprotective molecules of *ELAVL1* pathway differed between cell lines.

Conclusion: Both *AHR* and *ELAVL1* may play a role in regulation of each other and chemoresistance of PC cell lines. However different response of protein and RNA together with different response of cytoprotective molecules between PC cell lines shows that the effect of gene modulation is hard to predict and should be investigated further.

WHAT IS THE SIGNIFICANCE OF A FAECAL ELASTASE-1 LEVEL BETWEEN 200 – 500MG/G?

A. Mathew¹, D. Fernandes², J. Andreyev^{2,3}

¹Royal Derby Hospital, Derby, United Kingdom, ²Lincoln County Hospital, Gastroenterology, Lincoln, United Kingdom, ³University of Nottingham, The Biomedical Research Centre, Nottingham Digestive Diseases Centre, School of Medicine, Nottingham, United Kingdom

Contact E-Mail Address: dcrfernandes@gmail.com

Introduction: Pancreatic exocrine insufficiency (PEI) is a common cause of gastrointestinal (GI) symptoms relating to malabsorption. It is commonly diagnosed if faecal elastase-1 (FE-1) levels are below 200mg/g. However, there is insufficient data to define the significance of faecal elastase levels above 200mg/g but less than 500mg/g, with a suggestion that levels between these values being a deviation from normal pancreatic exocrine function. This study therefore sought to assess the response to treatment in patients who had a FE-1 level between 200-500mg/g.

Aims & Methods: This was a retrospective study that was approved by our local audit committee, audit registration L0448. Patient information was requested from the pathology laboratory at United Lincolnshire Hospitals NHS Trust for all FE-1 samples taken between April 2019 and March 2021. Those with results of <200 or >500 were excluded.

Notes and medical records of those remaining were reviewed with any seen in an outpatient setting having their presenting symptoms recorded before trialling Creon. Subsequent clinic letters were then reviewed following commencement and a positive response noted if the initial symptoms responded to treatment.

Results: 82 patients had a FE-1 result between 200-500. Ages ranged from 27 to 90 (median = 63). 78 were referred to the Gastroenterology department with a wide range of non-specific GI symptoms. 28 patients were given a trial of Creon. The dosing regime varied, with the majority being trialled on two capsules (50,000 units) with meals and one capsule (25,000 units) with snacks. Adjuvant treatment was given, with 8 taking multivitamins and 3 taking Proton Pump Inhibitors (PPIs). 20 patients showed an improvement in symptoms of diarrhoea, steatorrhoea and bloating. 3 patients did not tolerate Creon, developing nausea and vomiting and the remaining 5 showed no response.

Conclusion: Our results show that clinicians should exercise caution when using defined reference ranges to diagnose PEI and provide treatment with PERT. Although it is often believed patients with PEI will only display symptoms when pancreatic function has dropped to <10%, there

is now a consensus that these patients may instead demonstrate a graded response to reduced exocrine function and so will benefit from having earlier testing and treatment [4]. Indeed, our findings support this suggestion, with nearly ¼ of patients with a FE-1 of between 200-500 showing a response following treatment with PERT.

Introduction: Recent work has demonstrated the potential of machine perfusion (MP) to extend the period during which organs remain viable from hours to days (1). MP is considered to be superior in organ preservation compared to traditional static cold storage (SCS) in high-risk kidney and liver donor organs (2).

Whilst these preservation methods have enjoyed success in *ex vivo* kidneys and livers, pancreatic perfusion has been slow to progress and the current gold-standard for storage and transport of human pancreas remains SCS (3). This is due to the unique and challenging physiological parameters the pancreas demands to maintain its viability and functionality, namely tightly controlled pressure, and flow parameters and significant susceptibility to reperfusion and ischaemic injury (4).

A novel perfusion circuitry has been developed with an objective to produce a system to evaluate whole organs in a temperature-controlled, adaptable chamber with tightly regulated, pre-determined parameters. Here we present data from 3 porcine pancreatic head perfusions using autologous oxygenated blood with a pre-set pressure and flow rate and continuous real-time monitoring.

Aims & Methods: To investigate the machine perfusion parameters of isolated pancreas associated with maintaining physiological function.

Porcine pancreases were obtained from domestic pigs immediately after termination at an abattoir. 5 cm of the distal aorta was preserved, dissected, and flushed with 2 litres of heparinised normal saline. The pancreatic head and duodenum was dissected and transported to the lab on ice with attached major vessels. Blood from autologous porcine donation was collected in a pre-heparinised receptacle.

The perfusion circuit was designed to continuously monitor and control pre-determined flow and pressure measurements and was coordinated by a raspberry pi microcontroller using a MODBUS and RS232 serial communication protocol to communicate with the sensors. The aortic patch was cannulated directly as the inflow branch and passive venous drainage was returned to the reservoir, where it was filtered, re-oxygenated and reperfused. The organ was weighed immediately prior to the perfusion and at its conclusion.

Results: 3 porcine pancreatic heads were perfused for a maximum of 60 minutes. Input pressure was predetermined by directly adjusting the duty cycle of the centrifugal pump using a closed-loop proportional-integral-derivative (PID) controller. PID is a commonly used feedback controller to regulate process variables such as pressure or flowrate. Continuous measurement of input pressure and flow taken during the perfusion was set to a maximum input pressure of 22mmHg and flow rate of 400 litres/minute. Inspection of the pancreas during perfusion showed uniform perfusion and not organ oedema. The absence of oedema was confirmed by weighing the organ before and after perfusion.

Conclusion: Whole organ pancreatic perfusion is feasible and may provide an innovative research platform. Our perfusion system is unique in its capability to set a predetermined pressure and/or flow rate, making it of significant relevance to pancreatic perfusion due to the pancreas' susceptibility to excessive pressure and flow rates. The association between perfusion parameters and histological appearances of the graft is currently being addressed.

Future work: Work is underway to histologically assess for evidence of oedema and necrosis to demonstrate preserved viability of the perfused pancreas.

OPTIMIZATION OF DOSE LEVELS OF ORALLY ADMINISTERED PANCREATIC ENZYME SUPPLEMENTS IN THE TINY-TIMSG DYNAMIC IN-VITRO GASTROINTESTINAL MODEL

M.-L. Orera-Peña¹, H. de Voogd², S. Bellmann³, T. Garcia³

¹Viatris, Global Medical Affairs, Madrid, Spain, ²Viatris, Global Clinical Development, Amstelveen, Netherlands, ³The TIM Company, Delft, Netherlands

Contact E-Mail Address: luisa.orera@viatris.com

Introduction: In diseases like chronic pancreatitis or cystic fibrosis, pancreatic exocrine insufficiency (PEI) is common and is treated by orally administered pancreatic enzyme supplements

Aims & Methods: The aim is to establish the optimal dose range of orally administered pancreatic enzymes (Pancreatin/PANC), to improve food digestion in patients suffering from PEI, by using the tiny-TIMsg dynamic in vitro GI model.

Fat digestion of a high-fat meal was investigated in the tiny-TIMsg system set to mimic severe pancreatic insufficiency, using 5% pancreatin and no TIM gastric lipase, as seen in chronic pancreatitis conditions. Four PANC dose levels were tested containing 35,000, 70,000, 80,000 and 150,000 lipase units.

The 'healthy' level of fat digestion was measured (positive control), as well as fat digestion during simulation of severe pancreatic insufficiency without supplementation (negative control).

Administered pancreatic enzyme efficacy was established indirectly, by measuring digestibility of total fatty acids (TFA) in the small intestinal compartment.

Results: TFA bioaccessibility after 6 hours in the tiny-TIMsg model, expressed as a percentage of TFA input from the meal and bile, is shown in the table. All PANC doses effectively increased fat digestion compared to the negative control. Bioaccessibility was dose-dependent after the housekeeper wave at 180 min and most clear at doses from 70k PANC.

Conclusion: PANC increased the lipid digestion in simulated pancreatic enzyme deficient conditions at all dose levels, in a dose-dependent manner.

Disclosure: The study has been funded by Viatris. Hanka de Voogd and Maria-Luisa Orera-peña are Viatris employees

LOSS OF ONECUT1 ALTERS PANCREATIC EXOCRINE DEVELOPMENT

J. Krüger¹, S. Heller¹, M. Breunig¹, M.K. Melzer^{1,2}, A. Kleger¹

¹Ulm University Hospital, Internal Medicine 1, Ulm, Germany, ²Ulm University Hospital, Department of Urology, Ulm, Germany

Contact E-Mail Address: jana.krueger@uni-ulm.de

Introduction: Mutations or loss of One Cut Homeobox 1 (ONECUT1) have recently been associated with an impairment in endocrine pancreatic development and early onset of diabetes. Additionally, ONECUT1^{-/-} mice have been shown to present with enlarged, cystic pancreatic ducts, indicating a broader role of the gene in pancreatic development and lineage segregation.

Aims & Methods: To further unravel the role of ONECUT 1 in human pancreatic development with a focus on the exocrine department, we implemented a human embryonic stem cell (hESC) derived pancreatic duct-like organoid (PDLO) model to investigate the effect of ONECUT1 loss *in vitro*.

Results: Wildtype (WT) and ONECUT1 knockout (KO) cell lines were differentiated to pancreatic progenitor cells and further matured to PDLOs in 3D matrigel culture. Already at PP stage, KO cells harbored an altered expression of genes important for exocrine development and increase of markers relevant for other lineages, such as intestinal or biliary development. At PDLO stage, KO organoids showed an enlarged, cyst-like morphology, which was discovered to be caused by higher proliferation and reduced apoptosis compared to WT organoids.

Additionally, polarity was found to be impaired in KO organoids, resulting in a distribution of CFTR channels on both the luminal and basal side of the cells and impaired swelling upon forskolin treatment.

Conclusion: Taken together, ONECUT1 seems to play a vital role in pancreatic organogenesis and the development of ductal as well as endocrine pancreatic cells.

Disclosure: no conflict of interest.

Introduction: Johanson-Blizzard syndrome (JBS) is a rare genetic disorder with autosomal recessive inheritance. The condition is characterized by congenital exocrine pancreatic insufficiency, aplasia of the nasal wings, and multiple other symptoms of varying severity. We could previously identify mutations in the UBR1 gene encoding one of several E3 ubiquitin ligases of the N-end rule pathway as the cause of the disease.

Aims & Methods: As mouse models incompletely recapitulate the phenotype of the disease, we employ pluripotent stem cells (PSCs) to investigate pancreatic facets of JBS. We have implemented two independent but complimentary PSC models by editing human embryonic stem cells via CRISPR/Cas9 and by generating induced PSCs from two patients sharing a severe pancreatic phenotype.

Results: Stepwise pancreatic lineage differentiation of UBR1 mutant PSCs did not reveal an early developmental defect in agreement with a normal pancreatic anlage in JBS patients. Global quantitative proteomics, however, revealed a stage-specific upregulation of a set of proteins in UBR1 ablated cells.

Specifically, a list of candidate proteins with described roles in cellular homeostasis were significantly upregulated. Upon repair of one allele of iPSCs from one patient the deregulation of such proteins could be successfully rescued *in vitro*. Whether these proteins are direct UBR1 substrates and contribute to the JBS phenotype in the pancreas is part of our ongoing analysis.

Conclusion: In summary, the thorough analysis of our established JBS cellular models focusing on viability and cellular homeostasis together with quantitative proteome analysis will provide us a comprehensive picture of JBS in the pancreas.

Disclosure: Nothing to disclose.

Introduction: Background: Irritable Bowel Syndrome (IBS) is one of the most frequent disorders in clinical practice with a mean 7.6-10.8% world-wide-prevalence and is associated with mild inflammatory response. There are studies that demonstrate the relationship between pancreatitis and systemic proinflammatory cytokines

Aims & Methods: Aim: We aimed to explore if there is any difference in the cytokines levels in EPI vs IBS-D patients.

Methods: An exploratory, nested-case-control study of patients aged over 18 years presenting to tertiary hospital outpatient with Rome IV criteria for IBS-D. From those, cases with faecal elastase <100 ug/g were considered as EPI patients, thus ≥200 ug/g as IBS. Due to the expected larger control group than cases, a control sample was selected by randomization before performing cytokines.

Gordis's rule of 4 controls per case was applied. Cytokines were described in median (interquartile range, IQR) and compared cases and controls with the Wilcoxon test. An overall agreement sub-analysis was performed for cytokines with significant median differences among study groups.

Diagnostic odds ratio (OR) was estimated through binary logistic regression if necessary, and adjusted to BMI with multivariate analysis. Data analysis was performed in Rv.4.0 (R Foundation for Statistical Computing; Vienna, Austria).

A total of 27 serum markers (Bio- Plex Pro human cytokine 27-plex Assay, Bio- Rad Lab., Inc.) was measured in all patients (FGF basic, Eotaxin, G-CSF, GM-CSF, IFN-γ, IL-1β, IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12 (p70), IL-13, IL-15, IL-17A, IP-10, MCP-1 (MCAF), MIP-1α, MIP-1β, PDGF-BB, RANTES, TNF-α, VEG).

Results: 25 patients were included, 5 EPI (mean age 67 (66-71) years, females 60%) and 20 IBS (mean age 57 (42-70) years, females 70%) (**table 1**). EPI patients showed a significant increase in monocyte chemoattractant protein 1 (MCP-1) (Median 289 pg/ml [219-385] vs 187 pg/ml [124-224], p= 0.049).

With an optimal cut-off of ≥218.87 pg/ml, MCP-1 differentiated EPI from IBS non-EPI patients with a sensibility, specificity, positive, negative predictive value and observed agreement of 80% (4/5; 28-99%), 75% (15/20; 51-91%), 44% (4/9; 14-79%), 94% (15/16; 70-100%) and 76% (19/25; 55-91%), respectively.

ROC curve reached an area under the curve of 0.79. MCP-1(MCAF) ≥218.87 reached an OR 12.0 (95% CI 1.074 - 134.11; P=.04); and OR 19.281 (95% CI 1.728 - Inf; P=.037) when adjusted to BMI. None of the other cytokines from the 27-panel kit showed significant difference between both groups.

Conclusion: Patients with EPI showed a significant increase in MCP-1 pro-inflammatory cytokine compared with controls in an IBS-D population; this cytokine is associated with several inflammatory diseases, including

pancreatitis. With an optimal cut-off of ≥218.87, MCP-1 differentiated EPI from IBS non-EPI patients. Further studies may demonstrate the usefulness of this cytokine to identify EPI in patients whom fulfill Rome IV criteria for IBS-D.

Contact E-Mail Address: markus.breunig@uni-ulm.de

Introduction: Given their capability to differentiate into each cell type of the adult human body, human embryonic stem cells (hESCs) provide a unique platform for developmental studies. The generation of pancreatic progenitor (PP) cells from pluripotent stem cells follows the sequential induction of virtually pure definitive endoderm (DE), foregut endoderm (GTE), and pancreatic endoderm (PE).

Aims & Methods: In the current study, we implemented this culture system to understand the role of pancreatic progenitor differentiation and proliferation factor (PPDPF), an up to know nearly uncharacterized protein. A double nicking CrisprCas9 approach was used to ablate PPDPF in hESCs.

Results: Flow cytometry, immunofluorescence, qPCR, and RNA-seq experiments revealed an important role of PPDPF in facilitating a pancreatic fate. Such developmental function was accompanied by a decrease in apoptosis at the pancreatic endoderm in PPDPF deficient cells. In addition, we identified with KCTD12 and MAGED1 novel interaction partners of PPDPF and investigated the expression of PPDPF in normal and human pancreatic cancer tissue.

Conclusion: Thus, we report a novel signalling molecule playing a critical role during human pancreas development and identified a putative regulatory mechanism based on a pluripotent stem cell differentiation platform.

Disclosure: Nothing to disclose.

P0803

THE EFFECT AND MECHANISM OF LPS AND ASCITIC FLUID OF SEVERE ACUTE PANCREATITIS ON INTESTINAL BARRIER FUNCTION IN VITRO

Y. Song¹, F. Zhou¹, Y. Xie¹, X. Zhou¹

¹First Affiliated Hospital of Nanchang University, Nanchang, China

Contact E-Mail Address: songyanpingbg@163.com

Introduction: Severe acute pancreatitis (SAP) progresses rapidly and is often associated with systemic inflammatory response syndrome (SIRS) and persistent multiple organ failure (MOF), with a mortality of up to 40%. The disruption of intestinal barrier function in the early stage of SAP is the main reason for aggravating systemic inflammatory response and leading to poor progression.

The regulation of TLRs signal pathway in intestinal mucosa plays an important role in defending against the invasion of intestinal pathogens and maintaining the homeostasis of intestinal epithelial immune system. Studies have confirmed that the overactivation of TLRs signaling pathway occurs in multiple systems of the body during SAP, which is closely related to intestinal barrier dysfunction. In addition, inhibition TLRs signaling pathway can improve intestinal function and alleviate SAP.

Our previous study found that ascites fluid (AF) from SAP patients significantly upregulated TLR4 in macrophages and the downstream molecule MyD88, mediating NF- κ B activation and promoting the release of pro-inflammatory cytokines. Therefore, LPS and AF may be involved in the occurrence of intestinal barrier dysfunction by regulating the activation of TLRs signaling pathway in intestinal mucosa.

Therefore, the purpose of this study is to explore the causes and mechanisms of SAP intestinal barrier dysfunction based on TLRs signaling pathway. This study will help to find a new direction of intestinal barrier function protection and provide a new research idea for the treatment of severe acute pancreatitis.

Aims & Methods: The disruption of intestinal barrier function in the early stage of Severe acute pancreatitis (SAP) resulted in translocation of bacteria and lipopolysaccharide (LPS), which in turn aggravates systemic inflammatory responses and leads to poor progression. The Toll-like receptor (TLRs) signaling pathway is overactivated in many systems and organs throughout the body during SAP, which is closely related to intestinal barrier dysfunction.

The purpose of this study was to investigate the effects of ascites and LPS on intestinal epithelial cell barrier function in SAP patients through TLRs signal and the mechanism of action. And the monolayer intestinal epithelial cell barrier model was constructed by Caco-2 and IEC-6, and then the effects of LPS or SAP ascites on intestinal epithelial cell barrier function and TLRs signaling pathway were observed. SIGIRR knockdown Caco-2 cell line was constructed to verify the negative regulation of SIGIRR on TLRs signaling pathway.

Results: The integrity of intestinal epithelial cell barrier and paracellular permeability were disrupted after LPS and SAP ascites treatment. The expression of tight junction protein was significantly down-regulated. Intestinal barrier dysfunction was more severe in the hypertriglyceridemia ascites group.

In addition, we also found that intestinal epithelial cells not only showed overactivation of TLRs signaling pathway, but also significantly down-regulated SIGIRR expression. SIGIRR knockdown was also associated with a significant increase in expression of the TLRs signaling pathway.

Conclusion: Both LPS and SAP ascites can cause intestinal barrier dysfunction, in which HTG-AF is more toxic than B-AF. Excessive activation of TLRs signaling pathways may be one of the mechanisms by which LPS and SAP ascites destroy the barrier function of intestinal epithelial cells. The excessive activation of TLRs signals in intestinal epithelial cells may be related to the inhibition of the negative regulator SIGIRR.

Introduction: Genetic programs from early development are crucial for organ regeneration. Re-activation of such programs can be observed in pancreatic acinar cells during reconstitution from injury. *T-Box Transcription Factor 3 (Tbx3)* facilitates somatic reprogramming and is involved in self-renewal.

Aims & Methods: Therefore, we hypothesize that *Tbx3* is expressed during regeneration from acute pancreatitis. Furthermore, we speculate that *Tbx3* is involved in embryonic development of the pancreas.

Results: Analysis of publicly available single-cell transcriptomic datasets revealed expression patterns of *Tbx3* during different milestones of murine embryonic development in various cellular compartments of the pancreas. Correlation of the expression with an *in vitro* directed differentiation of human pluripotent stem cells toward the pancreatic lineage confirmed a high *TBX3* expression during lineage commitment compared to other *T-box* transcription factors. Protein expression of *Tbx3* was confirmed by immunofluorescence studies on embryonic mice from a *Tbx3-Venus* reporter mouse strain.

Here, we clearly demonstrate that *Tbx3* expression is:

- i. Augmented at different stages during embryonic development of the pancreas on protein levels,
- ii. Switches expression patterns from mesenchymal to epithelial expression and;
- iii. Is restricted in adult pancreata to stellate cells.

However, pancreas specific deletion of *Tbx3* already at embryonic stage using a *p48-Cre* mouse resulted only in mild phenotypic alterations in the adult pancreas compared to wildtype counterparts. Higher numbers of alpha cells were detected in *Tbx3-KO* mice. However, additional depletion in the mesenchymal compartment by an *Nkx3-2-Crere* recombinase did only lead to few phenotypic alterations.

Interestingly, induction of experimental acute pancreatitis by caerulein led to an upregulation of *Tbx3* expression during the regeneration phase in wildtype mice. Concordant with our hypothesis, we observed a delayed pancreatic regeneration after caerulein-induced acute pancreatitis in *p48-Cre* depleted homozygous *Tbx3* knockout mice, resulting in a higher rate of acinar-to-ductal-metaplasia, accumulation of fibrosis and excessive proliferation in *Tbx3-KO* mice.

Conclusion: Taken together, we observed differential *Tbx3* expression patterns during embryonic development and regeneration from acute pancreatitis. A knockout of *Tbx3* leads to delayed organ regeneration and excessive proliferation after induced damage. This may indicate that *Tbx3* favors tissue development and repair through regulation of stem cell compartments and fine-tuning of genetic programs from embryonic development.

Introduction: Acute biliary pancreatitis (ABP) involves inflammation of the pancreatic gland due to the presence of choledocholithiasis (CLT) that normally spontaneously expels into the duodenum. Persistent biliary lithiasis (PBL) in the common bile duct (CBD) increases the probability of both biliary pain, biliary infection, and recurrence of ABP.

The objective of this study was to determine the efficacy of a predictive model of PBL based on epidemiological, analytical and ultrasound data in patients with ABP.

Aims & Methods: A retrospective observational cohort study included patients 18 years of age or older, admitted for ABP (defined according to the revised Atlanta classification) in our center, between the years 2013-2018. Epidemiological, analytical, imaging, and endoscopic variables were collected. The final diagnosis of PBL was made by magnetic resonance imaging cholangiography (C-MRI), endoscopic ultrasonography (EUS), or endoscopic retrograde cholangiopancreatography (ERCP).

Comparative analyses were performed between patients with the presence and absence of PBL. Subsequently, a multivariate logistic regression analysis was performed to develop a predictive model of PBL.

Results: 204 patients with ABP were included. 65.7% women, mean age 73 years. PBL was detected in 49 patients (24%). 145 patients (71.07%) underwent only C-MRI; 44 patients (21.56%) underwent C-MRI and ERCP; 1 patient (0.49%) underwent EUS and ERCP and 14 patients (6.86%) underwent ERCP only.

The variables that showed the greatest association with the presence of PBL were dilation of the common bile duct (CBD) in emergency ultrasound ($p < 0.001$; OR = 27; 95% CI: 5.8-185.5), GGT in the analysis at 72h ($p = 0.008$; OR = 3.4; 95% CI: 1.5-8.9); the presence of biliary sludge in the gallbladder, which protected against PBL ($p = 0.008$; OR = 0.03; 95% CI: 0.001-0.3).

The predictive model showed an unvalidated AUC of 0.902 (95% CI: 0.837-0.967) and a validated AUC of 0.858 for the detection of PBL in patients with ABP. A nomogram was subsequently developed with the results of the model.

Conclusion: The predictive model obtained, with simple variables to determine, had a high efficacy in the detection of PBL in patients with ABP, so it could be used in clinical practice.

Introduction: Type 2 diabetes is known as a risk factor for acute pancreatitis, but the risk of acute pancreatitis according to glycemic status and body mass index (BMI) has remained unknown.

Aims & Methods: We aim to investigate the risk of acute pancreatitis according to BMI and glycemic status in patients with type 2 diabetes. We included 3,912,496 subjects from the Korean National Health Insurance System cohort who underwent the National Health Screening program in 2009. Each subject's clinical course was examined through follow-ups until December 2018.

BMI and glycemic status were each categorized into five groups. Hazard ratios (HRs) of acute pancreatitis according to BMI and glycemic status were calculated using the Cox proportional-hazards model with the adjustment of clinical factors.

Results: The adjusted HRs of acute pancreatitis were the highest in the underweight group (BMI < 18.5) in all five glycemic status categories. The HR of acute pancreatitis in the underweight group increased as the glycemic status worsened, excluding the category of diabetes for more than five years (HR 1.381 for normal fasting glucose; 1.805 for impaired fasting glucose; 2.332 for new-onset diabetes; 4.51 for diabetes duration < 5 years; 4.135 for diabetes duration ≥ 5 years). Sustained underweight group also showed the highest HR in those with and without type 2 diabetes (HR 1.674 for non-diabetes and 1.311 for diabetes).

Conclusion: We found that the risk of acute pancreatitis was further increased in the underweight group, depending on the glycemic status and duration of type 2 diabetes.

Disclosure: Nothing to disclose.

Introduction: Patients with history of acute pancreatitis (AP) or diabetes have an increased risk of pancreatic cancer. However, the association between AP and other gastrointestinal cancers in diabetic patients is currently not well understood. Thus, the objective of this nationwide cohort study was to investigate the association between AP and gastrointestinal cancers in type 2 diabetic patients.

Aims & Methods: Data from the Korean National Health Insurance Service database were analyzed. Participants with diabetes who underwent a general health examination between 2009 and 2012 were followed up for cancer development until December 2018. They were divided into two groups according to AP history. The primary outcome was the occurrence of gastrointestinal cancer.

Results: A total of 2,263,184 patients were included in the final analysis. Of them, 2,390 patients were assigned into the AP group. Patients in the AP group were found to have a significant higher risk for gastrointestinal cancer except for esophageal cancer as follows: gastric cancer (aHR = 1.637, 95% CI: 1.323–2.025), colorectal cancer (aHR = 2.183, 95% CI: 1.899–2.51), liver cancer (aHR = 2.216, 95% CI: 1.874–2.621), pancreatic cancer (aHR = 4.558, 95% CI: 4.078–5.095), bile duct cancer (aHR = 3.996, 95% CI: 3.091–5.269), and gallbladder cancer (aHR = 2.445, 95% CI: 1.459–4.099).

Conclusion: The history of AP particularly increases the risk of gastrointestinal cancer in diabetic patients. Thus, it is necessary to investigate the history of AP in diabetic patients and more actively recommend screening for gastrointestinal cancers in such patients.

Contact E-Mail Address: clararamosbel@gmail.com

Introduction: One of the complications of acute pancreatitis (AP) is the development of portosplenomesenteric venous thrombosis(1). In various published studies, its incidence varies between 1% and 24%, and may be associated with multiple complications such as liver failure, intestinal ischemia, and gastrointestinal bleeding from gastroesophageal varices(2–5).

The use of anticoagulation seems reasonable, although the evidence on its efficacy and safety is scarce.

Aims & Methods: The objective of this study is to determine the rate of recanalization of splanchnic thrombosis in patients with AP, as well as the associated factors.

Single-center, observational, retrospective study conducted at the Hospital General Universitario Gregorio Marañón (HGUGM) in Madrid. All patients diagnosed with AP and splanchnic thrombosis between January 2015 and December 2019 were included. Patients with chronic pancreatitis, previously diagnosed portal hypertension or invasive malignant disease were excluded.

Results: In the HGUGM, 1213 patients with AP were treated over 5 years and 30 splanchnic thrombosis meeting the study criteria (2.47%) were diagnosed. Of the 30 patients with thrombosis, more than half had splenic vein thrombosis (n=17). Almost all patients (96.7%) received anticoagulation. Recanalization was confirmed in 19 (63.3%) patients after one year from the diagnosis.

Factors associated with recanalization were studied and an association was identified with the history of previous acute pancreatitis (36.4% vs 5.3%; p=0.047) and with the presence of occlusive thrombosis (45.5% vs 5.3%, p=0.016). In the multivariate analysis, the presence of occlusive thrombosis was associated with a lower risk of recanalization (OR, 0.06; 95% CI, 0.004–0.87). 16.7% (n=5) had at least one bleeding complication that required red blood cell transfusion. 10% (n=3) died in the following 12 months.

Conclusion: Splanchnic thrombosis associated with acute pancreatitis is a relatively common complication with high rates of bleeding and mortality. In our study, practically all thrombosis were anticoagulated, recanalization was achieved in more than half, and occlusive thrombosis was identified as a factor associated with less recanalization.

Introduction: Intraductal Papillary Mucinous Neoplasms (IPMNs) are a mucin producing subtype of pancreatic cysts arising from the pancreatic duct system. The tick mucous produced by IPMNs can cause an obstruction of the main pancreatic duct leading to recurrent acute pancreatitis (RAP). Endoscopic pancreatic sphincterotomy (EPS) has been described as an alternative minimal invasive procedure to decompress the pancreatic ductal system and reduce the recurrence of ARP. The aim of this study is to assess the safety and effectiveness of ESP in reducing the episodes of RAP in patients with IPMNs related RAP.

Aims & Methods: Patients with IPMNs induced RAP treated with ESP from January 2004 to December 2020 were retrospectively collected. Clinical and technical data were recorded (demographics, type of IPMN, number of AP episodes, type of EPS, adverse events). A clinical follow-up was performed to assess the number of episodes of AP occurred after the EPS.

Results: 25 patients were included (Table 1). The mean follow-up from ESP period was 93.4 months (SD± 56.6). The mean number of AP before and after EPS were respectively 3.29 (SD ± 1.04) and 0.51 (SD ± 0.71) ($p < .00001$ paired samples t-test). A complete response (no further episodes of AP) and a partial response (>50% reduction of AP episodes) were obtained in 64% and 88% of the cases, respectively. One post-EPS bleeding and one minor-papilla stenosis were reported and were endoscopically managed. One patient underwent pancreatic resection for the occurrence of high-risk stigmata.

Demographics:

No. of patients treated, n	25
Age (years), mean ± SD	59.6 ± 15
Sex (men), n (%)	9 (45%)

Type of IPMN:

Main duct-IPMN, n (%)	6 (24%)
Side Branches-IPMN, n (%)	17 (68%)
Mixed type-IPMN, n (%)	2 (8%)

Endoscopic procedure:

Major Papilla Sphincterotomy, n (%)	20 (80%)
Minor Papilla Sphincterotomy, n (%)	5 (20%)
Nose-Pancreatic Drainage, n (%)	21 (84%)
Pancreatic stent, n (%)	4 (16%)

Procedure related adverse events:

Sphincterotomy stenosis (treated with re- sphincterotomy, no further episodes of AP)	1
Post-sphincterotomy bleeding (treated with adrenaline injection and endoclip)	1

IPMNs: Intraductal Papillary Mucinous Neoplasms; MD-IPMN: Main Duct-Intraductal Papillary Mucinous Neoplasm; SB-IPMN: Side Branches-Intraductal Papillary Mucinous Neoplasm; MT-IPMN: Mixed-Type-Intraductal Papillary Mucinous Neoplasm; AP: acute pancreatitis; SD: standard deviation.

Table 1. Demographic and technical data of endoscopic pancreatic sphincterotomy in 25 patients with IPMNs induced RAP.

Conclusion: The correlation between IPMN-related AP and an increased risk of high-grade dysplasia or invasive carcinoma is controversial. Although the major international guidelines consider IPMN related AP a relative indication for pancreatic surgery, pancreatic resection is still today

burdened by high morbidity and mortality and endoscopy may represent a less invasive approach to manage the recurrence of AP.

Few studies evaluated the role of ERCP in IPMN-related ARP. Bernardoni et al. reported a significant reduction in AP episodes after EPS (3.5 ± 2.32 vs. 0.56 ± 1.03 , $P < 0.0001$) in 16 patients with IPMN-related ARP, without IPMN progression and only mild adverse events were reported.

Gonzalez et al. in a multicenter retrospective study involving 21 patients with symptomatic BD-IPMN (including both ARP and pancreas related abdominal pain) treated with EPS reported a complete response in 71% of the cases and a partial response in 81% (with a better response in patients with ARP -90%- than those with pancreas related abdominal pain - 50%-). The present experience confirms that EPS is safe and effective in the management of IPMN-related ARP including BD-IPMN, MD-IPMN and MT-IPMN. After a long-term follow-up (mean 93.4 months), a statistically significant reduction of AP episodes was documented with a complete response and a partial response in 64% and 88% of the cases respectively with only mild adverse events.

The main limitations of the present study are the retrospective design, the limited number of patients enrolled, and the absence of a control group, prospective trials are needed to confirm these data.

Introduction: Acute pancreatitis (AP) is a relatively rare but serious complication that can occur after organ transplantation.

Aims & Methods: The aim of this study was to evaluate the incidence, potential risk factors and course of AP in patients following liver transplantation at a single large-volume transplant centre.

Results: Out of a total of 1850 transplanted patients, 49 (2.8%) were diagnosed with AP. Of this group, 37 (75.5%) exhibited a mild form of AP and 12 (24.5%) a severe form of AP.

The mortality rate was 10% overall and 42% in the group of patients with severe AP. An early form of AP (<30 days from transplantation) occurred in 13 patients (26.5%), most of whom presented with severe AP (10 patients, 76.9%); 4 patients died (40%). A late form of AP was diagnosed in 36 patients (73.5%), most of whom exhibited mild AP (34 patients, 94.4%); one of two patients with severe AP died.

The most common AP aetiologies were post-ERCP (38.8%), idiopathic (34.7%) and post-operative (18.4%). Chronic HBV infection proved a risk factor for the development of AP (p=0.01).

	With acute pancreatitis		Mortality	Without acute pancreatitis	
	n	%	%	n	%
Total	49	2,6	10,2	1801	97,4
Age (average)	53			49,5	
Men	30	61,2	10	1078	58,3
Women	19	38,8	10,5	772	41,7
Severe AP	12	24,5	42		
Mild AP	37	75,5	0		
Early AP	13	26,5	31		
Late AP	36	73,5	3		

Table. Characteristics of patients after liver transplantation in relation to acute pancreatitis (AP)

Conclusion: AP in liver transplant recipients was more frequent and more severe than in the general population. This unfavourable course was associated with the occurrence of AP in the early post-transplant period. Liver transplantation due to complications of HBV infection proved a risk factor for the development of AP.

Introduction: Pancreas divisum (PD) is a common congenital variant of the pancreatic ductal system and a potential cause of acute recurrent pancreatitis (ARP). Endoscopic minor papilla sphincterotomy (MiES) is the most common procedure performed in the management of PD-related ARP.

The aim of this study is to perform a meta-analysis estimating the efficacy and the safety of MiES in the management of patients with PD-related ARP.

Aims & Methods: A systematic review of the literature was performed with the purpose of finding papers focusing on MiES performed in patients with *Pancreas Divisum* (PD) suffering from Acute Recurrent Pancreatitis (ARP) through January 2022. The electronic databases searched included MEDLINE (PubMed) and Scopus (Science Direct).

The studies were reviewed and selected according to inclusion and exclusion criteria. Evaluation of Heterogeneity and publication bias was performed, and a random effect model was used to estimate the effect size of each study. Design, analysis, and report of findings were performed according to the most recent PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines.

Results: 113 articles were selected and reviewed, 13 met the inclusion criteria. All the studies were retrospective with a mean follow-up duration of 45.9 months. A total of 323 patients with PD-related ARP treated with MiES were included in the meta-analysis. The clinical success rate of MiES (defined as no further episodes of ARP, reduction of episodes of ARP, or improvement in QoL) was of 77% (95%CI: 72% – 81%; p=0.30).

The common fixed effects model disclosed a 25.5% overall complications rate (95%CI: 19.3% – 32.8%; p=0.42): acute pancreatitis in 14.3% (95%CI: 9.7% – 20.6%; p=0.36), bleeding in 5.6% (95%CI: 2.9% – 10.4%; p=0.98), and other AEs in 5.6% (95%CI: 2.9% – 10.4%; p=0.67).

Conclusion: MiES is a safe and effective treatment in the management of PD-related ARP. The retrospective nature of the studies selected is the main limitations of this metanalysis. Prospective trials are needed to confirm these data.

Disclosure: Nothing to disclose.

EXPLORING THE OPTIMAL TIMING OF PERFORMING ENDOSCOPIC ULTRASOUND AFTER AN EPISODE OF ACUTE IDIOPATHIC PANCREATITIS

W. Sbeit¹, A. Shahin¹, T. Khoury¹

¹Galilee Medical Center, Department of Gastroenterology, Naharia, Israel

Contact E-Mail Address: tawfik.khoury.83@gmail.com

Introduction: Patients with acute idiopathic pancreatitis (AIP) should undergo further imaging tests such as endoscopic ultrasound (EUS) for further investigation. The time interval from the episode of AIP and the timing of EUS is still controversial.

Aims & Methods: We aimed to explore the optimal for performing EUS and to reveal parameters that might predict longer interval needed for performing EUS. We performed a single-center retrospective study at Galilee Medical Center, at which we included all patients who underwent EUS for further investigation of AIP.

Results: Overall, we included 51 patients. The average age of all patients was 54.2 ± 17.6 years (range 22-69 years), and more than half of the study cohort were males (56.9%). Classifying patients to inflamed vs. normal pancreatic tissue on EUS, we found that among patients with normal pancreatic tissue, the EUS was performed up to 44.7 ± 28.3 days from discharge, while it was higher for patients with inflamed pancreatic tissue of 48.1 ± 22.3 days.

On descriptive analysis, we found only the radiological average severity score according to Balthazar was to be significantly associated with inflamed pancreatic tissue on EUS, as it was 2.4 ± 0.74 vs. 1.5 ± 1.3 in the normal pancreatic tissue group ($P=0.03$). There was no difference in the Bed-side index for severity in acute pancreatitis (BISAP) score and there was no difference in the average American Society of Anaesthesiologist physical status (ASA) score between the two groups. Notably, 26.3% of patients had inflamed pancreatic tissue when performing EUS at 4 weeks, as compared to 15.8% who had inflamed pancreatic tissue at EUS at $>4 \leq 6$ weeks.

Conclusion: Radiological severity score was the most important in determining the time interval of performing EUS after an episode of AIP. Six-weeks interval is seeming to be needed among patients with higher Balthazar score.

Disclosure: Nothing to disclose.

STUDY OF BILIARY MICROLITHIASIS IN THE CAUSATION OF ACUTE AND RECURRENT PANCREATITIS IN CHILDREN

S. Kumar¹, S.K. Yachha¹, M. Sarma¹, R.N. Rao², U. Poddar¹, A. Srivastava¹

¹Sanjay Gandhi Postgraduate Institute of Medical Sciences, Pediatric Gastroenterology, Lucknow, India, ²Sanjay Gandhi Postgraduate Institute of Medical Sciences, Pathology, Lucknow, India

Contact E-Mail Address: drsumitkgmu@gmail.com

Introduction: About one-third of children with acute and acute recurrent pancreatitis (AP/ARP) remain idiopathic and may progress to chronic pancreatitis. In adults, bile microlithiasis contributes to 7-79% of AP/ARP¹. However corresponding pediatric literature is lacking.

Aims & Methods: To study the occurrence of biliary microlithiasis in children with AP/ARP and to establish the causal relationship between them.

Consecutive children from 8-18 years with AP/ARP of idiopathic etiology were included over 2 years study period from November 2017 to October 2019.

Duodenal bile was collected by putting a naso-duodenal catheter under continuous cholecystokinin infusion. 10mL of the collected bile was centrifuged and examined under polarized microscope. Pellet obtained after centrifugation will be immediately observed at 37°C under a polarizing microscope (40X) fitted with a heating stage for the presence of cholesterol monohydrate crystals (CMC) and calcium bilirubinate granules (CBG). Cholesterol monohydrate crystals (CMC) will be identified as birefringent, rhomboid shaped crystals. The presence of brick-red, non-birefringent aggregates of any size will be recorded as calcium bilirubinate granules (CBG). Presence of any number of CMC or >5 CBG on at least 1 slide was considered positive. At least 3 slides will be examined. An average of the number of crystals found in 3 slide examined will be taken for the purpose of grading of abundance. Grading of the abundance will be done as follows Few: <10 /per slide, Moderate: 2-10per high-power field Abundant >10 per high-power field or clumps.

Patients found positive for the presence of microliths were started on ursodeoxycholic acid (UDCA) followed by a repeat bile microscopic examination after 6 months along with the assessment of symptoms.

Results: A total of 33 bile microscopic examinations were carried out in 29 children (22 male) with a median age of 14 (range, 8-17) years. Six children had AP and 23 were diagnosed as ARP. CMC were seen in 5 (17%) patients (AP=2, ARP=3). None of our patients was found to have CBG. All 5 children with CMC were started on UDCA therapy. Four of them underwent repeat bile microscopic examination after 6 months which was normal. None of the 5 children on UDCA treatment had any further episodes of AP over a median follow-up of 16 (4-22) months. There were no complications in any case while performing the bile collection.

Conclusion: A small (17%) but substantial proportion of children with idiopathic AP/ARP was found to have biliary microlithiasis. Resolution of microlithiasis and no recurrence of AP on UDCA therapy may substantiate biliary microlithiasis as a cause of AP/ARP in children.

Introduction: In up to 20% the etiology of acute pancreatitis (AP) remains elusive after routine work-up. Nevertheless, a biliary etiology warrants treatment to prevent recurrence. According to international guidelines EUS is recommended to exclude occult microlithiasis/biliary sludge as cause of pancreatitis. In a systematic literature review we analysed definitions of biliary sludge and microlithiasis.

In an expert survey we aimed for a consensus definition allowing to prospectively determine the risk of biliary pancreatitis from sludge and/or microlithiasis.

Aims & Methods: Following the PRISMA guideline and derived from a systematic review of the literature an online-survey (36 questions: clinical cases, definition, treatment strategy) was developed and sent to 30 HBP and EUS experts from 11 countries and 4 continents to coin definitions agreed on by audience voting (EPC 2021).

Results: The literature review demonstrated that in 13% of original articles and 19.2 % of reviews, microlithiasis and biliary sludge are used as synonyms and in the survey 41.7 % experts described the term “biliary sludge” and “biliary microlithiasis” as identical finding, illustrating the clinical dilemma. As result of the survey three definitions were proposed, agreed and confirmed.

1. The term “biliary sludge” can be used both to diagnose findings in the bile duct as well as the gallbladder.

2. Discrete, hyperechoic material inside the gallbladder or the bile duct, without acoustic shadowing, which sediments in the most dependent part of the gallbladder represents biliary sludge.

3. The term “biliary microlithiasis” should be used exclusively for cases in which EUS examination of the biliary tree reveals presence of stones bigger than 3 and less than 5 mm (in diameter).

Conclusion: We propose for the first time a definition of the localization, sonomorphology and size of biliary sludge as well as microlithiasis. Its relevance for risk assessment of pancreatitis and treatment recommendation needs testing in prospective studies.

Disclosure: Nothing to disclose.

Introduction: Post pancreatectomy acute pancreatitis (PPAP) is difficult to diagnose and poorly characterized in its early phases yet represents the ideal target for novel therapeutic opportunities.

Aims & Methods: This study aims to systematically investigate the early radiologic, biochemical, and clinical features of PPAP.

This is a prospective observational study of patients undergoing pancreaticoduodenectomy from September 2019 to January 2021. Diffusion-weighted (DW) magnetic resonance imaging (MRI) was performed on post-operative day (POD) 3. Serum pancreatic amylase and lipase were daily assessed until POD 5. Postoperative serum hyperamylasemia (POH) and PPAP (grade B-C) were defined based on the International Study Group for Pancreatic Surgery (ISGPS) definition.

Results: A total of 65 patients were enrolled according to the sample size calculation. Patients with POH and PPAP had significantly lower values of apparent diffusion coefficient(ADC) at DW-MRI but no macroscopic features consistent with acute pancreatitis (AP).

Subsequently, 21 patients (32.3%) underwent computed tomography imaging for clinical worsening, and six had radiologic features of AP. All these latter patients had POH and worse postoperative outcomes (p<0.05) in terms of local (postoperative pancreatic fistula: 83%) and systemic mor-

bidity (Clavien Dindo $\geq$ grade IIIb: 67%). The POH incidence was 21.5% (n=14), while PPAP occurred in 6 patients (9.2%), with 4 grade B (6.1%) and 2 grade C (3%).

Conclusion: PPAP is characterized by early biochemical alterations. Macroscopic radiologic features appear later and correlate with worse clinical scenarios. This paper paves the ground for the inclusion of PPAP in the spectrum of its medical counterpart, promoting future trials on its prediction, prevention and treatment.

ASGE SOP 2019 CHOLEDOCHOLITHIASIS CRITERIA ARE NOT RELIABLE IN PATIENTS WITH ACUTE BILIARY PANCREATITIS: A SINGLE CENTER EXPERIENCE

Ž.P. Černe¹, D. Drobne²

¹Medical Faculty, University of Ljubljana, Ljubljana, Slovenia, ²University Medical Centre Ljubljana Slovenia, Department of Gastroenterology and Hepatology, Ljubljana, Slovenia

Contact E-Mail Address: david.drobne@gmail.com

Introduction: American Society for Gastrointestinal Endoscopy (ASGE) Standard of Practice (SOP) Guideline 2019 removed gallstone pancreatitis as a criterion for early endoscopic retrograde cholangiopancreatography (ERCP). However, most clinicians still assess the risk of choledocholithiasis in patients with acute pancreatitis by using ASGE 2019 criteria although these criteria were not tested specifically in patients with acute pancreatitis.

Aims & Methods: In this retrospective study we aimed to identify clinical predictors of choledocholithiasis in patients with acute biliary pancreatitis. We also studied the reliability of high and intermediate risk ASGE 2019 predictors of choledocholithiasis in patients with acute biliary pancreatitis.

In our hospital, which is a tertiary referral center, all patients with acute biliary pancreatitis (except those with confirmed stones in common bile duct (CBD) with transabdominal US or clinical cholangitis) have performed endoscopic ultrasound (EUS) to confirm or exclude choledocholithiasis before potential ERCP within 24 hours of admission or planned cholecystectomy.

Here we studied whether EUS could be avoided in some patients with acute biliary pancreatitis by using ASGE 2019 high or intermediate risk predictors for choledocholithiasis. We thus calculated the proportion of

patients with presence or absence specific ASGE 2019 predictor (dilated CBD on transabdominal US, bilirubin level at the time of EUS, increased liver biochemistry, patient's age) according to the EUS result (CBD stone confirmed vs. excluded).

Furthermore, we also studied the potential predictive value of improvement of bilirubin and liver biochemistry from the time of admission until the EUS was actually performed.

Results: In total we included 73 consecutive patients who were admitted to our hospital due to acute biliary pancreatitis in year 2021 and had performed EUS. EUS was performed at a median of 1 day after admission (interquartile range 0-2 days). EUS confirmed choledocholithiasis in 15/73 (21%) patients. Among 8 patients with an ASGE high risk criterion (bilirubin >4 mg/dL + CBD dilatation as assessed by transabdominal US) only 3/8 (37.5%) had confirmed choledocholithiasis by EUS.

Intermediate risk ASGE criteria performed similarly with choledocholithiasis confirmed in 15/60 (25%), 8/42 (19%), 5/16 (31%) ($p=0.59$) patients with abnormal liver biochemical tests, age > 55 years or dilated CBD by transabdominal US, respectively. Different bilirubin levels were not reliable predictors of choledocholithiasis as patients with low (<1.81 mg/dL), intermediate (1.81-4 mg/dL) and high (>4 mg/dL) bilirubin had similar proportions of EUS-confirmed choledocholithiasis (4/22 (18%), 5/24 (21%), 6/22 (27%), respectively ($p=0.76$). Also, drop of bilirubin by 50% from admission until EUS examination was not predictive of choledocholithiasis vs. no choledocholithiasis (26% vs 33%, $p=0.69$).

Conclusion: In this retrospective cohort of patients with acute biliary pancreatitis ASGE 2019 and biochemical criteria were not reliable tool for prediction of choledocholithiasis. Our findings suggest that EUS should be performed in all patients with acute biliary pancreatitis before ERCP or cholecystectomy.

Introduction: Acute necrotizing pancreatitis (ANP) is a common pathology, associated with significant morbidity and mortality. The most common complications are related to the pancreatic necrosis (infection, organ compression). For several years, these complications have been managed

a "step-up" strategy, which involves endoscopic and/or radiological drainage, and only if unsuccessful: surgical necrosectomy. Bleeding complications from all causes are also frequent (10 to 29% of ANP) and severe (mortality 31 to 52%). No recent studies have investigated the specific bleeding complicating ANP caused by arterial rupture and their mechanism. The objective of our study is to highlight the risk factors for arterial bleeding complicating acute ANP at the time of the "step-up" management.

Aims & Methods: Main aim was to identify risk factors for arterial bleeding in patients with acute necrotizing pancreatitis (ANP).

This retrospective single-center case-control study have included patients with ANP (2017-2019) in a referral center. All patients diagnosed with AP and a CTSI severity score ≥ 4 for whom clinical and radiological data were available were included. Cases and controls were patients respectively with and without arterial bleeding. Clinical, laboratory, imaging, and follow-up data were collected. Two radiologists retrospectively reviewed CT-scans to identify culprit arteries, vascular lesions, presence and location of drains. A Cox-Mantel model was adjusted to identify risk factors for bleeding.

Results: A total of 148 patients (101 [68%] men, mean 54 ± 14.6 yrs) was included. Twenty-eight (19%) patients experienced bleedings after a mean 66 ± 50 days of ANP course. Warning signs (abdominal pain, deglobulization) preceded bleeding in 8/28 (29%) cases. The main culprit arteries were the gastroduodenal ($n=12$, 40%) and splenic arteries ($n=11$, 37%). Vascular anomalies concerned 26/28 (93%) patients in cases and 9/106 (8%, isolated narrowing artery in 2/3 of cases) in controls ($p<0.001$). In cases, vascular anomalies included pseudoaneurysms ($n=12$, 41%), arterial irregularities ($n=11$, 37%), narrowing ($n=5$, 17%) and interruption ($n=3$, 10%); 23% of patients presented several lesions. At least one was present on the previous recent CTscan in 11/21 (52%) cases.

An artery was in contact with a drain (radiological drain or endoscopic stent) in 9/28 (32%) cases and 12/120 (10%) controls ($p=0.01$). Multivariate analysis identified anticoagulation (OR=6.9, 95%CI 2.3-20.8), $p=0.001$) and a drain in contact with an artery (OR=3.9 95%CI 1.14 -13.3, $p=0.025$) as predictors of bleeding.

Embolization was performed in 24 (86%) cases. Bleeding recurred in 7 (33%) cases. Admission in ICU and mortality rates were significantly higher in cases compared with controls (93% vs. 58%, $p<0.001$, and 29% vs. 6%, log-rank $p=0.001$).

Conclusion: Arterial bleeding occurs in one out of five patients with acute necrotizing pancreatitis. Vascular anomalies are frequent, and are not limited to pseudoaneurysms. Curative anticoagulation appears as the main risk factor for bleeding.

Disclosure: Nothing to disclose.

Introduction: Jaundice can lead to poor prognosis in acute pancreatitis but whether mild elevations in total bilirubin (TB) can be related to severe acute pancreatitis has been scarcely studied.

Aims & Methods: The aim of our prospective study is to assess if mild elevations of TB are related to poor outcomes in acute pancreatitis. Patients admitted to our tertiary center for acute pancreatitis were included. Blood samples with markers routinely used in acute pancreatitis, including TB,

were taken on admission. Patients were divided into three groups: normal bilirubin (TB < 1.5mg/dL), mild hyperbilirubinemia (1.5 - 3mg/dL) and jaundice (> 3mg/dL). Patients were followed until discharge or death and poor outcomes such as severe acute pancreatitis based on Atlanta 2012 classification, death, ICU admission, as well as time to resuming oral feeding and length of stay were collected.

Results: 223 patients were recruited. 110 were men (49%), 22 (9.8%) had severe acute pancreatitis, 15 (6.7%) were admitted to ICU and 13 (5.8%) died. Patients with at least mild elevations in TB showed significantly higher rates of death, ICU admission and severe acute pancreatitis although no differences were found in length of stay or time to initiating oral feeding (Table 1). Among patients with elevated TB, no differences were found in severe acute pancreatitis or death between mild hyperbilirubinemia and jaundice ($p = 0.54$, $p = 0.82$) but patients with jaundice had higher rates of ICU admission ($p = 0.04$)

Total Bilirubin on admission	Total	Normal (0-1.5mg/dL)	Mild Hyperbilirubinemia (1.5-3mg/dL)	Jaundice (> 3mg/dL)	P
N (%)	223	123 (55.1)	56 (25.1)	44 (19.7)	-
Severe acute pancreatitis	22 (9.8)	7 (5.6)	8 (14.3)	7 (15.9)	0.02
Death	13 (5.8)	1 (0.01)	8 (14.3)	4 (9)	0.006
ICU admission	15 (6.7)	2 (1.6)	4 (7.1)	9 (20.5)	<0.001
Time to initiating oral feeding, days. Mean (SD)	2.6 (1.9)	2.6 (2)	2.2 (1.3)	2.9 (1.9)	N.S
Length of stay, days. Mean (SD)	9.6 (12.3)	9.9 (14.7)	8.4 (9.5)	10.3 (6.6)	N.S

Table 1.

Conclusion: Patients with mild elevations in TB over 1.5mg/dL have higher rates of death, severe acute pancreatitis and ICU admission. Few differences were found between patients with the defined thresholds of hyperbilirubinemia, although we observed a higher rate of ICU admissions in patients with clinically evident jaundice (TB > 3mg/dL).

Thus, even mild increases of TB on admission should be taken into account in the initial assessment of patients with acute pancreatitis and further studies should be performed to find the mechanisms that lead to worse prognosis in these patients for the identification of potential early therapies.

THE EFFECT OF IMMUNE ENHANCEMENT WITH TA1 ON THE INCIDENCE OF INFECTED PANCREATIC NECROSIS IN ACUTE NECROTIZING PANCREATITIS PATIENTS MAY BE DEPENDENT ON LYMPHOCYTE COUNT: A POSTHOC ANALYSIS OF A MULTICENTER RANDOMIZED TRIAL

W. Mao^{1,2}, J. Zhou^{1,2}, W. Li^{2,1}, L. Ke^{2,1}, Chinese Acute Pancreatitis Clinical Trials Group

¹Nanjing Medical University, Nanjing, China, ²Nanjing University, Nanjing, China

Contact E-Mail Address: wjm9485@163.com

Introduction: Though the primary analysis of the TRACE trial (a trial that investigated the effect of immune enhancement with Thymosin alpha 1 (Ta1) on the incidence of infected pancreatic necrosis (IPN) in patients with acute necrotizing pancreatitis (ANP)) demonstrated a negative result,

given that T cell is the pivotal effector cell during the pharmacological action of Ta1, the lymphocyte count at randomization may impact the effects of Ta1.

Aims & Methods: We aimed to investigate the effect of Ta1 on the incidence of IPN across subgroups of patients with or without baseline lymphopenia. Patients enrolled in the TRACE trial were included and who discontinued the Ta1 regimen prematurely and received less than 14 doses were excluded. The development of 90-day IPN was chosen as the primary outcome, and subgroup analyses were conducted based on three different definitions of lymphopenia or severe lymphopenia. The subgroup treatment interaction was investigated using a Cox proportional hazard model, and logistic regression models with broken-line relationships were used to determine the optimal baseline lymphocyte count interval where Ta1 treatment could exert the maximum effect in reducing the risk of IPN. **Results:** Table 1. Subgroup Analysis of Day-90 infected pancreatic necrosis. *p* value is from treatment × subgroup interaction term obtained from Cox proportional hazards model that controlled for treatment and subgroup main effects.

A total of 502 patients were enrolled in this study (248 in the Ta1 group and 254 in the placebo group). Patients with non-lymphopenia (defined as lymphocyte count at enrollment $\geq 0.8 \times 10^9/L$) (290/502) responded to the Ta1 treatment significantly differently than patients with lymphopenia (212/502) (RR, 2.55; 95% CI, 1.32–4.93; $p = 0.005$), while the other two subgroups showed no significant interaction.

Among those with a baseline lymphocyte count $\geq 0.8 \times 10^9/L$, the probability of developing IPN during the 90-day follow-up was significantly reduced with Ta1 treatment (19/138 (13.8%) vs. 40/152 (26.3%), Log-Rank $p = 0.009$), which could be partly explained by the elevated lymphocyte count at day 7 after randomization according to the ANCOVA analysis.

The results of the fitted logistic regression model showed that the estimated optimal interval was between 0.792 and 2.002 for baseline lymphocyte count, among which Ta1 could exert an effect in preventing IPN.

Day-90 infected pancreatic necrosis	Placebo (N=254)	Thymosin Ta1 (N=248)	Interaction RR (95%CI)	Interaction p
Severe lymphopenia at enrollment (lymphocyte count < $0.5 \times 10^9/L$)			1.65 (0.74-3.70)	0.220
Present, % (n/N)	9/30 (30.0%)	20/25 (40.0%)		
Not present, % (n/N)	56/224 (25.0%)	45/223 (20.2%)		
Lymphopenia at enrollment (lymphocyte count < $0.8 \times 10^9/L$)			2.55 (1.32-4.93)	0.005
Present, % (n/N)	25/102 (24.5%)	36/110 (32.7%)		
Not present, % (n/N)	40/152 (26.3%)	19/138 (13.8%)		
Lymphopenia at enrollment (lymphocyte count < $1.0 \times 10^9/L$)			1.56 (0.77-3.17)	0.216
Present, % (n/N)	42/151 (27.8%)	41/149 (27.5%)		
Not present, % (n/N)	23/103 (22.3%)	14/99 (14.1%)		

Table 1.

Conclusion: Ta1 may reduce IPN in ANP patients without lymphopenia. A new trial is needed to confirm our findings.

Disclosure: The authors have no conflicts of interest to declare.

Introduction: Acute pancreatitis (AP) is an acute inflammatory condition characterized by acute necrosis and inflammatory changes of the pancreas. Pain in AP is the most distressing symptom which brings the patient to the hospital. Both opioids and non-steroidal anti-inflammatory drugs (NSAIDs) have been used. However, evidence-based recommendations for analgesic of choice in AP is lacking. This study was aimed to compare the efficacy of diclofenac, an NSAIDs with Buprenorphine, an opioid for pain relief in AP.

Aims & Methods: In this double-blinded randomized controlled trial, patients presenting to a tertiary care centre in India, within 5 days of the onset of pain in AP were randomized to receive either diclofenac (75 mg q 8h IV) or buprenorphine (0.3 mg q 8h IV) for a total duration of 40 hours. Fentanyl, as a rescue analgesic was given via a patient-controlled analgesia (PCA) pump with a lockout interval of 15 minutes. Patients could use the PCA pump for a duration of 72 hours from enrolment.

Records were maintained of the PCA pump demands and the drug delivery with regards to:

1. Number of fentanyl-effective and ineffective demands;
2. Pain Free interval;
3. Dose of fentanyl delivered.

Visual Analogue Score (VAS) was recorded at baseline and subsequently at 4-hour intervals to assess the pain intensity. Pain relief was also measured objectively by the number of demands and the dose of fentanyl as a rescue analgesic and the pain free interval and by comparison of the VAS scores. Secondary outcomes included adverse events of the drugs.

Results: A total of 40 patients of AP (19 in Diclofenac group and 21 in Buprenorphine group) were recruited in the study. Buprenorphine group required significantly lesser dose of fentanyl as compared to the Diclofenac group (120 µg vs 720 µg; P<0.001) (Table 1).

The total number of effective and ineffective demands for the rescue analgesic were significantly fewer in the Buprenorphine group than Diclofenac group (7 vs 46; P<0.001). Buprenorphine arm had a significantly greater pain free interval compared to the Diclofenac arm (20 hours vs 8 hours; P<0.001). The VAS score recorded at each time point was significantly lower in the Buprenorphine arm except at baseline and at 4 hours, which were comparable between the two groups. Pain relief in terms of VAS score reduction was significantly more in the Buprenorphine group as compared to Diclofenac group at 24 hours (76% vs 5%, P<0.001), 48 hours (68.4% vs 27.2%; P=0.011), and 72 hours (79.1% vs 36.2%; P<0.001). Both drugs were comparable in terms of their safety profile.

Total (3 days)	Diclofenac arm (n=19)	Buprenorphine arm (n=21)	p value
Fentanyl Dose (ug)	720 (100-2180)	120 (20-960)	<0.001
Effective demands	36 (5-109)	6 (1-48)	<0.001
Ineffective demands	5 (0-69)	0 (0-4)	<0.001
Total demands	46 (7-178)	7 (1-50)	<0.001
Pain free interval (hours)	8 (0-20)	20 (0-60)	<0.001

Table 1. Comparison between Diclofenac and Buprenorphine groups in terms of dose of Fentanyl, effective and ineffective demands and pain free interval.

Conclusion: Buprenorphine, an opioid was found to be more effective than Diclofenac, an NSAID, for pain management in AP. Buprenorphine had lower rescue analgesic requirement, greater pain free interval and more significant reduction of pain scores.

Trial Reg no: CTRI/2020/07/034974

Disclosure: This abstract has also been selected for oral presentation in Digestive Disease week (DDW) to be held in May 2022. However, it remains doubtful if the presentation will go ahead in view of visa issues in the US consulate.

Introduction: The burden of obesity is increasing, representing a risk factor for numerous diseases. In 2016, more than 1.9 billion adults were overweight; of them over 650 million were obese.

Overall, 13% of the world's adult population is obese. Among the associated findings with obesity, is fatty pancreas or Non-alcoholic fatty pancreas disease, and is usually an incidental radiological finding. A recent systematic review with meta-analysis and meta-regression have showed that NAFLD prevalence approaches 33%.

Recent studies have shown the association of fatty pancreas with pancreatic cancer, pancreatic mucinous cystic lesions and with a predisposition for acute pancreatitis, however, no studies have evaluated whether fatty pancreas led to more severe acute pancreatitis.

Aims & Methods: To explore the effect of fatty pancreas on acute pancreatitis severity. We performed a cross sectional, retrospective study, using the databases of Galilee Medical Center. All patients who were hospitalized with documented acute pancreatitis confirmed by fulfilling at least 2 out of 3 criteria including: clinical (typical upper abdominal pain), laboratory (serum amylase or lipase more than 3 times the upper limit of normal values) and imaging (computed tomography (CT), magnetic resonance imaging (MRI) or ultrasonography (US)) criteria from 2010 until 2021 were included.

Acute pancreatitis severity was determined by Systemic inflammatory response syndrome (SIRS) score, according to "International Association of Pancreatology (IAP)/American Pancreatic Association (APA)" recommendation, at admission. Fatty pancreas was determined by two independent blinded radiologists.

Results: Overall, 411 patients were included. Among them, 42 patients (10.2%, group A) had fatty pancreas on imaging, as compared to 369 patients (89.9%, group B) who did not have. The average age in group A was 58.3 years, vs. 56.5 years in group B (P=0.25).

Expectedly, the rate of obesity and fatty liver was significantly higher in group A, as compared to group B (69.4% vs. 47.5%, P=0.006) and (85.7% vs. 34.1%, P<0.0001), respectively. The Baltzhar score in group A vs. group B was 1.4 vs. 1.2 (P=0.2).

Notably, the rate of positive SIRS (fulfilling 2 out of four parameters including: 1. Temperature < 36°C or >38°C,

2. Heart rate >90/min, (

3. Respiratory rate >20/min, and;

4. White blood cells < 4 x 10⁹/L, > 12 x 10⁹ or 10% bands) was significantly higher in group A as compared to group B (23.8% vs. 11.4%, P=0.01), respectively.

Regression analysis showed fatty pancreas significantly increases the risk of severe pancreatitis (OR 2.43, 95% CI 1.12-5.30, P=0.02).

Conclusion: Fatty pancreas represents a significant factor for severe acute pancreatitis as assessed by the clinical SIRS score. Recognizing this association is of paramount importance for clinicians, to urge patients for lifestyle modification and weight loss.

Introduction: The incidence of acute pancreatitis (AP) ranges from 13 to 45 per 100,000 per year. Its continued recurrence can lead to chronic pancreatitis (CP), which is currently an incurable disease. However, the incidence of recurrent acute pancreatitis (RAP) after first AP and CP after AP is still unknown.

Aims & Methods: Our systematic review and meta-analysis aimed to assess the incidence of RAP after first AP and the incidence of CP after different episodes of AP. Our protocol was prospectively registered on PROSPERO (CRD42021283252). The systematic search was conducted in three major databases (MEDLINE, CENTRAL, EMBASE) on the 18th of October, 2021.

All articles that reported on the follow-up of patients diagnosed with acute pancreatitis (defined by the Revised Atlanta Classification) were eligible. Our outcomes, the incidence of RAP and CP was assessed after the first episode of AP, while CP was evaluated after one RAP episode as well. A random-effect model was used to calculate the pooled incidence rates with 95% confidence intervals (CI). Heterogeneity was analyzed with the I^2 and the Cochrane Q tests. The risk of bias assessment was carried out with the Joanna Briggs Institute Critical Appraisal tool.

Results: Out of the 9382 articles, 20 were eligible for the quantitative synthesis. The incidence rate of RAP in patients after the first episode of AP was 0.059 person-year (CI: 0.04 to 0.086; $I^2=95\%$, CI: 0.915 - 0.966). The incidence rate of CP after the first episode of AP was 0.013 person-year (CI: 0.009 to 0.02; $I^2=80\%$, CI: 0.563 - 0.907) while after the first RAP was 0.039 person-year (CI: 0.024 to 0.064, $I^2=83\%$, CI: 0.48 - 0.944). The risk of bias was low in the majority of the included studies.

Conclusion: Acute pancreatitis progression affects a high proportion of patients. While RAP can develop in the first year in around 4-8.6% and CP in 0.9-2% of patients after the first episode of AP, the risk of CP is even higher, 2.4-6.4%, when the patient already suffered from a RAP episode.

Introduction: Acute pancreatitis (AP) is a potentially severe or even fatal gastrointestinal disease requiring hospitalization. Obesity is a major risk factor for several chronic comorbidities and is associated with worse outcome in acute inflammatory conditions.

Aims & Methods: Our objective was to investigate the characteristics and role of obesity in the course and outcome of acute pancreatitis.

Clinical data of 2461 AP cases were collected in the Acute Pancreatitis Registry run by the Hungarian Pancreatic Study Group. Data on body mass index (BMI) were available in 2244 cases. Patient groups were formed based on BMI categories according to the World Health Organization definitions. Anamnestic, admission and outcome parameters were analysed. Depending on the type of variables, Pearson's Chi-squared test, Kruskal-Wallis rank sum test, univariate linear regression and binary logistic regression model was used.

Results: In our cohort 2.8% of the patients were underweight, 30% normal weight, 35% were in the pre-obesity, 20% in the obesity class I, 8.2% in the obesity class II and 3.7% in the obesity class III groups. While female patients had a 43% and male had a 57% share in the total cohort, there was a 56% female share in the underweight, 41% in the normal, 39% in the pre-obesity and 47%, 48% and 48% in the obesity class I, II and III patient groups, respectively.

Compared to the normal BMI group, there are less alcohol consumption and smoking in the patient groups with higher than normal BMI. Odds ratio (OR) for comorbidities are higher in the underweight (OR=2.00; p=0.40), pre-obesity (OR=1.28; p=0.039) and in obesity class I, II and III groups (OR=2.00, 2.11 and 4.63, respectively; p<0.001 in all three). In the pre-obesity and obesity class I, II and III groups, the odds for diabetes (OR=1.61, OR=2.71, OR=4.32 and OR=6.15; p=0.002, p<0.001, p<0.001,

$p < 0.001$, respectively) hypertension (OR=1.76, OR=3.23, OR=3.00 and OR=4.39, respectively; $p < 0.001$ in all four groups), liver steatosis (OR=1.7, OR=2.76, OR=2.93 and OR=7.05, respectively; $p < 0.001$ in all four groups) and hyperlipidemia (OR=1.72, OR=1.64, OR=1.62 and OR=3.38; $p = 0.002$, $p = 0.010$, $p = 0.049$ and $p < 0.001$, respectively) increases substantially according to the degree of obesity.

Among on admission laboratory parameters, significantly higher glutamate-oxalacetate-transaminase (GOT) and gamma-glutamyltransferase (GGT) and lower estimated glomerular filtration rate (eGFR) were measured and calculated in the higher than normal BMI groups.

Higher prevalence of systemic complications were registered in the pre-obesity, obesity class I, II and III groups (OR=1.61, OR=2.51, OR=2.85, OR=3.53; $p = 0.032$, $p < 0.001$, $p < 0.001$, $p < 0.001$, respectively). The odds for renal failure were higher in all four groups compared to the normal BMI group (OR=2.66, OR=5.64, OR=5.34, OR=7.74; $p = 0.017$, $p < 0.001$, $p < 0.001$, $p < 0.001$), while only in obesity class I, II and III groups had higher odds for respiratory failure (OR=2.30, OR=3.37, OR=2.79; $p = 0.002$, $p < 0.001$, $p = 0.016$) and heart failure (OR=2.89, OR=5.53, OR=6.16; $p = 0.025$, $p < 0.001$, $p = 0.002$). The three obesity groups had higher odds for severe acute pancreatitis as well (OR=3.73, OR=4.24, OR=3.39; $p < 0.001$, $p < 0.001$, $p = 0.008$, respectively).

Conclusion: Not only obesity, but also the degree of obesity has a significant role in the development of complications of pancreatitis and other comorbidities. Gradual weight loss can also have a significant positive effect and should be included in patient reports and education.

Disclosure: Nothing to disclose.

Introduction: Current guidelines recommend cholecystectomy in patients with acute biliary pancreatitis (ABP) to prevent recurrence (1). Some studies suggest that a significant portion of patients with idiopathic acute pancreatitis (IAP) results from occult biliary disease and cholecystectomy, after an episode of IAP, reduces the risk of recurrent pancreatitis (2, 3). However, in these studies, the work-up for potential biliary cause is not extensive and do not include endoscopic ultrasound (EUS), which can detect a biliary disease up to one-third of patients with IAP. In this study, we aimed to ascertain whether cholecystectomy can prevent pancreatitis recurrence in patients with ABP and IAP.

Aims & Methods: Adult patients (over 18 years) with first episode of acute pancreatitis (AP) who admitted to inpatient clinic between January 1, 2015 and December 31, 2021 at a tertiary referral center were retrospectively reviewed. Medical records were scrutinized and relevant data extracted. In addition, a questionnaire either by mail or telephone was used. Patients with biliary and idiopathic AP were included in the analysis. Patients with chronic pancreatitis, previous pancreatic surgery, pancreatic cancer, and other etiologies were excluded.

Primary outcome was recurrence rate. The diagnosis of IAP was confirmed by exclusion of all known etiological factors for AP using extensive work-up, including EUS and/or magnetic resonance cholangiopancreatography (MRCP).

Results: A total of 500 patients with first episode of AP (300 patients with ABP and 200 patients with IAP) were identified. The mean age was 58 years and 267 women, 233 men. The patients were divided into three different

groups: Group 1; patients who had their first pancreatitis attack after cholecystectomy, Group 2; patients who had their gallbladder in situ during the first attack and followed by cholecystectomy and Group 3; patients who had their gallbladder in situ during the first attack but did not have cholecystectomy.

The number of patients with recurrence after the first episode of AP were not statistically different in whole study group (25%, 19% and 15%, respectively, $P = 0.176$). In the subgroup of patients with ABP, the recurrence was higher in group 1 as compared with group 2 and 3 (39%, 19% and 14%, respectively, $P = 0.018$).

On the other hand, in the subgroup of patients with IAP, there was no significant difference among the groups in terms of recurrence (15%, 18%, and 17%, respectively, $P = 0.999$). When patients with in situ gallbladder during their first attack were compared according to their cholecystectomy history (group 2 vs. group 3), no significant difference was found in neither the ABP nor the IAP subgroups (19% vs 14% and 18% vs. 17%, respectively, $P > 0.05$). In addition, the effect of endoscopic retrograde cholangiopancreatography (ERCP) on recurrence of pancreatitis was evaluated. In subgroup of ABP, ERCP was effective for reducing the recurrence in group 2 ($P = 0.008$), while it was not found statistically significant in group 1 and 3. In subgroup of IAP, it ERCP did not reduce the recurrence in any groups.

Conclusion: In ABP, the recurrence is high in patients who have their first pancreatitis attack after cholecystectomy. Cholecystectomy alone is not effective preventing recurrence in patients with gallbladder in situ during the first episode; however, the risk can be decreased with adding ERCP to cholecystectomy. On the other hand, cholecystectomy is not effective in reducing the recurrence in patients with IAP.

Introduction: Acute pancreatitis (AP) can lead to late complications, such as recurrent acute pancreatitis (RAP) and chronic pancreatitis (CP). Diabetes mellitus (DM) and exocrine insufficiency (PEI) is often detected after AP.

Aims & Methods: Our aim is to analyse the rate of DM and PEI after AP. GOULASH-PLUS is a 6-year observational study of AP, of which data of 224 patients from the first and 112 from the second year follow-up were analyzed. Each year oral glucose tolerance test (OGTT) was performed to detect newly DM, and a stool elastase test to measure PEI. Patients were grouped based on pre-existing CP, severity and RAP.

Results: Newly diagnosed DM was 25% (n=4) in the CP and 16% (n=28) in the non-CP group in the first year. These were 45% (n=5) and 8% (n=7) in the second year respectively. In the non-CP group, likely a higher rate of newly DM could be shown in severe AP than mild AP (15% vs 30%) in the first year.

PEI was newly diagnosed in 44% (n=8) in the pre-CP group and 10% (n=19) in the non-CP group in first year and it was 27% (n=3) and 5,5% (n=5) in the second year respectively. In the non-CP group the rate of PEI was likely higher in the patients who suffered from 2 or more RAP than without RAP (37% vs 7%), and for the second year more patients developed PEI, who suffered from moderate or severe AP, than mild AP (32% vs 40 vs 10%).

Conclusion: In our study population during the 2-year follow-up newly DM and PEI was prone to be detected more frequently in patients with moderate to severe AP. PEI also tended to occur more often after more AP attacks. In patients with preexistent CP both DM and PEI occurred more often. It is important to follow-up patients after AP.

COMPLIANCE WITH EVIDENCE-BASED CLINICAL GUIDELINES IN THE MANAGEMENT OF ACUTE BILIARY PANCREATITIS: THE MANCTRA-1 INTERNATIONAL COHORT STUDY

G. Pellino¹, Manctra-1 Collaborative Group
¹Università degli Studi della Campania "Luigi Vanvitelli", Department of Advanced Medical and Surgical Sciences, Naples, Italy

Contact E-Mail Address: gipe1984@gmail.com

Introduction: Despite advancements in treatment, acute pancreatitis (AP) is still associated with considerable adverse outcomes, with published overall mortality reaching up to 2% in Western countries and 7.5% in Asia.

Many scientific societies have issued practice guidelines and consensus statements over the past decades to guide surgeons and physicians in managing the disease. However, reports about the real-world implementation of evidence-based recommendations coming from AP guidelines are scant, and the impact of evidence-based guidelines on daily clinical practice has not been adequately investigated globally.

Aims & Methods: This study aimed to evaluate, on a patient-data basis, the contemporary practice patterns of management of biliary AP and to compare these practices with the recommendations by the most updated guidelines.

All consecutive patients admitted to any of the 150 participating general surgery (GS), hepatopancreatobiliary surgery (HPB), internal medicine (IM) and gastroenterology (GA) departments with a diagnosis of biliary AP between 01/01/2019 and 31/12/2020 were included in the study. Categorical data were reported as percentages representing the proportion of all study patients or different and well-defined cohorts for each variable.

Continuous data were expressed as mean and standard deviation. Differences between the compliance obtained in the four different subgroups were compared using the Mann-Whitney U, Student's t, ANOVA or Kruskal-Wallis tests for continuous data, and the Chi-square test or the Fisher's exact test for categorical data.

Results: Complete data were available for 5275 patients. The most commonly discordant gaps between daily clinical practice and recommendations included the optimal timing for the first CT scan (6.1%, $\chi^2 6.71, P=0.081$), the use of prophylactic antibiotics (44.2%, $\chi^2 221.05, P<0.00001$), CT-guided FNA aspiration to drive antibiotic therapy (33.6%, $\chi^2 15.15, P=0.001$), early enteral feeding (33.2%, $\chi^2 11.51, P=0.009$), and the implementation of early cholecystectomy strategies (29%, $\chi^2 354.64, P<0.00001$), with wide variability based on the admitting speciality.

Conclusion: The compliance with guidelines highlighted by this study was poor. A transfer of knowledge strategy is required to increase compliance with guideline recommendations.

Disclosure: Nothing to disclose.

ON ADMISSION RISK FACTORS AND PREDICTORS OF NON-MILD DISEASE COURSE OF PAEDIATRIC ACUTE PANCREATITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M.F. Juhász^{1,2}, Z. Sipos², K. Ocskay², A. Nagy¹, A. Párniczky^{1,2}
¹Heim Pál National Pediatric Institute, Budapest, Hungary, ²University of Pécs, Medical School, Institute for Translational Medicine, Pécs, Hungary

Contact E-Mail Address: flixjuhsz@gmail.com

Introduction: Paediatric acute pancreatitis (PAP) has an increasing incidence and is now estimated to be almost as common as in adults. 20-30% of PAP patients will have a non-mild disease course, characterised by organ failure, local or systemic complications. There is still no consensus regarding on-admission severity prediction in these patients.

Aims & Methods: Our aim was to conduct the first systematic review and meta-analysis of available predictive score systems and parameters and differences between on-admission parameters between PAP severity groups.

We conducted a systematic search on the 14th February, 2022 in MEDLINE, Embase and CENTRAL. We performed random-effects meta-analysis of on-admission differences between mild and non-mild PAP in laboratory parameters, PAP aetiology, demographic factors, etc. calculating risk ratios (RR) or mean differences (MD) with 95% confidence intervals (CI) and visualized the results on forest plots. For the meta-analysis of the performance of predictive score systems, we generated hierarchical summary

receiver operating characteristic curves using a bivariate model. Chi-squared tests were performed and I^2 values calculated to assess statistical heterogeneity.

Results: 45 studies – mostly retrospective cohorts – were eligible for inclusion. Among predictive score systems examined by at least 5 studies, the modified Glasgow scale had the highest specificity (91.5% for values 3), and the Pediatric Acute Pancreatitis Severity score the highest sensitivity (63.1% for values 3). The performance of other proposed score systems and values were summarized. Traumatic (RR: 1.70 95% CI: 1.09–2.67) and drug-induced (RR: 1.33 95% CI: 0.98–1.87) aetiologies were associated with a higher rate of non-mild PAP, while anatomical (RR: 0.6195% CI: 0.38–0.96) and biliary (RR: 0.72 95% CI: 0.53–0.99) tended to be less severe.

Conclusion: Many predictive score systems were proposed to assess the possibility of non-mild PAP course. While the most common ones provide good specificity, they all have subpar sensitivity. Our systematic review provides a rigorous overview of predictive options assessed thus far, that can serve as a basis of future improvement of scores via the addition of parameters with a better observed sensitivity: eg. lipase exceeding 7-times the upper threshold, hemoglobin, etc. Aetiological factors, although they can predispose to a more severe disease, are also not included in any of the available scores.

Disclosure: Nothing to disclose

Introduction: Within 5 years after an episode of acute pancreatitis (AP), one in four people develop diabetes (1), whereas three in five people develop dysglycaemia (2). However, little is known about the risk factors that may play a role in the development of diabetes.

Aims & Methods: Identifying risk and prognostic factors for developing diabetes or dysglycaemia after AP.

We performed a systematic review and meta-analysis of the association between the factors at the time of the index AP and new-onset diabetes or dysglycemia (prediabetes and/or diabetes). The search was carried out in 3 databases on 2021.11.18. The protocol was registered with PROSPERO (CRD42021281983) and follows the PRISMA guideline. For the meta-analysis, we used a random-effects model (DerSimonian-Laird) to calculate pooled odds ratios (OR) with 95% confidence intervals (CI).

Results: We identified 52 studies totalling 72,813 participants of whom 5,483 developed diabetes/dysglycaemia. Severe AP is associated with a significantly higher odds of new-onset diabetes (OR 2.06; 95% CI 1.17–

3.62) than mild and moderate disease. Having severe or moderate AP is associated with a significantly higher OR for new-onset diabetes (OR 3.13; 95% CI 1.31–7.47) than mild AP. The association is more pronounced for dysglycaemia in severe (OR 3.16; 95% CI 1.13–8.83) and severe or moderate disease progression (OR 4.75; 95% CI 2.07–10.90). Other factors significantly associated with increased diabetes and dysglycaemia development odds are necrosis development, infected necrosis, pseudocyst formation and alcohol aetiology.

No significant increase in odds of diabetes/dysglycaemia was found in case of: male sex, smoking, dyslipidaemia, obesity and liver disease as comorbidities, hypertriglyceridemia or biliary AP as aetiology, AP recurrence, organ failure development, biliary or pancreatic surgical interventions. Patients with idiopathic etiology had a significantly reduced odds (OR 0.61; CI 0.44; 0.85) of developing diabetes or dysglycaemia compared to other aetiologies.

Conclusion: Severe and moderate AP, local complications, alcoholic aetiology and necrosectomy are linked to a higher risk of developing diabetes and dysglycaemia. While all AP patients should be monitored for dysglycaemia development, a stricter follow-up is warranted for patients with these factors. This will facilitate early lifestyle and pharmacological interventions and reduce disease burden.

Introduction: Gut microbiota represents an emerging worldwide research area. Novel findings suggest that pancreatic disorders might be modulated by gut microbiota composition. Gut microbiome alteration in patients with chronic pancreatitis (CP) was depicted in only a very few studies, with conflicting results.

Aims & Methods: Our study aimed to characterize gut bacterial microbiota composition in patients with CP. Stool samples were collected and relevant clinical data were obtained from 92 study participants, 51 patients with CP of different origins (28 alcoholic, 15 idiopathic, 3 autoimmune, 5 familial), and 41 healthy controls (C). The V3 and V4 regions of the 16S ribosomal RNA gene were sequenced on the Illumina MiSeq platform.

Results: We found that alpha diversity was comparable in CP and C groups albeit it tended to be lower in CP subjects. For visualization of the similarity or dissimilarity of subjects, we used Principal Component Analysis (PCA) and we showed that CP patients tend to separate from control. Multivariable statistics (PERMANOVA) revealed significant differences in β -diversity

at the levels of phylum ($p=0.035$), order ($p=0.023$), family ($p=0.013$) and genus ($p<0.001$). Using univariable differential abundance analysis (Mann-Whitney-Wilcoxon test) followed by effect size analysis (Cliff's delta), we identified 9 phyla with significantly different abundance between groups ($FDR\leq 0.1$). Albeit this selection encompasses 7 very low abundant phyla ($< 0.01\%$), it also involves the most abundant phylum *Firmicutes* (median abundance C vs PC 32 vs 26%) and less abundant but clinically important phylum *Proteobacteria* (median abundance C vs PC 0.1 vs 2.5%).

Using the same approach, we identified 18 genera significantly differently abundant between groups. Interestingly, among genera enriched in CP, *Eggerthella*, *Lachnoclostridium*, *Escherichia*, *Shigella* or *Enterococcus* are mucin degraders that may promote gut barrier damage and trigger systemic inflammatory responses. In contrast, fecal microbiome of CP patients was depleted with short-chain fatty acid producers (*Christensenellaceae_R.7_group*, *Lachnospiraceae_NK4A136_group*, *Coproccoccus*, *Clostridia_UCG.014* or *Erysipelotrichaceae_UCG.003*).

Conclusion: Our results indicate that fecal microbiota is significantly altered in patients suffering from chronic pancreatitis and it is shifted towards a pro-inflammatory setting associated with a compromised intestinal barrier function.

Disclosure: Nothing to disclose.

P0833

MITOFUSIN 2 REGULATES THE NICOTINE INDUCED ACTIVATION OF PANCREATIC STELLATE CELL VIA PI3K/AKT/MTOR SIGNALING PATHWAY

R. Xue¹

¹Beijing Cancer Hospital, Department of Gastroenterology, Beijing, China

Contact E-Mail Address: xueran2@sina.com

Introduction: Nicotine is the major component of cigarette smoke which can facilitate pancreatic fibrosis. Pancreatic stellate cells (PSCs) have a vital role in pancreatic fibrosis. ROS are upstream in the activation of PSCs. MFN2 (mitofusin 2) is required for mitochondrial fusion and for mitochondria-endoplasmic reticulum interaction.

Aims & Methods: This study was aimed to analyze the function and mechanism of Mfn2 in the nicotine induced activation of PSCs. Isolated primary PSCs from C57BL/6 mice were treated with lentivirus-Mfn2 and si-Mfn2, as well as Rosup and PI3K/AKT/mTOR specific inhibitors. The effects of Mfn2 on the activation of PSCs, autophagy, collagen deposition and oxidative stress were analyzed via western blotting, immunofluorescence staining, reactive oxygen species (ROS) assay.

Results: Nicotine increased collagen deposition and activation of PSCs. Expression of α -SMA, LC3II, Beclin1 levels were significantly reduced in si-Mfn2 groups under nicotine treatment. Meanwhile, compared with the control group, there was also a significantly increased for the expression of p-PI3K, p-AKT and p-mTOR levels in si-Mfn2 groups. A significant decrease in ROS positive cells were observed after si-Mfn2 groups under nicotine treatment.

Conclusion: Our finding suggests that Mfn2 improves the activation of nicotine induced PSCs by the PI3K/AKT/mTOR signaling pathway. Mfn2 may act as a therapeutic target in PSC-related pathologies and/or anti-fibrotic approaches.

Disclosure: The study was supported by the Fund for Fostering Young Scholars of Peking University Health Science Center (BMU2021PY010), National Natural Science Foundation of China (No. 82002461), and Medjaden Academy and Research Foundation for Young Scientists (MJR20211110).

Introduction: Chronic pancreatitis (CP) is a progressive inflammatory disease characterized by irreversible functional and structural pancreatic damage leading to malabsorption, debilitating pain and a significant decrease in the life quality of CP patients. Moreover, CP is the strongest identified risk factor for pancreatic cancer. Clinical treatment of CP is based on surgical and endoscopic interventions accompanied by life-long conservative therapy such as pancreatic enzyme replacement, pain management and nutrition.

As different cell types of the exocrine pancreas – acinar, ductal and stellate cells – contribute to the tissue damage an effective, long-term treatment must act on drug targets, which simultaneously affect these cells. In acute pancreatitis (AP), inhibition of the plasma membrane Ca^{2+} channel ORAI1 decreased the severity of AP and protected acinar and ductal cell functions emphasizing ORAI1 as universal drug target in all cell types.

Aims & Methods: The purpose of this study was to investigate the utility of ORAI1 inhibition to decrease the severity of CP. Therefore, in wild type FVB/N mice, CP was induced by repeated administration of caerulein for two weeks (50 μ g/kg), followed by the administration of a selective ORAI1 inhibitor (CM5480; 20 mg/kg) on the last five days and histological parameters, fibrosis, pancreas weight/body weight ratio, hydroxyproline (HyP) content were quantified. Acinar and ductal functions were assessed with functional and morphological assays. Pancreatic stellate cells (PSC) were isolated and investigated in *in vitro* experiments.

Results: Our experiments revealed a marked decrease of SARAF – an endoplasmic reticulum resident protein, which inhibit ORAI1 activity – in pancreatic acinar cells from mouse and human CP tissue leading to over-activation of ORAI1 mediated extracellular Ca^{2+} influx. On the other hand, inhibition of ORAI1 significantly impaired tissue damage during experimental CP in mice, whereas the extent of fibrosis and immune cell infiltration were markedly decreased. In addition, a significant improvement of pancreatic acinar and ductal functions was observed in CM5480 treated mice.

Finally, ORAI1 inhibition decreased the activation of PSCs *in vitro* and *in vivo*, reduced the migration, whereas the proliferation was impaired due a cell cycle arrest and accumulation of the PSCs in the S phase.

Conclusion: In conclusion we established that overactivation of ORAI1 is a crucial pathogenetic event in the development of CP. Moreover, our results highlight ORAI1 inhibition as a novel universal therapeutic target in the treatment of CP. The translation of these observation shall be possible in the near future as selective ORAI1 inhibitors are currently in clinical trials to treat AP.

Disclosure: The selective ORAI1 inhibitor CM5480 was provided by CalciMedica.

Introduction: Due to the recent study [1] pancreatic exocrine cells express SARS-CoV-2 entry factors angiotensin-converting enzyme 2 (ACE2) and the transmembrane serine protease 2 (TMPRSS2) that confirms the possibility of the exocrine part of the pancreas to be susceptible to SARS-CoV-2 infection.

Although COVID-19 may present with acute pancreatic disorder in up to 32.5% cases [2], the question whether pancreas is involved in cases without clinical presentation is still unknown.

Aims & Methods: Our aim was to assess exocrine pancreatic function in patients after mild or moderate COVID-19 disease.

Adult patients after SARS-CoV-2 infection (PCR-confirmed) who were referred for outpatient GI-consultation by a family doctor in the period from December 2020 till December 2021 were included. The exclusion criteria were:

1. Severe or critical COVID-19 disease that required ICU hospitalization or oxygen support,
2. Any signs of active pancreatic inflammation during SARS-CoV-2 infection,
3. Previously diagnosed congenital or acquired pancreatic disorder,
4. Other chronic conditions that could influence on the level of faecal elastase-1 (eg. IBD, IBS, SIBO, chronic kidney disease etc.),
5. Other disorders that could explain GI symptoms.

Pancreatic exocrine insufficiency (PEI) was assessed determining the level of faecal elastase-1 (FE1) and using 13C-mixed triglyceride breath test (13C-MTGT). The results of FE1 test were interpreted as following: 200–500 µg/g - normal values; 100–200 µg/g - mild to moderate insufficiency; <100 µg/g - severe insufficiency. For 13C-MTGT the percentage cumulative dose recovered (PCDR) of 13C excretion at 360 min was calculated.

Results: After fulfilling the exclusion criteria, 68 adult patients (18–46 years, males-31) were included into the analysis. In most cases patients had complaints of upper abdominal pain, dyspeptic symptoms, bloating and stool changes (type 5–6 due to Bristol scale) that occurred for the first time after COVID-19. In 19 patients the FE1 levels corresponded to a moderate pancreatic insufficiency, and in 6 patients to a severe one.

The second FE1 test was done in 25 patients in one month after treatment with pancrelipase (the appropriate dose for each patient was calculated based on Cystic Fibrosis Foundation guidelines).

Five patients out of 25 still had decreased FE1 values that corresponded to a mild (3 patients) and a moderate (2 patients) pancreatic insufficiency. The PEI in those five patients was double checked using 13C-MTGT. Three subjects out of five had lower PCDR than normal.

Conclusion: Our data possibly indicate on the viral islet damage even in those patients who present with mild or no SARS-CoV-2 symptoms suggesting the risk of the development of long term post-COVID-19 pancreatic complications.

Introduction: Exocrine pancreatic insufficiency (EPI) leads to indigestion in the intestinal lumen. Undigested fats, proteins, and other food ingredients entering the lumen of the large intestine (LI) can significantly change its ecology and functional activity.

Aims & Methods: Evaluation of the characteristics of bacterial metabolism in the TC in patients with chronic pancreatitis (CP) with EPI. The study included 42 CP patients: 27 men and 15 women, mean age of 51.9±10.3 years. All of them completed the determination of fecal elastase enzyme immunoassay, hydrogen breath test with lactulose and determination of short-chain fatty acids (SCFA) in coprofiltrates by the method of gas-liquid chromatography. All studies were carried out before the start of a course of treatment in a hospital.

Results: According to the results of assessing the value of fecal elastase, EPI was detected in 62% of patients. This allowed us to divide the study participants into 2 groups: 1st – without EPI (n=16), and 2nd – with EPI (n=26). The study of the metabolic activity of the MC microflora showed that in patients with CP there is an increase in the enzymatic activity of the MC microflora compared to normal values (N) according to concentrations of fecal SCFA: sum of SCFA of the 1st group.

12.3±3.6 mg/g vs N 10.6±2.5 mg/g; p=0.048, and the presence of EPI further enhanced bacterial metabolism in TC. At the same time, changes were also observed in the spectrum metabolites: against the background of a decrease in the absolute and relative concentrations of acetate (C2) in almost all patients showed a significant increase in the proportions of propionate (C3) and butyrate (C4).

Availability of EPI in the participants of the 2nd group could be an additional factor in the development of the syndrome of excessive bacterial growth in the small intestine in some patients, although high hydrogen test rates (20–67 ppm; cf. 39.4±1.8 ppm) were noted only in 46% of the examined patients. The fact of increasing concentrations of C4 indicated an increase in the activity of fecal microflora producing butyrate and hydrogen.

Conclusion: All patients with CP have increased metabolic activity of the microflora of the TC with a change in structure of the main metabolites, more pronounced with the presence of EPI, which may be indirect evidence of the presence of bacterial overgrowth syndrome in CP patients with EPI.

Disclosure: Nothing to disclose.

Introduction: Endoscopic ultrasound (EUS) elastography is a non-invasive diagnostic method for evaluating tissue elasticity. The aims of this study were to compare shear-wave elastography (SWE) and conventional strain elastography (SE) in determination of the diagnosis and degree of chronic pancreatitis (CP).

Aims & Methods: Forty-nine patients who underwent computed tomography (CT), EUS-SWE, EUS-SE, and pancreatic exocrine function testing between January 2019 and January 2022 were prospectively evaluated. CP was diagnosed according to Japan Pancreatic Society criteria (JPSC) 2019, Rosemont criteria (RC), CT findings, and pancreatic exocrine dysfunction. The cut-off values, sensitivity, and specificity for CP diagnosed according to the four criteria were calculated for EUS-SWE and EUS-SE. Relationships between values measured by either of the EUS elastography methods and the number of EUS features were also assessed.

Results: EUS-SWE values were positively correlated with the severity grades of RC and JPSC, but EUS-SE values were not. EUS-SWE was significantly better than EUS-SE for diagnosing CP defined according to CT findings (area under the receiver operating characteristics curve [AUROC]: 0.77 vs. 0.61, $P < 0.001$), RC (AUROC: 0.85 vs. 0.56, $P < 0.001$), JPSC 2019 (AUROC: 0.83 vs. 0.53, $P < 0.001$), and exocrine dysfunction (AUROC: 0.78 vs. 0.61, $P < 0.001$). EUS-SWE values were positively correlated with the number of EUS features, but EUS-SE values were not.

Conclusion: EUS-SWE provides objective assessment for diagnosing and assessing the degree of CP defined according to the criteria of CT findings, RC, JPSC, or exocrine dysfunction, and it can be considered an alternative diagnostic tool to EUS-SE.

Contact E-Mail Address: yjf3303@zju.edu.cn

Introduction: The aim of this study is to evaluate the efficacy and safety of EUS-guided drainage with lumen-apposing metal stent (LAMS) and double-pigtail plastic stent (DPPS) for the treatment of walled-off necrosis (WON).

Aims & Methods: This prospective cohort study included 52 consecutive patients with pancreatic WON admitted to Hangzhou First People's Hospital from December 2018 to June 2021. The patients were divided into two groups based on the types of stents used: the LAMS group ($n = 25$) and the DPPS group ($n = 27$).

Technical success (successful stent placement), operation time, clinical success (WON resolution), the number of endoscopic transluminal necrosectomy (ETN) and adverse events were compared between the two groups.

Results: All 52 patients were successfully stented, indicating a technical success rate of 100% in both groups, while the operation time in LAMS group was less than that in DPPS group (26(19.5-39.8) vs 45 (25.5-55.8) min, $P = 0.02$). The clinical success rate in LAMS group was higher than that in DPPS group (76% (19/25) vs. 37% (10/27), $P = 0.005$. ETN was performed 2.5 (1.0, 5.0) times in LAMS group.

Adverse events were experienced by 28.0% (7/25) of the LAMS group and 14.8% (4/27) of the PS group ($P = 0.245$). LAMS group were associated with similar bleeding (8.0% vs. 7.4 %, $P = 0.936$) compared to DPPS group.

Conclusion: LAMS with ETN was more effective than DPPS in treatment with EUS-guided drainage for pancreatic walled-off necrosis, but did not increase the incidence of bleeding and adverse events.

Disclosure: Nothing to disclose.

Introduction: Fully covered self-expanding metal stents (FCSEMS) are a treatment option for patients with chronic pancreatitis (CP) who have pain associated with a dilated pancreatic duct (PD),¹ but patient selection, FCSEMS design, efficacy and safety remain uncertain compared to surgery or endotherapy using multiple plastic stents.

Aims & Methods: The aim of this study was to conduct a prospective, multicenter single-arm trial to evaluate 6-month indwell of an investigational 4-6 cm long, soft pancreatic FCSEMS (Boston Scientific Corporation, Marlborough, Massachusetts) for treatment of CP-associated pain. Adult patients with painful CP, a dominant downstream PD stricture in the head or proximal head of the pancreas and upstream PD dilation to ≥ 5 mm were enrolled, and had PD stone clearance where applicable.

The primary efficacy endpoint was self-reported pain scores assessed from baseline through 6 months after FCSEMS removal in patients with sufficiently severe and frequent pain at the time of FCSEMS placement as a first stent or in exchange of a plastic stent.

The primary safety endpoint was PD stenting-related serious adverse events (SAEs). Other outcomes were technical success, and proportions of patients with stent migration, restenting, incident secondary strictures, weight gain or improved self-reported quality of life (QOL) assessed during follow-up.

A post-hoc multivariate analysis examined factors associated with $\geq 50\%$ reduction in pain 6 months after FCSEMS removal or observation of complete distal migration (CDM) compared to baseline without a $\geq 50\%$ increase in narcotic use and without restenting.

Results: Among 67 patients (mean age 52.7±12.5 years, mean time since CP diagnosis was 6.4±6.4 years, 34 (50.7%) had plastic stent placement within 90 days of FCSEMS placement, and 46 (68.7%) were eligible for the primary efficacy endpoint analysis. Technical success was 97.0% (65/67). Results for the primary efficacy endpoint (26.1%, 12/46 patients) and primary safety endpoint (31.3%, 21/67 patients) failed to meet the a priori study hypotheses (Table). Study stent migration occurred in 47.7% (31/65) of patients.

Eleven patients had restenting during study follow-up: 7 at the time of and 4 after FCSEMS removal or observation of CDM. Clinically significant secondary strictures located at the intraductal edge of the FCSEMS were reported in 5 patients at the time of stent removal or observation of CDM; all were restented with a single plastic pancreatic stent. Twenty-four (39.3% of 61) patients had weight gain, and 43 (71.7% of 60) reported improved QOL at 6 months after FCSEMS removal or observation of CDM.

The multivariate analysis showed that at 6 months after FCSEMS removal or observation of CDM, patients receiving pancreatic enzyme replacement therapy, those taking narcotics at baseline, or those with higher baseline weight were less likely to report ≥ 50% reduction in pain compared to baseline without a ≥ 50% increase in narcotic use and without restenting.

	Rate	PG	Lower 95% CI	P value ²
Primary efficacy endpoint¹				
Pain relief	26.1% (12/46)	53.0%	14.3%	0.999
	Rate	PG	Upper 95% CI	P value ²
Primary safety endpoint				
Related SAEs	31.3% (21/67)	32.0%	43.8%	0.513

ITT intention to treat PG performance goal
¹Based on mean of VAS Pain Score and Izbicki Frequency of Pain subscore, with score ranging from 0 to 100
²P-value < 0.025 means the performance goal was met.

Conclusion: Some CP patients might benefit from 6-month FCSEMS treatment, but migrations and SAEs are common. Further study is needed to clarify optimal decompressive strategy, FCSEMS design and patient selection.

Contact E-Mail Address: c.deli@studenti.unisr.it
Introduction: In 10–30% of chronic pancreatitis (CP) cases without definite aetiology genetic testing is recommended. However, a large quote of CP cases remain idiopathic (ICP). Their distinctive features compared to genetic CP (GCP) or exotoxic cases (ECP) have been poorly described.
Aims & Methods: The aim of the study was to report demographics and clinical features in a consecutive cohort of CP cases according with their aetiology, focusing on these able to distinguish GCP from ICP and ECP. A retrospective analysis of a prospectively maintained database of definite/probable CP patients according to the M-ANNHEIM classification was performed. The groups were compared for continuous and categorical variables with Kruskal Wallis or Anova tests.

Results: 200 patients were examined. Aetiology was deemed exotoxic in 91 cases (45.5%), autoimmune (AIP) in 19 (9.5%), obstructive in 8 (4.0%) and due to recurrent acute pancreatitis in 11 (5.5%). The remaining 71 cases were considered for genetic testing when appropriate (onset age<40 or family history) that was performed in 49 of them, with findings of a genetic cause in 26 (13% of total; CFTR 53.8%, SPINK1 23.3%, PRSS1 15.4%, CTSC 7.7%). Thus 45 cases had ICP (22.5%) of whom 10 aged<35. Median age at diagnosis was lower in patients with GCP (27, IQR 17-36) compared to all other subgroups (55 ECP, 53 ICP; p<0.0001).
Diagnosis of painless, incidental CP was more frequent in ICP (35.6%) vs GCP (3.8%) (p=0.02). Patients with GCP presented more frequently with exocrine insufficiency (65.4% vs 40.7% in ECP and 37.8% in ICP; p=0.051) but less frequently with endocrine insufficiency (7.7% vs 40.7% in ECP and 22.2% in ICP; p=0.002).
The rate of calcifications at diagnosis was lower in ICP (24.4%) and GCP (26.9%) compared to ECP (39.6%) (p=0.014). Patients with GCP had a lower median BMI at diagnosis (21.4 vs 23.5 ECP and 24.2 ICP; p<0.0001) and were less frequently smokers (30.8% vs 94.5% of ECP and 44.4% of ICP; p<0.001).
Conclusion: While GCP displays distinct features, ICP is more frequently painless and shares some aspects both with ECP and GCP, possibly supporting a multifactorial aetiology.
Disclosure: Nothing to disclose.

Introduction: Chronic pancreatitis (CP) is a multifactorial fibroinflammatory disease that causes permanent morphological changes to the pancreatic tissue. This may lead to abdominal pain and pancreatic insufficiency, seen as secondary diabetes and malnutrition, as well as to various complications. Therefore, this disease can impact negatively on the quality of life (QoL) and result in disabling consequences for the patients.

Aims & Methods: Aims: To evaluate abdominal pain and health related QoL in a Spanish CP cohort.

Prospective multicenter registry of CP patients from 2 regions in the north of Spain, Navarre and Basque Country (PaN-Eus) using the AEG-RedCap platform. QoL data was collected through the validated questionnaire EQ-5D-5L and the visual analogue scale (VAS). Global health auto-perception was measure with VAS and health index (HI). Data from the National Health Survey¹, a monographic report on health-related QoL in the Spanish adult population, was used in order to make comparisons between CP patients and the general population.

Results: A total of 322 patients were included. Mean age was 61.6 ($\pm$ 10.9) and 77.6% were males. The main etiology of CP was toxic in 75.5% of our patients. At the time of inclusion 75.2% had pancreatic calcifications and 71.4% had at least a moderate ductal lesion. The incidence of exocrine pancreatic insufficiency (EPI) in our cohort was 72.6% and 51.4% had diabetes mellitus (DM).

In the last year, 25.6% of patients had CP-related pain, most with an intermittent pattern (85.3%). Frequency of pain was daily in 5.4% of patients, >1 episode a week in 5.4%, >1 episode a month in 6.6% and <1 episode a month in 8.2%. Most patients treated pain with first step analgesia and only 2.8% of the total cohort were on third step analgesia treatment. The presence of pain was associated with younger age (56.8 vs 63.3 years; $p < 0.001$) and active smoking (70.4% vs 52.3%; $p = 0.008$). A tendency although not significant towards a less active alcohol consumption (38.1% vs 51.0%; $p = 0.074$) was also observed. Pain was not associated neither with the presence of IPE nor DM.

Pancreatic duct stricture (29.6% vs 14.8%, $p = 0.003$), obstructive lithiasis (19.8% vs 7.6%, $p = 0.002$), splanchic venous thrombosis ($p = 0.034$), gastric emptying difficulty (11.1% vs 3.4%; $p = 0.018$), pancreatic fistula (12.3% vs 1.2%, $p < 0.001$) and ascites/pleural effusion (7.4% vs 1.7%, $p = 0.02$) were associated with pain. A higher number of endoscopic (37.5% vs 21.3%; $p = 0.004$) and surgical (18.8% vs 7.2%, $p = 0.003$) procedures were performed in patients with pain.

212 QoL questionnaires were included. Global health auto-perception in CP measured with VAS was 69.0 (vs 77.5 in the general population), and HI was 87.8 (vs 93.7 in the general population). The presence of abdominal

pain ($p = 0.001$) and diabetes ($p = 0.001$) were associated with lower QoL indexes (lower VAS and HI). 68.9% of patients declared at least one problem in one of the 5 fields from the EQ-5D-5L. In each field, the prevalence of problems was higher in the CP cohort compared to the general population: mobility (40.6% vs 14.3%), self-care (9.9% vs 6.22%), daily activities (24.1% vs 11.1%), pain/discomfort (48.6% vs 25.5%) and anxiety/depression (32.1% vs 15.0%).

Conclusion: Pain is the main complication of CP and these patients have a reduced QoL. The presence of abdominal pain is associated with younger age, active smoking and complications related to CP. CP patients have a worsened QoL compared to the general population and it is related to the presence of DM. QoL assessment should be included in the global management of CP patients.

EVOLUTION OF INDETERMINATE FOR CHRONIC PANCREATITIS AS DIAGNOSED ON EUS [ACCORDING TO ROSEMONT CRITERIA] IN PATIENTS OF RECURRENT ACUTE PANCREATITIS WITH 1 YEAR FOLLOW UP

A. Vaidya¹, K. Das¹, P.S. Parta¹

¹IPGME&R and SSKM Hospital, Department of Gastroenterology, Kolkata, India

Contact E-Mail Address: arunvaidyagastro@gmail.com

Introduction: Early chronic pancreatitis (CP) can present initially as Recurrent Acute Pancreatitis (RAP). In patients of RAP, outcome of Endoscopic Ultrasound (EUS) can be normal pancreas, indeterminate for CP, suggestive of CP and consistent with CP based on Rosemont criteria [1]. Till date there is no follow up study in literature on the outcome of RAP patients who are indeterminate for CP on EUS.

Aims & Methods: Our aim was to study the outcome of RAP patients with Indeterminate for CP in terms of clinical, biochemical, etiological and radiological evolution on 1 year follow up. We conducted prospective observational cohort study and included all the RAP patients above 12 years of age with normal CT Abdomen & MRCP and who fulfilled the diagnostic Rosemont criteria for Indeterminate for CP. Clinical history was noted and relevant investigations were done at enrollment.

All the patients were closely followed up in Pancreatic clinic at 3 monthly intervals. They were subjected to Ultrasound abdomen and Blood sugar profile 6 monthly. EUS was done after 12 months of baseline EUS.

Results: EUS was performed in 21 patients of RAP, out of which 14 patients were diagnosed as Indeterminate for CP and included in study. Males were 93% and females were 7% with median age of 26 years. Median duration between first documented attack of acute pancreatitis (AP) and EUS was 34 months with median of 4 attacks of AP prior to EUS. Most common etiology of RAP was idiopathic followed by ethanol & hypertriglyceridemia. History of smoking was present in 36% and Diabetes Mellitus & cholecystectomy in 7%.

Pain pattern was continuous in 28.6% and episodic in 71.4% with mean analgesics requirement was 4.5 days/month. On 1 year follow up, 43% patients remained pain free and 36% had AP attack. Mean analgesic requirement throughout the year was 1.2 days/month. Endocrine & exocrine insufficiency developed in 7% patients.

During 1 year follow up, ultrasound abdomen showed sludge in 2 patients and gall stones in 1 patient. Total 8 patients underwent follow up EUS at 1 year that revealed normal study in 1 patient, Indeterminate for CP in 2 patients, suggestive of CP in 3 patients and consistent with CP in 2 patients according to Rosemont criteria.

Conclusion: RAP presenting as Indeterminate for CP is more common in younger adults with idiopathic being most common etiology. Indeterminate for CP progress to CP in majority of patients. Close follow up & counselling regarding diet & lifestyle modifications including abstinence from smoking & alcohol can improve clinical outcome.

DEVELOPMENT OF A NEW LATERAL FLOW ASSAY FOR THE QUANTIFICATION OF FAECAL PANCREATIC ELASTASE AT POINT OF CARE

J. Afonso¹, M. Schneider¹, D. Guschin¹, C.-B. Gerhold¹, B. Ricken¹

¹BÜHLMANN Laboratories AG, Development, Schönenbuch, Switzerland

Contact E-Mail Address: jpa@buhlmannlabs.ch

Introduction: Pancreatic exocrine insufficiency (PEI) can be defined as a reduced pancreatic enzyme activity that leads to fat malabsorption, weight loss and malnutrition-related complications(1). Direct methods to evaluate digestive function, such as the secretin stimulation test or the ¹³C-mixed triglycerides assay, as well as imaging tests are used to diagnose PEI. In addition, less invasive and indirect tests are also available.

Faecal pancreatic elastase is an ideal biomarker for the assessment of pancreatic function in patients suffering from PEI, due to its important role in the digestive process as a proteolytic enzyme and the high stability of the enzyme during intestinal transit.

Aims & Methods: The aim of this work was to develop and optimize a new rapid test for the quantification of faecal pancreatic elastase. The BÜHLMANN Quantum Blue® fPELA is a quantitative lateral flow assay.

The test was designed for the selective measurement of elastase antigen concentrations from stool extracts by a sandwich immunoassay. A monoclonal detection antibody is conjugated to gold nanoparticles. Elastase present in the sample binds to this gold conjugate. A polyclonal capture antibody, highly specific for elastase, is immobilized on the analytical membrane and captures the complex of elastase bound to the anti-elastase gold conjugate, resulting in a coloring of the test line. The remaining free anti-elastase gold conjugate binds to the control line.

The signal intensities of the test line and the control line are measured quantitatively by the Quantum Blue® Reader. Pancreatic elastase is quantified in extracts of human stool samples collected with the BÜHLMANN CALEX® Cap device.

Several analytical studies, such as sensitivity, linearity and High Dose Hook Effect (HDHE), were performed during optimization phase to evaluate the performance of the assay. Moreover, a method comparison with the commercially available high throughput turbidimetric BÜHLMANN fPELA® turbo assay was also performed.

Results: Analytical evaluation during the optimization step revealed preliminary results of the assay performance. Analytical sensitivity was determined as 12.8 µg/g LoB, 16.6 µg/g LoD and 17.2 µg/g LoQ. The preliminary linearity evaluation revealed a linear range of 10 to 472 µg/g. No HDHE

was observed in native samples up to 4'000 µg/g. Method comparison of the new lateral flow assay with BÜHLMANN fPELA® turbo assay, with 80 clinical samples, revealed good analytical agreement with a slope of 1.04 (Passing-Bablok) and a bias at cutoff (200 µg/g) of 5.6%. Relative bias (Bland-Altman) of the two assays was 6.9%. Considering the turbidimetric assay as the reference method, the sensitivity and specificity were 92% and 83%, respectively.

Conclusion: The new BÜHLMANN Quantum Blue® fPELA, a quantitative lateral flow assay, is an accurate, non-invasive and rapid test to determine pancreatic elastase levels in faecal extracts. BÜHLMANN Quantum Blue® fPELA is an attractive alternative to ELISA with a turn-around time of only 15 minutes enabling patients' management in a more patient near clinical environment.

CHRONIC PANCREATITIS ASSOCIATED WITH HETEROZYGOUS CYSTIC FIBROSIS TRANSMEMBRANE CONDUCTANCE REGULATOR COMPARED WITH AN ALCOHOL-RELATED CHRONIC PANCREATITIS-19 YEARS COHORT STUDY

A.Y. Ahmed^{1,2}, J. McLaughlin², C. Fullwood¹, R. Harwood¹, A. Makin¹

¹Manchester Foundation Trust, Gastroenterology, Manchester, United Kingdom, ²The University of Manchester, Gastroenterology, Manchester, United Kingdom

Contact E-Mail Address: abubaker.ahmed@postgrad.manchester.ac.uk

Introduction: Alcohol is the most common cause of pancreatitis. Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) can be linked with chronic pancreatitis also. Previously we reported a milder course of disease in patients with CFTR-related pancreatitis who have two gene mutations (compound heterozygous) compared with one gene mutation (heterozygous).

Aims & Methods: To establish whether chronic pancreatitis-associated CFTR gene mutations are related to different clinical outcomes when compared with alcohol-related chronic pancreatitis.

Retrospective cohort analysis of patients with chronic pancreatitis and CFTR gene carrier status and a same-sized sample of alcohol-related pancreatitis attending Manchester University NHS Foundation Trust Pancreatology Unit between 1999 and 2020. Data were reported using appropriate descriptive statistics with comparisons made between the two groups using t-tests or Fisher's exact test. Cox proportional hazard models were used to compare time to endocrine or exocrine deficiency.

Results: Forty-one patients were identified as heterozygous for CFTR associated with chronic pancreatitis, 41 were recruited in the alcohol-related chronic pancreatitis group via random selection from the pancreas clinic. Clinical outcomes are compared in the table.

Conclusion: Our cohort of patients with chronic pancreatitis associated with heterozygous CFTR gene mutations had significantly lower age of presentation and lower requirements for opiates compared to a randomly selected cohort of alcohol-induced pancreatitis patients.

Although not statistically significantly different, the CFTR group tended to have a lower incidence of pancreatitis-related complications compared with alcohol-related chronic pancreatitis.

This study suggests CFTR-related chronic pancreatitis may have a milder course of disease when compared with alcohol-related chronic pancreatitis and CFTR mutations should be considered in young patients presenting with chronic pancreatitis. However larger prospective studies are needed.

Disclosure: None.

Introduction: It is sometimes difficult to distinguish between autoimmune pancreatitis (AIP) and pancreatic neoplasm. In imaging diagnostic examination, long or multiple strictures, or segmental/focal narrowing of pancreatic duct without marked upstream dilatation in endoscopic retrograde pancreatography is important finding to diagnose as AIP. It has been speculated that the narrowing of pancreatic duct is attributed to periductal lymphoplasmacytic infiltration characteristic of histology in AIP. We reported a resected case of AIP in which branch pancreatic duct wall thickening demonstrated by endoscopic ultrasound (EUS) reflected periductal lymphoplasmacytic infiltration¹. EUS that provides high resolution image of pancreas can delineate periductal lymphoplasmacytic infiltration as pancreatic duct wall thickening.

Aims & Methods: The aim of this study is to determine whether pancreatic duct wall thickening on EUS contributes to the diagnosis of AIP. From March 2017, when we began focusing on pancreatic duct wall thickening in AIP, to April 2022, there were 21 consecutive patients diagnosed with AIP in our department. EUS was performed in all of them, and the presence of pancreatic duct wall thickening was noted on the EUS report.

Pancreatic duct wall thickening was focused on a thickened wall with symmetry, irregular luminal caliber, and a smooth hyperechoic layer covering the surface¹. The international consensus diagnostic criteria for AIP were applied. The detection rate of pancreatic duct wall thickening on EUS, characteristics according to pancreatic duct wall thickening, and the change of pancreatic duct wall thickening after steroid therapy were investigated.

Results: All patients were diagnosed with type 1 AIP (definitive type 19, probable type 2). Median age was 70 years (range: 60-82), and male was 15 patients. The median serum IgG4 level at diagnosis was 467 mg/dL (range: 147-2600). The detection rate of pancreatic duct wall thickening on EUS was 81.0% (17/21). Localization was diffuse in 12 patients and segmental/focal type in 9 patients. Other organ involvement was observed in 12 patients. There was no difference in the above factors depending on the presence or absence of pancreatic duct wall thickening. Seventeen patients underwent steroid trial. Among them, 7 patients who underwent EUS after steroid trial showed improvement in pancreatic duct wall thickening.

Conclusion: Pancreatic duct wall thickening on EUS was often seen in patients with AIP and improved with steroid therapy. This new imaging finding may be useful in the diagnosis of AIP.

Introduction: Transmural drainage by placing lumen-apposing metal stents (LAMS) is currently the standard of care for abdominal fluid collections (AFC) that can be approached by endoscopic ultrasound (EUS). Despite they have proved to be safe, complications such as bleeding and obstruction have been described.

Aims & Methods: The aim of the study is to assess the efficacy and safety of placing a coaxial double pigtail plastic stent (DPPS) in the EUS management of AFC.

Observational, retrospective study including 70 consecutive patients undergoing EUS-guided drainage of AFC by placing LAMS ± coaxial DPPS, between March-2017 and January-2022. Evaluation of the impact of coaxial DPPS vs non-DPPS insertion on: efficacy, number of endoscopic revisions and complication rate. Specifically, a subgroup analysis with walled-off necrosis (WON) cases was conducted.

Results: 70 patients were included with a mean age of 54.80±13.95 years-old, 74% male. 94% were pancreatic fluid collections: 64% WON and 30% pancreatic pseudocysts, with a mean size of 118.68 mm. 76 LAMS were placed with 100% of technical success. The indications for drainage were: 41% compressive symptoms and 59% infection. 2 patients had immediate adverse events (bleeding and aspiration) but none of them were fatal. The 2 groups, LAMS + initial DPPS (n = 18) and LAMS with no initial DPPS (n = 58), showed similar basal characteristics. The overall clinical success was

90% (100% in initial DPPS group; 87.3% in no initial DPPS group). Significantly less endoscopic revisions (0.93 ± 1.27 vs 3.34 ± 3.75 ; $p = 0.021$) and time to LAMS retrieval (56.32 ± 45.87 vs 125.83 ± 50.56 days; $p < 0.001$) were observed in initial DPPS group. The overall adverse event rate was also lower in DPPS group (13.3% vs 24.1%; $p = 0.367$). The following adverse events related to LAMS were described: 1 sepsis because of stent migration, 2 sepsis because of stent obstruction and 2 upper gastrointestinal bleeding. There were less readmissions in the first group (6.7% vs 14.5%; $p = 0.374$).

In WON subanalysis we described even bigger differences between the 2 groups with better outcomes in patients managed with LAMS + initial coaxial DPPS: 100 % of clinical success vs 80% ($p = 0.167$), significantly less endoscopic revisions (1.38 ± 1.50 vs 4.39 ± 3.97 ; $p = 0.042$) and time to LAMS retrieval (45.75 ± 26.46 vs 149.00 ± 34.72 days; $p < 0.001$), and shorter hospital stay after LAMS insertion (16.60 ± 10.78 vs 36.21 ± 31.18 days; $p = 0.176$).

In general, 4 patients (5.7%) required surgery and 10 (14.28%) required percutaneous drainage of the AFC after EUS approach. We registered 8 deaths but just 1 of them was related to LAMS (late massive bleeding). The 81.6% of LAMS have been removed.

Conclusion: LAMS are safe and effective in EUS-guided drainage of pancreatic fluid collections, including pancreatic pseudocysts and walled-off necrosis.

The initial insertion of a coaxial DPPS reduces the rate of adverse events, endoscopic revisions and readmissions, especially in WON cases.

HIGHER VOLUME GROWTH RATE IS ASSOCIATED WITH DEVELOPMENT OF WORRISOME FEATURES IN PATIENTS WITH BRANCH DUCT-INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS

T. Innocenti^{1,2}, G. Danti³, E.N. Lynch^{1,2}, G. Dragoni^{1,2}, M. Gotti^{1,2}, F. Fedeli³, D. Palatresi³, M.R. Biagini^{1,2}, S. Milani^{1,2}, V. Miele³, A. Galli^{1,2}

Introduction: Branch duct-intraductal papillary mucinous neoplasms (BD-IPMNs) are the most common pancreatic cystic tumours and have a low risk of malignant transformation^{1,2}.

None of the current guidelines take volume of the cysts and its evolution over time into account³⁻⁵, although it has recently been shown that it is a highly reproducible parameter with low inter-observer variability⁶.

To date, there are no studies investigating the correlation between cyst volume growth rate and the risk of malignant degeneration in patients with BD-IPMN.

Aims & Methods: We aimed to assess both diameter and volume growth rate of BD-IPMNs and evaluate their correlation with the development of malignant characteristics. We retrospectively included all adult patients with a BD-IPMN who had had at least two MRI studies or CT scans at our centre and a 12-month minimum follow-up time.

Diameters of cystic lesions were measured on three planes, while the volume was calculated by segmentation. A region of interest was manually drawn along the edge of the cyst on each consecutive slice covering the whole lesion.

Then, a three-dimensional volume of interest was obtained with the calculated value expressed in cm³. Changes in size over time, and development of worrisome features (WF) or high-risk stigmata (HRS) were evaluated.

The primary outcomes were to assess the volume growth rate of BD-IPMNs without WF or HRS at baseline and to evaluate if a higher volume growth rate correlates with the development of WF or HRS. The secondary outcomes were the following:

1. to compare the impact of measuring volume vs diameters (axial, coronal, and longitudinal diameters);
2. to evaluate the impact of measuring volume growth rate vs diameter growth rate;
3. to test the ability of first-year volume growth rate to predict the development of WF or HRS.

The local Ethical Committee approved the study on July 13th, 2021.

Results: Baseline patients characteristics are reported in Table 1.

After a 40.5-month median follow-up, 10 patients developed WF. No patients developed HRS. Cysts at baseline were larger in patients who developed WF (diameters: 19 vs 9 mm, $p = 0.0035$; 18 vs 10 mm, $p = 0.00652$; 22.5 vs 9.5 mm, $p = 0.00424$ – volume: 5.28 vs 0.45 cm³, $p = 0.00222$).

At the end of the follow-up, patients who developed WF had a median cyst volume of 10.17 cm³, with a median growth of 4.01 cm³, and both were higher than in patients who did not ($p = 0.0005$, $p < 0.00001$).

Volume growth rate was higher in patients who developed WF (1.12 vs 0 cm³/year, $p = 0.0001$); diameter growth rate was higher too, but the difference did not reach statistical significance. The first-year volume – but not diameter – growth rate was higher in patients who developed WF (0.46 vs 0 cm³/year, $p = 0.00634$).

n= 98		
Males (%)	33 (33.7)	
Females (%)	65 (66.3)	
Median age at diagnosis (IQR)	69 (63-75)	
Familial history (%)	9 (9.2)	
History of diabetes (%)	16 (16.3)	
Former or active smokers (%)	22 (22.4)	
Never smoked (%)	76 (77.6)	
Multifocal (%)	57 (58.2)	
Largest cyst localization	Head (%)	44 (44.9)
	Isthmus/body (%)	40 (40.8)
	Tail (%)	14 (14.3)

Table 1.

Conclusion: Our study proved that not only flat size but also cyst volume growth rate is related to the emergence of WF. Moreover, in our cohort, the cyst volume increase in the first year of follow-up was a better early predictor of the development of WF than diameter alone. This suggest that measuring cyst volume routinely could be a useful tool to monitor low-risk IPMNs.

DIABETES MELLITUS AND THE RISK OF PROGRESSION OR MALIGNANCY OF PANCREATIC CYSTIC NEOPLASMS IN PATIENTS UNDERGOING SURVEILLANCE: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Sofi¹, S. Ahmad², M. Peerzada³, L. Hackett³

Introduction: Patients with pancreatic cystic neoplasms (PCN) generally undergo surveillance by cross-sectional imaging or endoscopic-ultrasound due to their pre-malignant potential. Several studies have shown association of certain clinical, morphological and cytological characteristics with high risk of malignant transformation of PCN in whom surgical

resection is indicated. Appearance of certain cyst characteristics during surveillance is associated with aggressive behavior or presence of malignancy. Patient characteristics associated with progression or induction of malignancy in PCN is unclear from current studies.

Aims & Methods: We performed this meta-analysis to determine the patient characteristics associated with progression or malignancy in patients with PCN who undergo surveillance.

We performed systematic research of several electronic databases for all the studies on surveillance of PCN which reported demographic data of patients who had progression or malignancy and controls. We included the observational studies which recorded the history of diabetes in patients at the initial diagnosis of PCN and compared the progression or malignant transformation of PCN in patients with and without diabetes during the surveillance. Studies which assessed the predictors of malignancy in a cohort of resected PCN were excluded.

We calculated Risk ratio (RR) or Hazard ratio (HR) with 95% confidence interval (CI) for each variable. Mantel-Haenszel method or Inverse-variance model was used to pool data of progression or malignant transformation into fixed or random effect model meta-analysis.

A separate analysis was performed to estimate the pooled univariable Risk Ratio (RR) and multivariable Hazard Ratio (HR) of potential risk factors. GRADE (Grading of Recommendations, Assessment, Development and Evaluation) framework was used to interpret the quality of evidence of our findings

Results: 11 observational studies, 4 assessing risk factors for malignancy (3955 patients) and 7 evaluating risk factors for progression of PCN (3144 patients) were included in the meta-analysis. Mean follow-up ranged from 23-96 months. Diabetes before surveillance was present in a total of 1033 (14.5%) patients and pooled malignant transformation or progression was seen in a total of 11.5 % patients. Diabetes mellitus was associated with higher risk for malignant transformation as well as progression of PCN (RR= 1.54, CI 1.23, 1.92).

Moderate heterogeneity was seen ($I^2 = 36\%$; $P = 0.11$). Funnel plot appeared asymmetric but Begg and Mazumdar test ($\tau = 0.145$; $p = 0.5332$) did not show evidence of publication bias. Pooled multivariable HR for association of progression in branch-duct IPMN (BD-IPMN) with DM was 1.44 (95% CI, 1.12-1.84).

Sub-analysis of studies with mean follow up of ≥ 60 months revealed significant association between DM and risk of malignant transformation of PCN with pooled RR 3.17 (CI, 1.69- 5.93). Advanced age was associated with higher risk of progression (RR= 2.78 (CI: 2.67, 2.88).

Male gender had higher risk for malignant transformation but not progression of PCN (RR= 1.33, CI: 1.07, 1.66). On GRADE framework, the level of quality of evidence was low for both progression and malignancy with diabetes because of observational nature of included studies.

Conclusion: Diabetes is associated with an increased risk of both malignancy and progression of PCN in patients who undergo surveillance. Advanced age is also associated with higher risk of progression of PCN. Males have higher risk for malignant transformation.

Disclosure: No Conflict of interest to disclose.

Introduction: The key feature of side-branch intraductal papillary mucinous neoplasms (SB-IPMN) is its connection with the pancreatic ductal system. This feature could be helpful to distinguish potentially premalignant SB-IPMN from benign lesions such as pseudocyst and serous cystic neoplasm.

However, ductal connection is often not well visible when conventional MRCP imaging techniques, which are used as golden standard to visualize ductal connection, are applied.

Therefore this study aimed to investigate if secretin-enhanced magnetic resonance cholangiopancreatography (s-MRCP) improved visualization of ductal connection in PCN.

Aims & Methods: We performed a prospective pilot study including consecutive adult patients who underwent follow-up for at least one pancreatic cyst without clear pancreatic duct (PD) connection on conventional MRCP. Patients provided informed consent to undergo additional s-MRCP with 0.2 mg/kg intravenous secretin during routine follow-up. All scans were re-read by two experienced abdominal radiologists.

Primary endpoint was clear PD connection (defined as the interpreting radiologist being more than 80% certain of PD connection). Secondary endpoints were artefacts, visibility of the ductal system and adverse events.

Results: We included 21 patients (median age 70 years [IQR 61-75 years], predominantly females [n=15, 67%], median cyst size 18 mm [IQR 13-24 mm]). Both readers reported significantly higher pancreatic ductal visibility after s-MRCP when compared to conventional MRCP (p=0.030 [Reader 1], p = 0.041 [Reader 2]).

This did however not result in improved visibility of PD connection after s-MRCP (p=0.166 for reader 1, p=0.807 for reader 2). Overall image quality and amount of artifacts were similar (p=0.090 and p=0.071 for reader 1, and p=0.084 and p=0.157 for reader 2, respectively). One patient experienced an episode of diarrhea after secretin administration.

Conclusion: The results of this pilot study showed that secretin-enhanced MRCP did increase pancreatic ductal visibility although it did not result in an increased visibility of PD connection in patients with PCN. Follow-up research should investigate if secretin-enhanced ductal visibility is of added value in more extensive MRI sequences to detect PD connection with PCN.

Contact E-Mail Address: lauri.galetano@hsr.it

Introduction: Intraductal Papillary Mucinous Neoplasms (IPMNs) are common but rarely evolve into invasive cancer (PDAC). Whether factors associated with PDAC risk have similar prevalence in IPMNs that show features considered relative or absolute surgical indication and in "trivial" IPMNs is unknown.

Aims & Methods: To investigate the prevalence of factors associated with PDAC risk in subgroups of "good" and "bad" IPMNs and PDAC.

Materials and Methods: Retrospective analysis of prospectively maintained databases of patients with IPMNs and PDAC. IPMNs with relative of absolute indication for surgery at diagnosis or within the first 48 months of follow-up ("bad IPMNs") were matched (same sex, age ± 5) 1:1 with BD-IPMNs without any surgical indication at diagnosis and during at least 48 months follow-up ("good" IPMNs) and with PDAC ("ugly") patients.

All environmental factors were recorded as present 12 months before diagnosis to avoid bias. The groups were compared for continuous and categorical variables with Kruskal Wallis or Anova tests with Bonferroni correction.

Results: 151 patients were enrolled in each group (49.6% male, median age at diagnosis 70.2, 70.3 and 69.7 for "good", "bad" and "ugly"). The 3 groups did not differ in terms of BMI, history of previous diabetes and related medications, of previous cancers or pancreatitis, chronic use of statins or aspirin.

While the rate of "ever smokers" was not different (46%, 54%, 51%) that of current smoking was progressively higher from "good" (8.8%) to "bad" (13.6%) IPMNs and PDAC (25.6%) (p<0.001). The rate of heavy smoking (>20 pack/years; 19%, 27%, 23%) and ever alcohol drinkers (47%, 49%, 42%) was similar.

A previous history of peptic ulcer was more common in PDAC (7.2%) compared to either "good" (1.3%) or "bad" (1.9%) IPMNs (p=0.012). 1st degree family history (FH) of PDAC was similar in the 3 groups (10.6%, 8.1%, 9.6%), but 2nd degree PDAC FH (4.7%, 1.3%, 8.2%) more frequent in PDAC patients, although not significant after Bonferroni correction (p=0.02). 1st degree FH of other cancers was not different.

Conclusion: Patients with both "good" or "bad" IPMNs share similar exposure with PDAC. Continuous smoking seems associated with the progression of IPMNs toward malignancy.

Disclosure: Nothing to disclose.

Introduction: Pancreatic cystic lesions (PCLs) are common findings in clinical practice with an estimated prevalence of 8% (1). These lesions have varied etiology and are associated with increased risk of pancreatic malignancy. However, this risk is almost exclusive of mucinous cystic lesions. Endoscopic ultrasound (EUS) plays a pivotal role in the diagnosis and characterization of these lesions. Nevertheless, the reported accuracy in the differentiation of mucinous from non-mucinous lesions varies significantly between studies (48-94%), with reported sensitivities and specificities as low as 36% and 45%, respectively (2).

The introduction of artificial intelligence (AI) algorithms to endoscopic practice, including EUS, has provided promising results (3). Convolutional neural networks (CNNs) are highly efficient artificial intelligence tools for image analysis.

Aims & Methods: This study aimed to develop a *deep learning* algorithm for the automatic diagnosis and differentiation of mucinous and non-mucinous PCLs using EUS images.

We developed, trained, and validated a CNN based on EUS images. Each frame was labelled as corresponding to a mucinous (intraductal papillary mucinous neoplasm or mucinous cystic neoplasm) or non-mucinous (serous cystadenoma or pseudocyst) PCL. The diagnosis of mucinous PCL was dependent on cyst fluid analysis (CEA fluid levels >192ng/mL and glucose levels <50mg/dL) and/or histopathologic analysis of intracystic biopsies or surgical specimens. The entire image dataset was split for constitution of training (80%) and validation (20%) datasets. The latter was used to evaluate the performance of the CNN. The sensitivity, specificity, positive and negative predictive values (PPV and NPV, respectively), accuracy and area under the curve were calculated.

Results: A total of 5505 images from 28 EUS exams were included (3725 of mucinous PCLs and 1780 of non-mucinous PCLs). The model had an overall accuracy of 98.5%, a sensitivity of 98.3%, a specificity of 98.9%, a PPV of 99.5% and a NPV of 96.4%. The AUC was 1.00. The image processing speed of the CNN was 191 frames/second.

Conclusion: In this pilot study we developed a deep learning algorithm for automatic differentiation of mucinous from non-mucinous PCLs using EUS images. Subsequent development of these tools may contribute to enhance the diagnostic performance of EUS in the characterization of PCLs, which may constitute a decisive step forward in improving the management of this group of patients, with potential impact in the overall patient prognosis.

PANCREATIC RESECTIONS FOR CYSTIC NEOPLASMS: FROM SURGEON'S PRESUMPTION TO PATHOLOGIST'S REALITY

A. Burelli¹, A. Nepi¹, C. Tomelleri¹, G. Perri¹, G. Marchegiani¹, R. Salvia¹

¹Verona University Hospital, Department of General and Pancreatic Surgery, Verona, Italy

Contact E-Mail Address: anna.burelli@libero.it

Introduction: Pancreatic cystic neoplasms (PCNs) incidence is increasing and postoperative morbidity and mortality after pancreatic resections are not negligible. In the early 2000s misdiagnosis rate ranged from 20 to 30% [1, 2].

Aims & Methods: The aim of the current study was to assess the misdiagnosis and malignant/non-malignant mismatch rate in the last ten years in a tertiary referral hospital for presumed PCNs who underwent resection. All patients who underwent pancreatic resection for presumed PCNs at the Verona Pancreas Institute between January 2011 and December 2020 were included.

The retrospective analysis was focused on cyst characteristics and preoperative diagnostic workup. Rate of misdiagnosis and of non-malignant/malignant mismatch, defined as the rate of incorrect preoperative characterization of a cyst as non-malignant or malignant, were assessed.

Results: A total of 601 patients were included. Three hundred one patients (50%) underwent EUS with or without fine needle aspiration/biopsy. Most of the EUS were performed at the Verona Pancreas Institute (n= 222; 74%), a tertiary referral hospital for pancreatic diseases, while 79 (26%) in primary or secondary hospital.

Overall misdiagnosis and non-malignant/malignant mismatch rate were 19% and 30%, respectively. There were no significant differences between patients who underwent EUS compared to those who did not (misdiagnosis: 18% vs 20% p= 0.663; non-malignant/malignant mismatch 29% vs 31% p= 0.613).

The lowest misdiagnosis rate was documented for solid pseudopapillary neoplasms (7%), followed by intraductal papillary mucinous neoplasms (16%), mucinous cystic neoplasms (23%), serous cystic neoplasms (28%) and cystic neuroendocrine tumors (62%). In 54 patients the preoperative diagnosis was serous cystic neoplasm, of those seven (13%) were malignant at final pathology (four malignant IPMNs; one malignant MCN; one SPT; one cystic NET with positive lymphnodes).

Conclusion: In the last ten years in a tertiary referral center misdiagnosis rate is still around 20% and comparable to the previous decade [1].

Introduction: Accurate diagnosis of pancreatic cystic lesions PCLs remains challenging despite advanced imaging techniques. They include a broad spectrum of pathology ranging from benign cysts to potentially malignant or malignant cystic lesions. EUS-guided fine-needle aspiration (FNA) cytology, EUS-guided fine needle-based confocal laser endomicroscopy (nCLE), and needle microforceps biopsy are currently used to differentiate mucinous and non-mucinous pancreatic cyst.

The combined use of both EUS findings with cystic fluid biomarkers along with clinical, radiologic, histologic, genetic, and molecular characteristics, would enhance the diagnostic accuracy of PCLs. Immunological responses have been demonstrated in multiple malignancies, including pancreatic adenocarcinoma. Cytokine markers of the Th1 and Th2 immune response have been shown to discriminate pancreatic cancer from chronic pancreatitis or normal pancreatic tissue in both serum and pancreatic juice samples.

Similarly, pancreatic cyst fluid cytokines may reflect the immunogenic/proinflammatory process induced by malignant transformation in PCLs. IL1b was postulated to have the ability to differentiate low from high-risk IPMN.

Aims & Methods: The aim of the current study was to determine the predictive value of cystic fluid IL-1β in detection of malignant pancreatic cystic lesions and its correlation to the different degrees of dysplasia. Between January 2018 and November 2020, 50 patients underwent EUS-guided fine needle aspiration (EUS-FNA) for cyst fluid analysis and cytology. Pancreatic fluid levels of IL-1β were measured using commercially available ELISA kits (Cat DLB-50; R&D, Minneapolis, Minn and RPN222; GE Healthcare Life Sciences, Pittsburgh, Penn).

The threshold value of IL-1β (>50 pg/mL).

The final diagnosis was established according to the histopathological diagnosis of the resected specimens in those who underwent surgery and FNA aspirate from the rest. All patients were followed for at least 6 months.

Results: Cyst fluid IL-1 β can differentiate between mucinous and non-mucinous pancreatic cysts at cutoff value >150 pg/ml; with a sensitivity and specificity of 83.33% and 53.78% respectively.

Also, it can differentiate between benign and malignant cysts at cutoff value >200 pg/ml; with a sensitivity and specificity of 84.00% and 56.00% respectively. On the other hand, it was unable to differentiate between variable degrees of dysplasia of IPMN.

	B	p value	Odds ratio (OR)	95% C.I. for OR
Age > 55 ys	3.401	0.000	30	5.294 -170.015
Size of cyst ≤ 55mm	1.992	0.007	7.333	1.716-31.343
C.F IL1b > 200 pg/ml	3.520	0.001	33.800	3.895 - 293.305
Mucin stain	3.386	0.002	29.545	3.428 - 254.667

Table. Univariate logistic regression analysis for predictors of malignancy.

Conclusion: Pancreatic cyst fluid IL-1β can be a promising biochemical cyst fluid marker to differentiate between mucinous and non-mucinous cysts as well as benign and malignant cysts. Further larger studies are needed to validate its role.

Introduction: von Hippel Lindau (VHL) disease is a rare, familial autosomal dominant disease. It can progress with involvement of many organs such as cerebellum, spinal cord, kidney, epididymis, pancreas, surrenal glands. In pancreatic involvement, simple cysts, serous cystadenomas and PNETs which can have malignancy potential can be seen.

Aims & Methods: In this study, we tried to reveal the involvement patterns and pancreatic involvement characteristics of the patients that we followed up for VHL in our own series.

Results: The mean age of 7 female and 4 male VHL patients was 30 years. Disease age was determined as the youngest 3 years and the highest 22 years. Considering the organ involvement patterns of VHL patients, 7 patients had brain and spinal cord involvement and 10 patients had kidney involvement. Of the patients with kidney involvement, 2 had a history of RCC and one had a history of surgery due to angiomyolipoma. Two patients had epididymal involvement. Retinal involvement was present in 5 patients, adrenal gland involvement was detected as pheochromocytoma in 2 patients and they were operated.

When the patients were evaluated in terms of pancreatic involvement, 8 of 11 patients had pancreatic involvement. All 8 patients with pancreatic involvement had multiple cysts. Cyst sizes were measured as the smallest 15 mm and the largest 80 mm. Cyst aspiration was performed from 4 of 8 patients with pancreatic cysts, and findings consistent with serous cyst adenoma were found in all patients who underwent cyst aspiration.

Conclusion: In our patient series, we found that the pancreas was the most common site of involvement in VHL patients, in accordance with the literature. Our patients were mostly found to have multiple cysts, and those who had cyst sampling were mostly diagnosed as serous cystadenoma.

EVALUATING THE USE OF IRREVERSIBLE ELECTROPORATION FOR PANCREATIC CANCER TREATMENT: PILOT IN VITRO STUDIES

I.A. Khawaja¹, Z.L. Rai¹, B.R. Davidson¹, P. Acedo²

¹University College London, Division of Surgery & Interventional Science, Royal Free Hospital, London, United Kingdom, ²University College London, Institute for Liver & Digestive Health, London, United Kingdom

Contact E-Mail Address: ibbikhawaja@hotmail.com

Introduction: Pancreatic cancer (PC) treatment continues to have exceedingly poor clinical outcomes, and therefore the need for novel and innovative methods to combat this disease remains a matter of urgency. Increasingly, loco-regional therapies used in conjunction with systemic chemotherapy, are being favoured in the clinical setting. Irreversible electroporation (IRE) is a non-thermal ablative therapy that has shown promise in this regard. IRE uses high voltage electrical current to destabilise cell membranes, subsequently causing cell death [1].

However, there is a lack of knowledge regarding effective treatment parameters or the signaling pathways induced by combining IRE with chemotherapy. Optimum field strength, pulse length and duration, as well as pathways of cell death induced after IRE, remain to be elucidated both in vitro, and in the clinic [2].

Aims & Methods: Even though IRE is already used in clinical practice, our research aims to establish optimum electroporation parameters and molecular mechanisms induced by IRE in pancreatic cancer models (2D and 3D) to aid with future device improvement. We also aim to identify possible chemotherapeutic agents that can be used in conjunction with IRE to potentiate its effects. Diverse PC cell lines (e.g. PANC-1, CFPAC-1) were electroporated using the Harvard Apparatus BTX electroporator generator. Key parameters such as voltage strength, pulse number, length and duration were evaluated.

Following treatment, cells were maintained in culture for up to 96-hours, to determine the effect of IRE on metabolic activity and viability using MTT, ToxiLight assays and LIVE/DEAD staining. Data was validated by flow cytometry and fluorescence microscopy. Upregulation of proteins involved in mitochondrial mediated cell death, such as caspases, were analysed using western blotting.

Results: Increasing voltage strength resulted in a reduction in cell proliferation and increased cell death, with a half maximal inhibitory voltage strength of 620V/cm 24-hours post-ablation. Similarly, increasing the pulse number also resulted in a reduction in cell proliferation and increased cell death, with 30 pulses being optimal. Increasing the pulse number to 50, resulted in almost total cell death, even at voltage strengths as low as 12V/cm.

Conclusion: Our research found that the two most important electroporation parameters in pancreatic cancer cell IRE treatment are voltage strength and pulse number. We have optimised these parameters for future research on ascertaining pathways of cell death post electroporation. Aggressive cancer cells such as PANC-1 and CFPAC-1 may have additional intra-cellular adaptations compared to normal pancreas cells making them resistant to electrical insults. Future work will investigate whether these adaptations can be overcome by combining IRE with diverse cytotoxic agents.

COMPARISON OF PBMC FUNCTIONS AND *AHR*, *ELAVL-1* EXPRESSION IN PANCREATIC CANCER VS HEALTHY PATIENTS

A. Bartkeviciene¹, A. Jasukaitiene², J. Matthews³, A. Gulbinas⁴, Z. Dambrauskas⁴

¹Lithuanian University of Health Sciences, Institute for Digestive Research, Laboratory of Surgical Gastroenterology, Kaunas, Lithuania, ²Lithuanian University of Health Sciences, Institute for Digestive Research, Kaunas, Lithuania, ³University of Oslo, Molecular Toxicology Group, Oslo, Norway, ⁴Lithuanian University of Health Sciences, Department of Surgery, Kaunas, Lithuania

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is one of the biggest challenges in today's oncology. PDAC consists of more than 90% of all pancreatic cancer (PC) cases. The World Health Organization based on 2020 statistics, presented that PC was still one of the deadliest cancers, with a 5-year survival rate of only 8%.

After undergoing resection for stage I, an overall 5-year survival had increased to almost 40%. Despite improved survival rates after resection combined with chemotherapy or immunotherapy, success for the treatment was limited [1].

The aryl hydrocarbon receptor (*AHR*) is a ligand-dependent transcription factor that acts in an important role in cell environmental, metabolic and immune regulation. This post-transcriptional regulator could allow tumor cells to avoid immunosurveillance after programmed death 1 ligand 1 (*PD-1* / *PD-L1*) inhibitors immunotherapy. *AHR* also modulates the RNA-binding protein *ELAVL-1* signaling pathway that leads to an increased translation of target mRNAs and subsequent overexpression of cytoprotective and anti-apoptotic proteins also induce chemoresistance in PDAC cells.

We think that *AHR* and *ELAVL-1* genes expression differences in blood between some patients regulating unsuccessful response to *PD-1* / *PD-L1* immunotherapy against cancer. Normalization of combined target immunotherapeutic genes should return immune cell function and improve immunotherapeutic efficacy.

Aims & Methods: Our main task was to compare PBMCs function differences of PDAC patients and healthy donors with expression and protein syntheses in *AHR*, *PD-1*, *PD-L1* and other target genes. Main material of this research was blood from PDAC patients and healthy donors. PBMC were isolated by Ficoll-Paque gradient centrifugation.

Monocytes subtypes were defined by multiparametric flow cytometry. Expression of target genes and cytokines were evaluated by qRT-PCR. Free circulating cytokines were measured with Luminex multiplex assay. Fluorometric assays were used to measure phagocytic activity after 4-hour PBMC activation with LPS, ROS production was measured at same period effecting with TBHP, and NO production was measured after 16-hour activation with LPS. Simultaneously PBMCs metabolic activity was measured by resazurin metabolism method.

Results: The results showed that after PBMC activation ROS, NO production and phagocytic activity increased less (not significant) in pancreatic cancer patients than healthy control. Although metabolic activity increased similarly in both groups. The M1 / M2 cell ratio became lower in cancer patients. Expression of *IL-1 β* concentration was higher in PBMC from control group but circulating IL-1 β concentration was higher in cancer patients' sera.

Other concentrations of measured cytokines were higher in PDAC patients and the relationship between these genes and proteins remained similar. In comparing with healthy control, the expression of PBMC target genes *AHR*, *ELAVL-1* and *HO-1* decreased but *PD-1* expression significantly increased in cancer group.

Conclusion: This PBMC research showed functional imbalance and immunosuppression in PDAC patient group compared with healthy control. In cancer patients PBMC target genes *AHR*, *ELAVL-1*, *HO-1* and measured phagocytosis, NO and ROS production, reduced relatively but *PD-1* and cytokines concentrations increased significantly. Need more studies with higher amount of PDAC patients and analyze their functional PBMC response in contrast *AHR*, *ELAVL-1* expression differences.

Introduction: Irreversible electroporation (IRE) is a novel loco-regional ablative therapy that is currently being investigated for the treatment of solid tumours. Whilst it has enjoyed success in the treatment of cancers such as prostate, IRE's treatment potential in more aggressive tumours like pancreatic cancer (PC) remains controversial (1).

It is thought IRE exerts its cytotoxic effect by increasing the transmembrane potential of the lipid bilayer. This results in pore formation, disrupting cellular homeostasis and causing cell death (2).

However, much remains unknown about the type of cell death that is initiated following IRE in PC and whether IRE's cytotoxic effect can be enhanced with concomitant synergistic therapies.

Calcium homeostasis has been implicated in cancer pathophysiology and studies have demonstrated the cytotoxic effect of supraphysiological doses of calcium in *in vitro* cell lines through acute ATP depletion and mitochondria mediated apoptosis (3).

Moreover, Ca²⁺ ions have been shown to impact resealing of damaged membranes (3) in addition to being a common second messenger in several intra-cellular pathways (4).

Aims & Methods: To understand the optimum electroporation voltage strengths when combined with supraphysiological calcium treatment.

2 immortalised pancreatic cancer cell lines; PANC-1 and CFPAC were used in addition to H6c7 an epithelial cell line, used as a healthy control. Cells were trypsinised to facilitate electroporation in 4mm cuvettes using BTX Electroporator generator from Harvard Apparatus. Pulse number, dura-

tion and inter-pulse length was standardised across all experiments to 30 pulses, 100ms long and 1s between pulses. Voltage strength varied between 250V/cm and 500V/cm and calcium concentrations between 25mM and 50mM. Following electroporation cells were plated in a 96-well plate and allowed to attach for 24-hours prior to exposure to Ca²⁺ for 24-hours. Cell viability assays were performed 24 and 48-hours following Ca²⁺ exposure.

Results: Combination therapy proved to be more cytotoxic compared to monotherapy with cell proliferation assays demonstrating a statistically significant reduction in proliferation ($p < 0.0001$) in combination therapy groups. Analysis between treatment groups revealed the greatest cytotoxic effect in cells treated with 250V/cm and 50mM Ca²⁺ treatment.

Conclusion: Our results indicate that combination therapy is more toxic compared to single therapy. Interestingly, cell death as measured by a bioluminescence assay, was highest in the cells treated with 250V/cm and 50mM of Ca²⁺ and significantly greater than that observed at 500V/cm. One explanation for this is that the higher voltage strength resulted in a reduction in cell attachment resulting in a reduction in the final number of Ca²⁺ treated cells.

IRE is thought to induce cell death through apoptosis; a pathway that relies significantly on Ca²⁺ signalling through changes in mitochondrial membrane potential (MMP). Future work will involve delineating the effect of single and dual therapy on MMP and mitochondria mediated apoptosis using Flow cytometry and Western Blotting.

ROLE OF ENDOSCOPIC ULTRASOUND COMBINED WITH A NEWLY MODIFIED SCORING SYSTEM TO DETECT PANCREATIC HIGH-GRADE PRECANCEROUS LESIONS

R. Sagami^{1,2}, T. Sato¹, H. Nishikiori¹, K. Murakami²

¹Oita San-ai Medical Center, Department of Gastroenterology, Oita, Japan, ²Oita University, Department of Gastroenterology, Faculty of Medicine, Yufu, Japan

Contact E-Mail Address: sagami1985@yahoo.co.jp

Introduction: Although pancreatic cancer (PC) has an extremely poor prognosis, the five-year survival rate of patients with pancreatic high-grade precancerous lesion without invasive carcinoma (PHP; high-grade pancreatic intraepithelial neoplasia [PanIN]) and high-grade intraductal papillary mucinous neoplasm [IPMN]) is favorable. PHP diagnosis and identification of patients requiring intervention are needed. We aimed to validate a modified PC detection scoring system regarding its detection ability for PHP and PC in the general population.

Aims & Methods: We modified an existing PC detection scoring system that incorporates low-grade risk (LGR) factors (family history, presence of type 2 diabetes mellitus [DM] or worsening DM, heavy drinking, smoking,

stomach symptoms, weight loss, and pancreatic enzyme) and high-grade risk (HGR) factors (new-onset DM, familial PC, jaundice, tumor biomarkers, chronic pancreatitis, IPMN, cysts, hereditary PC syndrome, and hereditary pancreatitis). Each factor was scored as one point; LGR score ≥ 3 points and/or HGR score ≥ 1 point (positive scores) were indicative of PC.

The newly modified scoring system incorporated main pancreatic duct dilation as an HGR factor. Patients who visited the Department of Gastroenterology at our hospital between March 2018 and July 2019 with any clinical symptoms or risk factors, and were screened by their initial EUS examination were prospectively enrolled. Patients with any pancreatic diseases undergoing repeated imaging examination in the surveillance program or who were strongly suggested to have pancreatic tumors using other imaging modalities were excluded.

The primary endpoint was the diagnosis rate of PHP without an invasive carcinoma among patients with positive scores. Additionally, the effectiveness of the LGR/HGR factors and scoring system was analyzed in patients with PHP and PC, compared with those without PHP and PC.

Results: Among 544 patients with positive scores, 10 had PHP (7 high-grade PanIN and 3 high-grade IPMN). The diagnosis rates were 1.8% for PHP and 4.2% for invasive PC.

Furthermore, 311 patients with negative scores according to our system were screened during the same period, and two (0.6%) patients had unresectable PC. No adverse events due to the EUS surveillance occurred. In the diagnosis of patients with PHP, resectable PC, and all lesions (PHP and PC), although the number of LGR and HGR factors tended to increase with PC progression, none of the individual factors were significantly different between patients with PHP and those without lesions. Sensitivity for PHP patient detection via LGR score positive, HGR score positive, and both scores positive were 60%, 80%, and 100%, respectively.

Score positive patients (N=544)	Score negative patients (N=311)
High-grade precancerous lesion 1.8% (N=10)	Pancreatic cancer 0.6% (N=2)
High-grade PanIN (N=7)	Unresectable PC 0.6% (N=2)
High-grade IPMN (N=3)	
Pancreatic cancer 4.2% (N=23)	
Resectable pancreatic cancer 1.8% (N=10)	
Unresectable pancreatic cancer 2.4% (N=13)	

Conclusion: The newly modified scoring system evaluating multiple factors associated with PC could potentially identify patients with higher risk of PHP or PC.

Disclosure: Nothing to disclose.

COMBINED EUS AND ERCP REDUCES TIME TO ONSET OF TREATMENT IN PANCREATOBILIARY MALIGNANCY

J. Gauci¹, W. On¹, B. Paranandi¹, M. Huggett¹, S.M. Everett¹

¹Leeds Teaching Hospital NHS Trust, Department of Gastroenterology, Leeds, United Kingdom

Contact E-Mail Address: jamesgauci111@gmail.com

Introduction: Standard ERCP sampling techniques for pancreaticobiliary (PB) malignancy have modest yields that could lead to delay in treatment. We aimed to evaluate whether combining EUS guided tissue acquisition (EUS-TA) with ERCP versus ERCP alone at time of index procedure improved time to treatment in patients with suspected PB malignancy.

Aims & Methods: All patients without a prior pathological diagnosis who underwent index ERCP at Leeds Teaching Hospitals NHS Trust for distal biliary obstruction from January 2015 to December 2020 were included.

Time to first clinical evaluation (for outpatients) and time to initial treatment were compared between ERCP alone and ERCP combined with EUS-TA.

Results: A total of 292 patients were included; 74.7% (n=202) underwent EUS-TA/ERCP and the remainder (n=90) underwent ERCP alone. EUS-TA/ERCP yielded a positive diagnosis more frequently than ERCP alone (96.5% (n=195) vs 57.8% (n=52), $p < 0.01$).

Further procedures for tissue acquisition were required in 2.0% (n=4) of the EUS-TA/ERCP group and 17.8% (n=16) of the ERCP group. Mean time to first outpatient oncological/surgical evaluation (16.9 days vs 24.5 days ($p = 0.01$)) and times to commencement of oncological (55.1 vs 79.3 days ($p = 0.03$)) and surgical treatment (50.7 vs 72.0 days ($p = 0.13$)) were shorter in the EUS-TA/ERCP than the ERCP alone groups.

However, 33.2% (n=86/292) of patients who had a positive tissue diagnosis did not undergo further oncological/surgical treatment, of whom 70.9% (n=61/86) were from the EUS-TA/ERCP group.

Conclusion: In our cohort of patients with malignant distal biliary obstruction, a combined approach of EUS-TA/ERCP at index procedure improved diagnostic yield, reduced the need for repeat sampling procedures and was associated with reduced time to treatment. Careful case selection is required to avoid offering unnecessary EUS procedures to patients who will not benefit from further treatment.

EPIDEMIOLOGY, CLINICAL CHARACTERISTICS, PROGNOSIS, AND NOMOGRAM FOR PRIMARY PANCREATIC LYMPHOMA PATIENTS: A SEER POPULATION-BASED STUDY

Y. Liu¹, Y. Xie¹

¹First Affiliated Hospital of Nanchang University, Gastroenterology, Nanchang, China

Contact E-Mail Address: doctor_liu0218@163.com

Introduction: Primary pancreatic lymphoma (PPL) is extremely rare, usually insidious in onset, and account for 0.5% or less of pancreatic tumors [1; 2].

There are different definitions available for PPL throughout the past decade [3; 4].

More recently, diagnostic criteria developed by the World Health Organization (WHO) are summarized as follow:

1. The pancreas is the primary lesion of PPL;
2. When the presence of lymph node and distant metastases, the main clinical presentation should involve the pancreas [5]. Diffuse large B-cell lymphoma (DLBCL) is one of the most common types of PPL [6; 7]. Other subtypes of lymphomas, comprising of follicular lymphoma (FL), non-Hodgkin lymphoma (NHL), Burkitt lymphoma (BL), Hodgkin lymphoma (HL), T cell lymphoma (TCL), and Not Otherwise Specified (NOS), etc.

Aims & Methods: Primary pancreatic lymphoma (PPL) is a rare type of digestive lymphoma of which the epidemiology, clinical features, and prognosis of survival are limitedly reported.

Therefore, this study aimed to evaluate the epidemiological characteristics of PPL and establish efficient nomograms to predict patient survival. Patients diagnosed with PPL were extracted from the Surveillance Epidemiology and End Results (SEER) program from 1983 to 2015.

The incidence rates of PPL were calculated from 1975 to 2018. The Joinpoint regression analysis to assess the temporal trends. Independent predictive factors for overall survival (OS) and disease-specific survival (DSS) were identified using univariate and multivariate Cox regression analyses. We constructed nomograms to predict the survival possibility of PPL patients by integrating independent clinicopathological factors.

Results: A total of 867 patients with PPL were diagnosed from 1983 to 2015. The average age was 65.7 y with a male-to-female of 1.5:1. The overall incidence of PPL was 0.44/1,000,000 from 1975 to 2018, with a significantly increasing trend reflecting an annual percentage change (APC) of 2.33 (95% CI 0.88-3.80, $P<0.05$). Multivariate Cox regression analysis indicated that age, sex, marital status, pathological classification, Ann Arbor stage, surgery, and chemotherapy were independent prognostic predictive factors for OS and DSS ($P<0.05$). Nomograms were constructed to predict the 1-, 5-, and 10-year OS and DSS. The predictive performance and compliance of the model were evaluated using the consistency index and the calibration curve.

Conclusion: PPL rarely occurs, but the incidence has been steadily increasing over the past four decades. Nomograms constructed can predict 1-, 5-, and 10-year OS and DSS. Nomograms can also distinguish high-risk PPL patients.

Introduction: Early detection of small pancreatic ductal adenocarcinoma (PDAC) requires pancreatic cancer screening method establishment for asymptomatic subjects. Current imaging technologies are limited in detecting small size PDACs. It is thus essential to identify the secondary changes of PDAC for early diagnosis. We have reported that a precancer-

ous lesion, high-grade pancreatic intraepithelial neoplasm, is accompanied by atrophy of the pancreatic acinar cell, which is detected as an indentation of the pancreas on imaging as focal pancreatic parenchymal atrophy (FPPA).

Aims & Methods: Radiological evidence of FPPA may consist in changes secondary to early PDAC. We aimed herein to verify the FPPA incidence via retrospective imaging analysis and clarify the clinicopathological features of PDAC with FPPA before diagnosis. Data on endoscopic ultrasonography-guided fine-needle biopsies and surgical samples in 170 patients who received imaging before their histological diagnosis of pancreatic cancer (n=1,011) between 2014 to 2019 were extracted from the pathological database of Komagome Hospital and Juntendo University Hospital. The FPPA incidence and clinicopathological features were then retrospectively evaluated.

Results: FPPA was identified in 52 of the 170 patients (31%) before PDAC diagnosis. The median duration from FPPA detection to diagnosis was 33.5 (range: 3-116) months. The atrophic region was later filled in 28 (54%) of the patients. The patients with (n=52) and without (n=118) FPPA had a tumor location in the head vs body-tail in 17/83 vs. 55/45 of cases [$P<0.001$]; a histopathological main pancreatic ductal lesion in a resected specimen in 47% vs. 23% of cases [$P=0.097$]; and positivity for malignancy at the surgical margin rate in 24% vs. 3% of cases [$P=0.031$], respectively. PDAC with FPPA, which was accompanied by malignancy at the pancreatic resection margin, stemmed from a high-grade, pancreatic, intraepithelial neoplasia.

Conclusion: FPPA occurred in 31% of the patients with PDAC and was detectable 33.5 months before diagnosis. The indentation in the FPPA area resolved before PDAC onset. Benchmarking pre-diagnosis images of the pancreas focusing on FPPA may enable prediction of PDAC occurrence. PDAC with FPPA presents widespread high-grade pancreatic intraepithelial neoplasia; thus, a wide surgical margin should be made.

Introduction: Pancreatic cancer (PC) is highly aggressive with a 5-year mortality that almost matches the incidence. In current practice the length of diagnostic procedure can take up to 50 days. As PC is a rapidly progressing disease, this delay might strongly affect prognosis.

Aims & Methods: We investigated if the time interval from the start of diagnostic procedure to therapy initiation (DgT) or from symptoms onset to diagnosis (SDg) (early versus (vs.) late), influences the prognosis of PC patients by performing a systematic review and meta-analysis.

Our protocol was previously submitted on PROSPERO (CRD: 282619) We systematically screened Pubmed, Embase and Central from 1st of January 2005 to 16th of October, 2021. without other filters.

Eligible studies compared prognosis, reported as overall (OS) or progression-free survival (PFS) of PC patients with shorter vs longer DgT and SDg intervals at various thresholds. The random effect model yielded the pooled hazard ratios (HRs) and 95% confidence intervals (CI).

Results: Altogether 23 articles (80542 patients) out of the 21632 were eligible. DgT interval length and disease stage varied across the studies. We analyzed the association between time from DgT and OS at different thresholds including all disease stages (2 weeks: HR=0.99; 95%CI: 0.98-1.01, I²=4%, 4 weeks: HR=1.02; 95%CI: 0.97-1.07, I²=68%, 6 weeks: HR=1.00; 95%CI: 0.97-1.03; I²=54%, 8 weeks: HR=1.05; 95%CI: 0.94-1.17, I²=84%) and found no significant differences.

The results for the resectable cases were similar. There was no significant association between SDg delay at 4 week threshold and OS for various stages of PC (HR=1.00; 95%CI: 0.99-1.03), suggesting that the start of therapy is too late in these time windows.

Conclusion: The outcome of pancreatic cancer can no longer be influenced by shortening the time in therapies started later than two weeks after diagnosis. Further studies are needed to determine what the time window is in the first 14 days in which the outcome of the disease can be improved by accelerating the start of therapy.

Disclosure: Nothing to disclose.

THE DIAGNOSTIC AND PROGNOSTIC VALUE OF APELIN (APLN) AND SERUM AMYLOID A3 (SAA3) ADIPOCYTOKINE MEASUREMENT IN PATIENTS WITH PANCREATIC DUCTAL ADENOCARCINOMA (PDAC) COMPARED TO CHRONIC PANCREATITIS (CP) AND HEALTHY SUBJECTS

M. Stasiak¹, B. Włodarczyk¹, E. Malecka-Wojcieszko¹

¹Medical University of Łódź, Department of Digestive Tract Diseases, Łódź, Poland

Contact E-Mail Address: michal_jakub_stasiak@o2.pl

Introduction: Despite extensive efforts, there are still no widely accepted, sensitive and specific early detection biomarkers for pancreatic cancer. APLN and SAA3 participate in carcinogenesis of multiple solid tumours, particularly connected to metabolic alterations. Their role in PDAC is not elucidated yet.

Aims & Methods: The aim of the study was to search for the possible diagnostic and prognostic value of serum APLN and SAA3 adipocytokines measurement in patients with PDAC compared to CP.

Serum samples (5-10 ml), fasting, were collected from 65 patients, including 34 subjects with PDAC, 11 with CP and 20 from the healthy subjects (Ctrl). APLN and SAA3 levels were measured by enzyme-linked immunosorbent assay (ELISA) (Corgenix UK Ltd R&D Systems).

The results were analysed by the non-parametric Kruskal-Wallis and Mann-Whitney U test; a peak was deemed to show a statistically significant difference in group means if its p-value was < 0.01. The study protocol was approved by the Bioethics Committee at the Medical University of Łódź.

Results: The serum mean APLN concentration level was significantly higher in CP compared to PDAC patients (1391.81 +/- 454.06 pg/ml vs 782.29 +/- 542.17 pg/ml, p<0.01). On the other hand, the patients with PDAC had significantly higher mean SAA3 level than those with CP (61.51

+/- 44.44 pg/ml vs 14.00 +/- 5.79 pg/ml, p<0.01). The APLN in Ctrl was significantly lower than in both PDAC (347.58 +/- 119.14 pg/ml vs 782.29 +/- 542.17 pg/ml, p<0.01) and CP (347.58 +/- 119.14 pg/ml vs 1391.81 +/- 454.06 pg/ml).

Serum mean SAA3 concentration in Ctrl was also significantly lower than in PDAC patients (37.01 +/- 19.37 pg/ml vs 61.51 +/- 44.44 pg/ml, p<0.01) but significantly higher than in CP patients (37.01 +/- 19.37 pg/ml vs 14.00 +/- 5.79 pg/ml, p<0.01). In PDAC group without metastases (M0), mean serum level of APLN was significantly higher compared to patients with metastases (M1) (879.34 +/- 526.37 pg/ml vs 554.29 +/- 391.16 pg/ml, p<0.01).

On the other hand, mean serum SAA3 level was significantly higher in M1 group than in patients M0 (84.83 +/- 41.83 pg/ml vs 46.95 +/- 39.67 pg/ml, p<0.01). Mean APLN and SAA3 levels were not different (p>0.05) in both, PDAC and CP groups depending on accompanying obesity or diabetes.

Conclusion: APLN and SAA3 may represent the possible biomarkers for CP and PDAC. APLN, but not SAA3 expression seems to be stronger in pancreatic inflammation than in malignancy. APLN and SAA3 concentration measurement may have the prognostic value in patients with PDAC. Additionally, those proteins may be potentially useful in PDAC and CP differentiation. Further studies are necessary to find out if this biomarkers could be useful in early PDAC detection.

Introduction: Pancreatic cancer is among the deadliest cancer types worldwide. Their incidence is increasing. There are several risk factors for the development of pancreatic cancer, however, data regarding medications that might be associated with pancreatic cancer are lacking. Proton pump inhibitors (PPIs) are among the commonest drugs used in gastroenterology, as their use was shown to be associated with certain diseases.

Recent data have shown that the profound acid suppression caused by PPI use, leads to hypergastrinemia and disrupts the normal gut microbiome, leading to dysbiosis and bacterial overgrowth that may increase the risk of pancreato-biliary malignancies.

Aims & Methods: We aimed To retrospectively explore whether PPI use is associated with increasing prevalence of pancreato-biliary malignancies. We performed a retrospective study including all patients who were referred for EUS from 2010 till 2021. Patients were divided into two groups, the first one will include all patients with radiological and histological diagnosis of pancreatic cancer, while the other group included all other patients and were served as a control group. PPI consumption in the two groups was assessed by logistic regression model.

Results: Overall, a total of 806 patients were included in the study. Among them, 69 patients were finally diagnosed with pancreatic cancer (group A), as compared to 737 without pancreatic cancer (group B). The average age was 68.6 ± 13.2 vs. 60.6 ± 18.2, in groups A and B, respectively (P=0.0001). In group A, 33 patients (47.8%) vs. 314 patients (42.6) in group B, were males (P=0.2). the rate of smoking and diabetes were significantly higher in group A, as compared to group B (34.8% and 49.3% vs. 19.7% and 32.3%, P=0.001 and P=0.002), respectively.

On the other hand, there was no difference in the rate of hyperlipidemia and hypertension (53.6% and 53.6% vs. 45.7% and 50.7%, $P=0.1$ and $P=0.32$), respectively. The rate of personal history of cancer was higher in group A (24.6% vs. 8.2%, $P<0.0001$). Notably, the rate of PPI use was significantly higher in group A (55.1%) vs. 37.9% in group B ($P=0.002$). After regression analysis, PPI use was significantly associated with pancreatic cancer (OR 2.01, 95% CI 1.22-3.31, $P=0.005$).

Conclusion: An association of PPI use with pancreatic cancer was found. Further large nationwide studies are needed to confirm our findings

Disclosure: Nothing to disclose.

Introduction: Diagnosis and treatment of pancreatic ductal adenocarcinoma (PDAC) can be challenging. Dense desmoplastic stromal reaction associated with the tumor is common, and tumor cells often comprise only 20% of lesion volume. This may negatively impact diagnostic yield at endoscopic ultrasound (EUS) with fine-needle aspiration or biopsy (FNA/B).

Current commercially available EUS needles utilize a single needle for tissue sampling, typically requiring multiple passes to obtain an adequate diagnostic specimen.

Aims & Methods: Diagnosis and treatment of pancreatic ductal adenocarcinoma (PDAC) can be challenging. Dense desmoplastic stromal reaction associated with the tumor is common, and tumor cells often comprise only 20% of lesion volume. This may negatively impact diagnostic yield at endoscopic ultrasound (EUS) with fine-needle aspiration or biopsy (FNA/B). Current commercially available EUS needles utilize a single needle for tissue sampling, typically requiring multiple passes to obtain an adequate diagnostic specimen.

Methods: In 6 live pigs, EUS-FNA procedures were done by 4 endoscopists with extensive clinical experience in EUS-FNA. There were three endoscopy sessions. A sampling of different intraabdominal structures with the multipronged needle device was done, with up to 4 passes made in several organs in each pig.

Ability to sample multiple foci simultaneously was assessed, as well as the ease of use of the multipronged needle device. In addition, post-mortem analysis of the animals was done to assess potential intra-abdominal tissue injury related to the needle.

Results: The 4 endoscopists did 15 needle passes in the 6 pigs. No problems were found with the passage of the multipronged needle device down the endoscope channel, and an FNA specimen could be obtained in all attempts. Physicians felt that the device was easy to use. Post-mortem analysis of the pigs did not demonstrate unanticipated tissue injury or perforation. Using fluoroscopy, Barium was injected at the end of the procedure and it ruled out leaks indicative of perforation.

One pig was left alive for 72 hours for observation and follow-up. No complications or adverse events were recorded.

Pathological analyses showed high-quality tissue samples in all cases.

Conclusion: The multipronged needle device represents a technological innovation enabling simultaneous needle penetration into 5 foci within a target lesion under EUS guidance.

The multisite penetrations have the potential to improve diagnostic yield with fewer needle passes. Based on this live animal study, the device appears safe and performs as intended, heralding a new era in EUS guided tissue sampling.

Disclosure: Jesse Lachter is a paid consultant to Onepass Medical and to Verily LLC.

Introduction: Multidisciplinary team (MDT) meetings aim to optimize patients' management by eliminating errors, decreasing the time to treatment initiation, and providing better adherence to guidelines. They are associated with changes in the initial diagnosis as well as in recommended treatment plan.

The aim of this study was to evaluate the impact of a MDT approach on the management and diagnosis of focal pancreatic lesions.

Aims & Methods: All patients discussed to our institution's MDT meeting of pancreatic diseases from 1/1/2020 to 31/12/2021 with an initial diagnosis of focal (solid or cystic) pancreatic lesion were included in the study. Patients' medical records were retrospectively reviewed. The impact of MDT discussion in patients' management, defined as a modification of the initially proposed therapeutic plan after MDT discussion, as well as the criteria leading to this modification were the study's primary outcomes, where its impact on patient's diagnosis, defined as a modification of the initially proposed diagnosis, was the secondary outcome.

Categorical and continue variables are presented as value (%) and as mean $\pm$ standard deviation, respectively. Comparisons were performed using a χ^2 test or Fisher's exact test with the Yates correction or non-parametrical tests, as needed. P value < 0.05 indicated statistical significance.

Results: 522 patients [257(49.2%) females, 65 ± 13.6 years] were included in the study (896 total number of MDT referrals; mean referrals per patient: 1.68 ± 0.9). Of them, 185 (35.4%) and 337 (64.6%) patients had an initial diagnosis of a cystic and a solid lesion, respectively. The most common referral query was about the management plan ($n=349/522; 66.9\%$). Most of the patients addressed with solid lesions were referred for a management question ($n=288/337; 85.5\%$) while for cystic lesions, the most

common query was regarding both the diagnosis and the management (n=68/185;36.8%). The most commonly proposed management before the MDT discussion was radiological follow-up for patients with cystic lesions (n=53/185;28.6%) and endoscopy for patients with a solid lesion (n=93/337;27.6%; p<0.001).

Overall, the MDT discussion led to modification of the management plan in 377/522 patients (72.2%), with a statistically significant difference between cystic and solid lesions [63.2% vs 77.2%; p<0.001; OR(95%CI):0.77(0.65-0.91)]. Among patients with solid lesions, chemotherapy was the most commonly proposed treatment after MDT (n=180/337; 53.7%), while for cystic lesions radiological follow-up most commonly proposed (n=89/185; 48.1%).

Among patients where a different management plan was proposed after the MDT discussion this was mainly driven by revision of the cross-sectional radiological images [n=87; 74.4% and n=157; 60.4% for cystic and solid lesions, respectively=0.11].

Regarding diagnosis, adenocarcinoma was the most common diagnosis before MDT (n=250; 47.9%) followed by Intraductal Papillary Mucinous Neoplasms (n=108;20.7%). MDT discussion led to modification of the diagnosis in 92/522 patients (17.6%), with a statistically significant difference between solid and cystic lesions [n=26 (7.7%) vs. n=66 (35.7%); p<0.001; OR (95%CI):0.15 (0.09-0.25)]. Once again, the most common criteria leading to modification of the initial diagnosis was cross sectional imaging review (n=50/92;54.3%).

Conclusion: MDT discussion significantly impacts the management of patients with both cystic and solid pancreatic lesions leading to a modification of the initially proposed management in two thirds of them, mainly due to revision of cross-sectional imaging.

Disclosure: Nothing to disclose.

OUTCOME OF METAL VERSUS PLASTIC STENTS FOR BILIARY OBSTRUCTION IN PATIENTS WITH PANCREATIC CARCINOMA UNDERGOING NEOADJUVANT CHEMORADIOTHERAPY: META-ANALYSIS

N. Kumar¹, A. Jena¹, V. Sharma¹, S. Shukla², J. Shah¹

¹Postgraduate Institute of Medical Education and Research, Gastroenterology, Chandigarh, India, ²Command Hospital, Gastroenterology, Chandigarh, India

Contact E-Mail Address: shahjamil22@gmail.com

Introduction: Preoperative biliary drainage (PBT) may be warranted in patients with borderline resectable or locally advanced pancreatic carcinoma before neoadjuvant chemoradiotherapy (NAT) to relieve obstructive jaundice. However, it is unclear if use of self-expanding metal stent (SEMS) has any benefit over plastic stent in this setting.

Aims & Methods: We searched electronic databases from inception to February 11, 2022 to identify studies comparing SEMS and plastic stents for PBT in patients with pancreatic carcinoma undergoing NAT. Random effect models were used to determine pooled rates of recurrent biliary obstruction (RBO) and/or need for re-intervention, stent related complication and surgical outcome.

Results: A total of 10 studies (474 patients; Metal group-37.1%) were included. Pooled risk ratio of RBO and/or need for re-intervention was lower in the metal group [RR, 0.23(95% CI, 0.11-0.45, I²=60%)]. Pooled risks of stent occlusion [RR, 0.43 (95%CI, 0.24-0.80, I²=45%)] and stent related cholangitis [RR, 0.37(95%CI, 0.17-0.78, I²=1%)] were lower in metal group. However, risks of stent related cholecystitis [RR, 1.51(95%CI, 0.36-6.41, I²=0%)] and pancreatitis [RR, 1.52(95%CI, 0.07-31.84, I²=66%)] were higher in metal group. Metal group was also associated with reduced risk of delay in NAT [RR, 0.38 (95%CI, 0.18-0.80, I²= 14%)].

Pooled risk ratio of R0 resection [RR, 1.12 (95%CI, 0.86-1.46, I²= 70%)] and post-operative complications [RR, 0.83 (95%CI, 0.55-1.25, I²= 0%)] was equal amongst both groups.

Author	Type of Study	Number of Patients (Metal/Plastic)	RBO and/or need for re-intervention (Metal/Plastic)
Adams MA et al	Retrospective	9/43	5/36
Kubota K et al	Retrospective	17/21	4/18
Nakamura K et al	Retrospective	17/26	3/13
Kuwatani M et al	Retrospective	17/12	1/10
Hasegawa et al	Retrospective	27/40	4/39
Kobayashi K et al	Retrospective	21/22	1/21
Vehviläinen S et al	Retrospective	15/91	0/26

Conclusion: Metal stents are associated with reduced risk of RBO and/or need for re-intervention, reduced risk of stent occlusion and cholangitis as compared to plastic stents in patients with pancreatic carcinoma undergoing NAT.

Introduction: Several needle designs are available in different sizes for endoscopic ultrasound (EUS)-guided tissue acquisition (TA) of solid pancreatic masses, and they offer different efficacy and safety profiles. No clear guidelines exist for the choice of needle for TA in this context.

We aimed to compare the needles in terms of efficacy (diagnostic adequacy, technical failures) and safety (adverse effects), and by means of network meta-analysis create a ranking of all available needle types.

Aims&Methods: This review was registered in Prospero (CRD42021284755). Randomized controlled trials comparing at least two needles of a specified gauge for TA of solid pancreatic masses were eligible for inclusion. MEDLINE (via PubMed), CENTRAL, Embase, Web of Science and Scopus were searched on October 15th, 2021, without filters or restrictions. Risk of bias was assessed using the Cochrane Risk of Bias tool (RoB2).

Results: 3665 records were identified, and 35 were finally included for analysis. For the outcome of histological adequacy, the 25G (p-score: 0.748) and 22G (0.746) Fork-tip performed best, the 25G (0.279) and 22G (0.264) Menghini worst. For the outcome of cytological adequacy, the best performing needles were the 22G Fork-tip (0.814) and 25G reverse-bevel (0.767), and worst were the 22G reverse-bevel (0.332) and 22G Menghini (0.175). For adverse events, the 25G reverse-bevel (0.797) and 20G forward-bevel (0.689) performed best, the 22G Franseen (0.319) and 19G Menghini (0.228) worst. For technical failures, the best performing needles were the 25G (0.845) and 22G (0.742) Franseen, the worst were the 22G

(0.199) reverse-bevel and 19G (0.060) Menghini needles. Significant results were only for technical failures: 19G Menghini needle was worse than 22G Franseen, 25G Franseen and 25G Menghini (all indirect), and 22G Menghini (indirect and direct). 22G Reverse-bevel was worse than 22G franseen (indirect) and 22G Menghini (direct).

Conclusion: Based on our results, fork-tip needles can be recommended for their higher diagnostic adequacy, but with a slightly increased risk of adverse events and technical failures. Menghini needles performed worst for nearly all outcomes. Limitations of the review are large uncertainties due to low event numbers for adverse events and technical failures, and a small number of direct comparisons.

Disclosure: Nothing to disclose.

Introduction: Most patients with pancreatic ductal adenocarcinoma (PDAC) are currently treated with intensified chemotherapy regimens as first-line. Besides stage, age and Ca 19-9 levels, there is limited knowledge on "patient-related factors" that are associated with the response to such treatments. Smoking has been associated with worse response to polychemotherapy in other tumor types, but data in PDAC patients are scanty and limited to single-drug regimen with gemcitabine

Aims & Methods: The aim is to investigate the role of smoking in patients with PDAC treated with intensified polychemotherapy as first line therapy. Consecutive patients affected by PDAC were prospectively enrolled within a biobank/exposome registry at our centre at time of diagnosis. We collected demographic, risk factors (smoking, BMI, alcohol, family history, diabetes mellitus, allergies, use of drugs), stage (resectable (1), borderline resectable (2), locally advanced (3), metastatic (4) as per NCCN classification), therapy (surgery, chemotherapy) and follow-up (overall survival (OS), progression free survival (PFS) or recurrence free survival (RFS)). For the present study patients' related factors associated with PFS of patients treated with first-line polychemotherapy were investigated by means of Cox regression analysis.

Results: 143 patients were treated with first-line gemcitabine+abraxane (AG; n=63), PAXG (cisplatin, nab-paclitaxel, capecitabine, gemcitabine) (n=40) or FOLFIRINOX (n=40). In the AG group 47.6% of patients were male; mean age was 69.1 years; 14.2% of patients were stage I, 31.7% stage II, 22.2% stage III, 31.7 stage IV. In the FOLFIRINOX group 52.5% of patients were male; mean age was 60.2 years; 17.5% of patients were stage 1, 57.5% stage 2, 17.5% stage 3, 7.5% stage 4. In the PAXG group 65% of patients were male; mean age was 61.6 years; 10% of patients were stage I, 35% stage II, 27.5% stage III, 27.5% stage IV. In the whole cohort, stage was the only factor significantly associated with PFS (HR 1.3; 95% CI 1.1-1.7 for increasing stage), while the mean progression-free survival was not different in ever smokers (n=75) vs never smokers (n=66) (8.4 vs 8.9 months; p=0.73; HR: 1.2 (0.7-2); p=0.29). Similar results were obtained for current smokers in the whole cohort and in the subgroups treated with AG

and PAXG. As for patients treated with FOLFIRINOX, the mean PFS of current smokers was 7 months vs 14 of non-current smokers, with an HR of 4.3 (1.2-16; p=0.02) in a multivariate Cox regression analysis corrected for stage and age. As for other exposome variables, alcohol intake, diabetes and BMI were not associated with PFS, but for higher BMI being associated with worse PFS in the subgroup treated with AG only (HR=1.1 (1-1.3) per increasing BMI unit; p=0.01).

Conclusion: The present results point toward smoking as a factor possibly associated with worse response to first-line FOLFIRINOX, but not to AG or PAXG. Whether this is due to molecular mechanisms induced by tobacco smoking, reduced tolerance or modified pharmacokinetics requires further investigation.

Disclosure: Nothing to disclose.

SHEAR-WAVE ELASTOGRAPHY VERSUS STRAIN ELASTOGRAPHY WITH HISTOGRAM ANALYSIS IN SOLID PANCREATIC LESIONS: A PILOT STUDY

V. Rednic¹, C. Cioltean¹, R.-I. Orzan¹, C. Pojoga¹, O. Mosteanu², C. Hagiu², I. Rusu¹, A. Seicean²

¹Regional Institute of Gastroenterology-Hepatology "Prof.Dr. Octavian Fodor", Gastroenterology, Cluj-Napoca, Romania, ²UMF Cluj-Napoca Dept. of Gastroenterology, Dept. of Gastroenterology 4, Cluj-Napoca, Romania

Contact E-Mail Address: rednicvoicu@gmail.com

Introduction: Strain elastography histogram endoscopic ultrasound (SH) has been proved as a valuable supplement to endoscopic ultrasound (EUS) in assessing solid pancreatic lesions, with sensitivity of 98% and specificity of 63%. However, the value of newly available shear wave EUS elastography (EUS-SWM) has been disappointing in one retrospective study.

Aims & Methods: Aim: to assess the diagnostic value of SH and EUS-SWM in solid pancreatic lesions.

Methods: Our prospective study was started in August 2021 in one tertiary medical center and were recruited patients with solid pancreatic masses >2 cm in diameter at CT scan for EUS assessment first with strain histogram (SH) (3 measurements), followed by EUS-SWM (3 measurements with VsN > 20). Patients with inconclusive pathology results were excluded. The final diagnosis was based on surgery or EUS tissue acquisition results.

Results: 37 patients with solid pancreatic lesions were evaluated. The final diagnosis was 26 pancreatic adenocarcinomas, 2 neuroendocrine pancreatic tumours (NETs). Nine patients (24,32%) were excluded because of inconclusive biopsy results or other kind of lesions. The mean value of SH for pancreatic adenocarcinoma was 35,93 and for NETs 38,83 (p<0,05). The mean values of EUS-SWM were 45,86kPa for pancreatic adenocarcinomas and 20,59kPa (p<0,05).

Conclusion: In this prospective study we found a significant difference between SH and EUS-SWM in differentiating pancreatic adenocarcinomas and NETs. Semiquantitative assessment by strain ratio was higher in neuroendocrine tumors compared with pancreatic adenocarcinoma, which was discordant compared to the results of shear-wave. Further research is needed in this topic with a larger database in order to face the challenges in standardizing the EUS-SWM procedure in pancreatic lesions.

Introduction: Pancreatic cancer is one of the most lethal malignancies in the population with a 5-year survival rate of only 8% and a poor response to oncological treatments. Hence, an early detection remains the most important prognostic criteria. However, the lack of validated disease biomarkers makes timely diagnosis challenging in most cases. Cell membrane and surface proteins play a crucial role in several routes of oncogenesis and tissue differentiation, as well as facilitating adhesion and metastasis.

Aims & Methods: This study aimed to evaluate the expression of six membrane antigens on pancreatic cancer cells (CA 19.9, MUC1, MUC4, Mesothelin, Annexin A10, and Glypican-1) and its relationship with clinical, laboratory, histological data and oncological outcomes, in terms of overall survival (OS) and disease free survival (DFS).

Surgical samples of 50 consecutive patients with pancreatic ductal adenocarcinoma (PDAC) undergoing pancreaticoduodenectomy were collected. Exclusion criteria were neoadjuvant therapy and history of other malignancies. Immunohistochemical staining for CA 19.9, MUC1, MUC4, Mesothelin, Annexin A10, and Glypican-1 using monoclonal antibodies was performed. The antigen expression was evaluated blindly by two different pathologists and classified according to Histoscore (H-score). The score was obtained considering immunostaining intensities (strong 3+, intermediate 2+, weak 1+, or no 0) and percentage of positive cells of the tumour (H-score=[0× percentage of immunonegative tumour cells]+[1× percentage of weakly stained tumour cells]+[2× percentage of intermediately stained tumour cells]+[3× percentage of strongly stained tumour cells]). The maximum possible H-score was 300. H-score for tumoral, ductal and acinar tissues was calculated. The patients were followed after surgery and clinical and laboratory data were collected.

Results: Median follow-up was 21,5 months. During the follow-up period, in 23 patients (47%) PDAC recurred, with a median DFS of 15 months, and 18 patients (36%) deceased, with a median OS of 21.5 months. Immunostaining for CA 19.9 and MUC1 showed a significantly higher expression in neoplastic tissue compared with non-tumoral ductal and acinar tissues (p<0.001). Moreover, the intensity of CA 19.9 and MUC1 staining of neoplastic tissue was very high, with mean H-score of 270 and 210 respectively. The expression of MUC4, Mesothelin, Annexin-10 and Glypican-1 were significantly different between normal and pathologic tissue (p<0.001), resulting completely absent in normal tissue and expressed in cancer cells in various percentages.

Neutrophil count > 4.8x10⁹/L and CA 19.9 H-score > 270 were found to be significantly correlated with OS (p=0.02 and p=0.05, respectively) and DFS

(p=0.04 and 0.05, respectively) in univariate analysis and, in multivariate analysis, they were confirmed to be independent predictor variables for OS.

Conclusion: CA 19.9 and MUC1 are highly expressed in PDAC cells. The histological expression of CA 19.9 may predict prognosis, in terms of OS, in patients with PDAC. MUC4, Mesothelin, Annexin-10 and Glypican-1 are selectively expressed by neoplastic tissue compared with non-tumoral pancreatic tissues and may represent a potential histological biomarker of disease.

Disclosure: Nothing to disclose.

Introduction: The oncogenic activation of KRAS gene is the leading event in pancreatic cancer (PC), and clinical studies have highlighted the prognostic importance of detecting KRAS mutations in tumor and plasma of PC patients. The lack of sensitive and rapid methods have hampered its utilization in clinic.

Aims & Methods: To develop and validate a single-step methodology based on amplification-refractory mutation system (ARMS) coupled with high-resolution melting analyses (HRMA) to assess the 2 most frequent codon 12 KRAS mutations detected by Sanger Sequencing (SS) in tumor and liquid biopsies of patients with PC; the prognostic value of such mutations was evaluated. Prospective study including patients with PC between 2017-2022; tumor and plasma samples were collected at diagnosis. Molecular profiling of samples was made via sequence-specific PCR primers that only allow amplification of DNA harboring the specific target allele (ARMS technique), which is then corroborated by HRMA for the correct calling of the allele profile with improved sensitivity, when compared to SS. Primary endpoint was overall survival (OS).

Results: We included 41 patients (59% males, 69±9 years): most (21, 51%) had resectable disease; 4(10%) had borderline resectable, 1(2%) had locally advanced and 15(37%) had metastatic disease. Tumor KRAS mutations were detected by SS in 24(59%) patients: G12D=13(32%), G12V=11(27%), WT=17(41%). ARMS-HRMA in tumor samples was feasible in 38(93%) patients and detected all mutations detected by SS (kappa 0.215, p<0.01; 100% Se and Sp) but also in 9 additional samples who were previously WT by SS: G12D=5(33%), G12V=4(27%) G12D/G12V=1(7%), WT=5(33%). SS was feasible in 21(51%) plasma samples but only detected a G12V mutation in 1 patient. ARMS-HRMA was feasible in 31(76%) plasma samples, and besides the mutation detected by SS, 6 other mutations were detected: G12D=3(10%), G12V=3(10%), G12V/G12D=1(3%), WT=24(77%). No differences regarding metastatic disease stage (43% vs 46%, p=0.89) or CA 19.9 levels (median 385 vs 63, p=0.11) were observed

between patients with or without mutations detected in plasma by ARMS-HRMA. There was no agreement between *KRAS* genotype determined by SS in tumor and plasma samples (κ 0.106, $p=0.15$), but a significant agreement was observed (κ 0.190, $p<0.01$ - table) when using ARMS-HRMA technique.

There was no significant association between mutations detected by SS and OS, but patients with plasma *KRAS* mutation detected by ARMS/HRMA had a tendency for lower disease progression (14% vs 54%, $p=0.05$) mainly if a G12V mutation was present (WT 54% vs G12V 0% vs G12D 25%, $p=0.04$). No significant differences were observed regarding OS between plasma *KRAS* mutated and WT (median 2 vs 11 months, $p=0.11$), but patients with G12D mutations had a lower OS comparing to G12V and WT (2 vs 7 vs 11 months, $p=0.03$).

Tumor \ Plasma	WT	G12V	G12D	G12V/G12D
WT	3	0	0	0
G12V	6	2	0	0
G12D	11	0	3	0
G12V/G12D	2	0	0	1

Conclusion: ARMS-HRMA technique seems to be a fast, accurate and reliable diagnostic tool to assess *KRAS* mutations in PC tumor and plasma samples. In our cohort, tumor and mainly plasma codon 12 *KRAS* mutation in PC patients was associated with lower OS, namely G12D mutation. Future studies should assess its value in monitoring disease progression and response to therapy.

Disclosure: No conflicts.

Introduction: Zollinger-Ellison syndrome (ZES) associated with gastrinoma may be sporadic (Sp), but in 25% of the cases, ZES is part of the inherited multiple endocrine neoplasia 1 (MEN-1) syndrome. Data comparing Sp and MEN-1/ZES forms are scanty.

Aims & Methods: We aimed to identify and compare the clinical characteristics of Sp and MEN-1/ZES.

Between 1995-2020, all the consecutive patients with a diagnosis of gastrinoma/ZES were evaluated at the Department of Gastroenterology, Ospedale Policlinico, Milan, Italy.

Results: 76 MEN-1 and 320 Sp-GEP-NEN patients were evaluated. Among the MEN-1 patients, 41 were diagnosed with a GEPNEN. Among the Sp-GEP-NENs patients, 19 were diagnosed with Sp-ZES. MEN-1/ZES patients were younger than Sp-ZES (43.7 vs 53.5 ys, $p=0.035$), primary MEN-1/ZES gastrinoma was smaller than Sp-ZES (13 vs 18 mm, $p=0.03$). Liver metastases were present in 10 patients both among the Sp-ZES and the MEN-1/ZES. Only Sp-ZES developed extra-hepatic metastases ($p=0.0197$). Surgery was performed in 13 Sp-ZES and 8 MEN-1/ZES. 15 patients received somatostatin analogs (SSAs). Median OS (mOS) of the entire cohort resulted in 204 months. Median OS was higher in MEN-1/ZES than in Sp-ZES (310 vs 168 months, $p=0.0347$). At univariate logistic regression, age at ZES diagnosis ($p=0.01$, OR 1.1, CI 1.0-1.1), G3 grading ($p=0.003$, OR 21.3, CI 2.8-162.0), MEN-1/ZES ($p=0.02$, OR 0.3, CI 0.1-0.9) and diffuse extra-hepatic metastases ($p=0.001$, OR 7.2, CI 2.2-23.4) were related to OS. At multivariate analysis, none of the variables was independently associated with OS. At univariate analysis, age ($p=0.04$, OR 1.0, CI 1.0-1.1), size ($p=0.039$, OR 1.0, CI 1.0-1.1), G3 grade ($p=0.008$, OR 14.6, CI 2.0-107.6) and diffuse extra-hepatic metastases ($p=0.005$, OR 4.6, CI 1.6-13.8) were independently associated with PFS. At multivariate analysis, only diffuse extrahepatic metastases ($p=0.05$, OR 3.4, CI 1.0-11.6) resulted associated with PFS. Among patients treated with SSAs, MEN-1/ZES patients showed a better progression-free survival (PFS) with a median PFS not reached in MEN-1/ZES vs 34.5 months in Sp-ZES ($p=0.0227$ at Log-Rank-Test).

Conclusion: MEN-1/ZES patients generally show better OS and PFS compared to Sp-ZES, and a better SSAs response, even if a significant proportion of patients die from ZES in both groups.

SINGLE CENTER 43 YEARS' EXPERIENCE OF ENUCLEATION OF PANCREATIC INSULINOMAS: EARLY- AND LONG-TERM RESULTS

A.C. Milanetto¹, G. Gabriel¹, E. De Carlo², C. Pasquali¹

¹Università degli Studi di Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy, ²Università degli Studi di Padova, Department of Medicine, Padova, Italy

Contact E-Mail Address: acmilanetto@unipd.it

Introduction: Insulinoma is the most common functioning pancreatic neuroendocrine neoplasm, and almost all patients can be cured with surgery. Whenever possible, a parenchyma-preserving procedure is advisable to prevent early/late onset of diabetes.

Aims & Methods: The objective is to analyze the clinical outcome of patients who underwent open enucleation of insulinoma in the early post-operative period, and the long-term outcomes (pancreatic endocrine function, disease recurrence and survival).

From 1979 to 2021 we performed 88 pancreatic operations for insulinoma. Clinical data collected were retrieved. All patients were followed on an outpatient basis. Follow-up (FU) till February 2022.

Results: Out of 88 patients operated on for insulinoma, 42 were enucleations (48%). There were 29 F/ 13 M, averaging 53 years (range, 20-83); none of them had a MEN-1 syndrome. All patients presented symptomatic with evidence of organic hyperinsulinism. Average tumor size was 1.4 cm (median size 1.3 cm, range 0.7-3.0 cm); only 3 (7.1%) neoplasms were > 2.0 cm in size. Twenty-five (60%) insulinomas were located in the pancreatic head, four in the uncinate process, and 13 in the body-tail region. Five insulinomas (12%) were classified as G2, while 26 out of 42 were G1. Thirty-one patients (73%) had an uneventful postoperative course. Average hospital stay was 10.8 days. Pancreatic fistula grade B occurred in four (9.5%) patients (12% reported biochemical leaks), bleeding occurred in one patient (who needed only a blood transfusion), and one patient was reoperated for an early incisional hernia. No post-operative mortality occurred. Average FU time was 211 months, and in this 43 year-long period, ten patients died of other causes. Thirty-two (76%) patients are alive with no evidence of disease (no disease recurrence). Only three out of 42 (7%) patients developed diabetes in long-term FU of more of 17 years (average, up to 39 years).

Conclusion: Enucleation in open pancreatic surgery was performed in nearly half (48%) of patients for the treatment of insulinoma, while in literature the rate of enucleations in laparoscopic procedures do not exceed 20%. Enucleation provides an excellent long-term outcome in terms of preserving endocrine function (7% of late diabetes), and the procedure in open surgery has a low rate (< 10%) of pancreatic grade B fistulas. Enucleation should be considered as the gold standard technique with whom to compare the results of the alternative treatments.

Introduction: We describe the development of nurse delivered advanced upper GI therapeutic endoscopy service, which has ensured timely and efficient access to urgent and elective therapeutic procedures.

Aims & Methods: We utilised the HEE accelerated Clinical Endoscopist training programme to train a nurse in diagnostic upper GI endoscopy. Training commenced Apr '16 with JAG accreditation in diagnostic OGD achieved Oct '16. From '17 we began regular weekly therapeutic training lists, initially in observer role but progressing to hands on training (on top of the 4 job planned independent diagnostic lists/week + other duties). The Clinical Endoscopist attended a weekly specialist upper GI clinic with a consultant gastroenterologist, progressing to an allocated patient list after 6 months.

This training was supplemented with regular attendance at MDTs, national conferences and external courses as well as a Master's Degree in Advanced clinical practice.

Over a 4 year period, competency was attained in multimodal assessment of Barrett's oesophagus, HALO radiofrequency ablation, endoscopic mucosal resection, pneumatic dilatation of oesophageal strictures, placement of oesophageal stents, the assessment and multi-modal treatment of emergency upper GI bleeding (and delivery of daily inpatient emergency endoscopy lists), and placement of percutaneous endoscopic gastrostomy feeding tubes.

Furthermore the Clinical Endoscopist is "train the trainer's" accredited and is a now major provider of upper GI endoscopy training to SpRs and consultants in our unit.

Results: No. of independent lists delivered over the most recent 12 month period:

Therapeutic OGD 26

RFA 6

Inpatient OGD lists 94

RFA list shared with trainer 15

TOTAL: 126 independent therapeutic / inpatient lists and 15 continued training lists.

Compared to a gastroenterology consultant's endoscopy commitment, this is the equivalent of 3 endoscopy lists per week over 42 weeks i.e. approximately the total amount of endoscopy that a consultant is contracted to deliver in a year.

Procedures performed in same time period:

Number of Procedures :737

Therapeutic modalities: Number

Argon plasma coagulation (APC)	28
Variceal Banding	6
Gold Probe / electrocoagulation	12
Injection – adrenaline	13
Endoclip placement	4
Endomucosal resection (EMR) <i>supervised in room</i>	10
HALO radiofrequency ablation	16
Stricture dilatation with balloon	41
Nasojejunal tube placement	16
Oesophageal Stent placement	9

Conclusion: We have shown that with the appropriate structured training, mentoring and clinical governance, Nurse Endoscopists can successfully and safely deliver an independent upper GI therapeutic service.

Disclosure: Nothing to disclose.

China (SAR), ²Combined Endoscopy Unit, Tin Shui Wai Hospital,
Hong Kong, Hong Kong, China (SAR)

Contact E-Mail Address: sgy442@ha.org.hk

Introduction: Cerebro is an artificial intelligence (AI) system that uses 29 views of 12 landmarks to enhance endoscopic coverage and increase pathology detection of the upper gastrointestinal tract. The endoscopist is encouraged to ensure complete coverage as the anatomical check-list is progressively completed. The inspection time for each site is recorded and shown in real-time to improve examination quality. The system can automatically capture photos of the landmarks and provide recommendations to improve image quality.

Aims & Methods: The objective of this report is to investigate the effect of Cerebro on the improvement of quality, and in training of young endoscopists of oesophagogastrroduodenoscopy (OGD). This is a descriptive report of OGDs performed with the application of Cerebro in Tin Shui Wai Hospital in Hong Kong in a two-month period. All procedures were performed by trained endoscopists. Commonly missed landmarks were summarised and impacts of the system were concluded.

Results: A total of 69 OGDs with Cerebro were done in our centre. The three most commonly missed views are lower gastric body (26.7%), gastric fundus-cardia (21.0%) and middle-upper gastric body (17.9%). There was an increase in the averaged views seen as time progresses with the use of Cerebro from 84.5% in the beginning to 97.3% at the end.

Conclusion: The number of missed areas from a single endoscopy is affected by the endoscopist's experience, reflected by the accuracy of the examination and total scope time. Other possible factors include system malfunction, and actions done during the procedure. Endoscopists reflected increased awareness of anatomy, more dedicated endoscopic

coverage and examination of areas under the presence of Cerebro. This provides improved quality assurance by setting benchmark in anatomical coverage, quality of images, and as a tool for training young endoscopists. **Disclosure:** Nothing to disclose.

A MULTICENTER, RANDOMIZED, DOUBLE-BLIND, CONTROLLED TRIAL OF EFFECTS OF USING INTRAVENOUS METOCLOPRAMIDE TO INCREASE MUCOSAL VISUALIZATION DURING ENDOSCOPY IN PATIENTS WITH ACUTE UPPER GASTROINTESTINAL BLEEDING

P. Manupeeraphant¹

¹*Vajira Hospital, Medicine, Bangkok, Thailand*

Contact E-Mail Address: salapao.muntou@gmail.com

Introduction: Acute upper gastrointestinal bleeding is a most common emergency condition and have high mortality if cannot achieve endoscopic management. ESGE recommend administered erythromycin intravenous before upper GI endoscopy. Erythromycin intravenous route is unavailable in Thailand. Therefore, we designed this study to evaluate the effects of metoclopramide before endoscopy in acute upper gastrointestinal bleeding.

Aims & Methods: Objective: We investigated the effects of an intravenous metoclopramide on mucosal visualization during EGD for acute upper gastrointestinal bleed in patients who were endoscopy within 24 hours after diagnosed or visited to hospital, assisted by subjective and objective criteria. The secondary endpoints including rate of repeat endoscopy, cause of upper gastrointestinal bleeding, adverse event, length of hospital stay were observed and recorded until patient discharge or death.

Methods: We designed multicenter, randomized, double-blind controlled trial included 154 patients who diagnosed acute gastrointestinal bleeding visited hospital or during admission and administered upper gastrointestinal endoscopy within 24 hours were enrolled. Participants were assigned to either metoclopramide group or placebo group by a blocked of four randomization. Modified Avgerinos Score were evaluated during endoscopy by endoscopist.

Results: There was no significant difference in baseline characteristic between 2 groups except syncope was higher in metoclopramide group. Metoclopramide was improved mucosal visualization in upper gastrointestinal bleeding within 24 hours, total score were 7.45 ± 1.08 vs 6.87 ± 1.62 ; p -value = 0.012. Successful in identifying lesion were 96.3% and 90.3% for metoclopramide and placebo. Rate of repeat endoscopy was not significant between both groups, 3.7% in metoclopramide and 8.3% in placebo; p -value = 0.217 and length of hospital stay was 5.39 ± 5.93 days vs 4.82 ± 6.06 days for metoclopramide and placebo.

We divided subgroup analysis high risk ulcer group compared results in visualization, metoclopramide no significant better mucosal visualization during endoscopy to placebo group. No neurologic and cardiogenic complication were found in this study.

Conclusion: Metoclopramide was improved visualization during endoscopy in upper gastrointestinal bleeding but was not helped to identifying causes of bleeding, intervention, length of hospital stay, and rate of gastrointestinal bleeding related death.

SINGLE CENTRE EXPERIENCE OF MANAGING BURIED PEG BUMPER USING FLAMINGO DEVICE

J. Fisher¹, I.M. Bell¹, H. Sharma¹

¹*Tunbridge Wells Hospital, Gastroenterology, Tunbridge Wells, United Kingdom*

Contact E-Mail Address: jennfisher@doctors.org.uk

Introduction: Buried bumper syndrome (BBS) occurs when the internal fixation of a percutaneous endoscopic gastrostomy (PEG) tube migrates outside of the stomach lumen along the stoma tract and becomes embedded in the gastric wall. (1)

It is a rare late complication which may result in loss of patency of the PEG, tube leakage and abdominal pain. There have been many non-surgical treatment options trialled in the past but none that have shown consistent results (2).

The Flamingo device is a novel tool specifically designed to enable endoscopic removal of buried bumpers. This would reduce the risks associated with a GA and surgical removal as well as improving patient experience. It is a sphincterotome like device connected to diathermy with a 180 degree cutting wire. The overgrown granulation tissue is cut until the bumper is exposed and can be advanced into the stomach. (3)

Aims & Methods: A retrospective data collection was performed for all patients with BBS in which the Flamingo procedure was attempted at our centre. We aimed to determine percentage success rate, average time of completion and whether a second PEG site was needed. We were also able to analyse the amount of sedation required for these procedures in comparison to GA needed for surgical removal.

Results: 12 Procedures were completed at Tunbridge Wells Hospital, a DGH, between June 2018 and October 2021. 11 of the patients were Male, 1 was female, with an age range of 41 to 88 years of age. 9 of the procedures were successful, a further 1 was successful on the second attempt and 2 needed surgical removal. The patient that needed to undergo a repeat procedure was agitated and desaturated after sedation and the procedure was abandoned. 1 patient was readmitted 4 days post procedure with sepsis secondary to cholecystitis. 1 Flamingo procedure was done under a general anaesthetic (GA). Average time of the procedure was 36mins. Average sedation use was 2mg Midazolam, (range 1-5mg) and 50mcg Fentanyl (range 25-75mcg).

Conclusion: The Flamingo device offers a reliable and reproducible non-surgical technique for the treatment of BBS. As this is a co-morbid group of patients this is particularly beneficial in avoiding the potential risks associated with GA and surgical removal. We have shown that it can be done with minimal sedation and is both safe and less resource intensive than the traditional surgical techniques. It can be done as a day case procedure and helps to avoid hospital admissions which is beneficial both for patients and hospital trusts.

The limitations of this study are the small sample size and relatively short study period.

ALGORITHM FOR ENDOCYTOSCOPIC DIAGNOSIS OF SUPERFICIAL NON-AMPULLARY DUODENAL EPITHELIAL TUMORS USING COMPUTER ANALYSIS

M. Kubo¹, M. Higashino¹, T. Sone¹, S. Matsumoto¹, Y. Nishimura¹, M. Ono¹, K. Yamamoto², S. Ono², N. Sakamoto¹

Introduction: Superficial non-ampullary duodenal epithelial tumors (SNADETs) has been increasing in recent years due to advanced endoscopic technology. Biopsy of SNADETs induced fibrosis of submucosal layer of SNADETs and makes endoscopic resection more difficult, therefore evaluation of histological atypia without biopsy is recommended. Endocytoscopy (ECS) is a novel ultra-high magnification endoscopic technique designed for gastrointestinal tract. ECS can provide up to 500x continuous zoom-focus magnification and is useful for evaluation of histological atypia. However, there have been no reports on ECS of SNADETs using computer analysis.

Aims & Methods: The aim of this study was to propose algorithm for endocytoscopic diagnosis of SNADETs based on computer analysis. This was a single-center, retrospective study. Between January 2017 and July 2021, patients who received ECS for SNADETs and who were histopathologically diagnosed by biopsy or endoscopic resection or surgery were included. ECS was performed followed white-light imaging and narrow-band imaging. For cell staining in vivo, 1% methylene blue and 0.05% crystal violet was used. All biopsy specimens and resected specimens were fixed in 10% formalin and stained with hematoxylin and eosin. Each 1 image with the most severe atypia from ECS images and histological images were selected and all images were converted to 8-bit gray scale to be computer analyzed using ImageJ v1.53c on Windows-based systems.

The number of glands per 1mm² and percentage of densely stained area with methylene blue (DSM) per one screen in ECS images were measured. Histopathological diagnoses of duodenal lesions were classified into 3 groups (C1, C3 and C4/5) according to the revised Vienna classification (VCL). A P value of <0.05 was considered statistically significant.

Results: Seventy-nine patients with suspected SNADETs were included in this study, and 9 patients were excluded because of unclear ECS images and VCL C2.

Finally, a total of 70 ECS images and histological images including 13 cases of C1, 12 cases of C3 and 45 cases of C4/5 were analyzed. The mean number of glands per 1mm² were 18.8 in C1, 60.3 in C3 and 125.0 in C4/5. There were significant differences in the mean number of glands between 3 groups (C1: C3, $P = 0.008$, C1: C4/5, $P < 0.001$, C3: C4/5, $P = 0.03$). Percentage of DSM per one screen were 6.75 in C1, 10.1 in C3 and 21.7 in C4/5. There was a significant difference in percentage of DSM per one screen between C4/5 and C1 ($P < 0.001$). Based on these results, the cutoff value

at 0.89 which was the highest AUC was calculated. Our algorithm recommends therapeutic intervention for the SNADETs as follows: the lesions in which the number of glands per 1mm² is 47 or more and percentage of DSM in one screen is 7.4% or more, the lesions in which the number of glands per 1mm² is less than 47 and percentage of DSM per screen is 20.8% or more.

Conclusion: Computer analysis of ECS images would be useful for optical biopsy of SNADETs and would provide quantitative algorithm.

Disclosure: This study was funded by JFE (The Japanese Foundation for Research and Promotion of Endoscopy) Grant. The funding source had no role in study design, data collection, data analysis, data interpretation, or writing of the report.

PREDICTORS OF SPONTANEOUS PASSAGE OF INGESTED FOREIGN BODIES IN ADULTS: A SINGLE-CENTER 13-YEAR EXPERIENCE

W. Sbeit¹, A. Shahin¹, T. Khoury¹

¹Galilee Medical Center, Department of Gastroenterology, Naharia, Israel

Contact E-Mail Address: tawfik.khoury.83@gmail.com

Introduction: Foreign body ingestion in adults is commonly encountered in clinical practice. Usually, the therapeutic approach whether to follow-up or extract is controversial.

Aims & Methods: We aimed to explore predictors for spontaneous passage of ingested foreign bodies by focusing mainly on foreign body type, location of impaction and length. We performed a retrospective single-center study over 13-years including a large number of patients. Logistic regression analysis was done to identify predictors of spontaneous passage.

Results: Overall, 365 patients with foreign bodies ingestion were included. The rate of spontaneous passage was the 53.7% in general, while the spontaneous passage rate in food impaction was 47.9%, 44.3% in sharp objects, 88.7% in blunt objects and only 22.2% among the long blunt objects (≥ 6 cm).

On regression analysis, esophageal location was associated with a higher impaction rate and lower spontaneous passage as compared to stomach, small and large intestine (OR 0.15, $P < 0.0001$, OR 0.18, $P < 0.0001$ and OR 0.02, $P = 0.0001$), respectively. Performing Receiver operating characteristics (ROC) analysis we found that the maximal length at which above it, the foreign body will fail to pass spontaneously was 3.5 cm and 3 cm in the stomach and small intestine, with area under the curve (AUC) of 0.8509 in stomach and 0.8073 in small intestine.

Conclusion: Spontaneous passage of ingested foreign body mainly depends on foreign body type, location and length. Endoscopic intervention should be considered based on these parameters.

Disclosure: Nothing to disclose.

STRATEGY OF ENDOSCOPIC TREATMENT FOR NON-AMPULLARY DUODENAL TUMORS IN OUR INSTITUTION

M. Ono¹, T. Sone¹, M. Higashino¹, S. Matsumoto¹, Y. Nishimura¹, M. Kubo¹, K. Yamamoto¹, S. Ono², N. Sakamoto¹

Introduction: There have been some reports that the number of non-ampullary duodenal tumors has been increasing in recent years, but they seem to be many problems concerning endoscopic treatment. First, the concordance rate of pathological biopsy is low between biopsies and specimens after endoscopic treatment. Next, endoscopic treatment is difficult and the rate of postoperative complications is very high.

Recently, cold polypectomy and underwater EMR (UEMR) have been reported as safe treatment options for endoscopic treatment. There have been some reports that UEMR can be safely performed even for relatively large lesions, and UEMR has therefore been introduced at our hospital.

Aims & Methods: Endoscopic treatment for duodenal tumors was retrospectively examined during the period from January 2017 to December 2021.

Results: There were 90 cases of duodenal tumors and 116 lesions during the observation period. The average age of the patients was 64.7 (44-86) years, and the male-female ratio was 63/27. There were 69 lesions (59.4%) in which biopsy was performed before endoscopic treatment.

The methods used for endoscopic treatment were EMR in 46 cases, cold polypectomy in 41 cases, UEMR in 25 cases, polypectomy in 1 case, EMR using a ligating device (EMRL) in 2 cases, and hybrid ESD in 1 case. As complications, postoperative bleeding occurred in 2 cases (in 1 case after UEMR and in 1 case after EMRL) and perforation occurred in hybrid ESD. In the 25 patients who underwent UEMR, the average tumor diameter was 10.4 mm (5-20 mm), the average procedure time was 10.4 min (4-50 min), and the endoscopic complete resection rate was 100% (25/25). The R0 resection rate was 64% (16/25), and there were 6 cases with an unknown horizontal margin and 3 cases with a positive horizontal margin, but all vertical margins were negative.

On the other hand, the average tumor diameter in the 46 patients who underwent EMR was 10.9 mm (2-30 mm), but the average resection time was 20.6 min (4-66 min), which was significantly longer than that in UEMR ($p < 0.001$). In those 46 patients, the endoscopic complete resection rate was 82.6% (38/46) and the R0 resection rate was 65.2% (30/46). There were 14 cases with an unknown horizontal margin, 1 case with a positive horizontal margin, and 4 cases with an unknown vertical margin.

Conclusion: Endoscopic treatment for non-ampullary duodenal tumors is relatively safe except for hybrid ESD cases. The procedure time for UEMR is shorter than that for EMR and the treatment results are comparable.

P0882

ENDOSCOPIC TRANS-ORAL OUTLET REDUCTION IS EFFECTIVE FOR BILIARY REFLUX AFTER LAPAROSCOPIC ONE ANASTOMOSIS GASTRIC BYPASS

R. Reicher¹, M. Shnell¹, S. Fishman¹

¹Tel Aviv Sourasky Medical Center, Bariatric Endoscopy Service, Department of Gastroenterology and Liver Disease, Tel Aviv, Israel

Contact E-Mail Address: rellyr@tlvmc.gov.il

Introduction: Biliary reflux (BR) represents a common complication of one anastomosis gastric bypass (OAGB), with a wide side-to-side anastomosis of the gastric pouch to the bilio-pancreatic and alimentary limbs. The symptoms may be severe with substantial impact on quality of life. Moreover, BR has been implicated in pre-cancerous conditions like Barrett's esophagus and increased risk for gastric cancer after Bilroth II surgery. To date, there is no pharmacotherapy effective for BR and surgical revision is the only option for refractory patients.

Aims & Methods: Patients after OAGB suffering BR were diagnosed upon typical symptoms. Possible acid reflux was treated with high-dose PPI in all patients. After gastroscopy excluding alternative causes of symptoms and contra-indications for endoscopic trans-oral outlet reduction (TORE) the procedure was carried out. Using circumferential argon plasma coagulation and endosuturing with two Z-shaped sutures, the anastomosis was narrowed to a diameter of less than 10mm. Patients were prospectively followed.

Results: Twelve OAGB patients (M:F=2:10) underwent TORE for BR between 5/2019 and 10/2021. Mean age was 48 (24-64) and mean pre-procedure BMI was 33 (26-44). Four patients suffered in addition to BR from dumping and weight regain and 5 suffered in addition to BR from weight regain alone. Technical success rate was 100% with all patients reaching anastomosis diameter of less than 10mm. Resolution of BR symptoms was achieved in 10 out of 12 patients (83%) with a mean follow up period of 11 months (4-34). One patient required repeat TORE due to recurrence of BR symptoms after initial improvement. Mean total body weight-loss (TBWL) at 6 months was 8% (0-15%). All six patients with concomitant Dumping syndrome had BR resolution and 4/6 (67%) had resolution of their Dumping syndrome.

Severe adverse events occurred in one patient experiencing a gastric perforation that was immediately sutured endoscopically during the procedure. The patient was admitted and treated with antibiotics with no further intervention needed.

Conclusion: TORE appears to be a safe and effective treatment for BR in OAGB patients, at least in the short term. A success rate of 83% was shown, with only one serious adverse event that was treated conservatively. BR represents a common side-effect of OAGB. Definitive objective diagnosis of BR remains problematic, with a paucity of reliable tests that demonstrate BR. Clinicians must be aware of this diagnosis especially in patients with altered anatomy that predisposes to BR.

The possible role that bile exposure has in increased risk for gastric and esophageal malignancies implies that these patients should be treated and remain in some sort of surveillance, at least until further more robust data is available.

Disclosure: Nothing to disclose.

Introduction: Endocytoscopy (EC) was recently introduced as new-generation endoscopic system that provides ultra-high magnification images and enables in vivo histologic assessment after appropriate staining of nuclear and cellular structures. Gastric precancerous lesions (GPL) have been assessed by EC only in a limited number of studies. No data are available on the diagnostic utility of EC for diagnosis of GPL both in antrum and corpus.

Aims & Methods: Aim of our study was to characterize endocytoscopic features related to GPL and to assess the diagnostic performance of EC compared to standard histopathology.

A total of 80 gastric areas (36 from antrum, 44 from corpus) of 25 prospectively recruited patients (12 men, mean age 58.1 ± 14.6 years), who underwent gastroscopy with EC between November 2020 and Mai 2021 were analyzed. All endoscopies were performed by one endoscopist (A) with expertise in EC using an Olympus endocytoscope (GIF-H290EC) and crystal violet-methylene blue for double staining.

Target biopsies were obtained from each area. Histopathological diagnosis was used as gold standard. EC diagnosis was made based on a preexisting EC classification¹.

By assessing cellular and glandular structures, lumen changes and nuclear morphology lesions were classified in EC 1, normal or chronic gastritis (CG); EC 2a, atrophic gastritis (AG); EC 2b, intestinal metaplasia (IM); EC 2ab, both AG and IM; and EC 3, dysplasia and/or gastric cancer (CGA).

After independent EC diagnosis 419 high-quality EC images were selected from video-documentation by endoscopist A and used for review by 3 endoscopists (B, with minor experience in performing EC, C and D, with no experience in performing EC but trained for EC images assessment), who were blinded to endoscopic findings and histopathology. Diagnostic accuracy values and concordance rates between observers were calculated by using the κ-value.

Results: Gastric areas were histologically classified as follows: normal, 6 (7.5%); CG, 45 (56.25%); AG with IM, 14 (17.50%); IM, 11 (13.75%); GCA, 3 (3.75%).

The diagnostic performances of EC for GPL detection are summarized in Table 1.

The mean sensitivity, specificity and accuracy for EC diagnosis of GPL (EC 2a/2b/2ab + EC 3 vs. EC 1) were 88%, 93% and 91% among endoscopists A and B and 86%, 68% and 74% among endoscopists C and D, respectively. The interobserver agreement was substantial (κ-value 0.75, p < 0.001) between the two EC experts and fair (κ-value 0.29, p = 0.006) between the two non-expert endoscopists.

Table 1. Diagnostic performances of EC for GPL detection as assessed by 4 endoscopists (A-D). Values are shown as percentage with 95% confidence intervals. Abbreviations: Sen (sensitivity), Spe (specificity), Acc (accuracy), PPV (positive predictive value), NPV (negative predictive value).

Conclusion: New-generation EC has a potential to identify GPL with high diagnostic accuracy, high reliability and good reproducibility. Training and experience in performing EC affect substantially the diagnostic performances. Further studies are needed to assess the cost-effectiveness of EC and the improvement in diagnostic accuracy compared to conventional endoscopy and virtual chromoendoscopy.

Introduction: Low body mass index (LBMI) was associated with longer colonoscopy procedure time and procedural failure, and commonly considered to be a risk factor for post-endoscopic adverse events (AE), but evidence is lacking.

Aims & Methods: We aimed to assess the association between serious AE (SAE) and LBMI.

A single center retrospective cohort of patients with LBMI (body mass index (BMI)≤18.5) undergoing an endoscopic procedure was matched (1:2 ratio) to a comparator group (19≤BMI≤30). Matching was performed according to age, gender, inflammatory bowel disease or malignancy diagnoses, previous abdomino-pelvic surgery, anticoagulation therapy and type of endoscopic procedure.

The primary outcome was any SAE, defined as bleeding, perforation, aspiration or infection, following the procedure. The attribution between each SAE and the endoscopic procedure was determined. The Secondary outcomes included each complication alone and endoscopy-attributed SAEs. Univariate and multivariate analyses were used to compare between groups.

Results: 1986 patients were included (662 in the LBMI group). Baseline characteristics were mostly similar between the groups. The primary outcome occurred in 31/662 (4.7%) patients in the LBMI group and in 41/1324 (3.1%) patients in the comparator group (p=0.075). Among the specific secondary outcomes, infections (2.1% vs. 0.8%, p=0.009) occurred more frequently in the LBMI group. Multivariate analysis revealed an adjusted association between SAE and LBMI (OR 1.64, 95% CI 1.00-2.67), male gender, diagnosis of malignancy, advanced endoscopic procedure and an ambulatory setting.

Characteristics	OR	95%CI	P value
Low BMI	1.64	1.00, 2.67	0.048
Male gender	1.81	1.12, 2.98	0.017
Diagnosis of Malignancy	2.36	1.44, 3.87	<0.001
Advanced endoscopy*	3.75	2.16, 6.35	<0.001
Hospitalized patients	0.53	0.32, 0.91	0.017

BMI - body mass index,

*Advanced endoscopy included ERCP, DBE, EUS with intervention, PEG and big-polyp EMR.

Table. Multivariate model to predict post-endoscopy severe adverse events

The model included BMI group, gender, age (as a categorical variable), previous diagnosis of IBD, malignancy, diabetes, chronic obstructive pulmonary disease, anticoagulation therapy, endoscopy type (dichotomized as advanced and non-advanced), hospitalization status (inpatients vs. ambulatory) and matching pairs. A forward selection/backward elimination procedure was then applied to yield the final model. OR – odds ratio. CI – confidence interval.

Conclusion: Low BMI was associated with higher post-endoscopic serious adverse events. Special attention is required when performing endoscopy in this fragile patient population.

Disclosure: Nothing to disclose.

Introduction: The horizon of diagnostic and therapeutic endoscopy had been extending for past decade. In recent years, the practice of endoscopy has been increased among surgical societies. Numerous professional surgical societies have implemented training on flexible endoscopy for surgeons.

However, there is scarce data on the practice of endoscopy among surgeons worldwide. This is a global survey conducted among surgeons worldwide on the practice of flexible endoscopy.

Aims & Methods: This is a global survey on the practice and training on endoscopy among surgeons conducted through an electronic platform. We invited leading surgical societies worldwide to assist in disseminating the invitation to their members, including Society of American GI & Endoscopic Surgeons (SAGES), the European Association of Endoscopic Surgery (EAES), Endoscopic and Laparoscopic Surgeons of Asia (ELSA), Japan Society of Endoscopic Surgery (JSSES), Indian Association of Gastrointestinal EndoSurgeons (IAGES), etc.

The WEO committee on Surgical Endoscopy designed a set of 28 questions targeting at assessing the practice, credentialing and training of endoscopy was delivered to the delegates. A structured database was designed to collect the results from the questionnaire.

Results: The survey was conducted in April 2021, and a total of 309 participants responded to the questionnaire survey including 179 from Europe, 58 from Asia, 22 from UK and 13 from US. 57% of responders are older than 45 yrs, and 86% of them were male. 139 of them received 1 to 5 years of endoscopy training, while 40% of them confirmed performance of digestive endoscopy by surgeons in their countries. 60.2% of them claimed that surgeons were performing less than 50% of the endoscopy in their countries, while a certain proportion of emergency endoscopy would be performed by surgeons.

Moreover, there is also a need for intraoperative and postoperative endoscopy performed by surgeons. Only 29% of the respondents claimed that there is a standard training program for surgeons to perform OGD and colonoscopy, while 17% claimed to have training program for ERCP.

Less than 15% of the countries had training program for ESD, POEM, EUS and Advanced ERCP for surgeons. 60% of the respondents believed that a training program is necessary to improve on the clinical outcomes of OGD, colonoscopy and ERCP. The role of surgeons seems to be important in development of procedures including endoscopic laparoscopic collabora-

tive surgery and bariatric endoscopy. Lack of training, granting of privilege and access to appropriate equipment are main barriers for surgeons to perform endoscopy.

Conclusion: There is a trend towards increasing practice of endoscopy among surgeons worldwide. The major barriers for surgeons to perform endoscopy should be addressed by surgical societies worldwide to safeguard clinical outcomes by surgeons.

Disclosure: The conduction of this survey is supported by Surgical Endoscopy Committee of World Endoscopy Organization (WEO).

Introduction: Foreign body (FB) ingestion and food bolus impaction are common indications for urgent esophagogastroduodenoscopy (EGD). Nevertheless, most of the ingested FB (80 to 90%) pass spontaneously through the gastrointestinal (GI) tract. Differently from upper GI bleeding, there is no currently validated score aiming to identify "low-risk" patients in suspected FB in the upper GI tract.

Aims & Methods: We aimed to create a score able to discriminate patients who are candidates to urgent EGD in this scenario. We conducted a retrospective study of consecutive patients referred to our endoscopic unit for suspected FB in the upper GI tract between 2016 and 2021.

Every patient was previously evaluated by an otorhinolaryngology specialist. The evaluated outcome was endoscopic confirmation of a FB in the upper GI tract. Variables significantly associated with the outcome on multivariate analysis were computed into a score predicting the confirmation of FB in EGD.

Results: Our sample included 228 patients, 122 (53.5%) of them female, with a mean age of 58.0±19.7 years. From these, 97 (42.5%) had a confirmed FB in EGD. Time since ingestion < 6h (OR=4.0; *p*=0.042); absence of any meal after FB ingestion (OR=7.1; *p*=0.005); dysphagia (OR=11.8; *p*<0.001); odynophagia (OR=4.6; *p*=0.004); and drooling (OR=15.1; *p*<0.001) were independent predictors of confirmed FB on EGD.

These variables were used to compute a confirmed FB predicting score – the Decision-To-Scope (DTS) score: time since ingestion < 6h (+1pt), absence of meals (+2pts), dysphagia (+3pts), odynophagia (+1pt), and drooling (+4pts), with a maximum value of 11 pts, which had an excellent accuracy to predict the outcome (AUC=0.953; 95%CI=0.928-0.977; *p*<0.001). The optimal cut-off to identify low-risk patients was a score ≤5 (sensitivity 85% and specificity 95%).

Conclusion: More than half of the suspected FB in the upper GI tract were not confirmed by EGD. The DTS-score presented an excellent accuracy at stratifying patients' risk, and may contribute to the decision to perform urgent EGD in suspected FB in the upper GI tract.

Disclosure: Nothing to disclose.

EFFECTS OF TRANEXAMIC ACID AND ADRENALINE INJECTATES ON HISTOPATHOLOGICAL HEALING AFTER GASTRIC AND COLONIC ENDOSCOPIC SUBMUCOSAL DISSECTION IN AN IN VIVO PORCINE MODEL

A. Bermont¹, S. Matalon¹, D.L. Cohen¹, H. Shirin¹, S. Vosko¹

Contact E-Mail Address: bermont@doctor.com

Introduction: Endoscopic submucosal dissection (ESD) has become a common minimally invasive therapy for resection of early colonic and gastric neoplasia, but there is limited data on the histopathological effects of the different haemostatic agents (HAs) used within the injection solution. We used an in vivo porcine model to compare the tissue effects of tranexamic acid (TXA) and adrenaline compared to controls.

Aims & Methods: Standard ESD, using a 2 mm flash-knife, was performed in three pigs. Lifting fluid was used based on a 4% succinylated gelatin solution and indigo carmine. Four resections were performed in the stomach and colon in each pig. HAs were blindly randomised to either TXA, adrenaline, or neither (control). Stomachs and colons were surgically removed after 7 days. A specialist pathologist blinded to the intervention assessed the specimens which were assigned a composite score (on a scale of 0-4) based on inflammation, necrosis, and granulation.

Results: Twenty four defects were analysed (8 per pig, median defect size 30X30 mm). For HA effects, 48 tissue sections were assessed. TXA was comparable to adrenaline and controls for deep involvement of the colon wall. However, in gastric wall specimens, TXA and adrenaline both showed less inflammation, necrosis, and better regeneration compared to controls (average scores of 3 as compared to 4).

Animal No./Tissue	Inflammation	Necrosis	Granulation Tissue	Total Score
Adrenaline/ Stomach	2	0	4	3
Adrenaline/ Colorectum	4	4	2	4
TXA/ Stomach	3	1	4	3
TXA/ Colorectum	3	2	2	3
Saline/ Stomach	4	4	1	4
Saline/ Colorectum	3	2	2	3

Table. A semi-quantitative analysis of the histopathological findings, using a scoring scale.

Conclusion: For ESD, HAs such as TXA and adrenaline added to the submucosal injectate may have protective effects on the depth and extent of injury to the underlying tissue.

Introduction: Endoscopic resection (ER) is recommended for the management of duodenal neuroendocrine tumors (D-NETs) confined to the submucosal layer, without lymph node or distant metastasis. While this is accepted practice for lesions < 10mm, consensus for larger lesions remains unclear.

Although endoscopic submucosal dissection (ESD) has been proposed as the preferred ER technique for DNETs ≥ 10mm, there is limited data on efficacy and safety, particularly in the Western setting.

Aims & Methods: We performed a retrospective analysis of patients with D-NETs who underwent ESD between 2012 and 2021 in three tertiary referral centers in Australia, France and Belgium.

Results: Fourteen patients with 15 D-NETs were evaluated. The median patient age was 64 years (IQR 58-70). All D-NETs were confined to duodenal bulb. The median D-NET size was 10 mm (IQR 7-12 mm) and the median specimen size was 15 mm (IQR 15-20mm). Median procedure time was 60 minutes (IQR 25-90 minutes). The rate of *en bloc* and curative resection was 100% and 40% respectively. Intra-procedural perforation occurred in 4 cases (26.7%), all of which were treated with endoscopic closure, without long-term sequelae. There were no episodes of clinically significant bleeding or stenosis. No local recurrence, lymph node or distant metastasis was observed during a median follow up period of 16.2 months (IQR 5.9-43.2 months).

Conclusion: In experienced hands, ESD for D-NETs can achieve a 100% *en bloc* resection rate. Despite a curative rate of 40%, there were no cases of local recurrence or distant metastatic spread, indicating that ESD may be a viable option for patients with D-NETs < 20mm that are not surgical candidates.

Disclosure: Nothing to disclose.

Introduction: Recently, artificial intelligence (AI) tools have been developed for clinical decision support in diagnostic endoscopy, but so far no algorithm has been introduced for therapeutic interventions. Considering the elevated risk of bleeding and perforation during third-space endoscopic procedures such as ESD and POEM, there is an apparent need for innovation and research into AI guidance in order to minimize operator-dependent complications. In this study we developed a deep learning algorithm for the real-time detection and delineation of relevant structures during third space endoscopy.

Aims & Methods: We used 2465 still images from 27 full length third space endoscopic procedures (21x ESD, 6x POEM) for the training of a DeepLabv3+ neural network architecture with KSAC and a 101-layer ResNeSt backbone. The images were annotated for the categories submucosal layer, muscle layer, blood vessel, electrosurgical knife and endoscopic instrument shaft by experts in third space endoscopy. The trained algorithm was evaluated by five-fold internal cross validation and validation using a separate dataset for the parameters Intersection over union (IoU), Dice Score and pixel accuracy.

Furthermore, vessel detection on video was evaluated using 31 video clips with 52 predefined vessels from 3 separate third space endoscopic procedures (1x POEM, 1x rectal ESD, 1x esophageal ESD).

Results: For delineation performance on still images the algorithm showed values of 63%, 76% and 81% for mean IoU, mean Dice Score and pixel accuracy respectively in the internal cross validation. Tested on the separate data set, the measures were 68%, 80% and 87% for the same parameters. The mean vessel detection rate on video (VDR) was 85%. Values of 92%, 95% and 70% were calculated for VDR of POEM, esophageal ESD and rectal ESD respectively. The mean false positive rate was measured as 0.75 structures per minute. 7 out of 9 vessels, which caused intra-procedural bleeding were identified by the algorithm.

Conclusion: The trained algorithm showed promising performance for the detection and delineation of relevant tissue structures on still images and on video. In surgery, AI has been successfully applied for various tasks including image-guidance, navigation and the detection of surgical instruments ("Smart Surgery"). This new technology may improve therapeutic endoscopic procedures in the same manner ("Smart ESD").

Disclosure: Nothing to disclose.

Introduction: Direct oral anticoagulants (DOACs) may increase the risk of major bleeding (MB) associated with endoscopic procedures. However, periprocedural interruption of anticoagulation may put patients with atrial fibrillation (AF) or venous thromboembolism (VTE) at risk of thromboembolic events. Therefore, physicians must determine an appropriate schedule for interruption.

Here we report in real-world practice the physician-guided periprocedural interruption of the DOAC edoxaban and clinical outcomes for patients with AF or VTE undergoing endoscopic procedures.

Aims & Methods: Baseline characteristics and data on periprocedural edoxaban interruption were prospectively collected from patients in Europe and South Korea/Taiwan enrolled in the Global EMIT-AF/VTE program (NCT02950168, NCT02951039). The observation window for interruption was 5 days pre- to 29 days post-procedure.

The incidences of any bleeding, MB, clinically relevant nonmajor bleeding (CRNMB), acute coronary syndrome (ACS), stroke, transient ischemic attack (TIA), systemic embolic events (SEE), and all-cause death were assessed from the procedure day to 30 days post-procedure; ratios of events per procedure were calculated. Endoscopic procedures included in this sub-analysis were not restricted to upper gastrointestinal tract endoscopies.

Results: Patients (n = 237) had a mean $\pm$ standard deviation age of 72.0 $\pm$ 8.2 years and were mostly male (60.8% [n = 144]). Of 288 endoscopic procedures (primarily gastroesophageal endoscopies [n = 140] or colonoscopies $\pm$ polypectomies [n = 112]), edoxaban was not interrupted in 84 (29.2%); interruption occurred only pre-procedurally in 91 (31.6%), only post-procedurally in 21 (7.3%), and both pre- and post-procedurally in 92 (31.9%). The median (range) periprocedural interruption duration within the observation window was 3 (1–35) days. The incidence of bleeding and thromboembolic events was ≤ 0.02 events/procedure for MB, CRNMB, ACS, stroke, TIA, and SEE (Table).

There were 5 periprocedural MB events, 1 stroke, and 1 TIA. Of 5 reported deaths, 3 (1 each: ischemic stroke, congestive heart failure, unknown) occurred during the first 3 days of edoxaban interruption; the 2 deaths that occurred >3 days after last edoxaban dose were categorized as resulting from non-cardiovascular “other” causes.

Conclusion: Physician-guided periprocedural edoxaban management was associated with short interruptions in patients with AF or VTE undergoing endoscopic procedures in routine clinical practice. The incidences of MB and thromboembolic events in this sub-analysis were consistent with previous studies of edoxaban and other DOACs.

Baseline demographics	Patients with endoscopic procedures (n = 237)	Periprocedural clinical events, n (events/procedure) [†]	Endoscopic procedures (N = 288)
BMI, kg/m ² , mean $\pm$ SD	26.6 $\pm$ 4.8	Any bleeding	15 (0.05)
Hypertension, n (%)	180 (75.9)	Major bleeding [†]	5 (0.02)
Dyslipidemia, n (%)	97 (40.9)	Clinically relevant nonmajor bleeding	3 (0.01)
Diabetes mellitus, n (%)	54 (22.8)	Acute coronary syndrome	0
Creatinine clearance, mL/min, mean $\pm$ SD	69.5 $\pm$ 29.5	Stroke	1 (0.003)
HAS-BLED, mean $\pm$ SD	1.9 $\pm$ 1.1	Transient ischemic attack	1 (0.003)
CHA ₂ DS ₂ -VAsC, mean $\pm$ SD	3.3 $\pm$ 1.5	Systemic embolic event	0
30 mg edoxaban, n (%)	72 (30.4)	All-cause death	5 (0.02)
60 mg edoxaban, n (%)	163 (68.8)		

N refers to number of procedures.

[†]Clinical events were recorded within 30 days of the procedure. [†]International Society on Thrombosis and Haemostasis definition.

CHA₂DS₂-VAsC, congestive heart failure, hypertension, age, diabetes, prior stroke/transient ischemic attack, vascular disease, and sex category; HAS-BLED, hypertension, abnormal renal and liver function, stroke, bleeding, labile international normalized ratio, elderly (age >65), prior alcohol or drug usage history.

Table.

BURIED BUMPER SYNDROME: AN INCIDENCE STUDY AND CLINICAL CHARACTERIZATION OF A RARE COMPLICATION OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY

E. Dias¹, J. Santos-Antunes¹, A. Peixoto¹, R. Ramalho¹, G. Macedo¹

¹Centro Hospitalar Universitário de São João, Gastroenterology, Porto, Portugal

Contact E-Mail Address: diasj0310@gmail.com

Introduction: Buried bumper syndrome is a rare complication of percutaneous endoscopic gastrostomy, in which the internal fixation device migrates alongside the tract of the stoma outside the stomach, with an incidence of approximately 1%. Inability to insert, loss of patency and leakage around the tube are considered to be a typical symptomatic triad. Upper digestive endoscopy is indicated in all cases where buried bumper syndrome is suspected. Although rare, it can be complicated by gastrointestinal bleeding, perforation or abscess, and these complications can lead to fatal outcomes, underscoring the importance of an early accurate diagnosis.

Aims & Methods: The aims of this study were to evaluate the incidence of buried bumper syndrome following percutaneous endoscopic gastrostomy and describe its main clinical characteristics. We retrospectively analyzed every patient who performed percutaneous endoscopic gastrostomy between January 2016 and December 2021 and included all cases with endoscopic diagnosis of buried bumper syndrome. Subsequently, their medical records were searched in order to retrieve relevant clinical data.

Results: A total of 9 cases of buried bumper syndrome were identified in a total of 774 patients who performed percutaneous endoscopic gastrostomy, which corresponds to an incidence of 1.2%. Most patients were male (n=8) and median age was 75 years (range 29-96). Indications for percutaneous endoscopic gastrostomy included stroke (n=2), Alzheimer's disease (n=2), Parkinson's disease (n=1), prolonged intensive care (n=1), laryngeal cancer (n=1), traumatic cord injury (n=1) and cerebral arteriovenous malformation (n=1). Percutaneous endoscopic gastrostomy had been performed by the "pull" technique at anterior surface of distal gastric body in all patients. The caliber of the gastrostomy tube was 24 Fr (n=5) or 20 Fr (n=4). There were no immediate adverse events in any patient. The mean time interval between percutaneous endoscopic gastrostomy placement and buried bumper syndrome was 4.8 months (range 0-23).

The most common clinical manifestations were local pain (n=4), leakage around the gastrostomy tube (n=4), local tumefaction (n=4), inability to insert food along the tube (n=3), local purulent exudate (n=2) and fever (n=1). Endoscopy revealed internal gastrostomy orifice at the anterior surface of gastric body with absence of migrated internal fixation device, with endoscopic signs of infection in 2 patients. Imaging techniques were performed in 8 patients and adjacent phlegmon was detected in 2 (25%). Overall, there was evidence of local infection in 5 patients and all were successfully treated with antibiotics. Gastrostomy tube was removed in all patients after diagnosis of buried bumper syndrome and replaced with a second gastrostomy tube in 5, after mean time interval of 5 weeks. Recurrence of buried bumper syndrome was detected in 1 patient.

Conclusion: Buried bumper syndrome is a rare complication of percutaneous endoscopic gastrostomy. It may be associated with local infectious complications that may negatively impact its prognosis and therefore early detection is essential. Removal of the migrated tube and posterior replacement with a second gastrostomy tube is usually an effective management strategy. Although uncommon, recurrence is possible and prophylactic measures to avoid it should be undertaken when a second tube is placed.

CAP ASSISTED ENDOSCOPY AS A TOOL FOR VATER PAPILLA AND DUODENAL SURVEILLANCE IN PATIENTS WITH COLONIC POLYPOSIS

C. Pinto¹, R. Ortigão¹, D. Ramos Silva², J. Chaves¹, M. Dinis-Ribeiro¹, C. Lopes Brandão¹

¹Portuguese Oncology Institute of Porto, Gastroenterology, Porto, Portugal, ²Hospital Amato Lusitano, Gastroenterology, Castelo Branco, Portugal

Contact E-Mail Address: claudia.marquespinto@gmail.com

Introduction: Colonic polyposis syndromes are not only characterized by colorectal adenomas but also as duodenal and ampullary adenomas. Duodenal endoscopic surveillance should include evaluation of the papilla of Vater by duodenoscopy.

Aims & Methods: Our aim was to evaluate the effectiveness of cap assisted endoscopy in the observation of the duodenal mucosa and particularly of the major papilla.

Patients with Familial Adenomatous Polyposis (FAP), MUTYH-associated Polyposis (MAP) or Polyposis without identified mutation with indication for surveillance were proposed to cap assisted endoscopy under sedation. The duodenal evaluation was considered completed if both the third duodenal portion and major papilla (including its orifice) were completely observed. When this evaluation was not accomplished, conventional duodenoscopy was performed.

Results: We included twenty-two (22) patients (n=16 FAP, n=4 MAP, n=2 polyposis without identified mutation) with a median age of 47 years. Thirteen (59%) were male. The major papilla was completely observed with cap assisted endoscopy in 21 (95.5%) patients. There was only one exam in which it was necessary to perform subsequent duodenoscopy. The mean time until identification of the papilla was 2 minutes and 15 seconds.

The difficulty in the evaluation of the major papilla was considered "easy" in 73% (n=16) and "medium" in 23% (n=5) of exams. Duodenal polyps were identified in 50% (n=11) and the papilla was described as adenomatous 32% (n=7). No exam required cap removal due to inadequate observation of the mucosa (esophageal, gastric or duodenal).

Conclusion: Cap assisted endoscopy seems to be a better alternative to duodenoscopy, allowing simultaneous conventional endoscopic procedure and major papilla evaluation. It may simplify surveillance protocols in these patients, with lower procedure time and friendly usability.

Disclosure: Nothing to disclose.

P0893

SUBJECTIVE ASSESSMENT OF THE PYLORIC SPHINCTER DURING ENDOSCOPY AND ITS CORRELATION IN FLIP PANOMETRY

I. Levenfus¹, J. Hente¹, M.C. Pott¹, D. Pohl¹

¹University Hospital Zurich, Gastroenterology and Hepatology, Zurich, Switzerland

Contact E-Mail Address: ian@levenfus.com

Introduction: Visual or haptic assessment of the pylorus during endoscopy sometimes results in the diagnosis of a pylorospasm. However, the visual assessment is a subjective evaluation and may be affected by inter-rater variability, the antro-duodenal motility phase as well as the distance to scope and has not been validated against technical measurements of pyloric dimensions.

We evaluated to what extent the visual impression and the endoscopic resistance of the pyloric sphincter correlates with objectively determined EndoFLIP measurements.

Aims & Methods: Patients scheduled for FLIP panometry of the upper gastrointestinal tract due to different medical conditions from January until November 2021 were considered for the study. Inclusion criteria were an EndoFLIP measurement of the pylorus using a standardized protocol for distensibility assessment (normal > 10 mm²/mmHg, borderline 8 - 10 mm²/mmHg, pathologic < 8 mm²/mmHg) as well as a documented visual impression of the pylorus size and resistance towards endoscopic intubation. The visual impression was evaluated at 10 cm distance to the pylorus by an experienced endoscopist (senior) as well as a fellow (junior) and the perceived state (tight, normal, wide) was documented for both participants separately.

Afterwards, the experienced endoscopist passed the endoscope through the pylorus to the duodenal bulb and endoscopic resistance (none, normal, strong) was documented. To quantify inter-rater variability, visual impressions by senior and junior were compared.

Results: A total number of 89 patients (65% female) with a mean age of 47.9 years ± 18 SD were included (range 15 to 87 years). In 81 patients, a visual assessment of the pylorus was performed. The endoscopic resistance was documented in 87 patients.

Group comparisons of distensibility measurements between each visually assigned group (tight, normal, wide) indicated significant differences ($p < .01$). In 76 % of cases, the visual impression of a closed pylorus was associated with a pathologic distensibility during EndoFLIP measurement. No significant differences regarding distensibility were found for endoscopic resistance. The specificity of a predicted pathologic pylorus distensibility based on visual assessment by a senior endoscopist was 85.7% with a sensitivity of 48.7% (PPV 0.76, NPV 0.64) when using the 8 mm²/mmHg cutoff for pylorospasm. The visual impression of the senior and junior investigators matched in 93.8% of the cases.

Conclusion: The visual assessment of the pyloric sphincter has a low sensitivity yet surprisingly high specificity in recognizing pylorospasm as objectified using FLIP panometry. This underlines the importance of measurements, not estimates, in the evaluation of pyloric function.

IMMEDIATE DISCHARGE AFTER PERCUTANEOUS ENDOSCOPIC GASTROSTOMY TUBE REMOVAL IN HEAD AND NECK CANCER PATIENTS IN ONCOLOGICAL REMISSION: A FEASIBILITY AND SAFETY STUDY

F. Francisco¹, S. Faia¹, I. Frade¹, P. Cruz¹, J. Gramacho¹, I. Claro¹

¹Instituto Português de Oncologia de Lisboa - IPOLFG, Gastroenterology, Lisboa, Portugal

Contact E-Mail Address: fatimafrancisco@sapo.pt

Introduction: In head and neck cancer patients (HNC), a significant number of percutaneous endoscopic gastrostomies (PEG) procedures are prophylactic (patients without significant dysphagia prior to starting chemoradiotherapy therapy). These patients require PEG tubes that provide exclusive or complementary enteral nutritional support to oral intake during chemoradiotherapy. Insufficient oral intake is due to anorexia and dysphagia generated by cancer and mucositis caused by cancer treatment. After treatment, patients with complete oncological response who reestablish adequate oral, a PEG tube removal procedure is scheduled.

Aims & Methods: To evaluate the feasibility and safety of PEG tube removal in patients with HNC followed by immediate discharge from the Endoscopy Unit medicated with omeprazole.

Prospective, observational, unicentric study. The current protocol assumes PEG tube removal with discharge to the outpatient clinics 30 minutes after the procedure and re-initiation of cold liquid diet after 3 hours. Additionally, patients get a prescription of omeprazole 40 mg bid orally for the next 4 weeks. All patients with PEG tube removal scheduled between October 2020 and February 2022 were included. We performed a descriptive statistical analysis.

Results: A total of 113 patients with HNC were referred for PEG removal, including 82 men and 31 women, with a mean age of 59.5±9.75 (range 39-81 years). A total of 103 patients were treated with chemoradiotherapy and 10 with radiotherapy alone.

From these 113 patients with PEG tubes, 104 (92%) had no adverse events related to the procedure, 3 had early infections, 4 late infection (all minor), 1 had immediate pain that prolonged hospitalization for 24 hours, and 1 had an hemoperitoneum that required surgery.

The average duration of PEG was 10.7±5.69 (range 3-30 months).

After PEG removal, 7 (6.19%) patients had a gastrocutaneous fistula patent for more than one month. Resolution of 5/7 fistulas occurred after 4 additional weeks of omeprazole 40 mg bid, 1/7 required endoscopic treatment with clips, and 1/7 had an associated parastomal hernia that was operated.

Conclusion: PEG removal with immediate discharge proved to be safe, with a low rate of complications. It benefited patients in terms of comfort and the Endoscopy Unit by reducing the time and resources allocated, and allowed to eliminate the waiting list for PEG tube removal procedures.

DEVELOPMENT AND VALIDATION OF A FEATURE EXTRACTION-BASED LOGICAL ANTHROPOMORPHIC DIAGNOSTIC SYSTEM FOR EARLY GASTRIC CANCER UNDER THE MAGNIFYING IMAGE ENHANCED ENDOSCOPY INCORPORATED WITH PRIOR KNOWLEDGE

J. Li¹, Y. Zhu¹, Z. Dong¹, L. Wu¹, H. Yu¹

¹Renmin Hospital of Wuhan University, Wuhan, China

Contact E-Mail Address: 2646962363@qq.com

Introduction: Early diagnosis of early gastric cancer (EGC) is crucial for improving patients' survival. However, most previous computer-aided diagnosis (CAD) systems did not concretize or explain diagnostic theories.

We aimed to develop a logical anthropomorphic artificial intelligence (AI) diagnostic system named ENDOANGEL-LA (logical anthropomorphic) for EGCs under magnifying image enhanced endoscopy (M-IEE).

Aims & Methods: We retrospectively collected 1897 images from 692 patients from Renmin Hospital of Wuhan University. The images were randomly assigned to the training set and test set by patient with a ratio of about 4:1. ENDOANGEL-LA was developed based on feature extraction combining quantitative analysis, deep learning (DL), and machine learning (ML). Seven quantitative diagnostic feature indexes including microstructures (MS) density, MS eccentricity, diameter ratio of microvessel (MV), MV tortuosity, MV cyclization, spectral principal component information of gastric mucosal background color, and image entropy of S-channel in HSI color space and four DL diagnostic feature indexes including the arrangement of M-IEE images, the demarcation line of lesions, the distribution of MV in the MV segmentation images, and the morphology of the lesions (including elevated, flat, and depressed) were integrated into seven ML models including random forest (RF), Gaussian Naive Bayes (GNB), k-Nearest Neighbor (KNN), logistic regression (LR), decision tree (DT), support vector machine (SVM), and gradient boosting decision tree (GBDT), and an optimal model was selected. The performance of ENDOANGEL-LA was evaluated and compared with endoscopists and sole DL models. The satisfaction of endoscopists on ENDOANGEL-LA and sole DL model was also compared.

Results: RF showed the best performance, and demarcation line and MS density were the most important feature indexes. The accuracy of ENDOANGEL-LA in images (88.76%) was significantly higher than that of sole DL model (82.77%, $p = 0.034$) and the novices (71.63%, $p < 0.001$), and comparable to that of the experts (88.95%). The accuracy of ENDOANGEL-LA in videos (87.00%) was significantly higher than that of sole DL model (68.00%, $p < 0.001$), and comparable to that of the endoscopists (89.00%). The accuracy (87.45%, $p < 0.001$) of novices with the assistance of ENDOANGEL-LA was significantly improved. The satisfaction of endoscopists on ENDOANGEL-LA was significantly higher than that of sole DL model.

Conclusion: We established a logical anthropomorphic system named ENDOANGEL-LA which can diagnose EGC under M-IEE with diagnostic theories concretization, high accuracy, and good explainability. It has the potential to increase interactivity between endoscopists and CADs, and improve trust and acceptability of endoscopists on CADs.

DETECTION OF GASTRIC NEOPLASMS WITH A NEW HEATMAP-BASED ARTIFICIAL INTELLIGENCE SYSTEM

H.Y. Kang¹, C. Chantaduly², P. Chang³, W. Karnes⁴

¹Seoul National University Hospital, Healthcare System Gangnam Center, Department of Internal Medicine, Seoul, Korea (Republic of), ²Center for Artificial Intelligence in Diagnostic Medicine, University of California, Irvine, United States, ³University of California, Department of Radiological Sciences and Center for Artificial Intelligence in Diagnostic Medicine, Irvine, United States, ⁴University of California, Department of Medicine and H.H. Chao Comprehensive Digestive Disease Center, Irvine, United States

Contact E-Mail Address: haeykang@gmail.com

Introduction: Endoscopic diagnosis of early gastric neoplasms is not easy even for experienced endoscopists. Recent studies showed that artificial intelligence (AI) can achieve high diagnostic accuracy in detecting upper gastrointestinal lesions. However, the endoscopic detection of gastric dysplasia and early gastric cancer (EGC) using AI still remains challenging.

Aims & Methods: We aimed to develop a novel deep learning convolutional neural network (CNN) model for detection and localization of gastric dysplasia and EGC using endoscopic images.

In this study, we included 1,010 consecutive patients (7,818 gastric cancer images and 1,067 gastric dysplasia images) who underwent EGD and were histologically diagnosed at Seoul National University Hospital. All endoscopic lesion images were obtained in 2 dimensions from standard views. Among the endoscopic images, representative images were manually selected from each patient for model development. Each lesion in any given image was manually annotated with a bounding box by one expert endoscopist.

A novel, custom CNN model was designed to predict a dense probability map output estimating likelihood of lesion at each image pixel. Application of various thresholds to the CNN output yields iso-probability lines which may be converted to a corresponding bounding-box prediction. All endoscopic images were randomly assigned to either training ($n=7,108$) or validation cohorts ($n=1,777$) using a five-fold cross-validation scheme. All model predictions were visually inspected for overall accuracy. Spatial overlap of CNN-predicted and ground-truth bounding boxes were evaluated using the Intersection-over-Union (IoU) metric. Additionally, the sensitivity of lesion detection was assessed as a function of minimum IoU overlap.

Results: Upon five-fold cross-validation, the algorithm yielded a median bounding-box IoU for 0.569 (IQR 0.393 to 0.696) across the entire 8,885 image dataset. Using a detection IoU threshold of 0.10, the algorithm was 90.9% sensitive in identifying all gastric dysplasia or EGC lesion in the dataset. In general, the intermediate probability heatmaps generated by the algorithm approximate lesion contours upon visual inspection.

In addition, false negative algorithm predictions that do not meet the minimum threshold for box prediction nonetheless exhibit mildly increased probability scores, suggesting that intermediate prediction heatmaps may be utilized as a high sensitivity diagnostic aid.

IoU Threshold	Sensitivity
0.05	0.91900
0.10	0.90900
0.15	0.89550
0.20	0.87880
0.25	0.85420
0.30	0.82270
0.35	0.78660
0.40	0.74300
0.45	0.68460

Conclusion: In this pilot study, newly developed pixel-based heatmap model was able to detect early gastric cancer and gastric dysplasia in endoscopic images with high accuracy with a speed that allows for real-time implementation. The combination of conventional bounding-boxes and probability heatmap predictions provides complementary values that facilitate the detection of subtle endoscopic findings.

A PROSPECTIVE STUDY OF DEVELOPING AND VALIDATING THE EFFECT OF ANARTIFICIAL INTELLIGENT ESOPHAGOGASTRODUODENOSCOPY REPORTING SYSTEM

L. Zhang¹, Z. Lu², L. Yao³, H. Yu¹

¹Renmin Hospital of Wuhan University, Department of Gastroenterology, Wuhan, China, ²Renmin Hospital of Wuhan University, Hubei Key laboratory of Digestive System, Wuhan, China, ³Renmin Hospital of Wuhan University, Hubei Provincial Clinical Research Center for Digestive Disease Minimally Invasive Incision, Wuhan, China

Contact E-Mail Address: 273320630@qq.com

Introduction: Gastrointestinal (GI) disorder is one of the most common diseases in humans, resulting of considerable health care utilization and spending¹. Gastrointestinal endoscopy plays an important role in GI disorder screening with direct mucosal exposure². Gastrointestinal endoscopy reports are the documentations to deliver findings in procedure, and they were essential materials for communication between different endoscopists during medical consultation, transferring treatment, surveillance and et al³.

With the increasing need for precise storage, standard recording of instant finding in both images and literature was especially vital for endoscopy⁴. European Society of Gastrointestinal Endoscopy of societies (ESGE) and the American Society for Gastrointestinal Endoscopy (ASGE) have incorporated standard reporting contents into the criteria for endoscopic quality measurement⁵. Minimal Standard Terminology (MST), accurate photo-documentation of anatomical landmarks and abnormal findings were required for reporting generation⁶. However, reports were sub-optimal in practice, with insufficiency of report contents and low consistency between endoscopists and institutions at present.

In this study, we aim to develop and validate an artificial intelligent system to generate standard structured endoscopic reports during endoscopy. We hypothesize that AI-assistant was effective to ensure the standardization and completeness of endoscopic records, improving the quality of upper gastrointestinal endoscopic reporting.

Aims & Methods: A total of 99174 esophagogastroduodenoscopy (EGD) images were retrospectively collected to conduct this system, 75742 images for anatomical landmarks identifying model, 15256 images for esophageal lesions classifying model, including dysplasia, heterotopic gastric mucosa, submucosal tumor, esophagitis, gastroesophageal reflux and Barrett's esophagus, 21460 images for gastric lesions classifying model, including including dysplasia, submucosal tumor, gastric ulcer, erosion, benign polyp, and xanthelasma. Other models were conducted to capture eligible images during endoscopy, selected by clarity, mucosal exposure, and confidence coefficient of lesion detection. Five-hundred esophagogastroduodenoscopy video clips containing lesions above were collected to validate the performance of the system. Forty-four esophagogastroduodenoscopy were prospectively collected for crossover study which aims to validate effect of the system on improving competence of endoscopic reports among 12 endoscopists.

Results: Our models achieved an accuracy of 90.45% and 89.1%, respectively, to classify gastric and esophagus lesions in image validation. In video validation, the system detected lesions with a sensitivity of 95%, reported lesions with standard structured description with an accuracy of 75.6% and missed only 2% lesions in automatic report. In crossover study, the system improved the completeness (with AI vs without AI: 73.84% vs 52.21%) and accuracy (with AI vs without AI: 65.87% vs 46.32%) of gastric lesions records. The reporting time with AI assistance was a little longer than that of traditional reporting system (191.76 seconds vs 175.87 seconds).

Conclusion: In this study, an artificial intelligent based system was developed and validated to generate structured literal recording and image capture. Its effect on improving the standardness, completeness and precise of endoscopic reports has been validated. This system holds the potential to facilitate and standardize endoscopic reporting procedure in clinical practice.

EFFECT OF AN AUTOMATED FLEXIBLE ENDOSCOPE CHANNELS BRUSHING SYSTEM ON IMPROVING THE REPROCESSING QUALITY: A PROSPECTIVE, RANDOMIZED CONTROLLED STUDY

R. Shang¹, J. Liu¹, H. Yu¹

¹Renmin Hospital of Wuhan University, Department of Gastroenterology, Wuhan, China

Contact E-Mail Address: riddle@whu.edu.cn

Introduction: Qualified reprocessing, of which meticulous channels brushing is the most crucial step, is essential for the prevention and control of endoscopy-associated infections. However, channels brushing is often omitted in practice, due to the pressure of endoscope turnover, the lack of reprocessing technicians and weak supervision.

Aims & Methods: This single-center, prospective, randomized controlled study aimed to evaluate the effect of an automated flexible endoscope channels brushing system (AECBS) on reducing bioburden and improving the quality of endoscope reprocessing. This study was conducted, between Nov 24, 2021 and Jan 22, 2022, at Renmin Hospital of Wuhan University, China. Eligible endoscopes were randomly allocated to the auto group (channels brushed by AECBS) or the manual group (channels brushed manually), with sampling and culturing after high-level disinfection and drying. The primary endpoint was the positive rate of cultures for endoscopes.

Results: 204 endoscopes in the auto group and 205 in the manual group were eventually analyzed. The positive rate of cultures was significantly lower in the auto group than in the manual group (15.2% vs 23.4%, relative risk 0.649 [95% CI 0.432-0.976]; p=0.035).

Conclusion: AECBS could reduce the endoscope bioburden and improve the reprocessing quality. It has great potential to replace manual channels brushing and lower the risk of endoscopy-associated infections, providing a new idea for the optimization of reprocessing protocols.

Disclosure: Nothing to disclose.

P0895

EVALUATION OF STANDARD BOWEL PREPARATION REGIMES VERSUS PLENVU (NOVEL LOW VOLUME REGIME): CLEANSE STUDY

A. Ahmad¹, S. Marshall¹, K. Thiruvilangam¹, A. Dhillon¹, B.P. Saunders¹

¹Wolfson Unit for Endoscopy, Imperial College London, London, United Kingdom

Contact E-Mail Address: ahmir.ahmad@nhs.net

Introduction: Poor bowel preparation is the leading cause of failed colonoscopies and increases procedure costs significantly. Poor preparation affects procedure quality and efficiency. Several 2 day regimes are currently available and recently, Plenvu, a low-volume regime that can be administered on the same day for afternoon/evening appointments has emerged.

Aims & Methods: The aim of this study is to assess efficacy and tolerability of bowel preparation regimes.

In this service evaluation, patients undergoing bowel cancer screening colonoscopy at St Mark's Hospital, London (Feb 2020-Dec 2021) were provided Plenvu (1 or 2 day regime), Moviprep (2 day regime), or Senna & Citramag (2 day regime).

During the colonoscopy, the Boston Bowel Preparation Scale (BBPS) score, fluid volumes, and procedure times were recorded. In addition, patients completed a bowel preparation experience questionnaire including assessment of taste, volume acceptability, completion and side effects.

Results: There were 545 patients invited to participate with 10 exclusions (flexible sigmoidoscopies). Of 535 included patients there were: 214 Moviprep 2 day, 108 Senna & Citramag 2 day, 150 Plenvu 2 days, and 63 Plenvu 1 day.

	Moviprep 2 day	Senna & Citramag 2 day	Plenvu 2 days	Plenvu 1 day	P value
n	214	108	150	63	
Boston Bowel Preparation Scale score (mean)	7.0	6.7	7.6	7.6	<0.001
Net fluid volume (mL; total introduced – total suctioned)	-82	-121	-125	-167	0.10
Total procedure times (minutes)	25.0	23.6	25.4	28.8	0.03
Inadequate preparation requiring repeat colonoscopy or CTVC (%)	6.1% (13/214)	6.5% (7/108)	7.3% (11/150)	3.2% (2/63)	0.72

Table 1. Summary of bowel preparation regime outcomes

BBPS scores were significantly higher in the Plenvu 1 day and 2 day regimes (p=0.01 and 0.001 respectively) compared with Senna & Citramag. BBPS score was also significantly higher in the Plenvu 2 day group compared with Moviprep (p=0.007). There were no other significant differences in BBPS score between regimes. There was no significant difference in inadequate bowel preparation rates between the groups (p=0.72).

In the patient questionnaire, taste was rated to be most pleasant with Senna & Citramag which achieved statistical significance when compared with Plenvu 1 day and 2 day groups (p<0.001) and compared with Moviprep (p=0.01).

Conclusion: In this service evaluation, there was a significantly improved BBPS score for both 1 day and 2 day Plenvu regimes compared with Senna & Citramag, and an improved BBPS score for 2 day Plenvu compared with Moviprep. Plenvu may offer the potential for improved bowel preparation outcomes with the potential advantage for patients of a lower volume and same-day administration for afternoon/evening appointments.

Disclosure: Nothing to disclose.

Contact E-Mail Address: rawen.kader.17@ucl.ac.uk

Introduction: Withdrawal time (WT) is a key performance indicator of colonoscopy. It is defined as the time taken from the endoscope reaching the caecum to exiting the anal canal minus time spent cleaning the colon and performing interventions such as polypectomy. Deducting these phases from the WT is not feasible in clinical practice as it requires manual measurement in real-time. The result is inaccuracies in the measurement of endoscopists WT. Recent years has demonstrated the ability of artificial intelligence (AI) models to measure WT by detecting caecal landmarks and the anal verge. However, its potential to detect phases of cleaning and intervention during withdrawal is yet to be explored.

Aims & Methods: Our aim was to develop convolutional neural networks (CNN) to detect phases of cleaning and intervention during colonoscopy withdrawal.

Lower gastrointestinal endoscopy videos were prospectively collected at a single centre. Individual video frames after the appendicular orifice or ileocaecal valve were first detected was reviewed. Frames during 'cleaning' and 'intervention' were annotated with image-level labels, with the remaining frames contributing to the procedural WT ('withdrawal' frames). The annotations were referenced as the gold standard.

The interventional phase was defined as:

1. Frames where the forceps were visualised
2. The first frame an instrument was visualised during polypectomy (e.g. injection needle, snare) up until the end of inspecting the resection margins post-polypectomy ('intervention'). The cleaning phase was defined as frames during suctioning of colonic content or washing colonic mucosa ('cleaning').

Two ResNet-101 CNNs pre-trained on ImageNet were developed to detect the phases of cleaning and intervention. For both CNNs, a prediction score of 0.66 – 1.0 was defined as a 'cleaning' or 'interventional' frame, and 0.0 – 0.65 as a 'withdrawal' frame.

Results: The dataset consisted of 87 procedures and 1,288,319 annotated video frames from the withdrawal of the colonoscope (Table 1). The videos were split into training (70%), validation (10%) and testing (~20%) with no overlap of patients.

	Withdrawal frames	Cleaning frames	Intervention frames	Total frames (withdrawal only)
Frame count	437,359	232,384	618,576	1,288,319

Table 1: Breakdown of the frame count of the three phases of withdrawal ('cleaning', 'intervention', 'withdrawal') in the dataset which consisted of a total of 87 videos.

Evaluated against a test set of 17 videos, on a per-frame analysis, the CNNs identified the interventional frames with 92.4% sensitivity, 95.8% specificity, 95.0% accuracy and area under the curve (AUC) of 94.1%. For cleaning, the sensitivity was 83.0%, specificity 89.5%, accuracy 88.2% and AUC of 86.3%.

Across the 17 videos, there was a total of 306 minutes of withdrawal (including cleaning and intervention phases) with a mean WT of 8 minutes and 51 seconds. The absolute mean error of the AI predicted WT was 39 seconds per procedure. The AI system correctly categorised a procedure as less than or more than 6 minutes in 16 of the 17 procedures (94%). One procedure of more than 6 minutes was incorrectly categorised as under 6 minutes.

Conclusion: This pilot study demonstrated the feasibility of CNNs to differentiate the phase of withdrawal and its potential to fully automate measurement of colonoscopy withdrawal time.

Disclosure: Professor Laurence Lovat and Professor Danail Stoyanov are shareholders in Odin Vision.

EFFECTIVENESS AND SAFETY OF 1L PEG-ASC VERSUS STANDARD BOWEL PREPARATIONS FOR COLONOSCOPY: A SYSTEMATIC REVIEW AND META-ANALYSIS

M.F. Maida¹, M. Ventimiglia², A. Vitello¹, E. Sinagra³, G. Marasco^{4,5}

¹S. Elia-Raimondi Hospital, Gastroenterology and Endoscopy Unit, Caltanissetta, Italy, ²Italian Ministry of Health, Directorate General of Medical Device and Pharmaceutical Service, Rome, Italy, ³Fondazione Istituto San Raffaele Giglio, Gastroenterology and Endoscopy Unit, Cefalù, Italy, ⁴IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, ⁵University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy

Contact E-Mail Address: marcello.maida@hotmail.it

Introduction: A 1L polyethylene glycol plus ascorbate (PEG-ASC) bowel preparation has been recently developed to improve patients' experience in colonoscopy.

Aims & Methods: This meta-analysis aims to estimate the effectiveness and safety of 1L PEG-ASC vs other bowel preparations for colonoscopy. MEDLINE via PubMed, Ovid Embase, Scopus and Cochrane Library were systematically searched through March 2022 for studies comparing 1L PEG-ASC vs other bowel preparations.

Cleansing success (CS) was defined by a total BBPS $\geq$ 6 with a partial BBPS $\geq$ 2 in each segment, and high-quality cleansing (HQC) of the right-colon by a partial BBPS=3. The adenoma detection rate (ADR) was defined by the percentage of patients with at least one adenoma in the analyzed population. Safety was evaluated through number of patients with AEs and the overall number of AEs. A random-effect model was applied for pooling results; heterogeneity was expressed as I^2 .

Results: Eleven studies met the inclusion criteria and were included in the meta-analysis (nine RCTs, two prospective observational studies, 5474 participants).

The analysis showed a significant higher CS for 1L PEG-ASC compared to other preparation both overall (OR 1.66; 95% CI 1.35-2.05; $p<0.01$, $I^2=34\%$) and in the split regimen subgroup (OR 1.44; 95% CI 1.17-1.77; $p<0.01$, $I^2=0\%$), as well as a significant greater HQC of the right colon overall (OR 2.00; 95% CI 1.41-2.85; $p<0.01$, $I^2=74\%$) and in the split regimen subgroup (OR 1.77; 95% CI 1.30-2.43; $p<0.01$, $I^2=57\%$).

The pooled estimate of ADR showed no significant difference among the two groups either overall (OR 1.02; 95% CI 0.87-1.20; $p=0.79$, $I^2=0\%$), or in the split regimen subgroup (OR 0.99; 95% CI 0.84-1.18; $p=0.94$, $I^2=0\%$).

A significant higher pooled estimate of patients with adverse events (AEs) (OR 1.35; 95% CI 1.05-1.73; $p=0.02$, $I^2=45\%$) and of AEs incidence (IRR 1.28; 95% CI 1.09-1.52; $p<0.01$, $I^2=71\%$) was observed for 1L PEG-ASC compared to other preparations. No serious AEs or deaths occurred.

Subgroup analysis including only studies comparing 1L PEG-ASC vs 2L PEG-ASC confirmed a significant higher CS (OR 1.52; 95% CI 1.16-1.99; $p<0.01$, $I^2=0\%$), as well as a greater HQC of the right colon (OR 1.86; 95% CI 1.43-2.42; $p<0.01$, $I^2=0\%$) for 1L PEG-ASC compared to 2L PEG-ASC. Also in this case, the analysis showed no difference in the pooled estimate of ADR among the two groups (OR 1.07; 95% CI 0.84-1.36; $p=0.60$, $I^2=0\%$) and a significant higher pooled estimate of patients with AEs (OR 1.56; 95% CI 1.17-2.09; $p<0.01$, $I^2=0\%$) for 1L PEG-ASC compared to 2L PEG-ASC.

Conclusion: Compared to traditional preparations, 1L PEG-ASC showed higher overall CS and HQC of the right-colon, and similar ADR. A significant higher number of patients with AEs and total AEs was observed for 1L PEG-ASC in the absence of serious AEs.

Introduction: Colorectal endoscopic submucosal dissection (ESD) remains challenging because of technical difficulties, long procedure time, and high risk of adverse events. The underwater ESD provides a clearer view and better traction of the submucosal layer compared with the conventional ESD. This pilot study aimed to compare the efficacy and safety between underwater ESD and conventional ESD in patients with superficial colorectal neoplasias (20-50 mm).

Aims & Methods: In this pilot study, we conducted underwater ESD and conventional ESD at each groups. This pilot study was conducted from May 2021 to March 2022. Exclusion criteria were as follows:

1. Lesions located at appendiceal orifice, ileocecal valve, anal involve,
2. Lesions exceed 50 mm on colonoscopy,
3. Patients with inflammatory bowel disease, uninterrupted antithrombotic therapy, and coagulopathy. Primary outcome was procedure time. Secondary outcomes were en bloc rates, complete resection rates, and adverse events.

Results: Twenty patients were included in this study. 10 patients were assigned to each group. Procedure time (median [range]) for the underwater ESD group was significantly shorter than that for the conventional ESD group (46.5 [20 - 74] min vs 68 [22 - 98] min, respectively; $P=0.035$). There were no significant difference in complete resection rates (100% vs 100%, $p=1.000$), en bloc resection rates (100% vs 100%, $p=1.000$), and mean size of lesions (33.8 ± 6.8 mm vs 33.1 ± 7.9 mm, $P=0.833$) between underwater ESD and conventional ESD. The adverse events rate was not significantly different between both groups.

Conclusion: In this pilot study, underwater ESD reduced the procedure time. Underwater ESD can be an alternative method for resection of superficial colorectal neoplasias. However, further prospective randomized controlled trials are needed to ensure our pilot study results of underwater ESD in superficial colorectal neoplasias.

Disclosure: Nothing to disclose.

Introduction: Snare devices play an important role for the treatment of intestinal polyps. However, there are no objective measurements for the characteristics of the various types of snare devices.

Aims & Methods: This study was aimed to characterize snares related to the quality of cold snare polypectomy. Seven snare devices from four manufactures were evaluated by the original measurements. The evaluated factors were stiffness, cutting quality, and the change in force required for cutting depending on the shape of the sheath. The latter two factors were evaluated by measuring the force required to cut 20% gelatin-cylinders, which simulated intestinal polyps. The cutting sharpness was evaluated by observation of the sectional surface of cut gelatin-cylinders using a stereoscope. The correlation between these measurements and the characteristics of the snare devices were investigated.

Results: A strong positive correlation, with an R^2 value of 0.863, was shown between the force required to cut gelatin-cylinders and the loop wire diameter. The loop wire diameter also had a strong correlation, with an R^2 value of 0.799, with the change in force required for cutting gelatin-cylinders depending on the shape of the sheath. No correlations were detected between the loop stiffness and the characteristics of the snare devices. Further, the edge-enhanced image revealed that the rougher surfaces of the gelatin-cylinders were cut by snares with a thicker diameter.

Conclusion: The thinner loop wire could provide a higher performance in cold snare polypectomy in an experimental model.

Disclosure: Nothing to disclose.

Introduction: Colonoscopy is currently the best modality for the detection of colorectal polyps and colorectal cancer (CRC), which is the third most common malignancy worldwide. The development of CRC can be prevented when the detection of colon adenoma is followed by polypectomy. Therefore revealing factors affecting polyp detection is very important for CRC prevention.

Aims & Methods: This study aimed to investigate factors affecting polyp detection in patient undergoing colonoscopy. Epidemiological, clinical and preparation data of patients undergoing colonoscopy in our department were prospectively collected. Age, sex, body mass index, history of digestive surgery, constipation, diabetes, thyroid disease, medica-

tion intake, type of preparation, method of administration, liquid intake and Boston bowel preparation scale (BBPS) were statistically analyzed, through multivariate analysis and correlated with polyp detection.

Results: Data of 775 consecutive patients (415 F, Av.Age 68.9) were analyzed. Average BMI was 27.5 (<18.5: 8.7%, 18.5-24.9: 34.7%, 25-29.9: 34.1%, >30: 24.9%). Clinical data analysis reveals 191 (24.6%) patients affected by constipation according to Rome IV criteria, 152 (19.61%) by hypothyroidism, 100 (12.9%) by type 2 diabetes. 308 (39.7%) patients had an abdominal surgery history and 75 (9.7%) were using anxiolytic therapy. BBPS data analysis demonstrate 142 (18.3%) non adequate and 663 (81.7) adequate bowel preparations (BBPS 0-6 and BBPS 7-9 respectively). 128 (16.5%) underwent split-dose while 647 (83.5%) non-split-dose bowel preparation. Multifactorial statistical analysis reveals that higher BMI ($p=0.016$), male sex ($p=0.014$), adequate BBPS ($p=0.016$), constipation ($p=0.015$), diabetes ($p=0.021$), higher liquid intake ($p=0.032$) positively correlates with polyp detection on screening colonoscopy.

Conclusion: Patients with high BMI, male sex, adequate BBPS, high liquid intake in bowel preparation, constipation and diabetes positively correlates with polyp detection. These factors are directly affecting the diagnostic outcome of their colonoscopy.

Introduction: Regular control of colonoscopy quality parameters is essential to ensure save and state of the art treatment for patients undergoing colonoscopy (1). We report the results of a colonoscopy quality study from our endoscopy unit in the East Tallinn Central Hospital in Tallinn, Estonia.

Aims & Methods: We evaluated cecal intubation rate, bowel preparation quality, adenoma detection rate (ADR) and draw back time for all colonoscopies performed in the year 2000. Since 01.01.2020, cecal intubation, bowel preparation quality (using a 4 grade scale: excellent, good, fair, inadequate) and draw back time are documented prospectively for each colonoscopy. To assess ADR we correlated polypectomy codes and histology diagnosis codes in patients ≥ 50 years and without chronic inflammatory bowel disease.

Results: 2691 colonoscopies were performed in our unit. The mean age of the patients was 60,4 years, 2074 (77%) of patients were ≥ 50 years old. 1772 (65,8%) colonoscopies were diagnostic ambulatory procedures, 418 (15,5%) day surgery procedures in sedation, 501 (18,6%) colonoscopies were performed in hospitalized patients, 432 (16,15) colonoscopies were performed within the national large bowel cancer screening program. Referring physicians were gastroenterologists in 71,1%, surgeons in 9,2%, family practitioners in 7,1% and other specialties (e.g. internal medicine, oncology) in 12,6%. The colonoscopies were performed by 6 gastroenterologists, doing each 402 procedures in average (n: 212 – 556).

Colonoscopy quality parameters were documented in 94,7% (2550) of the procedures. Cecal intubation rate was 95,3%, the bowel preparation was adequate (excellent, good or fair) in 85,8% of the patients, the draw back time in procedures without intervention was at least 6 min in 99,1%.

The average ADR in patients ≥ 50 years and without chronic inflammatory bowel disease was 29%, ranging from 16,8% - 37,9% between individual endoscopists.

Comparing different patient groups we found significant differences in the bowel preparation quality between ambulatory and hospitalized patients (adequate 87,9% vs. 74,9%; $p < 0,001$). In ambulatory patients the bowel preparation quality differed significantly between the referring specialty, being inadequate in 11% of patients referred by a gastroenterologist, 17% of patients referred by a family practitioner, 19% in patients referred by a surgeon and 28,7% in patients referred by another specialty ($p < 0,001$). The bowel preparation was the best in bowel cancer screening patients (adequate 90,6%).

Also the cecal intubation rate differed significantly between ambulatory and hospitalized patients (96,4% vs. 91,4%, $p < 0,001$). The ADR in screening colonoscopy patients was 58,1%, 40,2% in hospitalized patients and 23,3% in patients with diagnostic colonoscopy.

Conclusion: This is the first study reporting colonoscopy quality parameters from a large endoscopy unit in the Baltic states. Regarding cecal intubation rate, average ADR and draw back time our unit fulfills the minimum quality thresholds of ESGE. However, there is a need for improvement of ADR in individual endoscopists.

The main problem of colonoscopy quality in our unit is the high rate of inadequate bowel preparation in hospitalized patients and ambulatory patients referred by other specialties. Upon these results we plan to optimize the bowel preparation process in hospitalized patients and launch a study to clarify the reasons for inadequate bowel preparation in ambulatory patients. Colonoscopy quality will be part of an annual clinic quality audit in future.

Introduction: The curative treatment of rectal neuroendocrine tumor (NET) is an endoscopic or surgical resection, but the efficacy of endoscopic resection for ≥ 10 mm sized rectal NET remains controversial.

Aims & Methods: We evaluated the clinical outcomes and risk factors related with poor prognosis after endoscopic resection for the confirmation the efficacy and proper indication of endoscopic resection in these cases. From January 2009 to November 2020, ≥ 10 mm sized rectal NETs resected by endoscopic methods in four tertiary hospitals were enrolled and the data related with clinical outcomes and prognosis were retrospectively analyzed.

Results: A total of 105 rectal NETs resected by endoscopic methods (ESD (n=65, 61.9%), modified EMR (n=31, 29.5%), conventional EMR (n=9, 8.6%)) were enrolled. The mean follow-up period was 33.8 ± 28.1 months. In gross/endoscopic findings, the mean size was 11.6 ± 2.2 mm, the shape was mostly polypoid (96.2%), and depression in surface was showed in 41.9%. In histologic findings, G1 and G2 in WHO classification was showed in 87.6% and 12.4% respectively. In clinical characteristics and outcomes according to endoscopic methods, large size ($P = 0.01$) and long procedure time ($P < 0.01$) were significantly related to ESD group, respectively. In margin involvement in histology, depression in the surface ($P = 0.02$) was only significant related. Regional or distant recurrences developed in 3 patients (2.9%) and were significantly related to female gender ($P = 0.045$), redness in surface ($P = 0.046$), G2 in WHO classification ($P = 0.04$) and non-ESD methods ($P = 0.041$).

Conclusion: Endoscopic resection of large rectal NET had good prognosis, but, the risk factors with female gender, redness in surface, G2 WHO classification and non-ESD methods were associated with regional or distant recurrences. Therefore, the patients with above risk factors may require careful monitoring.

Disclosure: Nothing to disclose.

Introduction: Identification and photo-documentation of the ileocecal valve (ICV) and appendiceal orifice (AO) confirm completeness of colonoscopy examinations. We hypothesized that an artificial intelligence (AI)-empowered solution could help us automatically differentiate anatomical landmarks such as AO and ICV from polyps and normal colon mucosa.

Aims & Methods: We aimed to develop and test a deep convolutional neural network (DCNN) model that can automatically identify ICV and AO, and differentiate these landmarks from normal mucosa and colorectal polyps. We prospectively collected annotated full-length colonoscopy videos of 318 patients undergoing outpatient colonoscopies.

We created three non-overlapping training, validation, and test datasets with 25,444 unaltered frames extracted from the colonoscopy videos showing four landmarks/image classes (AO, ICV, normal mucosa, and polyps). For each landmark, we extracted an average of 30 frames for each time of its appearance. As consecutive frames within a video are correlated, we introduced a stride of 4 frames (i.e., the amount of movement over the frames of a video) for the AO, ICV, and polyp landmarks, and a random stride of between 4 and 15 frames for the normal mucosa landmark during the frame extraction.

All the extracted frames were reviewed and annotated by a team of three clinicians. Using a quality assessment tool, the clinicians examined a total of 86,754 frames (7982 AO, 8374 ICV, 32,971 polyps, and 37,427 normal mucosa) and verified whether or not the frame contained one unique landmark. For this research, all frames were extracted from the white-light

colonoscopies, and all narrow-band imaging frames were excluded. A DCNN classification model was developed, validated, and tested in separate datasets of images containing the four different landmarks.

The primary outcome was the proportion of patients in whom the AI model could identify both ICV and AO, and differentiate them from polyps and normal mucosa, with an accuracy of detecting both AO and ICV above a threshold of 40% (representing a value in which reliable identification of the landmarks can be assumed without increasing false-positive alerts).

Results: We trained a DCNN AI model on 21,503 unaltered frames extracted from the recorded colonoscopy videos of 272 patients, and validated and tested the model on 1,924 (25 patients) and 2,017 (21 patients) unaltered frames, respectively.

The DCNN model used in the current study is an off-the-shelf network based on the Inception V3 architecture¹ and pre-trained on the ImageNet dataset.²

We applied a transfer learning technique to fine-tune the model parameters to the endoscopic images using a cross-entropy loss function and back-propagation algorithm.³

After training and validation, the DCNN model could identify both AO and ICV in 18 out of 21 patients (85.71%), if accuracies were above the threshold of 40%. The accuracy of the model for differentiating AO from normal mucosa, and ICV from normal mucosa were 86.37% (95% CI 84.06% to 88.45%), and 86.44% (95% CI 84.06% to 88.59%), respectively. Furthermore, the accuracy of the model for differentiating polyps from normal mucosa was 88.57% (95% CI 86.60% to 90.33%).

Conclusion: This model offers a novel tool to assist endoscopists with automated identification of AO and ICV during colonoscopy. The model can reliably distinguish these anatomical landmarks from normal mucosa and colorectal polyps. It can be implemented into automated colonoscopy report generation, photo-documentation, and quality auditing solutions to improve colonoscopy reporting quality.

Contact E-Mail Address: mahtakbar@gmail.com

Introduction: The effectiveness of colonoscopy screening to prevent colorectal cancer (CRC) is directly linked to its procedural quality. An independent observer (Hawthorne effect) can improve colonoscopy procedural quality metrics, including adenoma detection rate (ADR). However, the results of studies are limited or controversial.

Aims & Methods: In a single-center, case-control study, consecutive patients aged 45–80 years who underwent a routine screening or diagnostic colonoscopy at the Centre Hospitalier de l'Université de Montréal (CHUM) were prospectively enrolled.

We aimed to evaluate the colonoscopy quality metrics in a group of patients undergoing screening or diagnostic colonoscopies under stringent observer conditions, meaning all procedural steps and quality metrics were observed and documented during the procedure by an independent research assistant, and each colonoscopy was video recorded in full length (*case group*).

Findings were compared with those of a *control group* of patients in whom standard and routine colonoscopies were performed without any form of procedural observation or documentation. Colonoscopy quality metrics such as polyp, adenoma, serrated lesions, and advanced adenoma detection rates (PDR, ADR, SLDR, AADR), the mean number of adenomas detected per patient (MAP), and the mean number of adenomas and serrated lesions detected per patient (MASP) were compared. A propensity score was estimated to balance baseline patient and procedural characteristics between case and control groups using logistic regression, with the presence of a research assistant as the dependent variable and the following variables as the independent variables: sex (male vs. female), age, colonoscopy indications (screening, adenoma or CRC surveillance, fecal immunologic test [FIT], diarrhea, anemia or bleeding, other [such as a change in bowel habit]), endoscopists (considering the ADRs among endoscopists with various level of experience), period of colonoscopy (performed in the same month), procedure time (morning vs. afternoon procedure, considering lower afternoon ADR due to endoscopist fatigue), and physician-assessed bowel preparation quality (adequate vs. inadequate). Then, the probabilities of increased quality metrics were evaluated through regression analyses weighted by the inversed probability of observation during the procedure (IPTW).

Results: We included a total of 687 patients (327 cases and 360 controls) in the final analyses. The case group had significantly higher PDRs (62.4% vs. 53.1%) and ADRs (39.4% vs. 28.3%) compared with the control group. The SLDR was also higher in the case group than in the control group, but the difference was not significant (7.3% vs. 4.4%; $P = 0.14$). The AADR was not significantly increased.

After adjusting for potential confounders, the ADR and SLDR were 50% (odds ratio [OR] 1.51; 95%CI 1.05–2.17) and more than twofold (OR 2.17; 95%CI 1.05–4.47) more likely to be higher in the case group than in the

control group. The MAP and MASP were significantly increased in the case group compared with the control group ($P < 0.001$). The regression analyses for both metrics demonstrated the direct and significant association between the Hawthorne effect and elevated MAP/MASP.

Conclusion: The presence of an independent observer documenting colonoscopy quality metrics and video recording the colonoscopy resulted in a significant increase in ADR and other quality metrics. The Hawthorne effect should be considered an alternative strategy to advanced devices to improve colonoscopy quality in routine practice.

Disclosure: DvR is supported by a "Fonds de Recherche du Québec Santé" career development award. He has also received research funding from ERBE, Ventage, Pendopharm, and Pentax, and is a consultant for Boston Scientific and Pendopharm. Introduction: Polyp detection and characterization using artificial intelligence already reached the clinic. Artificial intelligence to distinguish and document endoscopic interventions after polyp identification is not established yet.

Aims & Methods: The aim of this work is to recognize endoscopic interventions and differentiate between polypectomy with snare and grasper. A total of 1,083 different examinations from 8 different centers using 4 different processor types were screened for instruments and represented the training dataset (10,449 images in total). 476 of these images contained a grasper, 927 contained a snare. The validation dataset included 50 full-colonoscopy videos that were analysed for the recognition of visible instruments. The highest confidence image in each sequence of at least 2 seconds with continuous and simultaneous detection of polyp and an instrument were presented to a physician for evaluation. The physician rated if the predicted instrument was correct and assigned each image a polyp number to identify duplicates or images without polyp.

Results: Overall, 103 polyp resections, 91 with a snare and 12 with a grasper, were documented in the report of the 50 full-colonoscopy validation data set. The artificial intelligence predicted 133 sequences with polyp and instrument with one representative image per sequence. From these 133 corresponding images, 1 did not contain a polyp and 20 did not predict the correct instrument. For 2 images both were the case. Overall, 111 (83.46 %) predictions were correct. Further analysis revealed that these 111 sequences represented 78 (75.73 %) of the 103 reported polyp resections.

Conclusion: Detection and recognition of endoscopic instruments in colonoscopy using artificial intelligence technology is reliable and achieves high sensitivity. Consequently, the new convolutional neuronal network could be used to automatically generate standardized colonoscopy reports in real-time during the procedure. Thereby, helping the examiner to save time in writing the endoscopic report.

Introduction: Colorectal cancer (CRC) remains the fourth most common cancer worldwide and is responsible for the second highest cancer mortality in developed countries. Screening for CRC with use of faecal occult blood test and subsequent colonoscopy has proven to reduce mortality. Increasing adenoma detection (ADR) rate correlate inversely with the risk of interval cancers, making ADR one of the most important quality indicators in colonoscopy. Polyp detection rate and cecal intubation rate have been shown to correlate inversely with cleansing quality. Recently, studies evaluating the efficacy of a novel 1 litre polyethylene glycol with ascorbate (1L PEG + Asc) versus standard 2 litre polyethylene glycol with ascorbate (2L PEG + Asc) have shown promising results regarding bowel cleansing. Nonetheless superiority of the novel 1L PEG + Asc has not been shown.

Aims & Methods: The aim of this study was to evaluate the bowel cleansing efficacy of either 1L PEG + Asc in a single-center randomized controlled superiority trial. The hypothesize of the study was that participants randomized to 1L PEG + Asc will show superior efficacy of the bowel cleansing compared to participants randomized to 2L PEG + Asc. A power calculation based on an expected cleansing success of 90% in the 2L PEG + Asc and 95% in the 1L PEG + Asc group, a significance level of 5%, a power of 90% and an expected dropout rate of 10% resulted in 637 participants in each group.

Primary endpoint was colonoscopy incompleteness rate due to insufficient bowel cleansing.

Efficacy of the bowel preparation was assessed according to the Boston Bowel Preparation Scale (BBPS). Adequate bowel preparation was defined as a score of ≥ 2 for either right, transverse or left colon. Eligible study participants were participants in the Danish national colorectal screening program. Participants were randomized 1:1 to receive 1L PEG + Asc or 2L PEG + Asc, both administered as evening/morning split-dose. All participants underwent colonoscopy by an experienced endoscopist. Endoscopists and investigators were blinded to the randomization.

EudraCT number: 2018-003304-39

	1L PEG + Asc	2L PEG + Asc	p-value
Overall colonoscopy data, n (%)	617 (98.3)	629 (97.4)	
Complete colonoscopy, n (%)	582 (94.3)	569 (90.5)	0.010*
Incomplete colonoscopy, n (%)	35 (5.7)	60 (9.5)	
Insufficient cleansing	20 (3.2)	46 (7.3)	0.001*

Right colon, mean (sd)	2.71 (0.45)	2.59 (0.49)	<0.001***
Total, mean (sd)	8.16 (1.23)	7.81 (1.33)	<0.001***

* Chi²

** Fisher's Exact test

*** Wilcoxon rank sum test

Table.

Results: From September 2019 until April 2022, 1274 participants were randomized to 1 L PEG + Asc (n=628) or 2 L PEG + Asc (n=646). In the 1L PEG + Asc respective 2L PEG + Asc group 322 (51%) and 310 (48%) were male, mean age was 63.0 (sd 7.6) and 62.9 (sd 7.8) years, ASA classification was 1.76 (sd 0.57) and 1.78 (sd 0.58), 54 (8.6%) and 60 (9.3%) had diabetes and the usual mean Bristol stool score was 3.85 (sd 1.30) and 3.97 (sd 1.24).

Conclusion: In conclusion this single-center randomized controlled superiority trial showed superior bowel cleansing efficacy of 1L PEG + Asc in all colonic parts and resulted in a significantly higher colonoscopic completion rate compared to 2L PEG + Asc.

Introduction:

Colorectal polypectomy is commonly incompletely performed with high variability between endoscopists resulting in the potential for interval cancer or repeated procedures. Existing scores to assess polypectomy technique are cumbersome and difficult to use.

Aims & Methods:

We developed a simple, user-friendly online assessment tool for any colorectal polypectomy (small or large polyps (≥ 20 mm), Hot or Cold snare): the Global Polypectomy Assessment Tool (GPAT). [1] We aimed to validate this tool with endoscopists of varied experience through demonstrating the inter-rater agreement.

GPAT was developed using statements derived from a Delphi-consensus between 11 internationally recognized polypectomy-experts. The score has 20 items (Table 1) and calculates an overall quality score and a complexity score. Evidence-based statements and videos demonstrating the technique enhance the reliability of the score.

We included nine endoscopic-view videos of polypectomies and recruited twelve international assessors (4 gastro-enterologists, 2 surgeons, 3 trainees and 3 medical students) via email. The videos were assessed in random order after watching a 2 minute 37 second explanatory video of GPAT. The assessors scored the SMSA-score [2] and GPAT-criteria for each video. The inter-rater agreement was calculated with the Fleiss Kappa-value (κ).

Results: We analyzed 108 GPAT-assessments of 12 assessors.

Moderate agreement on the overall GPAT score was demonstrated for the target population (gastroenterologists κ : 0.413 95%CI [0.348-0.478] and trainee gastroenterologists κ : 0.460 95%CI [0.360- 0.560]). The surgeons and medical students demonstrated fair agreement (respectively κ : 0.381 95%CI [0.226- 0.537] and κ : 0.248 95%CI [0.134-0.362]). Moderate agreement was found when analyzing the SMSA-scores separately for the gastroenterologists (κ : 0.415 95%CI [0.095-0.735] and trainee-gastroenterologists (κ : 0.518 95%CI [0.043-0.993]). Positive feedback was received regarding content and ease of use of GPAT.

Global competencies	- Tip control - Fully appreciates/demonstrates extent of the polyp to be resected - Positioning with respect to the polyp - Technique selected is appropriate for the polyp resected?
Injection Technique	- Correct Plane - Dynamic Injection - Lesion Access improved
Snare Placement Technique	- Stable 6 'o clock position - Stable position with lesion at 6 'o clock OR transformed to 6 'o clock - Snare visualised during placement and closure - Residual islands avoided if piecemeal resection OR macroscopically complete if en-bloc resection attempted
Safety Checks (Hot Snare only)	- Checks mobility in relation to deeper structures prior to resection - Lifts the snare away from the muscularis propria prior to application of diathermy
Defect Assessment	- Looks for, detects and removes residual at margin and within defect - Thermal ablation of the POST EMR margin - Looks for, detects and treats any bleeding vessels within the defect - Looks for, detects and treats Deep Mural Injury ($\geq$ Type 2 on the Sydney Classification)
Accessory Techniques	- Appropriate placement of clips - Appropriate use of Polyp Retrieval device - Appropriate use of the coagulation grasper

Table 1. Components of Global Polypectomy Assessment Tool (GPAT)

Conclusion: This validation demonstrates standardized scoring of colorectal polypectomy quality and difficulty with moderate inter-observer agreement amongst a varied panel of gastroenterologists and trainee-gastroenterologists with similar agreement found for the broadly used SMSA-score.

With further study, GPAT may allow standardized assessment of trainees' polypectomy competency with feedback on performance, demonstration of improvement over time and a method to accredit endoscopists in different levels of polypectomy.

Introduction: Due to neurogenic bowel alterations patients with spinal cord injury (SCI) present with poorer bowel preparation and the colonoscopies itself remain incomplete frequently [1]. The water exchange technique shows certain advantages in the routine setting [2-5], but the feasibility and impact in SCI patients is unknown.

Aims & Methods: The aim was to evaluate common quality parameters of water exchange colonoscopy (WEC) such as completeness and cleansing level in SCI patients in a retrospective cohort study. Two age-, gender- and time-of-performance-matched control groups (SCI patients with carbon dioxide-based colonoscopy and non-injured patients with WEC) were evaluated in a 1:1:1 ratio.

Patients were compared regarding completeness of the endoscopy, cleansing level based on a five step scale during forward feed and drawback, complications and polyp and adenoma detection rate. The study protocol was approved by the institutional review board (registry number 22-7450-BR).

Results: A total of 93 patients were included (61.2 ± 12.5 years, 75 male, 80.6 %). Only a minority of colonoscopies were performed for screening purposes (9.7 %), with slight, but significant differences between the groups. The other indications included anaemia and overt or occult bleeding (29.3 %), constipation (25.3 %), abdominal pain (20.2 %), follow-up (13.1 %), weight loss (7.1 %), diarrhoea (6.1 %) and others (9.1 %). A total of 24 colonoscopies (24.2 %) resulted in a normal finding. In decreasing order the pathologies included polyps (51.5 %), any kind of inflammation (17.2 %), diverticula (21.2 %), anal prolaps (15.2 %), angiodysplasia (1.0 %), carcinoma (1.0 %) and others (3.0 %).

Water exchange colonoscopy achieved similar results both in SCI patients and the general population. The caecum and the terminal ileum was intubated in every case of WEC; in the SCI standard colonoscopy group the respective intubation rates were 93.5 % (*ns*) and 64.5 % ($p < .001$).

The cleansing level during forward feed did not differ between both SCI groups while the control group presented a significantly better bowel preparation.

On the contrary, during drawback both WEC groups showed better cleansing results than the SCI standard carbon dioxide colonoscopy group. Among the SCI patients the improvement of the cleansing was highest in the WEC group (improvement based on the five step scale 1.4 ± 0.8 vs. 0.8 ± 0.8 , $p = .001$).

Though not significantly the polyp detection rate was highest in the SCI WEC group and lowest in the WEC control group (61 % vs. 55 % vs. 42 %, *ns*). Similarly, the mean number of polyps detected in the SCI WEC group exceeded both other groups (1.7 ± 1.9 vs. 1.2 ± 1.5 vs. 1.3 ± 2.0 , *ns*). The adenoma detection rate (46 % vs. 33 % vs. 33 %, *ns*) as well as the average number of adenomas resected (1.2 ± 1.8 vs. 0.9 ± 1.7 vs. 0.9 ± 1.7) were numerically highest in the SCI WEC group. Except of one bleeding after extensive piecemeal mucosectomy in the rectum no relevant complication occurred.

Conclusion: Water exchange colonoscopy in SCI patients is feasible and safe and has the potential to improve the quality of colonoscopies in SCI patients substantially. A controlled randomised trial is warranted to confirm the encouraging results.

Introduction: Small colonic (6-9 mm) and diminutive (1-5 mm) polyps are frequently found at colonoscopy. Histology remains to this day the gold-standard for the evaluation of polyps despite important histo-pathological inter-observer differences in the distinction between adenomas and hyperplastic polyps.

Due to the relatively high prevalence and clinical insignificance of small hyperplastic polyps on the left side of the colon, the cost associated with their removal and pathological study remains unjustified.

Aims & Methods: The aim of this study was to identify the histological features of diminutive and small polyps in order to verify the safety of strategies proposing to resect only polyps of 10 mm or more. Patients who underwent polypectomy during 12 months were identified through our endoscopy database and those with polyps <1 cm were enrolled.

Results: Two hundred and four patients (117 men and 87 women, sex ratio M / W = 1.34) were identified. The mean age was 63.57 ± 12.14 years (31 to 90 years). There were 431 polyps of which 239 (55.45%) were diminutive. Sixty-three percent of all polyps were on the left colon and 30.3% (n = 131) were hyperplastic. Eighteen percent of the polyps on the right side were hyperplastic versus 37.26% on the left side. This histological difference was statistically significant ($p < 0.0001$). High grade dysplasia (HGD) was present in 14% of adenomatous polyps and serrated polyps were observed in 11.5% of cases. Adenocarcinoma was found in 3 small polyps on the left side (9 mm) causing a rate of degeneration at 0.69%.

Conclusion: These data demonstrate that only a third of the polyps on the left side were hyperplastic, mainly represented by diminutive polyps (<5 mm). However the pathological findings of small polyps (6-9 mm) are not reassuring proving that polypectomy remains well justified.

CHARACTERISTICS AND RENTABILITY OF URGENT COLONOSCOPY IN LOWER GASTROINTESTINAL BLEEDING. EXPERIENCE IN A THIRD LEVEL CENTER

M.M. Rodriguez Gonzalez¹, N. Garcia Morales¹, N. Fernández Fernández¹, L.A. Cid Gomez¹, M. Ayude Galego¹, S. Alonso Lorenzo¹, D. Nogueira Senties¹, A. Iglesias Doallo¹, V. Pena¹, A. Alonso¹, V. Marquez¹, M. Casares¹, J.I. Rodriguez Prada¹

Introduction: Colonoscopy is an useful tool on the management of patients with lower gastrointestinal bleeding (LGIB). Its diagnostic and therapeutic yield varies and the optimal timing for its performance is a reason of controversy.

Aims & Methods: Aims: We aim to describe the characteristics of patients with LGIB having an urgent colonoscopy done, as well as the diagnostic and therapeutic yield of this procedure.

Methods: Descriptive and observational study of the urgent colonoscopies due to LGIB done at the Vigo University Hospital between June 2019 and April 2021.

Results: A total of 110 urgent colonoscopies were done, from which 92 were due to LGIB, meaning a 10.4% of all the urgent endoscopies done at the said period of time. The average age of patients presenting LGIB was 68.84 years old (SD 14) and 58 (63%) of them were male. At the moment of bleeding, 16 (17.4%) were receiving anticoagulant treatment and 17 (18.5%) antiagregant treatment. We registered 56 colonoscopies (60.9%) being done in the morning and 36 (39.1%) during the afternoon and evening.

At the endoscopy unit 64 colonoscopies were done (69.6%), while 28 (30.4%) were done at the Intensive Care Unit. In 79 patients (85.9%) the procedure was done under sedation. The etiology of the bleeding was post-polypectomy in 24 patients (26.1%), colon ischemia in 8 patients (8.7%), inflammatory bowel disease in 5 patients (5.4%), diverticular disease in 12 patients (13%), vascular disease in 1 patient (1.1%) and other causes in 26 patients (28.3%). In 16 patients (17.4%) the etiology was not filiated. Only 29 patients (31.5%) received endoscopic treatment, which was successful in 28 (96.6%).

No complications were documented. The need for surgical/radiologic intervention was registered in 4 patients (4.3%). A total of 56 (61.5%) colonoscopies were made within the first 24 hours of presentation (urgent colonoscopy), while 35 (39.4%) were made after this period of time.

We found that timing to colonoscopy is associated with the possibilities to apply endoscopic treatment ($p < 0.05$), but not with the diagnostic capability ($p 0.154$). Previous bowel preparation was given to 28 patients (30.4%) and not given to 64 (69.6%), mostly of whom underwent recto-sigmoidoscopy and not a complete colonoscopy. Giving previous bowel preparation was related to the diagnostic capacity of the colonoscopy ($p 0.05$). The 40.2% were complete colonoscopies, the 18.5% uncomplete colonoscopies and the 41.3% rectosigmoidoscopies, which was related to giving previous bowel preparation ($p < 0.01$) and with the diagnostic findings ($p < 0.05$). Dead from bleeding occurred in a 2.2 % and it was not related to colonoscopy timing ($p 0.691$).

Conclusion: Urgent colonoscopy is an infrequent indication for diagnostic and treatment in LGIB. Performing an urgent colonoscopy does not increase the diagnostic yield of the procedure, but it does increase the possibilities of applying endoscopic treatment.

Giving adequate previous bowel preparation improves the chance of endoscopic diagnose, so it seems that performing colonoscopy without it is not profitable.

Contact E-Mail Address: laroussirachid89@gmail.com

Introduction: Sigmoid volvulus is the twisting of the sigmoid loop on its mesocolic axis, achieving a low occlusion, by strangulation. The etiology remains unknown, however there are factors that are incriminated in the occurrence of this pathology.

The therapeutic management of sigmoid volvulus in emergency is controversial between endoscopic and surgical treatment. The objective of this work is to evaluate the results of the treatment of sigmoid volvulus by endoscopic detortion and exsufflation.

Aims & Methods: This is a retrospective study including patients who underwent endoscopic exsufflation between December 2017 and March 2022. All emergency exsufflation colonoscopies performed for sigmoid volvulus were collected. The results of the endoscopic management, the percentage of recurrence as well as the need for recourse to surgery were evaluated.

Results: During the study period, 16 patients with acute intestinal obstruction due to sigmoid volvulus underwent emergency exsufflation colonoscopy. There were 12 men and 4 women with an average age of 59.8 years [26-81 years]. Endoscopic exsufflation was performed successfully and without incident in 13 patients, i.e. a primary success rate of 81.25%.

No complications were noted. Failure of exsufflation was observed in 3 patients, two patients had signs of endoscopic colic pain and only one patient had stenosis of the neck of the volvulus which was impassable requiring emergency performance. of a colectomy with a colostomy. Early recurrence within an average of 11 days [7.20] was observed in four patients, representing a secondary success of endoscopic treatment of 69.2%.

Sigmoidectomy was performed in 69.2% of patients who underwent endoscopic exsufflation ($n=9$) within an average of 29 days [5.50].

Conclusion: In the absence of signs of severity, devolvulization and primary endoscopic exsufflation is the treatment of choice for sigmoid volvulus occlusions. Its primary and secondary success rates are satisfactory. It thus makes it possible to get out of the acute phase, and to program the sigmoidectomy in better conditions.

Disclosure: None.

P0913

COMPARISON OF SYNERGISTIC SEDATION WITH MIDAZOLAM AND PROPOFOL VERSUS MIDAZOLAM AND PETHIDINE IN COLONOSCOPES: A PROSPECTIVE, RANDOMIZED STUDY

Y. Lee¹, D.H. Kim¹, H. Kim¹, S.-Y. Park¹, E. Cho¹, H.A. Cho¹, Y. Jung¹

¹Chonnam National University Hospital, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Gwangju, Korea (Republic of)

Contact E-Mail Address: tgb-follower@daum.net

Introduction: Benzodiazepines, combined or not with opioids, has been used as standard regimen for gastrointestinal endoscopy for decades, also referred to as "traditional sedation"(1). However, there has been a strong interest in propofol-based sedation recently and tends to replace traditional sedation in several countries(2). Propofol sedation showed better patient satisfaction, efficacy and similar safety versus traditional sedation for colonoscopy(3, 4). However, data directly comparing midazolam with propofol and midazolam with pethidine in colonoscopy are limited.

Aims & Methods: The aim of our study was to compare the safety and efficacy of the synergistic sedation with midazolam combined with propofol versus midazolam and pethidine for conscious sedation in colonoscopy. We performed prospective randomized single blind study. Forty-two patients were randomly assigned to one of two medication regimens in colonoscopy. Patients in group A received midazolam and propofol. Patients in group B received midazolam and pethidine.

Results: A total of 42 patients were enrolled and 20 were assigned to group A and 22 to group B. Median dose of propofol was 40mg (range 10-80) in group A, and median dose of pethidine was 25 mg (range 25-75) in group B.

Pain score index was 1.1 versus 1.8 ($p = 0.083$). Cecal intubation rate was 100% in both groups and cecal intubation time was 7.8 minutes versus 9.3 minutes ($p = 0.468$). Patient's position change frequency was 1.0 versus 1.5 ($p = 0.019$). Manual compression was applied on 50% versus 77.3% ($p = 0.065$). Difficulty of the procedure was 2.3 vs 3.3 ($p = 0.170$). Elapsed time until discharge criteria are satisfied was 22.5 minutes versus 22.1 minutes ($p = 0.837$). Patient's satisfaction score was 96.5 points versus 94.1 points ($p = 0.497$). Adverse events rate was 25.0% versus 13.6% respectively ($p = 0.445$).

	Group A (n = 20)	Group B (n = 22)	P value
Drop in O2 saturation	0 (0%)	1 (4.5%)	ns
Drop in blood pressure	2 (10%)	0 (0%)	ns
Alteration in heart rate	3 (15%)	2 (9.1%)	ns
Pain (VAS)	1.7 ± 1.2	2.0 ± 1.4	ns
Cecal intubation time	7.8 ± 5.3	9.3 ± 7.0	ns
Position change frequency	1.0 ± 0.5	1.5 ± 0.7	0.01
Manual compression	10 (50%)	17 (77.3%)	ns
Aldrete score (20 min)	9.9 ± 0.3	9.8 ± 0.5	ns
Satisfaction score	96.5 ± 11.4	94.1 ± 11.4	ns

Table 1 The efficacy and safety of two groups.

Conclusion: Safety and recovery profile was similar in both groups. In terms of efficacy, the combination of midazolam and propofol resulted in fewer position changes. In addition, the cecal intubation time, the number of manual compressions, and the difficulty of the procedure showed a better trend. Patients also tended to feel less pain and be more satisfied.

Contact E-Mail Address: agolebiewska111@gmail.com

Introduction: Outcomes of endoscopic treatment of large colorectal polyps depends on many variables, of which size and morphology (flat, sessile or pedunculated) are assumed to be important predictors of technical success. Up to date, there was no assessment of both short- and long-term (including colorectal cancer [CRC] risk) outcomes of endoscopic treatment of large lesions with regards to polyp morphology.

Aims & Methods: To assess technical success rate and risk of CRC after endoscopic removal of large colorectal polyps.

We performed an observational, retrospective study of all patients referred for colonoscopy at our Department between 2000 and 2015, with the intention to remove the large (>20mm) colorectal lesion. We collected data on patient and lesion characteristics, technical factors, histology findings and follow-up date, including local recurrence and CRC occurrence. Polyps' morphology was divided into three groups, based on Paris and LST classification: I. Sessile polyps (SP, 0-Is), II. Pedunculated polyps (PP, 0-Ip), III. Flat polyps (FP, 0-IIa-c, LST, LST-Is). We used forward stepwise regression at 0.1 significance level for variable selection. Adjusted risk (AR) was calculated using margins at the means of the models' covariates. All hypothesis were tested at 5% significance level.

Results:

	Technical success OR* (95% CI)	Carcinomatous polyp OR** (95% CI)	Bleeding OR*** (95% CI)	Disease recurrence OR†(95% CI)
Polyp's morphology (ref. FP)				
PP	9.33 (1.18-73.54)	3.84 (2.19-6.72)	1.00 (0.63-1.60)	0.09 (0.03-0.24)
SP	0.50 (0.25-0.99)	4.76 (2.88-7.88)	0.69 (0.42-1.12)	0.45 (0.29-0.71)
Polyp's histology (ref. LGD)				
HGD	1.34 (0.59-3.05)	N/A	1.46 (0.97-2.21)	0.86 (0.58-1.28)
Carcinomatous polyp		N/A	2.98 (1.68-5.27)	1.48 (0.78-2.81)
Polyp's size (ref. <30 mm)	0.15 (0.07-0.33)			
30-39 mm	0.25 (0.10-0.63)	1.35 (0.88-2.09)	1.75 (1.14-2.68)	1.45 (0.94-2.25)
≥40 mm	0.08 (0.03-0.20)	2.50 (1.43-4.37)	2.03 (1.21-3.39)	2.10 (1.33-3.31)

Table 1. Multivariable logistic regression models.

Abbreviations: LGD= low-grade dysplasia, HGD= high-grade dysplasia. OR were adjusted for variables found significant in stepwise selection, i.e. *missing histology and year of colonoscopy, **use of APC, ***missing histology, year of colonoscopy and use of forceps, †use of APC and forceps, patient's age.

We identified 1,814 procedures of endoscopic treatment of 1,983 large lesions in 1,723 patients. We excluded 332 (16.7%) lesions (4 due to administrative error, 64 due to inflammatory bowel disease, 3 due to lack of information on morphology and 261 were disqualified by the endoscopist). In total, 1,651 polyps (24.9% SP, 31.5% PP, 43.6% FP) among 1,441 patients (mean age, 64.6 years; 54.6% males) were analyzed.

The adjusted technical success rate was 98.6% for FP, 99.8% for PP ($p=0.034$ compared to FP) and 97.2% for SP ($p=0.048$ compared to FP). The AR of carcinomatous polyp for FP was 3.0% which was significantly less than for PP (10.3%, $p<0.001$) and SP (13.1%, $p<0.001$).

There was no significant difference in AR of bleeding: FP (7.8%) and PP (7.9%, $p=0.983$) or SP (5.5%, $p=0.130$). AR of disease recurrence was higher in FP (15.9%) than in PP (1.6%, $p<0.001$) and SP (7.9%, $p=0.001$).

Results of logistic regression can be found in Table 1. During the median follow up of 4 years, a total of 8 CRCs were found, which turned out to be too small group to perform analyzes of risk for CRC incidence and mortality.

Conclusion: Endoscopic removal of large colorectal lesions is effective and the incidence of CRC is very low in long-term follow-up. These findings could be helpful for community centers as a first-step qualification for removal of large lesions and to inform decisions on which lesion should undergo endoscopic treatment in referral centers.

P0915

PRE-COLONOSCOPY PREPARATION GUIDED BY A PERSONALIZED DIGITAL PLATFORM IS ASSOCIATED WITH LOWER RATES OF INADEQUATE PREPARATION COMPARED TO DIGITAL WRITTEN INSTRUCTIONS

L. Deutsch (Mlynarsky)^{1,2}, O. Shibolet^{1,2}

¹Tel Aviv University, Sackler School of Medicine, Tel Aviv, Israel, ²Tel Aviv Sourasky Medical Center, Gastroenterology and Hepatology, Tel Aviv, Israel

Contact E-Mail Address: Liatml@tlvmc.gov.il

Introduction: Inadequate Bowel preparation is a cause of failed cecal intubation, leading to missed colonic lesions.

Aims & Methods: Study aim was to evaluate whether implementation of a new personalized digital platform leads to better bowel preparation and patient related outcomes through better patient engagement.

We retrospectively analyzed prospectively collected data regarding ambulatory colonoscopies. The GistMD digital platform includes a patient-tailored animated video of bowel preparation instructions, individualized according to age, gender, comorbidities and language, links to instruction forms and consent forms, and a set of reminders. A link to the GistMD system was randomly sent to patients before a scheduled colonoscopy during platform implementation period (04/2021-10/2021). The control group received standard written instructions.

The selection of prep regime was according to the referring physician discretion prior to prep instructions assignment. Patients with any history of colorectal surgery were excluded.

Results: Out of 2447 colonoscopies, the GistMD link was randomly sent to 913 (37.3%) patients and standard written prep instructions to 1534 (62.7%) controls. Inadequate bowel preparation (Boston bowel preparation scale (BBPS)<6) was documented in 27.6% of controls and only in 21.2% of the "GistMD link" group ($P<0.001$). Among the "GistMD link" receivers, 470/913 (51.5%) watched >75% of the video ("GistMD full-users") while 443/913 (48.5%) did not. BBPS<6 rate was the lowest among "GistMD full-users" compared to less-users and the control group (19.1%, 23.5% and 27.6%, respectively, $P<0.001$).

Cecal intubation rates were higher among "GistMD" link group compared to the control group (881(96.5%) vs.1450 (94.5%), $P=0.026$) and propofol dose was lower (233.7 ± 97.5 mg vs. 244.3 ± 105.9 mg, $P=0.020$). Logistic regressions adjusted for age, gender and morning/afternoon colonoscopy, showed that "GistMD link" and "GistMD full-users" were each independently associated with BBPS $\geq$ 6 [(OR 1.459, $P<0.001$) and (OR 1.639, $P<0.001$), respectively].

In sub-group analysis "GistMD link" showed the same benefit in achieving BBPS $\geq$ 6 among native Russian speakers (OR 1.769, $P=0.018$), female patients (OR 1.589, $P=0.004$), male patients (OR 1.366 $P=0.015$), and 50-70years old patients (OR 1.636, $P=0.001$). Polyp detection rate and adenoma detection rate were comparable between the "GistMD link" and the control group (36.8% vs. 40.3%, $P=0.095$, and 27.1% vs. 28.2%, $P=0.531$, respectively).

Conclusion: A personalized digital platform for pre-colonoscopy preparation guidance leads to lower rates of inadequate preparation and higher procedure completion rates.

Disclosure: Nothing to disclose.

ACUITY OF ARTIFICIAL INTELLIGENCE ASSISTED COLONOSCOPY IN LYNCH SYNDROME PATIENTS

C. Pinto¹, R. Ortigão¹, J. Chaves¹, D. Ramos Silva², M. Dinis-Ribeiro¹, C. Lopes Brandão¹

¹Portuguese Oncology Institute of Porto, Gastroenterology, Porto, Portugal, ²Hospital Amato Lusitano, Gastroenterology, Castelo Branco, Portugal

Contact E-Mail Address: claudia.marquespinto@gmail.com

Introduction: Lynch Syndrome (LS) is the most common cause of hereditary colorectal cancer. In these patients, the adenoma-carcinoma progression is faster – hence, precursor lesion detection should be optimized to reduce false-negatives and subsequent potential interval cancer. Artificial intelligence (AI) based systems have been used during colonoscopy to raise both adenoma detection rate and the number of adenomas detected by patient.

Aims & Methods: Our aim was to determine the sensitivity of AI assisted colonoscopy in LS patients.

We included patients with LS submitted to screening colonoscopies. Patients were submitted to two passages in both the ascending colon and cecum. The first passage was performed with the AI-assisted system (GI Genius®) – all identified polyps (true-positives) were removed. The second passage was aided by high-definition white light – all identified polyps were removed (false-negatives). We also described polyps identified by the AI-assisted system but not by an endoscopy expert (false-positives).

Results: We included 36 patients with a median age of 50 years. Twenty-six (26, 72.2%) were male. Polyps were detected in 11 patients (30.5%). In the first passage, 13 polyps were identified – 11 (84.6%) with dimensions <10mm and 9 (69.2%) adenomas. In the second passage, 6 additional polyps were identified – 5 (83.3%) with dimensions <10mm and 4 (66.7%). AI-assisted colonoscopy has an estimated sensitivity of 68.4% (95% Confidence Interval – 63.8-72.0). False-positives were identified in 31 (86.0%) colonoscopies.

Conclusion: AI based systems may be useful in minimizing detection errors during colonoscopy in LS patients. Our preliminary results show the need for optimization of these systems, especially due to high percentage of false-positives.

Disclosure: Nothing to disclose.

P0917

IMPACT OF REINFORCED EDUCATION BY TELEPHONE AND SHORT MESSAGE SERVICE ON THE QUALITY OF BOWEL PREPARATION: A RANDOMIZED CONTROLLED STUDY

A. Ait errami¹, I. Haraki¹, K. Krati¹

¹UHC Mohammed VI, Hepatogastroenterology, Marrakech, Morocco

Contact E-Mail Address: harakiimane@gmail.com

Introduction: Inadequate preparation of the bowel for colonoscopy can result in both missed pathological lesions and cancelled procedures.

Aims & Methods: This study aimed to assess the impact of reinforced education by telephone or short message service (SMS) on the quality of bowel preparation.

A prospective, endoscopist-blinded, randomized, controlled study was conducted. Reinforced education groups received additional education via reminders by telephone or SMS 2 days before colonoscopy. The primary outcome was the quality of the bowel preparation according to the Boston Bowel Preparation Scale (BBPS). The secondary outcomes included polyp detection rate (PDR), adenoma detection rate (ADR), tolerance, and subjective feelings of patients.

Results: A total of 220 patients were included. Total BBPS score was significantly higher in the reinforced education groups than in the control group (mean [SD] telephone vs. control: 7.1 [1.2] vs. 6.3 [1.4], $P < 0.001$; SMS vs. control: 6.8 [1.3] vs. 6.3 [1.4], $P = 0.027$).

Between the two interventions, there was no significant difference in total BBPS score. PDR and ADR were not different among groups. Reinforced education groups showed lower anxiety and better tolerance compared with controls.

A preparation-to-colonoscopy time of >6 hours and $<80\%$ of the purgative ingested were independent factors associated with inadequate bowel preparation (BBPS < 5), whereas re-education by telephone was inversely related to inadequate bowel preparation.

Conclusion: SMS was the optimal education modality, and was as effective as telephone reminders for the quality of bowel preparation. A reinforced educational approach via telephone or SMS should be individualized, depending on the resource availability of each clinical practice

Disclosure: Nothing to disclose.

SEDATION FOR COLONOSCOPY IN PATIENTS WITH SPINAL CORD INJURY DEPENDS ON THE INJURY'S CHARACTERISTICS, BUT IS FEASIBLY AND SAFELY ADMINISTERED AS NURSE ASSISTED SEDATION

M. Beckmann¹, M. Aach², T.A. Schildhauer³, W. Schmiegell⁴, T. Brechmann^{5,1}

¹Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Department of Gastroenterology and Hepatology, Bochum, Germany, ²Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Department of General and Trauma Surgery, Spinal Cord Injury Unit, Bochum, Germany, ³Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Department of General and Trauma Surgery, Bochum, Germany, ⁴Ruhr University Bochum, Bochum, Germany, ⁵St. Elisabeth Hospital, Internal Medicine and Gastroenterology, Gütersloh, Germany

Contact E-Mail Address: thorsten.brechmann@rub.de

Introduction: Colonoscopy is a routine method both for screening and work-up of suspected diseases of the lower gastrointestinal tract. Though it has been shown that colonoscopy is feasible and safe even in patients

with spinal cord injury (SCI), there is no data available that describes the utilisation and safety of the sedation applied during SCI patients' colonoscopy.

Aims & Methods: Consecutive patients with SCI who underwent colonoscopy between 2008 and 2018 were included in a retrospective matched case control study. On that account a gender-, age-, and year-of-performance-matched control group (CG) without SCI was assigned.

The demographic characteristics including parameters of the spinal cord injury, the indication and results of the endoscopy, the medication and the staff involved in the procedure as well as adverse events were collected from the electronic data base. Hypotension was defined as a fall below 75% of the baseline.

The primary objectives were the rate of adverse events and severe adverse events related to the sedation.

Secondary objectives included the frequency of demanding a sedation, dose of medication administered, the occurrence of adverse events such as desaturation, need of mechanical ventilation, hypotension, bradycardia, premature discontinuation, need for intensive medical care, nausea/vomiting, intolerance reaction, need for resuscitation and death related to the sedation. Characteristics of SCI, such as the aetiology, AIS classification, and duration were investigated as risk factors for sedation.

For the statistical analyses descriptive statistics, Chi squared test, Fisher's Exact test, paired t-test, variance analysis (ANOVA), Mann-Whitney-U-test, and Kruskal Wallis test were used. Potentially influencing factors on hypotension were evaluated by a regression analysis.

Results: Of 282 patients with SCI, 169 (59.9%) demanded a sedation during colonoscopy (CG: 259 (91.8 %), $p < .01$). Although the sedation lasted 5.5 min longer in the SCI group ($p < .05$), fewer sedative drugs were administered (Propofol: 0.08 ± 0.07 mg/kg/min vs. 0.11 ± 0.07 mg/kg/min, $p < .01$; Midazolam: 3.2 ± 1.2 mg vs. 3.7 ± 1.3 mg, $p < .01$). Hypotension occurred significantly more often in patients with SCI (60.0 % vs. 42.3 %, $p < .01$); other adverse events were equally distributed in both groups.

The SCI's characteristics had a relevant influence on the sedation and its adverse events. The average propofol dose was higher in subjects with chronic than acute injuries (0.09 ± 0.07 mg/kg/min vs. 0.05 ± 0.04 mg/kg/min, $p < .01$) and lumbar (0.14 ± 0.12 mg/kg/min) than thoracic (0.08 ± 0.05 mg/kg/min) than cervical (0.06 ± 0.05 mg/kg/min $p < .05$) lesions; the midazolam dose presented similarly (3.7 ± 1.2 mg vs. 3.2 ± 1.2 mg vs. 2.8 ± 1.0 mg, $p < .05$).

Both drugs differed according to the AIS classification (propofol: AIS-A: 0.08 ± 0.05 vs. AIS-B: 0.10 ± 0.06 vs. AIS-C: 0.12 ± 0.16 vs. AIS-D: 0.07 ± 0.05 mg/kg/min, $p < .05$; midazolam: AIS-A: 3.1 ± 1.1 vs. AIS-B: 3.1 ± 1.2 vs. AIS-C: 3.3 ± 1.2 vs. AIS-D: 3.4 ± 1.4 mg, $p < .05$).

Hypotension was more likely in persons with chronic lesions (65.4 % vs. 34.6 %, $p < .01$) and associated to the level of the injury (thoracic 70.3 % vs. cervical 51.2 % vs. lumbar 33.3%, $p < .01$).

Conclusion: Compared to the able-bodied population SCI patients demand a sedation during colonoscopy significantly less often. The sedation differs depending on the SCI's characteristics. Though mild hypotension occurs frequently, nurse assisted sedation is feasible and safe even in the particular setting of colonoscopy in SCI patients.

Disclosure: Nothing to disclose.

CLINICAL OUTCOMES: A PILOT FIT PROGRAM TO TRIAGE NON-URGENT COLONOSCOPY REFERRALS

L. Kumar¹, E. Shannon¹, S. Sihag², H. Kerr², C. Steele², E. Slattery¹
¹University Hospital Galway, Gastroenterology, Galway, Ireland,
²Letterkenny University Hospital, Gastroenterology, Donegal, Ireland

Contact E-Mail Address: kumarl@tcd.ie

Introduction: In the post-COVID era, colonoscopy waiting lists poses a significant challenge. Faecal Immunochemical Test (FIT) is mainly used in colorectal cancer screening to predict pre-malignant/malignant lesions on colonoscopy but their utility beyond cancer screening has yet to be determined.

Aims & Methods: To assess the utility of FIT as a safety net in addition to conventional triaging methods to determine the outcomes of patients undergoing non-urgent colonoscopies.

Patients awaiting for a routine colonoscopy (waiting >3 months), in 2 tertiary referral centres, were sent a FIT kit. Positive-FITs (i.e. >50ng/mL) were re-triaged for urgent colonoscopy. Basic demographics, colonoscopy and histology findings were collected, and median FIT levels calculated to correlate with findings on colonoscopy.

Results: In total, 1226 patients were invited to perform a FIT to which 715 (58%) participants responded. Of these 115 (16.1%) samples were positive and results in re-triaging for an urgent colonoscopy. 102 underwent a colonoscopy. The median age was 58 years (IQR:47-72) and 47.1% were male. The median time to endoscopy from a positive-FIT result was 56 days (IQR:49-62).

Most common indications for colonoscopy included altered bowel habit (29.4%) and rectal bleeding (22.5%). Positive findings were seen in 77.5% of procedures (0% malignancies, 43.1% polyps, 33.3% diverticulosis, 11.8% colitis, 9.8% haemorrhoids). High risk adenomas were found in 16 (15.7%) patients. Patients with a FIT ≥1000ng/mL were more likely to have a positive finding compared to those with a FIT of <1000ng/mL (96% vs 72%, p=0.02).

Conclusion: Reassuringly there were no findings of malignancy, although diagnostic yield was high. This highlights the importance of good clinical triage. Further comparison with the negative-FIT group after colonoscopy along with patient reported outcomes are being followed-up in this study.

Disclosure: Nothing to disclose.

Contact E-Mail Address: carlosokm@yahoo.es

Introduction: Screening colonoscopy has decreased the incidence of colorectal carcinoma in the previous decades. However, several factors affect polyp/adenoma detection rate: bowel preparation, percentage of mucosal surface evaluation, and the training levels of operators. The Discovery Artificial Intelligence assisted polyp detector (Pentax Medical, Hoya Group) was recently launched for clinical practice.

This AI software was trained with 120,000 files from approximately 300 clinical cases. The visual aided detection (bounding box locating a polyp on the monitor) alerts the endoscopist if a polyp/adenoma was missed during the standard, screening procedure.

Aims & Methods: We aim to evaluate the real-world effectiveness of AI-assisted colonoscopy in clinical practice. Consecutive patients who underwent HD colonoscopy (Nov/2020-Mar/2021). Patients >45 years old were invited to participate during outpatient clinic visits. Patients with BBPS≤6, history of inflammatory bowel disease, familial polyposis syndrome, colorectal carcinoma, colorectal surgery or uncontrolled coagulopathy were not considered. A first operator was assessed only with HD colonoscopy, and a second operator (blinded to previous findings) with an AI-assisted HD colonoscopy. The study protocol and written consent form were approved by the local Institutional Review Board (IRB).

The study protocol was conducted according to the declaration of Helsinki. All patients provided informed written consent. Data were analyzed in R v4.0.

Results: A total of 115 colonoscopies were performed on 115 patients. Mean age 57.0 (51.0 - 67.5) years old, 82 (71.3%) females, with a BMI index <25, 25-30 and >30 kg/m² in 6/115 (5.2%), 89/115 (77.4%) and 20/115 (17.4%) patients, respectively. At the morning, 93/115 (80.9%) procedures were performed. An expert endoscopist performed 67.8% of procedures, while a GI fellow in training 32.2%. The median time until withdrawal was 09:05 minutes. The polyp and adenoma detection rate were 132 (64.3%) and 73 (35.6%), respectively detected in 58/115 (50.4%) patients: 19/205 (9.3%) NICE II, 7/205 (3.4%) >10 mm (Table 1).

	Total (n=205)	Rectum (n=46)	Sigmoid (n=34)	Descending (n=20)	Trans- verse (n=24)	Ascending (n=54)	Cecum (n=27)
Nice (I/II/III)	186/19/-	44/2/-	32/2/-	16/4/-	22/2/-	49/5/-	23/4/-
Size (mm), 0-5/5-10/>10	132/66/7	44/2/-	28/6/-	13/7/-	22/2/-	1/48/5	24/1/2
Removal (forceps/cool loop/hot loop)	181/16/8	44/1/1	29/3/2	14/6/-	21/3/-	48/3/3	25/-/2

Table 1. Polyp/adenoma characterization.

From them, 44 polyps and 4 adenomas were detected by the second operator assisted by AI. The frequency of patients with polyps/adenomas appropriately detected by AI (sensitivity) among different colon segments ranged from 56.25% (rectum) to 78.26% (ascending colon). Meanwhile, the capability of AI for appropriate polyp/adenoma presence discharging (negative predictive value, NPV) ranged from 61.54% (sigmoid) to 89.09% (cecum). However, there were observed lower rates for specificity (8.42-49.49%) and positive predictive value (PPV, 9.89-19.78%) due to high false positives.

Conclusion: The Discovery Artificial Intelligence assisted polyp detector is a feasible tool to aid endoscopists during screening colonoscopy. However, a high rate of false-positive limits its overall accuracy. Development of this technology with more normal colonoscopies videos could decrease the false-positive rate, increasing overall accuracy.

Disclosure: Nothing to disclose.

Contact E-Mail Address: shichijyou-ky@umin.ac.jp

Introduction: Sessile serrated lesions (SSLs) act as precursors to colorectal cancer and sometimes harbor carcinomas. With indistinct margins, SSLs are sometimes incompletely resected.

Aims & Methods: This prospective, single-arm, observational study was performed at eight Japanese tertiary institutions to evaluate the local recurrence after endoscopic resection of SSLs ≥ 10 mm. Colorectal lesions ≥ 10 mm were resected endoscopically and the pathological diagnosis of the lesion was either SSL or hyperplastic polyp (HP). Central pathological review was performed for all the registered lesions. Follow-up colonoscopy was performed 1 year later, and the local recurrence was evaluated by biopsy.

Results: From October 2018 to October 2019, a total of 104 cases with 123 lesions were registered. Size was 15.6 ± 6.6 mm. The macroscopic type was IIa in 107 cases (87%) and Is in 13 cases (11%). Endoscopic mucosal resection (EMR) was performed for 59 (48%) lesions, underwater EMR (UEMR) in 39 (32%), endoscopic submucosal dissection in 12 (10%), and cold snare polypectomy in 8 (6.6%). En bloc resection was achieved in 98 (80%). Two delayed bleeding events occurred after EMR and were managed by endoscopy. Regarding pathological margins, two (1.6%, both treated by UEMR) were positive, 80 (66%) were negative, and 40 (33%) were indeterminate. Among the pathologically diagnosed 105 SSLs and 18 HPs, 95 and 7 were diagnosed as SSL and HP, respectively, by central pathological review (Table).

Among the 104 endoscopically diagnosed SSLs, 86 were diagnosed with SSLs, while among the 11 endoscopically diagnosed HPs, 2 were diagnosed as HPs by central pathological review (the rest were SSLs). Follow-up endoscopy was performed for the 95 patients with 113 lesions after 0.99 ± 0.38 years (4–24 months) until September 2021. Among them, resection scars were identified in 95 (84%) lesions. Three (3.1%; 95% confidence interval 0.6–8.7%) local recurrences were diagnosed pathologically

among ninety-eight pathologically diagnosed SSLs. Three cases with local recurrences were 1) Is lesion sized 25 mm in the cecum, and performed UEMR with indeterminate pathological margins, 2) IIa lesion of 10 mm in the ascending colon resected en bloc by EMR, resulting in negative margins, and 3) 30 mm, Is lesion in the sigmoid colon, resected en bloc by underwater EMR with negative margins. Cases 1) and 2) were diagnosed as local recurrences by follow-up endoscopy, and confirmed pathologically. Case 3 was not suspected recurrence endoscopically, but biopsy revealed recurrence. When classified by size, 2 out of 15 (13%) SSLs ≥ 25 mm and 1 out of 83 (1.0%) SSLs < 25 mm were diagnosed with local recurrence ($p = 0.06$).

Central pathological review	SSL with CD	SSL without CD	Hyperplastic polyp	Tub1	TSA	Total
Endoscopic diagnosis						
SSP with dysplasia		2				2
SSP without dysplasia	4	85	13	1		103
Hyperplastic polyp	1	8	2			11
adenoma	2	4		1		7
Pathological diagnosis at each institute						
SSL with dysplasia	1	3				4
SSL without dysplasia	5	86	8	1	1	101
Hyperplastic polyp	1	10	7			18
Total	7	99	15	1	1	123

Table.

Conclusion: The local recurrence rate after endoscopic resection of SSL ≥ 10 mm was 3.1%. Careful follow-up is recommended after endoscopic resection of large SSLs. Endoscopically diagnosed HPs ≥ 10 mm were sometimes pathologically diagnosed as SSL and should be considered for resection.

Disclosure: Nothing to disclose.

ARTIFICIAL INTELLIGENCE ASSISTANCE IMPROVES AS ENDOSCOPIST FATIGUE INCREASES: SECONDARY ANALYSIS OF TWO RANDOMIZED TRIALS

Z. Lu¹, L. Yao¹, L. Zhang¹, H. Yu¹

¹Renmin Hospital of Wuhan University, Gastroenterology, Wuhan, China

Contact E-Mail Address: 704941677@qq.com

Introduction: Ensuring high adenoma detection rate (ADR) is paramount in the prevention and prognosis of colorectal cancer (CRC). Endoscopist-related characteristics especially endoscopist fatigue had been proved to be an indispensable factor that related to decline ADR. Unfortunately, objective approaches to minimize the degradation of colonoscopy quality caused by endoscopists fatigue are still lacking. We further hypothesized that AI system may be an effective tool to address this challenge.

Aims & Methods: The aim of this study was to evaluate whether estimate of endoscopist fatigue at the time of the day was associated with ADR, and further evaluate whether the assistance of AI system overcome the inversely effect of endoscopist fatigue, based on secondary analysis of two randomized trials^{1,2}.

The AI group was defined as the combination of all intervention groups, including a computer-aided polyp detection (CADE) system and a computer-aided quality improvement (CAQ) system based on deep learning.

There's no intervention in the control group. We use time of the day as a surrogate of endoscopist fatigue. Colonoscopy procedure start time was therefore divided into two groups. The first group consisted of procedures commenced in the early session per half-day (08:00-11:00 or 13:00-15:00), which was defined as non-fatigue group, and the second group consisted of procedures commenced in the later session per half-day (11:00-13:00 or 15:00-17:00), which was defined as fatigue group. Adjusted odds ratio (OR) with 95 %CIs and corresponding P values were calculated.

Results: A total of 1780 patients were enrolled in this study, among which, 34.83% (620/1780) procedures were randomized into the control group, with 61.61% (382/620) performed at non-fatigue time and 38.39% (238/620) at fatigued time, and 65.17% (1160/1780) procedures were randomized into the AI group, with 61.38% (712/1160) performed at non-fatigue time and 38.62% (448/1160) at fatigued time. In the control group, the ADR at non-fatigue time was significantly higher compared with that of fatigued time (12.83% vs 6.30%, $P<0.05$).

With the assistance of AI systems, as expected, no statistically significant difference was found in the ADR between the non-fatigue and fatigue time (23.74% vs 20.76%, $P=0.238$), which demonstrated that AI systems could overcome the limitation of endoscopist fatigue during colonoscopy.

Furthermore, the assistance capabilities of AI systems were compared through OR values. The AI systems had higher assistance capabilities in fatigue group (OR=4.68, 95%CI: 2.66, 8.23) compared with non-fatigue group (OR=1.87, 95%CI: 1.32, 2.66), which demonstrated the potential benefit of using AI to improve the lower ADR during fatigue period.

Conclusion: In conclusion, our results suggest that later session per half-day, as a surrogate of endoscopist fatigue, was associated with decline ADR. Also, we found no such relationship between time of the day and adenoma detection after the assistance of AI systems, which indicating that the AI system has the potential to be an effective tool minimizing the inversely effect of endoscopist fatigue in colonoscopy.

P1041

LONG-TERM EFFECTIVENESS OF ARTIFICIAL INTELLIGENCE SYSTEM IN IMPROVING ADENOMA DETECTION RATE: A MULTICENTER SELF-CONTROLLED STUDY

Z. Lu¹, L. Huang¹, L. Wu¹, H. Yu¹

¹Renmin Hospital of Wuhan University, Gastroenterology, Wuhan, China

Contact E-Mail Address: 704941677@qq.com

Introduction: Colorectal cancer (CRC) is the third most common cancer worldwide. Adenoma detection rate (ADR) is a quality measure of screening colonoscopy and associated inversely with the risks of interval CRC. Artificial intelligence (AI) has been successfully applied to medicine and demonstrated its positive impact in colonoscopy. To date, the short-term effectiveness of AI system in increasing ADR had been demonstrated through randomized control trials. However, little is known about the long-term effectiveness of AI system in real clinical practice.

Aims & Methods: The aim of this study was to estimate the long-term efficacy of AI system for colonoscopy through multicenter self-control study. We constructed a real-time computer-aid system based on deep learning

for polyp detecting and withdrawal speed monitoring during colonoscopy. Colonoscopy procedures for screening, diagnostic, and surveillance were retrospectively collected from 6 hospitals between 2017 and 2021, including Renmin Hospital of Wuhan University (RHWU), Central Hospital of Wuhan (CHW), the First Hospital of Wuhan (FIRHW), the Fourth Hospital of Wuhan (FOURHW), the First People's Hospital of Yichang (FPHYC), Yichang Central People's Hospital (YCPH).

Pathological results were also collected except for CHW and FIRHW. The ADR and polyp detection rate (PDR) in these hospitals were compared before and after the use of the AI system.

Specially, the ADR and PDR in YCPH were compared between colonoscopy procedures with or without the assistance of AI system during the same time. A total of 7164 and 39160 colonoscopy procedures were collected without and with the use of the AI system in RHWU, respectively, and 12866 and 7508 in CHW, 10759 and 1911 in FIRHW, 4935 and 478 in FOURHW, 6390 and 10843 in FPHYC, 13660 and 7344 in YCPH, respectively.

Results: For adenoma detection, the ADR was significantly increased with the use of the AI system compared with that of without the use of it in RHWU (16.4% vs 9.5%, $P<0.001$), and FOURHW (3.8% vs 2.2%, $P<0.05$), FPHYC (2.7% vs 4.7%, $P<0.001$), respectively. In YCPH, the ADR was found increase from 7.80% without the use of the AI system to 7.98% with the use of it, but this didn't reach statistical significance ($P=0.667$).

For polyp detection, the PDR was significantly increase with the use of the AI system compared with that of without the use of it in RHWU (40.3% vs 29.1%, $P<0.001$), CHW (25.2% vs 30.4%, $P<0.001$), FOURHW (26.5% vs 42.5%, $P<0.001$), FPHYC (29.8% vs 34.9%, $P<0.001$), YCPH (30.6% vs 28.7%, $P<0.05$), respectively. However, no such relational was found in FOURHW (27.6% vs 27.4%, $P=0.890$).

Conclusion: The AI system significantly improved adenoma and polyp detection through long-term application and has the potential to improve the quality of colonoscopy in clinical practice.

Disclosure: Nothing to disclose.

CHOLANGIOSCOPY-GUIDED BIOPSY IN THE DIAGNOSIS OF INDETERMINATE BILIARY STRICTURES- DISAPPOINTING RESULTS AFTER 6 YEARS HARD WORK

P. Karagyozov¹, I. Zhecheva², I. Tishkov¹, K. Draganov²

¹Acibadem City Clinic Tokuda University Hospital, Department of Interventional Gastroenterology, Sofia, Bulgaria, ²Acibadem City Clinic Tokuda University Hospital, Sofia, Bulgaria

Contact E-Mail Address: petko.karagyozov@gmail.com

Introduction: Indeterminate biliary strictures remain a significant clinical problem despite the advancements of imaging modalities, endoscopy and biopsy techniques. By definition no tumor mass can be detected on imaging. Despite the high suspicion of malignancy the results of biliary forceps biopsy and/or brush cytology are negative or inconclusive. Most of the strictures are malignant but could be benign in up to 15% of cases. Precise diagnosis is crucial for the proper therapy.

Aims & Methods: To access the role of cholangioscopy-guided forceps biopsy in the diagnostic work-up of indeterminate biliary strictures.

Data were collected retrospectively from March 2016 to August 2021. All the patients with indeterminate biliary strictures underwent cholangioscopy with the SpyGlass DS System. After visual assessment of the stricture at least 4 biopsies were taken under direct visual control using the specially dedicated mini forceps.

Results: One hundred and eighty patients (n=180, 111 men, 69 women) underwent cholangioscopy for evaluation of indeterminate biliary strictures for the study period. The biliary stenosis were classified according

to the histology results as follows :72 malignant, 71 benign, 37 inconclusive for malignancy. Final diagnosis was made on the basis of definitive malignant histology, surgical findings, diagnostic laparoscopy or clinical follow-up of at least 6 months. Among the 71 patients with benign histology, the final diagnosis was changed to "malignant" in 50. Among the 37 patients with histology "inconclusive for malignancy", the final diagnosis was malignant in 35.

Conclusion: Despite the significant technological advancements in the cholangioscopy in recent years, making the procedure easier, more accessible and with very good image quality, further improvement of biopsy technique is needed. The biliary strictures still remain a diagnostic challenge for the pancreato-biliary endoscopist due to the low sensitivity of the visually guided sampling.

Disclosure: Nothing to disclose.

RISK FACTORS FOR POST-ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY PANCREATITIS (PEP) IN CHILDREN WITH CHRONIC PANCREATITIS AND ITS PREDICTION USING 4-HOUR POST-PROCEDURE SERUM AMYLASE AND LIPASE LEVELS

A. Samanta¹, S. Vadlapudi¹, A. Srivastava¹, S. Mohindra², U. Poddar¹, M. Sen Sarma¹, V. A. Saraswat²

¹Sanjay Gandhi Post Graduate Institute of Medical Sciences, Department of Pediatric Gastroenterology, Lucknow, India,

²Sanjay Gandhi Post Graduate Institute of Medical Sciences, Department of Gastroenterology, Lucknow, India

Contact E-Mail Address: arghyasamanta2905@gmail.com

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) has a reported incidence of 10-20% in children undergoing ERCP for any indication.^{1,2}

Literature on PEP in children with chronic pancreatitis (CP) is scarce. As PEP carries potential risk of morbidity and mortality, early PEP prediction would allow earlier detection and timely management. Serum amylase and lipase levels, measured at 4 hours post-ERCP, predict PEP with good sensitivity and specificity in adults.³ Literature regarding the same in children is not available.

Aims & Methods: This cross-sectional study was done to identify risk factors for PEP in children with CP and to assess the usefulness of 4-hour post-ERCP serum amylase and lipase levels for early PEP prediction.

Children with CP who were admitted and underwent ERCP between January 2021 and March 2022 were enrolled. The diagnosis of CP was according to INSPPIRE criteria.⁴ Definition and severity of PEP was classified according to the consensus criteria.⁵

Detailed history of previous and current ERCP procedures (prior ERCP and PEP, difficult cannulation [>5 attempts], endoscopic sphincterotomy, contrast injection, balloon dilatation, presence of pancreatic duct stone, pancreatic duct stent placement, etc) and complications were noted in a pre-designed proforma. Patients with PEP were given standard treatment as per protocol. Serum amylase and lipase levels before the procedure, at 4 hours and 24 hours after the procedure were measured.

Univariate and multivariate analysis was done to compare patients with and without PEP. The receiver operating characteristic (ROC) analysis was done to determine the predictive efficacy of 4-hour post-ERCP amylase and lipase levels for diagnosis of PEP.

Results: Total 62 ERCP procedures were done in 30 children (27 boys). Eight children had PEP. One child who underwent ERCP 3 times, had PEP twice. Thus, PEP occurred in 9(14.5%) out of 62 ERCP procedures (5 mild, 2 moderate, 2 severe). There was no mortality. In the univariate analysis, endoscopic sphincterotomy (p 0.04), difficult cannulation (p 0.004) and

prior PEP (p 0.036) were identified as risk factors while prior ERCP (p 0.04) was protective. In the multivariate analysis, difficult cannulation [Odds ratio 5.83, 95% confidence interval (CI) 1.329-25.592; p 0.008] was the sole independent risk factor for PEP (Table 1).

On ROC analysis, 4-hour post-ERCP serum amylase [area under the curve (AUC) 0.930, 95% CI 0.858-0.999, p < 0.001] and lipase level [AUC 0.948, 95% CI 0.890-0.998, p < 0.001] showed good test performance as predictor of PEP. A 4-hour serum amylase of 298 U/L [upper normal limit (UNL) 90 U/L] showed sensitivity of 90%, specificity of 84.2%, positive predictive value (PPV) of 50%, negative predictive value (NPV) of 98%, comparable to 4-hour serum lipase of 186 U/L (UNL 40 U/L; sensitivity 90%, specificity 89.5%, PPV 60%, NPV 98%).

Variables	ERCP sessions with PEP, n=9	ERCP sessions without PEP, n=53	Univariate p value	Multivariate p value	Adjusted Odds ratio (95% Confidence interval)
Prior ERCP	3/9(33.3%)	39/53(73.6%)	0.041	0.728	
Prior post-ERCP pancreatitis	2/9(22.2%)	2/53(3.7%)	0.036	0.698	
Endoscopic sphincterotomy	7/9(77.8%)	16/53(30%)	0.041	0.076	
Difficult cannulation (>5 attempts)	8/9(88.9%)	13/53(24.5%)	0.004	0.008	5.832 (1.329-25.592)
Minor papilla cannulation	2/9(22.2%)	7/53(13%)	0.907		
Pancreatogram	9/9 (100%)	53/53(100%)	1		
Stricture dilatation	7/9(77.8%)	37/53(70%)	0.638		
Pancreatic duct stent placement	7/9(77.8%)	37/53(70%)	0.386		
Pancreatic duct stone	6/9 (60%)	23/53(38.3%)	0.22		

Table 1: Logistic regression analysis of procedure-related risk factor for post-ERCP pancreatitis (PEP) in children with chronic pancreatitis.

Conclusion: PEP complicated 14.5% of ERCP procedures in children with CP. On multivariate analysis, difficult cannulation significantly increased risk of PEP. Post-ERCP 4-hour serum amylase and lipase have good sensitivity and specificity for predicting PEP early.

Contact E-Mail Address: martasfreitas@gmail.com

Introduction: The SARS-CoV-2 pandemic emerged in 2019 and conditioned the optimal timing of some endoscopic procedures. ESGE guidelines recommend replacement or removal of the plastic biliary stents within 3-6 months to reduce the rate of complications, mainly cholangitis.

Aims & Methods: Our aim was to analyse the outcomes of patients who had delayed plastic biliary stent removal following endoscopic retrograde cholangiopancreatography (ERCP).

We performed a retrospective study including consecutive patients submitted to ERCP with plastic biliary stent placement between January 2019 and December 2021. Delayed removal was defined as presence of biliary stent >6 months after ERCP. The evaluated outcomes were stent migration, stent dysfunction, hospitalization, obstructive jaundice, acute cholangitis, acute pancreatitis, and biliary pathology-related mortality.

Results: One-hundred and twenty patients were submitted to ERCP with plastic biliary stents placement, 56.7% were male, with mean age of 69.4±15.7 years. Indications for plastic biliary stent insertion were bile duct stones (72.5%), benign biliary stricture (20.0%) and post-cholecystectomy biliary fistula (7.5%), and did not differ between patients with or without delayed stent removal. Delayed stent removal occurred in 32.5% of the patients. The median time to stent removal was 3.5±1.3 (min 2, max 6) months for early removal and 8.6±3.1 (min 7, max 19) months for delayed removal.

Patients who had delayed stent removal did not have a significant higher frequency of stent migration (20.5 vs 11.1%, $p=0.17$), stent dysfunction (17.9 vs 13.6%, $p=0.53$), hospitalization (17.9 vs 14.8%, $p=0.66$), obstructive jaundice (2.6 vs 0.0%, $p=0.33$), acute cholangitis (10.3 vs 13.6%, $p=0.77$), acute pancreatitis (0.0 vs 1.2%, $p=1.0$), or biliary pathology-related mortality (2.6 vs 1.2%, $p=0.55$).

Conclusion: Delayed plastic biliary stent removal does not seem to have a negative impact on patients' outcomes. In the current pandemic situation, while scheduled endoscopic procedures may be delayed, replacement or removal of plastic biliary stents can be safely deferred.

Disclosure: No conflicts of interest.

THE ROLE OF PROPHYLACTIC OCTREOTIDE IN PREVENTING ERCP INDUCED PANCREATITIS

A. Garg¹

¹Vydehi Institute of Medical Sciences, Medical Gastroenterology, Bengaluru, India

Contact E-Mail Address: achal1210@gmail.com

Introduction: Post ERCP Pancreatitis (PEP) has been defined into 3 categories as mild, moderate and severe according to Revised ATLANTA Classification.

Octreotide is a synthetic somatostatin analogue with a longer half-life.

Similar to somatostatin, octreotide is a potent inhibitor of pancreatic enzyme secretion and effect on the contractility of sphincter of Oddi.

Aims & Methods: ESGE 2020 guidelines recommends that future studies to evaluate the efficacy of Octreotide in a dose ≥ 0.5 mg.

The present study is a Double Blinded Randomised Control Study which was carried out in the Department of Gastroenterology and a total of 150 patients were taken which were divided into 2 groups as Control group (N=74) receiving Normal Saline and Study group (N=76) receiving Octreotide.

2 ml of normal saline and octreotide were given according to respective groups subcutaneously 1 hour before procedure followed by 6 hour and 12 hours after ERCP and Serum Amylase and Lipase were measured along with clinical features. The following protocol was followed based on previous studies.

Results: The overall mean age of the study population including study and control group was 52 years.

Most common Indications for ERCP was Choledocholithiasis (50%) followed by malignant cause (30%), Benign Biliary Stricture (10-15%).

Clinical and Procedure related risk factors according to ESGE Guidelines were present in nearly 50-60%.

Hyperamylasemia was present in Study group in 36 patients (47.5%) and amongst Control group in 33 patients (45.7%).

Incidence of Post ERCP Pancreatitis was present in only 5% in study group and 11.4% in control group though statistically it was not significant ($p=0.47$).

Conclusion: Though, Hyperamylasemia was more in Study group but there is decrease in the incidence of Post ERCP pancreatitis in the group receiving octreotide, but the same was not statistically significant as compared with the control (5% vs 11.4%).

RADIATION DOSE OPTIMIZATION IN ERCP: PROSPECTIVE INTERVENTIONAL STUDY

C. Frias Gomes¹, B. Morão¹, C. Nascimento¹, J. Revés¹, E. Barjas¹, C. Gouveia¹, J. Cortez-Pinto¹, R. Loureiro¹, M.L. Gloria¹, A.O. Ferreira¹

¹Hospital Beatriz Ângelo, Gastroenterology, Loures, Portugal

Contact E-Mail Address: catarinagomes27@gmail.com

Introduction: Radiation exposure during endoscopic retrograde colangiopancreatography (ERCP) has led to major concerns in medical societies because of its potential harmful health effects, including increased cancer risk.

Aims & Methods: Our goal was to compare the radiation dose (RD) before and after introducing RD optimization procedures during ERCP (reducing the frameset and magnification; collimation use). An educational session on how to minimize radiation exposure was performed to doctors, nurses and radiologic technicians who are involved in ERCP.

Results: Overall, 162 patients were included (45 control group, 117 post-intervention group). In 52% (84/162) of the cases, the exam was performed by an experienced endoscopist, with the participation of a fellow or training nurse in 78% (127/162). The exams were difficult in 52% (84/162). The mean RD was not different between the two groups (2064 vs 1630 cGycm², p=0.34).

The post-intervention group had higher participation rates of a fellow or training nurse (89% vs 51%, p < 0.001). The RD was lower in the presence of an experienced endoscopist (1126 vs 1580 cGycm², p=0.01) and higher in difficult exams (1653 vs 987 cGycm², p<0.001).

In multiple linear regression, no difference was found between the two groups (B=-171, p=0.67). A more difficult exam (B=1184, p=0.001) and lower endoscopist experience (B=845, p=0.01) were associated with higher RD. The participation of a fellow or training nurse did not influence RD (B=-203, p=0.63).

Conclusion: No difference was found in RD between the two groups, but difficult exams and lower endoscopist experience were associated with higher RD.

WIRE-GUIDED CYSTOTOME DILATATION OF DIFFICULT BENIGN BILIO-PANCREATIC STRICTURES: SINGLE CENTER EXPERIENCE

O. Ksissa¹, L. Dioscoridi¹, E. Forti¹, F. Pugliese¹, M. Cintolo¹, G. Bonato¹, M. Bravo¹, A. Palermo¹, M. Mutignani¹

¹Niguarda-Ca' Granda Hospital, Endoscopy Unit, Milan, Italy

Contact E-Mail Address: kramo89@hotmail.it

Introduction: Usually, benign biliary and pancreatic strictures are dilated endoscopically by using standard devices over a guidewire (such as Soehendra dilator or dilatation balloons) preliminary to place a stent (plastic or metal stent).

Sometimes these techniques fail to overpass the stricture. In these cases, difficult strictures can be managed using other devices (Soehendra screw/cystotome). We report our experience in the use of cystotome for the treatment of difficult strictures.

Aims & Methods: Data were collected from October 2018 to December 2021 and 12 consecutive patients were included (5 males, 7 female; mean age 53 years old).

Total Nr Cases	12
• Males	5 (42%)
• Females	7 (58%)
Age	53 years (mean); range 24-83
Biliary strictures	7 (58%)
• Post surgery	5
• Chronic flogosis	2
Pancreatic strictures	5 (42%)
• Chronic pancreatitis	4
• Post surgery	1

Table 1. Patients characteristics.

Results: Of the 12 patients, 7 had difficult biliary and 5 difficult pancreatic strictures. The treatment using cystotome was successful in 11 patients and allowed to place a stent. Nobody developed major post-procedure adverse events.

Conclusion: The use of a cystotome can be considered an alternative method for dilation of difficult pancreatic and biliary strictures, after the failure of conventional modalities.

Introduction: Endoscopic papillectomy (EP) for duodenal ampullary tumors is rare. Thus, there is insufficient information. Gradually, procedural details regarding EP have been established. However, most clinical reports have been small case series, complicating success rate and complication frequency analyses. Therefore, we conducted a large-scale retrospective multicenter study to clarify the outcomes of EP.

Aims & Methods: We retrospectively collected data on the backgrounds, procedure details, and outcomes of patients with an ampullary tumor who underwent EP at 22 institutions between January 2009 and December 2019. Then, we analyzed the endoscopic complete resection, en bloc resection, adverse events (AEs), clinical success, and overall recurrence rates. Clinical success was defined as endoscopic complete resection without remnant recurrence after one year.

Results: We included 890 patients with a median age of 66 (range, 58–73) years; 534 patients were men (60 %), and 48 had familial adenomatous

polyposis (9.3 %). The median lesion size was 14 (range, 10–20) mm. There were 812 pathological adenoma and adenocarcinoma cases, and the endoscopic complete resection rate was 94.6 %, the en bloc resection rate was 84.7 %, and the R0 resection rate was 44.0%. Furthermore, the pathological negative vertical margin, negative horizontal margin, and negative ductal margin rates were 65.6 %, 68.5 %, and 82.5 %, respectively. Overall, 23.8 % of the patients experienced AEs, 19.4 % experienced delayed bleeding, 13.6 % had pancreatitis, 2.1 % had cholangitis, 2.0 % had perforation, and 2.3 % had bile duct stricture, and 2.4 % had pancreatic stricture; one patient died from procedure-related complications. The clinical success rate was 85.2 %, and the overall recurrence rate was 17.2 % (n = 140). In total, 102 and 35 patients required additional endoscopic treatment or surgical resection, respectively. Multivariate analysis determined that bile duct invasion (odds ratio [OR]: 0.40, p = 0.046), adenocarcinoma component (OR: 0.367, p < 0.0001), pathological R0 resection (OR: 6.2, p < 0.0001), and en-block complete resection (OR: 2.8, p < 0.0001) were independent factors for clinical success without remnant recurrence.

Conclusion: EP is feasible and suitable owing to its high clinical success rate. However, the incidence of complications and remnant recurrence is high, which is cause for concern.

Disclosure: Nothing to disclose.

P0928

ERCP IN PATIENTS WITH ROUX-EN-Y RECONSTRUCTION AFTER GASTRECTOMY: A SINGLE-CENTER OBSERVATIONAL STUDY

A. Palermo^{1,2}, L. Dioscoridi¹, E. Forti¹, F. Pugliese¹, M. Cintolo¹, G. Bonato¹, M. Bravo¹, O. Ksisa¹, M. Mutignani¹

¹ASST Grande Ospedale Metropolitano Niguarda, Digestive and Interventional Endoscopy Unit, Milan, Italy, ²Università degli Studi di Milano Bicocca, Medicine & Surgery, Milan, Italy

Contact E-Mail Address: a.palermo21@campus.unimib.it

Introduction: Roux-en-Y reconstruction after gastrectomy is generally challenging for performing therapeutic ERCP. Principal issues are the difficulty in reaching the papilla and the cannulation in not-standard orientation.

Aims & Methods: This is a retrospective cohort study of consecutive patients with total and subtotal gastrectomy and Roux-en-Y reconstruction (without biliary anastomosis) who underwent ERCP from February 2019 to March 2022 at a tertiary endoscopy center. Use of pediatric colonoscope with or without see-through cap on the tip was the standard method. Alternative approach was EUS-guided approach. Technical success meant as reaching and cannulation of the papilla and clinical success intended as resolution of the indication for ERCP were evaluated as primary outcomes.

Results: Thirty patients with Roux-en-Y reconstruction after gastrectomy underwent ECRP (15 M, 15 F, age 74.5 ± 8.9 yr). Twenty patients underwent subtotal gastrectomy (67%), while the remaining 10 underwent total gastrectomy (33%). ERCP was performed previously to surgery in 10% of patients (3/30).

ERCP indications included common bile duct stones/intrahepatic stones in 67% (20/30), undetermined biliary strictures in 10% (3/30), biliary leak after cholecystectomy in 10% (3/30), chronic pancreatitis in 6.5% (2/30), acute cholangitis in 6.5% (2/30).

In all cases, a forward-viewing pediatric colonoscope was used, with a cap mounted on the tip in 40% of the cases (12/30).

Overall technical success was 84% (25/30). The papilla was reached retrogradely in 60% (18/30) of the cases, and the access to common bile duct/main pancreatic duct was performed using a ball-tip and straight hydrophilic guidewire. Needle knife sphincterotomy in 72% (13/18) and

endoscopic papillary balloon dilation in 28% (5/18) of the cases were subsequently performed. In 23% (7/30) of cases, EUS-guided ERCP was performed: in 57% of cases (4/7), ERCP was conducted anterogradely through hepatico-gastric access; in the remaining 43% (3/7), the papilla was reached across endoscopic entero-enteral bypass [Mutignani et al., 2019]. Technical insuccess was due to impracticability of a EUS-guided trans-gastric access in 3 cases or cannulation failure in the remaining two cases.

Clinical success was achieved in 100% of treated cases (25/25). Bile duct stones extraction was performed in 13 patients; biliary stenting was made using fully covered self-expandible metal stents in 4 cases or plastic stent in one case; plastic pancreatic stents were placed in 3 cases; double pig-tail cholecystic plastic stents were positioned in 3 cases; a naso-gallbladder drainage in one patient.

Adverse events were observed in 7% (2/30) of the patients: one case of post-ERCP pancreatitis, and another case of acute cholangitis.

Conclusion: ERCP in patients with Roux-en-Y reconstruction after gastrectomy remains a challenge and endoscopic multimodal approach may be the key to achieve the best clinical outcome.

Introduction: Hepatic hydatid cyst usually runs asymptotically, while clinical symptoms, are usually due to complications that supervene. The most commonly encountered complication is rupture into the biliary tree with secondary biliary obstruction by intracystic material or cholangitis

Aims & Methods: The objective of our study is to evaluate the contribution of endoscopic retrograde cholangio-pancreatography (ERCP) in the diagnostic and particularly therapeutic management of ruptured liver hydatid cysts in the bile ducts.

Retrospective descriptive and analytical study, from January 2002 to August 2021, which included 50 patients with a hydatid cyst fistulized in the bile ducts. ERCP and endoscopic sphincterotomy were performed in all patients. Overall success was defined by definitive vacuity of the main bile duct.

Results: Among the ERCPs performed in our department during the study period, 4.6% (n = 50) were for a hepatic hydatid cyst communicating with the bile ducts.

The mean age was 46.1 ± 14.8 years with a male predominance of 66%.

For our 50 patients included in the study, ERCP was performed in 52.2% of cases preoperatively, and in 47.8% postoperatively.

ERCP was indicated for acute angiocholitis in 44.9% and persistent external biliary fistula in 34%.

The median bile duct diameter was 10[7-14]mm and the median cyst diameter was 35[27-47].

Sphincterotomy was performed in 96% of patients allowing extraction of hydatid material by balloon or Dormia in 87.8%. Nevertheless 24% required naso-biliary drainage and 8% benefited from biliary prosthesis placement.

The overall success rate was 96% (n=46). The immediate complication rate was 8%(n=4), 1 patient had hemobilia and 3 patients had edge bleeding.

The evolution was marked by the disappearance of jaundice after 5 to 10 days and by the drying up of the external biliary fistula after 10 days.

Conclusion: Our study confirms that endoscopic treatment of ruptured hydatid cyst in the bile ducts is an effective therapeutic alternative, with a low rate of immediate complications and a good long-term evolution.

SECONDARY SCLEROSING CHOLANGITIS IN PATIENTS WITH COVID-19 ARDS - A CLINICAL-ENDOSCOPIC ANALYSIS

P. Göggelmann¹, V. Pavel¹, S. Schmid¹, P. Dobsch¹, I. Zuber-Jerger¹, M. Müller-Schilling¹, A. Kandulski¹

¹University Hospital Regensburg, Internal Medicine I, Gastroenterology, Endocrinology, Rheumatology, Infectiology, Emergency Medicine, Regensburg, Germany

Contact E-Mail Address: pavel_vlad2008@yahoo.com

Introduction: The SSC-CIP (sclerosing cholangitis in critically ill patients) is a separate entity of SSC in patients with long intensive care stay. Hypotension and prolonged vasopressor therapy are discussed as risk factors. In the context of the COVID-19 pandemic, an increased prevalence of SSC-CIP was seen at our center, especially in the second and third pandemic "waves", which made an intervention using endoscopic retrograde cholangiography (ERC) necessary.

Aims & Methods: The aim of the study was to analyse the clinical, laboratory, microbiological and endoscopic findings and therapies of patients with SSC-CIP and COVID-19 ARDS in association with the clinical course. Retrospectively, the data of 15 patients who were treated by ERC in the Clinic and Polyclinic for Internal Medicine I at the University Hospital Regensburg between February 1st, 2020 and February 1st, 2022 due to SSC-CIP on the basis of a COVID-19 ARDS were analyzed. The focus was on the endoscopic findings, the laboratory values at the time of the initial diagnosis and the microbiological results.

Results: 12 male and 3 female patients were included in the analysis. The mean age was 61 years (range 40-76). All patients had COVID-19 ARDS and were mechanically ventilated. All required catecholamines.

On average 2.4 ERCs were performed. Biliary casts were found in all patients and rarefaction of the intrahepatic bile ducts in 60%. Bile duct stenosis could only be detected in 3 patients. The casts were therapeutically extracted and the stenoses dilated.

9 patients died within the study period. 6 patients are in follow-up with repeated endoscopic intervention and close re-evaluation with regard to a future liver transplantation.

Conclusion: The mortality rate in patients who develop SSC-CIP as part of a COVID-19 infection is high. Endoscopic treatment may improve temporarily liver function, however these patients must be evaluated for liver transplantation.

Disclosure: Nothing to disclose.

OUTCOMES OF ENDOSCOPIC DRAINAGE IN CHILDREN WITH PANCREATIC FLUID COLLECTIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Z. Nabi¹, R. Talukdar¹, S. Lakhtakia¹, D.N. Reddy¹

¹Asian Institute of Gastroenterology, Gastroenterology, Hyderabad, India

Contact E-Mail Address: zaheernabi1978@gmail.com

Introduction: Endoscopic drainage is an established treatment modality in adult patients with pancreatic fluid collections (PFCs). There is limited data regarding the efficacy and safety of endoscopic drainage in pediatric cases.

Aims & Methods: In this systematic review and meta-analysis, we aim to analyze the outcomes of endoscopic drainage in children with PFCs. Literature search was performed in Embase, PubMed, Google scholar for studies evaluating the outcome of endoscopic drainage with or without endoscopic ultrasonography (EUS) guidance in pediatric PFCs from inception to May 2021. Primary objective of the study was clinical success defined as resolution of PFCs. Secondary outcomes included technical success, adverse events and recurrence rates.

Results: 14 studies (187 children, 70.3% boys) with pooled mean age of 11.7 years (95%CI 10.2-13.2 years) were included in the review. The subtypes of fluid collection included pseudocysts in 60.3% and WON in 39.7%. Endoscopic drainage of PFCs were performed with and without EUS guidance in ten and three studies, respectively. The most common route for drainage was trans-gastric (n=139) followed by trans-esophageal (n=4) and trans-duodenal (n=2). The type of stent used for endoscopic transmural drainage were reported in ten studies including one or more plastic stents in six, either plastic or metal stent in three, and exclusively metal stents in one study.

The pooled technical success rates in studies performing drainage of PFCs with and without EUS guidance were 95.3% (95% CI 89.6 - 98%; $I^2=0$) and 93.9% (95% CI 82.6 - 98%; $I^2=0$), respectively. The pooled clinical success after one and two endoscopic interventions was 88.7% (95% CI 82.7 - 92.9%; $I^2=0$) and 92.3% (95% CI 87.4% - 95.4%; $I^2=0$), respectively.

The pooled mean follow-up after endoscopic drainage reported in ten studies was 26.6 months (95% CI 20.9 - 32.3 months; $I^2=78\%$). The pooled rate of recurrent PFCs after endoscopic drainage was 10.4% (95% CI 6.1 - 17.1%; $I^2=0$). The pooled rates of overall and major adverse events were 16.8% (95% CI 9.8% - 27.2%; $I^2=28.6\%$) and 6.3% (95% CI 3.3%-11.4%; $I^2=0$), respectively.

Conclusion: Endoscopic drainage is a safe and effective procedure in selected children with PFCs. Future studies are required to compare endoscopic versus EUS guided drainage of PFCs in children.

Disclosure: Nothing to disclose.

Introduction: Intraparenchymal lung masses inaccessible through bronchoscopy or endobronchial ultrasound guidance pose a diagnostic challenge.

Furthermore, some fragile or hypoxic patients may be poor candidates for transbronchial approaches. Endoscopic ultrasound-guided fine-needle aspiration/biopsy (EUS-FNA/FNB) offers a potential diagnostic approach to lung cancers adjacent to the esophagus.

Aims & Methods: We aimed to evaluate the feasibility, accuracy, and safety of trans-esophageal EUS-FNA/FNB for tissue sampling of pulmonary nodules. We retrospectively analyzed data from patients with pulmonary lesions who underwent EUS-FNA/FNB between March 2015 and August 2021 at eight Italian endoscopic referral centers.

Results: A total of 47 patients (36 males; mean age 64.47 ± 9.05 years) were included (22 EUS-FNAs and 25 EUS-FNBs). Overall diagnostic accuracy rate was 88.9% (76.3%-96.2%). The sensitivity and diagnostic accuracy were superior for EUS FNB sampling versus EUS-FNA (100% vs 78.73%); $p = 0.05$, and (100% vs 78.57%); $p = 0.05$ respectively. Additionally, sample adequacy was superior for EUS FNB sampling versus EUS-FNA (100% vs 78.5%); $p = 0.05$.

Multivariate logistic regression analysis for diagnostic accuracy showed nodule size at the cut-off of 15 mm (OR 2.29, 1.04-5.5, $p = 0.05$) and use of FNB needle (OR 4.33, 1.05-6.31, $p = 0.05$) as significant predictors of higher diagnostic accuracy. There were no procedure-related adverse events.

Conclusion: This study highlights the efficacy and safety of EUS-FNA/FNB as a minimally invasive procedure for diagnosing and staging of periesophageal parenchymal lung lesions. The diagnostic yield of EUS-FNB was superior to EUS-FNA.

Disclosure: Nothing to disclose.

Introduction: Endoscopic ultrasound-guided fine needle core biopsy (EUS-FNB) is currently the procedure of choice to obtain samples to reach the definitive diagnosis of lesions of the gastrointestinal tract and of surrounding organs. It has the advantage of providing well preserved tissue for histologic grading and subsequent molecular biological analysis.

Aims & Methods: The aim of this study was to assess the performance of EUS-FNB using a new needle with multi-blade three-prong tip for histologic diagnosis of lesions, accessible for endoscopic ultrasound-guided biopsy. Data was collected retrospectively from April 2021 to October 2021. All the patients underwent endoscopic ultrasound with a linear scope (Fujifilm EG-580UT) and fine needle biopsy using a new needle with multi-blade three-prong tip-22G Trident™ (Micro-Tech Endoscopy).

Results: Forty nine patients (24 men, 25 women) underwent EUS-guided biopsy during the study period. Pancreatic ductal adenocarcinoma was proven in 25. Only 2 patients with solid pancreatic lesions had false negative histology. Gastric adenocarcinoma(after negative forceps biopsy) was proven in 2. Metastatic paraesophageal lymph nodes were proven in 6. Liver metastasis from pancreatic cancer were proven in 2. Gastric, esophageal and colonic GIST were proven in 7 patients. Gastric lipoma was proven in 1. Benign pancreatic lesions (pseudocysts) were proven in 2. Mediastinal lymphoma was proven in 2. Median number of needle passes was 3,45 (2-5).

No complications were observed during the first 48 hours and after 30 days follow-up. The procedure yielded tissue for histologic diagnosis in 95,92% of cases. Imunochemical analysis was possible in all where needed.

Conclusion: Endoscopic ultrasound-guided fine needle biopsy using the new needle with multi-blade three-prong tip is safe and highly effective. Histologic diagnosis is possible in nearly 100% in all accessible areas.

Disclosure: Nothing to disclose.

ENDOSCOPIC ULTRASONOGRAPHIC FINDINGS OF SUBEPITHELIAL LESION IN THE UPPER GASTROINTESTINAL TRACT WITH AN INCREASE IN SIZE

S.Y. Cho¹, D.H. Kim¹, H.-S. You¹, C.H. Park¹, H.-S. Kim¹, S.K. Choi¹, S.-Y. Park¹

¹Chonnam National University Hospital, Division of Gastroenterology, Department of Internal Medicine, Gwangju, Korea (Republic of)

Contact E-Mail Address: chouseyeon@hanmail.net

Introduction: Endoscopic ultrasonography (EUS) is beneficial modality for evaluating subepithelial lesion (SEL) in the upper gastrointestinal (GI) tract¹. It can provide useful information such as size, layer of origin, echo-

genicity and specific foci of SEL². One of the most worrisome characteristics of SEL is its large size³. Therefore, it is helpful to predict an increase in size of SEL in deciding proper follow-up and management strategy.

Aims & Methods: We aimed to figure out EUS findings of SEL with an increase in size at the first examination. Medical records of 2539 patients with SEL in the upper GI tract (esophagus, stomach, duodenum) detected in our hospital between 2004 and 2016 were reviewed retrospectively. We analyzed 672 of SELs which were evaluated by EUS at the first detection and were followed-up over at least 36 months.

We evaluated size, echogenicity, border, anechoic foci, calcification, deep attenuation, septation and involving layer of SEL on EUS. The size of SEL was measured by visual estimation compared to size of biopsy forceps. We defined 'an increase in size' as 25% increase in the longest diameter of SEL. We performed Cox proportional hazards regression and controlled relevant variables in a regression analysis.

Results: SEL in the esophagus accounted for 22.6% (152/672), 64.0% (430/672) of SEL was in the stomach and 13.4% (90/672) of SEL was in the duodenum. Mean initial diameter of SEL was 10.7±4.1mm (range, 3–20 mm). During the mean follow-up period of 68 months (range, 36–190months), 14.4% (97/672) of SEL showed an increase in size.

There was a difference in age (age 56.8±10.6 VS 54.2±10.6, P=0.03) and initial size (11.7±4.2mm VS 10.5±4.1mm, P=0.01) at the time of diagnosis of SEL in the upper GI tract between a group with an increase in size and a group without an increase in size. An increase in size of SEL was more frequently observed in the stomach than in the esophagus and duodenum (P<0.01).

Cox regression analysis showed that homogeneity of echo, border, septation and deep attenuation of SEL are not related to an increase in size. Anechoic foci and calcification of SEL are negatively correlated with an increase in size and deep involving layer (4th layer) is positively correlated with an increase in size.

Variables	Crude odds ratio	95% CI	P-value	Adjusted odds ratio	95% CI	P-value
Age	1.039	1.018-1.061	<0.001	1.039	1.018-1.061	<0.001
Initial diameter in EUS	1.126	1.074-1.181	<0.001	1.112	1.063-1.164	<0.001
Homogeneity (Homogenous/Heterogenous)	Reference/1.146	0.475-2.764	0.762			
Border (Indistinct / Distinct)	Reference/0.793	0.289-2.173	0.652			
Anechoic foci	0.381	0.122-1.189	0.096	0.326	0.129-0.827	0.018
Calcification	0.306	0.092-1.012	0.052	0.297	0.093-0.949	0.040
Deep attenuation	0.514	0.121-2.189	0.368			
Septation	0.444	0.153-1.287	0.135			
Involving layer (Superficial: 1~3rd layer/ Deep:4th layer)	Reference/1.644	1.038-2.604	0.034	1.870	1.212-2.884	0.005

Table.

Conclusion: SEL in older age, with larger initial size and in the stomach tends to show an increase in size. Also, SEL involving deep layer, absence of anechoic foci and absence of calcification on EUS is more likely to increase in size. Therefore, short-term follow-up and endoscopic or surgical management have to be considered in upper GI SEL presenting such characteristics on EUS.

SAFETY AND EFFICACY OF ENDOSCOPIC CONVENTIONAL CYANOACRYLATE GLUE VS EUS-GUIDED COIL PLUS CYANOACRYLATE TECHNIQUE IN THE TREATMENT OF GASTRIC VARICES: A RANDOMIZED CONTROLLED TRIAL (NCT05038319)

T.S.A. Satya Maharshi¹, J. Basha¹, R. Gupta¹, S. Lakhtakia¹, R. Yarlagadda¹, M. Ramchandani¹, Z. Nabi¹, N. Jagtap¹, P. Pal¹, M. Vamsi Turpati¹, S. Asif¹, D. Nageshwar Reddy¹

¹Asian Institute of Gastroenterology, Hyderabad, India

Contact E-Mail Address: maharshi2059@gmail.com

Introduction: Gastric varices are typically treated by Endoscopic injection of cyanoacrylate glue. Various complications have been described related to this treatment, with systemic embolism being the most severe. Endoscopic Ultrasound (EUS) offer a unique opportunity to directly visualize and access gastric varices for the treatment.

Aims & Methods: Aim: This was a randomized controlled trial (RCT) to compare the safety and efficacy of Endoscopic conventional Cyanoacrylate injection technique to the EUS guided coil with cyanoacrylate injection for the treatment of gastric varices.

Methods: This RCT was done at a large tertiary care center from 1st February 2020 to 31st August 2021. Patients with gastric varices requiring endoscopic treatment constituted the study population and were randomized into 2 groups (Group A & B).

Group A patients received standard endoscopic treatment with injection of a cyanoacrylate and Group B patients received EUS-guided coils deployment and cyanoacrylate injection.

Patients were assessed for immediate complications including bleeding, embolism, pain. A Contrast CT scan of the Chest was performed in all the patients post procedure to detect any evidence pulmonary embolism. Patients were followed at 1, 3 and 6 months.

The Primary outcome was to compare the occurrence of pulmonary embolism between the 2 groups. Secondary outcome was to evaluate the efficacy of the 2 techniques in the complete obliteration of the varices, rebleed rates and reinterventions required in both the groups.

Results: In this RCT, a total of 34 patients were enrolled and 17 patients were included in each group. Pulmonary embolism was documented on CECT Chest, in 3 (17.6%) patients in group A and in only 1 (5.8%) patient in group B ($p=0.591$). All cases of embolism were asymptomatic. Though there was no significant difference between the 2 groups, a greater tendency towards embolism was observed in the group A.

Of the 16 patients in group A, 10 (62.5%) had complete obliteration at 1 month, whereas 15 (93.75%) had complete obliteration of the gastric varices in group B ($p=0.03$).

In group A, 7 (43.75%) required reintervention on follow up due to incomplete obliteration, whereas in group B, only 1 out of 16 (6.25%) required reintervention ($p=0.03$). In group A, 2 (12.5%) had rebleed at 3 months follow up whereas in group B, none of the patient had rebleed ($p=0.144$). The

mean quantity of cyanoacrylate required for varix obliteration was found to be significantly lower in group B when compared to group A (1.18 ± 0.39 ml vs. 2.47 ± 0.71 ml; $p=0.001$).

Outcome measures	Group A (n=17) (Endoscopic Glue)	Group B (n=17) (EUS Coil + Glue)	P value
Primary outcome			
Pulmonary embolism	3/17 (17.6%)	1/17 (5.8%)	P=0.59
Secondary Outcomes			
Complete obliteration of varix at 1 month	10/16 (62.5%)	15/16 (93.75 %)	P=0.03
Overall Rebleeding	2/16 (12.5 %)	0/15 (0%)	P=0.14
Overall Reintervention	7/16 (43.75%)	1/16 (6.25%)	P=0.01

Conclusion: EUS-guided coil and cyanoacrylate injection was highly effective in obliteration of gastric varices and reducing the need for reinterventions when compared to conventional endoscopic cyanoacrylate injection. Also, the risk of embolism with EUS guided treatment was low when compared to Endoscopic treatment, though the difference was not statistically significant.

Disclosure: Nothing to disclose.

Introduction: Endoscopic ultrasound (EUS) guided elastography allows the evaluation of tissue stiffness. It is considered a very useful tool in the differential diagnosis of solid pancreatic tumors.

Aims & Methods: The aim of our study was to evaluate the accuracy of EUS-guided elastography to confirm malignancy of solid pancreatic tumors in clinical routine.

Material and Methods: Analysis of a prospective EUS registry at the University Hospital of Santiago de Compostela, Spain, of patients who underwent EUS-guided elastography for the evaluation of a solid pancreatic tumors between 2008 and 2020. Patients with a definitive histological diagnosis (based on cyto-histological findings of biopsy and/or surgical specimens) were identified and included in the study. EUS-guided elastography was performed with linear Pentax echoendoscopes and Hitachi systems. Elastographic patterns were evaluated, defining hard lesions (blue predominant pattern) as malignant. Sensitivity, specificity, positive and negative predictive value, and overall diagnostic accuracy for malignancy were calculated.

Results: 864 patients were finally included, mean age 67.7 ± 12.3 years, 486 males (56.3%). Mean size of pancreatic tumors was 34.2 ± 13.8 mm (range 6-112). 511 tumors (59.1%) were located in the head of the pancreas, 263 (30.4%) in the body, 64 (7.4%) in the tail and the remaining 26 (3.01%) in the uncinate process. Final diagnosis was a malignant tumor in 746 patients (86.5%) and a benign lesion in 116 (13.5%).

Sensitivity, specificity, positive and negative predictive value, and overall diagnostic accuracy for determining malignancy was 98.5%, 86.8%, 98%, 90% y 97%, respectively.

Conclusion: EUS-guided elastography is a very useful tool for the evaluation of solid pancreatic tumor, allowing the confirmation or exclusion of malignancy with a very high accuracy.

Introduction: Endoscopic ultrasound (EUS)-guided tissue acquisition is an accurate technique for the diagnosis of solid focal lesions from different locations. Current clinical guidelines have included solid liver lesions (SLL) as an accepted indication for this method.

Aims & Methods: Aim of our study was to analyze the diagnostic yield of EUS-guided tissue acquisition for the pathological evaluation of SLL.

Material and Methods: Patients who underwent EUS-guided tissue acquisition (fine needle aspiration –FNA– or biopsy –FNB–) for the evaluation of SLL between January 2013 and March 2021 were identified from a prospective EUS registry. EUS and EUS-guided tissue acquisition were performed with linear Pentax echoendoscopes and Hitachi systems.

Sampling was performed with cytological (FNA) and/or histological (FNB) needles. Samples were analyzed on-site by an expert pathologist (FNA) or collected in a cytological solution (Cytolit®) and processed for histological evaluation (FNB). Data are shown as mean and/or percentage as appropriate. Indications, number of needle passes, complications and diagnostic accuracy were evaluated using the histopathological analysis of the surgical specimen or the clinical-radiological evaluation and a minimum follow-up of 6 months in non-operated patients, as gold standard.

Final Diagnosis	Number of cases (correct diagnosis base on EUS-guided tissue acquisition)
Metastasis:	
adenocarcinoma of unknown origin	6 (6)
pancreatic cancer	43 (39)
gastric cancer	8 (8)
lung cancer	15 (14)
neuroendocrine tumor	11 (10)
colo-rectal cancer	8 (7)
biliary tumor	9 (7)
others	7 (4)
Liver cell carcinoma	3 (2)
Benign lesions	4 (4)

Table.

Results: 114 patients (mean age 68.05 years, range 32-88, 64 males) were included. Mean size of SLL was 25.0 mm (range 9-60 mm). Cytological needles were used in 43 cases (37.7%) [22-gauge in 19 cases and 25-gauge in 24]; and histological needles in 71 (62.3%) [19-gauge in 4 cases, 20-gauge in 5, 22-gauge in 37 and 25-gauge in 25]. An adequate sample for the cyto-histological evaluation was obtained in all cases (100%) after a mean of

1.4 passes (range 1-4). In 27 cases (23.7%) FNA samples were evaluated on-site by the pathologist. Table shows the final diagnosis and cases correctly diagnosed by FNA/FNB.

Sensitivity, specificity, and overall accuracy of EUS-guided tissue sampling was 89.1%, 100% and 89.5%, respectively. There was only one minor complication (self-limited mild bleeding at the puncture site).

Conclusion: EUS-guided tissue acquisition is a safe and accurate method for the cyto-histological diagnosis of SLL.

Introduction: Large rectal lesions can conceal submucosal invasion and cancer nodules. Despite the increasing diffusion of high-definition endoscopes in the Western countries and the importance of an accurate morphological evaluation, a complete assessment in this setting can be challenging.

Endoscopic ultrasound (EUS) plays an established role in the locoregional staging of rectum cancer although with a tendency to an over-estimation of the loco-regional (T)-staging. However, there are still few data on the possible use of contrast-enhanced endoscopic ultrasound (CH-EUS), especially if this ancillary technique may increase the accuracy for predicting invasive nodules among large rectal lesions.

Aims & Methods: We performed a case series of consecutive large (≥20 millimeters) superficial rectal lesions assessed by CH-EUS.

Results: From January 2020 to December 2021 we evaluated eight cases with high-definition endoscopy, characterized by focal areas suggestive for V type according to Kudo Classification. All lesions corresponded to sessile or Granular Lateral Spreading Tumors (LST-G), mixed type or not granular (LST-NG) according to Paris Classification, with size ranging from 30 to 180 mm.

We performed EUS using II generation contrast agent.. Six cases, corresponding to invasive pattern at CH-EUS, were treated with surgery, confirmed as pT2 at final staging. Two cases, with non-invasive pattern at CH-EUS, underwent to curative endoscopic submucosal dissection (ESD) corresponding to pT1a tumors.

Conclusion: CH-EUS can provide additional information for the characterization of rectal superficial lesions with focal areas suggestive for invasive cancer, by improving the performance of EUS in T1 staging.

SELECTIVE TISSUE SEPARATION IMPROVES DIAGNOSTIC YIELD OF EUS GUIDED TISSUE ACQUISITION

S. Akerkar¹, R.F. Havre^{1,2}, K.D.-C. Pham¹, Bergen Research Group for Advanced Gastrointestinal Endoscopy (BRAGE)

¹Haukeland University Hospital, Medicine, Bergen, Norway,

²University of Bergen, Department of Clinical Medicine, Bergen, Norway

Contact E-Mail Address: ramaker.birr@gmail.com

Introduction: Endoscopic Ultrasound-guided fine-needle aspiration (EUS-FNA) has been the primary method to obtain cellular material for cytopathological diagnosis in mural lesions, lymph nodes, and tumors along the GI tract¹.

The efficacy of EUS-FNA depends on the site, size, and characteristics of the target tissue as well as the experience of the endosonographer, and the availability of an on-site cytopathology service^{2,3}.

Fine-needle biopsy (FNB) needles are designed to take core samples. Even though the diagnostic yield might have improved with FNB needles, there is still a high miss rate⁴.

One of the challenges with EUS-FNA and FNB is the risk of either non-conclusive or false-negative results, and the procedure must be repeated to procure conclusive biopsy.

Aims & Methods: At our institution, we have previously prepared the tissue samples in 70% ethanol and 3-6 cellular smears that were preserved with fixation buffer spray. From 2018, however, we changed our approach by manually selectively separating the solid fragments of the specimens into formalin aldehyde for histology, and the non-solid materials in a methanol-based fixative for cytology, which also allows the creation of cell block. This manual selective tissue separation (STS) technique has not been previously reported for EUS-guided sampling. In this study, we compared patients who underwent EUS-FNA/FNB in 2017 and 2020. Patients who had cystic lesions were excluded from the study.

We retrospectively registered the relevant parameters from the electronic patient journal (EPJ) including the cytology and histology reports. The aim was to compare the diagnostic accuracy of EUS guided tissue sampling in solid lesions in two time periods before and after the introduction of STS and the methanol-based fixation agent.

Results: During 2017, we performed 117 EUS-FNA and FNB procedures out of which 97 (83%) were for solid lesions. In 2020, 120 out of 130 EUS-FNA and FNB procedures were for solid lesions (92%). The patient's average age in 2017 was 66.7 years, while it was 63.9 years in 2020.

Among patients in 2017, 36 (37.1%) were female and 61 (62.9%) were male while in 2020, 47 (39.2%) were female and 73 (60.8%) were male. In 2017, 32 (33%) procedures were performed using FNA needles while 64 (66%) used FNB needles. In 2020, 41 (34.2%) procedures were performed using FNA needles while 79 (65.8%) used FNB needles ($p=0.90$). The mean number of needle passes during EUS-FNA in 2017 was 2.56 (SD 0.89), while in 2020 it was 2.21 (SD 0.67) ($p=0.001$). Rapid on-site cytopathology service was available during 78 (67%) of procedures in 2017 and 108 (83%) of procedures in 2020 ($p>0.05$). In 2017, 66 out of 97 (68%) procedures provided accurate diagnosis, whilst in 2020, 100 out of 120 (83.3%) procedures were diagnostic ($p<0.02$).

Conclusion: Our analysis suggests that the STS technique and introduction of the new fixation agents have improved the diagnostic accuracy of EUS guided tissue sampling in solid lesions from 2017 to 2020.

COMPARISON OF DIAGNOSTIC ACCURACY OF EUS GUIDED FINE-NEEDLE BIOPSY AND CYTOLOGY WITH ROSE IN PANCREATIC SOLID LESIONS (PSLS) USING NEWER GENERATION BIOPSY NEEDLES

S. Sundaram¹, U. Chhanchure¹, V. Seth¹, P. Patil¹, S. Mehta¹

¹Tata Memorial Hospital, Department of Digestive Diseases and Clinical Nutrition, Mumbai, India

Contact E-Mail Address: drsridharsundaram@gmail.com

Introduction: There have been significant advances in Endoscopic ultrasound guided tissue sampling, with better acquisition using biopsy needles. Whether Rapid On-site examination (ROSE) increases yield in patients who undergo biopsy has been a matter of debate. We aimed to compare yield of EUS guided biopsy with smear cytology with adequacy confirmed by ROSE, acquired using the same needle.

Aims & Methods: Consecutive patients with solid pancreatic lesions (PSLS) who underwent EUS-guided sampling of pancreatic solid lesions from January 2021 to December 2021 were included. Demographic details, details of site of lesion, size of lesion, number of passes, adequacy by ROSE, diagnosis as achieved by cytology and histopathologic assessment of core tissue were noted.

Those patients where ROSE was not performed or where core tissue acquisition was not done for histopathology were excluded from the analysis. EUS was performed by 2 experts having experience of more than 100 EUS procedures performed independently.

Sampling was done using 22G Acquire™ needle in all cases using slow stylet pull-through method, with patient either under conscious sedation or general anaesthesia. Minimum of 2 passes, one for ROSE and other for core tissue sampling were done. The first pass was given for ROSE to assess for adequacy. This sample was subsequently sent to cytology for diagnosis. If sample was adequate, additional passes were taken subsequently to acquire core tissue from the solid masses.

This sample was submitted for histopathologic assessment in formalin jars. The adequacy of core tissue was confirmed by Macroscopic On-site Evaluation (MOSE) of whitish core of more than 4 mm length. Final cytology and histopathology reports were compared for diagnostic accuracy. Statistics were performed using SPSS version 26.0 (IBM, Armonk, NY, USA).

Results: 110 patients underwent EUS guided sampling for pancreatic solid lesions during the study period. Of these, 7 patients either underwent only single pass for ROSE or core tissue acquisition without ROSE.

One hundred and three patients were included in the analysis during the study period (mean age 55.5 ± 12.7 years; 57.3% male). Majority of lesions were located in the head of pancreas (82.5%, 85/103) followed by body of pancreas (8.7%, 9/103). Mean largest dimension of lesions was 3.7±1.05 cm (Range 1.5 to 8.0 cm).

Final diagnosis was malignancy in 90 (adenocarcinoma-76, NET-10, SPEN-1, Lymphoma-3) with negative for malignancy in 13 (Autoimmune Pancreatitis-2, Tuberculosis-3). Median number of passes required were 3 (Range 2-6) (3 passes were needed in 33 (32.0%) patients; 4 passes in 31 (30.1%)). In 11 (10.6%) patients more than one pass was required for confirming adequacy on ROSE. Sensitivity and specificity for malignant PSLs for ROSE+cytology was 95.6% and 100% respectively. Final histopathology of core tissue could diagnose malignant PSLs with sensitivity and specificity of 95.6% and 100% respectively.

Comparison using McNemar Chi Square for paired nominal data showed no significant difference (p=1.0) between final HPR and ROSE+Cytology taken with FNB needle.

Conclusion: EUS FNB has high diagnostic accuracy in PSLs. ROSE may not increase diagnostic yield in solid pancreatic lesions sampled using newer generation EUS biopsy needles. Utility of ROSE should be reviewed considering added costs.

THE USE OF ANTITHROMBOTIC AND ANTICOAGULANT AGENTS DID NOT INCREASE THE BLEEDING RISK AFTER ENDOSONOGRAPHY (EUS)-GUIDED PUNCTURE

S. Bota¹, M. Razpotnik¹, M. Kutilek², C. Urak¹, G. Essler¹, J. Weber-Eibel¹, A. Maieron², M. Peck-Radosavljevic¹

¹Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized Endoscopy Service, Klagenfurt, Austria, ²University Hospital St. Pölten, Internal Medicine 2, St. Pölten, Austria

Contact E-Mail Address: bota_simona1982@yahoo.com

Introduction: Endoscopic ultrasound guided puncture is considered as high bleeding risk procedure.

Aims & Methods: Aim: compare the bleeding rate after EUS fine-needle aspiration (FNA) or biopsy (FNB) in different tumors according to the use of antithrombotic and anticoagulant agents.

Methods: Our bicentric retrospective study included EUS-FNA/FNBs performed between 01/2016-10/2021 in Klagenfurt and 11/2018-04/2021 in St. Pölten.

Minor bleeding was defined as an event with a duration of more than one minute, no need for intervention, a large coagulum on the puncture site, or a decrease in hemoglobin ≥ 1.5g/dL (but less than < 2 g/dL). Major bleeding was defined as a reduction in hemoglobin level ≥ 2 g/dL, need of a transfusion, or interventional hemostasis.

According to newly updated ESGE guidelines, acetylsalicylic acid can be continued in the case of EUS-FNA/FNB, while clopidogrel should be discontinued seven days for procedure, warfarin five days, and DOACs three days before the intervention. Medication discontinued fewer days than recommended was classified as "ongoing".

Results: 618 EUS-FNA/FNB were assessed (Klagenfurt – 423 and St. Pölten – 195). FNB was performed in 47.4 % of cases.

EUS-FNA/FNB was performed for the following indications: solid pancreatic masses – 53.1%, pancreatic cysts – 21.1%, subepithelial gastrointestinal tumors – 12.1%, and other indications – 13.7%.

Bleeding occurred in 41 cases (6.6%) : 3 cases with major bleeding (0.5%) - immediate endoscopic treated without hemodynamic instability, and 6.1% minor bleedings.

The use of antithrombotic and anticoagulants was not associated with an increased bleeding risk regardless of the tumor type or use of FNB needles.

	All patients with antithrombotic and anticoagulant medication (n=161)	Ongoing medication (n=105)	Discontinued medication (n=56)	No medication (n=457)
Overall bleeding rate	6.8%	8.5%	5.3%	6.5%
Solid pancreatic tumors	9.9%	12.1%	9.1%	8.1%
Pancreatic cysts	2.6%	3.7%	0%	1.1%
FNB needle	7.9%	9.1%	6.2%	6.9%

Conclusion: The bleeding risk after EUS-FNA/FNB was similar in patients with or without antithrombotic and anticoagulant agents.

Disclosure: Nothing to disclose.

ENDOSCOPIC ULTRASOUND (EUS) STILL RELEVANT IN DIFFICULT PSEUDOACHALASIA WORKUP

C. Chia¹, J. Meenan², I. Koumoutsos², S. DeMartino²

¹Tan Tock Seng Hospital Dept. of Gastroenterology, Gastroenterology & Hepatology, Singapore, Singapore, ²St Thomas' Hospital, Gastroenterology, London, United Kingdom

Contact E-Mail Address: tzechris@gmail.com

Introduction: Pseudoachalasia is an infrequent secondary form of achalasia which can result from malignant or benign tumours, postoperative complications or paraneoplastic syndromes. Management can be vastly different between achalasia and pseudoachalasia, making it important to exclude the latter condition. Oesophago-gastro-duodenoscopy (OGD), high resolution manometry (HRM), barium oesophagram, CT scan and EUS play complementary roles to procure a diagnosis of achalasia and exclude pseudoachalasia.

This is one of the few studies that aims to evaluate the role of EUS in excluding pseudoachalasia for patients referred for achalasia workup.

Aims & Methods: Data was collected retrospectively from hospital electronic records over 7 years. Our study group comprised 77 patients (female=44, male=33) with a mean age of 62 years. All cases had a prior OGD and EUS performed. Only cases with a non-diagnostic OGD (including negative oesophageal biopsies) were included. Cases with obvious mass seen on OGD were excluded.

Work up included the following: (A) classic achalasia symptoms, (B) normal OGD, (C) positive HRM +/- barium for achalasia/gastro-esophageal junction outflow obstruction (GEJ-OO) and (D) had CT scan performed. Yield of excluding pseudoachalasia with addition of EUS was analysed in 4 groups: (1) A+B, (2) A+B+C, (3) A+B+D and (4) A+B+C+D.

Cases referred without information on manometry, barium or CT findings were excluded appropriately in the subgroup analysis. Surveillance was performed within 6-12 months to detect any missed cases of pseudoachalasia. Statistical analysis was performed using SPSS V20 using the McNemar Chi-Square and Cochran's Q.

Results: Almost all patients (98.7%) had dysphagia as one of the main symptoms. OGD was non-diagnostic in all cases. EUS was performed in all patients. Number of pseudoachalasia cases detected in Group (1)[n=77], Group (2)[n=53], Group (3)[n=38] and Group (4)[n=26] were 0, 0, 3 and 0 respectively. With addition of EUS, incremental detection of pseudoachalasia in these respective cohorts were 7.8% (p=0.031), 1.9% (p=NS), 0% (p=NS) and 0% (p=NS). EUS showed a sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of 85.7%, 100%, 100% and 98.6%.

There was only 1 case of pseudoachalasia that was not picked up which manifested 2 years later. Other modalities (B, C and D) complemented each other to give excellent values of sensitivity, specificity and NPV (Table 1).

Pseudoachalasia Detection	Sensitivity	Specificity	Positive Predictive Value (PPV)	Negative Predictive Value (NPV)
OGD (n=77) [95% C.I.]	0% [0.00-40.96%]	100% [94.87-100.00%]	NA	90.91% [82.16-96.27%]
HRM +/- barium (n=53) [95% C.I.]	100% [15.81-100.00%]	15.69% [7.02-28.59%]	4.44% [0.54-15.15%]	100% [63.06-100.00%]
CT scan (n=39*) [95% C.I.]	75% [19.41-99.37%]	97.14% [85.08-99.93%]	75% [19.41-99.37%]	97.14% [85.08-99.93%]
EUS (n=77) [95% C.I.]	85.71% [42.13-99.64%]	100.00% [94.87-100.00%]	100.00% [54.07-100.00%]	98.59% [92.40-99.96%]

Table 1.

Conclusion: In excluding pseudoachalasia, addition of EUS to a well complemented workup (typical symptoms, OGD, HRM and/or CT scan) may not yield statistically significant benefit. However, EUS demonstrated good sensitivity and excellent specificity, PPV and NPV for pseudoachalasia detection clinically and should be considered on a case-by-case basis especially in any diagnostic dilemma.

ENDOSCOPIC ULTRASOUND GUIDED CYSTOGASTROSTOMY IS TECHNICALLY FEASIBLE, SAFE AND EFFECTIVE IN TODDLERS AND SMALL CHILDREN

S. Sundaram¹, P. Patil¹, S. Mehta¹

¹Tata Memorial Hospital, Department of Digestive Diseases and Clinical Nutrition, Mumbai, India

Contact E-Mail Address: drsridharsundaram@gmail.com

Introduction: Endoscopic ultrasound guided cystogastrostomy (EUS-CG) is the intervention of choice for management of peripancreatic fluid collections (PFCs).¹ A previous study suggested role of EUS-CG in management of PFCs in children between 9 and 18 years of age.²

No previous data on feasibility, safety and efficacy of EUS-CG in toddlers and small children. We aimed to evaluate the safety and efficacy of EUS-CG in toddlers and small children.

Aims & Methods: Retrospective review of prospectively maintained endoscopy database was done for children ≤8 years of age referred for endoscopic management of PFCs between January 2021 to January 2022. Children who underwent percutaneous or surgical intervention for management of PFCs were excluded. Details of demographics, underlying chronic pancreatitis, type of PFC, size and site of PFC, mode of drainage (plastic stents or Biflanged metal stent (BFMS)), technical success, adverse events

and clinical success. EUS-CG was performed by endoscopist (SS) with experience of over 500 EUS procedures performed independently. All EUS procedures were performed using standard linear echoendoscope (GIF UCT180, Olympus, Tokyo, Japan) with 19G needle (Expect needle, Boston Scientific, USA) for aspiration.

To achieve drainage, double pigtail plastic stents (DPPS) (Cook Medical, USA) of 7 Fr 5 cm were used. Nagi Stent (14 mm X 20 mm) (Taewoong Medical, South Korea) was used as BFMS as indicated. Technical success was defined as successful placement of plastic or BFMS with drainage of cyst contents confirmed endoscopically. Clinical success was defined as reduction in size of PFC to <2 cm size on follow up imaging. Adverse events were graded as per standard ASGE lexicon.

Results: Six children were screened for EUS-CG, and 5 underwent EUS-CG (Mean age 6.2 years, Range 4-8 years, 3 females). Persistent abdominal pain was the most common symptom (80%) followed by vomiting (40%). Underlying chronic pancreatitis was evident in 1 patient.

Three patients had pseudocyst while 2 had Walled off pancreatic necrosis (WOPN). Of these, one patient had recurrent pseudocyst after surgical cystogastrostomy. Site of the PFC was body in 4 patients and tail of pancreas in 1 patient. Mean largest dimension of PFC was 8.1 cm (Range 7.2-10.6 cm). Nagi stent was placed in 2 patients and DPPS in 3 patients. Technical success was achieved in 100%. No moderate or severe adverse events were reported.

One patient developed persistent fever after drainage of WOPN which was managed with intravenous antibiotics. Clinical success was achieved in 4 (80%) patients. One patient had spontaneous extrusion of plastic stent with persistence of small collection of 4 cm size.

All patients underwent MRCP subsequently at 3-4 weeks with evidence of disconnected pancreatic duct (DPD) seen in 3 patients (of whom 1 had spontaneous extrusion of plastic stent). Of patients with DPD, exchange to DPPS was done in 2 patients and stent exchange was not feasible in one patient. Stent removal could be done in 2 patients.

Conclusion: EUS guided cystogastrostomy using standard linear echoendoscope is safe and effective in toddlers and small children and should be the procedure of choice for drainage of PFCs.

THE RISK OF MALIGNANCY OF DIAGNOSTIC CATEGORIES DEFINED BY PAPANICOLAOU SOCIETY OF CYTOPATHOLOGY SYSTEM IN EUS-FNA SAMPLING OF SOLID PANCREATIC LESIONS

B. Vasas¹, R. Bor², Z. Bősze², A. Fabian², T. Tóth², A. Balint², Á. Milassin², P. Bacsur², M. Rutka², T. Resál², K. Farkas², T. Molnár², Z. Szepes²

¹University of Szeged, Department of Pathology, Szeged, Hungary,

²University of Szeged, First Department of Medicine, Szeged, Hungary

Contact E-Mail Address: vasas.bela@gmail.com

Introduction: The aim of the standardized diagnostic categories defined by Papanicolaou Society of Cytopathology (PSC) System is to facilitate the communication between pathologists and other members of the multidisciplinary team involved in the management of pancreatic cancer. Furthermore, it provides information about the risk of malignancy.

Aims & Methods: This observational cohort study retrospectively enrolled all consecutive patients with solid pancreatic lesions who underwent endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) sampling in University of Szeged from 2014 to 2021. The predictive value of diagnostic categories defined by PSC System was determined by histologic outcome and/or clinical follow-up.

Results: A total of 522 EUS-FNA sampling of solid pancreatic lesions was performed during the study period, in which the initial diagnosis based on the EUS morphology was benign in 50 cases and malignant in 472 cases. The diagnostic accuracy of EUS-FNA was 79.12% with 78.21% sensitivity, 93.55% specificity and 99.41% positive predictive value. The risk of malignancy was 100% for “malignant” and 100% for “suspicious for malignancy” categories. In 21 cases, follow-up data was not available in “non diagnostic” and “atypical” categories, which were excluded from the analysis. The proportion of malignancy in these categories was 50.82% and 86.20%, respectively. There were no cases in the “neoplastic: benign” category. The final diagnosis in the “neoplastic: other” category was ductal adenocarcinoma in 3 cases, solid pseudopapillary neoplasm in 3 cases, low grade neuroendocrine tumor in 12 cases and IPMN in 7 cases. Based on this, the risk of malignancy was 72.00%.

Conclusion: Our data confirmed that the “non diagnostic” category does not provide any information about the lesion being sampled. The “atypical” category represents some diagnostic uncertainty, however a high risk of malignancy should be considered. The “neoplastic: other” category by definition contains premalignant lesions and low-grade malignancies which could cause confusion in the interdisciplinary communication, therefore, the reclassifying of this category would be beneficial.

Disclosure: No conflict of interest.

ROLE OF NOVEL MOTORIZED SPIRAL ENTEROSCOPY IN THE EVALUATION OF SMALL BOWEL DISEASES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Z. Nabi¹, J. Samanta², R. Chavan¹, J. Dhar³, R. Talukdar¹, D.N. Reddy¹

¹Asian Institute of Gastroenterology, Gastroenterology, Hyderabad, India, ²Post Graduate Institute of Medical Education and Research, Gastroenterology, Kolkata, India, ³Post Graduate Institute of Medical Education and Research, Gastroenterology, Chandigarh, India

Contact E-Mail Address: zaheernabi1978@gmail.com

Introduction: Device assisted enteroscopy is an established tool for the evaluation and treatment of various small bowel diseases. Recently, motorized spiral enteroscopy (MSE) has been introduced. Preliminary data suggest safety and efficacy of MSE for the evaluation of small bowel diseases.

Aims & Methods: In this systematic review and meta-analysis, we aim to analyze the performance of MSE for evaluation of small bowel diseases. Literature search was performed in Embase, PubMed, Cochrane database for studies evaluating MSE between Jan 2010 to July 2021. Primary outcome of the study was rate of pan-enteroscopy by antegrade or bidirectional routes. Secondary outcomes included technical success, depth of maximum insertion, procedure duration, diagnostic yield and adverse events.

Results: 10 studies (382 patients, 179 males) were included in the review. Procedures included antegrade in 276, retrograde in 38 and combined in 51 patients. Pooled rate of technical success was 95.6% (95% CI 92.8% - 97.4%; $I^2=0$). Overall, the pooled rate of total enteroscopy rate was 45.9% (95% CI 21.5%-72.5%; $I^2=90.7\%$), by antegrade route in 25.8% (95% CI

12.1%-46.6%; $I^2=82.8\%$) and combined route in 71.3% (95% CI 47.9%-87.1%; $I^2=60.5\%$) of cases. Mean depth of maximum insertion by antegrade and retrograde routes were 444.1 cm (95% CI 381.5-506.7; $I^2=94.9\%$) and 232.8 cm (95% CI 132.5 to 333.2; $I^2=95.4\%$) cm, respectively. Pooled mean duration for antegrade MSE was 43.1 (95% CI 38.6-47.6; $I^2=84.5\%$) minutes and retrograde route was 36.5 (95% CI 28.9-44.1; $I^2=78.1\%$) minutes. Overall, diagnostic yield was obtained in 65.9% patients (95% CI 60.8 - 70.7%; $I^2=72\%$). Pooled rates for all and major adverse events were 17.4% (95% CI 11.7%-25.1%; $I^2=49.5\%$) and 3% (95% CI 1.5% -5.9%; $I^2=0$), respectively.

Conclusion: MSE is safe and effective tool for the evaluation of small bowel disorders. Pan-enteroscopy is possible in more than two-third of patients by combined route with minimal adverse events and relatively shorter procedure duration.

Disclosure: Nothing to disclose

	Single balloon enteroscope	Double balloon enteroscope	Spiral enteroscope	Motorized spiral enteroscope
Total enteroscopy rates (%)	15 to 25	40 to 60	8	3 to 100
Depth of maximal insertion (antegrade), cm	204 to 258	200 to 346	175 to 262	395 to 530
Procedure duration, min	46 to 96	42 to 105	43 to 55	25 to 62
Diagnostic yield (%)	43 to 53	42 to 61	33 to 69	25 to 80
Adverse events (%)	0 to 23	0 to 24	0 to 23	0 to 28
Advantages	Shorter procedure time, easy to use	Higher depth of maximum insertion, extensively evaluated in studies	Short procedure time	Shorter procedure time, high pan-enteroscopy rates
Limitations	Lower depth of maximum insertion	Long procedure duration	Low depth of maximum insertion, two operators required	Limited data on safety, requirement of general anaesthesia

Table. Comparison of available device assisted enteroscopy techniques.

Introduction: Double-balloon small intestine endoscopy is longer in duration and more painful than other endoscopic procedures despite the use of high-dose sedatives and analgesics. A combination of midazolam and pethidine hydrochloride is normally used.

However, the current method of intermittent midazolam administration by giving additional doses during body movements fluctuates the blood concentration of midazolam and is not sufficient to provide the necessary sedation and analgesia.

Aims & Methods: The efficacy and safety of 'continuous intravenous midazolam plus pethidine hydrochloride' (new group) with those of 'intermittent midazolam plus pethidine hydrochloride' (standard group) was compared with a prospective, randomised, controlled trial conducted by 14 centres of the National Hospital Organization Gastroenterology Research Group.

Both groups were sedated with a single intravenous dose of 2.5 mg midazolam at the beginning of the examination. The continuous midazolam infusion was adjusted at 2.5–6.0 mg/h to maintain appropriate sedation levels in the new group. The standard group added 2.5 mg midazolam as needed during body movements if sedation was insufficient.

There were sedation evaluators and anaesthesia personnel along with the endoscopist, but patient assignment was only disclosed to the anaesthesia personnel. Ramsay sedation scale (RSS) was used to assess the sedation status. An RSS score of 3–4 was defined as adequate.

Results: From May 2020 through September 2021, 76 patients were enrolled; 39 were assigned to the new group and 37 to the standard group. Discontinuations prior to drug initiation (one case in each group) were excluded from the analysis. This resulted in a total of 74 patients in the analysis population (FAS, PPS and safety analysis population); 38 in the new group and 36 in the standard group.

The primary endpoint was the mean (standard deviation) rate of adequate sedation of 0.637 (0.315) for the new group and 0.609 (0.272) for the standard group, with an estimated difference (new group – standard group) of 0.024, 95% CI = –0.111–0.160, $p = 0.721$.

The percentage of physical movements requiring treatment interruption was 7.9% (3/38) in the new group and 25.0% (9/36) in the standard group ($p = 0.091$). In terms of surgeon satisfaction, the percentage of patients who wanted to receive the same sedation on the day of examination was 89.5% (34/38) in the new group and 97.2% (35/36) in the standard group ($p = 0.392$).

The percentage of test discontinuation was 5.3% (2/38) in the new group and 2.8% (1/36) in the standard group ($p = 1.000$). The median (range) pethidine dose per hour (mg/hr) was 52.2 (28.6–112.5) in the new group and 48.9 (27.2–116.7) in the standard group ($p = 0.287$). The median (range) midazolam dose per hour (mg/hr) was 8.4 (1.1–21.7) in the new group and 5.7 (1.6–19.1) in the standard group ($p = 0.003$).

Conclusion: The new group had fewer body movements that required interruption, but advantage over the standard group was not established. Continuous infusion might serve as an alternative for sedation in some patient populations, particularly those having difficulty with sedation, owing to its acceptable safety profile.

Disclosure: No conflict of interest.

P0947

HIGHER LEVELS OF OPIOID ANALGESIA AND SEDATION ARE REQUIRED TO MAINTAIN ADEQUATE PATIENT COMFORT AND IMPROVE PROCEDURE SUCCESS IN DEVICE ASSISTED ENTEROSCOPY. IS CONSCIOUS SEDATION ENOUGH?

Introduction: Device assisted enteroscopy (DAE) enables identification, biopsy and therapeutic intervention of small bowel pathology. The joint position statement by BSG, JAG and RCoA highlight patient intolerance as an important factor in procedure success and recommend considering deep sedation for protracted and complex procedures, including DAE. While ESGE guidelines from 2018 suggest the choice and level of sedation employed should be guided by patient, procedure, and hospital factors. To this end, we assessed sedation requirements and outcomes for DAE compared to other standard and interventional endoscopic procedures.

Aims & Methods: Our aim was to compare conscious sedation and analgesia requirements for DAE with other standard and interventional endoscopy procedures.

A single centre retrospective comparison study was undertaken. Elective DAE's from 2018 – 2021 identified from our endoscopy database were included. Comparative endoscopic procedures were randomly selected

over the same time period. Cases performed under general anaesthesia or on inpatients were excluded. Patient demographics, procedure type, sedation and analgesia dosages, Modified Gloucester Comfort Scores (CS) (range 1-5), and DAE outcomes were documented. Data was compared between groups with a t-test or Fisher's exact test as appropriate.

Results: In all 786 cases were included; 200 OGD's, 200 Anterograde DAEs (ADAE), 62 Retrograde DAEs (RDAE), 124 Colonoscopies and 200 ERCP's. All cases were performed under conscious sedation with a combination of IV midazolam and fentanyl. Overall mean age was 61.3 years (range 20-90) and 49% (n=386) were male. Demographics were similar between groups, other than for age in the RDAE group, who were younger (mean 54 years, $p < 0.02$).

The mean midazolam dose was significantly higher for ADAEs 5.3mg versus OGDs 2.1mg, $p < 0.0001$. Similarly, mean midazolam dose in RDAE 5.0 mg was higher than for colonoscopy 2.7mg, $p < 0.0001$. More midazolam was also employed for DAEs versus ERCPs 5.2mg and 4.7mg respectively, $p = 0.032$. Of note DAEs and ERCPs required above the maximum recommended 5mg dose; 35% ADAE, 29% RDAE, ERCPs 29% compared to 0.5% of OGDs and 1.6% of colonoscopies, $p < 0.0001$.

There was also a significantly higher fentanyl requirement for both ADAE and RDAE compared to OGD and colonoscopy groups, 68.7mg v 30.6mg and 71.9mg v 42.1 mg respectively, $p < 0.0001$. Again, mean fentanyl dose for DAEs was significantly more than for ERCP, 69.2mg v 63.0mg, $p = 0.02$.

Overall reported comfort was adequate and similar for all procedures (1.1 OGD, Colonoscopy, 1.3, ERCP - 1.3, ADAE - 1.2, RDAE - 1.3).

However, increased midazolam and fentanyl use was associated with more discomfort. CS 1 versus CS 2, 3.6mg and 50mg versus 5mg and 67.1mg, respectively, $p < 0.0001$.

Overall, the success rate based on indication for DAE was acceptable 69% (n=181) and was higher for ADAE 74% (n=147) versus RDAE yield 53% (n=33), $p < 0.002$. Similarly mean depth of insertion was higher for ADAE V RDAE, 180cm v 75.4cm, $p < 0.0001$. Higher levels of sedation use was associated with increased depth of insertion and procedure success, $P < 0.001$.

Conclusion: More opioid and benzodiazepine agents are required to maintain acceptable patient comfort and to allow for adequate depth of insertion and therapeutic intervention in DAE compared to other diagnostic and interventional endoscopies. Where available deeper levels of sedation could offer both a significant procedural advantage and improved patient reported outcomes.

Disclosure: Nothing to disclose.

Introduction: Capsule endoscopy (CE) is a widespread modality for a non-invasive evaluation of the gastrointestinal (GI) tract. Several CE models were introduced throughout the last two decades. In this systematic review we evaluated CE performance measures such as completion, detection, and retention rates.

Aims & Methods: Available literature through August 2021 was screened for papers regarding all capsule types: small bowel, double-headed capsule for the colon or PillCam® Crohn's capsule, magnetically-controlled capsule endoscopy, esophageal capsule and patency capsule. Primary outcomes included detection (DR), completion (CR) and capsule retention rates (RR). A sub-analysis on the outcomes was performed regarding CE main indications such as obscure GI bleeding (OGIB), known/suspected Crohn's disease (CD), celiac disease (CeD), neoplastic lesions (NL) and clinical symptoms (CS).

Results: 328 original articles were included in the study, involving 86,930 patients who underwent CE. The most common indication was OGIB (n=44,750), followed by CS (n=17,897), CD (n=11,299), NL (n=4,989) and CeD (n= 947). Small bowel CE was the most used capsule type (236 studies). DR, CR and RR overall were, respectively, 59%, 89.6% and 2%. According to specific indications, DR, CR and RR were: OGIB (55%, 90.6%, 2%), CD (66%, 86.5%, 4%), NL (63%, 78.2%, 1%), CeD (52%, 94%, 6%), CS (62%, 92.8%, 2%).

No significant difference was seen in the pooled lesion detection per indication group according to capsule type, although the highest DRs were seen with PCC and CCE.

No statistically significant difference was seen in CR, regarding the two most common indications (OGIB and CD, 90.6% and 86.5% respectively), even in the subgroup analysis per capsule type. The overall RR was low (2%), in line with previous literature results. The high value seen in CeD (6%) might be explained by the low number of studies (only 6) providing heterogeneity of the analysis.

Indications	Detection rate (DR)	Completion rate (CR)	Retention rate (RR)
OGIB	55%	90.6%	2%
CD	66%	86.5%	4%
NL	63%	78.2%	1%
CeD	52%	94.0%	6%
CS	62%	92.8%	2%
All indications	59%	89.6%	2%

Conclusion: Overall pooled DR, CR and RR were acceptable for all CE types, with no statistically significant difference. CE confirmed its substantial role in the detection of GI pathology, expanding the scope in the last years thanks to technological advancements, with acceptable rates for a complete examination.

Disclosure: Nothing to disclose.

SMARTPILL™ WIRELESS MOTILITY CAPSULE ASSESSMENT OF INTRA- AND INTER-INDIVIDUAL VARIABILITY OF SPECIFIC GASTRIC PH RANGES FOLLOWING A LOW-FAT, LOW-CALORIE MEAL: IMPLICATIONS FOR DRUG DELIVERY

H.M. Fadda¹, P.M. Hellström², D.-L. Webb²

¹Butler University, Department of Pharmaceutical Sciences, College of Pharmacy and Health Sciences, Indianapolis, United States, ²Uppsala University, Gastroenterology & Hepatology Unit, Medical Sciences, Uppsala, Sweden

Contact E-Mail Address: dominic-luc.webb@medsci.uu.se

Introduction: Food can alter drug bioavailability through gastric pH changes. Gastric pH can have a significant effect on pH-dependent dissolution of ionizable drugs and enteric delivery systems, including formulations for the next generation of orally ingested peptides, which continue to suffer from poor bioavailability.

Aims & Methods: The aim was to investigate time spent at different pH ranges during a low fat, low calory breakfast, conditions under which medications could be consumed. Along with time within distinct gastric pH ranges, variability was studied. Healthy subjects (n=20) from local population were recruited for 3 visits. Exclusion criteria were: acute or chronic abdominal pain, dysphagia, gastric bezoars, strictures, fistulas, bowel obstructions, diverticulitis, celiac disease, Crohn's disease, ulcerative colitis or proctitis, inflammatory or stenotic gastrointestinal changes, previous GI surgery (except for appendectomy), implanted electromechanical or cardiac pacemaker devices or medications shown to influence gastrointestinal (GI) motility and transit time (prokinetics, antidiarrheals, antiemetics, laxatives) as well as NSAIDs. Participants should refrain from alcohol or smoking and were limited to 5 cups of coffee/day throughout the study. Subjects were fasted overnight. In the morning, they ingested a light, mixed, standardized meal for 10 min consisting of two egg whites, buttered toast and jelly (260 kcal: 3% fat, 21% protein and 76% carbohydrate of which ~3% was fiber). SmartPill™ wireless motility capsule (WMC) was then ingested. This was twice repeated (3 visits total). Gastric phase pH was sorted into pH <2, 2-3, 3-4, 4-5 and >5. All visits and all subjects were pooled to determine median (25-75th percentiles) in min. Data was then

stratified for inter- and intra-subject variability, which were calculated as robust coefficient of variation% (RCV%), which is median absolute deviation / median x 100.

Results: Of 60 possible visits, pH data was obtained for 53. Reference values for gut transit times in these subjects have been published (1). Gastric emptying time was median 176 (137-205) min, mostly spent at pH <2, 111 (67 – 163) min. Following a drop of pH <2, some recordings revealed an upward rebound in the middle of the gastric phase to pH >2, which again dropped below pH 2 prior to when the WMC was expelled from the stomach. This occurred in 2 of the 3 visits in some subjects. Therefore, simple measurements of time to drop to a specific pH can be misleading. This legitimized sorting the gastric phase pH data into time spent within different pH ranges.

Minutes at pH 2-3 and 3-4 were similar: 17 (5.7 – 35.6) and 18 (7.2 - 29.3). Minutes at pH 4-5 was 9 (1.3 - 20.6) and at pH >5 0.7 (0 - 4.4). Inter-subject RCV% was 49% for pH <2, 89% for pH 2-3, 54% for pH 3-4, 97% for pH 4-5 and 148% for pH >5. Intra-subject RCV% was 30% for pH <2, 57% for pH 2-3, 71% for pH 3-4, 106% for pH 4-5 and 144% for pH >5. Variability was less consistent at higher pH ranges, with main differences explained by skewness in inter-subject values, albeit much less time was spent at these pH ranges, particularly pH >5. Of 53 total visits, 16 (30%) never attained pH >5 (i.e., time = 0 min), impacting variability values.

Conclusion: Inter-subject variability can be twofold higher than intra-subject variability, especially in the pH<2 range, where most of the gastric phase is spent under light meal conditions. The data obtained differs from other published values with large, high fat meals. The present data is pertinent, since a substantial number of medicines may be taken in the morning with a light breakfast.

Introduction: Artificial Intelligence (AI) promises to revolutionize the field of capsule endoscopy by reducing reading time while maintaining high diagnostic accuracy. Preliminary results show that Convolutional Neural Network (CNN)-based algorithms demonstrate promising diagnostic accuracy in detection of small bowel lesions with relevant reduction of reading time.

Aims & Methods: Primary aim of this study was to compare the diagnostic accuracy of AI-assisted reading with standard reading, when both are performed by expert readers (>500 cases), in detection of significant pathology of the small bowel. Secondary aim was to compare mean reading time of both reading modalities.

A consecutive series of 20 patients who performed Small Bowel Capsule Endoscopy (SBCE) (NaviCam® SB System, Ankon, China) from July to November 2021 at Fondazione Poliambulanza Hospital was prospectively enrolled. All capsule examinations were evaluated by an expert reader according to the standard of care (i.e. ESGE standards). A second blinded

expert reader reviewed all videos in the “AI-assisted” modality (ProScan™, Intelligent Reading Support). In case of discordant results between AI and Standard Reading (SR) a panel of experts was used to resolve the discrepancies. Main diagnoses (suspected SB neoplasia or high potential bleeding lesions -P2 lesions using Saurin classification) reported by each reader were compared, considering SR as the gold standard. Mean reading time of the two readers was also measured and compared.

Results: Of 20 patients (13 females, mean age 69 ± 12) who underwent SBCE, 19 patients had a complete SB examination and were included in the interim per-patient analysis (in 1 patient the capsule remained in the stomach for the entire recording). Both standard and AI-assisted readings detected small bowel pathology in 15 patients while 4 patients had negative examination, with an overall match of main diagnoses reported by two readers. Sensitivity, specificity, positive and negative predictive values of AI-based reading compared to SR were 100%. Mean SB reading time in SR and AI-assisted modality were $41.25 \text{ min} \pm 14.14$ and $4.75 \pm 2.86 \text{ min}$, respectively ($p < 0.0000001$).

Conclusion: AI-assisted CE reading showed 100% diagnostic accuracy in detection of significant small bowel pathology with a significant reduction of reading time.

ROLE OF ARTIFICIAL INTELLIGENCE IN SMALL BOWEL CAPSULE ENDOSCOPY TRAINING

S. Piccirelli^{1,2}, A. Bizzotto¹, E.V. Pesatori^{1,2}, D. Salvi^{1,2}, E. Tettoni^{1,2}, N. Belluardo^{1,2}, C. Spada^{1,2}

Introduction: Reading of small bowel capsule videos still represents the main limitation since it requires time and prolonged attention. Training in capsule endoscopy is also critical for its time consumption and the number of capsules that make a reader “proficient”. In this scenario, Artificial Intelligence in Small Bowel Capsule Endoscopy (SBCE) might represent a key strategy not only in clinical use but also in a training setting.

Aims & Methods: The primary aim of this study was to measure the inter-observer agreement among novices and experts when both perform standard or AI-assisted SBCE reading. The secondary aim was to evaluate reading time with or without the assistance of AI in both young and expert readers.

10 videos of patients who performed SBCE (NaviCam® SB System, Ankon, China) from July to September 2021 at Fondazione Poliambulanza Hospital were retrospectively evaluated by 2 experts (>500 cases) and 4 novices (<5 cases). Readers were randomized to blindly review videos in standard modality (1 expert reader -E1- and 2 novices -T1 and T2), or with the assistance of Artificial Intelligence (ProScan™, Intelligent Reading Support), (1 expert reader -E2- and 2 novices -T3 and T4). Findings were classified according to the Saurin classification. The agreement between experts and novices was evaluated only for P2 lesions in a per-patient analysis using Cohen's kappa statistic.

Results: 10 SBCE videos of patients (30% males, mean age 68, SD 13) referred for suspected small bowel bleeding were evaluated. At per-patient analysis, expert readers reported the same main diagnoses (100% inter-observer agreement). Inter-observer agreement between novices and experts resulted from moderate to substantial. Mean reading time was also evaluated (see the table below). Standard reading time between experts and novices was comparable.

Conversely, AI-assisted reading time was significantly shorter in experts than in novices. ($p < 0.005$, 95% IC). Overall, the AI-assisted reading time for both expert and novices was significantly shorter when compared to standard reading. ($p < 0.005$, 95% IC).

	Cohen's K	Mean reading time +/- SD
Expert 1 – SR	1	43.7 ± 10.97
Expert 2 – AI	1	4 ± 1.49
Trainee 1 – SR	1	42.1 ± 9.8
Trainee 2 – SR	0.58	40 ± 6.6
Trainee 3 – AI	0.61	14 ± 4.35
Trainee 4 – AI	0.61	10.1 ± 2.96

Conclusion: In a training setting, these preliminary data suggest that artificial intelligence significantly reduces the reading time of non-expert readers without affecting the overall accuracy and the agreement with expert readers. Moreover, AI may have a minor impact on reading time in CE training with respect to that measured for expert readers.

P0952

EFFICIENCY OF THE CAPSULE ENDOSCOPY, ARE THE QUALITY CRITERIA OF THE ESGE MET? EXPERIENCE IN A CENTER

M.d.M. Díaz Alcázar¹

¹Hospital Universitario Clínico San Cecilio, UGC Aparato Digestivo, Granada, Spain

Contact E-Mail Address: mmardiazalcasar@gmail.com

Introduction: The European Society of Gastrointestinal Endoscopy (ESGE) and United European Gastroenterology (UEG) have indicated as a high priority the need to establish quality benchmarks in endoscopic procedures. To this end, in 2019, the ESGE published a guide with quality improvement initiatives in small bowel endoscopy.¹

Aims & Methods: The aim of this study was to assess whether an endoscopy unit met the quality recommendations in capsule endoscopy procedures.

A retrospective descriptive study. Review of capsule endoscopy procedures performed during 2021 and comparison with minimum and objective quality standards.

Results: We performed 81 capsule endoscopy examinations. Compliance with quality criteria and comparison with standards are summarized in Table 1.

Domain	Compliance	Minimum standard	Target standard	Compliance (yes/no)
Indication according to ESGE guideline	78,82%. In anemia 59,52%	≥95%	≥95%	No
Rate of adequate bowel preparation	70,37%	≥95%	≥95%	No
Identify retention risk and prior evaluation with Patency®	Patency® not available	≥95%	≥95%	Not valuable
Complete cecal or stomal visualization	82,72%	≥80%	≥95%	Yes (minimum)
Lesion detection rate	81,93%	≥50%	≥50%	Yes
Timing of capsule for overt bleeding	100%	≥90%	≥90%	Yes
Reading speed	Not registered	≥90%	≥95%	Not valuable
Appropriate referral for enteroscopy	59,09%	≥75%	≥90%	No
Capsule endoscopy retention	2,47%	<2%	<2%	No

Table 1. Quality criteria for capsule endoscopy procedures

Conclusion: 1. The indication for capsule endoscopy should be adequate to increase efficiency and avoid work overload. Moreover, adequate indication prevents unnecessary procedures with the risk of complications. In our series, this criterion is not met, probably because some examinations due to anemia are not appropriate. Before indicating a capsule endoscopy for iron-deficiency anemia, a complete evaluation, including gastric and duodenal biopsies, is important.

2. Currently, the assessment of preparation is based on subjective judgments. The use of purgatives is also unclear. In our center we use simethicone and we recommend maintaining 2 hours of fasting and 4 hours without solids after taking the capsule. 7 hours without solids could be evaluated to improve the cleanliness.

3. Patency® capsule has proven useful in assessing the risk of retention. Its availability would reduce this complication.

4. The capsule endoscopy is a diagnostic procedure. If lesions are found, the enteroscopy should be considered, and the recommendation should be included in the capsule report.

5. It is important to know the quality standards and analyze their compliance to make improvements in order to provide quality assistance.

Introduction: Although several studies showed the usefulness of artificial intelligence to identify abnormalities in small bowel capsule endoscopy (SBCE) images, few have proven actual clinical usefulness.

Aims & Methods: We aimed to examine whether meaningful results could be obtained when reanalyzing negative SBCE video with a deep convolutional neural network (CNN) model. We retrospectively collected clinical data of patients who received SBCE at Yeouido and Seoul St. Mary's hospital between February 2018 and September 2019. All SBCE videos read as negative were reanalyzed with the CNN algorithm developed in our previous study.¹

Meaningful findings including angioectasia or ulcer were finally decided after reviewing the CNN-selected images by two gastroenterologists (KSC and HHL).

Results: A total of 113 (35.8%) among 316 SBCE videos were read as negative or non-specific. After reviewing with AI, meaningful findings were found in 70 (61.9%) videos. Red spot or angioectasia were 80 in 42 videos, and erosions or ulcers were 87 in 44 videos. Diagnosis of 9 patients (8.0%) was changed.

During a mean follow-up of 15.8 months, rebleeding occurred in 20.5% (16/78) of overt GI bleeding patients. Rebleeding rate was 23.5% (12/51) of patients with meaningful findings and 14.8% (4/27) of patients without meaningful findings, respectively (Table 1. P = 0.36). 8 patients received additional small bowel examinations such as 2nd SBCE or small bowel enteroscopy. When reanalyzing 1st SBCE with AI, the prognosis could be altered in 3 patients (37.5%).

	Meaningful finding (-) group	Meaningful finding (+) group
Rebleeding (+)	12 (23.5 %)	4 (14.8%)
Rebleeding (-)	39 (76.5 %)	23 (85.2%)
Total	51	27

Table 1. The Rebleeding rate in Overt GI bleeding.

Conclusion: Our CNN algorithm additionally detected meaningful findings in negative SBCE videos, which were probably missed by humans. It is expected that SBCE image reading by deep CNN could be used to compensate for human error and improve patient outcomes.

IS VIDEO CAPSULE ENDOSCOPY SUPERIOR TO CT-ENTEROGRAPHY IN ASSESSING SMALL INTESTINAL PATHOLOGY IN OCCULT GASTROINTESTINAL BLEEDING FOLLOWING NEGATIVE UPPER ENDOSCOPY AND COLONOSCOPY? A DIAGNOSTIC TEST ACCURACY META-ANALYSIS

M. Yaghoobi¹, J. Tan¹, Y.T.A. Alshammari¹

¹McMaster University, Division of Gastroenterology, Hamilton, Canada

Contact E-Mail Address: yaghoobi@mcmaster.ca

Introduction: Both CT-enterography (CTE) and video capsule endoscopy (VCE) are used in identifying small intestinal pathology in patients with occult gastrointestinal bleeding (OGIB) following normal upper gastrointestinal endoscopy and colonoscopy. Identifying accurate diagnostic accuracy including the sensitivity and specificity of these two modalities, which we aimed at determining by using Cochrane methodology, is crucial for healthcare decision making.

Aims & Methods: A comprehensive electronic search was performed for studies on CTE and/or VCE using double balloon enteroscopy (DBE) as the reference standard. Literature search, data extraction and quality assessment were done by two independent reviewers. Cochrane methodology was used to perform a diagnostic test accuracy meta-analysis. Indices of diagnostic accuracy of CTE and VCE were calculated. Cochrane tool was used to assess risk of bias. We used STATA version 16.0 using bivariate mixed-effects regression framework to calculate sensitivity, specificity, diagnostic odds ratio (DOR), positive and negative likelihood ratios.

Results: Twenty-one studies on VCE and 11 on CTE were included with no visual evidence of publication bias. Six of these studies were head-to-head comparison of CTE and VCE using DBE as reference standard. Positivity rate was 56% for VCE and 33% for CTE. Sensitivity was 0.82 (0.75-0.88) and 0.58 (0.34-0.78) for VCE and CTE, while specificity was 0.62 (0.42-0.77) and 0.89 (0.81-0.94), respectively. The positive likelihood ratio was 2.16 (1.33-3.51) for VCE and 5.44 (2.81-10.51) for CTE while the negative likelihood ratio was 0.28 (0.19-0.41) for VCE and 0.47 (0.27-0.82) for CTE.

Overall, DOR was 7.67 (3.53-16.61) for VCE and 11.48 (4.02-37.70) for CTE (p =non-significant). In sensitivity analysis of only head-to-head studies, CTE showed a sensitivity of 0.50 (0.21-0.77), specificity of 0.89 (0.75-0.96) and DOR of 8.08 (0.65-15.50) as compared to 0.79(0.58-0.91), 0.59 (0.24-0.87) and 5.46 (0-12.7) for VCE, respectively.

Conclusion: Neither VCE nor CTE is a perfect test in identifying etiology of OGIB in small intestine. VCE provided better sensitivity while CTE ensured superior specificity. Our results remained robust in sensitivity analysis. Cost-effectiveness analysis is recommended to further elaborate on practicality of these findings, meanwhile, clinicians should choose the appropriate modality depending on whether better sensitivity or specificity is required in each clinical scenario.

NON-INVASIVE PAN-ENTERIC EVALUATION IN CROHN'S DISEASE – USEFULNESS OF CAPSULE ENDOSCOPY IN UPSTAGING AND CHANGING DISEASE MANAGEMENT

J.P. Laranjeira Correia¹, M.M. Estevinho¹, E. Afecto¹, A. Ponte¹, A. Rodrigues¹, R. Pinho¹, T. Freitas¹

¹Centro Hospitalar de Vila Nova de Gaia/Espinho, Gastroenterology, Vila Nova de Gaia, Portugal

Contact E-Mail Address: joaopaulo_laranjeira@hotmail.com

Introduction: Pan-enteric capsule endoscopy (PCE) allows a non-invasive assessment of endoscopic healing, which has been associated with improved long-term outcomes in inflammatory bowel disease. We intended to evaluate the impact in clinical practice of PCE studies in patients with established and suspected Crohn's disease (CD).

Aims & Methods: A retrospective analysis of all consecutive PCE studies performed in a tertiary centre between March 2018 and February 2022 in patients with established or suspected CD was undertaken. The Capsule Endoscopy Crohn's Disease Activity Index (CECDALic) was used in patients with established CD; this score was compared with clinical features (using the PRO2 questionnaire) and biochemical markers (using C-reactive protein). The percentage of disease upstaging and change in medical management after PCE was also evaluated. Univariate and multivariate binary logistic regression analyses were applied to identify independent predictive factors of treatment intensification.

Results: Overall, 67 PCE studies were included - 26(38.8%) for suspected and 41(61.2%) for established CD. CD was confirmed in 8 patients in whom the diagnosis was suspected (32%). Concerning patients with established CD, median CECDALic was 8 (IQR 14), median C-reactive protein was 4.2 (IQR 6.3) mg/L and median PRO-2 score was 0 (IQR 1).

No significant association between CECDALic and PRO2 score ($rs=0.182$, $p=0.261$) nor C-reactive protein ($rs=0.159$, $p=0.327$) was identified. PCE upstaged Montreal Classification in 6 (14.6%) patients, changed disease management in 14 (34.1%) and resulted in treatment intensification in 12 (29.3%). CECDALic score was an independent predictor of treatment intensification ($p=0.02$).

On the other hand, disease location and behaviour, presence of L4 disease, PRO-2 score, and C-reactive protein were not.

Conclusion: This study corroborates the usefulness of PCE in assessing mucosal activity in CD, which was the only independent predictor of treatment intensification, as well as the role of this technique for appropriate disease staging.

Introduction: The most important factors in achieving an adequate colon capsule endoscopy (CCE) study are bowel cleansing and capsule excretion during the CCE battery time.

Aims & Methods: The aim of this study was to evaluate demographic and clinical factors associated with inadequate bowel preparation in patients undergoing CCE, predicting the need to adjust bowel preparation regimens. A retrospective single-center study including consecutive adult patients undergoing CCE during a 2-year period was performed. Patients' demographic and clinical data, including comorbidities, were recorded, as well as quality of bowel preparation according to CC-CLEAR^a. Patients with insufficient data were excluded.

Results: A total of 86 patients undergoing CCE were analysed. The most common indication for CCE was incomplete screening colonoscopy. CCE was incomplete in 28% of patients. Bowel preparation was adequate (good or excellent) in 55 patients (64%) and it was excellent in 26 patients (31%). In 29 patients (35%), bowel preparation was inadequate. Smoking history was associated with 5.8 times higher risk of inadequate bowel preparation ($p=0.001$; OR 5.8; 95% CI [1.9–17.9]).

Additionally, diabetes and smoking significantly prevented the achievement of an excellent bowel preparation in the CCE: the odds of having sub-optimal (non-excellent) preparation were 5 times higher in diabetic patients ($p=0.029$; OR 5.0; 95% CI [1.1–23.3]) and 4.6 times higher in active or former smokers ($p=0.040$; OR 4.6; 95% CI [1.0–21.7]).

Conclusion: Smoking history and diabetes were associated with sub-optimal (non-excellent) bowel preparation, with smoking having a greater influence and being a risk factor for inadequate bowel preparation. In these patients, adjustments may be considered aiming to improve bowel preparation regimens.

CAPSULE ENDOSCOPY WITH ARTIFICIAL INTELLIGENCE ASSISTED TECHNOLOGY: AI IN CLINICAL PRACTICE

Introduction: Capsule endoscopy (CE) has revolutionized the management of small bowel (SB) diseases owing to its convenience and non-invasiveness. However, capsule reading is a time-consuming and often tedious process with average reading times in the literature ranging between 30–120 minutes.

The use of artificial intelligence (AI) in CE is an attractive solution for reducing reading time by removing redundant images and simplifying the identification of intestinal landmarks and suspicious abnormalities.

While previous studies have demonstrated impressive sensitivity and specificity in created datasets of capsule images, real-world data is lacking.

OMOM[®] HD Capsule (Jinshan group) introduced in 2020 includes Smartscan technology which includes redundancy deletion, lesion detection, and classification software.

Aims & Methods: Our aim was to evaluate the OMOM HD Smartscan software in a real-world setting against experienced capsule readers.

The OMOM[®] HD Capsule was employed prospectively over a 4-week period in unselected patients presenting to our unit for CE. Procedures were performed as per standard departmental protocols.

Recordings were then read by 2 separate modalities; (i) "Standard reading mode" (SR) which was reading at a 10-fps single image mode which was deemed the current gold standard and (ii) "Smartscan reading mode" (SS) which was read at 5fps after image processing by AI-assisted technology. A findings report was generated separately for each reading technique. For each study the following were documented and compared:

- Reading time,
- Intestinal landmark identification,
- Bowel preparation (Brotz Score), and d) pathology.

The reading time required for examination of the data by each method was recorded using a stopwatch. Data was analysed using SPSS software.

Results: In this pilot study, 25 cases have been analysed to date. The mean age was 51 years (18–74); 74% were men. All patients completed the procedure uneventfully. Complete visualization of the SB was achieved in 96% ($n=24$) of patients. No capsule retention was recorded.

44% ($n=11$) of studies detected significant pathology.

The indications for procedure were occult gastrointestinal bleeding 52% ($n=13$), suspected Crohn's disease 40% ($n=10$), and Crohn's disease assessment in 8% ($n=2$).

The mean SB reading time was significantly shorter using SS vs SR (2.5min vs 27.3min, $P < 0.001$).

Evaluation of adequate bowel cleansing by the Brotz score correlated moderately between the two reading methods with agreement in only 44% ($k = 0.6$).

Recognition of the intestinal landmarks by the software was poor, with an average discrepancy between SS and SR of ± 86 min (range ± 9 to 543min) for first duodenal image and ± 132 min (range ± 23 to 237min) for first caecal image.

There was excellent agreement between both modalities for lesion detection with 100% correlation for positive and negative studies. While a per lesion analysis ($n = 321$) also showed excellent correlation ($k = 0.997$). The only lesions not recorded by SV were 2 small angiodysplasias in an otherwise positive study.

Conclusion: Correlation between OMOM HD SmartView technology and expert reader for detection of pathology is excellent. However, recognition of intestinal landmarks is poor and assessment of bowel preparation is unreliable. With recognition of these limitations by the operator Smartscan can significantly improve reading time in CE without negatively affecting pathology recognition and diagnostic yield.

Disclosure: Nothing to disclose.

Contact E-Mail Address: tiagofcribeiro@outlook.com

Introduction: Capsule endoscopy (CE) has a decisive role on the approach to patients with suspected small bowel disease. However, reading CE exams is a time-consuming, error prone and monotonous task and so, artificial intelligence tools may be helpful in the CE videos analysis. In this pioneer work, we aimed to develop a CNN-based model for identification and differentiation of multiple small bowel lesions and their classification according to their hemorrhagic potential.

Aims & Methods: We developed, trained, and validated a denary CNN based on CE images. Each frame was labeled according to the type of lesion (lymphangiectasia, xanthomas, ulcers, erosions, vascular lesions, protruding lesions, and blood) by three experts in CE. The hemorrhagic potential was assessed by Saurin's classification: P0 – lesions without bleeding potential; P1 – lesions with uncertain bleeding potential; P2 – lesions with high bleeding potential; P3 – luminal blood. A training dataset was used for development of the model (80% of the full image dataset). The CNN's prediction was compared to the experts' labeling. The performance of the network was evaluated using an independent dataset (20% of the full image dataset). The performance of the CNN was measured by the area under the receiving operating characteristic curve (AUROC), sensitivity, specificity, positive and negative predictive values (PPV and NPV, respectively).

Results: A total of 53555 CE images were included from 1229 patients. The model had an overall accuracy of 99%, a sensitivity of 88%, a specificity of 99%, a PPV of 87% and NPV of 99% for detection of multiple small bowel abnormalities and respective classification of bleeding potential.

Conclusion: We developed and tested a CNN-based model for automatic detection of multiple types of small bowel lesions and classification of the respective bleeding potential. This system may improve the diagnostic yield of CE for these lesions and overall CE efficiency.

Disclosure: Nothing to disclose.

VIDEO CAPSULE ENDOSCOPY IN PATIENTS WITH SURGICALLY ALTERED PROXIMAL SMALL BOWEL IS ASSOCIATED WITH LONGER TRANSIT TIMES, INADEQUATE PREPARATION AND REDUCED DIAGNOSTIC YIELD

T. Thurm^{1,2}, M. Shnell^{1,2}, L. Deutsch (Mlynarsky)^{2,1}

¹Tel Aviv Sourasky Medical Center, Gastroenterology and Liver Diseases, Tel-Aviv, Israel, ²Tel Aviv University, Sackler School of Medicine, Tel-Aviv, Israel

Contact E-Mail Address: tamarth@tlvmc.gov.il

Introduction: Video capsule endoscopy (VCE) is an effective, noninvasive modality for small bowel (SB) investigation. Its usage in patients with prior SB surgical interventions is rising. However, data in patients with altered SB anatomy regarding diagnostic yield and feasibility are lacking.

Aims & Methods: Our aim was to evaluate and compare safety and efficacy of VCE among patients with surgically altered proximal SB anatomy, patients with other SB resections and the normal anatomy (non-surgical) patients.

This is a retrospective study of prospectively maintained database. All consecutive VCEs of patients ≥ 18 years (03/2018-02/2022) were included. All patients received SB preparation protocol based on low residue diet followed by liquid diet and a 12 hour fast as instructed by the manufacturer (PillCam®, Given imaging, Israel). The cohort was divided into three groups: 1. Patients with surgically altered SB anatomy (e.g. gastric bypass, single anastomosis gastric bypass, pancreaticoduodenectomy (Whipple procedure) and bilroth II gastrojejunostomy); 2. Other SB resections (e.g. segmental SB resection, ileocectomy, right hemicolectomy, ileal pouch anal anastomosis (IPAA) and ileostomy); 3. Controls without gastrointestinal surgery. Patients with any history of other gastrointestinal surgery were excluded. Diagnostic yield, VCE completion rate and transit times were compared between groups.

Results: A total of 1121 VCEs were performed. Ten repeated VCEs, and 45 studies of patients with prior non-SB gastrointestinal surgery were excluded. Twenty-one patients with altered SB anatomy and 55 patients with other SB resections were compared to 990 controls. Age was similar between the groups (53.8 ± 14.1 y, 50.5 ± 20.1 y and 52.4 ± 20.9 y respectively,

$p=0.842$). Endoscopic insertion of the SB capsule according to physician's discretion was significantly more common in patients with altered SB (47.6%) compared to resected SB (3.6%) and controls (4.3%, $p<0.001$). The prevalence of clinically significant VCE findings was the highest among patients with resected SB (61.1%) and the lowest among patients with altered SB (28.6%, controls - 41.9%, $p=0.009$ between groups). Adequate SB preparation and visualization was significantly lower in altered SB (47.6%) compared to similar rates among resected SB (72.7%) and controls (75.9%) respectively, ($p=0.011$). Moreover, altered SB (vs. controls) was an independent risk factor for inadequate preparation in a logistic regression adjusted for gender, age and endoscopic placement (OR 2.846, 95%CI 1.133-7.145, $p=0.05$). Study completion rates (cecal or colon documentation) were comparable (altered SB - 95.2%, resected SB - 94.5% and controls - 98.3%, $p=0.102$). However, SB transit time was significantly longer in altered SB and comparable between SB resection and controls (308 ± 110 min, 252 ± 111 min and 249 ± 94 min, $p=0.006$ and $p=0.843$ respectively).

Conclusion: In patients with surgically altered proximal SB anatomy, VCE is as safe as in controls or patients with other resections of SB. However, longer SB transit times and inadequate SB preparation may result in reduced diagnostic yield. Patients with altered SB anatomy might benefit from tailored preparation protocol prior to VCE.

VIDEO CAPSULE ENDOSCOPY STUDIES IN PATIENTS WITH DIABETES MELLITUS ARE CHARACTERIZED BY INADEQUATE PREPARATION AND LONGER TRANSIT TIMES

N. Akerman¹, N. Fliss-Isakov^{2,1}, T. Thurm^{2,1}, O. Shibolet^{2,1}, L. Deutsch (Mlynarsky)^{2,1}

¹Tel-Aviv University, Sackler School of Medicine, Tel-Aviv, Israel, ²Tel Aviv Sourasky Medical Center, Gastroenterology and Hepatology, Tel Aviv, Israel

Contact E-Mail Address: Liatml@tlvmc.gov.il

Introduction: Type 2 Diabetes Mellitus (DM) is a global epidemic that poses a significant challenge to health systems around the world. Its incidence has been rising in the last decades. Gastrointestinal motility disorders are common among patients with T2DM. Data on the safety and efficacy of video capsule endoscopy (VCE) among patients with T2DM is still lacking.

Aims & Methods: This was a retrospective study of a prospectively maintained database in order to evaluate safety and efficacy of VCE among patients with DM compared to patients without DM. All consecutive VCEs of patients' ≥ 35 years, performed between 03/2018-03/2022 were included. Patients with and without DM were compared regarding diagnostic yield, cleansing score and transit times (TT).

Results: A total of 1184 VCEs were performed during study period while 512 patients were excluded due to: age < 35 ($n=339$) previous intestinal surgery ($n=121$), endoscopic placement ($n=31$), technical malfunction ($n=13$) and repeated studies ($n=8$). Out of 672 included patients, 189 patients reported the diagnosis of DM (28.1%, DM group) and 483 patients were defined as controls (without DM).

Fifty DM patients (26.5%) were treated with insulin, 22 (11.6%) patients were treated with glucagon-like peptide 1 (GLP-1) agonist medications and 159 (84.1%) with other oral anti-diabetic medications.

Only one patient in the control group was treated with GLP-1 agonist. Patients with DM were older than those without DM (70.4 ± 9.6 vs. 58.8 ± 15.1 years, respectively, $p<0.001$). The prevalence of medications and co-mor-

bidities, potentially effecting intestinal motility in the entire cohort was rare: Parkinson's disease 0.6%, connective tissue disease 0.6%, multiple sclerosis 0.4% ($p=0.07$ between groups), prescribed narcotics were comparable between patients with and without DM (0.5% vs. 1.6%, $p=0.296$). VCE completion rates (cecal documentation) were similar between DM and controls (98.4% vs. 99.0%, respectively, $P=0.553$). No capsule retention (>2 weeks) occurred in the entire cohort.

Angioectasia and active bleeding were more common among patients with DM compared to those without DM (28.3% vs. 19.7%, $p=0.02$ and 10.9% vs. 6.2% $p=0.04$), yet ulcers were significantly less common (20.1% vs 34.6%, $p<0.001$). Gastric TT was similar between patients with and without DM (37.5 ± 45.5 vs. 34.3 ± 48.6 minutes= 0.42) while small bowel TT was longer (261.8 ± 95.6 vs. 244.9 ± 98.4 , $p=0.04$) and reported bowel movement frequency was lower ($1.42\pm 1.15/\text{day}$ vs. $1.74\pm 1.73/\text{day}$, $p=0.008$).

Inadequate visualization due to poor preparation was more prevalent among patients with DM compared to those without DM (31.2% vs. 23.4%, $p=0.04$). Moreover, insulin-users had higher rates of inadequate preparation compared to DM without insulin (44.0% vs. 26.6%, $p=0.006$).

In a multi-variate analysis adjusted for age, gender and bowel movements frequency, diagnosis of DM was not independently associated with inadequate preparation. However, insulin usage was significantly associated with inadequate preparation (OR 2.477, 95%CI 1.335-4.596, $p=0.004$ adjusted for age, gender and bowel movements frequency). The association was not seen for patients with DM without insulin ($p=0.675$ vs. patients without DM).

Conclusion: Higher rates of inadequate preparation, longer small bowel transit time and reduced bowel movements were observed among patients with DM compared to patients without DM. DM treated with insulin was positively associated with inadequate preparation for VCE. Future studies should focus on personalized protocols for pre-VCE preparation and post-swallowing acceleration.

AUTOMATED PROMPTS RESULT IN HIGH PROKINETIC USE WITHOUT IMPROVING COLON CAPSULE PERFORMANCE

C. Costigan¹, R. Bourke¹, D. McNamara¹

¹Tallaght University Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: conorcostigan92@gmail.com

Introduction: Colon capsule endoscopy (CCE) relies on timed small bowel and colonic boosters to ensure passage through the gastrointestinal tract resulting in complete colonic visualisation. Prokinetics are recommended for delayed gastric transit (>30 minutes) and can be detected by either direct visual assessment (DVA) or an automated (Alert 0) system.

Aims & Methods: The aim was to compare the impact of DVA & Alert 0 assessments on CCE performance.

CCE cases were sequentially assigned to either DVA or automated (Alert 0) gastric transit assessment. Patient demographics, metoclopramide use and CCE key performance measures were documented and compared between groups using Chi² and t-tests as appropriate.

Results: In all 71 patients were recruited (38 DVA and 33 (Alert 0), 66% ($n=47$) were female, mean age was 60 years. Demographics were similar between groups. Overall CCE completion rate was 76% and diagnostic yield was 66%. In all 36% ($n=23$) had delayed gastric transit and received metoclopramide. CCE Completion rates were the same in both groups (76%). Diagnostic yield was statistically similar in both groups (72% vs 55%).

Significantly more patients in the Alert 0 cohort received Metoclopramide (64% Alert 0 versus 19% DVA, $p<0.0001$, OR 9.6, 95% CI 2.9936 to 30.7858). Notably, Metoclopramide use had no significant impact in mean colonic transit times (210 mins vs 193 mins), SB transit times (100 mins vs 97 mins), nor was there any difference in CCE completion rates (70 % v 76%).

Conclusion: This study demonstrates an increase in Metoclopramide use with automated gastric transit assessment, which does not improve CCE completion, and questions the early use of prokinetics in CCE.

Disclosure: Nothing to disclose.

Contact E-Mail Address: akoulaouzidis@hotmail.com

Introduction: Reading small-bowel capsule endoscopy (SBCE) is a tedious task for clinicians^{1,2}; a new method should be applied to solve this issue and free clinical time. Artificial intelligence (AI) algorithms seem to perform well here^{3,4}.

Aims & Methods: We aimed to evaluate the performance of a Convolutional Neural Network (CNN) algorithm (*SmartScan*)-assisted reading in the setting of real-life clinical care. 5,825 SBCE video examinations (comprising 295,314,067 images) performed in 51 Chinese medical centres were collected. 2,927 SBCE examinations from 29 medical centres were used to train *SmartScan* to detect 17 categories of CE structured terminology (CEST) findings. *SmartScan* was later validated in 2,898 SBCEs collected from 22 medical centres.

Eight specialist gastroenterologists read all 2,898 SBCEs with both Conventional Reading (CR) and *SmartScan*-Assisted Reading (SSAR). If finding(s)/results by both types of reading in a patient were concordant, the result was taken as the Combined Agreed Comparator (CAC) for that case. In discordant cases, the consensus result by three expert readers was taken as the CAC for the case.

Main Outcomes & Measures: The detection rate and efficiency of CEST findings detected by SSAR and CR were compared. The missed findings of CEST were also added to the evaluation. This study was registered in the Chinese Clinical Trial Registry (reg no. ChiCTR2100042455).

Results: SSAR achieved an overall higher detection rate (79.30%) for CEST findings compared to CR (70.67%). From a total of 6,084 SB findings, SSAR detected 95.89%, significantly higher than CR (76.10%). SSAR achieved an overall higher sensitivity (98.80%), for the 17 CEST subtypes of findings, 10.75% higher than CR (88.05%). With SSAR, the number of images requiring review per SB CE video was reduced to 779.17 ± 337.18 min, with reading time shortened to 5.37 ± 1.51 min.

Conclusion: A commercially available CNN algorithm (*SmartScan*) can increase the detection rate of SB findings while drastically reducing SBCE reading times.

EVALUATION OF SPLEEN STIFFNESS IN HEALTHY POPULATION: A VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY STUDY

H.T. Kani¹, Ç. Keklikkiran¹, I. Ergenç¹, Y. Yilmaz¹

¹Marmara University School of Medicine, Gastroenterology, Istanbul, Turkey

Contact E-Mail Address: htkani@yahoo.com

Introduction: Vibration-controlled transient elastography (VCTE) is an accurate technique that has an increasing use. In recent years, VCTE was started to use in predicting spleen stiffness (SS). Portal vein pressure and flow have an impact on SS and in previous studies it was used to predict portal hypertension, esophageal varices.

Aims & Methods: Our aim was to evaluate the SS measurements in healthy population and its correlation with age, sex, liver stiffness measurement (LSM), continued attenuation parameter (CAP) and body mass index (BMI). We enrolled healthy volunteers who were agreed to participate to the study and collected age, sex, smoking history, alcohol consumption, body mass index before the VCTE procedure. Liver and spleen elastography were performed to all patients by VCTE.

Results:

All Patients (n=82)	
Sex	
Female (n%)	49 (59.8%)
Male (n%)	33 (40.2%)
Age (years) (mean ± SD)	37.80 ± 11.13
BMI (kg/m²) (mean ± SD)	26.67 ± 5.12
Tobacco use (n%)	
Current smoker	16 (19.5%)
Ex-smoker	17 (20.7%)
Non-smoker	49 (59.8%)
Alcohol consumption (n%)	38 (46.3%)
LSM (kPa) (median, min – max)	4.40 (2.10 – 75.00)
CAP (dB/m) (mean ± SD)	231.78 ± 51.93
SS(kPa) (median, min – max)	18.35 (7.20 – 80.10)

A total of 97 participants were enrolled to the study, 15 patients were excluded and 82 patients included for the final analysis. There was no significant difference in SS, liver stiffness measurement LSM, CAP and BMI

between females and males. There was no correlation between age and SS. There was a weak correlation between SS and LSM, SS and CAP and no correlation was found between SS and BMI.

Conclusion: SS had a weak correlation with LSM and CAP but not with BMI, age and sex. There is no extra-large probe use in SS measurement and it was a challenge in participants with increased submucosal fat thickness. Multiple and repeatable studies needed to set an accurate cut-off point and evaluate the factors that impact on SS in healthy individuals.

EUS-GUIDED HEPATICOGASTROSTOMY: CLINICAL OUTCOMES AND COMPLICATIONS. EXPERIENCE OF A MAIN FRENCH REGIONAL HOSPITAL

H. El Moufid^{1,2}, E. Siegel¹, P. Claude¹, G. Bors¹, S. Husson-Wetzel¹

¹Groupe Hospitalier Mulhouse et Sud-Alsace, Gastro-Entérologie, Mulhouse, France, ²Hôpital Cheikh Zayd, Gastro-Entérologie, Rabat, Morocco

Contact E-Mail Address: elmoufid.houda@gmail.com

Introduction: Hepaticogastrostomy guided by echo-endoscopy (HG) represents an option for the management of obstructive jaundice, as an alternative to surgery or percutaneous drainage, after failure or impossibility of endoscopic retrograde drainage. The technical success rate of this technique is higher than 90% in most studies.

Aims & Methods: The aim of this study is to evaluate the efficacy and morbidity of EUS guided hepatico-gastric drainage in our center.

Single-center retrospective study. All patients with malignant tumor pathology who required hepatico-gastrostomy drainage between June 2015 and December 2021 were included. Anatomical, technical, and clinical characteristics were studied. Technical (stent placement) and clinical success (clinico-biological improvement of angiocholitis and jaundice), as well as complications were considered.

Results: A total of 34 patients were included (16F/18M, mean age 72 years, range 40-96). Obstructive jaundice was caused in all patients by malignant disease (pancreatic cancer in 41%, liver metastasis 20%, cholangiocarcinoma 17%, gall bladder carcinoma 11%, biliary compression by carcinoid nodules 5% and Ampulloma 2%).

The stenosis was localized at the hilar level in 17 cases (50%), at the hepato-cojejunal anastomosis in 2 (5%) and at the choledochal level in 15 patients (44%).

The indication was failure of ERCP in 13 cases (38%), tumor duodenal stenosis in 8 cases (23%), presence of a duodenal stent in 5 cases (14%), incomplete left biliary drainage in 5 cases (14%), and altered post-surgical anatomy (post gastrectomy or whipple surgery) in 4 cases (11%).

Hepatico-gastrostomy were performed after punctures with 19-gauge needles, drilling of the tract using the 6, 7, 8, or 10F cystotome in 22, 2, 1, and 9 patients respectively, and placement of 8 cm semi-covered metal stent in 28 cases (82%), Completely covered 8cm metal stent in only 1 case (2.9%), semi-covered 10 cm metal stent in 3 cases (8.8%), and double semi-covered 8cm metal stent in 2 cases (5.8%).

Technical success was achieved in 33 cases (97%) after a median follow-up of 19.5 weeks (0.1-84). Among these 33 patients, 10 (30%) presented a complication: infectious syndrome (4/10, 40%), obstruction (3/10, 30%), migration (2/10, 20%) and hemorrhage (2/10, 20%). No choleperitoneum occurred.

The clinical success is 81% with a reduction of Bilirubin rate day 7 of more than 50% obtained in 19 cases (57%), a reduction of Bilirubin between 20-49% obtained in 8 cases (24%). Improvement of angiocholitis at 72 hours post-drainage in 16 cases (47%). 16 (47%) patients had received chemotherapy after drainage.

The reintervention rate was 15%. Mortality related to the procedure was 2.9% (Hemorrhagic shock).

Conclusion: Hepaticogastrostomy guided by echo-endoscopy is an interesting alternative for neoplastic obstructive jaundice. The complication rate, particularly infectious, seems high (12%), but this can be explained by the large proportion of patients with complex hilar stenosis, often multi-drained with chronic bacterial contamination of the bile ducts.

SELF-EXPANDABLE METALLIC STENTS FOR PALLIATION OF MALIGNANT DYSPHAGIA - EFFICACY AND SAFETY

F. Bordalo Ferreira¹, M.A. Rafael¹, L. Carvalho Lourenço¹, A.M. Oliveira¹, R. Carvalho¹, D. Horta¹

¹Hospital Professor Doutor Fernando Fonseca, Gastroenterology, Amadora, Portugal

Contact E-Mail Address: filipamvpbferreira@gmail.com

Introduction: Esophageal self-expandable metallic stent (SEMS) placement allows for oral feeding in patients with dysphagia caused by malignant esophageal stenosis, contributing for a significant improvement of quality of life in these patients.

Aims & Methods: We performed a single-center retrospective study which evaluated the results of esophageal SEMS placement for malignant dysphagia palliation, between 2015 and 2021, with a maximum follow-up (FUP) of 3 years.

Results: Sixty-two (62) patients who underwent esophageal SEMS placement for malignant dysphagia palliation were included. Malignant esophageal stenosis was often caused by esophageal or gastroesophageal junction neoplasms (81%), followed by lung origin (15%). A total of 72 esophageal SEMS were placed, with high technical (100%) and clinical (94%) success. Previous dilatation was performed in 7% of the procedures. Complication rate was 3%, which included intra-procedural bleeding (1%), stent migration into the stomach (1%) and aorto-esophageal fistula (1%). The latter two were late complications (3 and 4 months after the procedure, respectively) and occurred in patients on chemotherapy.

Thirty percent (30%) of all patients were on chemotherapy during or after the procedure. Tumor ingrowth causing recurrence of dysphagia occurred in 15% of the patients (median interval of 7.5 months) and was resolved by placement of additional SEMS (the maximum number of stents per pa-

tient was 4). Median FUP time was 3 months (interquartile range of 2-6 months). Survival rate was 82% at 1 month, 56% at 3 months, 29% at 6 months, 23% at 1 year e 16% at 3 years.

Conclusion: These results reinforce that esophageal SEMS placement for palliation of malignant dysphagia is an effective and safe procedure, with a low rate of complications.

RISK FACTORS FOR REFRACTORY BENIGN ESOPHAGEAL STRICTURES

A. Sair¹, S. Mrabti¹, A. Benhamdane¹, T. Addajou¹, R. Berraida¹, S. Sentissi¹, E. ilham¹, F. Rouibaa¹, A. Benkirane¹, H. Seddik¹

¹The Military Teaching Hospital of Rabat, Gastroenterology II Department, Rabat, Morocco

Contact E-Mail Address: asmae-sr@hotmail.fr

Introduction: Endoscopic dilatation remains the mainstay of therapeutic management of benign esophageal strictures, expressed primarily as dysphagia, which can significantly impair quality of life. They can be caused by various disorders or lesions of the esophagus.

Aims & Methods: Our aim is to report the results of dilatation, as well as the different risk factors of refractory benign esophageal strictures.

This is a retrospective descriptive and analytical study of 33 patients with benign esophageal stenosis who underwent esophageal dilation between 2016 and 2021. Refractory (or recurrent) stenosis was defined as the inability to maintain esophageal caliber at 14 mm diameter over 5 dilatation sessions, or the inability to maintain satisfactory luminal diameter for 4 weeks once a 14 mm diameter was achieved.

Results: Of the 33 patients who underwent dilatation for benign esophageal strictures, 38.7% had refractory strictures. The mean age was 50 ± 20.9 years with a male predominance of 66.7% and a sex ratio (M/F) of 2.9. All patients had dysphagia and 45.5% had chronic gastroesophageal reflux disease (GERD). Endoscopy revealed low stenosis in 65.6%, medium in 15.6% and high in 18.8%. 50% had peptic stenosis, 31.3% achalasia, 9.4% anastomotic, 6.3% Schatzki ring and 3.1% caustic.

78.8% of the stenoses were dilated by balloon and 21.2% by candles with a mean dilatation caliber of 18.8 ± 6.8 mm.

After univariate analysis, refractory stenoses were associated with the presence of a peptic stenosis (p=0.002) and dilatations of caliber less than 16 mm (p=0.012), after multivariate analysis only peptic stenosis was associated with refractory stenoses (p=0.034).

Conclusion: In our series, refractory stenosis was present in 38.7%. Peptic stenosis was statistically significantly associated with refractory oesophageal stenosis.

Disclosure: Nothing to disclose.

ENDOSCOPIC STRICTUROTOMY VERSUS ENDOSCOPIC BALLOON DILATION FOR THE TREATMENT OF INTESTINAL STRICTURES IN CROHN'S DISEASE

G. Casanova¹, A. Giordano¹, M. Urpi¹, J. Llach¹, M. Escapa¹, I. Ordás², B. Caballol Oliva², A. Fernández-Clotet², A. Gines¹, M.G. Fernández-Esparrach¹, E. Ricart², B. González-Suárez¹

¹Hospital Clínic de Barcelona, Endoscopy Unit, Gastroenterology Department, Barcelona, Spain, ²Hospital Clinic de Barcelona, Inflammatory Bowel Disease Unit, Gastroenterology Department, Barcelona, Spain

Contact E-Mail Address: gscasanova@clinic.cat

Introduction: Endoscopic stricturotomy with needle-knife (STK) is a recently introduced therapy for the treatment of intestinal strictures in Crohn's disease (CD). Data on its efficacy and safety are scarce as well as comparative studies with other techniques.

Aims & Methods: **Aim:** To compare the efficacy and safety of STK with endoscopic balloon dilation (EBD).

Methods: A prospective cohort of CD patients undergoing STK from July 2019 to April 2022 were compared with a retrospective cohort of patients treated with DEB using Propensity Score Matching to ensure similar demographic and clinical characteristics. Patients with up to 3 intestinal strictures were included. Technical success (passage of endoscope through the stricture after endoscopic treatment), clinical success (remission of abdominal pain), surgery-free survival rate and adverse events after 1-year follow-up were described.

Results: A total of 13 patients treated with STK (median age 38 years, IQR 31-44) and 13 with DEB (median age 47 years, IQR 38-58) were included. There were no significant differences in technical success between the two treatment groups (69.2 vs 84.6%, $p=0.645$). No differences were detected in surgery-free survival rate (76.9% vs 92.3%, $p=0.593$), however clinical success at 1 year was higher in STK group (61.5 vs 23%, $p=0.04$). No early or late major adverse events were detected during follow-up with both techniques.

Conclusion: Present data show that STK has similar efficacy and safety rates as DEB after 1-year follow-up. Clinical success at 1 year was higher in STK group.

Disclosure: Nothing to disclose.

Contact E-Mail Address: sfstruck@gmail.com

Introduction: Surgical gastrojejunostomy and enteral self-expanding metal stents are efficacious for the management of malignant gastric outlet obstruction (GOO) but limited by high complication rates and short-term efficacy. As such, EUS-guided gastroenterostomy (EUS-GE) has emerged as an attractive procedure to treat patients with GOO as an alternative to surgery and enteral self-expanding metal stents. We aimed to prospectively assess clinical outcomes and safety of EUS-GE for the management of gastrointestinal obstruction in Taiwan.

Aims & Methods: Patients who underwent EUS-GE between July 2020 and April 2022 as part of a prospective multicenter registry at ten academic centers in Taiwan were included.

Technical success was defined as successful placement of a lumen-apposing metal stent (LAMS). Clinical success was defined as the ability of the patient to tolerate an oral diet or clinical symptom relief. Post-procedural adverse events were recorded.

Results: This prospective study included 52 patients, of whom 32 (61.5%) were male and 34 (65.4%) were diagnosed as pancreatic cancer. 22 patients (95.7%) receiving EUS-GE for the palliation of malignant gastric outlet obstruction. The mean procedural time was 53.4 minutes.

Technical and clinical success was achieved in 51 patients (98.1%) and 50 (96.2%), respectively. The mean change in the gastric outlet obstruction scoring system (GOOSS) after EUS-GE was 2.2. During a mean follow-up of approximately 100 days, 3 patients (5.8%) need reintervention. Adverse events, including bleeding and migration, occurred in 3 patients (6.3%).

Conclusion: EUS-GE is an emerging and minimally invasive procedure that has efficacy and safety comparable with those of current therapies for the management of malignant gastric obstruction.

Disclosure: No Any Conflict of Interest.

PERCUTANEOUS CHOLECYSTOSTOMY FOR ACUTE CALCULOUS CHOLECYSTITIS AN OBSERVATIONAL STUDY FROM A SINGLE INSTITUTE

K. Abdelsaid¹, B. Jayasanakar¹, M. Hassan¹, M. Jeilani¹, H. Ali¹

¹Maidstone and Tunbridge Wells NHS Trust, General Surgery, Tunbridge Wells, United Kingdom

Contact E-Mail Address: Kirolos.Abdelsaid@nhs.net

Introduction: Although percutaneous cholecystostomy (PC) is generally accepted as a bridge to definitive therapy for acute cholecystitis (AC), which remains cholecystectomy, some patients did not undergo cholecystectomy primarily due to contraindications to surgery. Here, we aimed to audit our clinical practice from a single institute.

Aims & Methods: The study included one hundred fifty-three patients who presented with Acute Cholecystitis and were initially managed with a Percutaneous Cholecystostomy tube. In addition, the proportion of patients who did not undergo subsequent LC and their characteristics were analysed.

Period: January 2016 till December 2021

Characteristics of patients who did not undergo subsequent LC were analysed.

Results: 27% (41/153) of the study cohort underwent LC, while the remaining patients (n=112) did not receive any surgical intervention. 22/122(20%) were presented with AC and coexisting hepatobiliary malignancy.

The mean age of the remaining patients (n=90) was 75±13 years, and the median length of drain insertion of those patients was 40 days.

The majority (57%) was presented with severe AC, while 8% had AC with adjacent liver abscess.

55% of those patients did not develop any further attacks of AC after PC removal, while 25% were deemed unfit for surgery.

The rest of the patients (20%) either refused the operation or died before LC.

The American Society of Anaesthesiologists (ASA) score was IV in 9% of patients (8/90).

15% (13/90) experienced post PC complications, including blocked stent, pain or cellulitis around the tube.

The 60-day mortality rate of patients who did not undergo LC was 11% (10/90).

Conclusion: The majority of AC patients treated initially with PC did not undergo subsequent LC. PC in high surgical risk patients with AC could be considered a definitive treatment.

EFFECT OF AN AUTOMATED FLEXIBLE ENDOSCOPE CHANNELS BRUSHING SYSTEM ON IMPROVING THE REPROCESSING QUALITY: A PROSPECTIVE, RANDOMIZED CONTROLLED STUDY

R. Shang¹, J. Liu¹, H. Yu¹

¹Renmin Hospital of Wuhan University, Department of Gastroenterology, Wuhan, China

Contact E-Mail Address: riddle@whu.edu.cn

Introduction: Qualified reprocessing, of which meticulous channels brushing is the most crucial step, is essential for the prevention and control of endoscopy-associated infections. However, channels brushing is often omitted in practice, due to the pressure of endoscope turnover, the lack of reprocessing technicians and weak supervision.

Aims & Methods: This single-center, prospective, randomized controlled study aimed to evaluate the effect of an automated flexible endoscope channels brushing system (AECBS) on reducing bioburden and improving the quality of endoscope reprocessing.

This study was conducted, between Nov 24, 2021 and Jan 22, 2022, at Renmin Hospital of Wuhan University, China. Eligible endoscopes were randomly allocated to the auto group (channels brushed by AECBS) or the manual group (channels brushed manually), with sampling and culturing after high-level disinfection and drying. The primary endpoint was the positive rate of cultures for endoscopes.

Results: 204 endoscopes in the auto group and 205 in the manual group were eventually analyzed. The positive rate of cultures was significantly lower in the auto group than in the manual group (15.2% vs 23.4%, relative risk 0.649 [95% CI 0.432-0.976]; p=0.035).

Conclusion: AECBS could reduce the endoscope bioburden and improve the reprocessing quality. It has great potential to replace manual channels brushing and lower the risk of endoscopy-associated infections, providing a new idea for the optimization of reprocessing protocols.

FIRST EXPERIENCE OF ENDOSCOPIC STENTING OF THE MAIN PANCREATIC DUCT IN PATIENTS WITH PANCREATIC FLUID COLLECTIONS AFTER PANCREAS TRANSPLANTATION

Y. Teterin¹, S. Suleymanova¹, I. Dmitriev¹, P. Yartcev¹¹Sklifosovsky Research Institute for Emergency Medicine, Endoscopy, Moscow, Russian Federation**Contact E-Mail Address:** shabi_s@mail.ru

Introduction: One of the most common complications after pancreas transplantation are pancreatic fluid collections (PFCs), which are often complicated not only by infection and subsequent disfunction of the pancreatoduodenal graft (PDG), but also with a rather high mortality rate of recipients. Drainage is not always effective and often requires repeated open surgical interventions, which worsens the outcome of the surgery. Percutaneous drainage of PFCs combined with endoscopic stenting of the main pancreatic duct of the pancreatoduodenal graft (MPDPDG) showed high efficiency in the treatment of PFCs.

Aims & Methods: From 01.01.2012 to 31.12.2021 at the Sklifosovsky Research Institute for Emergency Medicine were performed 64 transplantations of PDG. In 11 cases (17.2%), the early postoperative period was complicated by the formation of PFCs.

Of these, 7 patients underwent percutaneous drainage of pancreonecrosis with high efficiency and did not required additional methods of treatment. In the remaining 4 patients, drainage was ineffective and was an indication for endoscopic stenting of the MPDPDG. They were the ones who made up the study group.

Among them were 3 men and 1 woman. The mean age of the patients was 36,4 years. PFCs in these patients formed on days 1, 12, 18, and 47 after PDG transplantation. We used a gastroscope to stent the MPDPDG, due to anatomical features of the location of the duodenoduodenal anastomosis after PDG transplantation.

Through the endoscope channel was performed selective catheterization of the MPDPDG, using a catheter and a guidewire, followed by its contrasting with a water-soluble contrast agent. Due to the extravasation of the contrast, was determined the localization of the defect in the PDG duct system.

After that, a plastic pancreatic stent with a diameter of 7 Fr. and a length of 7 cm. was installed along guidewire. The stent was installed in such a way that its proximal edge completely covered the defect zone, and the distal one was determined in the intestinal lumen.

Results: In all patients PDG pancreaticography revealed extravasation of a contrast in the area of the isthmus and body of the pancreas, which required stenting of the MPDPDG. In 1 (25%) case, the patient had a dislocation of the stent into the intestinal lumen (III degree according to Clavien-Dindo (2009)). This patient underwent repeated endoscopic stenting of the MPDPDG.

On average 23 days after endoscopic stenting of the MPDPDG, the drainage tubes were removed and after approximately 40 days all patients were discharged in a satisfactory condition with follow-up endocrinologist and surgeon consultation. Pancreatic stents were removed after 6 months $\pm$ 7 days.

Conclusion: Endoscopic stenting of the main pancreatic duct of the donor pancreas is by far the most highly effective and minimally invasive method in the treatment of PFCs after transplantation of the pancreatoduodenal complex.

Disclosure: Nothing to disclose.

P0970

RISK FACTORS AND TREATMENT STRATEGIES OF DELAYED GASTRIC EMPTYING AFTER LAPAROSCOPIC PANCREATODUODENECTOMY

Y. Liu¹, J. Kong², T. Wang², J. Liu¹¹Shandong University, Department of Liver Transplantation and Hepatobiliary Surgery, Shandong Provincial Hospital, Jinan, China, ²Shandong Provincial Hospital Affiliated to Shandong First Medical University, Department of Liver Transplantation and Hepatobiliary Surgery, Jinan, China**Contact E-Mail Address:** dr1027188507@163.com

Introduction: With the development of laparoscopic technology and instruments, laparoscopic pancreaticoduodenectomy (LPD) has been applied in the surgical treatment of pancreatic head tumors, periampullary tumors and lower common bile duct tumors in an increasing number of medical centers.

However, LPD takes a long time, excises many organs, involves accurate perivascular anatomy and complex digestive tract reconstruction techniques, and has a high incidence of postoperative complications. Delayed gastric emptying (DGE) is one of the most common postoperative complications of LPD, with an incidence of up to 30%. The mechanism of DGE is still unclear. At present, there is still a lack of effective strategies for DGE prevention and treatment.

Aims & Methods: To explore the risk factors and key points of management of delayed gastric emptying (DGE) after laparoscopic pancreaticoduodenectomy (LPD), the clinical data of 832 patients who underwent LPD in the Department of Liver Transplantation and Hepatobiliary Surgery, Shandong Provincial Hospital Affiliated to Shandong First Medical University between March 2017 and November 2021 were analyzed retrospectively. According to the occurrence of DGE, patients were divided into DGE group and non-DGE group. The clinical characteristics between the two groups were compared, the risk factors for DGE were analyzed, and the effects of various treatment strategies were evaluated.

Results: A total of 194 (23.3%) patients developed DGE after LPD. Patients in the DGE group had a significantly higher rate of preoperative hypoalbuminemia and incidence of other kinds of postoperative complications. Multivariate logistic regression analysis showed that preoperative hypoalbuminemia, intraoperative blood transfusion and intra-abdominal infection were independent risk factors for DGE; furthermore, intraoperative blood transfusion, postoperative pancreatic fistula and bile leakage were the main risk factors for the development of grade B and C DGE. The modified surgical strategy, which put the gastrojejunal anastomosis in the input loop of the jejunum, could reduce the incidence of DGE.

Sixty-two patients developed grade B and C DGE, 48 of whom had intra-abdominal infection combined with stomal leakage. Among them, 42 patients underwent abdominal puncture drainage, 6 received continuous internal negative pressure flushing and drainage, and all of them recovered rapidly after treatment.

Conclusion: Treatment of preoperative hypoalbuminemia, rational gastrojejunum anastomosis, controlling intra-abdominal infection and reducing the occurrence of stomal leakage could reduce the incidence of DGE after LPD. Drainage is vitally important for the treatment of grade B and C DGE patients who have intra-abdominal infection combined with stomal leakage.

ENDOSCOPIC OVERSTITCH SUTURE OF PARIETAL LEAKS AFTER GASTROINTESTINAL COMPLEX RESECTIONS IS FEASIBLE, SAFE AND REDUCE THE NEED FOR HOSPITALIZATION

G. Grande¹, H. Bertani¹, S. Cocca¹, F. Pigò¹, S. Mangiafico¹, R. Salvatore¹, M. Lupo¹, G. Pontillo¹, R. Conigliaro¹
¹Azienda Ospedaliero Universitaria of Modena, Gastroenterology and Digestive Endoscopy Unit, Modena, Italy

Contact E-Mail Address: grande.giuseppe@aou.mo.it

Introduction: Endoscopic submucosal dissection (ESD) and endoscopic full thickness resection (EFTR) are recognized as useful advanced techniques for the treatment of pre-neoplastic, neoplastic and sub-epithelial lesions of the gastrointestinal tract.

However, complication rate and the need for hospitalization still remain a matter of discussion. The application of suturing devices have been suggested as an option to prevent complications and reduce hospital stay.

Aims & Methods: The aim of our study was to analyse the feasibility and safety endoscopic Overstitch suturing devices applied after large and deep ESD and EFTR. The secondary aim was to evaluate the efficacy of suturing system to reduce hospital stay and complication rate.

From September 2020 to April 2022 (in Covid-19 pandemic era) all consecutive patients sutured with Apollo SX Overstitch after complex resections were prospectively enrolled. Feasibility, complications, hospital stay were analyzed.

Results: Seventeen patients (8 female, mean 78, range 48-89) were enrolled; lesions were located in the stomach (3), in the rectum (9), in the sigmoid colon (3), in the descending colon (2). Final diagnosis were 1 occludent sub-epithelial lesion, 10 HGD/T1 (sm1) and 4 T1 (sm2/3) or T2 cancer. Eleven patients were treated with ESD (10 as outpatients) whereas 6 underwent eFTR, 5 of them as inpatients during uneventful medium hospital stay of 4.7 days (range 4-6).

Overstitch suture was feasible in all the lesions, and all locations. No major complications occurred. One minor complications (descending colon luminal stenosis) occurred and was successfully treated with temporary placement of covered metal stent.

Conclusion: Endoscopic overstitch system is safe and a useful tool to close large wall defect after ESD/EFTR

COMPARISON BETWEEN LAPAROSCOPIC AND OPEN APPROACHES FOR SECOND COLORECTAL RESECTION AFTER COLECTOMY OR PROCTECTOMY

H. Nozawa¹, K. Sasaki¹, K. Murono², S. Emoto¹, S. Ishihara¹
¹University of Tokyo, Department of Surgical Oncology, Tokyo, Japan, ²University of Tokyo, Department of Surgical Oncology, Tokyo, Japan

Contact E-Mail Address: hiroanozawa@yahoo.co.jp

Introduction: Past randomized controlled trials demonstrated that a laparoscopic approach provides several benefits in patients who undergo colon or rectal surgery without jeopardizing oncological outcomes. Laparoscopic approach in second colorectal surgery in such patients is considered more challenging than that in surgery-naïve patients because of potential intra-abdominal adhesion, resulting in an elevated risk of unexpected trauma [1].

Unfortunately there is a paucity of studies comparing outcomes of laparoscopic and open approaches for second primary colorectal lesions after colectomy or proctectomy.

Aims & Methods: The current study is aimed to compare the surgical outcomes of laparoscopic vs open resection of the colorectum after colectomy or proctectomy. Among patients with colorectal disease who underwent surgery between 2008 and 2021 at our hospital, we selected 73 consecutive patients who had previous colorectal surgery for this retrospective study. Here, reoperation aimed at managing complications of preceding colorectal surgery, e.g. anastomotic leakage or stenosis, or bowel obstruction, local resection of tumors near the anus, and surgical cases of familial adenomatous polyposis or inflammatory bowel disease were excluded.

Based on the second surgery approach (laparoscopic or open), patients were divided into the Lap group (n=38) or Op group (n=35). Patients' baseline characteristics and surgical outcomes, such as operative time, blood loss, first bowel movement, postoperative complications, and survival were compared between the groups.

Categorized data were compared by the chi-squared or Fisher's exact test, whereas continuous variables were compared by the unpaired t or Wilcoxon's test. Kaplan-Meier methods were used to estimate survival curves. The log rank test was used to examine the difference in OS between patients in the Lap and Op groups.

Results: Four patients (11%) required conversion to open surgery in the Lap group; all of these patients had received open surgery for the first colorectal lesion. The median volume of blood loss was 50 ml in the Lap group and 210 ml in the Op group (p=0.0003). The median time to first bowel movement was shorter in the Lap group than the Op group (2.7 days vs 3.5 days, p=0.004). The operative time, frequencies of postoperative complications, and overall survival were similar between the groups.

Variable		Lap (n=38)	Op (n=35)	p-value
Interval from previous colorectal surgery, month	Mean ± SD	121 ± 100	122 ± 110	0.98
Resection including previous anastomosis		13 (34%)	14 (40%)	0.61
Operative time, min	Mean ± SD	321 ± 152	279 ± 139	0.22
Blood loss, ml	Median (IQR)	50 (15-403)	210 (125-420)	0.0003
Time until first bowel movement, day	Mean ± SD	2.7 ± 1.1	3.5 ± 1.2	0.004
Complications	Any Grade 2-	11 (29%)	13 (37%)	0.46

SD standard deviation, IQR interquartile range.

Table 1. Perioperative parameters according to second surgical approach.

Conclusion: Laparoscopic surgery was safe and beneficial for selected patients undergoing second colorectal resection after colectomy or proctectomy in terms of blood loss and bowel function recovery without affecting other outcomes. Encouragingly, there were no conversion cases when considering patients who had undergone preceding colorectal surgery via a laparoscopic approach presumably owing to less intraabdominal adhesion [2-4]. Our findings need to be verified using a larger number of patients in multiple institutes.

Introduction: Hemorrhoidal disease is benign but can decrease the quality of life of patients. Hemorrhoidectomy according to Milligan Morgan is an effective surgery method but often has a long and painful postoperative course. Also, “minimally invasive” procedures are currently being developed.

The use of a radio frequency current allowing the destruction of the internal hemorrhoidal tissue is a recent technique, little evaluated, and only in monocentric studies.

The objective of this multicenter study was to prospectively evaluate the efficacy and tolerance of radiofrequency in patients suffering from internal hemorrhoidal disease.

Aims & Methods: Patients with isolated internal hemorrhoidal disease had radiofrequency surgery (Rafaelo®) under general or spinal anesthesia. Patients were evaluated at 1, 3, 6 and 12 months after surgery. The primary endpoint was the change in the HEMO-FISS-QoL score at month 3 (vali-

dated score to assess the impact of hemorrhoidal disease on quality of life via a self-administered questionnaire [1]). The secondary endpoints were the changes of this score at 1, 6 and 12 months, the evolution of symptoms, complications, scores of postoperative pain and duration of work interruption.

Results: Between January 2019 and March 2021, 129 patients (69% males, median age 49 years) were included in 16 French centers for minimally invasive procedure. The hemorrhoidal disease initial grades were, respectively, grade 1 in 2%, grade 2 in 41%, grade 3 in 54% and grade 4 in 3% of patients. The median joules delivered per patient was 3925 with a median operating time of 15 minutes.

Three months after surgery, the median of the HEMO-FISS-QoL score dramatically and significantly decreased from 15.8/100 to 0/100 ($p < 0.0001$) with a median score remaining at 0/100 at M6 and M12. There was also a significant decrease at month 3 in the rates of patients reporting bleeding (21% vs 84%, $p < 0.001$), prolapse (34% vs 91.3%, $p < 0.001$) and anal discomfort (median 0/10 vs. 5/10, $p < 0.0001$). The median work interruption was 4 days. The median maximum scores of postoperative pain were 1.7/10, 0.4/10, 0/10 and 0/10 at weeks 1, 2, 3 and 4, respectively. A total of respectively 32%, 25%, 12% and 3% of patients consumed level 2 analgesics during weeks 1, 2, 3 and 4. Opioids were administered in 8.5% of patients, most often due to postoperative external hemorrhoidal thrombosis.

At year 1, only 7 patients (5%) had to be re-operated, all using the Milligan and Morgan technique.

Three patients (2.3%) had postoperative hemorrhage, one of which had to have hemostasis under general anesthesia. Patients on DOACs (4 patients) or antiplatelet agents other than aspirin (3 patients) did not have any bleeding complications.

Three patients (2.3%) had dysuria requiring urinary catheter, 2 had abscess, 2 a fecal impaction. A patient was operated for an anal fissure. Finally, 10 patients (7.7%) presented postoperative external hemorrhoidal thrombosis.

Regarding patient satisfaction, 86% of patients would agree to repeat the same procedure if necessary and 80% would recommend it to those around them.

Conclusion: The “minimally invasive” surgical treatment of internal hemorrhoidal disease by radiofrequency can significantly improve the quality of life of patients and their symptoms at 1 year. Postoperative pain was not significant in most cases and the work interruption short.

MANAGEMENT OF SUPERFICIAL GASTROINTESTINAL NEOPLASTIC LESIONS ASSOCIATED WITH SEVERE SUBMUCOSAL FIBROSIS - ENDOSCOPIC SUBMUCOSAL DISSECTION TO THE RESCUE!

R. Mendo¹, A. Mascarenhas¹, C. O'Neill¹, A.R. Franco¹, I. Simao¹, P. Barreiro¹, C. Chagas¹

¹Centro Hospitalar Lisboa Ocidental, Gastroenterology, Lisbon, Portugal

Contact E-Mail Address: mendorui@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is a technically complex and demanding procedure that allows for the *en bloc* removal of gastrointestinal epithelial neoplasms regardless of size. Previous resection/manipulation, surgery or radiotherapy prior to ESD are associated with severe submucosal fibrosis, greatly enhancing the complexity of the procedure. Nevertheless, little is known about the outcomes of these patients that undergo ESD.

Aims & Methods: We retrospectively analysed, in a single center, consecutive patients that underwent ESD for gastrointestinal lesions previously subjected to resection or ablation therapy, surgery or radiotherapy, using our prospectively collected database. Short and long-term outcomes were evaluated, including efficacy, safety and complications associated with ESD in these patients.

Outcomes and complications were compared between groups. High local-risk resection was considered if piecemeal resection and if positive horizontal margin for the presence of dysplasia or carcinoma (HM1d and HM1c, respectively).

High-risk resection was defined if R1 resection or in the presence of R0 resection associated with poor prognostic histopathologic findings, defined by lymphovascular invasion, poorly differentiated carcinoma, or if deep submucosal invasion, defined as >200 µm for squamous cell cancer, >500 µm for Barrett's or gastric adenocarcinoma and >1000 µm for colorectal adenocarcinoma.

Results: From all ESD performed (n=605), 40 lesions (6.6%) had undergone previous manipulation (esophageal, n=3; gastric, n=5; colon, n=4; rectal, n=28). Previous endoscopic mucosal resection (EMR) was the most common cause of prior manipulation (65%, n=26), followed by surgery (15%, n=6), radiotherapy (5%, n=2) and ESD (5%, n=2); 10% (n=4) had prior manipulation by more than one technique. Complete procedure was achieved in 97.5% of cases (n=39), with *en bloc* resection rate of 80% (n=32), and curative resection (R0) of 51.3% (n=20).

For non-curative resected lesions, 68.4% (n=13), there was a high local-risk resection (piecemeal resection, n=7; HM1, n=6) and 31.6% (n=6) were high-risk resection. Three cases (50%) of high-risk resected lesions were submitted to surgery. Local recurrence was 5% (n=2), that were successfully retreated endoscopically. Complication rate was 12.5% (n=5) (bleeding 7.5%, n=3; perforation 5%, n=2) all successfully treated during the procedure. Mean follow-up time was 842 ± 513 days (mean ± standard deviation).

Conclusion: Lesions typically associated with severe submucosal fibrosis are associated with a lower rate of *en bloc* and of curative resection. However, ESD was associated with a high efficacy treatment rate with a good safety profile, making this minimal invasive treatment a first-line therapy in the management of superficial gastrointestinal neoplastic lesions associated with severe submucosal fibrosis.

DEVELOPMENT OF A NEW 3D PRINTED ENDOSCOPIC GRASPING INSTRUMENT

B. Sudarevic¹, J. Troya¹, K.H. Fuchs¹, A. Hann¹, A. Meining¹

¹University Hospital Würzburg, Interventional and Experimental Endoscopy (InExEn), Internal Medicine II, Würzburg, Germany

Contact E-Mail Address: sudarevicboban@gmail.com

Introduction: The constant flow of innovative ideas regarding interventional endoscopic procedures and instruments requires a quick response from the side of developers and engineers to create prototypes following these ideas. Early testing of new ideas allows for early selection of those ideas and instruments, which may have a high potential of becoming successful in future clinical practice. Using 3D printing technology may assist in the production of prototypes.

Aims & Methods: The aim of this study is the use of 3D printing technology to develop and produce a new endoscopic grasping instrument.

The design of the "new grasper" was developed at an initial conference between gastroenterologists, engineers, and endoscopic surgeons, listing the wished features of such a new instrument. The instrument should be designed for endoscopic procedures in the upper and lower GI tract. It should have a superior grasping surface and force to provide a safe grip.

The engineers created a 3D printed prototype, which could be quickly produced and subsequently tested by the involved endoscopists, who could determine the flaws and limitations.

Furthermore, versions 2.0 and 3.0 were developed and tested regarding the following criteria: maneuverability, grasping and pulling abilities, force measurements, and durability.

Results: The new 3D-printed graspers provide improved maneuverability compared to traditional endoscopic instruments with an increased working radius by its steering capacity of 220 degrees and could be advanced and withdrawn as well as angulated towards a lesion within a median 120-sec resp. 70 sec. It can be rapidly produced and assembled in the endoscopic laboratory. The correlation between rigidity and flexibility was sufficient, while the pulling force was 7.85 Newton (conventional instrument 7.68N).

Conclusion: 3D-printed grasping instruments show sufficient stability and grasping force for the tasks in interventional endoscopic procedures. In addition, the 3D printed graspers provide improved maneuverability. In the future, they may be customized to special patients or tasks, medically necessary in an individualized patient approach.

GUT MICROBIOME TO REDUCE CARBON EMISSION

H.S. Bozkurt¹

¹Maltepe University, Gastroenterology, Istanbul, Turkey

Contact E-Mail Address: sancarb79@gmail.com

Introduction: It is estimated that the total waste generated during all endoscopic procedures alone performed in the USA annually would weigh 38 000 metric tons (equivalent of 25 000 passenger cars) and the net waste mass would increase by 40% if all endoscopic procedures were performed with single-use endoscopes (1). It is worth noting that more than 100 million endoscopic procedures are performed yearly in around the world. New approaches are needed to reduce global warming and increase the protection of petroleum-based scopy devices. We aimed to reveal the bio-hybrid biomaterial that we obtained as a result of the combination of probiotic bifidobacteria which have carbon binding/reducing properties (2) with sodium alginate.

Aims & Methods: In these study which was designed in Yıldız Technical University / Istanbul, bio-hybrid films were produced by using both *Bifidobacterium animalis subsp. lactis* BB-12 probiotic strain and *Bifidobacterium infantis* in combination with sodium alginate (SA), which demonstrates biocompatibility and facilitated gelation properties in aerobic atmospheric condition. Bio-hybrid films were characterized by using different methods.

Results: Based on the spectroscopic and mechanical analysis, it was found that mechanical strength increased in films produced by adding *Bifidobacterium infantis* in SA while this increase was relatively lower as compared to those containing *Bifidobacterium animalis subsp. lactis* BB-12 as crosslinking ratio increases. Besides, bacteria contained in bio-hybrid films increased the percentage of amorphous zone of SA in SA/bacteria films, which reduced the crystallinity ratio. This indicated that crystalline chains contained in the structure of SA are degraded by probiotic bifidobacteria.

Conclusion: "Mechanical properties" are crucial for biodegradable and/or non-biodegradable materials used in tissue engineering applications. Biohybrid biofilm that contains probiotic bifidobacteria and SA structures coated endoscopy devices and sets can be a pioneering approach to reduce carbon emissions, as well as to prevent secondary infections and increase device protection (3). This is the first study to demonstrate the usability of bifidobacterium as a biomaterial.

Introduction: Gastrointestinal immune-mediated inflammatory diseases are chronic conditions generally causing abdominal pain and diarrhoea (sometimes bloody)^{1,2} among other symptoms, which entail a high burden for patients and society.

In Spain, Crohn's disease (CD) and ulcerative colitis (UC) are the most frequent gastrointestinal immune-mediated inflammatory diseases, with a joint prevalence of 0.78%³ affecting about 370,000 people.

With the introduction of biological treatments, such as adalimumab (ADA), there has been an improvement in the clinical outcomes for patients with moderately to severely active CD and UC who have had an inadequate response with, lost response to, or were intolerant to 1st line therapy⁴.

However, until biosimilars arrived, the high cost of biologics was a barrier to its prescription⁵. Cost-effectiveness analysis can be a useful tool in decision-making for the treatment of these pathologies.

Aims & Methods: Our objective was to assess the cost-effectiveness of ADA and its clinical alternatives in CD and UC in Spain.

All the effectiveness information for ADA (biosimilar) and its comparators (infliximab, tofacitinib, ustekinumab, and vedolizumab) was gathered using a PICO-S-T strategy. Two reviewers evaluated the inclusion of the studies and assessed their quality using PRISMA-NMA Checklist.

A cost-effectiveness model was built based on meta-analyses (direct or indirect) conducted between 2018-2021. Cost data (€2021) was obtained from Spanish drug cost datasets⁶ and literature review⁷.

Effectiveness was measured as the number needed to treat (NNT) versus (vs) placebo (PLC) to achieve clinical remission according to Crohn's disease activity index (CDAI) for CD or Mayo Score for UC.

Efficiency score was cost per NNT vs. PLC to achieve clinical remission according to CDAI or Mayo Score. The model was designed from a hospital perspective (only direct costs) with a 1-year time horizon.

With all this information, a cost-effectiveness analysis between ADA and the suitable alternatives was performed. A deterministic and probabilistic sensitivity analysis (PSA) was also carried out.

Results: Two meta-analyses, one for CD⁸ and one for UC⁹, met the inclusion criteria and both fulfilled 91% of the 32 points on the PRISMA-NMA Checklist items.

For CD, no statistically significant differences were seen in NNT to achieve clinical remission according to CDAI between infliximab, ADA, ustekinumab, and vedolizumab. The annual cost for ADA was 5,230€ vs 5,351€ - 10,714€ for the other treatments. As no effectiveness difference was seen, a cost minimization analysis was performed. Therefore ADA, was the most cost-effective treatment.

For UC, there were no statistically significant differences in NNT to achieve clinical remission, according to Mayo score, between infliximab, ADA,

tofacitinib, and vedolizumab. Annual cost for ADA was between 121€ - 5,484€ less expensive than the other treatments. Therefore, ADA was the most cost-effective treatment.

We performed a sensitivity analysis for both pathologies, obtaining similar results. In the deterministic sensitivity analysis, ADA was the best option with average and maximum discounts. In the PSA, ADA was the best option in 63% of the cases.

Conclusion: According to our model, ADA was the most cost-effective option for the treatment of CD and UC in Spain.

UNMET MEDICAL NEEDS IN SHORT BOWEL SYNDROME WITH INTESTINAL FAILURE IDENTIFIED FROM A QUALITATIVE SURVEY OF PATIENTS AND HEALTHCARE PROVIDERS

D. Wolin¹, K. Kosa¹, N.N. Youssef², L. Zografos¹

¹RTI Health Solutions, Research Triangle Park, United States,

²VectivBio, Basel, Switzerland

Contact E-Mail Address: nader.youssef@vectivbio.com

Introduction: Short bowel syndrome with intestinal failure (SBS-IF) is a complex and heterogeneous malabsorptive disorder. The burdensome current standard of care includes parenteral support (PS), symptomatic management, and the first-generation daily glucagon-like peptide-2 (GLP-2) analogue.

Aims & Methods: In an effort to identify perception of current treatment and unmet needs in the GLP-2 era, pilot qualitative interviews were conducted with healthcare providers (HCPs) and patients treated with tedu-

glutide. Participants (N=22; 11 patients, 5 physicians, 3 nurses, 3 dieticians) were recruited based on SBS-IF diagnosis for patients and number of SBS-IF patients for HCPs. Interview material was reviewed and exempted by institutional review board and included topics of patient experience with SBS-IF, PS and current treatment, as well as preferences for future treatments.

Results: Mean age of the 11 patients was 42.5 years (range 27-75). The majority was female (n=6), non-Hispanic White (n=8), either unemployed or receiving disability (n=7), and at least some college education (n=8). Mean time since diagnosis was 10.7 yrs (range 0.25-54). Mean length of remaining colon was 11.1 inches (0-27). Six patients had stoma. All patients had received teduglutide with a mean duration of 11.4 months (range 0.5-42). Of the 11 patients, 4 discontinued teduglutide due to end of clinical trial, allergic reaction, abdominal cramps, and intestinal blockage. Separately, 4 of the 11 patients reported no noticeable change with teduglutide treatment, while others reduced or eliminated PS, improved digestion/absorption, decreased output, improved overall wellbeing, and had more energy. The challenges reported by patients with current first generation GLP-2 treatment included suboptimal efficacy, self-injection, injection preparation, and tolerability (abdominal pain). Patients wanted future GLP-2 medications to further reduce or eliminate PS, earlier onset of action, decrease injection frequency, prefilled syringe, different mode of administration, improve overall wellbeing, and reduce bowel emptying frequency. The 11 HCPs indicated the current challenges with GLP-2 as adverse effects, increased monitoring required, and insurance/reimbursement issues. HCPs would like to see improved efficacy, less side effects, more flexibility with diet and ease of administration.

Conclusion: Progress has been made in the treatment of SBS-IF patients with first generation GLP-2 analogue. However, notable limitations and challenges still exist, including the need for daily injections, pre-mixing procedures, and suboptimal tolerability and efficacy in certain patients. Patients perceived the lack of efficacy as one of the most important challenges with current GLP-2, while physicians identified adverse events as limiting. These observations from HCPs and patients indicate the continued significant opportunities for further improvement in the management of SBS-IF.

Introduction: Several recent outbreaks of infection with carbapenem-resistant Enterobacteria associated with duodenoscope use have forced endoscopists to reassess the risk of infection transmission related to endoscopic procedures. The manual component of reprocessing appears to be the most prone to errors. Immersion cleaning in an enzyme detergent solution is very useful, and the removal ability is independent of human involvement. In addition, the usefulness of adenosine triphosphate (ATP) as an indicator to determine the endoscope cleaning effectiveness has been reported in recent years.

Aims & Methods: This study aimed to evaluate the usefulness of enzymatic cleaning using a thermostatic bath containing ATP. This prospective cohort study was conducted at 22 facilities in Japan between January 2019

and March 2021. Endoscope types included gastroscope, colonoscope, duodenoscope, echoendoscope, and enteroscope. The primary endpoint was the amount of ATP in the suction-biopsy channels after manual cleaning. For duodenoscopes, the amount of ATP in the elevator guide-wire channel was also evaluated.

The secondary endpoints were the bacteria detection rate in endoscopes, re-cleaning rate, and relationship between years of endoscope use and ATP levels. The recleaning rate was defined as the percentage of endoscopes with an ATP content ≥ 200 relative light units (RLUs) in the endoscope channel after a single cleaning.

There was no specification for the thermostatic chamber used in this study, but a neutral or alkaline enzyme detergent diluted at 0.5–1% was used, and the temperature of the enzyme detergent was controlled at approximately 40°C. ATP testing was performed on the rinsates using the CleanTrace Water/Swab ATP test (3M Co, Maplewood, Minn), and ATP RLUs were determined using a handheld luminometer.

Results: A total of 489 endoscopes were registered during the study period, and the amount of ATP in 5979 samples was assessed. The mean $\pm$ standard deviation amount of ATP (RLU) suction-biopsy channels of total endoscopes, gastroscopes, colonoscopes, duodenoscopes, echoendoscopes, and enteroscopes before and after the introduction of the thermostatic chamber was 135.3 ± 1092.7 and 40.2 ± 123.0 , 124.2 ± 423.0 and 36.1 ± 64.1 , 48.7 ± 176.3 and 20.7 ± 33.1 , 386.6 ± 3714.0 and 45.7 ± 56.2 , 425.1 ± 746.9 and 189 ± 437.0 , and 103.1 ± 386.6 and 45.3 ± 56.2 , respectively. The ATP levels after cleaning were significantly lower for all endoscopes except enteroscopes ($p < 0.0001$). The bacterial detection rate and recleaning rate improved significantly from 7.5% to 3.2% and 11.9% to 2.1%, respectively, after the introduction of the thermostatic chamber ($p < 0.001$). The amount of ATP in the elevator guidewire channels of duodenoscopes improved from 731.5 ± 3754.9 RLU to 484.6 ± 2966.8 RLU. Despite the significant decrease after the introduction of the thermostatic chamber, the amount of ATP in the elevator guide-wire channels remained high. No correlation was found between the number of years the endoscope was used and amount of ATP.

Conclusion: Enzymatic cleaning using a thermostatic chamber significantly decreased the amount of ATP, bacteria detection rate, and recleaning rate. However, the amount of ATP in the elevator guidewire channels of duodenoscopes was high, suggesting the need for special care when cleaning duodenoscopes.

Disclosure: Nothing to disclose.

Introduction: Patients with Crohn's disease (CD) frequently experience fatigue,¹ which may reduce quality of life and work productivity, thereby contributing to patient and societal costs. Few studies have analyzed the indirect cost burden associated with fatigue; this analysis used Phase 3 clinical trial data in patients with CD to assess this relationship.

Aims & Methods: The study used pooled 12-week data from patients with moderate to severe CD who received risankizumab (600 mg or 1200 mg IV) or placebo in ADVANCE and MOTIVATE. Patients completed Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) and Work Productivity and Activity Index (WPAI) questionnaires at Baseline and Week 12. All risankizumab or placebo IV treated patients with non-missing values were analyzed. Correlation between FACIT-F and WPAI was assessed by Pearson correlation. Mean change from Baseline to Week 12 in WPAI was assessed and stratified by quartiles of the mean change from Baseline FACIT-F scores. The linear relationship between improvements from baseline in FACIT-F and WPAI Overall Work Impairment (OWI) was assessed; results from the regression analyses were used to calculate cost savings based on corresponding WPAI scores and average hourly wages in the US and Europe. Annualized cost savings were determined in patients who achieved a clinically meaningful improvement (≥ 9 -unit increase) in FACIT-F and compared between patients who achieved or did not achieve a FACIT-F score $>$ normative value (>40) at Week 12.

Results: Mean age (standard deviation) of patients was 38.4 (13.3) years and 53.1 percent were male in the study population. Moderate correlation was observed between FACIT-F and all four domains of WPAI (Pearson coefficient range -0.55 to -0.30, $P < 0.0001$) at Week 12. Greater improvements in WPAI scores from Baseline were consistently observed among patients with greater mean change from Baseline scores in FACIT-F (Table) at Week 12. A ≥ 9 -unit change from Baseline in FACIT-F at Week 12 corresponded to a 12% reduction in OWI, which resulted in 4.8 hours of improved work productivity per week and an annualized cost savings per person of \$7,749 in US and €7,117 in Europe. Patients with a normative FACIT-F score of >40 at Week 12 had a corresponding reduction in OWI score of 29%, resulting in 12 hours less work impairment per week and an annualized cost savings per person of \$18,726 in US and €17,199 in Europe.

Conclusion: A significant correlation was observed between fatigue and work productivity in the induction trials of risankizumab. Early clinically meaningful improvements, as well as achieving fatigue normality, were associated with improvements in work productivity that lead to substantial indirect cost savings.

A RETROSPECTIVE STUDY COMPARING THE USE OF THE AGE, BLOOD TESTS AND COMORBIDITIES (ABC) SCORE TO PREDICT 30-DAY MORTALITY IN ACUTE UPPER AND LOWER GI BLEEDING WITH CURRENT SCORES USED AT MATER DEI HOSPITAL

G. Costa¹, F. Mercieca¹, M. Aquilina², N. Azzopardi³

¹Mater Dei Hospital, Msida, Malta, ²University of Edinburgh, Deanery of Molecular, Genetic and Population Health Science, Edinburgh, United Kingdom, ³Mater dei Hospital, Gastroenterology, Msida, Malta

Contact E-Mail Address: glenncosta110@gmail.com

Introduction: Gastrointestinal (GI) bleeding is a common problem that medical practitioners encounter in both the emergency department as well as the primary care setting⁽¹⁾.

During assessment, it may be difficult to distinguish between upper GI bleeding (UGIB) and lower GI bleeding (LGIB). Ideally, clinicians should use a single score for both acute UGIB and LGIB. This was recommended in the recent 2015 UK National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report on GI bleeding⁽²⁾.

Accurate and early stratification of mortality risk could allow targeted management that may improve outcome.

Aims & Methods: The purpose of this study was to assess and compare the performance of the Age, Blood tests and Comorbidities (ABC) score⁽³⁾ in predicting 30-day mortality in acute UGIB/LGIB against established scores including the Glasgow Blatchford score (GBS), Oakland, Rockall and AIMS65 scores.

The salient data of 137 patients presenting with GI bleeding at Mater Dei Hospital Malta between July 2018 and July 2020 were recorded. Patients who developed UGIB or LGIB while already inpatients were excluded.

UGIB was defined as presentation with coffee-ground vomiting, melaena or haematemesis. LGIB was defined as presentation with fresh red blood (haematochezia) or clots per rectum, maroon-coloured stool or blood mixed in with stool.

Patient demographics, investigations (blood tests, parameters), comorbidities, medications and management (including endoscopy) were obtained using the Mater Dei Hospital electronic database and the patients' medical notes. The risk scores were then calculated using the data collected.

All cause 30-day mortality, ASA score, transfusion requirements and the need for surgical/endoscopic interventions were used as the primary outcome measures to classify patients as being in high/low risk of mortality. The ABC score's performance in both UGIB/LGIB was compared with existing scores by calculating the area under receiver operating characteristic curve (AUROCs), sensitivities, specificities and outcome among patients classified as low risk and high risk. Statistical analysis was carried out using the pROC R package,⁽⁴⁾ with the AUROCs compared using DeLong's method⁽⁵⁾

Results: After statistical analysis, the ABC score showed a clear AUROC improvement over all the other scores in LGIB, most of which were also statistically significant, with a p-value less than 0.05. It is clear that the LGIB is significantly more discriminative than all other standard scores for the LGIB case.

In the UGIB case, the ABC score AUROC continued to show improvement over all other scores. However, the statistical significance of this higher AUROC is much weaker, which means that the ABC score is at least as capable as other scores in classifying high/low risk UGIB patients, but not necessarily more discriminative.

Conclusion: An accurate diagnosis of location of bleeding cannot always be made on presentation. The discriminative performance of existing scores for prediction of mortality in patients with GI bleeding is relatively poor.

From this study we can conclude that the ABC score is a reliable tool which can be used as a single metric for all GI bleed cases.

It has shown good performance in predicting mortality and stratifying patients into high or low risk of death.

Furthermore, the ABC score shows superior performance to other standard metrics in the majority of LGIB and some of the UGIB cases.

The clinical application of this score should improve patient management as well as produce more accurate prognostic information for both clinician and patient.

INFORMED CONSENT FOR GASTROINTESTINAL ENDOSCOPY: RESULTS OF A SURVEY ON CURRENT PRACTICES IN MEMBER SOCIETIES OF THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY

G. Tziatzios¹, J. Gauci², K. Triantafyllou³, S.M. Everett⁴

¹Attikon University General Hospital, Hepatogastroenterology Unit, Second Department of Internal Medicine – Propaedeutic, Research Institute and Diabetes Center, Medical School, National and Kapodistrian University of Athens, "Attikon" University General Hospital, Athens, Greece, ²Department of Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, ³Attikon University General Hospital, Hepatogastroenterology Unit, Second Department of Propaedeutic Internal Medicine, Medical School, National and Kapodistrian University of Athens, "Attikon" University General Hospital, Athens, Greece, ⁴Leeds Teaching Hospitals NHS Trust, Dr., Hemel Hempstead, United Kingdom

Contact E-Mail Address: g_tziatzios@yahoo.gr

Introduction: Obtaining valid informed consent prior to endoscopic procedures is considered a fundamental requirement in most countries. We aimed to understand current practice, guidance and regulations in each member nation of the European Society of Gastrointestinal Endoscopy (ESGE) with the intention of informing the need for, and content of a ESGE Position Statement on Consent.

Aims & Methods: A dedicated 12-item, web-based survey assessing practices regarding the process of informed consent prior to gastrointestinal endoscopy was anonymously disseminated to two leading representatives of each member society of the ESGE.

Results: Forty-six (47.4%) representatives from 32/50 (64.0%) societies responded. The process of obtaining informed consent prior to any endoscopic procedure is a prerequisite in all countries, and this is usually recorded in writing (93.8%, n=30).

The legal age above which an individual can provide informed consent varies from 14 years (10.9%) to 18 years (65.6%, n=21). Whilst endoscopists in most countries are routinely required to assess the patient's capacity to provide informed consent (65.6%, n=21), an official legal definition of capacity is in place in only 43.8% (n=14).

In situations where the patient lacks capacity, the appropriate path will be determined by the patient's next of kin or the caring medical team in 43.8% and 21.9% of countries respectively.

National guidance on consent, either from specialist or general medical governing bodies, is not available in more than half (56.3%, n=18) of countries. Relevant case law or legislation is available in only 18.8% of countries (n=6), whilst the remainder were not aware of any such documentation. The development of ESGE guidance on the process of informed consent prior to endoscopy was deemed valuable by most participants (95.7%, n=44). Popular key areas proposed by respondents included the level of information provided to patients about adverse events and risk/benefit ratios, process for consent in emergency situations and assessment of capacity.

Conclusion: Although the process of obtaining informed consent prior to endoscopy is commonplace among ESGE member states, there is a wide variation in practice with national guidance frequently not available. The development of ESGE guidance may allow for standardization of approach but will need to account for variations in national legislature.

Disclosure: All authors declare no conflict of interest.

REASONS FOR CHOICE OF ADVANCED THERAPIES (BIOLOGICS AND JAKIS) FOR THE TREATMENT OF ULCERATIVE COLITIS IN EUROPE

G. O'Neill¹, F. Hennessy¹, S. Barlow¹, J. Kumar², F. Brellier², F. Sheikh², K. Davé²

¹Adelphi Real World, Bollington, United Kingdom, ²Bristol Myers Squibb, Princeton, United States

Contact E-Mail Address: grace.oneill@adelphigroup.com

Introduction: Many factors influence treatment choices in ulcerative colitis (UC). Currently approved advanced treatments (ATs) for moderate-to-severe UC include biologics and small molecules (Janus kinase inhibitors [JAKis] and sphingosine 1-phosphate receptor modulators) and it is important to understand how those therapies are chosen.

Aims & Methods: We assessed reasons for choice of biologics and JAKis using data collected September 2020–March 2021 in France, Germany, Italy, Spain, and the United Kingdom by the Adelphi Disease Specific Programme for UC (1), a point-in-time survey of gastroenterologists (GIs) and patients. GIs provided demographics, clinical characteristics, and treatment history for 7 consecutive UC patients and an additional 2 patients receiving JAKis. Mann-Whitney U test, t-test, and Fisher's exact test were used to compare patients on biologics with those on JAKis.

Results: The study included 253 GIs and 1030 patients on biologics and 503 on JAKis. Patients had a mean age of 40 years (SD 13.33) and mean disease duration of 6 years (SD 5.8); over half were male (biologics, 54%; JAKis, 58%). JAKis were more commonly given as third-line or greater therapy (73%) vs biologics (45%). Patients on JAKis had more severe disease at initiation (biologics, 40%; JAKis, 50%). GIs chose ATs mainly because of efficacy; however, a significantly higher proportion of patients were receiving biologics because of safety and access ($P<0.05$), and JAKis were more often chosen for mode of administration ($P<0.05$).

Only 37% of patients receiving biologics were deemed suitable to receive JAKis but were not switched because GIs either wanted to exhaust other treatment options first, had safety concerns, or there were formulary restrictions (Table).

	Biologic (n=1030)	JAKi (n=503)	P value
Number of treatment lines, mean (SD) ¹	2.5 (1.1)	3.2 (1.3)	<0.0001
Number of AT lines, mean (SD)	1.3 (0.6)	2.2 (1.0)	<0.0001
Severity at initiation of AT, n (%)			
Mild	14 (1.4)	8 (1.6)	0.0009
Moderate	602 (58.5)	246 (48.9)	
Severe	414 (40.2)	249 (49.5)	
Reasons for choice of AT, n (%)			
Efficacy	1017 (98.7)	494 (98.2)	0.4922
Safety/tolerability	537 (52.1)	187 (37.2)	<0.0001
Treatment administration and monitoring	374 (36.3)	347 (69.0)	<0.0001
Access/cost	423 (41.1)	143 (28.4)	<0.0001
Areas of improvement for AT, n (%)			
Efficacy	631 (61.3)	220 (43.7)	<0.0001
Safety/tolerability	340 (33.0)	270 (53.7)	<0.0001
Treatment administration and monitoring	402 (39.0)	47 (9.3)	<0.0001
Access/cost	224 (21.8)	147 (29.2)	0.0015
Suitable candidate for JAKi, n (%)	380 (36.9)	–	–
Suitable candidate for biologic, n (%)	–	165 (32.8)	–
Top 3 reasons for not receiving a JAKi, n (%) (n=380)			
Prefer to exhaust other treatment options	175 (46.1)		
Safety factors ²	94 (24.7)		
Formulary restrictions	86 (22.6)		
Top 3 reasons for not receiving biologic, n (%) (n=165)			
Prefer to exhaust other treatment options		41 (24.9)	
Does not want to go to an infusion center		40 (24.2)	
Patient dislikes injections/ infusions		37 (22.4)	

¹Treatment line includes any combination of 5-ASA, steroids, immunomodulators and AT.

²Safety factors include 'Concerns regarding: infection, malignancy, and blood clots' and 'other safety/side effect concerns.'

Table. GI-reported clinical and treatment characteristics of patients with UC receiving biologics and JAKis

Conclusion: GIs treating patients with UC largely prescribed JAKis as third-line or later treatment and identified a greater need for JAKis with improved safety; biologics with improved efficacy and treatment administration overall were identified as needed. These data point to a need for additional AT options that address efficacy, safety, and administration unmet needs and facilitate treatment choice.

CLINICAL AND HEALTH OUTCOMES ASSOCIATED WITH TREATMENT SEQUENCES FOR MODERATE-TO-SEVERE ULCERATIVE COLITIS

M.C. Dubinsky¹, S. Rivolo², M. Suryavanshi³, A. Ambavane², N. Agnihotri², C. Franco-Villalobos², M.T. Osterman³, K. Gupte-Singh³
¹Icahn School of Medicine at Mount Sinai, Department of Pediatrics and Medicine, New York City, United States, ²Evidera, Inc., London, United Kingdom, ³Bristol Myers Squibb, Princeton, United States

Contact E-Mail Address: marla.dubinsky@mssm.edu

Introduction: Clinical guidelines recommend various treatments for moderate-to-severe ulcerative colitis (UC), including anti-TNFs (infliximab, adalimumab) and other advanced therapies (vedolizumab, tofacitinib, ustekinumab). Ozanimod (OZA), a selective oral sphingosine-1-phosphate receptor modulator, was recently approved for UC.

Aims & Methods: Given the availability of multiple treatment classes, the aim of this study was to evaluate the optimal sequencing of available treatments to control UC disease activity and delay the need for treatment switching. A patient-level simulation was developed to predict changes in Mayo score, based on patients' baseline characteristics and treatment received, and consequent clinical outcomes (response, remission, relapse) at the end of the induction and maintenance phases, associated with 3 lines (1st line [1L], 2nd line [2L], 3rd line [3L]) of UC treatment. The modeled sequences evaluated OZA either replacing the current 1L treatments or shifting them to 2L, across multiple 1L treatment baskets (Table). On each line, patients could switch to the subsequent line because of either relapse or adverse events. The average time spent on each line of treatment and the overall life-years (LYs) and quality-adjusted life years (QALYs) were estimated over patient lifetime and discounted at 3% annually.

Multivariate risk equations were developed for OZA outcomes based on the phase 3 TRUENORTH randomized controlled trial. Matching adjusted indirect treatment comparison was conducted for the comparators vs. OZA using published randomized controlled trial data stratified by prior anti-TNF exposure. Due to data gaps, the reduction in comparator efficacy post exposure to non-anti-TNFs was assumed to be 50% of the reduction observed post anti-TNF exposure for all treatments. In scenario analysis, two scenarios with 0% and 25% reduction post non-anti-TNFs exposure for all treatments were evaluated. Further extensive scenario analyses were conducted to test alternative input sources, clinical assumptions, or shorter time horizon.

Results: OZA was associated with higher or similar 1L QALYs (2.00 years [yrs]) and 2L QALYs (1.62-1.79 yrs) compared to all other treatment scenarios in all baskets evaluated (1L: 0.91-2.01, 2L: 0.66-1.73 yrs) (Table). The overall QALYs (16.46-16.67 yrs) and 1L-3L QALYs (4.33-5.76 yrs) were similar for all sequences. Testing alternative scenarios of 25% and 0% reduction in efficacy after non-anti-TNFs exposure favored OZA starting sequences, leading to comparable or higher 1L-3L QALYs in comparison to all other sequences in the study (1L-3L QALYs difference: 0.00-0.69 yrs). The results were robust across all other sensitivity analyses performed.

Conclusion: This study found that positioning OZA as either 1L or 2L therapy was associated with improved time on treatment and QALYs in 1L and 2L compared to most of the advanced treatments baskets considered, primarily driven by OZA efficacy.

Contact E-Mail Address: jim.kershaw@adelphigroup.com

Introduction: Crohn's disease (CD) is a chronic inflammatory bowel condition that requires lifelong management. Cycling through ineffective treatments can have adverse impacts on patients; however, there remains limited data on how treatment switches affect patients with inflammatory bowel disease (IBD).

Aims & Methods: This study aimed to evaluate the impact of treatment switch on clinical symptoms and functional impairment. Data from the Adelphi Real World IBD Disease Specific Programme™, a real-world, point-in-time survey of Gastroenterologists (GEs) and their consulting CD patients in the United States, France, Germany, Italy, Spain and the United Kingdom between 2020 and 2021 were analyzed. GE patient extracted Data includes information on demographics, CD symptoms, and treatment.

Patients in our analysis were diagnosed and treated for CD between ≥ 1 years and < 3 years prior to data collection and split into 2 groups (those that had switched treatment in the past 12 months (switchers), and those that had not switched in the past 12 months or had never switched (non-switchers)).

Treatment switch was defined as the initiation of a new treatment or discontinuation of a treatment. Inverse probability weighted regression adjustment was used to assess the impact of switching on clinical characteristics, adjusting for CD severity, most prevalent symptoms at diagnosis, and time since diagnosis.

Results: Data were from 207 GEs and 483 patients with CD receiving treatment at the point of data collection. Patients were mean age 34.9 years, had a mean BMI of 23.6, mean disease duration of 5.6 years and 55% were female. In total, 119 patients were identified as switchers and 364 were identified as non-switchers. When adjusting for covariates (weighting of covariates resulted in a standardized mean difference of $< 10\%$, indicating a good balance), patients who switched were more likely to have moderate-severe CD ($p < 0.05$), and more likely to be currently experiencing a flare than non-switchers ($p < 0.05$) (Table). Switchers were also more likely to experience key disease symptoms than non-switchers ($p < 0.05$). Switchers were more likely to experience worsened severity of symptoms ($p < 0.05$), as well as worsened outcomes such as increased impairment in the ability to go to work and to conduct normal daily activities ($p < 0.05$), compared with non-switchers (Table).

Conclusion: We found significant associations between treatment switch and worsened clinical symptoms and functional impairment. This highlights the importance and significant unmet need for effective treatment early in the CD treatment journey.

	Switchers (n=119)	Non-switchers (n=364)	p value
<i>Current disease status</i>			
Physician subjective disease severity (0: mild, 1: moderate/severe)	0.42	0.18	< 0.05
Flaring status (0: not flaring, 1: flaring)	0.18	0.04	< 0.05
<i>Current symptoms (0: no symptom, 1: symptom experienced)</i>			
Abdominal pain	0.41	0.28	< 0.05
Non-bloody diarrhea	0.29	0.14	< 0.05
Night-time bowel movement urgency	0.08	0.02	< 0.05
Fatigue	0.34	0.24	< 0.05
<i>Mean symptom Severity (0: none, 5: extremely severe)</i>			
Overall symptom severity	2.03	1.49	< 0.05
Abdominal pain severity	1.82	1.27	< 0.05
Sleep disturbance severity	1.50	0.95	< 0.05
Fatigue severity	1.98	1.38	< 0.05
Impairment in ability to go to work	1.48	1.08	< 0.05
Impairment in ability to conduct normal daily activities	1.56	1.08	< 0.05

IMPACT OF SUBOPTIMAL RESPONSE ON CLINICAL AND HUMANISTIC BURDEN IN CROHN'S DISEASE

J. Kershaw¹, M. Sanon², S. Kachroo³, S. Barlow¹, T. Hoops², D. Naessens⁴, C. Willey⁵

¹Adelphi Real World, Cheshire, United Kingdom, ²Janssen Global Services, Horsham, United States, ³Janssen Scientific Affairs, Horsham, United States, ⁴Janssen Pharmaceutica NV, Beerse, Belgium, ⁵College of Pharmacy, University of Rhode Island, Department of Pharmacy Practice, Kingston, United States

Contact E-Mail Address: jim.kershaw@adelphigroup.com

Introduction: Current treatments for Crohn's Disease (CD) are associated with loss of treatment response, however studies assessing the burden of non-response in the real-world are scarce and the clinical and humanistic burden remains unknown.

Aims & Methods: We aimed to describe the burden of active disease on symptom severity, health-related quality of life (HRQoL) and work impairment in patients with CD. A retrospective analysis of physician-reported and patient-reported 2020-2021 data drawn from the Adelphi Real World Inflammatory Bowel Disease Specific Programme™ which is a real-world point-in-time survey of gastroenterologists (GEs) and their consulting patients with CD in the United States, France, Germany, Italy, Spain and the United Kingdom was conducted. Data included patient demographics, clinical status, treatments, and patient completed questionnaires including the EuroQoL 5-dimension 5-Level (EQ-5D-5L) and Work Productivity and Activity Impairment (WPAI). Patients were stratified into 3 groups by remission status: Remitters (RE): 'symptomatic remission, full mucosal healing', Partial Responders (PR): 'symptomatic remission, full mucosal healing not achieved or unknown', and 'full mucosal healing, symptoms remain', and Non-Remitters (NR): 'not in remission'.

Multivariate regression models adjusted for severity, symptoms, and age at diagnosis assessed impact of remission status on clinical and HRQoL outcomes.

	Remitters vs Partial Responders		Remitters vs Non-Remitters	
	Odds ratio	p value	Odds ratio	p value
<i>Symptom Severity (Scale: 0-5, where 0 = none, 5 = extremely severe) (Ordered Logistic Regressions)</i>				
Overall symptom severity (n=1786)	3.46	< 0.05	30.80	< 0.05
Abdominal pain severity (n=1783)	3.15	< 0.05	26.40	< 0.05
Sleep disturbance severity (n=1715)	2.28	< 0.05	10.02	< 0.05
Fatigue severity (n=1786)	2.59	< 0.05	15.90	< 0.05
<i>Treatment Patterns</i>				
Switched CD therapy in past 12 months (n=561) (logistic)	1.71	0.09	2.96	< 0.05
Number of treatment lines (n=1786) (linear)	Coefficient	P value	Coefficient	P value
	-0.01	0.92	0.21	< 0.05
<i>Patient-Reported Outcomes (Linear Regressions)</i>				
EQ-5D-5L	-0.03	< 0.05	-0.12	< 0.05
WPAI: % overall work impairment due to CD (n=326)	7.44	< 0.05	16.13	< 0.05

EQ-5D-5L: standardized instrument for measuring generic health status, completed by the patient at the time of consultation; a max. score of 1 = best health state; WPAI: measures patient's ability to perform regular activities; all measures: 0-100% (total impairment), higher percentage = worse impairment. Available for working patients only.

Table: Impact of suboptimal response on patient outcomes compared with remitters.

Results: 337 GE and 1,786 CD patients receiving treatment for ≥ 3 months were included (mean age 38.9 years, 53% female, mean BMI 24.0, mean disease duration 5.6 years). Patient group sizes were: RE (n=431), PR (n=949), NR (n=406).

Compared with RE the odds of having worsened symptom severity was higher amongst PR and NR, notably 26 to 30 times higher for NR patients for overall symptom severity and abdominal pain severity ($p < 0.05$) (table). NR was associated with receiving more treatment lines than RE, as well as having higher odds of switching CD therapies in the past 12 months ($p < 0.05$). PR and NR groups reported a decrease in HRQoL ($p < 0.05$) (table).

Conclusion: Not achieving or maintaining remission impacted symptom severity, treatment patterns, and patients' quality of life. Notably, non-remitters had up to 30 times higher odds of experiencing worsened symptom severity including fatigue, sleep disturbance, and abdominal pain thus impacting daily living. This highlights the importance and significant unmet need for effective treatment early in the CD treatment journey.

IMPACT OF DISEASE FLARES ON RESOURCE USE, HEALTH-RELATED QUALITY OF LIFE AND PRODUCTIVITY IN PATIENTS WITH ULCERATIVE COLITIS IN EUROPE: AN ANALYSIS OF NATIONAL HEALTH AND WELLNESS SURVEY DATA

M. Sanon¹, S. Kachroo², C. Willey³, A. LaPrade⁴, N. Sternbach⁴, T. Hoops¹

¹Janssen Global Services, Horsham, United States, ²Janssen Scientific Affairs, Horsham, United States, ³College of Pharmacy, University of Rhode Island, Department of Pharmacy Practice, Kingston, United States, ⁴Cerner Enviza, Malvern, United States

Contact E-Mail Address: msanon@its.jnj.com

Introduction: Ulcerative colitis is a chronic inflammatory bowel disease that affects the colon and rectum. It requires lifelong treatment and often hospitalization and surgery. An important goal of treatment is managing and easing disease symptoms and increasing the length of clinical remission; however, despite the use of treatments, many treated patients continue to experience debilitating disease flares that can impact their daily life and wellbeing.

Aims & Methods: This study describes the burden of active ulcerative colitis flares on resource use, health-related quality of life (HRQoL), and work productivity in patients receiving ulcerative colitis treatment. The 2020 National Health and Wellness Survey in Germany, Spain, Italy, France, and the United Kingdom, which provides real-world information regarding disease characteristics, diagnosis, treatment, and patient-reported outcomes, was analyzed. Survey participants with diagnosed ulcerative colitis and on ulcerative colitis treatment were categorized by disease flare frequency as infrequent (0-2/year), intermediate (3-6/year), or frequent (> 1 /month to < 7 /week) based on response to the survey question, "How often did you experience disease flares as a result of your Crohn's disease or ulcerative colitis?" HRQoL was measured using the 5-dimension Euro-QoL questionnaire (EQ-5D), and work activity impairment using the Work Productivity and Activity Impairment questionnaire.

Results: A total of 62,319 respondents participated in the survey, of whom, 252 reported being diagnosed with ulcerative colitis and on treatment for ulcerative colitis. The average age of patients with frequent disease flares was lower than those with less frequent flares (infrequent, 53 years; intermediate, 48 years; frequent, 40 years).

Current smoking was most common in the group with the highest disease activity (infrequent, 18%; intermediate, 27%; frequent, 40%). In the past year, 19%, 31%, and 33% of patients with infrequent, intermediate, and frequent flares, respectively, had experienced depression.

The mean EQ-5D summary score decreased with increasing disease activity (infrequent, 0.75; intermediate, 0.73; frequent, 0.63), and mean EQ-5D VAS score was lower in patients with more active disease (infrequent, 65.5; intermediate, 60.0; frequent, 60.0), indicating poorer HRQoL. Absenteeism and presenteeism were highest in the group with frequent flares, and overall work impairment was reported by 32%, 38%, and 67% of respondents with infrequent, intermediate, and frequent flares, respectively. Additionally, within the past six months, a greater percentage of patients with frequent flares had emergency room visits or were hospitalized (50%, 53%) than patients with infrequent (22%, 16%) or intermediate flares (22%, 27%). Within the past 12 months, the proportion of patients for whom $> 25\%$ of flares had been treated with steroids was higher in patients with frequent (53%) or intermediate (51%) flares versus patients with infrequent flares (30%).

Conclusion: This analysis of real-world data demonstrates that patients with ulcerative colitis who were on a prescribed treatment for ulcerative colitis continue to experience disease flares, and those with more frequent flares experienced lower HRQoL, higher healthcare resource use, and lower work productivity. These results highlight the high disease burden in patients with ulcerative colitis and existing unmet needs with current treatment options for the disease.

IMPACT OF DISEASE FLARES ON RESOURCE USE, HEALTH-RELATED QUALITY OF LIFE AND PRODUCTIVITY IN PATIENTS WITH CROHN'S DISEASE IN EUROPE: AN ANALYSIS OF NATIONAL HEALTH AND WELLNESS SURVEY DATA

M. Sanon¹, S. Kachroo², C. Willey³, A. LaPrade⁴, N. Sternbach⁴, T. Hoops¹

¹Janssen Global Services, Horsham, United States, ²Janssen Scientific Affairs, Horsham, United States, ³College of Pharmacy, University of Rhode Island, Department of Pharmacy Practice, Kingston, United States, ⁴Cerner Enviza, Malvern, United States

Contact E-Mail Address: msanon@its.jnj.com

Introduction: Crohn's disease is a chronic inflammatory condition that affects the gastrointestinal tract. It is characterized by debilitating symptoms such as diarrhea, abdominal pain, rectal bleeding, and fatigue with disease progression leading to bowel damage and disability. Despite receiving treatment, many patients continue to experience disease flares, which can significantly affect patients' emotional wellbeing and capacity to perform daily activities.

Aims & Methods: This study describes the burden of active disease on resource use, health-related quality of life (HRQoL), and work productivity in patients with Crohn's disease receiving treatment. Data from the 2020 National Health and Wellness Survey in Germany, Spain, Italy, France, and the United Kingdom were analyzed. This survey provides real-world information regarding disease characteristics, diagnosis, treatment, and patient-reported outcomes.

Based on responses, survey participants with Crohn's disease and receiving Crohn's disease treatment were categorized by the frequency of Crohn's disease flares (per the survey question, "How often in the past year did you experience disease flares as a result of your Crohn's disease or ulcerative colitis?"): infrequent (0-2/year), intermediate (3-6/year), and frequent (>1/month to <7/week). HRQoL was assessed using the 5-dimension EuroQoL questionnaire (EQ-5D), and work activity impairment using the Work Productivity and Activity Impairment questionnaire.

Results: A total of 62,319 respondents participated in the survey, of whom, 226 reported being diagnosed with Crohn's disease and using a prescription medication to treat their condition. The mean age of patients with frequent flares was lower than those with less active Crohn's disease (infrequent, 48 years; intermediate, 42 years; frequent, 37 years).

Within the past 12 months, 25% and 24% of patients with infrequent or intermediate flares, respectively, had experienced depression, compared with 43% of those with frequent flares. Mean EQ-5D summary score decreased with increasing flare frequency (infrequent, 0.71; intermediate, 0.64; frequent, 0.59), and mean EQ-5D VAS score was lowest in patients with frequent flares (infrequent, 60.2; intermediate, 61.4; frequent, 50.1), indicating poorer HRQoL.

Absenteeism and presenteeism were highest in patients with frequent flares, and overall work impairment was reported by 44%, 51%, and 65% of patients with infrequent, intermediate, and frequent flares, respectively. In the past 6 months, a greater percentage of patients with frequent flares visited an emergency room or had been hospitalized (63%, 53%) than patients with infrequent (26%, 23%) or intermediate flares (41%, 30%).

The proportion of patients for whom >25% of flares had been treated with steroids in the past 12 months was higher in patients with intermediate (54%) or frequent (56%) flares versus patients with infrequent flares (32%).

Conclusion: This analysis of real-world data shows that in Europe, patients receiving treatment for Crohn's disease continued to experience disease flares, and those with frequent flares experienced poorer HRQoL, lower work productivity, and had higher healthcare resource use. The results demonstrated that the disease burden in patients with Crohn's disease is high, despite treatment, and highlights the importance for more effective treatment early in the CD treatment journey.

PRE-ENDOSCOPY ANESTHESIOLOGY CLINIC EVALUATION DOES NOT REDUCE COMPLICATION RATES IN HIGH-RISK PATIENTS FOR SEDATION

T. Thurm^{1,2}, N. Zmora^{1,2}, R. Bruck^{1,2}, N. Bar^{1,2}, A. Philips^{1,2}, O. Shibolet^{1,2}, L. Deutsch (Mlynarsky)^{1,2}

Contact E-Mail Address: nivz@tlvmc.gov.il

Introduction: Preoperative or pre-anesthesia evaluation is an established highly regulated practice in patients undergoing surgery [1-2], which has been shown to reduce complications, reoperations and mortality [3] and increase patient satisfaction [4]. However, the efficacy of employing a similar practice in patients undergoing endoscopic procedures, where the risk of acute severe complications induced by sedation is lower [5], has not been determined to date.

At our center, the pre-procedural evaluation strategy for ambulatory patients undergoing endoscopic evaluation included a gastroenterologist reviewing patients referral letters (an 'open access' approach) and assigning them to an anesthesiologist-supervised procedure in case of severe comorbidities (ASA score of III-b and above, class III (severe) morbid obesity (BMI>40), or Mallampati score of 3 and above), subjecting them to a potential high risk for sedation [6]. Since late 2016 there was a policy change, and all patients deemed as high-risk for sedation have been referred to a pre-endoscopy clinic evaluation carried out by an anesthesiologist.

Aims & Methods: We aimed at comparing endoscopy- and sedation-related complication rates between these two strategies. A retrospective review of an administrative database of all ambulatory upper and lower endoscopies performed at a single tertiary medical center between the years 2016-2017 was performed, as well as a review of the patients' records, including emergency room (ER) admissions, hospitalizations, imaging studies, operations and mortality 14 days following the procedures. Cases performed before policy change (BPC) were compared to cases performed after policy change (APC) with the primary endpoints of endoscopy- and sedation-related complications and death in the peri-procedural period.

Results: During the study period 18,240 ambulatory upper and lower endoscopic procedures were performed in 14,906 patients, 7,447 (49.96%) BPC and 7,459 (50.04%) APC, of which 580 were supervised by an anesthesiologist. The proportions of anesthesiologist-supervised procedures were comparable between the two time periods (BPC 295 vs APC 285, P=0.721), however APC there was a 25-fold increase in pre-endoscopy anesthesiology clinic assessments for high-risk patients for sedation compared to BPC (BPC 6 patients, 2.03% vs APC 146 patients, 51.22%, P<0.001). Nevertheless, no differences in post-procedural ER admissions, incidence of endoscopy- and sedation-related complications, number of imaging studies, hospitalizations, duration of hospitalizations and surgeries were observed between the two periods (p=0.065, p=0.065, p=0.109, p=0.445, p=0.366, p=0.314, respectively). Procedural-related mortality was also comparable between the periods.

Conclusion: Anesthesiology clinic evaluation of patients deemed a high-risk for sedation before endoscopic procedures does not conduce to decreased rates of procedure- and sedation-related complications. A selective, rather than a universal, referral of high-risk patients to a pre-endoscopy evaluation by anesthesiologist could increase the effectiveness of medical care and reduce the financial burden on health economies.

ESTIMATING THE ENVIRONMENTAL IMPACT OF ENDOSCOPIC ACTIVITY AT A TERTIARY CENTER: A PILOT STUDY

T. Ribeiro¹, R. Morais¹, C. Monteiro¹, A. Carvalho¹, S. Barros¹, G. Macedo¹

¹Centro Hospitalar Universitário de São João, Gastroenterology, Porto, Portugal

Contact E-Mail Address: tiagofcribeiro@outlook.com

Introduction: Healthcare services are a major generator of waste, with significant environmental impact and potential harm for community health. The growing number of endoscopic procedures, frequently requiring the use of single-use disposable instruments, is responsible for the production of a large amount of waste. To this date, the reality of waste production at large European gastroenterology centers is not known.

Aims & Methods: This study aimed to estimate the amount of waste due to endoscopic practice at tertiary center in Portugal.

We calculated the mass (in Kg) of residues generated in the course of endoscopic practice during a period of 5 working days. We included residues produced at endoscopy suites, pre and postprocedure areas and during endoscope reprocessing. Residues were categorized as non-dangerous (group I - equivalent to urban residues and group II - non-hazardous hospital residues), of biologic risk (group III) and specific hazardous hospital residues (group IV). The production of residues which were separated for recycling/valorization (paper/card and plastic) was also quantified.

Results: During the analyzed period, 241 endoscopic procedures were performed. A total of 443.2 kg of waste (22.6 kg from groups I/II, 266.9 kg from group III e 3.9 kg from group IV) were produced. The endoscopy suite was responsible for 73.1% of the mass of residues, while pre/postprocedure areas and endoscope reprocessing were responsible for 13.0% and 13.9%, respectively. For each endoscopic procedure, 1.8 kg of waste was generated. Individual protection equipment accounted for 32.1 kg (7.3%) of waste. Of the total mass of waste only 17.8% (79 kg) were separated for recycling/valorization.

Conclusion: We performed a pioneer quantitative analysis of the waste production from a large-volume endoscopy service. These analyses are essential to accurately apprehend the reality of each center, which is a pivotal step to implement effective measures to improve resource utilization and more sustainable practices.

Disclosure: Nothing to disclose.

Introduction: Hypermobile Ehlers Danlos Syndrome (hEDS), is a non-inflammatory connective tissue disorder characterised by joint hyper flexibility, skin hyperelasticity, and tissue fragility. Functional GI disorders (FGID) are reported in 98%, most commonly functional dyspepsia (FD) and irritable bowel syndrome (IBS) (1). Other comorbidities include chronic pain and fatigue, postural tachycardia syndrome, and anxiety. These patients, therefore, present to a variety of hospital settings. Patients with hEDS have poor quality of life, and high medication and healthcare use compared to the general population (1). Despite the increasing health burden in hEDS, no study has systematically explored healthcare utilisation in these patients or compared this in subgroups.

Aims & Methods: We aimed to evaluate the resource utilisation in hEDS patients diagnosed with FGID and compare this in those with IBS vs FD. We conducted a cross-sectional study from August '21 to January '22. hEDS patients from the charity organisation Ehlers-Danlos Support UK and tertiary Neurogastroenterology clinics completed questionnaires including the ROME IV questionnaire for FGID and the healthcare utilisation questionnaire, specifically developed to assess resource use.

Results: 660 subjects (median age 39 (range; 16-76), 95.8% female, 16.8% clinic) completed the questionnaires, of which 98.6% met the ROME-IV criteria for at least one FGID and 81.8% for at least 2 FGID. 62.9% had FD, 45.5% had IBS, and 32.1% had overlap FD and IBS.

81.7% had seen a healthcare professional in the last 6 months, most commonly GPs (60.9%) and physiotherapists (39.2%). Despite the high prevalence of GI symptoms, only 25.4% had seen a gastroenterologist. 18.6% presented to A&E. 10.4% were admitted to hospital - 31.9% stayed longer than 3 nights (range 1-118 inpatient days) and 30.4% had more than one admission over the last 6 months.

In terms of investigations in the entire cohort over the prior 6 months, imaging was performed in 43.0% - with the incidence of having an X-ray, CT, and MRI being 29.6%, 13.3%, and 20.4% respectively. 11.5% underwent endoscopy.

	IBS Only (N=90)	Functional Dyspepsia Only (N=197)	p value
% With gastroenterology input	17.8	34.0	0.004
% Attending A&E	12.2	23.9	0.02
% Admitted to hospital	2.2	16.2	0.0003
% With hospital stay >3 nights	0.0	6.1	0.2
% Imaging	41.1	39.1	0.7
% Endoscopic procedures	7.8	17.3	0.03
% On neuromodulators	46.7	52.3	0.4
% On opiates	46.7	40.1	0.3

Table 1: Comparison of healthcare use in IBS vs FD over the last 6 months.

The most common classes of prescribed medication were analgesics - simple analgesia (64.5%), neuromodulators (47.27%), and opiates (39.70%). PPI (52.1%), H1 antagonist (43.4%), and laxative use (37.4%) were also

notable. A high proportion paid for additional therapies e.g., 60.1% paid for their vitamin supplements, 31.4% paid for probiotics and 24.5% paid for acupuncture.

Compared to hEDS patients with IBS, those with FD were more likely to have gastroenterology input, attend A&E, be admitted, and have endoscopies. There was no difference in medication use (e.g., opiates) in the 2 groups (Table 1).

Conclusion: This large study of over 600 hEDS patients confirms high health resource utilisation in this cohort. Almost all patients had a FGID, with FD and IBS being the most common. Patients with FD had higher healthcare utilisation than those with IBS. These findings will have an impact on how services should be commissioned for this very co-morbid group of patients.

APPLICATION OF MACHINE LEARNING ALGORITHM BASED ON MULTI-FEATURE FITTING IN THE DIAGNOSIS OF WHITISH NEOPLASTIC GASTRIC LESIONS UNDER WHITE LIGHT GASTROSCOPY

X. Zeng¹, Z. Dong¹, D. Gong¹, L. Yang², P. Jin², H. Yu¹

¹Renmin Hospital of Wuhan University, Department of Gastroenterology, Wuhan, China, ²PLA Army General Hospital, Department of Gastroenterology, Beijing, China

Contact E-Mail Address: 1018725972@qq.com

Introduction: Esophagogastroduodenoscopy (EGD) is the pivotal procedure in the diagnosis of upper gastrointestinal lesions, which helps to find gastric lesions, locate and qualitatively judge them, and further guide the formulation of treatment plans. Gastric cancer is one of the most lethal malignancies in the world and has become one of the most important causes of cancer death worldwide. Asymptomatic patients can detect early gastric cancer with aggressive gastroscopy screening.

Early detection of gastric cancer can provide opportunities for minimally invasive endoscopic treatment, such as endoscopic submucosal dissection (ESD). However, some gastric cancers appear as pale, depigmented lesions on endoscopy, such as signet ring cell carcinoma, and the typical appearance on routine endoscopy is pale, flat lesions that are easily overlooked even by experienced endoscopists.

Therefore, accurate diagnose of whitish gastric neoplastic lesions is crucial to improve prognosis, improve patient quality of life, and reduce patient disease burden. In recent years, great progress has been made in the application of artificial intelligence technology in the field of digestive endoscopy.

This abstract aims to develop machine-learning based multi-feature fitting algorithm to diagnose whitish neoplastic gastric lesions under white light endoscopy and enhance interpretability. Compare the diagnostic performance of the multi-feature fitting algorithm with the sole deep learning algorithm.

Aims & Methods: To develop machine-learning based multi-feature fitting algorithm to diagnose whitish neoplastic gastric lesions under white light endoscopy and enhance interpretability. Compare the diagnostic performance of the algorithms with the sole deep learning algorithm.

Retrospectively collected 210 non-neoplastic images from Renmin Hospital of Wuhan University, the Seventh Medical Center of PLA General Hospital, and Nanjing Drum Tower Hospital from November 2012 to December

2020, of which 170 were used as training set, the remaining 40 images were used as test set; 207 neoplastic images were collected, of which 165 pictures are used as training set, and the remaining 42 images are used as test set. The general shape of the lesion, whether the boundary is clear or not, whether the surface shape is regular, the background mucosa, and the location of the lesion are selected as key features.

The key features of each image was labeled by expert endoscopists. Multiple machine learning models were applied for training and testing. Use deep learning framework to train binary classification model to distinguish whether the lesion was neoplastic or not.

Results: In the test set, the accuracy, sensitivity and specificity of the sole deep learning algorithm were 81.96%, 71.43% and 92.5%, respectively. The accuracy, sensitivity, and specificity of KNN(K-Nearest Neighbor algorithm) were 86.9%, 90.7% and 82.93%, respectively; the accuracy, sensitivity and specificity of SVM(support vector machine) algorithm were 84.52-85.71%, 88.37-90.70% and 78.05-82.93% respectively.

Conclusion: Multi-feature fitting machine learning performed better than the sole deep learning algorithm for diagnosing whitish neoplastic gastric lesions under white light endoscopy.

Disclosure: Nothing to disclose.

Introduction: R0 or tumour-free surgical margins resection represents the strongest prognosticator of survival in locally advanced primary (LAPRC) and locally recurrent rectal cancer (LRRC). Magnetic resonance imaging (MRI) is the technique of choice to assess the infiltration of surrounding structures, currently representing the ideal tool for preoperative planning. In LAPRC, MRI negative predictive value of infiltration is reported to be 94%, however, a 54% positive predictive value has been estimated. In addition, diagnostic accuracy of MRI might not exceed 60% in LRRC.

Aims & Methods: The aim of this study was to assess the usefulness of a three-dimensional image processing and reconstruction (3D-IPR) model to achieve R0 resections and to compare the diagnostic accuracy between MRI and 3D-IPR regarding the infiltration of surrounding structures in LAPRC and LRRC.

This is a prospective study performed at two referral centres for rectal cancer between January 2020 and January 2022. 3D-IPR was applied to MRI of patients with LAPRC or LRRC, before surgery. The MRI findings were compared with those of 3D-IPR, focusing on predicted surgical margins. The standard of reference was definitive pathology of the specimen.

Results: Twelve patients were evaluated (7 LAPRC and 5 LRRC). A complete agreement between MRI and 3D-IPR was observed in 16% of cases. One patient received anterior resection of the rectum, 4 en bloc rectal resection extended to surrounding structures, and 7 pelvic exenteration; 75% of specimens were classified as R0. The diagnostic accuracy was 33% for MRI and 91% for 3D-IPR.

Conclusion: The 3D-IPR method can be useful to improve diagnostic accuracy of MRI scans in assessing the relationship with surrounding structures in patients with LAPRC and LRRC.

Introduction: Digital health solutions have been taking healthcare by storm, with a plethora of activity tracking tools emerging for self-monitoring and behavior adjustments toward health goals. While digital medicine has undergone an unprecedented boost during the COVID-19 pandemic, it is imperative that medical innovation in the digital health space is developed with a thorough understanding of the deployment context and

through a co-creation process with all the stakeholders to ensure a sustainable result for patient outcomes and healthcare system integration.¹ With this principle, the current study placed importance on integrating clinical relevance and understanding of patients through concurrent streams of technical and behavioral research when developing a new digital health tool.

Aims & Methods: We aimed to develop an artificial intelligence (AI)-based stool type classifier and bowel movement counter for constipation management tailored to Asian patients. In the *technical* stream, an image classifier that analyses stool consistency was developed using classical machine learning and deep neural network models on a clinician-annotated image dataset. The models were trained using 1541 images of potato-based stool models and 1322 web-scraped images of real stools, classified into Bristol Stool Form Scale (BSFS). The performance of the models were validated using 330 real stool images.

In the *behavioral* stream, 15 participants with chronic constipation (age range = 28-79 years, 10 females) were interviewed to further understand patients' attitudes and perception towards constipation-related digital health solutions. Additionally, we surveyed 153 Singapore doctors on their understanding of constipation and its treatment.

Results: In gold standard classification, the clinical team showed satisfactory agreements. The image classifier achieved 74.2% overall accuracy in classifying real stool images into three clinically relevant groups for the management of constipation – constipation (BSFS 1, 2), normal (BSFS 3, 4, 5), loose (BSFS 6, 7). When asked about stool classification and bowel movement frequency, participants expressed uncertainty about what is normal. The idea of using an AI-based stool classifier was perceived as potentially useful for personal tracking and relaying accurate information to their healthcare providers, however three participants voiced disinterest in taking pictures of their own stools.

Participants stated the importance of knowing when their stool is abnormal and receiving feedback from the digital tool regarding informative next steps and preventative warnings, which indicate the need for the image classifier to prioritize recall when balancing with precision.

The doctors' survey revealed knowledge deficit in constipation diagnosis and treatment, with 22.2% of doctors unable to describe the accurate stool scale and type for constipation. 83.0% of the doctors agreed that digital technology can potentially help close that gap.

Conclusion: Our AI-based stool image classifier and bowel movement counter is a promising digital health tool for supporting constipation monitoring.

Overall, both patient and doctor groups were receptive to digital health tools for constipation management, and provided clinical and behavioural insights to drive further development efforts and guide optimal digital tool design and implementation.

Future work can focus on patient segmentation, e.g. identification of patients with psychosomatic personas that will benefit the most from such solutions, and meaningful integration of the digital health solution into doctors' daily practice.²

CLINICAL VALIDATION OF DEEP LEARNING-BASED BOWEL PREPARATION ASSESSMENT SYSTEM: A SINGLE CENTER, PROSPECTIVE, TANDEM STUDY

L. Yao¹, H. Chen², H. Xiong², Q. Li², H. Yu³

¹Renmin Hospital of Wuhan University, Wuhan, China, ²The Eighth Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China,

³Renmin Hospital of Wuhan University, Gastroenterology, Wuhan, China

Contact E-Mail Address: 292779656@qq.com

Introduction: Inadequate bowel preparation can have multiple negative impact on colonoscopy, including incomplete visualization of colorectal mucosa, higher miss rate of lesions (22–48%), more procedural difficulties, prolonged operation time, reduced interval time, and increased cost of colonoscopy. Patients with unqualified bowel preparation should receive early repeated colonoscopy to avoid the interval colorectal cancer. Manual bowel preparation assessment in clinical practice is easily affected by subjectivity and clinical experience. Therefore, we have developed a deep learning based bowel preparation assessment system. Such system has shown a strong correlation with the adenoma detection rate (ADR). However, the performance of the system in predicting missed adenomas due to poor bowel preparation remains to be explored.

Aims & Methods: This is a prospective, single center, tandem study. Patients who underwent screening colonoscopy in the Eighth Affiliated Hospital of Sun Yat-sen University from October 7, 2021 to March 4, 2022 were prospectively enrolled. The endoscopists and the system evaluated the bowel preparation independently during the colonoscopy withdrawal and the assessment results were blinded to each other. If the bowel preparation was judged as qualified by both of endoscopists and the system, the patient will receive a second colonoscopy immediately; if the bowel preparation was judged as unqualified by either of them, the patient will undergo colonoscopy again after re-cleaning the bowel. All polyps were biopsied with forceps once they were detected.

Results: As of March 4, 2020, a total of 105 patients were included, with an average age of 54.8 years. The overall polyp detection rate was 91.4% (96/105), and the adenoma detection rate was 55.2% (58/105). Among them, 37.1% (39/105) of patients was considered unqualified bowel preparation by doctors, and 42.9% (45/105) of patients was considered unqualified bowel preparation by artificial intelligence, with a consistent Kappa value of 0.518.

According to the endoscopists judgement, the adenoma missed rate (AMR) was 28.8% (19/66) in patients with qualified bowel preparation, and 43.6% (17/39) in patients who were unqualified. According to the deep learning system, the AMR in patients with qualified bowel preparation was 25% (15/60), and the AMR in patients who were unqualified was 46.7% (21/45). According to the endoscopists judgement, the missed detection rate of ≥ 5 mm adenomas in patients with qualified bowel preparation was 6.1% (4/66), and the missed detection rate of ≥ 5 mm adenomas in unqualified patients was 7.7% (3/39).

According to deep learning system, the missed detection rate of ≥ 5 mm adenomas in patients with qualified bowel preparation was 3.3% (2/60), and the missed detection rate of ≥ 5 mm adenomas in unqualified patients was 11.1% (5/45).

Conclusion: There is a significant difference in the AMR between qualified and unqualified patients with bowel preparation assessed by the deep learning system, and the performance is non-inferior to that of endoscopists. The system is expected to replace the existing manual assessment methods and provide automatic, accurate and objective bowel preparation assessment for the clinic.

Disclosure: Nothing to disclose.

PSYCHOLOGICAL INTERVENTIONS IMPROVE QUALITY OF LIFE IN PATIENTS WITH CANCER – A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

A.S. Bognár¹, S. Bunduc¹, B. Fogarasi¹, N. Vörhendi¹, D.S. Veres², K. Márta¹, P. Hegyi¹

¹Centre for Translational Medicine, Semmelweis University, Budapest, Hungary, ²Semmelweis University, Department of Biophysics and Radiation Biology, Budapest, Hungary

Contact E-Mail Address: bognar.sara@gmail.com

Introduction: Cancer is a leading cause of death worldwide carrying not only physical but emotional burden to the patients. Psychological symptoms are common among cancer patients and they can modulate the disease course and treatment adherence. During the treatment period patients' quality of life (QoL) may deteriorate.

Aims & Methods: This systematic review and meta-analyses investigated the effect of psychological interventions on the QoL and survival in cancer patients.

The systematic search was performed on PubMed, Cochrane and Embase from inception until 11 November 2021, without any restrictions. Eligible studies were RCTs investigating differences in QoL and survival in all type cancer patients undergoing psychological interventions besides standard of care (SOC) versus (vs.) SOC alone (experimental vs. control group).

The standardized mean differences (SMD) with 95% confidence intervals (95%CI) were calculated in the meta-analysis by the random effects model. I^2 -values and chi-squared tests indicated the statistical heterogeneity. The study protocol is registered on PROSPERO (CRD42021282327).

Results: Out of 10612 articles, we included 271 RCTs in the meta-analysis. Disease type and stage, intervention type and time of outcome assessment varied across the studies. We compared the differences in QoL measured at 12 weeks after the psychological intervention in the experimental vs. control group.

Our analysis showed a significant improvement in physical QoL in patients receiving group-based psychological interventions [SMD=0.29; CI=0.04 to 0.54; I^2 =95% (91%; 98%)]. A tendency was also observed in global QoL in the experimental group [SMD=0.37; CI=-1.75 to 2.49; I^2 =0% (0%; 90%)]. Individual psychological interventions as well increased the global QoL [SMD=0.35; CI=-0.07-0.78; I^2 =86% (78%; 91%)], physical QoL [SMD=0.33; CI=-0.03 to 0.69, I^2 =84% (73%; 91%)] and social functioning [SMD=0.22; CI=0.00 to 0.43; I^2 =63% (23%; 82%)] in the experimental group, respectively and significantly.

Conclusion: Our results revealed a medium to large effect of psychological interventions on both global and specific dimensions of QoL in all type cancer patients. Adding psychological interventions in SOC of cancer patients is justified. Further analysis of the interventions provider, environment, disease type and stage and other timepoints for outcome measurement, will substantiate more specific recommendations.

P0997

THE STATUS OF CLINICAL NUTRITION EDUCATION IN IRELAND: INTEGRATING CLINICAL NUTRITION EDUCATION INTO UNDERGRADUATE TRAINING. AN INITIATIVE OF THE IRISH SOCIETY OF CLINICAL NUTRITION AND METABOLISM

N. McGettigan¹, K. Allen¹, C. Dunne², K. Boland¹

¹Beaumont Hospital, Gastroenterology, Dublin, Ireland, ²St James Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: neasamcgettigan@hotmail.com

Introduction: One-third of patients in Irish hospitals are at moderate-to-high risk of disease-related malnutrition with a recognised economic burden due to obesity and malnutrition. The Irish Society for Clinical Nutrition and Metabolism (IrSPEN) aim to increase integration of nutrition education into the postgraduate/undergraduate curricula in line with educational goals of ESPEN.

Aims & Methods: To survey practicing physicians on attitudes to clinical nutrition in the under- and postgraduate curriculum and unmet needs in clinical nutrition.

An anonymous online survey was distributed nationally among Irish doctors. A total 35 questions probing respondent demographics and facts to the ESPEN consensus on Nutrition Education in Medical Schools. Descriptive statistics and χ^2 testing was completed using Graphpad. $P < 0.05$ denoted statistical significance.

Results: Of 168 responses received, 41% ($n=58$) were male. Most worked in academic hospitals (93.4%, Table 1).

Demographic	N=168 (%)
Male	58 (34.7%)
Age:20-30 years	86 (51.5%)
31-40 years	59 (35.3%)
41-50 years	12 (7.2%)
>50 years	10 (6%)
Work Setting:Full time academic centre	146 (87.4%)
Part time academic centre	10 (6%)
Community Practice	11 (6.6%)
Grade:Intern	8 (4.8%)
Senior House Officer	42 (25%)
Registrar	81 (48.5%)
Consultant/Attending	36 (21.6%)
Speciality: Gastroenterology	43 (25.75%)
Surgery	12 (7%)
Respiratory	12 (7%)
Paediatrics	37 (22%)
Medicine for the Elderly	11 (6.6%)
Oncology	9 (5.4%)
General Practice	9 (5.6%)
Endocrinology	5 (3%)
Anaesthetics/Critical Care	4 (6.7%)
Cardiology	3 (1.8%)
Other	16 (12%)

Table 1. Respondents Demographics.

Fifty-eight (34.7%) were regularly involved in nutrition support but 24% ($n=40$) rarely/never. Despite 20% ($n=33$) of respondents regularly managing patients on parenteral nutrition (PN) and a fifth ($n=34$) regularly managing complications of obesity, confidence in assessment for artificial nutrition was low; 15.7% ($n=26$) for enteral nutrition and 8% ($n=13$) for PN. One-third ($n=54$) did not believe they had sufficient knowledge to manage complications of malnutrition feeding including refeeding syndrome, line sepsis or thrombosis. Trainees were less confident than attending staff in assessment of need for/management of artificial enteral feeding ($p=0.022$) and complications of PN ($p=0.01$). Over 70% of respondents reported they received <2 hours clinical nutrition education.

Furthermore, only 32% ($n=52$) received any formal training (lectures, tutorials, course modules) within postgraduate training (PGT), and these were more likely to be GI trainees ($p=0.01$). Ninety-two percent reported more focus/provision of education was required. A striking 99% felt additional focus on nutrition education in PGT was needed to educate patients and manage complications of malnutrition/obesity.

Conclusion: This survey elicits physician attitudes relating to nutrition education in the undergraduate and postgraduate curricula in Ireland. Practicing physicians identify the need to increase clinical nutrition education within the undergraduate and postgraduate curricula. Improved education and nutrition support teams have been shown to improve patient care, reduce complications and are cost effective in managing complications of malnutrition/artificial nutrition. IrSPEN are actively engaging with Irish medical schools and training bodies to address these deficits with multidisciplinary engagement from expert physicians and allied dietetic colleagues.

COMPARATIVE ANALYSIS OF NUTRITIONAL BEHAVIOUR OF THE UKRAINIAN AND FOREIGN STUDENTS OF DANYLO HALYTSKY LVIV NATIONAL MEDICAL UNIVERSITY

C. Nasadyuk¹

¹Danylo Halytsky Lviv National Medical University, Biochemistry, Lviv, Ukraine

Contact E-Mail Address: nasadyukch@gmail.com

Introduction: Heart attack is the main cause of death globally, however over 70% of cardiovascular diseases is caused by modifiable risk factors, in particular tobacco, alcohol, diet, physical activity and sodium intake [1].

Aims & Methods: Aim of research was to evaluate nutritional habits of medical students from different countries. A modified Mediterranean Quality Diet Index Survey [2] (27 questions) was taken anonymously by 161 foreign students (FS) from India, Egypt, Zambia, Ecuador, Ghana, Greece, Lebanon, Morocco, Poland and 54 Ukrainian students (US), aged 18-25, on a voluntary basis. Number of answers for every question was expressed in %. Sampling error without design effect at 95% confidence did not exceed 7.72% for values close to 50%.

Results: The analysis of the survey showed that sunflower oil was the major fat used both by US and FS (72% of FS vs 55.6% of US), 17.4% of FS used olive oil vs 31.5% of US). Only US reported to consume pig fat (3.7%). 81.4% of FS consume meat vs 100% of US. Only 9.9% of FS consume fish 2-3 times per week vs 37% of US. 32.9% of FS eat fresh fruit every day vs 27.8% of US. 56.5% of FS eat vegetables every day vs 37% of US. 6.2% of FS eat fast food every day vs 1.9% of US; 9.9% of FS never eat fast food vs 13% of US; 72.7% of FS are having fast food several times per month vs 70.4% of US. 46.6% of FS consume nuts 2-3 times per week vs 31.5% of US. Only 31.7% of FS have breakfast regularly vs 57.4% of US; 61.5% of FS have breakfast sometimes vs 38.9% of US and 6.8% of FS never have breakfast

vs 3.7% of US. 9.3% of FS have sweets several times per day vs 35.2% of US. Only 28.6% of FS always read the nutritional value of food they buy vs 18.5% of US. 81.4% of FS never smoke vs 64.8% of US; 52.8% of FS never consume alcohol vs 14.8% of US. For 59.6% of FS the main daily drink is still water vs 75.9% of US. More than 90% of FS and US cook for themselves and about 70% answered that they liked to cook. 95% of FS are interested in healthy diet vs 70.4% of US.

Conclusion: The survey revealed some disturbing facts about eating habits of medical students (sweets abuse, low consumption of fish, nuts, fruits and vegetables). Questioned FS appeared to smoke less, rarer consume alcohol, eat more fruits and vegetables, however US more frequently consume olive oil, fish and prefer still water as a main daily drink but eat more sweets. During the professional training of medical students more attention should be paid to the issues of healthy eating.

THE RELATIONSHIP BETWEEN DIET, THE GUT MICROBIOME AND HEALTH OUTCOMES: PERCEPTIONS OF CONSUMERS AND NUTRITION PROFESSIONALS

G. Williams¹, L. Tapsell¹, E. Beck¹

¹University of Wollongong, Nutrition and Dietetics, Wollongong, Australia

Contact E-Mail Address: georgina.williams@newcastle.edu.au

Introduction: The influence of diet on the gut microbiome and subsequent health effects is increasingly of interest across popular media and scientific literature yet an exact definition for 'gut health' remains elusive. Evidence-based dietary guidelines to improve overall health via gut-mediated mechanisms are also not available, largely due to the multifactorial and individualised nature of the microbiome, and heterogenous study designs.

Engaging consumers and nutrition professionals to explore what is required for practice change in this field, could direct future study design to improve translatability.

Aims & Methods: The aim of this qualitative study was to explore the perspectives of both consumers and nutrition professionals towards gut health. We aimed to complement the predominantly quantitative data in this field to improve evidence translation towards better clinical practice, and subsequently improved health outcomes.

We conducted online focus groups (adults; no formal medical or nutrition training) and interviews (adults; with formal dietetics qualifications), questioning the understanding of 'gut health' and its influences, associated health outcomes and perceptions of evidence-based recommendations in this field. Discussions were transcribed verbatim and inductive thematic analysis was completed in duplicate.

Results: Fourteen focus groups (n=38, 15 males, 23 females) and 14 interviews (2 males, 12 females) were conducted. Consumers considered 'gut health' important for 'overall wellbeing' despite the role of the microbi-

ome being poorly understood. Consumers were more likely to report fermented foods or probiotic supplements as beneficial to 'gut health' before food groups recommended by national dietary guidelines. A barrier to dietary changes to promote gut health was the lack of transparent and practical guidelines as well as the perception that dietary change was required only for curative, rather than preventative, health measures.

Nutrition professionals reported an understanding of the significance of diet in influencing both gastrointestinal function and the microbiome. A balanced whole food-based diet, as recommended by current dietary guidelines, was generally considered ideal for gut optimisation. Despite this, dietitians reported higher levels of confidence in managing specific, diagnosed gastrointestinal conditions and symptoms rather than 'gut microbiome' related health outcomes. Reasons for this included uncertainty around current literature and a lack of evidence-based guidelines or tangible outcome measures in this area of dietetics practice and the multifaceted and highly individualised nature of 'gut health'.

Participating nutrition professionals mentioned the importance of multidisciplinary and personalised management of 'gut health', which included assessment and management of environmental, social and psychological influences.

Conclusion: While current research does not infer that dietary choices for 'gut health' differ to general dietary guidelines, opportunistic framing of these recommendations as good for 'gut health' may motivate improved adherence at a population level given the current interest in this term.

Food-based research that involves nutrition professionals, is needed to inform nutrition education for consumers on the potential role of the gut microbiome in preventative health care. Practical food-based recommendations can be used to support gut-related behavioural change as well as assist nutrition professionals to promote dietary choices consistent with current dietary guidelines.

PHENOMENON OF AN INCREASE OF THE BLOOD-BRAIN BARRIER PERMEABILITY IN RATS WITH STRESS-INDUCED METASTATIC COLON ADENOCARCINOMA

I. Agranovich¹, A. Khorovodov¹, A. Terskov¹, N. Navolokin^{2,1}, A. Shirokov^{1,3}, I. Fedosov¹, O. Semyachkina-Glushkovskaya¹

³Institute of Biochemistry and Physiology of Plants and Microorganisms, Russian Academy of Sciences, Saratov, Russian Federation

Contact E-Mail Address: ilana.agranovich@yandex.ru

Introduction: There is evidence that an increase in the permeability of the intestinal mucosa (IM) affect the permeability of blood-brain barrier (BBB) [1]. In our previous study, we discovered significant IM leakage in rats with stress-induced metastatic colon adenocarcinoma (SICA) associated with (1) a high expression of inducible nitric oxide (NO) synthase and beta2-adrenoreceptors; (2) a high production of NO and beta-arrestin 1 playing a crucial role in the regulation of IM permeability [2; 3].

Aims & Methods: Here, we aimed to answer the question, whether is interaction between the IM leaky and the BBB permeability in rats with SICA.

To answer to this question, we performed in rats SICA and in healthy rats:

1. The simultaneous study of the permeability of the mesenteric blood vessels (MeBVs) to FITC-Dextran 70 kDa and the mesenteric lymphatic vessels (MeLVs) to Evans blue (Eb) using *in vivo* multiphoton imaging with the further *ex vivo* confocal imaging of permeability of MeLVs and MeBVs using the specific markers of blood and lymphatic endothelium;

2. The analysis of the permeability of the blood brain barrier (BBB) to FITC-dextran (FITCD) 70 kDa using ex vivo multiphoton visualization and the quantitative analysis Eb in the brain tissues using spectrofluorimetric assay;
3. The study of the expression of tight junction (TJ) proteins, such as the Zonula 1 (ZO1), the Clandin-5 (CLDN), in the Junction Adhesion Molecule (JAM) in MeBVs/MeLVs and in the brain of healthy rats and rats with SICA using confocal assay.

N=10 in each group of all series of experiments.

To induce SICA, the rats underwent to a long term combination (during 9 months) of social stress (overpopulation) and daily diet including of toluidine (2 g/kg) in food and water with nitrites (2 g/l). The analysis of SICA presence was performed using in vivo photodynamic diagnosis with 5-aminolevulinic acid (20 mg/kg, per os) and ex vivo using histological method.

Results: Our results revealed that 83% of rats (25 of 30) demonstrated the SICA development with metastasis spreading in 64% of rats (16 of 25) in the liver (11 of 25) and in the lungs (5 of 25).

In all rats with SICA was observed the high permeability of MeLVs to Eb and MeBVs to FITC-Dextran that was accompanied by a decrease in the expression of CLND, ZO1 and JAM. There were not the leakage of tested tracers and the changes in the expression of TJs in MeLVs and MeBVs in healthy rats.

Interesting notice that only rats with SICA and metastatic spreading showed the high BBB permeability to FITCD and to Eb in the 13 areas of the brain vs. healthy rats, including the cortex, hippocampus, thalamus, cerebellum, pons and medulla. The high BBB leakage in rats with SICA was accompanied by decrease of the expression of CLND, ZO1 and JAM in the brain vs. healthy rats.

Conclusion: Our data clearly demonstrate the high permeability of MeBVs and MeLVs associated with the decreased expression of TJs in all rats with SICA. However, the leakage of BBB with the TJ integrity injuries were observed only in rats with SICA and metastasis spreading. Thus, there is a direct link between the high permeability of BBB and the spread of metastases in animals with SICA, associated with a decrease in the expression of TJ and an increase in vascular leakage throughout the body.

Contact E-Mail Address: jost.langhorst@gmx.de

Introduction: Patients with Crohn's Disease suffer from impaired health-related quality of life (HrQOL). Environmental and lifestyle factors are well excepted factors modifying the course of disease in CD. There is a need for structured programs which address non-pharmacological treatment options in CD.

Aims & Methods: The aim of this study was to investigate the effect of a comprehensive mind-body lifestyle-modification day clinic program in patients with Crohn's disease.

N=35 patients in clinical remission with impaired QOL (IBDQ < 170) were randomly assigned to the intervention group (IG, n = 19) or control that received a single workshop of intense training in non-pharmacologic self-help strategies (CG, n=16). The intervention group participated in a 60-hour day clinic over 10 weeks (6h once a week - average attendance: 9.1 ± 1.1; Min.: 7) including mindfulness, stress management, exercise therapy, meditative movement therapies, mediterranean diet, self-help strategies and social support. Health related quality of life (IBDQ), disease activity (HBI), fecal inflammation marker lactoferrin, psychological symptoms (HADS), core self-efficacy (CSES) and perceived stress (PSS) were measured with standardized questionnaires at baseline (Week 0) and post intervention (week 12).

Results: Subjects were predominantly female (63%), 48.1 ± 12.3 years old with a mean time of disease of 20.5 ± 11.6 years and did not differ in sociodemographic characteristics and medication. Intention to treat analyses provided evidence for a significant improvement in quality of life (p=.021), psychological symptoms in general (p = .013), anxiety (p = .006) and core self-efficacy (p= .010) among participants in the IG compared to CG at the end of the intervention. No effect on disease activity, depression and perceived stress were observed.

Conclusion: A comprehensive mind-body lifestyle-modification day clinic program in patients with Crohn's disease based on non-pharmacologic therapy modules can improve health related quality of life, psychological symptoms and self-efficacy in patients with Crohn's disease.

Introduction: Violation of the defecation rhythm regularity is a risk factor for colorectal cancer and cardiovascular mortality. However, the relationship between bradyenteria syndrome and comorbidity remains poorly understood.

Aims & Methods: The aim of this study was to prove the fact that bradyenteria is a risk factor for comorbidity.

334 people aged from 24 to 68 years were examined, 66% of women. Weekly monitoring of the circadian enteral rhythm was used to identify the frequency and acrophase of this rhythm in patients with a cardiologic profile. Euenteria corresponded to the daily defecation rhythm with a frequency of at least 7 times a week. Bradyenteria was detected by the frequency of defecation rhythm from 1-2 to 5-6 times a week. The risk of obesity was assessed by Body Mass Index. The risk of hypertension was compared for individuals with euenteria and bradyenteria. The level of anxiety and depression was determined by the hospital scale (HADS), the propensity to take laxatives was analyzed.

Results: In persons with euenteria, the morning bowel habit dominated, which was 3.5 times more common than evening defecation. In patients with bradyenteria, the absence of morning bowel habit prevailed, which was 3.2 times less common than evening defecation.

There were three main stages of bradyenteria. The first bradyenteria stage (light) was at a frequency of 5-6 times a week. The second bradyenteria stage (moderate) was at a frequency of 3-4 times a week. The third (severe) was at a frequency of 1-2 times a week.

It was shown that mild and moderate stages of bradyenteria occurred (in 61% and 30% of cases) almost 10 times more often than the severe stage (9% of cases). Violation of the circadian sleep-wake cycle increased the risk of bradyenteria by 1.7 times.

It was found that in patients with euenteria, the incidence of arterial hypertension was 12% but in people with bradyenteria – 34%. In patients with euenteria, the achievement of the target blood pressure level (in 77% of patients) was 4.8 times higher than in individuals with bradyenteria syndrome (in 16% of patients).

The risk of obesity in patients with euenteria was 7%, and in patients with bradyenteria – 24%. Bradyenteria syndrome increased the risk of obesity by 3.4 times. Clinically significant depression occurred in 12% of patients with stage I bradyenteria, in 17% of patients with stage II bradyenteria and in 43% of patients with stage III bradyenteria.

The propensity to take laxatives increased from the mild stage of bradyenteria (16% of patients) to the moderate stage (30%) and to the severe stage of bradyenteria (64%).

Conclusion: 1. The absence of a morning bowel habit increased the risk of bradyenteria by 3.2 times.

2. Mild and moderate stages of bradyenteria were almost 10 times more common than the severe one.

3. Bradyenteria syndrome increased the risk of arterial hypertension by 2.8 times.

4. Bradyenteria syndrome increased the risk of obesity by 3.4 times.

5. Depression was detected in 12%, 17% and 43% of patients with stage I, II and III of bradyenteria.

6. Laxatives were taken by 16%, 30% and 64% of patients with stage I, II and III of bradyenteria.

7. Bradyenteria syndrome is a predictor of comorbidity.

EXPERIENCE IN ORGANIZING URGENT TRAINING FOR GI PROFESSIONALS ON EMERGENCY CARE FOR ABDOMINAL INJURIES DURING THE WAR IN UKRAINE

O. Popova¹

¹Military Medical Clinical Center of the Eastern Region, Elling Training Center, Surgery Department, Dnipro, Ukraine

Contact E-Mail Address: oksana.nikolaevna.popova@gmail.com

Introduction: The war with Russia, which began on February 24, 2022, posed new challenges to the health care system in Ukraine. A large number of doctors weren't ready to work effectively in such conditions. This trend was observed not only in civilian health facilities, but also among military medics who were called up to the medical service of the Armed Forces from the civilian level, but did not have sufficient experience.

The issue of triage and providing emergency care for abdominal injuries has become particularly acute, as it is one of the most common types of injuries, the clinical manifestations of which are often unclear and the consequences - fatal.

Aims & Methods: The Board of the ELLING training center, together with the heads of health care facilities, decided to organize an express course on emergency care. The main requirements for the course were short deadlines, the ability to study without leaving work and the maximum ability to quickly apply the acquired knowledge.

The training was conducted online, but only one health care facility was recruited to one group. This was done in order to enable colleagues to immediately discuss, agree and adapt to the conditions of a particular institution changes that will occur in daily activities, providing an opportunity to immediately implement the acquired skills in practice.

The training took place in blocks of 1.5-2 hours during non-working hours for all group members. The course was built on a three-step scheme.

The first stage was universal for all trainees and included triage and the use of emergency ultrasound, including E-FAST. The educational material was illustrating each of which a clinical case. The clinical case was first discussed with the trainees, and then as a conclusion - a training unit was provided, which allowed to improve the quality of perception of the material.

The next step was training in profile groups. For surgeons it was a mastery of the concept of damage control, for gastroenterologists - the peculiarities of endoscopic examination for abdominal trauma, which allowed to involve these specialists more widely to emergency care.

Usually for the second degree one clinical case was developed, on which all possible "mistakes" were made, which were then discussed with the trainees.

The third stage was a round table, which took place two weeks after the completion of basic training. It discussed the main difficulties faced by experts in practice.

Results: For 6 weeks of work we were able to conduct training for 217 doctors from different regions of Ukraine. According to the forms of feedback, 10 from 12 heads of health care facilities, whose staff was trained, rated it as extremely useful in their work, 2 - as useful, but with some difficulties in practical implementation.

Among the trainees, the course received an average score of 4.65 out of 5 for the relevance of the material provided and 4.87 out of 5 for compliance with the learning process.

Conclusion: In our opinion, more attention should be paid to training all physicians to work in conditions of mass admission of wounded, injured and sick and in conditions of danger and limited resources. It is desirable to do it preventively. In the training of all GI professionals, special attention should be paid to emergency ultrasound and high-quality mastering of the basics of endoscopy.

Step-by-step approach and analysis of specific clinical cases with integration into the work of a particular health care facility, taking into account its features, became the key to the success of this course and greatly facilitated the work of our doctors.

USE OF VIDEO GAMES AND ACQUISITION OF ENDOSCOPIC SKILLS. A STUDY FROM TERTIARY CARE HOSPITAL, PAKISTAN

F. Kayani¹, J. Khan²

¹Bolan Medical College, Gastroenterology, Quetta, Pakistan,

²Bolan Medical College, Medicine, Quetta, Pakistan

Contact E-Mail Address: farhana_kayani@hotmail.com

Introduction: Performance of Gastrointestinal endoscopy requires adequate hand-eye coordination. Video games are an effective way to judge one's hand-eye coordination, and practicing these games may improve one's skills.

Aims & Methods: Our goal was to see if there is a correlation between skill in video games and skill in endoscopy. Also, we hoped to demonstrate that practicing video games can improve one's endoscopic skills.

Fifteen Gastroenterology residents (nine male, six female) volunteered to participate. On day 1, the students performed three endoscopic tasks (banding, targeted biopsy and object transfer) and were assessed for time to complete the task, number of errors committed, and hand-eye coordination. The students were then randomized to control (group A) or, training' (i.e., video game practicing; group B) arms.

In group B, each resident played three commercially available video games for 30 min on an X-box (Microsoft, Seattle, WA) for four weeks. 4 weeks later, all residents repeated the endoscopic skills and were reassessed.

Results: Spearman correlation coefficients demonstrated a significant relation between many of the parameters, particularly time to complete each task and hand-eye coordination at the different games. The hand-eye coordination also improved in group B residents. There was a weaker association between video game performance and endoscopic errors committed. Group B subjects improved significantly over those in group A.

Conclusion: We conclude that Gastroenterology residents with ongoing video game experience have superior endoscopic skills for tasks in terms of time to completion, improved efficiency and fewer errors when compared to nongaming counterparts. however, a larger study with more practice time is required to prove games to be helpful.

Disclosure: Nothing to disclose.

TOWARDS A GREENER ENDOSCOPY ROOM: RECYCLING PLASTIC WASTE

D. de Jong¹, A. Volkers¹, E. de Ridder², G.R. D'Haens¹, P. Fockens¹, M. Duijvestein³

¹Amsterdam UMC, location AMC, University of Amsterdam, Gastroenterology and Hepatology, Amsterdam, Netherlands,

²MINT Zorgadvies, The Hague, Netherlands, ³Radboudumc, Gastroenterology and Hepatology, Nijmegen, Netherlands

Contact E-Mail Address: d.c.dejong@amsterdamumc.nl

Introduction: About 6-8% of the Dutch CO₂ emission is attributed to the healthcare sector and this includes the use of energy, travelling to the hospital or the processing of waste (1). Recently, the environmental impact of the gastrointestinal (GI) endoscopy unit is gaining attention as it is the second highest clinical procedure-related waste generating department (2, 3). Despite the huge amounts of (plastic) waste produced daily by the endoscopy department, the bulk is currently not recycled. However, sustainable waste management is relatively easy to implement in daily practice. Nevertheless, the majority is not recycled.

Aims & Methods: This project aims to investigate the net benefit of a plastic waste recycling program in a GI endoscopy unit in terms of recycling percentage, carbon footprint and associated costs.

In this single-centre study, the type and amount of waste that was produced during routine endoscopies was collected and examined during a baseline measurement. The waste was collected in different waste streams; paper/cardboard, glass, contaminated residual waste and non-contaminated residual waste. Sustainable waste management scenarios were examined and compared in terms of CO₂ footprint, recycling rate, and waste treatment costs by using the Healthcare Sustainability Mode and Effect Analysis (HSMEA). The endoscopy employees were given a waste recycling training (i.e. presentation, Q&A and posters). A mobile waste bin was installed in every endoscopy room to segregate the plastic waste. Finally, the waste of 'post-training' endoscopic procedures was collected, compared with the baseline procedure and tested for correct waste separation.

Results: In total, 14.6 kg of waste was collected during 15 procedures during the baseline measurement (0.97 kg per procedure) with a proportion of recyclable plastic waste of 9.6%. Waste processing costs increased from €1.60 (all residual waste) to €2.06 (+28%) with recycling of plastic. The post-training measurement was comparable with the baseline measurement. However, 15% of the plastic waste contained 'incorrectly separated' plastics, mainly consisting of empty syringes and tubes.

After counselling, it is expected that this proportion will drop to 0% as the incorrectly separated waste consists of only two product types. Recycling the plastic waste led to a reduction of the carbon footprint with approximately 3%. Per endoscopic procedure, this results in a reduction of 0.14 kg CO₂ emission. Over the year 2019, this would have led to a reduction of 1481 kg CO₂ emission in our centre, which corresponds to 6875 km drive in a non-electric car.

Waste type	Kilogram	Kilogram per procedure	Percentage	CO ₂ -reduction
Recycling (clean)	1,42	0,09	9,7	-3 %
plastics	1,40	0,09	9,6	-2,9 %
paper/cardboard	0,02	0,001	0,1	-0,1 %
Clean, but not suitable for recycling	0,75	0,05	5,1	
Residual waste (contaminated)	12,40	0,83	85,1	
Total	14,57	0,97	100	-3 %

Table.

Conclusion: Recycling plastic waste is a small, but easily implementable step towards a more sustainable practice in the endoscopy department. The demonstrated environmental benefit, but also the enthusiasm of the personnel, are compelling reasons to implement this at other endoscopy rooms as well.

Contact E-Mail Address: a.hann@posteo.de

Introduction: Colonoscopy for colorectal cancer screening is one of the most common endoscopic examinations. It is highly standardized by national and international guidelines. In contrast, endoscopic training is limited by time available during daily clinic routine, experience of the trainer, the available patient population of the clinic, and patient safety.

We developed a publicly funded virtual reality (VR) based simulator called ViGaTu to enable physician and non-physician professionals to acquire knowledge and skills to perform guideline-compliant screening colonoscopy.

Aims & Methods: The aim of this study was to evaluate the first version of ViGaTu by a hands-on-training in VR using specialist endoscopy staff. Learning objectives included device knowledge, preparation for the procedure, sedation and complications.

Nurses and physicians from different hospitals were asked to participate in the study. Testing was performed with a conventional VR headset (Oculus Quest 2). Time spent in VR was measured. Subsequently, standardized questioning of baseline characteristics, professional experience, achievement of the above mentioned learning objectives and feasibility was performed.

Results: 9 physicians (6 male, 3 female, most common age group 35-39 years) with 7-9 years of professional experience participated. Additionally, 26 nurses (9 male, 17 female, most common age group 40-44 years) with 10-12 years of professional experience participated. Participants had performed or assisted in over 500 endoscopies. Mean time spent in VR was 20 min (standard deviation +/- 3.7). The learning objectives device knowledge, monitoring, propofol sedation and use of Team-Time-Out checklist were rated well with 4 out of 5 points. 5 of 9 physicians and 13 out of 26 nurses noticed the high degree of realism and practical relevance, the

high degree of immersion, and the richness of the content as positive. 3 physicians and 8 nurses noticed deficiencies in control/navigation. Many participant wished for the ability to perform polypectomy or other interventions (e.g. irrigation).

Conclusion: This first version of ViGaTu is already accepted by endoscopy-experienced nurses and physicians and is evaluated as useful and feasible.

By additional integration of a digital curriculum and implementation of polypectomy and other interventions in the final version of the simulator, VR-based learning can become an integral part of endoscopic training and simplify the teaching of current guidelines.

Disclosure: Nothing to disclose.

GOOD FOR THE ENVIRONMENT AND THE POCKET – AN AUDIT OF WASTE GENERATION AND RECYCLING PRACTICES WITHIN AN IRISH ENDOSCOPY UNIT

N. O'Morain¹, E. Donohoe¹, C. Regan¹, E. Joy², R. Stack¹, J. Doherty¹, G. Horgan¹, H. Mulcahy¹, E. McDermott¹

¹St. Vincent's University Hospital, Centre for Colorectal Disease, Dublin, Ireland, ²University College Dublin, School of Medicine, Dublin, Ireland

Contact E-Mail Address: neilmoran@gmail.com

Introduction: Ireland has one of the highest greenhouse gas emissions per capita in the European Union, at 13.3 metric tons of CO₂ equivalent per person (1).

Healthcare accounts for 30% of all public sector greenhouse gas emissions. General waste accounts for almost 60% of all waste generated in Irish hospitals. It has been estimated that one third of this could be recycled. A large volume of recyclable waste is generated in Endoscopy, however sustainable practices are not currently championed.

Aims & Methods: This quality improvement project sought to determine the volume of recyclable waste generated within Endoscopy and whether use of green bins in Endoscopy would be a cost-effective strategy. Total waste generated by patient-related activity during one week was audited. Non-clinical and clinical waste was weighed and sorted.

The percentage of recyclable waste was documented and the net cost savings calculated. The net savings on an annualised basis was estimated. Reduction in carbon dioxide emissions (CO₂e) were calculated using the Waste Reduction Model (WARM) (2).

Results: In total, 70 non-clinical and 56 clinical waste bins were collected. The median weight for non-clinical waste bins was 20.1kg (IQR 19.7-21.7kg) and 40kg (IQR 28.8-39.0kg) for clinical bins. A median of 14.1kg (70.5%) of non-clinical waste and 3kg (7.5%) of clinical waste was recyclable. Disposal cost/tonne was calculated based on most recently available Health Service Executive (HSE) waste management estimates. Net savings of €337/week by sorting 60.1kg was generated, and a reduction in carbon footprint by 21.7kg CO₂e. This equates to a cost saving of €17,524 per year, and a reduction in CO₂e of 1,128.4kg.

Conclusion: This project highlighted the impact sustainable practices can have on reducing the inappropriate use of non-clinical and clinical waste bins in Endoscopy. A considerable volume of waste generated can be recycled with considerable cost savings, and a significant environmental impact.

Following this project, green recycling waste bins, monthly educational sessions as well as a 'Green Endoscopy' noticeboard have been introduced into the Endoscopy Department. We plan to audit the effect of this initiative and determine how accurate these estimated cost and environmental savings are in time to present at UEGW.

EFFECT OF TRADITIONAL CHINESE MEDICINE HOT IRONING THERAPY ON RECOVERY OF GASTROINTESTINAL FUNCTION IN PATIENTS AFTER GASTROINTESTINAL ANASTOMOSIS

T. Zhang¹

¹Zhengzhou University, Henan, China

Contact E-Mail Address: 344780762@qq.com

Introduction: To explore the effect of hot ironing of dried ginger and *Evdia rutaecarpa* on the recovery of gastrointestinal function after gastrointestinal anastomosis based on ERAS concept.

Aims & Methods: A total of 100 patients with gastric cancer who received gastrointestinal anastomosis were selected as the research object. They were randomly divided into the control group and the intervention group. Patients in the control group were given routine western intervention methods of accelerated rehabilitation surgery, while patients in the intervention group were given routine western intervention methods+dried ginger, *Evdia rutaecarpa* hot ironing at Shenque point in abdomen and Renmai Jiuwei point to Guanyuan point. Observe the following indexes of patients in the two groups:

1. Recovery time of gastrointestinal function, including postoperative exhaust time, postoperative defecation time, eating time and hospitalization time;
2. Subjective clinical scores of patients on the 1st day before operation, 1st day, 3rd day and 5th day after operation, including abdominal pain, abdominal distension and gastrointestinal symptoms.

Results: The first exhaust time, first defecation time, first feeding time and total hospitalization time in the intervention group were shorter than those in the control group, with statistical significance ($P < 0.05$). There were no significant differences in abdominal pain, abdominal distension and gastrointestinal symptom scores between 2 groups 1d before surgery and 1d after surgery ($P > 0.05$). The abdominal pain, abdominal distension and gastrointestinal symptom scores in the intervention group were lower than those in the control group on the 3rd and 5th day after surgery, with statistical significance ($P < 0.05$).

Conclusion: Based on ERAS concept, hot ironing of dried ginger and *Evdia rutaecarpa* at Shenque point and Renmai Jiuwei point to Guanyuan point can further promote the recovery of gastrointestinal function after operation and shorten the recovery time of gastrointestinal function.

TRANSCRIPTIONALLY INACTIVE NRF2 INFLUENCE COLON MORPHOLOGY AND FUNCTION IN FEMALE MICE VIA MODULATION OF ESTROGEN LEVEL AND ESTROGEN RECEPTORS EXPRESSION

A. Piechota-Polanczyk¹, D. Klimczyk¹, M. Kopeć¹, A. Kopacz¹

¹Jagiellonian University, Department of Medical Biotechnology, Faculty of Biochemistry, Biophysics and Biotechnology, Kraków, Poland

Contact E-Mail Address: aleksandra.piechota-polanczyk@uj.edu.pl

Introduction: One of the determinants of homeostasis in the intestines is the proper function of Nrf2 (nuclear factor erythroid 2-related factor 2). It is a transcriptional factor that regulates many antioxidant and detoxification genes.

However, the Nrf2 gene polymorphism is related to ulcerative colitis, inflammatory bowel diseases (IBD) and its transcriptional deficiency may trigger IBD-like changes in the colon of older female mice without visible symptoms of bowel diseases.

Therefore, our objective is to address the sex-dependent impact of Nrf2 transcriptional deficiency on colon function and to delineate the possible mechanisms that govern intestinal homeostasis in these mice.

Aims & Methods: We used the 3- and 6-month old (m.o.) C57BL/6J mice with functional Nrf2 (wild-type (WT)), with transcriptionally inactive form of Nrf2 (transcriptional knockout (KO)) or lacking IL-10 (IL-10 KO), which spontaneously develop IBD. Mice were subjected to whole gastrointestinal transit, castor-oil induced diarrhea and colonic bead expulsion tests. Blood was collected for morphology and serum for IFN- γ , IL-1b, TNF- α and estradiol assay. The colon samples were stored for histological and immunofluorescent analysis of intestinal damage, myeloperoxidase (MPO) activity, glutathione assay, estrogen receptor (ER)- α , ER- β and, GPR30. Further, the effect of estrogen on GI tract functionality was verified in 3-month-old Nrf2 WT and Nrf2 KO female mice treated with estradiol for 28 days.

Finally, to confirm that estrogen receptors can influence colon contractility, organ bath assay on isolated colon tissue was performed. To inhibit Nrf2 transcriptional activity, 3 m.o. and 6 m.o. female mice were treated intraperitoneally with ML385 (30mg/kg/day), or DMSO for 7 days prior to tissue isolation and isolated colon samples were treated with selective ER- α or ER- β inhibitors.

Results: The results indicated that Nrf2 TA abrogation, alike IL-10 deficiency, in females trigger functional and microscopical phenotype, resembling IBD. Females had significantly changed GI function and younger Nrf2 tKO females had significantly higher WBC, GRA, and LYM blood counts, which were comparable to IL-10 KO mice. Histologically, in Nrf2 KO female mice, there was an enlargement of the lamina propria and depletion of goblet cells in all parts of the colon, as well as significant thickening of muscularis mucosae in the proximal colon.

Further results showed that lack of Nrf2 TA in young females does not lead to increased oxidative stress or fibrosis, however, it impacts the inflammation as only young Nrf2 KO females had significantly elevated colon MPO activity.

Importantly, Nrf2 TA influences estrogen level and estrogen receptor location. Nrf2 KO females have significantly reduced serum level of estradiol and altered expression of the ER- α and ER- β , especially in the proximal and middle colon.

Conversely, the expression of GPR30 was significantly reduced in the whole colon. Of note, estradiol treatment led to a notable improvement in colon motility in Nrf2 KO mice and raised the level of ER- α and GPR30 to a comparable level between genotypes.

Finally, organ bath assay on isolated colon tissue showed that stimulation of ER- β receptors, but not ER- α , significantly influences colon contractility in control but not in ML385-treated mice.

Conclusion: Summing up, our data suggest that Nrf2 transcriptional activity may modulate GI function and especially colon contractility by influencing estrogen and estrogen receptor signaling in females. (Supported by the Sonata 14 program of the National Science Centre 2018/31/D/NZ4/00077 to APP).

HIGH PREVALENCE OF SIGNIFICANT GASTROINTESTINAL PATHOLOGIES AMONG PATIENTS REFERRED FROM PRISON TO GASTROENTEROLOGY

M.G. Shiha¹, A.R. Robertson¹

¹University Hospitals of Leicester, Department of Gastroenterology, Leicester, United Kingdom

Contact E-Mail Address: Shiha202@gmail.com

Introduction: Great Britain has the highest rates of imprisonment in western Europe. Although equal access to healthcare is a universal human right, many prisoners experience substantial health inequalities leading to an increased morbidity and mortality risk compared with the general population.

Aims & Methods: We aimed to examine the clinical outcomes of patients referred from prison to secondary care gastroenterology and endoscopy at a large university hospital between January 2020 and December 2021. Referrals, clinic records and endoscopy reports were retrospectively reviewed.

Results: A total of 47 patients (100% male, median age 46 years) were referred from prison to gastroenterology outpatient clinics (n=35, 74.4%) or directly to endoscopy (n=12, 25.5%). The most common indications for referrals were dysphagia (n=10, 21.2%), rectal bleeding (n=9, 19.1%), diarrhoea (n=7, 15.2%) and abdominal pain (n=6, 12.7%), follow-up for known inflammatory bowel disease (n= 6, 12.7%) and viral hepatitis (n=3, 6.3%). Twenty-seven (57.4%) patients underwent endoscopic evaluation including gastroscopy (n=16), flexible sigmoidoscopy (n=10), colonoscopy (n=4) and video capsule endoscopy (n=2). Clinically significant endoscopic findings included new diagnosis of colitis (n=5), colonic polyps (n=2), oe-

sophageal cancer (n=1), Barrett's oesophagus (n=1), gastrointestinal stromal tumour (n=1), bleeding haemorrhoids (n=1) and ileitis (n=1). Only five patients had normal endoscopy.

Conclusion: Patients referred from prison with gastrointestinal symptoms have a high prevalence of significant pathologies. One-in-four patients had inflammatory bowel disease, half of whom were newly diagnosed. We call for policies and actions to ensure equal access to secondary health-care for this group of incarcerated vulnerable young patients.

Disclosure: Nothing to disclose.

P1012

ESTROGEN REGULATES DUODENAL GLUCOSE ABSORPTION THROUGH THE EFFECT OF ESTROGEN RECEPTOR- α ON GLUCOSE TRANSPORTERS

W. Shan¹, J. Xu¹, R. Xie¹

¹Affiliated Hospital of Zunyi Medical University, Department of Gastroenterology, Zunyi, China

Contact E-Mail Address: shanweixi1994@126.com

Introduction: Obesity is closely related to abnormal glucose metabolism and absorption. Clinical studies have found that the obesity rate of middle-aged and elderly women, especially menopausal women, has increased significantly, but the specific regulation mechanism is not clear. It is known that menopausal women are accompanied by a significant decrease in estrogen, but whether this change in estrogen level can regulate the metabolism and absorption of glucose is rarely reported at home and abroad.

This study clarified estrogen through in vivo animal experiments and in vitro cell experiments. The effect of changes on the absorption of glucose in the duodenum and possible regulatory mechanisms.

Aims & Methods: C57 mice were selected to establish an ovariectomized surgery model, and the sham-operated group was used as a control to dynamically compare the body weight, venous blood glucose levels and observe the changes in body fat distribution of the two groups of mice. Immunohistochemistry was used to detect the expression of estrogen receptors (ER- α , ER- β) and sugar transporters (SGLT1 and GLUT2) in the duodenum of the two groups of mice.

The Ussing chamber experiment compares the short-circuit current changes caused by glucose absorption in the duodenum of ovariectomized mice. Western-blot detects the expression changes of the target gene protein, agonists and inhibitors verify the important role of the PKC signaling pathway, construct ER- α and ER- β shRNA lentiviruses to transfect SCBN cells, and observe the changes in the expression of SGLT1 and GLUT2.

Results: We first observed the correlation between estrogen and blood glucose in women, which found that blood glucose in healthy women during menstruation was significantly higher than that during ovulation. Similarly, in ovariectomized (OVX) mice, with serum estradiol level decreased and ER- α and ER- β in the duodenum reduced, the weight, abdominal fat and blood glucose increased significantly. However, interestingly, the expression of SGLT1 and GLUT2 and the glucose absorption in duodenal decreased significantly.

It was further confirmed that estrogen could significantly up-regulate the expression of SGLT1 and GLUT2 in SCBN cells, and this trend can be reversed after silencing ER- α , but it doesn't work after silencing ER- β , suggesting ER- α may be the key receptor of estrogen regulating glucose transporter. Mechanism study found that estrogen downstream can activate PKC pathway.

Overall, our findings indicate that estrogen promotes glucose absorption, estrogen and its receptor (ER- α) deficiency can inhibit the expression of SGLT1 and GLUT2 through PKC signaling pathway, thereby reducing the glucose absorption.

Conclusion: estrogen promotes glucose absorption, estrogen and its receptor (ER- α) deficiency can inhibit the expression of SGLT1 and GLUT2 through PKC signaling pathway, thereby reducing the glucose absorption.

THE IMPACT OF THE COVID-19 PANDEMIC ON PATIENTS WITH ULCERATIVE COLITIS: RESULTS FROM A GLOBAL UC PATIENT SURVEY

L. Peyrin-Biroulet¹, K. Ylänne², A. Sipes³, M. Segovia^{4,5}, S. Gardiner⁶, J.C. Cappelleri⁷, A. Mulvey⁸, R. Panaccione⁹

¹University of Lorraine, CHRU-Nanc, Inserm, NGERE, Department of Gastroenterology, Nancy, France, ²Sidekick Health, Kopavogur, Iceland, ³Patient Representative, Columbia, United States, ⁴Pfizer Inc, Collegeville, United States, ⁵Rutgers University, New Brunswick, United States, ⁶Pfizer Inc, New York, United States, ⁷Pfizer Inc, Groton, United States, ⁸The Harris Poll, Chicago, United States, ⁹Division of Gastroenterology and Hepatology, Department of Medicine, University of Calgary, Calgary, Canada

Contact E-Mail Address: peyrinbiroulet@gmail.com

Introduction: The COVID-19 pandemic presented challenges around disease management, lifestyle changes and provision of care for patients with ulcerative colitis (UC).

Aims & Methods: This UC Narrative global survey (United States, Canada, Japan, France and Finland) was conducted by The Harris Poll between 25 August and 13 December 2021, among 584 patients with UC (confirmed by endoscopy) aged ≥ 18 years who had attended a gastroenterologist or internist's office in the past 3 years, had not had a colectomy, and had ever taken prescription medication for UC. The survey aimed to understand how the COVID-19 pandemic impacted patients with UC and assessed overall disease management, telehealth use, healthcare experience and perceived quality of care, emotional well-being, reliance on alternative support systems and preferences for virtual/in-person interactions with doctors. Data were from patients who consented and completed the survey; analysed using descriptive statistics.

Results: Overall, 25% of patients experienced more UC flares during the pandemic than in 2019. Most patients taking prescription medication (88%) were very/somewhat satisfied with their current treatment plan but overall, 53% strongly/somewhat agreed that they were hesitant to change their treatment plan during the pandemic.

Factors that patients agreed helped to control UC symptoms included having fewer social outings (37%), working from home (29%) and having less busy schedules (28%).

Factors that patients agreed made controlling UC symptoms more difficult included having more anxiety/stress (43%), hesitancy to visit a hospital or office (34%) and being unable to get an appointment with their doctor (23%). Virtual appointments were more common during the pandemic than before and more patients relied on alternative support systems for management of UC (Table).

Overall, 79% were very/somewhat satisfied with their ability to access needed healthcare during the pandemic, and patients who used each appointment type were equally very satisfied/satisfied with the overall quality of care at in-person (81%) and virtual (81%) appointments. However, in-person appointments were preferred by 68% of patients when meeting a new doctor, 55% when experiencing a flare, 52% for regular check-ups and 21% for UC prescription refills.

Conclusion: During the pandemic, most patients with UC were satisfied with their current treatment plan and ability to access healthcare, and more patients relied on alternative support for management of UC, but many were negatively impacted by anxiety/stress.

	Prior to the pandemic	During the pandemic	Plan to do after the pandemic	Have never done or plan to do
Talked openly with their doctor about how their disease impacts their life	54%	54%	44%	17%
Set goals with their doctor for managing their disease	48%	46%	40%	25%
Communicated with a nurse at their doctor's office between appointments	45%	40%	34%	32%
Used an online patient portal to contact their doctor's office or see lab results	31%	47%	33%	32%
Used social media to connect with other patients or learn about ulcerative colitis	24%	39%	27%	46%
Used symptom tracking or disease management apps	23%	31%	29%	48%
Relied on information from patient advocacy groups	19%	27%	22%	54%
Relied on patient support groups	15%	22%	22%	59%
Had virtual appointments with their doctor	13%	55%	32%	31%

Table. Disease management before, during and after the COVID-19 pandemic: reliance on alternative support systems for management of ulcerative colitis.

ZONULIN CONCENTRATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES WITH AND WITHOUT COVID-19 INFECTION

O. Knyazev^{1,2}, A. Kagramanova¹, D. Kulakov¹, A. Lishchinskaya¹, B. Nanaeva², R. Gudkova¹, A. Parfenov¹

¹Moscow Clinical Scientific Center named after A.S. Loginov, IBD, Moscow, Russian Federation, ²State Scientific Centre of Coloproctology named after A.N. Ryzhyh, IBD, Moscow, Russian Federation

Contact E-Mail Address: kagramanova@me.com

Introduction: Zonulin is a protein, reversibly increasing the permeability of the intestinal wall by changing the structure of tight junctions of the lateral surfaces of intestinal epithelial cells. Fecal zonulin is used for non-invasive assessment of increased intestinal permeability.

Normal values of zonulin in stool (≤ 110 ng/ml) indicate the absence of damage of the intestinal villous mucosal surface and normal density of intercellular contacts.

Aims & Methods: The aim of the study was to determine the level of fecal zonulin (FZ) in the feces of IBD patients with exacerbation of the disease and the presence of COVID-19 in the acute period and without COVID-19 to assess the degree of intestinal permeability.

Material and methods: 34 patients with IBD without COVID-19 (Me age — 32 years) and 19 patients with IBD with the presence of COVID-19 infection in the acute period (Me age — 44 years) were examined.

Untreated stool samples of patients were frozen and stored at a temperature of 80°C. FZ was measured by ELISA (IDK® Zonulin ELISA Kit, Immunodiagnostik AG, Germany) in ng/ml. Reference values: < 83.15 ng/ml - a variant of the norm, $83.15-110$ ng/ml - an elevated level, 110 ng/ml - a high level.

Results: In the stool samples of patients with IBD exacerbation without COVID-19 FZ was detected from 186.4 to 563.9 ng/ml (Me - 326), the average value was 333.4 ± 16.9 ng/ml. In the stool samples of patients with IBD exacerbation and COVID-19 infection, FZ was detected from 321.8 to 598.3 ng/ml (Me - 469.9), the average value was 464.9 ± 16.4 ng/ml ($p=0.000001$).

Conclusion: FZ concentration in the feces of IBD patients is significantly higher in IBD patients with the presence of COVID-19 infection in the acute period, which indicates a higher permeability of the intestinal wall.

Disclosure: Nothing to disclose.

P1015

DIFFERENCE BETWEEN COVID-19 ALPHA VARIANT, B.1.1.7, AND THE ORIGINAL VIRUS IN GASTROINTESTINAL SYMPTOMS AND MORTALITY, IS A NEGATIVE CORRELATION EXISTS?

Y. Niv¹

¹Ariel University, Medicine, Pardesia, Israel

Contact E-Mail Address: nivaron80@gmail.com

Introduction: Covid-19 disease was first diagnosed in Israel at the end of February 2020. Until the end of June 2021 842,536 confirmed cases and 6428 deaths were accumulated. In our multicenter, retrospective cohort study, we looked for gastrointestinal signs and symptoms in 2 periods (period I represents the 1st and 2nd waves and the original virus; period II represents the 3rd wave and the alpha variant), and correlated them with mortality.

Aims & Methods: Out of 22302 patients hospitalized in general medical centers we randomly selected 6329 admissions for the study. Of these, 3582 and 1106 were eligible for the study in the first period and in the second period, respectively.

Results: Gastrointestinal signs and symptoms, diarrhea, vomiting, abdominal pains and taste/smell loss, were more prevalent in the first period than in the second period (Table 1). Thirty-day mortality and in-hospital mortality were significantly higher in the 2nd period than in the 1st period, 25.20% versus 13.68%, and 21.17% versus 12.87%, respectively ($P<0.001$).

Parameter	Original virus (%)	Alpha variant (%)	RR
Age > 60 y	58.23	71.01	1.22
Gender men	55.06	57.89	1.05
Diarrhea	9.39	4.96	0.53
Vomiting	6.80	5.23	0.77
Abdominal pain	5.94	3.54	0.60
Taste/Smell loss	42.41	34.68	0.82
In Hospital Mortality	12.87	21.17	1.64
30-day Mortality	13.68	25.20	1.84

Table 1.

Conclusion: Mortality rates were 1.64 to 1.84 times higher on the 2nd period than in the 1st period and in negative correlation with gastrointestinal symptoms and signs.

Disclosure: Nothing to disclose.

P1016

FEATURES OF MICROBIOTA DISTURBANCES INTESTINE IN PATIENTS WHO UNDERWENT COVID-19

M. Adkhamova¹, S. Shamsiev², S. Kuranbaeva³

Contact E-Mail Address: adkhamova0511@mail.ru

Introduction: It is well known that COVID-19 affected not only the respiratory system but the general body system, including digestive system.

Aims & Methods: We aimed to study the intestinal microflora in patients who have had a coronavirus infection, caused by COVID-19.

We examined 42 patients aged 34 ± 7 years with the diarrheal syndrome (stools 7 ± 3 times a day) that developed after coronavirus infection. Viral pneumonia was detected in 26/42 patients, in connection with which courses of antibiotics were carried out. In 16/42, COVID-19 proceeded without the development of pneumonia. The microbiota was studied in stool cultures and bacterial growth in the lumen of the small intestine (SIBO) was determined by the hydrogen breath test. Feces were examined for Clostridium difficile toxins, as well as laboratory and instrumental examination was carried out.

Results: In all patients, stool cultures showed a decrease in obligate and growth of opportunistic microflora, in 12/42 - signs of SIBO. 31/42 were found to have C. difficile toxins, among which 26/42 received courses of antibiotics, and 5 had no antibiotic therapy during the last year. Colonofibroscopy revealed erosive hemorrhagic colitis in 31/42 patients.

In blood tests, 40/42 had lymphopenia. Clostridial infection was treated, followed by a combined probiotic course. 11 patients with intestinal dysbacteriosis in the absence of C. difficile received probiotic monotherapy. As a result of therapy, all patients had regular stools up to 1–2 times a day, and there were no C. difficile toxins on re-examination.

After a monthly course of the multi-strain probiotic, the composition of the fecal microbiota was restored and was not determined by SIBO. Colonofibroscopy showed no signs of inflammation, and lymphocyte counts returned to normal.

Conclusion: In all patients who underwent coronavirus infection, a violation of the fecal microbiota was revealed, with *C. difficile* activation in 73%. 28% of patients developed SIBO. Lymphopenia was found in 95% of patients with intestinal dysbacteriosis. Coronavirus infection COVID-19 leads to changes in the intestinal microbiota, which creates conditions for the growth of clostridial infection against the background of a decrease in the tension of the immune system.

Disclosure: Nothing to disclose.

BNT162B2 MRNA COVID-19 VACCINE SAFETY IN INFLAMMATORY BOWEL DISEASE PATIENTS ON BIOLOGIC THERAPY: A MONOCENTRIC REAL-WORLD STUDY

R. Pellegrino¹, G. Pellino², L. Selvaggi², F. Selvaggi², R. D'Onofrio¹, N. de Gennaro¹, A. Federico¹, M. Romano¹, A.G. Gravina¹

¹University of Campania Luigi Vanvitelli, Department of Precision Medicine, Naples, Italy, ²University of Campania Luigi Vanvitelli, Department of Advanced Medical and Surgical Sciences, Naples, Italy

Contact E-Mail Address: raffaele.pellegrino@unicampania.it

Introduction: During COVID-19 pandemic, vaccines were developed with the intention of providing a primary preventive intervention. Patients with Inflammatory Bowel Disease (IBD) were excluded from most of trials that led to the approval of anti-COVID-19 vaccines and are therefore worthy of real-life studies providing information on the safety of these vaccines in this clinical setting and especially for specific subgroups such as patients on biologic therapy this also in consideration of a certain degree of reluctance of IBD patients to get vaccinated.

Aims & Methods: A prospective observational real-life study was performed for estimating local and systemic adverse events (AEs) incidence related to BNT162b2 vaccine administration in IBD patients in therapy with biological drug. We also wanted to evaluate whether there was a vaccine-induced change in IBD activity or an AEs increase depending on the disease activity as well as whether there were subgroups more exposed to AEs or predictors of systemic AEs. Questionnaires regarding the occurrence of AEs were administered after each of the three doses of vaccine as well as gastroenterologic visits were performed before the first, second, third dose, and after the third dose for Partial Mayo Score (PMS) and Harvey-Bradshaw Index (HBI) evaluation.

Results: 80 patients were initially enrolled (43.75% with Crohn's Disease and 56.25% with Ulcerative Colitis, median age 47.5) and evaluated at the first-second doses and 74 patients at the third dose. Local AEs rate was 37.5%, 58.75%, 28.37% at the first, second, and third dose of vaccine, respectively. In contrast, the systemic AEs rate was 52.2%, 48.75%, 43.24%. There were no differences in the occurrence of local and systemic AEs between patients with Crohn's Disease and Ulcerative Colitis patients ($p > 0.05$). Non-hypertensive and non-diabetic ($p < 0.05$) patients experienced significantly fewer local AEs at first and second doses. Vaccination did not affect disease activity and no statistically significant difference in PMS and HBI was observed between the three doses. Comorbidities and concomitant therapies were not discriminating in the occurrence of AEs ($p > 0.05$). Clinic-demographic predictor variables for AEs were not identified and PMS and HBI were not found to be predictors of systemic AEs. No serious AEs were observed.

Conclusion: BNT162b2 vaccine showed a good clinical safety profile in our setting of IBD patients on biologic therapy in the absence of severe AEs and changes in baseline disease activity.

Disclosure: Nothing to disclose.

Introduction: Management of inflammatory bowel disease (IBD) often relies on biological and immunomodulatory agents for remission through immunosuppression, raising concerns regarding the SARS-CoV-2 vaccine's effectiveness and safety. Recent evidence suggests that these patients can adequately neutralize the virus after two doses of the mRNA-COVID-19 vaccine. Nonetheless, the rapidly appearing variants have hindered the characterization of the vaccine's capacity.

We report the humoral response of patients with IBD without and with biologic and/or immunomodulatory therapy against seven SARS-CoV-2 variants 60 days after the third vaccine dose of COVID-19.

Aims & Methods: Subjects ≥ 21 years of age with Crohn's disease (CD) and ulcerative colitis (UC) with and without biological and/or immunomodulatory therapy were recruited. Blood samples were collected after 60 ± 7 days after receiving the third dose of mRNA COVID-19 vaccine [BNT162b2 (Pfizer-BioNTech) or mRNA-1273 (Moderna)]. Neutralizing capability using SARS-CoV-2 surrogate virus neutralization test (sVNT%) was measured against seven variants of SARS-CoV-2 virus: Alpha, Beta, Gamma, Epsilon, Kappa, Delta, and Omicron. A result of $\geq 30\%$ was positive for effective viral inhibition. Results were stratified by the mechanism of action of those subjects receiving therapy and compared with a healthy control group. The study is approved by the MSC IRB.

Results: 54 subjects with IBD unexposed and exposed to biological and/or immunomodulatory after 60 ± 7 days of third vaccine dose and 12 healthy controls after 60 ± 10 days of third vaccine dose are reported. For subjects with IBD, 81% (44/54) had a diagnosis of CD, 61% were males (33/54), and the mean age was 42. The majority of the subjects were receiving anti-TNF therapy (29/54), and one was on a concomitant corticosteroid. All subjects with IBD developed detectable antibodies.

Twenty-four subjects with IBD did not develop effective neutralizing capability against the Omicron variant. 70% (17/24) of those subjects were receiving anti-TNF therapy (10= adalimumab, 7= infliximab), two of them (2/17) had a history of COVID-19 infection, and one subject (1/17) did not develop neutralization against three other variants: Gamma, Epsilon and Kappa. All 12 healthy controls developed detectable antibodies and effective humoral responses against all seven variants of SARS-CoV-2.

Conclusion: Our study shows that humoral response after third vaccine dose from patients with IBD on anti-TNF therapy might not be protective against COVID-19 variants, particularly against Omicron. These patients might benefit from an additional vaccine dose, thus prospective and larger studies are needed to ensure optimal immunity for patients with IBD.

PATIENTS WITH LOW ALT LEVELS ARE AT INCREASED RISK FOR SEVERE COVID-19

D. Genzel¹, L.H. Katz¹, R. Safadi², J.M. Jacobs³, A. Shafrir^{1,4}

¹Hadassah Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Department of Gastroenterology, Jerusalem, Israel, ²Hadassah Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Liver Institute, Jerusalem, Israel, ³Hadassah Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Department of Geriatrics and Geriatric Rehabilitation, Jerusalem, Israel, ⁴Meuhedet Meuhedet Health Maintenance Organization, Jerusalem District, Tel Aviv, Israel

Contact E-Mail Address: ashershaf@gmail.com

Introduction: Alanine transaminase (ALT) levels are usually used as a sign of liver health. However, low ALT is associated with sarcopenia and frailty. The COVID-19 pandemic has caused immense morbidity and mortality, especially in older and frail patients. We evaluated the association of pre-infection low ALT and the risk for severe COVID-19.

Aims & Methods: We used data from Meuhedet Health Services, a national state-mandated HMO in Israel, serving more than 1.3 million patients from all over the country. Data regarding all subjects tested for SARS-CoV-2 from 1 March 2020 – to 31 December 2021 was collected. Clinical and laboratory data were collected, including ALT from the year prior to infection. Severe COVID-19 was defined as ≥ 10 hospitalization days, ICU admission, or death within 30 days of the infection. Patients with low ALT (ALT < 10 IU/l) were compared to patients with normal ALT (11–40 ALT/l). Patients younger than 18, with above-normal ALT levels and those without ALT in the year prior to COVID-19 infection, were excluded.

Results: During the study period, 58,961 adult patients with low or normal ALT levels were tested positive for SARS-CoV-2. 5,515 (10.32%) of the study population were in the low ALT group. The low ALT group was younger (40.53 ± 20.20 vs. 42.73 ± 17.28 , $p < 0.001$), less likely to be male (12.3% vs. 38.7%, $p < 0.001$), and had lower BMI (26.1 vs. 27.4 , $p < 0.001$).

There were more deaths in the low ALT group (2.4% vs. 0.6%, $p < 0.001$) and more lengthy hospitalizations (2.6% vs. 1% $p < 0.001$). ICU hospitalization were similar in both groups (0.5% vs. 0.4%, $p = 0.47$).

In a multivariate logistic regression controlling for age, sex, vaccination status, socioeconomic status, sector, hypertension, diabetes mellitus, and BMI, low ALT was associated with increased risk for 30-day mortality (OR 1.94, $p < 0.001$) and prolonged hospitalization (OR 1.93, $p < 0.001$).

Conclusion: Low ALT is associated with an increased risk for severe COVID-19 infection. This association may be due to frailty and sarcopenia, yet further studies are warranted to explore this association.

Disclosure: Nothing to disclose.

Introduction: The objective of this study is to investigate the defining characteristics of COVID-19 vaccinated and unvaccinated patients with moderate-to-severe Crohn's disease (CD) in the EU4+UK and highlight key differences between these two cohorts, as well as identifying driving factors for gastroenterologists to advise COVID vaccination.

Aims & Methods: A multi-centre online medical chart review study of patients with CD and UC was conducted between July – September 2021 among EU4+UK (UK, FR, DE, IT & ES) gastroenterologists practicing across hospital and private practices. Recruited from a large access panel, physicians were screened for duration of practice in their specialty and caseload. Respondents completed a three-part survey; doctor demographics, perceptual questionnaire, and patient record forms of their next 6 CD patients seen following receipt of the survey.

Results: In Q3 21, 203 EU4+UK gastroenterologists reported on 1106 CD patients. Rates of COVID-19 vaccination among this patient cohort were 86.1% vaccinated, 13.9% unvaccinated.

Reported vaccinated CD patients, when compared to the unvaccinated cohort, had a significantly higher average age (41 years vs 33 years, respectively; $p \leq 0.01$), a significantly higher physician stated rate of controlled disease (83% controlled vs 68%; $p \leq 0.01$), a significantly higher physician stated rate of remission (74% vs 61%; $p \leq 0.01$).

Reported vaccinated CD patients also had a significantly higher number of hospitalisations compared to unvaccinated patients (13.1 times vs 6.5 times; $p \leq 0.01$), as well as a significantly higher average number of surgeries compared to unvaccinated patients (1.3 surgeries vs 1.1; $p \leq 0.01$).

Reported unvaccinated CD patients were prescribed TNFi therapies at a significantly higher rate than those who are vaccinated (87.7% of overall market vs 78.3%; $p \leq 0.01$), while vaccinated patients experienced a significantly higher average time on their current therapy (17.1 months vs 13.2 months; $p \leq 0.05$).

Reported unvaccinated patients had a significantly higher average CRP score than vaccinated patients (14.8 vs 10.4; $p \leq 0.01$); a directionally higher average ESR score (22.5 vs 21.8); a directionally higher average CDAI score (155.4 s 146.0), and a significantly higher average daily frequency of diarrhoea (6.1 times per day vs 5.2; $p \leq 0.01$). First line reported patients have a directionally lower rate of vaccination than later line patients; patients on second and later lines of therapy constitute 25.4% of the vaccinated cohort vs 12.3% of the unvaccinated cohort.

'COVID-19 impact' was cited as a reason for choice of current biologic therapy directionally more frequently for reported unvaccinated patients than those who are vaccinated (5.5% vs 3%).

Conclusion: EU4+UK gastroenterologists sampled in this study appear to be more comfortable advising COVID-19 vaccinations to older patients, who are stable on their biologic therapy and are in remission, having a physician-defined controlled case of CD, and lower disease scores. COVID-19 impact may not have been top of mind for gastroenterologists; patient status played a more considerable role in defining a biologically treated CD patient's suitability for COVID vaccination.

These findings align with clinical guidelines in relation to COVID vaccinations for those with autoimmune disease or immunocompromised status, helping to protect this vulnerable cohort from more severe disease outcomes and increased rates of hospitalisation. Further investigation using comparator cohort is warranted.

P1021

THE SAFETY OF ENDOSCOPY UNITS DURING THE COVID-19 PANDEMIC

M.G. Gonçalves¹, A. Guimarães¹, T. Carvalho¹, P. Antunes¹,
S. da Silva Mendes¹, J.B. Soares¹, B. Arroja¹, A. Rebelo¹,
R. Gonçalves¹

¹Braga Hospital, Department of Gastroenterology, Braga, Portugal

Contact E-Mail Address: margaridagoncalves21@gmail.com

Introduction: The COVID-19 pandemic drastically changed the daily routine of all healthcare systems worldwide and endoscopy units were no exception. Endoscopic exams were considered to have a high risk of transmission, and therefore the safety of endoscopy units and the consequent need for pre-endoscopy SARS-CoV-2 screening were questioned early on.

Aims & Methods: The aim of our study was to assess the safety of endoscopy units during the COVID-19 pandemic, as well as the effectiveness/necessity for SARS-CoV-2 screening prior to endoscopies. This is a prospective and single-center study carried out in a Portuguese Tertiary Hospital. All patients who underwent endoscopic procedures between 1st September of 2020 and 28th February 2021 were included. The pre-endoscopy screening consisted of a specific questionnaire or a RT-PCR test for SARS-CoV-2 (nasal and oropharyngeal swab). Data were obtained through patient's clinical records and the Trace COVID platform.

Results: A total of 2166 patients were included. Patients had a mean age of 61.8 years and were predominantly male (56.2%, n=1218). Eighty-one (3.7%) patients had previous SARS-CoV-2 infection, with a median difference of 74 days (IQ 40,5:160,5) between infection and endoscopy. Most patients (70.2%, n=1521) underwent PCR screening for SARS-CoV-2 up to 72 hours before the procedure, with the remaining patients (29.8%, n=645) answering a questionnaire of symptoms and risk contacts up to 3 days before endoscopy. Of the patients who underwent RT-PCR screening for SARS-CoV-2, 21 (1.4%) tested positive, and all were asymptomatic at the time of the screening. The evaluation for SARS-CoV-2 infection up to 14 days after the endoscopic exams, identified 9 positive patients (0.42%) for SARS-CoV-2. The median difference in days between endoscopy and the diagnosis of infection was 10 days.

Conclusion: Pre-endoscopy screening with RT-PCR test for SARS-CoV-2 identified a very small number of patients with COVID-19 infection as well as patients with COVID-19 infection in the following 14 days. Therefore, the risk of infection in endoscopy units is negligible if screening of symptoms and risk contacts is applied and individual protective equipment is used.

Disclosure: Nothing to disclose.

Contact E-Mail Address: manolakis@uth.gr

Introduction: Throughout the COVID-19 pandemic, several symptoms have been attributed to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. SARS-CoV-2-induced thrombosis, olfactory migration and autoimmunity have been implicated in the onset of neurologic

manifestations. Meanwhile, dysphagia emerged as a rather rare, neglected COVID-19-related symptom, initially linked to intubation. Its occurrence, however, in non-intubated patients as well shows that the pathogenesis of post-COVID-19 dysphagia remains unclear.

Aims & Methods: To examine whether post-COVID-19 dysphagia results from esophageal motility disorder(s). Patients presenting with post-COVID-19 dysphagia between January 2021-March 2022, underwent esophagogastroduodenoscopy, esophagram, computed tomography and two esophageal high-resolution manometry (HRM) studies 4-8 months apart. HRM studies were performed using a system with a 15mmHg integrated relaxation pressure (IRP) threshold for the diagnosis of esophago-gastric junction (EGJ) disorders and the Chicago classification version 4.0. SARS-CoV-2 infection was documented through at least one positive reverse transcriptase polymerase chain reaction (RT-PCR) test.

Demographics, history of anti-SARS-CoV-2 vaccination, need for hospitalization, symptom profile and duration, Eckardt scores (ES), treatment modalities were also recorded. Informed consent was obtained along with approval from the Ethical Committees of the University Hospital of Larissa and Evangelismos General Hospital of Athens, Greece.

Results: Twelve patients (9 female; mean age±SD: 63±6years) were included, seven with new-onset dysphagia (median ES:7) and five with aggravation of pre-existing dysphagia (median ES:8 vs 3). Based on HRM, all patients with new-onset dysphagia had EGJ outflow obstruction (EGJ-oo) whereas those with pre-existing dysphagia exhibited type II Achalasia. No other major abnormalities were recorded.

A female predominance was evident in the EGJ-oo group (female:male ratio of 2.5:1). Median time (interquartile range-IQR) from positive RT-PCR until development of dysphagia was 20(6) days. Achalasia patients exhibited higher median IRP values compared to the EGJ-oo group: 22.5(1.7) vs 17.3(1.8) (supine position;P=0.006) and required pneumatic dilatation for resolution of symptoms. In patients with EGJ-oo, dysphagia resolved spontaneously over a median(IQR) of 4(3.5) months and upon second HRM no EGJ-oo was documented based on intrabolar pressurization pattern and IRP: 13.6(1) vs 17.3(1.8) (supine position;P=0.06).

No differences regarding vaccination status or symptomatic/asymptomatic infection were recorded. Only one patient was hospitalized and received corticosteroids while no patients received antiviral therapy. All patients had no signs of meningitis/encephalitis, Guillain-Barré syndrome or myopathy. In two patients with EGJ-oo who had anti-SARS-CoV-2 antibody testing at 3-4weeks and at 3.5-4months from RT-PCR positivity, improvement of dysphagia coincided with a marked 3-fold drop in anti-SARS-CoV-2 antibody titres.

Conclusion: Post-COVID-19 dysphagia may result from EGJ disorders either triggered or fueled by SARS-CoV-2 infection. New-onset dysphagia is associated with EGJ-oo and seems to decrease and resolve spontaneously over time.

This improvement seems to coincide with waning anti-SARS-CoV-2 immunity, indirectly suggesting an (auto)immune pathogenetic pathway. On the other hand, post-COVID-19 aggravation of dysphagia corresponds to type II Achalasia and requires intervention in order to resolve.

INFLAMMATORY BOWEL DISEASES DURING THE SARS-COV2 PANDEMIC ERA: THE EFFECTS OF COVID-19 ON PSYCHOLOGICAL STATUS AND DISEASE ACTIVITY

M.G. Demarzo¹, L. Caserta¹, B. Clivio¹, M.c. Parodi¹

¹Gastroenterology Unit, San Martino Hospital, Department of Surgery, Genova, Italy

Contact E-Mail Address: mgiulia.demarzo@gmail.com

Introduction: Covid-19 pandemic is responsible for a dramatic increase in mental health problems in the general population. Some categories have been identified to be at higher risk of psychological distress, such as people with pre-existing mental diseases, people from a lower socioeconomic background and young adults. There is a close correlation between stress and gastrointestinal symptoms¹.

Studies have shown that negative experiences may influence the immune system and cause illness. Particularly, inflammatory bowel disease (IBD) is known to may be exacerbated by negative emotional experiences².

Aims & Methods: The aim of our study was to evaluate the health-related quality of life (HRQoL) and the perception of stress in IBD patients affected by Covid-19 compared to IBD subjects who never got Sars-CoV-19 infection.

We recruited 41 IBD patients affected by Covid-19 and 43 age- sex- and race matched IBD controls in clinical remission. All patients were asked to complete by mail both the Short IBD Questionnaire (SIBDQ) and the Perceived Stress Scale (PSS) between September and December 2021. The evaluation was completed by telephone interview. Disease activity was assessed by the Harvey-Bradshaw Index (HBI, remission defined by HBI<5) for Chron Disease (CD) patients and by partial Mayo score (PMS, remission defined by PMS<2) for Ulcerative Colitis (UC) patients.

The primary endpoint was to determine the influence of Covid-19 on HRQoL of IBD patients. Secondary outcome was to observe if Covid-19-induced stress can exacerbate IBD disease activity.

Results: All 43 (100%) IBD controls filled in both questionnaires whereas only 29 (71%) Covid-19 positive patients completed both forms. No patient included experienced severe disease. Median age was 47 [(25-82 years, Covid-19 positive patients), (23-84 years, IBD controls)] in both groups; approximately half of population was male (n=16, 55%; n= 22, 51% in Covid-19 positive and control patients, respectively).

Considering the type of disease, we noticed a slight preponderance of Ulcerative Colitis among both patients (n=19, 66%) and controls (n=27,63%). Covid-19 patients had higher self-perceived stress compared to controls ($p=0.03$).

No difference was observed in SIBDQ between the two groups ($p=0.2$). Contracting Covid-19 was associated to a higher stress level (RR 1.54, 95% CI 1.16-2.04) and to an increased risk of disease flare (RR 2.15, 95% CI 1.17-3.95). Nevertheless, the health-related quality of life is quite similar (RR 1.25, 95% CI 0.91-1.72) in both IBD Covid-19 patients and controls.

Conclusion: Covid-19 appears to significantly influence psychological status of IBD patients compared to controls and to be associated with clinical recurrence in our cohort. Surprisingly HRQoL seems to be unaffected by Covid-19. Longer follow-up and larger sample size are needed to confirm our results.

PARAMETRIC IMAGING WITH CONTRAST-ENHANCED ULTRASOUND (CEUS): A NOVEL APPROACH TO ASSESS SMALL BOWEL MANIFESTATION IN SEVERE COVID-19 DISEASE

H. Tews¹, A. Kandulski², S. Schmid³, S. Schlosser¹, S. Schirner¹, F.-J. Putz⁴, L.-S. Cosma¹, K. Gülow¹, M. Müller-Schilling¹, E.-M. Jung⁵

¹University of Regensburg, Departement of Internal Medicine, Regensburg, Germany, ²University Hospital Regensburg, Department of Internal Medicine, Regensburg, Germany, ³University Hospital Regensburg, Internal Medicine I, Regensburg, Germany, ⁴University of Regensburg, Department of Nephrology, Regensburg, Germany, ⁵University of Regensburg, Department of Radiology, Regensburg, Germany

Contact E-Mail Address: Hauke.Tews@ukr.de

Introduction: In this study, we investigate the effects of SARS-CoV-2 infection on the small intestine using state-of-the-art ultrasound methods including parametric analysis. In terms of intestinal diagnosis, CEUS is of particular importance for diagnosis and follow-up of structural bowel disease.

In pathophysiology of severe COVID-19 disease, a combination of hyperperfusion in the context of a systemic cytokine storm and hypoperfusion in the context of microemboli is suggested to account for COVID-19 affection of the small intestine.

Aims & Methods: The aim of our work was to evaluate the increasing evidence of gastrointestinal tract involvement during SARS-CoV-2 infection using CEUS. An additional focus was to enhance understanding of the nature of small intestinal involvement based on image morphology and to gain insight into pathophysiology using parametric analysis. We studied thirteen patients with severe SARS-CoV-2 infection. Modern ultrasonography with elastography, CEUS and parametric analysis was performed.

CEUS examinations of critically ill patients and the performance of intra-operative CEUS are supported by the new guidelines of the "European Federation of Societies for Ultrasound in Medicine" (EFSUMB). Contrast-enhanced computed tomography with an arterial, portal venous, and venous phase served as the reference method.

Results: Thirteen patients (8 male/5 female) with a mean age of 54 years were included in the study. Eight patients suffered from obesity of varying degrees. 85% of the severely ill patients had not been vaccinated against SARS-CoV-2. Delta variant of SARS-CoV-2 was the dominant variant in the study cohort. Five patients required ECMO therapy. Using CEUS microbubbles entered the intestinal lumen in 7 patients.

Early contrast enhancement in the mesenteric vessels was seen in 4 patients and very early contrast enhancement in one patient. A combination of segmental early and delayed contrast enhancement in the small intestine was detected in 5 patients.

Conclusion: Intestinal barrier disruption resulting from SARS-CoV-2 infection is common. Parametric analysis of contrast-enhanced ultrasound (CEUS) allows assessment of perfusion and of barrier disruption in the small intestine. We assume that intestinal barrier disruption in severe COVID-19 disease is a combination of hyperemia in the setting of systemic infection and hypoxemia in the setting of microemboli in a subset of patients.

THE IMPACT OF COVID-19 ON GASTROENTEROLOGY DEPARTMENT

D.I. Negru-Vodă¹, A. Stemate¹, E. Guluta¹, T. Spataru¹, L. Negreanu²

¹Carol Davila University of Medicine and Pharmacy, Gastroenterology Department, Emergency University Hospital, Bucharest, Romania, ²Spitalul Universitar de Urgență București, Internal Medicine Gastroenterology, Bucharest, Romania

Contact E-Mail Address: delia-ionela.mihop@drd.umfcd.ro

Introduction: There have been more than two years since a small particle known as Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-COV2) came to our lives to completely change them and a lot of other functional rules. As a consequence, the extent of this pandemic led to a transformation of many hospital departments into places used to attend patients with Coronavirus Disease (COVID-19).

In this context, the usual activity of the Gastroenterology Department in the Emergency University Hospital of Bucharest has temporarily changed, becoming a COVID-19 Department, where we noticed an increased prevalence of liver injuries associated with this disease.

Aims & Methods: We conducted a retrospective observational study, aiming to evaluate clinical and paraclinical characteristics of patients with COVID-19 and to investigate the impact of liver injury on COVID-19 severity. There have been included all the patients admitted to the Gastroenterology Department with moderate to severe SARS-COV2 infection from the period of January 1, 2020 to November 30, 2021. They were followed up to the discharge, death or transfer to other hospitals.

We created and analyzed a database from electronic health records, including demographic data, associated pathologies, symptoms on admission, results of biologic and imaging studies performed in our department, the requirement of Intensive Care Unit (ICU) admission and mechanical ventilation, length of hospitalization and mortality.

Results: From 816 patients older than 18 years old and without previously known liver disease, 284 (34,80%) of them presented liver injury (defined as an abnormal value of alanine transaminase, aspartate transaminase, alkaline phosphatase, gamma-glutamyl transferase or total bilirubin more than 2 times over the upper limit of normal on admission). Hepatic impairment at diagnosis was associated with pre-existing metabolic syndrome, pulmonary afflictions or acute hepatitis B.

After excluding the transferred patients, we remarked that a higher proportion of subjects included in the liver injury group needed ICU admission comparing to the other group (44.84% versus 37.80%, $p < 0.05$).

Furthermore, the requirement of mechanical ventilation was more increased in the first group (44.84%) whereas in the second one only 38.24% of the patients needed a modality of mechanical ventilation ($p = 0.05$).

The results of logistic regression analysis after the adjustment for sex, age and presence of cardiovascular, lung, oncologic comorbidities and metabolic syndrome confirm that liver injury on admission is the secondly most important risk factor after the age, for the mortality.

There have not been observed significant statistical differences between hepatic impairment group and the group without it on: sex, vaccination status, digestive symptoms on admission, inflammatory syndrome, length of hospital stay or cycle threshold values.

Conclusion: The results of this study are consistent with the hypothesis that hepatic function impairment in patients with COVID-19 represents a negative prognostic factor concerning ICU admission, the requirement of mechanical ventilation and mortality.

Disclosure: Nothing to disclose.
