Background: Frontotemporal dementia (FTD) is the leading cause of pre-senile dementia, characterized by behavioural or language impairments. Pathogenic mutations in GRN, MAPT, and C9orf72 are the most frequent genetic causes of FTD. We investigated the expression of 56 genes involved in autophagy, inflammation, and aging in FTD patients carrying these mutations, compared to sporadic FTD patients and healthy controls. While these pathways are central to FTD pathogenesis, their roles remain unclear.

Material and Methods: Total RNA was extracted from Paxgene-stabilized blood samples of 20 healthy controls, 10 C9orf72, 10 GRN, 10 MAPT mutation carriers, and 10 sporadic FTD patients. Real-time PCR analysis was performed using Custom TaqMan OpenArray technology, enabling simultaneous detection of 56 mRNAs. Gene expression levels were compared across groups using ANOVA with post hoc multiple comparisons.

Results: Several genes exhibited differential expression patterns among groups. Autophagy-related genes (ATG5, BECN1) were altered in mutation carriers, particularly C9orf72 carriers. Inflammation-associated genes (B2M, TYROBP) were deregulated in MAPT and C9orf72 carriers compared to sporadic FTD. NFE2L2, a key antioxidant and anti-inflammatory regulator, was significantly increased in MAPT but decreased in C9orf72 carriers, indicating differential oxidative stress regulation. SERPINB1 was upregulated in GRN carriers compared to controls.

Conclusion: Our findings support the involvement of autophagy, inflammation, and oxidative stress in FTD and highlight molecular differences between genetic and sporadic cases. These insights could help identify novel biomarkers and therapeutic targets for personalized interventions in FTD.

P11.050.A De novo variant analysis of childhood-onset obsessive-compulsive disorder in the French-Canadian population

Kate Bornais[1,2], *Jay P. Ross*[1,2], *Zoe Schmilovich*[1,2], *Miranda Medeiros*[1,2], *Dan Spiegelman*[3,2], *Bernard Boileau*[4], *Jean-Jacques Marier*[4], *Ghislain Laurin*[4], *Patrick A. Dion*[3,2], *Guy A. Rouleau*[3,2]

[1]*Department of Human Genetics, McGill University, Montreal, QC, Canada,* [2]*Montreal Neurological Institute-Hospital, Montreal, QC, Canada,* [3]*Department of Neurology and Neurosurgery, McGill University, Montreal, QC, Canada,* [4]*Le Centre Hospitalier Universitaire Sainte-Justine, Université de Montréal, Montreal, QC, Canada.*

Background: Childhood-onset obsessive-compulsive disorder (CO-OCD) is a neuropsychiatric disorder with a strong genetic component. De novo variants (DNVs) contribute to CO-OCD risk, but to date, no DNV analysis of CO-OCD has been performed in a genetically isolated population. Here, we investigated the impact of rare de novo single nucleotide variants (dnSNVs) on CO-OCD risk in the French-Canadian population.

Material and Methods: Whole-exome sequencing was performed on 42 trios ($n = 126$). Variants were filtered for heterozygous genotype in the proband and wildtype in both parents. Protein-coding dnSNVs with minor allele frequencies <1% were retained. DNV rate (μ) was calculated as: μ = (number of observed dnSNVs/proband)/(size of RefSeq hg19 coding exome x number of gametogeneses). DenovolyzeR assessed the genome-wide burden of dnSNVs by variant class. Genes harbouring dnSNVs were examined for overlap with genes previously associated with OCD and other psychiatric disorders. Our candidate gene list was combined with those from previous CO-OCD DNV studies for functional enrichment meta-analyses.

Results: 34 dnSNVs in 34 genes were observed across 36 probands (0.94 dnSNVs/proband, average CADD = 16.1). μ was 1.40E-08 per nucleotide per generation (95%CI:9.36E-09,1.86E-08). A nominal enrichment of splice-site dnSNVs was detected ($p\text{-}adj = 0.0519$). Four genes were previously associated with OCD. All 34 genes overlapped with genes associated with 11 related neuropsychiatric disorders. Genes involved in clathrin-dependent endocytosis (GO:0072583) and the fetal brain were overrepresented in the combined gene list ($p\text{-}adj < 0.05$).

Conclusion: This study provides the first comprehensive list of candidate CO-OCD genes specific to the French-Canadian population, offering a framework for DNV analyses in isolated populations.

P11.051.B Genome-wide copy number variation association study in schizophrenia

Sinja Hanebaum[1,2], *Simone Montalbano*[1,2], *Mads Kristian Holm*[1,2], *Anders Rosengren*[1,2], *Thomas Werge*[1,2,3], *Andrés Ingason*[1,2]

[1]*Institute of Biological Psychiatry, Mental Health Services, Copenhagen University Hospital, Roskilde, Denmark,* [2]*The Lundbeck Foundation Initiative for Integrative Psychiatric Research (iPSYCH), Copenhagen and Aarhus, Denmark,* [3]*Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: Copy number variations (CNVs) are a class of structural variations that have been linked to a number of psychiatric disorders, including schizophrenia spectrum disorder (SSD). Although genomic studies have successfully identified (common) risk variants in SSD, the rarity of CNVs in the general population, the complexity of CNV detection, and the focus on a limited number of known and well-studied CNVs have limited the scope of previous studies and restricted more comprehensive analysis of CNVs in SSD.

Material and Methods: This study aims to perform a comprehensive genome-wide CNV enrichment analysis, utilizing microarray data from the iPSYCH2015 case-cohort sample, which includes 13,147 SSD cases and 43,177 population controls. Specifically, the genome-wide burden of recurrent and non-recurrent CNVs in SSD will be assessed, as well as the overall CNV heritability. Furthermore, we will investigate the genome-wide association of CNVs in SSD in the Danish population and examine CNV enrichment in defined brain-expressed gene sets to provide functional insights.

Results: : Preliminary results suggest a higher overall burden of CNVs in brain-expressed genes among individuals with SSD compared to population controls, and that their aggregation in specific gene networks may provide insights into the genetic etiology of SSD.

Conclusion: Our findings will enhance the understanding of the contribution of CNVs to SSD, leading to better estimates of individual risk and establishing a foundation of future studies.

P11.052.C Polygenic scores for dyslexia are associated with lower general cognitive ability and reduced accuracy in UK Biobank participants with psychiatric disorders

Priyatam Dutta[1,2], *Lisa Sindermann*[1,3], *Christina Fell*[4], *Andreas J. Forstner*[1,5], *Silvia Paracchini*[2,1]

[1]*Institute of Human Genetics, University of Bonn, School of Medicine & University Hospital Bonn, Bonn, Germany,* [2]*University of St Andrews, School of Medicine, St Andrews, United Kingdom,* [3]*Department of Psychiatry and Psychotherapy, University Hospital Bonn, Bonn, Germany,* [4]*School of Computer Science, University of St Andrews, St Andrews, United Kingdom,* [5]*Institute of Neuroscience and Medicine (INM-1), Research Center Jülich, Jülich, Germany.*

Background: Polygenic scores (PGS) for dyslexia have shown associations with cognitive skills, and psychiatric disorders share genetic overlaps with cognitive dimensions. This study investigated whether dyslexia PGS (i) correlate with PGS of cognitive and psychiatric phenotypes, and (ii) predict cognitive profiles in patients with psychiatric disorders.

Methods: PGS for schizophrenia (SCZ), bipolar disorder (BD), major depressive disorder (MDD), dyslexia (DYX, based on 23andMe, Inc. GWAS), word reading (WR), and educational attainment (EA) were calculated using PRS-CS and correlated with cognitive measures from 406,842 UK Biobank participants after genetic quality control. Using confirmatory factor analysis, we modeled 12 measures from seven cognitive categories through a bifactor model, revealing a general cognitive factor with specific speed and accuracy components. Additionally, the association between DYX PGS and cognitive factors was tested in a subset of 28,666 individuals with mental disorders based on ICD-10 F-codes.

Results: Positive significant ($p < 0.001$) correlations were observed between DYX PGS and psychiatric PGS (SCZ, BD, MDD; $r = 0.02–0.06$). The bifactor model displayed good fit indices (CFI = 0.99, RMSEA = 0.027). In patients with psychiatric disorders, DYX PGS was significantly associated with lower general cognitive ability ($\beta = -0.013$, padj = 0.01), accuracy ($\beta = -0.021$, padj < 0.001), and alphanumeric trail-making speed ($\beta = -0.071$, padj < 0.001). The strongest associations regarding accuracy were between DYX PGS and fluid intelligence ($\beta = -0.104$, padj < 0.001) and numeric memory ($\beta = -0.122$, padj < 0.001).

Conclusions: Polygenic risk for dyslexia predicted lower cognitive performance in patients with psychiatric disorders, particularly for general ability, accuracy, and processing speed. Genetic overlap between dyslexia and psychiatric risk may partly explain comorbidities.

P11.053.D Biallelic missense variant c.497G>A in *PTPN23* is associated with hereditary spastic paraplegia

Selinda Mascarenhas[1], *Purvi Majethia*[1], *Hitesh Shah*[2], *Anju Shukla*[1], *Vivekananda Bhat*[1]

[1]*Department of Medical Genetics, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India,* [2]*Department of Pediatric Orthopedics, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India.*

Background: Biallelic variants in *PTPN23* are associated with neurodevelopmental disorders and structural brain anomalies, with or without seizures and spasticity (NEDBASS, MIM #618890), a severe early-onset disorder.

Material and Methods: Clinical evaluation of the proband and her affected sibling was performed. Singleton exome sequencing (ES) was done for the proband, followed by Sanger validation and segregation in the family. Subsequently, in silico mutagenesis analysis was performed.

Results: A clinical diagnosis of hereditary spastic paraplegia (HSP) was considered in a 23-years-old female and her brother with progressive difficulty in walking and hyperreflexia of lower limbs. ES identified a rare homozygous missense variant c.497G>A p.(Ser166Asn) in *PTPN23* (NM_015466.4). Sanger sequencing showed the variant in homozygous state in both siblings with parents as carriers. Multiple in silico prediction tools predicted the variant to be damaging to the protein function. This variant is present in the BRO1 domain of PTPN23 protein, an essential binding site for the formation of multivesicular bodies. In silico mutagenesis analysis showed altered interactions with its neighbouring residues in the mutant protein compared to wild-type. Twelve individuals from 12 unrelated families were reported with NEDBASS had missense and frameshift variants situated across all domains of PTPN23, however, recently one family with six individuals presenting with HSP and microcephaly had a biallelic frameshift variant in the C-terminal region of PTPN23.

Conclusion: We herein report a family with HSP harbouring a biallelic missense variant in *PTPN23*. Further functional studies are underway to establish the consequences of the variant using patient fibroblasts.

P11.054.A *FLNA*Genomic Rearrangements in a 391 French Bilateral Periventricular Nodular Heterotopia Cohort: Prevalence and Phenotypic Correlations

Henri MARGOT[1], *Chloé ANGELINI*[2], *Benoit Arveiler*[2], *Caroline ROORYCK THAMBO*[2], *Cyril GOIZET*[2], *Patricia FERGELOT*[2]

[1]*HUG, Geneve, Switzerland,* [2]*CHU de Bordeaux, Bordeaux, France.*

Background: *FLNA* loss of function manifests across a broad spectrum of phenotypes, ranging from severe prenatal onset to asymptomatic cases. Bilateral periventricular nodular heterotopia (BPNH) consistently occurs in affected individuals. This retrospective study involving French patients with BPNH evaluates the prevalence of *FLNA* gene dosage anomalies and investigates genotype-phenotype correlations in a large cohort of French patients with BPNH.

Methods: A retrospective observational study was conducted on 391 individuals diagnosed with BPNH confirmed by brain MRI. Sequencing analysis using Sanger or Next-Generation Sequencing was complemented by targeted array-comparative genomic hybridization to identify CNVs.

Results: *FLNA* variants were identified in 40% of females and 12% of males. Among these, 87% were SNVs, while CNVs accounted for 13%, all of which were deletions. Half of the CNVs involved a recurrent deletion spanning exons 31–48, often accompanied by a duplication of the neighboring *EMD* gene. This del-dup was associated with a milder phenotype, whereas smaller de novo deletions correlated with severe outcomes. Mosaicism was also detected in 3 cases.

Conclusion: *FLNA* CNV analysis, particularly for recurrent deletions and mosaicism, is essential in the genetic evaluation of BPNH. Integrating CNV detection with SNV analysis improves diagnostic accuracy and enhances understanding of genotype-phenotype correlations.

P11.055.B *POLG* variants in Parkinson's disease: a pilot study

Gloria Brescia[1], *Mariarosa Ferrara*[2], *Silvia Maria Tabano*[1,2], *Edoardo Monfrini*[3,4], *Alessio Barnaba Di Fonzo*[3,4], *Marco Percetti*[3,4]

[1]*Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy., Milan, Italy,* [2]*Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Laboratory of Medical Genetics, Milan, Italy., Milan, Italy,* [3]*Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, Milan, Italy., Milan, Italy,* [4]*Dino Ferrari Center, Neuroscience Section, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy., Milan, Italy.*

Background: *POLG* variants are associated with variable clinical manifestations, including extrapyramidal syndrome, and have been rarely reported in patients with Parkinson's disease (PD). The aim of the study was to establish the frequency of POLG variants in patients with PD.

Material and Methods: PD subjects and patients with other neurological disorders (non-PD) consecutively underwent genetic analysis. Exomes from unrelated Italian healthy controls were obtained from the Network for Italian Genomes (NIG-ExIT) cohort. Only *POLG* variants with a Combined Annotation Dependent Depletion (CADD) score more than 20 and classified as variant-of-unknown-significance (VUS), likely pathogenic, or pathogenic, were considered.

Results: Genomic data from 982 PD patients, 1080 non-PD patients, and 1686 healthy controls were analyzed. *POLG* variants were identified in 26 PD (2.65%), 21 non-PD (1.94%), and 39 healthy subjects (2.31%). A total of 48 *POLG* variants were detected, of which 15 (31.25%) were found only in PD patients. According to the chi-square test, no significant differences in *POLG* frequencies were found between PD and non-PD patients ($p = 0.29$) or healthy controls ($p = 0.96$).

Conclusion: No significant differences in *POLG* frequencies were detected between PD and non-PD patients or healthy subjects. However, several rare *POLG* variants were identified only in PD patients. The role of *POLG* in PD pathogenesis remains unclear. Case-control studies are limited due to the clinical heterogeneity of *POLG* and its possible onset in advanced age. Further studies with larger cohorts are needed to better understand the role of *POLG* in PD.

P11.056.C Long-read sequencing reveals an unexpected complexity of repeat architecture in *C9orf72*/FTDALS1 families

Stefania Magri, *Viviana Pensato, Marinella Corbetta, Monica Pingue, Franco Taroni, Cinzia Gellera*

Fondazione IRCCS Istutito Neurologico Carlo Besta, Unit of Medical Genetics and Neurogenetics, Milan, Italy.

Background: Repeat expansion (RE) in *C9orf72* gene is the most frequent genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Systematic definition of *C9orf72* RE size and sequence in a clinical settings it crucial for precise genetic definition, making it possible to discover clinicopathological associations, and to improve genetic counselling and patient stratification. The aim of this study is to exploit long-read sequencing (LRseq) technologies to precisely define length and architecture of *C9orf72* RE in a clinical setting.

Material and Methods: *C9orf72* expanded region was analyzed in 11 subjects (3 sporadic patients, 6 familial cases, and 2 presymptomatic probands) with both Southern blot (SB) and LRseq with Oxford Nanopore Technologies (ONT) and PacBio HiFi sequencing.

Results: Size mosaicism of expanded allele was estimate by SB (61-4659), ONT (38-3878) and PacBio (53-4412), with a good correlation up to 1500 repeats. Significant intergenerational variability was observed in one family that exhibits allele contraction from an affected father to his asymptomatic daughter. Interestingly, both ONT and PacBio LRseq revealed the presence of mosaic repeat interruptions in expanded alleles. Moreover, PacBio LRseq allowed us to identify a novel alternative motif allele $((G_4C_2)(CG_3CG))_n(G_4C_2)_n$, proving to be crucial for the resolution of cases in which Repeat Primed-PCR approach fails to define the presence of the expansion.

Conclusion: These results demonstrate the essential contribution of LRseq approaches to the understanding of the variability and structure of repeat regions as well as their intergenerational and somatic instability, with crucial implications for diagnosis and pathogenic studies.

P11.057.D Novel *UBA7* gene variants disrupt ISGylation and are associated with neurodevelopmental disorders

Myrrhe Venema[1], *Venkateshwarlu Bandi*[2], *Merel Mol*[1], *Anita Nikoncuk*[1], *Rachel Schot*[1], *Iona Wallace*[3], *Emilia Bijlsma*[4], *Amjad Khan*[5], *Kirby Swatek*[3], *Francisco Bustos*[2], *Tahsin S. Barakat*[1]

[1]*Department of Clinical Genetics, Erasmus MC Medical Center, Rotterdam, Netherlands,* [2]*Pediatrics and Rare Diseases Group, Sanford Research, Sioux Falls, SD, USA,* [3]*MRC Protein Phosphorylation and Ubiquitylation Unit, School of Life Sciences, University of Dundee, Dundee, United Kingdom,* [4]*Department of Clinical Genetics, LUMC Medical Center, Leiden, Netherlands,* [5]*Department of Zoology, University of Lakki Marwat, Lakki Marwat, Pakistan.*

Background: UBA7 is an enzyme belonging to the family of E1-ubiquitin activating enzymes. It is involved in the activation of ubiquitin-like protein ISG15, which then leads to a ubiquitin-like enzymatic cascade called ISGylation. While UBA7 and ISGylation are involved in various disease processes, such as cancer and neurodegenerative disease, so far no disease-causing genetic variants have been described. Here we identify the first instance of genetic *UBA7* variants presenting with neurodevelopmental disorders, and provide functional data on expression and enzymatic function.

Methods: Through international cooperation, three individuals carrying *UBA7* variants were identified. Genetic variants were identified through exome sequencing. Functional analyses of variants, including ISGylation activity assays and protein and transcript expression, were performed.

Results: Individual A presented with intellectual disability/global developmental delay, early onset seizures, repetitive

behaviour, mild microcephaly and recurrent infections. Individual B presented with intellectual disability/developmental delay, autism and obesity. Individual C presented with severe epilepsy and regression, and passed away at age three. The genetic variants identified in *UBA7* were, respectively, a homozygous c.933G>A; p.W311*, a homozygous c. 2126_2129delAACA; p.Lys709Serfs*45 and a homozygous c.1642G>T; p.Val548Leu. Functional analyses showed decreased protein and transcript expression of the Lys709Serfs*45 variant, as well as decreased ISGylation activity. The Val548Leu variant showed increased ISGylation activity.

Conclusion: This study is the first to identify and provide functional data on novel variants in *UBA7* associated with neurodevelopmental disorders. Our results show the potential importance of UBA7 and ISGylation in neurodevelopment, and identify a new gene to be considered in future diagnostics.

P11.058.A Per-domain rare variant burden analysis in 150 Parkinson's risk genes reveals novel functional targets

Sitki Cem Parlar, *Cloe Chantereault, Konstantin Senkevich, Ziv Gan-Or*

McGill University, Montréal, QC, Canada.

Background: Numerous genes have been associated with Parkinson's Disease (PD), and many more have been nominated as potentially associated based on a combination of genome-wide association and machine learning (ML) studies. In this study, we perform a per-domain rare variant burden analysis across PD-associated or -nominated genes to uncover novel, functionally specific associations.

Material and Methods: We meta-analyzed 150 PD risk-associated/ML-nominated genes for per-domain rare variant burden (minor allele frequency ≤0.01) using optimized kernel association test (SKAT-O). The study population consisted of UK Biobank (UKBB) and Accelerating Medicines Partnership program for Parkinson's disease (AMP-PD) cohorts (Table 1). The analysis was conducted separately with and without proxy cases. Variants were grouped by domain and stratified into exonic, non-synonymous, loss-of-function, and CADD>20 categories, applying false discovery rate corrections.

Results: Post-corrections, without proxies, we only observed statistically significant rare variant burden in the *LRRK2* kinase domain in UKBB ($P_{exonic} = 0.003$; *Pnon-synonymous* $= 0.003$; $P_{CADD\text{-}score>20} = 0.003$) and in the meta-analysis ($P_{exonic} = 0.002$; $P_{non\text{-}synonymous} = 0.002$; $P_{CADD\text{-}score>20} = 0.002$). In the meta-analysis, including proxies from UKBB cohort, domain-level strong novel post-correction associations emerged in three genes: *PITX3* (OAR domain) ($P_{exonic} = 1.22 \times 10^{-6}$; $P_{non\text{-}synonymous} = 1.28 \times 10^{-7}$), *SATB1* (NLS) ($P_{CADD\text{-}score>20} = 3.66 \times 10^{-3}$), and *POLR2A* (RNA_pol_Rpb1_R) ($P_{CADD\text{-}score>20} = 7.51 \times 10^{-3}$).

Conclusion: *LRRK2* associations remain robust. Incorporating proxy cases revealed novel domain-specific signals in *PITX3*, *SATB1*, and *POLR2A*, nominating potentially valuable therapeutic targets for PD and warranting further functional investigation.

P11.059.B Moyamoya angiopathy in pediatric European patients: novel candidate genes and their associated biological roles

Elena M. Cabello[1], *Katharina Steindl*[1], *Ivan Ivanovski*[1], *Paranchai Boonsawat*[1], *Zanoni Paolo*[2], *Michael Papik*[1], *Angela Bahr*[1], *Nadia Khan*[3], *Anita Rauch*[1]

[1]*Institute of Medical Genetics - UZH, Zurich-Schlieren, Switzerland,* [2]*Genetica AG, Zurich, Switzerland,* [3]*Universität Kinderspital Zürich, Zurich, Switzerland.*

Background: Moyamoya angiopathy (MMA) is a rare condition characterized by stenosis of the intracranial internal carotid artery and its branches resulting in transient ischemic attacks and strokes. Previous studies, mainly focused on adults and/or Asians, have suggested several susceptibility genes, with *RNF213* variant p.R4810K being the only recurrent. In adult European MMA patients, diverse *RNF213* variants have been positively associated, but not p.R4810K.

Material and Methods: Exome sequencing was performed from blood samples in a pediatric cohort of 104 MMA patients and 520 healthy controls. We performed a rare-variant enrichment test using the R package SKAT and a trio analysis of 62 patients. We repeated the test with a sub-cohort of 80 cases and 381 controls predicted as 100% of European origin.

Results: Both tests identified a significant enrichment of rare variants in genes previously associated with MMA, *RNF213* and *NF1*, including several de novo variants. When interrogating the full cohort, 24 genes are significantly enriched, six of them being novel and common in both tests. Gene Ontology analysis unraveled their association in diverse biological activities, including angiogenesis, endothelial, developmental, and neurobiological processes. Among the top enriched genes was *COL18A1*, for which one patient even showed a de novo variant. *COL18A1* is located on chromosome 21 and thus might be involved in the increased MMA risk of Trisomy 21 patients.

Conclusion: We present an international MMA case-control study focusing exclusively on pediatric patients, predominantly of European origin. The results show novel candidate genes that could advance the understanding of MMA.

P11.060.C Network analysis for gene discovery in ataxia: exploring antibody targets

Maaike A. Hoogland[1,2], *Lydia Sagath*[1], *Jeroen Kerstens*[3], *Maarten Titulaer*[3], *Alexander Hoischen*[1], *Bart van de Warrenburg*[2], *ACT-MD consortium*[4], *Solve-RD consortium*[4]

[1]*Genomic Technologies for Immune-mediated and Infectious diseases, Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Rare and Genetic Movement Disorders, Department of Neurology, Radboud University Medical Center, Nijmegen, Netherlands,* [3]*Department of Neurology, Erasmus MC, University Medical Center, Rotterdam, Netherlands,* [4]

Background: Recent discoveries have identified novel autoimmune diseases manifesting as neurological movement disorders such as ataxia. Some target proteins of these antineuronal antibodies are encoded by genes associated with ataxia,

presenting an opportunity to uncover new ataxia-related genes through a network analysis with known antibody targets as primary seeds.

Methods: We performed a network analysis using genes encoding epitopes targeted by known antineuronal antibodies associated with ataxia. Protein-protein interaction data from the STRING database were analyzed to identify candidate genes directly interacting with known ataxia genes. Genes with the strongest connections to these ataxia genes were prioritized as potential novel monogenic causes of ataxia.

Results: From a combined list of ~80 antibody target genes and ~300 known movement disorder genes related to ataxia, we identified 64 novel potential candidate genes for ataxia, including 20 known antibody target genes. Currently, we are analyzing >1,500 exome/genome datasets from previously undiagnosed patients and families with ataxia retrieved from Solve-RD and Radboudumc to identify rare variants in the genes identified through this network analysis. Amongst 2,000 rare SNVs in Solve-RD's cohort of unsolved ataxia cases, filtering and prioritization is ongoing, considering e.g. inheritance mode, recurrence, and variant-effect predictions.

Conclusion: Our network analysis has identified 64 new potential candidate genes for ataxia. Ongoing analyses of rare variants in these genes, conducted within cohorts with available exomes and datasets from patients with suspected monogenic forms of ataxia, will provide information on the actual potential of this approach.

P11.061.D Pathway polygenic risk scores analysis in an East Asian treatment resistant scizophrenia cohort

Perry BM Leung[1,2], *Kenneth CY Wong*[3], *Yuanxin Zhong*[2,4], *Marta Di Forti*[1,5], *Robin M. Murray*[1,5], *Hon Cheong So*[3], *Pak C. Sham*[2], *Simon SY Lui*[2]

[1]*Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom,* [2]*Department of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong,* [3]*School of Biomedical Science, The Chinese University of Hong Kong, Hong Kong, Hong Kong,* [4]*Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, USA,* [5]*South London and Maudsley NHS Foundation Mental Health Trust, London, United Kingdom.*

Background: Schizophrenia is a highly heritable disease with typical onset during adolescent and early adulthood. Around 25% of schizophrenia patients eventually develop treatment-resistant schizophrenia (TRS), a severe type associated with poor prognosis and response to non-clozapine antipsychotics. Neuroimaging evidence suggested that TRS patients have less striatal presynaptic dopamine synthesis capacity than non-TRS patients, which is highly interconnected with the synaptic functions. This study aims to clarify whether TRS and non-TRS patients would differ in synaptic pathways using genetic data.

Material and Methods: We performed whole genome sequencing in a 407 schizophrenia patients cohort recruited from Castle Peak Hospital in Hong Kong between 2014–2018. As of 2022, 142 were having TRS. To test the hypothesis that TRS and non-TRS patients could differ in brain synaptic pathways, we calculated pathway polygenic risk scores (pPGSs) using expert curated pathway gene sets related to synapses. Competitive and non-competitive tests were performed with software PRSet, to estimate the level of associations and enrichments.

Results: We found one pathway, extracellular matrix of synaptic cleft, reached the significance level after Bonferroni-correction ($p < 1 \times 10^{-4}$) in both competitive and non-competitive tests. An associated quantile plot suggested significant differences in extracellular matrix of synaptic cleft among those who carried the top 20th and bottom 20th percentiles of the associated pPGSs.

Conclusion: Our pPGSs findings with synapses gene sets implicates the involvement of extracellular matrix of synaptic cleft in TRS; these gene sets are more enriched than the rest of the genome in TRS patients.

P11.062.A Epigenetic markers linked to early-onset schizophrenia in the Chinese population

N. Zhan[1], *P. Leung*[1,2], *Y. Zhong*[1], *C. C. Wong*[2], *H. So*[3], *P. Sham*[1], *S. Lui*[1];

[1]*The University of Hong Kong, Hong Kong, China,* [2]*King's College London, London, United Kingdom,* [3]*Chinese University of Hong Kong, Hong Kong, China*

Background: Age at onset (AAO) is a key phenotype in schizophrenia. Early-onset schizophrenia (EOS; AAO < 18) is linked to greater neurological and neurodevelopmental impairments and a poorer prognosis compared to adult-onset schizophrenia (AOS). While most genetic research on AAO and EOS has focused on candidate genes and genome-wide association studies (GWAS), the role of DNA methylation, an epigenetic mechanism influenced by both environmental and genetic factors, remains less extensively studied in the context of EOS and AAO.

Methods: Peripheral blood DNA samples were collected from 120 Chinese patients diagnosed with schizophrenia, with a mean AAO of 15 for the 49 EOS cases and 36 for the 71 AOS cases. The Illumina Infinium Human Methylation EPIC v2.0 BeadChip was utilized, and an epigenome-wide association study (EWAS) was performed to compare methylation patterns between EOS and AOS groups, with adjustments for age, sex, smoking status, and blood cell composition.

Results: We identified 49 differentially methylated positions (DMPs) for EOS that achieved a suggestive significance level (p-value < 5e-05). Several genes annotated from these DMPs, including *ORMDL1*, *ANXA4*, and *TRRAP*, were located in genomic regions associated with schizophrenia or EOS. Additionally, we discovered novel regions linked to cognitive performance, including *AKAP8L*, *C4orf45*, and *GTF2I*. Enrichment analysis suggested that processes involving kinase activity, cell cycle regulation, and microRNAs in cancer may relate to EOS.

Conclusion: This research provides new insights into the distinct DNA methylation patterns linked to EOS in the Chinese population and highlights several potential biological pathways involved in the condition.

P11.063.B Exploring Parkinson's disease pathogenesis using a multi-omics approach: insights from DNA methylation and circular RNA profiles in discordant monozygotic twins

Marta Brumana[1,2], *Claudia A. Giudici*[1,2], *Valeria Rimoldi*[1,2], *Luca Magistrelli*[3], *Gianni Pezzoli*[3], *Ioannis U. Isaias*[3], *Rosanna Asselta*[1,2], *Letizia Straniero*[1,2]

[1]*Humanitas University, Via Rita Levi Montalcini 4, 20072 Pieve Emanuele, Milan, Italy,* [2]*Humanitas Clinical and Research Center,*

IRCCS, Via Manzoni 56, 20089 Rozzano, Milan, Italy, [3]Parkinson Institute, ASST G. Pini-CTO, via Bignami 1, 20126, Milan, Italy.

Background: Parkinson's disease (PD) is a neurodegenerative disorder characterized by dopaminergic neurons loss in the substantia nigra. While both genetic and environmental factors contribute to PD, its etiology remains unclear. This study investigates unknown factors contributing to PD using a unique cohort of 30 monozygotic (MZ) twins discordant for the disorder through a multi-omics approach including transcriptome, circular RNA (circRNA), and methylome profiling.

Material and Methods: NGS libraries were prepared starting from DNA and RNA extracted from blood samples of MZ twins. DNA methylation was analyzed with the Bismark Bisulfite Mapper software and the MethylKit R package, while DCC and DESeq2 were used for circRNA and transcriptomics analyses.

Results: We detected 471 differentially methylated positions, with 169 showing ≥8% differential methylation. Among these, the top hypermethylated region (+22%, q = 6.96E-27) locates in the *MTF1* intron 2. This gene plays a potential neuroprotective role against oxidative stress. Among the 2,307 circRNAs identified, 40 were deregulated in PD twins. Notably, a circRNA -derived from exons 2–4 of *SNCA* (circSNCA)- exhibited reduced expression in affected twins compared to both their healthy counterparts (log2FC = −0.545, p = 0.024) and an unrelated control cohort (log2FC = −1.493, p = 0.024).

Conclusion: The identification of differential methylation in *MTF1*, a gene with potential neuroprotective functions, and the deregulation of circSNCA, a key PD-related circRNA, could highlights novel biomarkers that may drive PD pathogenesis. In the future, we plan to integrate all the omics data collected for this cohort to enhance the overall understanding and gain deeper insights into the molecular mechanisms underlying PD.

P11.064.C Uncovering hidden causes in developmental epileptic encephalopathy: high resolution structural variant detection with optical genome mapping

Sanem Keskin Yilmaz[1], Enise Avci Durmusalioglu[2], Dilara Ece Toprak Dogan[1], Seda Kanmaz[1], Tahir Atik[2], Mehmet Burak Mutlu[3], Uluc Yis[4], Unsal Yilmaz[5], Aycan Unalp[5], Sarenur Gökben[6], Nur Selvi Gunel[7], Cumhur Gunduz[7], Hasan Tekgul[1], ***Esra Isik***[2]

[1]Ege University Department of Pediatrics, Division of Pediatric Neurology, Izmir, Turkey, [2]Ege University Department of Pediatrics, Division of Pediatric Genetics, Izmir, Turkey, [3]Detagen Genetic Diseases Evaluation Center, Kayseri, Turkey, [4]Dokuz Eylul University Department of Pediatrics, Division of Pediatric Neurology, Izmir, Turkey, [5]University of Health Sciences Dr. Behçet Uz Child Disease and Pediatric Surgery Training and Research Hospital, Department of Pediatrics, Division of Pediatric Neurology, Izmir, Turkey, [6]Ege University Department of Pediatrics, Division of Pediatric Neurology (Retired), Private Practise, Izmir, Turkey, [7]Ege University Department of Medical Biology, Izmir, Turkey.

Background: Despite the use of standard genetic diagnostic methods, the underlying cause remains unidentified in a significant proportion of developmental epileptic encephalopathy (DEE) cases. Optical genome mapping (OGM) is a novel technology that enables high-resolution detection of structural variants (SVs). This study aimed to evaluate the diagnostic contribution of OGM in DEE cases with unresolved genetic causes.

Material and Methods: The study included 38 DEE cases, aged 0–18 years, who remained undiagnosed despite conventional karyotyping, chromosomal microarray analysis, and whole-exome sequencing (WES). Patients were reassessed based on clinical, electrophysiological, biochemical, and radiological criteria. Genetic data of eligible patients were reanalyzed, and OGM was applied to cases with no identified etiology. Potential findings from OGM were validated using appropriate laboratory techniques.

Results: Reanalysis of WES data identified two pathogenic variants in two cases (5.2%): SCN2A (c.221T>C, p.Val74Ala) and WDR45 (c.827+5G>A), leading to definitive molecular diagnoses. OGM was performed on the remaining 32 cases, detecting five potentially pathogenic SVs, of which three were excluded after validation. Two SVs (6.3%) were confirmed and corresponded to the following molecular diagnoses: Fragile X syndrome [ogm[GRCh38] ins(X;?)(q27.3;?)] and PHACTR1-related DEE [ogm[GRCh38] 6p24.1(13083829_13279761)x1].

Conclusion: Reanalysis processes and OGM improved the diagnostic success rate in DEE cases with unresolved genetic causes. OGM provides significant diagnostic contributions by identifying high-resolution SVs. When standard methods are insufficient, genomic data reanalysis and innovative techniques like OGM offer promising pathways for discovering rare variants and refining diagnostic strategies.

P11.065.D 5mC and 5hmC detection highlights how psychedelics affect brain epigenetic patterns

Uri Bertocchi

Tel Aviv Univeristy, Tel-aviv, Israel.

Background: Psilocybin, a serotonergic psychedelic compound, has demonstrated long-term antidepressant effects, yet its underlying mechanisms remain unclear. Emerging evidence suggests that epigenetic modifications, particularly 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC), may play a role in its therapeutic action. Unlike passive demethylation, which requires cell division and occurs infrequently in neurons, active demethylation via TET enzymes rapidly converts 5mC to 5hmC, a process abundant in the brain. This study investigates changes in 5mC and 5hmC levels in key brain regions following psilocybin treatment.

Material and Methods: Male C57BL/6 mice were divided into two groups: psilocybin-treated (n = 3) and saline-treated control (n = 3). After 72 hours post-treatment, prefrontal cortex (PFC) tissue was collected for DNA methylation analysis using nanopore sequencing, enabling genome-wide detection of 5mC and 5hmC at single-base resolution.

Results: A total of 1,404 DhMRs were identified in psilocybin-treated mice, showing significant enrichment in the glutamatergic synapse pathway (q = 0.0009). In contrast, only 51 significant DMRs were found for 5mC, with no pathway enrichment detected. These findings suggest that 5hmC modifications, rather than 5mC, play a critical role in psilocybin's effects on synaptic plasticity and neuroplasticity.

Conclusion: Preliminary findings suggest that psilocybin induces rapid epigenetic changes, primarily via 5hmC, in key brain regions involved in mood regulation. These changes may underlie the sustained antidepressant effects of psilocybin, potentially offering new therapeutic targets for Major Depressive

Disorder (MDD). Future studies will focus on validating these results and exploring their long-term implications.

P11.066.A Pathogenicity of missense neurogenetic variants: a focus on the NMDA receptor subtypes

M. Biçer[1], *A. Arslan*[2,1];

[1]*Istanbul Atlas University, Istanbul, Turkey,* [2]*Uskudar University, Istanbul, Turkey*

Background: Identification of variants, particularly in genes encoding the subunits of NMDA receptors (NMDARs), mediating gulutamatergic signals, is crucial for diagnosing diseases linked to NMDAR channelopathies, including epilepsy. Computational prediction of variant pathogenicity is important, but the performance of predictive models in this specific gene context remains underexplored. This study evaluates state-of-the-art models against neural network-based AlphaMissense for the classification of missense variants in genes encoding NMDAR subtypes.

Material and Methods: Pathogenic and benign missense variants in GRIN1, GRIN2A, and GRIN2B (GRIN genes) encoding the subunits of NMDAR subtypes were retrieved from the ClinVar database and classified using AlphaMissense, REVEL, BayesDel, ClinPred, PrimateAI, and CADD. Accuracy metrics were calculated using a custom Python script. Additionally, AlphaMissense performance was analyzed across NMDAR subunit domains. Statistical significance of performance differences was assessed using Fisher's exact test. Correlation of AlphaMissense scores with variant functional impact obtained from the literature was also evaluated by calculation of Spearman's Correlation Coefficient.

Results: AlphaMissense showed superior performance for variant classification compared to the other predictive models (Table 1). NMDAR subunit domain-based variant classification of AlphaMissense highlighted performance differences across different regions ($p < 0.05$). Moderate correlation between AlphaMissense scores and variant functional impact was found especially for cell surface expression.

Conclusion: Our findings contribute to the understanding of the variant effect of the GRIN genes, bottleneck in bridging the gap between genetic findings and the development of personalized treatment strategies for neurogenetic diseases linked to NMDAR channelopathies.

P11.068.C Remodelling of neuronal RNA metabolism during Prader-Willi syndrome

Alexandra Lehmann, *Aleksandra Helwak, Diego Oyarzún, David Tollervey*

University of Edinburgh, Edinburgh, United Kingdom.

Background: Deletions in the paternally imprinted genomic region at 15q11.2-q13 that include two human C/D box small nucleolar RNAs (snoRNAs), SNORD115 and SNORD116, cause the neurodevelopmental disorder Prader-Willi syndrome (PWS). Both snoRNAs are strongly accumulated during neurodevelopment. Canonical box C/D snoRNAs carry the RNA methyltransferase Fibrillarin (FBL). During neuronal differentiation, FBL expression decreases. In contrast we saw a dramatic increase in expression of FBLL1; a largely uncharacterized, 83% identical, FBL homolog. FBL is required for the stabilization of small nucleolar ribonucleoprotein (snoRNPs) and methylation of target RNAs. We hypothesized that FBLL1 has similar functions, specifically in neuronal cells.

Material and Methods: Transcriptome changes upon FBLL1 deletion were identified using small RNA sequencing and total RNA sequencing. Pulldowns followed by mass spectrometry will determine protein binding partners. Small RNA sequencing in strains lacking SNORD115 or SNORD116 assessed the roles of these snoRNAs.

Results: FBLL1 is not required for neuronal stabilization of SNORD115 or SNORD116; we are determining effects on other snoRNAs. Cells lacking either SNORD115 or SNORD116 showed altered levels of several other ncRNAs. The multiple tandem snoRNA repeats in these clusters are related, but non-identical, and differ in relative accumulation.

Conclusion: Increased expression of FBLL1 during neuronal differentiation suggests functions related to this process. However, FBLL1 does not stabilize SNORD115 or SNORD116. We are testing the effects of FBLL1 gene knockout on the transcriptome during neuronal differentiation, and identifying protein and RNA binding partners. Links between RNAs altered by loss of SNORD115 or SNORD116 and PWS phenotypes are being tested.

Salsano[3], Davide Pareyson[3], Cinzia Gellera[1], Mariotti Caterina[2], Franco Taroni[1]

[1]Fondazione IRCCS Istituto Neurologico Carlo Besta Unit of Medical Genetics and Neurogenetics, Milan, Italy, [2]Fondazione IRCCS Istituto Neurologico Carlo Besta Unit of Neurology - Clinical Research, Milan, Italy, [3]Fondazione IRCCS Istituto Neurologico Carlo Besta, Unit of Rare Neurological Diseases, Milan, Italy.

Background: SCA27B is a common cause of dominant adult-onset spinocerebellar ataxia due to an intronic heterozygous GAA repeat expansion in the *FGF14* gene. Uninterrupted expansions ≥300 GAA are considered pathogenic, while uninterrupted expansions ≥250 exhibit incomplete penetrance. The role of the expansion between 180 and 250 GAA is still debated.

Material and Methods: The *FGF14* expansion was analysed by long-range PCR, bidirectional fluorescent RP-PCR, and LongRead-sequencing to 1) screen for the FGF14 expansion a cohort of Italian patients with ataxia (n = 404) or episodic ataxia (EA) (n = 88); 2) identify the exact architecture of the repeated sequence; 3) evaluate the threshold of pathogenicity.

Results: Expansions ≥250 GAA were identified in 25% of EA patients and in 7.5% of patients with chronic-progressive ataxia. Interestingly, the frequency rises to 80% in a subset of patients presenting with down-beating nystagmus, that was effectively treated with 4-aminopyridine. In both patients and controls, approximately 1% of alleles have an alternative/interrupted expanded repeat configuration. Furthermore, 1% of patients with ataxia present 1 or even 2 expanded alleles in the range 180–250. In these cases, LongRead-sequencing allows the precise definition of allele size and sequence, suggesting a wider range of pathogenic expansions.

Conclusions: *FGF14* expansion accounts for up to 25% of Italian non-EA1/non-EA2 families, presenting with late-onset EA characterized by disequilibrium, eye movement abnormalities, followed by a slowly chronic-progressive ataxia. LongRead-sequencing is crucial to determine the pattern and the size of the uncertain expanded alleles and to estimate the pathogenic threshold of the repeat expansion.

P11.070.A Description of the clinical phenotype of metachromatic leukodystrophy in la reunion island due to a new variation with a founder effect

Anais Dominique CALAYA

CHU de la Reunion, Saint Pierre de la Reunion, France.

Background: Metachromatic leukodystrophy is a rare recessive autosomic neurodegenerative disorder, insufficiently known and misdiagnosed. Four main phenotypes defined by the age at onset, have been described. Nowadays, there is a avaible curative treatment by gene therapy, to propose to MLD pre-symptomatic and early symptomatic patients only. Early diagnosis is therefore crucial. In the population of La Reunion island we have found 2 molecular variations wich are link to the disease and not found abroad. Maybe it's due to a founder effect, because it's an isolated entity. The aim of this study was to describe the natural history of the presentation of MLD in La Reunion island, and to investigate the process that led to final diagnosis in patients.

Material and Methods: Monocentric, retrospective study based on the description of clinical data of pediatric MLD patients, followed within the hospital of La Réunion.

Results: 15 patients were included to study epidemiological features, 12 to analyze the initial medical presentation leading to diagnosis and 12 to describe the clinical evolution. All the patients were diagnosed with the both same molecular variations wich are from La Reunion and not found abroad.

Conclusion: This study brings a better understanding of the natural history and the initial clinical presentation of MLD in the population of La Reunion island. It emphasizes the importance to raise awareness of the disease existence, and how to identify its alarms signs. We would like to propose a preconception diagnosis to patients from La Reunion island.

C.O.I. Disclosure:

P11.071.B Findings from single center exome sequencing in pediatric autism: an analysis of genetic variants and clinical correlations

*Gulsum Kayhan[1], **M. Fatih Mulayim**[1], Ahmet Ozaslan[2], Elvan Iseri[2], Esra Güney[2], Dicle Büyüktaskın[2], Mehmet Ali Ergün[1], Ferda Emriye Percin[1]*

[1]Department of Medical Genetics, Gazi University Faculty of Medicine, Ankara, Turkey, [2]Department of Child and Adolescent Psychiatry, Gazi University Faculty of Medicine, Ankara, Turkey.

Background: Autism spectrum disorder (ASD) is a complex neurodevelopmental condition marked by difficulties in social interaction and communication, along with restricted and repetitive behaviors. Affecting approximately 1 in 100 children, ASD has a strong genetic component. This study aimed to investigate the relationship between genetic variants identified in pediatric ASD patients and their clinical manifestations to enhance the understanding of ASD's genetic basis.

Material and Methods: Exome sequencing (ES) was performed on these patients from whom chromosomal abnormalities and Fragile X syndrome were excluded previously.

Results: The study involved 90 pediatric patients diagnosed with ASD (aged under 18), who were categorized into isolated (54 patients: 39 males and 15 females) and syndromic ASD groups (36 patients: 24 males and 12 females). In the isolated group, exome sequencing detected pathogenic variants in 16 individuals (29.6%), with a diagnostic yield of 30.7% in males and 26.6% in females. The syndromic group, which presented additional conditions like epilepsy and brain anomalies, showed a higher diagnostic yield, with 21 patients (58.3%) found to have pathogenic variants.

Conclusion: Our findings highlight the genetic heterogeneity of ASD, demonstrating that genes involved in transcriptional regulation, chromatin remodeling, and neurogenesis contribute to its pathogenesis, with key genes such as *MECP2, PTEN, EP300*, and *AGAP1* implicated in its development. Genetic factors were found to be twice as influential in syndromic ASD cases. These results support the use of ES as a primary diagnostic approach for understanding the genetic complexity of ASD.

P11.072.C Gene Network-Based Partitioned Polygenic Risk Scores Reveal Clinical Insights into Schizophrenia

Mads Kristian Holm[1,2], *Sinja Hanebaum*[1,2], *Mona Nourbakhsh*[1,2], *Yu-Han Hsu*[3], *Greta Pintacuda*[3], *Anders Rosengren, PHD*[1,2], *Kasper Lage*[3], *Andrés Ingason*[1,2], *Thomas Werge*[1,2,4]

[1]*Institute of Biological Psychiatry, Mental Health Services, Copenhagen University Hospital, Roskilde, Denmark,* [2]*The Lundbeck Foundation Initiative for Integrative Psychiatric Research (iPSYCH), Copenhagen and Aarhus, Denmark,* [3]*Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA 02142, USA; Novo Nordisk Foundation Center for Genomic Mechanisms of Disease, Broad Institute of MIT and Harvard, Cambridge, MA 02142, USA, Boston, MA, USA,* [4]*Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: Schizophrenia is a severe mental disorder. Many genetic variants have been identified as risk factors for developing the condition, but translating these insights into actionable biological mechanisms remains a challenge. Gene networks defined by cell type-specific protein-protein interaction partners of high-risk schizophrenia variants have been proposed to be enriched in biologically relevant pathways related to schizophrenia. We propose a framework to prioritize genetic variants by assessing whether polygenic risk scores (PRS) partitioned to genetic variants in such networks are associated with clinical features of schizophrenia.

Material and Methods: Using genotypes from approximately 14,000 Schizophrenia Spectrum Disorder patients in the Danish iPSYCH cohort, in combination with publicly available summary statistics, we calculate PRS partitioned to gene networks. We investigate the pairwise associations between these partitioned PRSs and relevant clinical endophenotypes from the Danish national health registers. This approach aims to identify functional signatures of gene networks that could point toward novel schizophrenia-related biological mechanisms.

Results: The PRS for schizophrenia, partitioned to gene networks characterized by Neural Progenitor Cell expression, were significantly associated with an ADHD diagnosis in individuals with schizophrenia spectrum disorders, but not in those without. This suggests the potential functional relevance of these gene networks in specific clinical manifestations.

Conclusion: Partitioned PRS provides a promising framework for studying pathways involved in polygenic disorders such as schizophrenia. This approach may, in time, help provide insight into the identification of actionable biological mechanisms of schizophrenia.

P11.073.D An investigation of the role of tubulin genes in human handedness

Bing Dong[1], *Krzysztof Marianski*[2], *Dorothy V. M. Bishop*[3], *Silvia Paracchini*[2]

[1]*School of Biology, University of St Andrews, St Andrews, United Kingdom,* [2]*School of Medicine, University of St Andrews, St Andrews, United Kingdom,* [3]*Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom.*

Background: Handedness, the preference to use one hand for specific tasks, is partly influenced by genetics with heritability consistently estimated to be ~25%. A higher prevalence of left-handedness has been reported for different neurodevelopmental traits including language-related conditions. Recent GWAS and whole-exome sequencing studies (WES) suggested tubulin genes are associated with left-handedness. These has been conducted in large population samples e.g. UK Biobank. Here we conducted a target study to assess whether the association between tubulin genes and left-handedness could be detected in smaller samples enriched with language-related difficulties.

Material and Methods: WES data were analysed in a sample of 242 twin children aged 6–11, recruited for an over-representation of developmental language disorders (Wilson and Bishop 2018). Handedness was assessed with the Edinburgh Handedness Inventory. Variants in *TUBB*, *TUBB1*, *TUBB2A*, *TUBB2B*, *TUBB3*, *TUBB4A*, *TUBB4B*, *TUBB6*, *TUBB8*, *ANKS1B*, *MAP2*, *NDRG1*, *NME7*, *TRIM36*, *TUBA1B*, *PTEN*, *LRRK2*, *ZNF207*, *TUBB4BP1*, *TUBB4BP2*, *TUBB4BP3*, *TUBB4BP4*, *TUBB4BP5*, *TUBB4BP6*, *TUBB4BP7* and *TUBB4BP8* were tested for association with left-handedness. Bonferroni correction based on number of tested genes was applied to correct for multiple testing.

Results: We did not observe any significant associations between the tubulin genes and left-handedness, neither did we identify the specific left-handedness associated variants reported by Cuellar-Partida et al (2021) and Schijven et al (2024).

Conclusion: Our study does not provide evidence that variants in tubulin genes influence left-handedness. Our sample size was small and it is possible that tubulin genes influence left-handedness in few individuals requiring large samples for their potential effect to be detected.

P11.075.B Novel BRAT1 deep intronic variant affects splicing regulatory elements causing cerebellar hypoplasia syndrome: genotypic and phenotypic expansion

Tomer Poleg[1], *Regina Proskorovski-Ohayon*[1], *Vadim Dolgin*[1], *Noam Hadar*[1], *Amit Safran*[1], *Nadav Agam*[1], *Matan M. Jean*[1], *Ofek Freund*[1], *Libe Gradstein*[1], *Ilan Shelef*[2,1], *Ohad S. Birk*[1,3]

[1]*Ben-Gurion university of the Negev, Beer-Sheva, Israel,* [2]*Department of Radiology, Soroka Medical Center and Faculty of Health Sciences, Beer-Sheva, Israel,* [3]*Genetics Institute, Soroka Medical Center, Beer-Sheva, Israel.*

Background: Biallelic mutations in *BRAT1* are implicated in a spectrum of neurodevelopmental disorders, ranging from lethal neonatal rigidity and multifocal seizure syndrome to a milder form characterized by cerebellar atrophy, with or without seizures (NEDCAS). This study investigated three siblings from a consanguineous Bedouin family with NEDCAS, whose causative mutation had eluded standard genetic testing methods.

Material and Methods: Whole-genome sequencing (WGS) was employed to investigate non-coding regions, complemented by linkage analysis using Homozygosity-Mapper. In silico splicing predictions were performed using tools such as SpliceAI, Human Splicing Finder, and ESEfinder. Molecular verification was carried out through Sanger sequencing and real-time PCR to confirm the functional impact of the identified variant.

Results: Using a combination of linkage analysis and WGS, we identified a novel deep intronic *BRAT1* variant (NM_152743.4:c.128-1585T>G) in three siblings presenting with NEDCAS. The siblings exhibited shared clinical features, including cerebellar atrophy, developmental delay, and variable ataxia, with significant phenotypic variability despite identical genotypes. In silico and molecular splicing analyses demonstrated that this variant disrupts splicing regulatory elements, creating a cryptic exon that results in a deleterious frameshift and an aberrant transcript.

Conclusion: This study reports the first deep intronic pathogenic variant in *BRAT1*, highlighting the critical role of intronic splice regulatory elements in disease pathogenesis. It underscores the utility of WGS in resolving unexplained cases and broadens the genotypic and phenotypic landscape of *BRAT1*-related disorders.

P11.076.C Targeted Next-Generation-Sequencing panels in the diagnosis of hereditary motor neuropathies

Francesca Balistreri[1], *Chiara Pisciotta*[2], *Federica R. Danti*[3], *Silvia Baratta*[1], *Isabella Moroni*[3], *Davide Pareyson*[2], *Franco Taroni*[1], *Stefania Magri*[1]

[1]*Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [2]*Rare Neurological Diseases Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [3]*Department of Pediatric Neurosciences, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy.*

Background: Distal hereditary motor neuropathies (dHMN) are a group of rare heterogeneous disorders characterized by a slowly progressive distal pure motor neuropathy, presenting phenotypic and genotypic overlap with Charcot-Marie-Tooth disease (CMT), amyotrophic lateral sclerosis (ALS), and hereditary spastic paraplegia (HSP). Although <30 genes are associated with these forms, about 60% of cases remain genetically unsolved.

Material and Methods: We analysed a consecutive series of 20 index cases (8 dHMN and 12 predominantly motor CMT) referred to our centre over a period of one year and tested negative for single-gene analysis. NGS analysis was performed by a custom panel including 209 neuropathy-associated genes.

Results: The 65% (13/20) of index cases carried likely pathogenic or pathogenic variants in 9 genes associated to dHMN and predominantly motor CMT. In particular, we identified disease-causing variants in 5 genes associated with autosomal dominant forms, *BICD2* (n = 2), *HSPB1* (n = 1), *GARS1* (n = 1), *DYNC1H1* (n = 1), and *TRPV4* (n = 1), and in 3 genes with autosomal recessive pattern of inheritance, *VRK1* (n = 1), *SORD* (n = 4), *DNAJB2* (n = 1). Moreover, we identified a novel homozygous splicing pathogenic variant in the *RTN2* gene, previously associated with dominant HSP and very recently associated to recessive dHMN.

Conclusion: The use of NGS multigene panel has allowed the genetic diagnosis in 65% of the analysed cases. Compared with previously reported patient series, our results show a higher diagnostic rate confirming the reliability of this approach for the detection of the molecular causes of neuropathies with high genetic heterogeneity.

P11.077.D Further evidence of *RNU4ATAC* variants causing Joubert syndrome with skeletal involvement

Fulvio D'Abrusco[1], *Simone Gana*[1], *Chiara Di Fini*[2], *Valentina Serpieri*[2], *Enrico Alfei*[3], *Emanuela Scarano*[4], *Francesco Nicita*[5], *Domenico Barbuti*[6], *Eleonora Carlicchi*[7], *Stefano D'Arrigo*[8], *Enrico Silvio Bertini*[9], *Ginevra Zanni*[9], *Enza Maria Valente*[2,1]

[1]*IRCCS Fondazione Mondino, Neurogenetics Research Centre, Pavia, Italy,* [2]*University of Pavia, Department of Molecular Medicine, Pavia, Italy,* [3]*Buzzi Children's Hospital, Pediatric Neurology Unit, Milano, Italy,* [4]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Pediatric Unit, Bologna, Italy,* [5]*IRCCS Bambino Gesu' Children's Research Hospital, Unit of Neuromuscular and Neurodegenerative Disorders, Roma, Italy,* [6]*IRCCS Bambino Gesù Children's Hospital, Imaging Department, Roma, Italy,* [7]*Buzzi Children's Hospital, Imaging Department, Milano, Italy,* [8]*IRCCS Fondazione Istituto Neurologico Carlo Besta, Developmental Neurology Unit, Milano, Italy,* [9]*IRCCS Bambino Gesu' Children's Research Hospital, Research Unit of Neuromuscular and Neurodegenerative Disorders, Roma, Italy.*

Background: Joubert syndrome (JS) is a neurodevelopmental ciliopathy defined by the "molar tooth sign" (MTS) on brain imaging and characterized by multiorgan involvement. A recent study has suggested a potential link between JS and biallelic variants in *RNU4ATAC*, a non-coding gene crucial for the correct functioning of the minor spliceosome. While *RNU4ATAC* is already associated with a spectrum of syndromic skeletal dysplasias, its role in JS remains underexplored.

Material and Methods: We reanalyzed whole exome sequencing (WES) data from 53 patients affected by JS, lacking pathogenic variants in known JS-associated genes. The analysis focused on the *RNU4ATAC* locus, which had initially been misannotated as an intronic region of *CLASP1*. Sanger sequencing was performed to confirm and segregate the variants. Clinical and radiological findings were collected and compared to previously described *RNU4ATAC*-related phenotypes.

Results: Compound heterozygous *RNU4ATAC* variants were identified in 3 probands (yield: 6%), including n.16G>A, n.51G>A, n.13C>T, and n.30G>A. All patients displayed the MTS, along with features overlapping JS and other *RNU4ATAC*-related disorders, such as severe intellectual disability, growth retardation, microcephaly, and abnormalities of the skeleton, skin, and genitals.

Conclusion: Our findings support the association between *RNU4ATAC* variants and JS, expanding the phenotypic spectrum of this gene to include this complex neurological-skeletal ciliopathy. The study highlights the importance of accurate WES reanalysis as a key diagnostic tool for uncovering non-coding variants that might otherwise remain undetected. Further research is required to refine genotype-phenotype correlations, explore the frequency of *RNU4ATAC* variants in JS, and assess their long-term clinical impact.

P11.078.A SNORD3C, a blood biomarker associated to suicide attempts in patients with anorexia nervosa

Camille Verebi[1,2], *Nicolas Lebrun*[1], *Philibert Duriez*[1,3], *Lucie Adoux*[4], *Benjamin Saint Pierre*[4], *Philip Gorwood*[1,3], *Nicolas Ramoz*[1,3], *Thierry Bienvenu*[1,2]

[1]*Institut de Psychiatrie et de Neuroscience de Paris, Paris, France,* [2]*Fédération de Génétique et de Médecine Génomique, APHP Centre - Université Paris Cité, Hôpital Cochin, Assistance Publique Hôpitaux de Paris, Paris, France,* [3]*Centre des Maladies Mentales et de l'Encéphale, GHU-Paris Psychiatrie et Neurosciences, Hôpital Sainte-Anne, Paris, France,* [4]*Genomic, Institut Cochin, Inserm, Paris, France.*

Background: Suicide is the second leading cause of mortality in individuals with anorexia nervosa (AN), a psychiatric disorder with high heritability. Despite advances in genomics, the molecular pathways linking AN to suicidality remain poorly understood. This study investigates the role of SNORD3C and related genetic pathways as potential biomarkers for suicide risk in patients with AN.

Material and Methods: Peripheral blood mononuclear cells were collected from a discovery cohort of 15 patients with AN (5 with a history of suicide attempts and 10 without). RNA-sequencing was performed, followed by differential gene expression analysis, pathway enrichment analysis, and replication in an independent cohort of 34 patients. Functional annotations were conducted using STRING and Panther databases to identify dysregulated pathways.

Results: We identified 58 significantly dysregulated genes in the discovery cohort, including SNORD3C, consistently upregulated across cohorts. SNORD3C is a small nucleolar RNA involved in RNA metabolism, priorly associated with psychiatric conditions like depression and vitamin D deficiency. Notably, patients with suicidal behavior indeed exhibited lower vitamin D levels. Pathway analyses revealed enrichment in RNA metabolism and immune pathways.

Conclusion: Our study identifies SNORD3C as a candidate biomarker for suicide risk in AN and confirm the role of immunity in suicidality. The findings provide novel insights into the interplay between genetic and environmental factors in AN and suicidal behavior. Such evidence might lead to the implementation of simple personalized interventions such as vitamine D level management to prevent suicide comorbidity in AN.

P11.079.B Proteomic insights into SCAR10: Engineering and analysis of CRISPR-edited ANO10 mutant cell lines

Androniki Chrysanthou, *Antonis Ververis, Kyproula Christodoulou*

The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Background: Mutations in the *ANO10* gene cause SCAR10, a rare form of autosomal recessive spinocerebellar ataxia. Anoctamin 10 (ANO10/TMEM16K) functions as both an ion channel and a phospholipid scramblase; however, its exact role in SCAR10 pathogenesis remains unknown. To explore the function of ANO10 regarding SCAR10, four mutant cell lines were generated using CRISPR-Cas9 technology: a knockout and three cell lines carrying known SCAR10-causing variants; c.289delA[p.Thr96_Met97ins*], c.1529T>G[p.Leu510Arg], and c.1009T>G[p.Phe337Val]. Proteomic analysis was performed to identify differentially expressed proteins (DEPs) between mutant and control cell lines.

Methods: SH-SY5Y cells were modified via CRISPR-Cas9 editing, with donor DNA templates facilitating homology-directed repair. Following nucleofection, editing efficiency was evaluated, and single-cell clones were isolated using FACS. Successfully edited clones were expanded and assessed through immunoblot for ANO10 expression. Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS) was employed to identify differentially expressed proteins between control and mutant cell lines after differentiation. DEPs were identified based on a fold-change of ≥ 2 or ≤ 0.5.

Results: Four ANO10-modified cell lines were successfully engineered and established. Western blot analysis confirmed ANO10 downregulation, and the edited cell lines showed no off-target effects. Proteomic analysis showed that 473, 717, 757, and 1142 proteins were significantly differentially expressed in SH-SY5Y ANO10$^{-/-}$, c.289delA, c.1529T-G, and c.1009T-G cell lines, respectively, compared to wild-type cells.

Conclusion: The engineering and analysis of ANO10-modified cell lines revealed significant proteomic changes associated with SCAR10 mutations. Further investigation is expected to uncover the biological pathways involved in SCAR10 pathogenesis and provide deeper insights into the disease biology.

P11.080.C Identification of rare variants for Anorexia Nervosa in Genomics England database

Natasha Ali, *Gerome Breen, Chloe Wong*

King's College London, London, United Kingdom.

Background: Anorexia nervosa is a severe eating disorder characterized by restrictive eating and low body weight, with the highest mortality rate among psychiatric disorders. Given its high heritability (50–60%), identifying key genetic contributors is crucial for developing effective treatments.

Material and Methods: As part of the Genomics England 100K project, we recruited a cohort of individuals with severe familial anorexia nervosa and their relatives (57 cases, 52 relatives), who underwent whole-genome sequencing using Illumina short-read technology. Additional cases ($n = 97$) were recruited for other studies across the broader 100K program. Our primary objective was to investigate rare genetic variants contributing to anorexia nervosa risk. To limit the search space, we used data from a 2019 GWAS of AN, which previously identified eight genome-wide risk loci, including 4 single loci: *CADM1*, *MGMT*, *FOXP1*, and *PTBP2*. Using summary statistics from this GWAS, we applied KGWAS, a deep-learning tool leveraging a functional knowledge graph of variants and genes to identify reliable associations.

Results: The KGWAS analysis confirmed *FOXP1* and *CADM1* as significant single-gene loci. Within the Genomics England Research Environment, we used bcftools and the Interactive Variant Analyser to assess whether anorexia nervosa participants ($n = 154$) harboured damaging variants in these two loci at an allele frequency of <0.01. Our preliminary analyses revealed 9 participants with damaging variants in *FOXP1* and 16 participants with damaging variants in *CADM1*.

Conclusion: Rare damaging variants in *FOXP1* and *CADM1* further implicate these genes as important factors in the aetiology of AN.

Gemelli University Polyclinic Foundation, Sacred Heart Catholic University, Roma, Italy,* [3]*Medical Genetics, University of Siena, Siena, Italy,* [4]*Pediatric Neurology Unit, Fondazione Policlinico Universitario A.*

Gemelli IRCCS, Roma, Italy, [5]Institute of Genomic MedicineCatholic University, Policlinico A. Gemelli Foundation, Rome, Rome, Italy.

Background: The nosological classification of neurodevelopmental disorders (NDDs), particularly autism spectrum disorder (ASD), remains ambiguous. NDDs exhibit a complex etiology that may be monogenic or multifactorial. While genomic advances have facilitated the identification of causative genes, the diagnostic yield of exome sequencing (ES) is significantly higher in monogenic cases than in multifactorial ones.

Aim: (1) Refine the nosological classification of NDDs in relation to pathogenesis, (2) define the appropriateness of genetic testing, and (3) establish a standardized diagnostic workflow.

Methods: We analyzed standardized clinical data from 500 consecutive patients who underwent genetic counseling at Policlinico Gemelli for the diagnosis of NDDs, all of whom underwent pre-test genetic evaluation. By comparing clinical assessments with genetic findings, we identified 14 predictive criteria distinguishing monogenic from multifactorial ASD/intellectual disability (ID).

Results: Statistically significant differences in clinical phenotypes allowed us to develop a clinical scoring system incorporating prenatal anomalies, birth abnormalities, hypertonia/hypotonia, delayed motor milestones, epilepsy/EEG abnormalities, dysautonomia, respiratory abnormalities, moderate/severe ID, concurrent ASD and ID, congenital heart defects, CNS anomalies, macrocephaly/microcephaly, dysmorphic features, and a non-Mendelian family history of neuropsychiatric disorders. Most multifactorial cases had a score of ≤3, while most monogenic cases had a score of ≥4.

Conclusions: We propose guidelines for genetic testing in ID/ASD to optimize its application, limit testing in primary ASD, and facilitate the selection of families with primary ASD for omics studies.

P11.082.A NBIA diagnosis : lessons from ten years experience in a French reference lab

Valeria Gioiosa[1,2,3], *Chloé Angelini*[1,2,4], *Manon Degoutin*[1], *Isabelle Coupry*[2,2], *Julie Deforges*[4], *Patricia Fergelot-Maurin*[2,1,4], *Jean Paul Lasserre*[2], *Claudio Gradito*[4], *Giovanni Battista Stevanin*[2,1], *Cyril Goizet*[1,2]

[1]French reference center for rare diseases – Neurogenetics, Medical genetic department, Pellegrin Hospital, CHU Bordeaux, Bordeaux, France, [2]University of Bordeaux, CNRS, INCIA, UMR 5287, NRGen Team, Bordeaux, France, [3]Department of Medico-Surgical Sciences and Biotechnologies, University of Rome Sapienza, Rome, Italy, [4]Reference laboratory for NBIA diagnosis, molecular genetics laboratory, Pellegrin Hospital, CHU Bordeaux, Bordeaux, France.

Background: Neurodegeneration with Brain Iron Accumulation (NBIA) comprises a group of rare, inherited disorders characterized by abnormal iron deposition in the basal ganglia, detectable via specific brain MRI sequences. NBIA is genetically and clinically heterogeneous, with variable presentations and ages of onset.

Material and Methods: We analyzed 363 patients with clinical and radiological features suggestive of NBIA. Targeted Sanger sequencing of *PANK2* and *FTL* or a next-generation sequencing (NGS) panel of 9 genes (*ATP13A2, CP, DCAF17, FA2H, FTL, C19orf12, PANK2, PLA2G6, WDR45*) was performed. Whole-genome sequencing was conducted in cases with negative panel results but strong clinical suspicion of NBIA.

Results: A molecular diagnosis was achieved in 78 patients, with *PANK2* being the most frequently implicated gene. Detailed analyses of age at onset, initial symptoms, and main clinical manifestations were performed for each subtype.

Conclusion: Our study identified atypical NBIA forms, including four families with dominant MPAN due to *C19ORF12*variants, two of which involved mosaic carriers with late-onset presentations, the only reported mosaic cases for *C19ORF12* to date. Additionally, post-zygotic mosaicism was suspected in monozygotic twins, clinically discordant for a pathogenic *WDR45* variant. We also described an attenuated form of Woodhouse-Sakati syndrome in a compound heterozygous patient (*DCAF17*), carrying both a missense and a nonsense variant, with missense variant never described in *DCAF17*.

Our work provides detailed genetic, clinical, and radiological descriptions of NBIA, highlights atypical phenotypes, and underscores the utility of trio exome and genome sequencing in identifying novel genetic causes of iron accumulation.

P11.083.B Biallelic *RFC1* expansions as a rare cause of familial and early onset Parkinson's disease in the Slavic population

Anja Kovanda[1,2], *Lara Šušmelj*[1], *Tadeja Lukežič*[1], *Aleš Maver*[1,2], *Valentino Rački*[3], *Vladimira Vuletić*[3], *Marina Svetel*[4], *Ivana Novakovic*[5], *Borut Peterlin*[1]

[1]Clinical Institute of Genomic Medicine, University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [3]Department of Neurology, University of Rijeka, Faculty of Medicine, Rijeka, Croatia, [4]Neurology Clinic, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [5]Institute of Human Genetics and Neurology Clinic, Faculty of Medicine University of Belgrade, Belgrade, Serbia.

Background: Parkinson's disease is a common, progressive neurodegenerative disease, presenting with tremor, bradykinesia, muscle rigidity, and non-motor symptoms. Only 10% early-onset and familial Parkinson's disease patients (EOPD/FPD) receive a genetic diagnosis. The cerebellar ataxia, neuropathy and vestibular areflexia syndrome (CANVAS) is a rare type of late-onset ataxia primarily caused by biallelic pathogenic $(AAGGG)_n$ repeat expansions in the *RFC1* gene. While recent evidence shows genetic overlap between EOPD and CANVAS, but its prevalence in FPD remains unknown. Our aim was to determine the possible presence of CANVAS-specific pathogenic expansions in a well-characterized cohort of 135 FPD and EOPD patients with previously negative genetic testing.

Material and Methods: We performed CANVAS testing by using a two-step fluorescent polymerase chain reaction (PCR), based on the initial exclusion of long expansions in CANVAS, and a second stage confirmation of long pathogenic expansions, with the detection based on fragment analysis. Finally, we tested for SNV pathogenic variants in RFC1 gene using reinterpretation of exome sequencing data.

Results: By applying this method, we found two patients with homozygous pathogenic expansions in *RFC1* in our cohort of FPD and EOPD patients. We show biallelic pathogenic CANVAS variants are present in 1.5% of our independent FPD and EOPD cohort,

which in our population makes them more common than the established autosomal recessive PD genes such as PARK2.

Conclusion: Based on these results, we suggest biallelic *RFC1* pathogenic expansions should be considered when performing genetic diagnostics of FPD and EOPD.

P11.084.C Combined family history and polygenic score prediction of anxiety disorders

Rujia Wang[1,2], *Megan Skelton*[1,2], *Sang-hyuck Lee*[1,2], *Jonathan R.I. Coleman*[1,2], *Evangelos Vassos*[1,2], *Raquel Iniesta*[3,4], *Thalia C. Eley*[1,2], *Gerome Breen*[1,2]

[1]*Social, Genetic, and Developmental Psychiatry Centre; Institute of Psychiatry, Psychology and Neuroscience; King's College London, London, United Kingdom,* [2]*National Institute for Health and Care Research Maudsley Biomedical Research Centre, South London and Maudsley NHS Trust, London, United Kingdom,* [3]*Department of Biostatistics and Health Informatics, King's College London, London, United Kingdom,* [4]*King's Institute for Artificial Intelligence, King's College London, London, United Kingdom.*

Background: Anxiety disorder is a complex psychiatric disorder influenced by genetic, social, and environmental factors. This study modelled the combined effects of family history of multiple psychiatric disorders (mFH), polygenic risk scores of multiple traits (mPRS), childhood trauma (ChT) and sociodemographic factors on the development, recurrence, and duration of generalized anxiety disorder (GAD) and panic disorder (PD).

Material and Methods: Data were obtained from the Genetic Links to Anxiety and Depression Study (GLAD+) and UK Biobank (UKB). Diagnosis of GAD and PD were based on DSM-5 criteria. Family history was reported for 9 psychiatric disorders. MegaPRS was used to calculate PRSs based on large genome-wide association studies. Childhood trauma was assessed via the five-item childhood trauma screener. Elastic net regression with nested cross-validation was applied to select the most associated predictors.

Results: In GLAD+, mFH, mPRS, ChT, and sociodemographic factors explained 40% of GAD variance (5,128 cases and 4,226 controls, AUC-ROC = 0.86) and 38% of PD variance (3,470 cases and 4,459 controls, AUC-ROC = 0.86). These predictors accounted for 28% and 22% of variance in the number of episodes for GAD and PD, and 32% of variance in episode duration for both conditions. In UKB, these predictors explained 24% of GAD variance (19,746 cases and 66,233 controls, AUC-ROC = 0.76) and 36% of PD variance (5,057 cases and 28,298 controls, AUC-ROC = 0.82).

Conclusion: Integrating mFH, mPRS, ChT, and sociodemographic factors provides a robust model for predicting GAD and PD risk, recurrence, and chronicity. This approach may support early diagnosis and personalized interventions for anxiety disorders.

P11.085.D Genetic epidemiology of congenital and very-early-onset ataxia

Anna Gerasimenko[1], *Alexandra Afenjar*[1], *Madeleine Harion*[2], *Christelle Rougeot-Jung*[3], *Odile Goze-Martineau*[4], *Stéphanie Valence*[2], *Lydie Burglen*[5]

[1]*APHP.Sorbonne Université, GH Pitié Salpêtrière et Armand Trousseau, Service de Génétique, Centres de référence « Déficiences intellectuelles de causes rares », et « Malformations et Maladies congénitales du cervelet », Paris, France,* [2]*Service de Neurologie Pédiatrique, Hôpital Trousseau, APHP, Sorbonne Université, Paris, France,* [3]*Département de Neurologie Pédiatrique, Hôpital Femme Mère Enfant, Hospices Civils de Lyon, CHU, Lyon., Lyon, France,* [4]*Département de Neurologie Pédiatrique, Hôpital Roger Salengro, CHU, Lille, Lille, France,* [5]*Centre de référence des malformations et maladies congénitales du cervelet, Département de génétique, APHP.Sorbonne Université, Hôpital Trousseau, 75012 Paris, France, Paris, France.*

Between 2015 and 2024, 810 individuals with congenital ataxia were referred to our reference center on Cerebellar Malformations and congenital diseases in order to identify the genetic etiology. All patients presented clinical cerebellar symptoms before the age of two years. We excluded i) patients with a clearly progressive ataxia at the time of inclusion, ii) patients whose brain MRI were suggestive of a specific diagnosis (Joubert syndrome, acquired cerebellar damage, etc), and iii) patients with cerebellar atrophy without clinical ataxia (intellectual disability, severe encephalopathy). We carried out a systematic genetic analysis that has evolved over the years, from Sanger sequencing to high-throughput sequencing. Three successive NGS genes panels allowed a total diagnostic yield of 35%. Pangenomic analysis (WES or WGS) is ongoing in patients without a genetic diagnosis after the first screening. We will present the genetic epidemiology in congenital ataxia in our cohort, and genotype-phenotype analysis. As previously reported, pathogenic variants in ITPR1 and CACNA1A, were among the most frequent diagnoses. We were able to identify several patients affected with a metabolic disease with a very insidious onset mimicking a congenital ataxia. WES/WGS has already increased the diagnosis rate to 46 % and allowed identification of new genes. However, regarding the high diagnostic yield of the panel, WES was not used at first-line. As validation of the variants generated by NGS is now the main challenge, we are developing RNAseq analysis routinely in our laboratory.

P11.086.A Gut microbiome changes in major depressive disorder and investigation of causality by Mendelian Randomization and mediation

Maria Kardakova[1,2], *Zhanna Balkhiiarova*[1,3], *Vasiliki Lagou*[1], *Robert Loshkarev*[2], *Anna Popenko*[2], *Inga Prokopenko*[4,5], *Ayse Demirkan*[1,6]

[1]*University of Surrey, Guilford, United Kingdom,* [2]*Atlas Biomed study group, London, United Kingdom,* [3]*People-Centred Artficial Intelligence Institute, University of Surrey, Guildford, United Kingdom,* [4]*University of Surrey, Guildford, United Kingdom,* [5]*People-Centred Artficial Intelligence Institute, University of Surrey, Guilford, United Kingdom,* [6]*People-Centred Artficial Intelligence Institute, University of Surrey, London, United Kingdom.*

Background: The gut microbiome composition, which is a potential predictor of the host's health status, is determined by diet, medication, and host genetics. The current study explored the intricate links between the gut microbiome and major depressive disorder (MDD) in the Atlas Biomed discovery and replication studies.

Material and Methods: The microbiome was characterised by 16S rRNA gene sequences, QCed and processed by QIIME2 to get

the relative abundance of each bacterial genus. Linear regression was used to assess the association between MDD and bacterial relative abundance in both discovery (544/3,912 cases/controls) and replication (285/2,167 cases/controls), adjusting for region, age, gender, and batch effects. Meta-analysis of each association summary statistics was performed using a random effects model. Mendelian Randomization (MR) and mediation analysis were used to assess causal links.

Results: Meta-analysis identified nine taxa significantly associated with MDD, including Romboutsia, Clostridium sensu stricto, Agathobacter, Bacteroides pectinophilus group, Flavonifractor, Coprococcus, Victivallis, Tyzzerella, and Bacteroides ($q < 0.05$). MR analysis did not support causal relationships between MDD and bacterial abundances of associated taxa. Mediation analyses showed that Bacteroides mediated 61% of total lifestyle effects on MDD, with notable contributions of healthy weight, physical activity, and diet. Integrating multiple bacterial taxa into a microbiome risk score outperformed single-taxon associations, achieving an AUC of 0.6 and demonstrating its potential to capture broader microbial patterns.

Conclusion: Our findings reveal consistent microbial signatures linked to MDD and underline the importance of the microbiome in studying psychiatric outcomes.

P11.087.B *AP4B1* hypomorphic variants cause autosomal recessive adult-onset ataxia

Quentin Sabbagh[1], *Natalia Hernandez Poblete*[2], *Chloé Angelini*[2], *Clément Hersent*[3], *Mehdi Benkirane*[3], *Pointaux Morgane*[3], *Lise Larrieu*[3], *Anna Castrioto*[4], *Louise Deberge*[2], *Frédérique Fluchère*[5], *Francis Ramond*[6], *Gaetan Lesca*[7], *Michel Koenig*[3], *Cyril Goizet*[2]

[1]*Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Bordeaux University Hospital, Bordeaux, France,* [3]*Montpellier University Hospital, Montpellier, France,* [4]*Grenoble-Alpes University Hospital, Grenoble, France,* [5]*Marseille University Hospital, Marseille, France,* [6]*Saint Etienne University Hospital, Saint Etienne, France,* [7]*Lyon University Hospital, Lyon, France.*

Background: Biallelic loss-of-function variants in *AP4B1* have been primarily documented in hereditary spastic paraplegia type 47 (SPG47, MIM 614066), a severe genetic disorder characterized by a broad spectrum of symptoms encompassing global developmental delay, intellectual disability and infantile-onset hypotonia evolving into spastic diplegia with progressive loss of independent ambulation. Although late-onset cerebellar ataxia, along with other related neurodegenerative diseases, has recently been associated with high rate of hypomorphic variants in various severe disease-causing genes, involvement of AP4B1 in such moderate phenotypes has never been established thus far.

Methods: Through a national collaboration, clinical and molecular data of three previously unreported individuals displaying a sporadic form of isolated adult-onset ataxia associated with compound heterozygous variants in *AP4B1* were systematically gathered, and a comparative analysis was conducted between this series and existing literature.

Results: Affected individuals we are documenting manifest comparable forms of slowly evolving adult-onset ataxia, primarily characterized by gait ataxia coupled with progressive dysarthria and moderate cerebellar atrophy. Pangenomic analyses identified two novel missense variants, namely c.320G>A p.(Arg107Gln) and c.1558C>T p.(Arg520Cys), detected in *trans* with either a frameshift or a canonical splicing site variant in *AP4B1*.

Discussion: These pathogenic missense variants are strongly suspected to act as hypomorphic, thereby allowing for residual AP4B1 activity consistent with the attenuated phenotype observed across this series. From a broader standpoint, this study will contribute to refine the genetic landscape currently involved in sporadic late-onset ataxia, while assisting molecular geneticists in the interpretation of pangenomic analyses conducted on individuals displaying mild neurological phenotypes.

P11.088.C Trio-WES in pediatric-onset epilepsy: assessing diagnostic yield and widening genotypic landscape

Vidal Yahya[1], *Edoardo Monfrini*[1,2], *Maria T. Molisso*[2], *Eleonora Zirone*[2], *Roberto Del Bo*[1], *Antonella Giacobbe*[2], *Eleonora Mauri*[2], *Linda Borellini*[2], *Alessio B. Di Fonzo*[2], *Robertino Dilena*[2]

[1]*University of Milan, Milan, Italy,* [2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Background: Whole-Exome Sequencing (WES) is a cost-effective genetic test for epilepsy with an expected diagnostic yield of ~32%. We aim to assess the diagnostic yield of trio-based WES in pediatric-onset epilepsy, identify novel variants associated with epilepsy, and evaluate the clinical impact of genetic diagnosis.

Material and Methods: 30 patients with pediatric-onset epilepsy were enrolled in EPIEXOME, a prospective monocentric study on genetic epilepsies, and underwent trio-WES. The variants were classified according to ACMG criteria.

Results: The cohort included 11 patients with isolated epilepsy and 19 with cognitive and/or motor disturbances. Epilepsy was focal in 15/30 and generalized in 15/30 cases. Mean age at onset was 5.75 years [0-16]. Trio-WES resulted positive in 11/30 (37%, table 1), uncertain in 8/30, and negative in 11/30 cases. Among positive cases, 7 variants were de novo, one variant was inherited in autosomal dominant fashion by an affected father, 3 cases were recessive.

Conclusion: In a monocentric cohort, trio-WES achieved a diagnostic result in 37% of the cases. The high representation of de novo variants stresses the relevance of trio analysis in epilepsy. We link *GABRB1* gene with two novel epileptic phenotypes (EIMFS and Lennox-Gastaut Syndrome) and report a case of steroid-responsive para-infectious acute encephalopathy in a patient with biallelic *QARS1*-variants. The clinical impact of genetic diagnosis included personalized therapeutic possibilities (*KCNT1*, *CACNA1A*, *QARS1*), reverse phenotyping with systemic evaluation (*SON*), and adhesion to patient advocacy groups (*SLC6A1*).

Background: Amyotrophic lateral sclerosis (ALS) is an adult-onset, progressive, fatal neurodegenerative disorder characterized by progressive loss of motor neurons. Approximately 15% of individuals diagnosed with ALS have a known genetic variant that contributes to disease. Herein, we present clinical and genetic data of a large Greek ALS cohort.

Patients and Methods: The cohort consisted of 353 Greek consecutive index patients with ALS. Next generation sequencing raw data (obtained from the NYGC ALS Consortium) were further analyzed and used to screen for causative variants in known implicated genes. Repeat expansions in *C9ORF72* and *ATXN2* were investigated using ExpansionHunter software, repeat-primed PCR and fragment analysis.

Results: Pathogenic repeat expansions in *C9ORF72* were detected in 41 patients (11.6%). In addition, 30 patients (8.5%) carried a causative variant in one of the genes studied. Known causative variants were identified in 27 cases (9 in *SQSTM1*, 7 in *TARDBP*, 5 in *SOD1*, 3 in *NEK1* and 1 each in *SETX*, *VCP*, *FUS*), whereas novel causative variants were identified in 3 cases (*SOD1*, *FIG4*, *TBK1*). In total, 71 cases received a molecular genetic diagnosis (20.1%). Additionally, 7 cases (2.0%) carried an intermediate repeat expansion (30–33 CAG) in *ATXN2*.

Conclusion: Our results reveal the distinct genetic profile of Greek ALS patients. These findings will have an impact on genetic counselling, the design of diagnostic gene panels for the Greek population and on genotype-specific therapeutic interventions. Understanding the genetic causes of ALS in different populations is becoming increasingly important, especially with the advent of personalized medicine.

Background: Gaucher disease (GD) is a lysosomal storage disorder caused by biallelic *GBA1* variants, which represent the most common genetic risk factor for Parkinson's disease (PD) and dementia with Lewy bodies (DLB). The aim of the study was to investigate the occurrence of PD and DLB in a cohort of type 1 and type 3 GD patients (GD1, GD3), and to identify possible predictors of PD or DLB phenoconversion in these patients.

Material and Methods: GD patients from multiple centers were consecutively evaluated by neurologists with expertise in movement disorders at two different time-points (T0, at baseline; T1, after 4 ± 2y).

Results: One-hundred-thirty-six GD1 and 13 GD3 patients were evaluated at T0 (mean age-at-T0 47.6 ± 15.6y). The mild N409S variant in compound heterozygosity with another *GBA1* variant (N409S/other) was the most frequent genotype (72.1%). Diagnosis of PD and DLB was reached in 18 (13.2%) and two (1.5%) GD1 patients, respectively. Fifty-four GD1 and five GD3 patients were re-evaluated at T1. PD and DLB phenoconversion were observed in four (7.4%) and seven (13%) GD1 patients, respectively. Two

(15.4%) GD3 patients developed PD. PD diagnosis preceded that of GD in six (4.4%) GD1 patients. The lifetime risk to develop PD was 25.5% in N409S/other GD1 patients and 0% in homozygous N409S patients at 60y ($p = 0.003$), 34.8% and 33.3% respectively at 70y ($p = 0.54$).

Conclusion: This study highlights the potential of close follow-up of GD patients to identify possible predictors of phenoconversion to PD or DLB.

P11.091.B Genomic SEM and GWAS subtraction: isolating mania's genetic architecture in bipolar disorder

Giuseppe Pierpaolo Merola[1], *Johan Zvrskovec*[1], *Rujia Wang*[1], *Kaye Li Yuen*[1], *Giovanni Castellini*[2], *Valdo Ricca*[2], *Jonathan Coleman*[1], *Evangelos Vassos*[1], *Gerome Breen*[1]

[1]*Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom,* [2]*Psychiatry Unit, Department of Health Sciences, University of Florence, Florence, Italy.*

Background: Bipolar disorder is characterized by episodes of mania and depression, often accompanied by psychotic symptoms. While substantial progress has been made in unraveling the genetic basis of depression and psychosis, the genetic underpinnings of mania remain relatively understudied.

Material and Methods: We applied Genomic Structural Equation Modeling to disentangle the genetic contributions of major depressive disorder (MDD) from bipolar disorder, aiming to isolate a genetic factor specific to mania.

Results: The SEM model demonstrated strong factor loadings for "mania" (0.90, $p < 0.001$) and "depression" (0.43, $p < 0.001$), with mania and MDD accounting for 81.5% and 18.5% of the genetic variance in bipolar disorder, respectively. Seventy-one genome-wide significant SNPs linked to mania were identified across 37 genomic loci. Furthermore, mania displayed distinct genetic correlations compared to bipolar disorder in relation to psychiatric, substance use, somatic, social, and neurological traits. Notable differences were observed in genetic correlations with tiredness ($rg = -0.13$ vs -0.17), subjective well-being ($rg = 0.08$ vs -0.13), and educational attainment ($rg = 0.26$ vs 0.14). Pathway analysis revealed significant enrichment in the voltage-gated calcium channel activity pathway (GO:0086007).

Conclusion: These results refine our understanding of the genetic architecture of bipolar disorder, potentially enabling a more mania-specific GWAS. This knowledge could inform future therapeutic approaches, particularly targeting calcium channel pathways in the treatment of mania.

P11.092.C Genetic Prevalence of Cerebral Cavernous Malformations in the UK Biobank

Delia Gagliardi[1,2], *Lanfranconi Silvia*[3], *Chiara Villella*[4], *Stefania Corti*[4,5], *Giacomo Comi*[4,1], *Arianna Tucci*[6,7], *Henry Houlden*[2,8], ***Dario Ronchi***[4,1]

[1]*IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, Milan, Italy,* [2]*Department of Neuromuscular Diseases, Institute of Neurology, University College London, London, United Kingdom,* [3]*IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Stroke Unit, Milan, Italy,* [4]*University of Milan, Dino Ferrari Center, Milan, Italy,* [5]*IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Neuromuscular Unit, Milan, Italy,* [6]*William Harvey Research Institute, Queen Mary University of London, London, United Kingdom,* [7]*Department of Neurodegenerative Disease, UCL Queen Square Institute of Neurology, London, United Kingdom,* [8]*Neurogenetics Unit, National Hospital for Neurology and Neurosurgery, London, United Kingdom.*

Background: Cerebral cavernous malformations (CCM) consist of clusters of irregular dilated capillaries and represent the second most common type of vascular malformation affecting the central nervous system. CCM might be asymptomatic or cause cerebral hemorrhage, seizures, recurrent headaches and focal neurologic deficits. Causative mutations underlining CCM have been reported in three genes: KRIT1/CCM1, MGC4607/CCM2 and PDCD10/CCM3. Therapeutic avenues are limited to surgery. This condition is likely underestimated: up to 50% remain asymptomatic for life. We aimed to determine the prevalence of CCM disease in UK Biobank.

Material and Methods: We sought KRIT1, CCM2 and PDCD10 gene variants in exome sequencing data from 470 000 individuals aged 40 years or older). We focused on variants previously established as pathogenetic as well as novel nonsense variants or variants impacting (in silico validation) on canonical splice sites. We compared demographic data and ICD-10 (International Classification of Diseases version-10) codes with those without pathogenic variants.

Results: We identified 68 different pathogenetic molecular defects (KRIT1: 41; CCM2: 26; PDCD10: 1). 172 subjects (KRIT1 73%; CCM2 26%, PDCD10 <1%) carried one of these pathogenetic alleles. Male to female ratio was equal to 1. 88% of the mutated subjects were asymptomatic at enrollment.

Conclusion: The genetic prevalence of CCM disease in UK Biobank (1:2700) exceeds the known estimate of the genetic form (1:5000 - 1:10000). Incomplete and age-dependent penetrance likely explains the reduced number of symptomatic patients. Clinical and radiological monitoring is fundamental to prevent neurological complications of CCM.

P11.093.D WES analysis in individuals with dyslexia and reading difficulties

Krzysztof Marianski[1], *Joel B. Talcott*[2], *John Stein*[3], *Anthony P. Monaco*[4], *Simon E. Fisher*[5], *Dorothy V.M. Bishop*[3], *Dianne F. Newbury*[6], *Silvia Paracchini*[7]

[1]*University of St Andrews, St Andrews, United Kingdom,* [2]*Aston University, Birmingham, United Kingdom,* [3]*University of Oxford, Oxford, United Kingdom,* [4]*Tufts University, Medford, MA, USA,* [5]*Radboud University, Nijmegen, Netherlands,* [6]*Oxford Brookes University, Oxford, United Kingdom,* [7]*University of St Andrews, School of Medicine, St Andrews, United Kingdom.*

Background: Dyslexia is a specific difficulty in learning to read, significantly influenced by genetic factors. Recently, we reported whole exome sequencing (WES) in 53 cases with dyslexia (https://doi.org/10.1101/2024.12.19.24319320). The top results were followed up in a replication sample of 38 individuals with reading difficulties, highlighting five genes of interest, including two voltage-gated calcium channel genes.

Methods: We reanalysed our data by combining the two WES datasets (N = 53 + 38) and an additional 17 individuals with dyslexia (Ntotal = 108). We applied filtering criteria based on allele frequency (MAF in gnomAD < 1%) and high predicted pathogenicity. FUMA was utilised for gene-set enrichment analysis (GSEA). An association analysis of the top variants with cognitive and psychiatric traits was conducted in the UK Biobank.

Results: The *CFTR* gene had the highest number of variants, with 10 distinct variants identified among 12 individuals. Additionally, rare coding variants in *ABCA4*, *CLDN3*, and *FLNC* were each observed in six individuals. In a phenotyped control group (N = 82), we observed two variants in *CFTR* and one in *FLNC*. One variant was observed in *CLDN3* but differed from the single variant detected in the cases. GSEA highlighted pathways related to ion transport and the activity of voltage-gated channels. A UK Biobank preliminary analysis found no associations.

Conclusion: Our WES supports the role of rare variants in dyslexia. In line with patterns observed in other traits, the lack of association in general population samples suggests that the impact of rare variants may be observable in clinical samples that could be enriched for additional risk factors.

P11.094.A Diagnostic yield and copy number variants findings in 220 adult patients with developmental and epileptic encephalopathies

Laura Licchetta[1,2], *Tania Giangregorio*[3], *Raffaella Minardi*[2], *Elisa Mannini*[4], *Giulia Bruschi*[4], *Lorenzo Serra*[5], *Carlotta Stipa*[2], *Barbara Mostacci*[2], *Tommaso Pippucci*[3], *Francesca Bisulli*[2,4], *Pamela Magini*[3]

[1]*Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy,* [2]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Full Member of European Reference Network EpiCARE, Bologna, Italy,* [3]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [4]*Department of Biomedical and NeuroMotor Sciences, University of Bologna, Bologna, Italy,* [5]*Department of Pharmacy and Biotechnology (FaBiT), University of Bologna, Bologna, Italy.*

Background: Most Developmental and epileptic encephalopathies (DEE) are caused by pathogenic de novo SNV in genes, each contributing to a limited proportion of cases[1]. WES is the most convenient approach[2], although chromosomal microarray for CNVs detection would be the first-tier genetic test for patients with DEE and/or dysmorphisms[3]. Most of the studies on CNVs focused on paediatric cohorts[4], data on adults are scant. We investigate the role of CNVs in a cohort of adult DEE.

Material and Methods: Patients with undiagnosed DEE underwent CNV analysis by Agilent Technologies array-CGH 8 × 60K platform and Cytogenomics software or SNP-array from Epi25 data using PennCNV and AnnotSV software for variant calling and annotation.

Results: 220 unrelated DEE patients (M/F:104/116, mean age at seizures onset:9.3 ± 5.04 years) underwent array-CGH or SNP-array at a mean age of 35.13 ± 14.95 years. We identified causative CNVs in 18 (8.2%), 8 of whom de novo (44.4%): del1p36.33-p36.23, dup1q21.1q21.2, del2p16.3, mosaic del2q23, del2q23.3q24.2, del2q37.3, del3p14.2p14.1, del3q29, del6q27, del13q13.2q13.3, del15q11.2q13.1 compatible with Angelman syndrome, dup15q11.2q13, 15q13.2q13.3 × 3+15q11.2q13.2 × 4 compatible with an inv-dup (15) syndrome, dup16p13.1, del 17q21.31, del 19q12-q13.11, del 22q11.2, del 22q13.33. The mean age at diagnosis was 32.4 ± 13 years. Of the remaining, 24(10.9%) had VUS, 178(80.9%) were negative.

Conclusions: We identified causative CNVs in 8.2% of patients with a diagnostic delay of 23 years. The diagnostic yield aligns with data on pediatric series. Although WES is recommended as the initial approach to reduce diagnostic costs and time, incorporating CNV analysis is recommended in the diagnostic workflow for adult patients with DEE, as well.

P11.095.B Genetic overlap between dementia and psychiatric disorders: insights from GWAS and genomic SEM

Günes Sayan Can[1], *Heval Şeker*[2], ***Yavuz Oktay***[1]

[1]*Izmir Biomedicine and Genome Center, Izmir, Turkey,* [2]*Dokuz Eylül University Faculty of Medicine, Izmir, Turkey.*

Background: Epidemiological and clinical studies suggest an association between psychiatric disorders and increased dementia risk (1–3), with evidence indicating that dementia develops earlier in individuals with psychiatric disorders (4). However, the genetic basis of these associations remains unclear.

Material and Methods: We investigated the genetic correlation between dementia subtypes (alzheimer's disease, vascular dementia (VaD), frontotemporal dementia subtypes (FTD, FTDbv, FTDmnd, FTDpnfa, FTDsn), lewy-body dementia) and psychiatric disorders (attention-deficit/hyperactivity disorder (ADHD), problematic alcohol use (ALCH), cannabis use disorder (CUD), autism spectrum disorder (AUT), anxiety disorders (ANX), bipolar disorder subtypes (BD, BD1, BD2), depressive disorder (MDD), post-traumatic stress disorder (PTSD), schizophrenia (SCZ)) using summary statistics from genome-wide association studies. LD Score regression (LDSC) was used to estimate genetic correlations (rG), and genomic SEM was applied to model the genetic covariance structure, revealing a well-fitting five-factor model (Dementia, Affected, Neurodevelopment, Psychotic, Substance).

Results: VaD showed significant genetic correlations with ADHD, CUD, ALCH, BD, ANX, MDD, and SCZ. BD1 was specifically correlated with VaD, while BD2 was linked to FTDbv. The dementia factor was significantly correlated with affected (rG = 0.13, p = 0.01), substance (rG = 0.24, p = 0.008), and psychotic (rG = 0.18, p = 0.001) factors.Table: Significant genetic correlations estimated using LDSC

Dementia subtypes	Psychiatric disorders	rG	SE	Z-score	p-value
FTDbv	BD2	0.6024	0.3026	1.9907	0.0465
VaD	ADHDadult	0.3055	0.1275	2.3961	0.0166
VaD	ADHDchild	0.3091	0.1077	2.8700	0.0041
VaD	CUD	0.3110	0.1239	2.5101	0.0121
VaD	ALCH	0.3012	0.1222	2.4648	0.0137
VaD	BD	0.3394	0.1385	2.4505	0.0143
VaD	BD1	0.2086	0.0918	2.2723	0.0231

Dementia subtypes	Psychiatric disorders	rG	SE	Z-score	p-value
VaD	ANX	0.2744	0.1205	2.2772	0.0228
VaD	MDD	0.2303	0.0731	3.1505	0.0016
VaD	SCZ	0.2014	0.0765	2.6327	0.0085

Conclusion: Our findings highlight a strong genetic association between dementia and psychiatric disorders, with VaD exhibiting the most extensive shared genetic background. Additionally, BD subtypes show distinct genetic correlations with different dementia subtypes. Identifying common biological pathways may aid in dementia prevention and the development of targeted therapies for psychiatric disorders.

Background: Epigenetic mechanisms, particularly DNA methylation, have emerged as crucial regulators of gene expression in both health and disease contexts. Global DNA methylation levels, along with the activity of DNA methyltransferases (DNMTs), play a pivotal role in maintaining genomic stability and regulating gene transcription. This study aims to evaluate global DNA methylation levels and mRNA expression of DNMT1 and DNMT3b in peripheral blood cells from Alzheimer's disease (AD) patients.

Material and Methods: Relative mRNA levels of DNMT genes, were examined in 69 AD patients and 33 controls by RT-PCR. Global DNA methylation levels were measured using ELISA in 8 AD and 7 controls.

Results: We found an increase in global DNA methylation in AD patients compared to controls ($p = 0.028$). DNA methylation negatively correlated with age (Spearman $r = -0.62$, $p = 0.017$). The expression of DNMT1 and DNMT3b, was decreased in AD patients compared to healthy controls ($p < 0.05$).

Conclusion: This study highlights significant epigenetic alterations in Alzheimer's disease (AD), providing evidence of increased global DNA methylation and reduced mRNA expression of DNMT1 and DNMT3b. The observed inverse correlation between DNA methylation levels and age further underscores the complex interplay between aging and epigenetic regulation in AD pathogenesis. These findings suggest that dysregulated DNA methylation and impaired activity of DNMTs may contribute to the molecular mechanisms underlying AD. Future research should aim to expand sample sizes, investigate the functional consequences of these epigenetic changes, and explore their potential as biomarkers for early diagnosis or therapeutic intervention in AD.

P11.097.D Whole Exome Sequencing Revealed Ultra-Rare Genetic Variations in Juvenile Myoclonic Epilepsy

Amjad A. Mahasneh[1], *Ansam Yacoub*[2], *Ahmed Yassin*[2], *Rowida F. Almomani*[2], *Suha Aqaileh*[2], *Abdel-Hameed Al-Mistarehi*[3]

[1]*American University of Sharjah, Sharjah, United Arab Emirates,* [2]*Jordan University of Science and Technology, Irbid, Jordan,* [3]*Johns Hopkins University, Baltimore, MD, USA.*

Background: Juvenile Myoclonic Epilepsy (JME) is the most common adolescent and adult-onset genetic generalized epilepsy. In this study, we aimed to identify all rare variants present in exons and exon-intron junctions in patients who met the criteria of JME, determine potentially pathogenic variants, and find the assumed genotype/phenotype correlation between the identified variants and the JME clinical features.

Material and Methods: Whole Exome Sequencing (WES) was performed for ten JME patients from different families. Validation, co-segregation and mode of inheritance were determined using Sanger DNA sequencing.

Results: Predictable damaging variants were found in six families with positive co-segregation. Eight variants in eight genes (SCN1B, KCNQ2, CACNA1I, GABRA3, BSN, RYR3, SEZ6, and RYR2) and one novel variant in (TNR) gene were found to be associated with JME. All these genes play key roles in the interactions between neurons, neurotransmitter release, and maintenance of the balance between neuronal excitation and inhibition.

Conclusion: Since the identified genes are involved in the molecular mechanisms underlying seizures, such variants can potentially be epileptogenic. In conclusion, the identified variants that co-segregate with JME symptoms and likely contribute in creating the adequate genetic background for the JME phenotype.

P11.098.A Genetic study of copy number variants in Greek patients with early-onset Parkinson's disease

Nikolaos Ragazos[1], *Chrisoula Kartanou*[1], *Zoi Kontogeorgiou*[1], *Nikolaos Papagiannakis*[2], *Christos Koros*[2], *Athina Simitsi*[2], *Ioanna Alefanti*[2], *Matina Maniati*[3], *Georgia Xiromerisiou*[4], *Iro Boura*[5], *Cleanthe Spanaki*[5], *Leonidas Stefanis*[2,3], *Georgios Koutsis*[1], *Georgia Karadima*[1]

[1]*Neurogenetics Unit, 1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece,* [2]*1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece,* [3]*Biomedical Research Foundation of the Academy of Athens, Athens, Greece,* [4]*Department of Neurology, School of Medicine, University of Thessaly, Larisa, Greece,* [5]*Department of Neurology, University General Hospital of Heraklion, Heraklion, Greece.*

Background: Parkinson's disease (PD) is a multifactorial progressive neurodegenerative disorder characterized by motor and non-motor symptoms. PD is the second most prevalent neurodegenerative disorder. Monogenic forms account for about 10–15% of PD cases and are often characterized by early onset (<50 years). Single nucleotide variants (SNVs), insertion or deletion (Indels) and copy number variants (CNVs) in PD-associated genes have been detected across many populations and ethnic groups. This study aimed to estimate the frequency of CNVs in Greek patients with early-onset PD (EOPD).

Patients and Methods: The study cohort consisted of 71 Greek index EOPD patients. All patients had been previously screened for the pathogenic variants p.A30G and p.A53T in *SNCA* (common causes of PD in the Greek population) by RFLP, and for causative variants in other PD-associated genes by next generation sequencing and tested negative. Multiplex ligation-dependent

probe amplification (MLPA) was used for the molecular investigation of CNVs

Results: MLPA identified a heterozygous deletion in exon 2 of the *PARK2* gene in a single patient known to harbor a pathogenic SNV in heterozygosity in *PARK2*. This was a sporadic case with age at onset of 30 years and mild disease course. The frequency of CNVs in this EOPD cohort was 1.4%.

Conclusion: The detection rate of CNVs in the present study is in accordance with previous studies in other populations. Our findings may contribute to the development of an appropriate diagnostic algorithm for genetic testing of Greek patients with EOPD, providing timely and accurate diagnosis.

P11.099.B Acute childhood psychosis - ultra-rapid genome sequencing confirms a rare presentation of Radio-Tartaglia syndrome

Fahaz Nazer[1,2], *Tegan French*[1,2], *Joshua Schultz*[1,3], *Andrew Paul Fennell*[1,2], *Michael Fahey*[1,2]

[1]*Monash Genetics, Monash Health, Clayton, Australia,* [2]*Department of Paediatrics, Monash University, Clayton, Australia,* [3]*Department of Paediatrics, Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Parkville, Australia.*

Background: Radio-Tartaglia syndrome is a rare neurodevelopmental disorder caused by *SPEN* haploinsufficiency. This is characterized by developmental delay, intellectual disability, multiple congenital anomalies, and facial dysmorphism. Individuals with neurodevelopmental conditions have a higher prevalence of mental health conditions, and early identification of these concerns can improve their quality of life. Children with mental health concerns should be evaluated for features of genetic neurodevelopmental conditions, as genomic testing facilitates accurate diagnosis and targeted interventions. **Case**: We report a case of a 12-year-old boy of Vietnamese background who presented with Cotard delusions. This is a condition rarely reported at this age, where an individual believes they are dead. Additionally, he had periventricular heterotopia on MRI and exhibited bilateral upper limb dystonia and slow upward saccades on examination.

Results: Ultra-rapid trio genome sequencing revealed a de novo heterozygous pathogenic variant in *SPEN*, c.9766_9767insA which is predicted to result in nonsense mediated decay.

Discussion: A literature review has identified 38 individuals with *SPEN* haploinsufficiency, yet our patient presents a unique clinical presentation. In this case, genomic diagnosis informed the therapeutic approach, guiding the decision to utilise a mood stabiliser rather than traditional antipsychotic medications. As genome sequencing is becoming more widely used in clinical medicine, further data is required for the development of clinical practice recommendations to guide genetic counselling in childhood psychosis.

Conclusion: This case furthers our understanding of presentations of Radio-Tartaglia syndrome. In addition, it highlights the potential utility of rapid genomic sequencing in young children with atypical neuropsychiatric presentations.

P11.100.C Detection of *AGO2* gene mutation associated with an ultra-rare neurodevelopmental syndrome

Renáta Szalai, *Kira Dorogi, Agnes Till, Kinga Hadzsiev*

University of Pecs Medical School Department of Medical Genetics, Pecs, Hungary.

Background: Lessel-Kreienkamp syndrome (LKS) is a rare neurodevelopmental disorder characterized by intellectual disability, global developmental, speech and language delay. Additional features are seizure, hypotonia, gait abnormality, cardiac defects, dysmorphic facial features, behavioural problems. Brain imaging in some patients show white matter abnormalities, thin corpus callosum, enlarged ventricles. LKS is caused by heterozygous mutation in the *AGO2* (Argonaute 2) gene. To date, only 21 patients were reported with LKS worldwide.

Material and Methods: A five-month-old male patient was referred to genetic counseling due to hypotonia, delayed development, feeding difficulties, gastrointestinal problems, failure to thrive, dysmorphic facial features. Later, he exhibited CNS involvement, gait abnormality. Based on MRI findings, the presumed diagnosis was leukodystrophy, therefore a multigene NGS leukodystrophy panel test was carried out, but the result was negative. Since the clinical diagnosis of leukodystrophy was not confirmed by NGS panel, an expanded WES Plus examination was performed.

Results: Exome sequencing analysis identified a c.1092G>A (p.Met364Ile) heterozygous likely pathogenic mutation in *AGO2* gene based on ACMG classification. It has never been reported. Pathogenic mutations in *AGO2* result in associated condition consistent with the phenotype of our patient.

Conclusion: In those cases when the symptoms are well-defined, a multigene panel test may be a useful tool to determine the disease. However, when symptoms are non-specific and multiple organ systems are affected, a more comprehensive genetic examination is more appropriate, especially in neurodevelopmental disorders to identify the genetic abnormality underlying the disease as soon as possible.

P11.101.D Chronic psychiatric disorder caused by adult-onset metachromatic leukodystrophy

Paula Michel[1], *Luise Linnebank*[2], *Christopher Weise*[3], *Saskia Biskup*[4], *Lutz Müller*[5], *Pablo Villavicencio Lorini*[6,1]

[1]*Center for Pediatrics and Human Genetics, MVZ University Hospital Halle (Saale) gGmbH, Halle, Germany,* [2]*Department of Psychiatry, Psychotherapy and Psychosomatics, University Hospital Halle (Saale), Halle, Germany,* [3]*Department of Neurology, University Hospital Halle (Saale), Halle, Germany,* [4]*Praxis fur Humangenetik, Tubingen, Germany,* [5]*Department of Internal Medicine, Hematology and Oncology, University Hospital Halle (Saale), Halle, Germany,* [6]*Institute of Clinical Genetics, Brandenburg Medical School Theodor Fontane, Neuruppin, Germany.*

Background: Neurodegenerative diseases exhibit a broad phenotypic spectrum, often beginning with subtle symptoms that lead to underdiagnoses in early stages. Their heterogeneous etiology represents a diagnostic challenge, especially in light of the therapeutic urgency of early intervention, as seen in rare lysosomal storage disorders such as the adult-onset subtype of metachromatic leukodystrophy (MLD). Most patients are referred

to human genetics at advanced disease stages, when complex motor and cognitive dysfunctions have already developed.

Material and Methods: We established an interdisciplinary framework for the clinical assessment of patients presenting with behavioral and personality abnormalities, integrating early-stage genetic evaluation. Our differential diagnostic approach includes targeted gene or whole-exome sequencing (WES), depending on prior clinical findings. Brain imaging plays a key role in refining the diagnostic focus.

Results: We report on a 42-year-old male patient exhibiting progressive psychiatric symptoms over ten years. His primary manifestations included formal thought disorder, impaired comprehension, mood fluctuations, reduced concentration and mild spastic ataxia. MRI revealed leukoencephalopathy and frontoparietal atrophy. WES identified two heterozygous pathogenic variants c.542T>G; p.Ile181Ser and c.465+1G>A; p.? in the arylsulfatase A (*ARSA*) gene, confirming MLD. We conducted enzymatic analysis and referred the patient to our hematological board to assess eligibility for allogeneic stem cell transplantation.

Conclusion: Although rare, MLD should be considered in young adults with behavioral changes and personality alterations, particularly when specific brain imaging abnormalities are present. An interdisciplinary framework incorporating early genetic testing facilitates timely and accurate diagnosis of heterogeneous underlying causes and may provide access to emerging therapeutic options.

P11.102.A Transcriptome sequencing reveals aberrant splicing due to novel synonymous *GCDH* variant in Glutaricaciduria Type I

M. R, *H. Padmanabha, G. Udupi, A. Kotambail, R. K, C. Ghati, Y. Markandeya, V. Gowda, R. M B, D. M;*

National Institute of Mental Health and Neurosciences, Bengaluru, India

Background: Synonymous variants can disrupt native splice, introduce de novo splice sites, activate cryptic splice sites, exon skipping, partial exon deletions or intron retention. In some cases, several splicing prediction tools often fail to reliably detect splice alterations due to synonymous variants. Employing transcriptome sequencing is essential to uncover the pathogenicity of such synonymous variants on splicing patterns especially when the clinical phenotype in question is clear.

Material and Methods: A 11-month-old female was suspected with glutaric aciduria type 1 based on clinical manifestations, Tandem Mass Spectroscopy results of elevated blood glutaryl carnitine and MR imaging features of widened sylvian fissures, diffuse cerebral atrophy with bilateral lentiform, caudate, and periventricular T2/FLAIR hyperintensities with diffusion restriction. Exome sequencing identified a homozygous novel synonymous variant NP_000150.1:p.Lys111= in exon 5 of the *GCDH* gene. Transcriptome sequencing was performed to determine the effect of the synonymous variant on splicing.

Results: The NP_000150.1:p.Lys111= synonymous variant [NC_000019.10:g.12892177A>G; NM_000159.4:c.333A>G] is located 2 bp upstream of the consensus donor splice site. The variant was not predicted to disrupt the consensus splice site by any of the splicing algorithms. However, transcriptome sequencing revealed that the synonymous variant disrupted the consensus donor splice site, causing exon skipping, resulting in nonsense mediated decay. The variant was reclassified as pathogenic and submitted to ClinVar (Accession ID: VCV003544377.1).

Conclusion: Our results highlight the need for performing transcriptome sequencing or other approaches for the evaluation of ultra-rare synonymous variants near the splice site, in individuals with a classic phenotype and absence of other significant variants.

P11.104.C Biallelic *NDUFA9* variants cause a progressive neurodevelopmental disorder with prominent dystonia and mitochondrial complex I deficiency

E. Ghayoor Karimiani[1], *F. Magrinelli*[2], *L. Taylor*[3];

[1]*Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology, London, United Kingdom,* [2]*Department of Clinical and Movement Neurosciences, UCL Queen Square Institute of Neurology, University College London, London, United Kingdom,* [3]*Mitochondrial Research Group, Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne NE2 4HH, United Kingdom, Newcastle, United Kingdom*

Background: Biallelic NDUFA9 variants have been associated with disease in four individuals. Hence, clinicogenetic features of NDUFA9-related disorder remain largely unexplored.

Material and Methods: To delineate the pheno-genotypic spectrum of NDUFA9-related disorder, we screened genetic databases worldwide and collected phenotypic data on individuals with biallelic NDUFA9 variants, which were functionally investigated when possible.

Results: Eight new and four reported cases were identified. Four individuals died by age 13. Neurodevelopmental disorder (NDD) was observed in 90.0% of cases surviving beyond age 4 months. Neurological deterioration always started in the first decade. Among nine affected surviving beyond infancy, major clinical features included dystonia and feeding difficulties/dysphagia/failure to thrive (88.9%), pyramidal involvement (77.8%), moderate-to-severe intellectual disability, seizures and muscle weakness/atrophy (66.7%). All showed basal ganglia MRI signal alterations, with atrophy (50.0%) and swelling (25.0%). We identified five new *NDUFA9* variants and Arg360 as mutational hotspot. Protein modelling suggested that variants cause NDUFA9 misfolding and/or disruption of binding interfaces. Loss of fully assembled complex I with decreased NDUFA9 steady-state levels and/or complex I activity was documented in fibroblasts from three affected.

Conclusion: Our study strengthens the evidence that NDUFA9-related complex I deficiency presents with a broad spectrum of progressive NDD, often accompanied by prominent dystonia, and characteristic Leigh-syndrome MRI pattern.

P11.105.D A world-wide study of epilepsy genetic testing in resource rich and resource limited countries - closing the diagnostic and treatment gap

Gaetan Lesca[1], *Mia Reid Bashir*[2], *Alina Esterhuizen*[3], *Katherine Helbig*[4], *Michael Hildebrand*[5], *Iscia Lopes-Cendes*[6], *Rebecca Macintosh*[7], *Gagandeep Singh*[8], *Sarah Weckhuysen*[9], *chahnez Charfi Triki*[10], *Andreas Brunklaus*[2]

[1]*Lyon University Hospital, Bron, France,* [2]*Royal Hospital for Children, Glasgow, United Kingdom,* [3]*University of Capetown, Capetown, South Africa,* [4]*Children's Hospital of Philadelphia, Philadelphia, PA, USA,* [5]*Murdoch Children's Research Institute, Melbourne, Australia,*

[6]University of Campinas, Campinas, Brazil, [7]Sydney Children's Hospital, Sydney, Australia, [8]Danayand Medical College and Hospital, Ludhiana, India, [9]University of Antwerp, Antwerp, Belgium, [10]Hédi Chaker University Hospital, Sfax, Tunisia.

Background: Advances in precision medicine emphasise the importance of genetic testing in the epilepsies. These developments could increase the gap between resource rich and poor countries. This study aims to determine the access to genetic testing and services and associated challenges worldwide.

Material and Methods: The task force on clinical genetic testing in the epilepsies of the International League Against Epilepsy (ILAE) distributed a global survey between May and Nov 2023 among the ILAE chapters and genetic societies.

Results: 1568 responses were received from 127 countries. Next-Generation sequencing (gene panel/exome sequencing/genome sequencing) was accessible to 90.4% responders in high-income countries as opposed to 16.3% in low-income countries. Personal funding was reported the most common funding source for 37.5% responders in low-income countries as opposed to 8.6% in high-income countries. Consent for genetic testing was obtained by a clinical geneticist for 51% (530/1038) of the responders. It was obtained by a genetic consellor for 26% (270/1038), ranging from 11% in Latin America to 72% in North America. Genetic results were discussed with the family by a clinical geneticist for 63% (652/1041). They were discussed by a genetic counsellor for 37% (385/1041), ranging from 13% in Latin America to 77% in North America.

Conclusion: This global survey show that high cost, funding shortage and poor infrastructure are the source of clear disparity in access to genetic testing across lower income countries. Collaboration in genetic testing initiatives and engagement of local funding bodies in resource-limited countries may be key to addressing these challenges.

P11.106.A Purinergic receptor gene variants in neurodevelopmental disorders

Gül Ünsel-Bolat[1], *Halil Emir Kaplan*[1], *Hilmi Bolat, MD, PhD*[2]

[1]Balıkesir University, Balıkesir, Turkey, [2]Balikesir University, Balikesir, Turkey.

Background: Purinergic receptors (P2XRs) are ATP-gated ion channels including seven members (P2X1-7). Their expressions were mainly shown in neurons and immune cells. They have been associated with cancer, mood disorders, neurodegenerative disorders and inflammation-related diseases. P2XRs are important for inflammation processes that are emphasized in neurodevelopmental disorders to uncover etiological factors. Although inflammation processes were emphasized in studies for neurodevelopmental disorders, studies investigating P2XRs are very limited.

Material and Methods: We evaluated variants in P2X receptor genes in patients with neurodevelopmental disorders using clinical and whole exome sequencing data.

Results: In our study, the genetic data of 194 patients diagnosed with neurodevelopmental disorders were determined, and we detected variants of P2X receptor genes in 35 patients diagnosed with intellectual disability, autism spectrum disorder, or epilepsy. We presented detailed clinical findings of cases carrying heterozygous P2RX1 (c.11G>A), P2RX2 (c.943C>T), P2RX3 (c.1165G>A), P2RX4 (c.64C>T, c.427+5G>C, c.1095_1096del, c.964_966del, c.949A>G), P2RX5 (115T>C, c.95T>A, c.274G>A, c.382G>A, c.436+8C>T, c.556G>A c.729C>A, c.928C>T), P2RX6 (c.85A>T) and P2RX7 (c.448G>A, c.462_463del, c.614+1G>A, c.797T>C, c.827G>A, c.886G>A, c.882-60_882-59dup, c.1209T>G, c.1733G>A) gene variants.

Conclusion: COST Action CA21130 "P2X receptors as a therapeutic opportunity (PRESTO)" aims to foster collaboration across European countries for purinergic signaling pathways. Effective pharmacological treatment need is still a big problem for autism spectrum disorders. Suramin is one of the purinergic pathway antagonists and clinical trials are still going on the cases diagnosed with autism spectrum disorder. The available results of these studies are complicated. Testing treatment options in patients carrying specific variants of P2XR genes may be more useful.

G. Ünsel-Bolat: None. **H. Kaplan:** None. **H. Bolat:** None.

P11.107.B Functional investigation of novel splice-affecting variants in the *SCN9A* gene in patients with Congenital Insensitivity to Pain

Peter Sparber[1], *Nikolai Zernov*[1], *Tatiana Markova, MD*[1], *Inna Sharkova*[1], *Valeriya Matkova*[2], *Irina Nikishina*[2], *Fedor Konovalov*[3], *Philipp Sviridov*[1], *Victoria Zabnenkova*[1], *Oxana Ryzhkova*[1], *Olga Shchagina*[1], *Vyacheslav Tabakov*[1], *Mikhail Skoblov, Head of the Department*[1]

[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Federal State Budgetary Scientific Institution "V.A. Nasonova Research Institute Of Rheumatology", Moscow, Russian Federation, [3]Independent Clinical Bioinformatics Laboratory, Moscow, Russian Federation.

Background: Congenital insensitivity to pain is one of the rarest and most unusual pain disorders, primarily caused by pathogenic variants in the *SCN9A* gene, which encodes the α-subunit of the Nav1.7 voltage-gated sodium channel. To date, most of the described variants in *SCN9A* associated with congenital insensitivity to pain are biallelic frameshifting variants, and the extent to which splice-affecting variants contribute to this rare phenotype remains largely unknown.

Material and Methods: Pathogenic variants in the *SCN9A* gene were identified through WES or WGS. Functional analysis was performed using RT-PCR using patient-derived samples followed by deep next-generation sequencing. Patients were clinically evaluated by expert clinical geneticist to assess genotype-phenotype correlations

Results: WES and WGS identified 4 novel intronic variants in the *SCN9A* gene: c.596+1G>A, c.596+1del, c.2841+5G>A and c.1108-1921G>T located deep in intron 9. Functional analyses demonstrated that all variants affect mRNA splicing, leading to both out-of-frame and in-frame isoforms. The deep intronic variant was shown to lead to inclusion of a pseudo-exon in intron nine leading to a frameshift and formation of a premature stop-codon. Genotype-phenotype analysis did not reveal significant differences in phenotype severity between variants leading to in-frame or out-of-frame transcripts.

Conclusion: Our results suggests that in-frame shortening of the Nav1.7 protein completely disrupts its function in the same manner as frameshifting variants. These findings broaden the understanding of SCN9A-related pain insensitivity and uncover the molecular mechanisms of novel non-coding variants in the SCN9A gene, which is crucial for the development of future tailored therapeutic approaches

P11.108.C Evaluation of the impact of two homozygous VPS13A mutations in patients with chorea acanthocytosis

Francesca Luisa Conforti[1], *Viviana Mosca*[2], *Benedetta Perrone*[1], *Martina Pecoraro*[2], *Paola Ruffo*[1], *Francesco Perrone*[1], *Rossella Spataro*[3]

[1]*University of Calabria, Rende (Cosenza), Italy,* [2]*University of Palermo, Palermo, Italy,* [3]*Intensive Neurorehabilitation Unit, Villa delle Ginestre Hospital, Palermo, Italy.*

Background: Chorea-acanthocytosis (ChAc) is a severe neurodegenerative disorder with clinical features resembling Huntington's disease, resulting from pathogenic loss-of-function mutations in the VPS13A gene encoding the protein called chorein. In this study, we examined the functional effects of two previously unreported VPS13A homozygous mutations in cases of sporadic neuroacanthocytosis.

Material and Methods: We evaluated the functional impact of two VPS13A mutations identified through exome sequencing: the nucleotide substitution c.9276-2A>T and the 2.8 kb deletion involving exons 69–70 of the gene. In silico tools such as SpliceAI, NNSPLICE, and Netgene2 were employed for the intronic variant to predict the consequences of splicing alterations. The protein expression and in silico characterisation of skin fibroblasts from the ChAc patient with the VPS13A deletion (2.8 Kb), as well as from their relatives and healthy individuals, were assessed.

Results: Our findings revealed that the c.9276-2A>T variant is predicted to modify the highly conserved AG dinucleotide in the intron-69 splice acceptor site, with scores of 0.99 (SpliceAI), 0.97 (NNSPLICE), and 0.38 (Netgene2). Western blot and immunofluorescence analyses on skin fibroblasts demonstrated reduced expression of VPS13A in the affected patient carrying the homozygous deletion of exons 69–70, compared to the mother and control samples.

Conclusion: We described two rare homozygous VPS13A mutations in two cases of suspected ChAc. In silico and functional studies confirmed that these are pathogenic loss-of-function mutations. Our results support the need for regular genetic screening in patients with complex neurological phenotypes, such as neuroacanthocytic syndromes, to allow appropriate genetic counselling and to avoid misdiagnosis.

P11.109.D A familial case of epilepsy and focal malformation of cortical development suggests a multi-step pathogenic mechanism

Valentina Cetica[1], ***Claudia Mandorlini***[1], *Claudia Bianchini*[1], *Alice Dainelli*[1], *Elena Cellini*[1], *Domenico Rutigliano*[1], *Simona Virdò*[1], *Dalila De Vita*[1], *Daniela Pucatti*[1], *Flavia Fineschi*[1], *Aurelia Iuliana Timis*[1], *Marta Lo Monaco*[1], *Domenica Immacolata Battaglia*[2], *Renzo Guerrini*[1], *Elena Parrini*[1], *Davide Mei*[1]

[1]*Neuroscience and Medical Genetics Department, Meyer Children's Hospital- IRCCS, Florence, Italy,* [2]*Neuropsichiatria Infantile Dipartimento Scienze della salute della Donna, del Bambino e di Sanità Pubblica, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy.*

Background: Focal malformations of cortical development (MCDs), such as focal cortical dysplasia (FCD) and hemimegalencephaly (HME), are major causes of intractable childhood epilepsy. They are primarily driven by pathogenic variants affecting the mTOR pathway. We describe a family with multiple members affected by focal epilepsy, including two sisters with focal epilepsy and HME.

Material and Methods: We performed next-generation deep sequencing with a UMI-based targeted panel optimized to detect low-level mosaic variants, in brain-derived DNA from a 5-year-old girl with focal epilepsy and HME. We then analyzed all affected family members.

Results: In the proband's brain-derived DNA, we identified a low-level mosaic MTOR variant (p.Cys1483Tyr, 1% VAF), absent in her blood and a heterozygous NPRL3 deletion which segregated in all family members affected by focal epilepsy, including her older sister with HME. The DNA analysis of paraffin-embedded brain tissue of the older sister excluded the MTOR variant but did not allow a complete analysis of MTOR pathway genes, leaving the presence of a second-hit unresolved.

Conclusion: This family, presenting with familial focal epilepsy and HME in two sisters, suggests a novel pathogenic mechanism underlying the development of focal MCDs. Specifically, the heterozygous deletion of NPRL3 may prompt a second somatic event, which is essential for the structural malformation. We hypothesize that a second somatic variant was also present in the older sister but remained undetected due to poor DNA quality. Future studies on patients with HME could help to validate this hypothesis.

P11.110.A The clinical and molecular spectrum of Neurodegeneration with Brain Iron Accumulation in the largest national cohort

Darya Baranik[1], *Artem Sharkov*[2], *Nikita Beskorovainyi*[1], *Ekaterina Zakharova*[1], *Sergey Korostelev*[2], *Mikhail Skoblov*[1], *Peter Sparber*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Genomed ltd., Moscow, Russian Federation.*

Background: Neurodegeneration with brain iron accumulation (NBIA) is an ultra-rare group of neurological disorders characterized by progressive dystonia, dysarthria, spasticity, neuropsychiatric abnormalities, and iron deposition in the basal ganglia. Due to its rarity, only a limited number of single-gene cohorts have been reported. The most prevalent clinical form of NBIA remains unclear, with some sources suggesting PKAN and others BPAN. In Russia, the NBIA spectrum within a large national registry remains undetermined.

Material and Methods: This study utilized retrospective analysis of DNA tests from the two largest Russian medical genetics centers (2017–2024). Over 7,000 whole-genome sequencing (WGS) samples were analyzed for variants in nine NBIA-related genes (*WDR45, C19orf12, PANK2, PLA2G6, FA2H, COASY, CP, FTL, ATP13A2*). Variants were annotated using wANNOVAR, and potential splice-affecting variants were predicted with SpliceAI. Clinical significance was assessed following ACMG/AMP guidelines.

Results: The study identified 114 patients with 74 unique variants across nine NBIA-related genes. SpliceAI predicted 20 variants (27%) as splice-disrupting. BPAN was the most common

subtype (34%), followed by MPAN (32%) and PKAN (16%). Pathogenic variants were found in 50.4% of cases, likely pathogenic in 27%, and variants of uncertain significance (VOUS) in 22.7%. Milder clinical forms associated with *WDR45* and *C19orf12* genes were identified for the first time.

Conclusion: This research describes the largest national NBIA cohort to date, revealing a distinct NBIA spectrum in Russia, with BPAN and MPAN comprising two-thirds of cases, differing significantly from global patterns.

P11.111.B *A homozygous NAV3 variant further strengthens links to neurodevelopmental disorder*

M. Umair, *M. Alfadhel;*

King Abdullah International Medical Research Center (KAIMRC), King Saud Bin Abdulaziz University for Health Sciences (KSAU-HS), Ministry of National Guard Health Affairs (MNGH), Riyadh, Saudi Arabia

Background: Neurodevelopmental disorders (NDDs) represent a diverse and heterogeneous group of conditions, including neurodevelopmental delay, autism spectrum disorder (ASD), and neurodevelopmental encephalopathy with epilepsy (NDEE). While these disorders often share phenotypic similarities, their underlying genetic causes can vary widely, complicating clinical diagnosis.

Methods: In this study, we performed whole-genome sequencing (WGS) on a family with autosomal recessive inheritance of indeterminate neurological symptoms. The proband (II-2) underwent WGS, followed by variant filtering using an in-house bioinformatics pipeline. Sanger sequencing was employed to confirm the identified variants. Furthermore, 3D protein modeling was performed for structural predictions, and RT-qPCR analysis was conducted to assess gene expression.

Results: A novel biallelic missense variant in NAV3 (c.3430T>C; p.Ser1144Pro) was detected, segregating with the phenotype in the family. Subsequent 3D protein modeling revealed significant alterations in the structure of the NAV3 protein, and RT-qPCR analysis showed a decrease in the expression of the NAV3 gene compared to the control and other healthy family members, suggesting a potential pathogenic effect.

Conclusion: This finding further implicates NAV3 in neurodevelopmental processes, confirming its role in autosomal recessive neurodevelopmental disorders. Notably, this is the third report linking NAV3 mutations to NDDs. Further research, including functional studies and the identification of additional cases, is needed to fully understand the role of NAV3 in human neurodevelopmental disorders.

P11.112.C Clinical and Genetic Spectrum of Syndromic Epilepsies: Insights from a Cohort in a Highly Consanguineous Population

*F. Agrebi[1], **S. Karoui**[1,2,3], T. Ben Younes[4,3], M. Essid[1], S. Hizem[1,3], H. Jilani[1,3], I. Kraoua[4,3], L. Ben Jemaa[1,3,2];*

[1]Department of Genetics, Mongi Slim Hospital, La Marsa, Tunis, Tunisia, [2]Research Laboratory LR22SP01, CHU Mongi Slim, La Marsa, Tunis, Tunisia, [3]Faculty of Medicine of Tunis, University of Tunis el Manar, Tunis, Tunisia, [4]Department of Pediatric Neurology, Mongi Ben Hamida National Institute of Neurology, Tunis, Tunisia

Background: Syndromic epilepsies exhibit significant clinical and genetic heterogeneity, requiring high-throughput sequencing for accurate diagnosis. In populations where sequencing is not routinely available, the genetic landscape remains insufficiently characterized. This is particularly relevant in highly consanguineous populations, where the incidence of autosomal recessive disorders is higher.

Material and Methods: We conducted a clinical and genetic study on patients with syndromic epilepsy followed at the Genetics Department of Mongi Slim Hospital, Tunis, with at least one index case per family undergoing exome sequencing (ES).

Results: We analyzed 37 patients from 34 families with a consanguinity rate of 35%. Developmental delay and/or intellectual disability were present in 94%, and facial dysmorphisms and congenital anomalies in 68% and 86%, respectively. Seizures manifested early, with a mean onset at just 10 months, and a concerning 22% of cases presenting in the neonatal period. Neurological comorbidities were found in 73% of cases, and nearly half had drug-resistant epilepsy. ES identified 35 variants, including 32 SNVs and 3 CNVs, with a definitive genetic diagnosis in 81% of cases. Notably, 30% of pathogenic variants were in actionable genes.

Conclusion: This study provides the most comprehensive genetic landscape of syndromic epilepsy in a Tunisian cohort. Understanding the genetic makeup of North African populations is crucial, as they are an integral part of European society. Expanding genomic studies to underrepresented populations will not only enhance local diagnostic capabilities but also contribute to global scientific advancements by refining gene-disease correlations and broadening the mutational spectrum of epilepsy-related genes.

P11.113.D Unraveling the genetic landscape of corpus callosum malformations (CCM) and autism spectrum disorders: Toward precision diagnosis

Bochra Khadija[1,2,3], *Wafa Dahleb[1], Hamza Hadj abdallah[1], Wafa Slimani[1], Ayda Bennour[1,2], Adnen Mlika[4], Najla Soyah[5], Khouloud Rjiba[1], Dr Attia[6], Ali Saad[1,2], Christel Depienne[7], Soumaya Mougou-Zerelli[1,2]*

[1]Laboratory in cytogenetics, molecular genetics and human reproductive biology at the university hospital farhat hached of Sousse-Tunisia, Sousse, Tunisia, Tunisia, [2]Common service unit for research in genetics, Faculty of Medicine of Sousse, University of Sousse, Tunisia, Sousse, Tunisia, [3]Higher institute of biotechnology of monastir, Tunisia, Monastir, Tunisia, [4]Pediatric Service CHU Farhat Hached Sousse, Tunisia, Sousse, Tunisia, Tunisia, [5]Pediatric Service CHU Farhat Hached Sousse,Tunisia, Sousse, Tunisia, Tunisia, [6]Pedopsychiatry CSB Sousse, Tunisia, Sousse, Tunisia, Tunisia, [7]Institute of Human Genetics, University Hospital Essen, University of Duisburg-Essen, 45122 Essen, Germany, Essen, Germany.

Background: Corpus callosum malformations (CCM) are common congenital brain anomalies, ranging from complete or partial agenesis to hypoplasia or dysplasia. These malformations may occur isolated or alongside other conditions and are frequently associated with neurodevelopmental disorders, particularly autism spectrum disorders (ASD). The clinical and genetic heterogeneity of CCM complicates genotype-phenotype correlations, especially in prenatal diagnosis.

Material and Methods: This study, conducted on a cohort of patients from Farhat Hached university hospital in Sousse (2010–2024), employing cutting-edge techniques like array CGH and exome sequencing.

Results: Our research focused on six patients with CCM and ASD, uncovering significant genetic abnormalities in three cases. Array CGH revealed two critical copy number variations (CNVs) in two patients: a 3.69 Mb deletion in 1p32 involving the *NFIA*, a key regulator of gliogenesis and callosal development and a 1,8 Mb duplication in 1q31.1 affecting *BRINP3* implicated in neurodevelopmental pathways. Exome sequencing further identified a double variant in *WLS* and *ERCC8*, linked to Zaki and Cockayne syndromes, respectively. Additionally, a variant in *MAPK8IP3*, a gene crucial for axonal transport and neuronal connectivity, was discovered, reinforcing its role in CCM and ASD pathogenesis. These findings highlight the involvement of these genes in key neurodevelopmental processes, providing novel insights into CCM and ASD pathogenesis.

Conclusion: The integration of array CGH, exome sequencing, psychiatric assessments, brain imaging and functional studies provides a complete understanding of the genetic bases of CCM and ASD. This multidisciplinary approach promises improved diagnosis, clinical management, and future developments in prenatal care and genetic counseling.

P11.114.A Autism spectrum disorder in a child carrying a novel truncating variant in *DIP2B*, a gene previously associated with repeat expansion disorder

Gioia Mastromoro[1], *Martina Rinelli*[2], *Nader Khaleghi Hashemian*[3], *Daniele Guadagnolo*[3], *Daniela Miraglia*[3], *Antonio Pizzuti*[3], *Mario Mastrangelo*[3], *Angelo Minucci*[2], *Mauro Ciro Antonio Rongioletti*[1]

[1]*Ospedale Isola Tiberina - Gemelli Isola, Rome, Italy,* [2]*Policlinico Agostino Gemelli, Rome, Italy,* [3]*Policlinico Umberto I, Rome, Italy.*

Background: Autism spectrum disorder includes a group of conditions that may vary based on their association with additional clinical features. Although it is a multifactorial condition, in some cases causative variants of neurodevelopmental alterations and autism have been found.

Material and Methods: A 8-year-old male child was referred for motor stereotypies and mannerisms of the distal extremities of the upper limbs. Cognitive and behaviour reassessment showed an autism spectrum disorder without intellectual disabilities and without language disorders. Standard karyotype, chromosomal microarray analysis and exome sequencing were requested.

Results: Cytogenetic assays did not detect imbalances. Exome sequencing revealed the de novo nonsense c.265C>T; p.(Arg89-Ter) variant in the *DIP2B* (MIM *611379) brain-expressed gene. The loss of a functional *DIP2B* allele, caused by promoter methylation in presence of a CGG expansion in the 5-prime untranslated region, has been associated with a form of neurodevelopmental disorder with autosomal dominant inheritance, related to the FRA12A fragile site (MIM #136630). The DIP2B protein contains a DMAP1-binding domain, involved in DNA-methylation processes. The affected cases reported in literature show the methylated repeat expansion, exhibiting low mRNA levels, while unaffected carriers with unmethylated less elongated expansion presented increased gene expression. We propose that rare truncating variants in *DIP2B* might exert a loss-of-function effect comparable to the large methylated expansions.

Conclusion: This is the first case of a child with autism spectrum disorder detected with a novel truncating variant in *DIP2B*, showing a different molecular basis in a gene previously considered to cause a repeat expansion disorder.

P11.115.B Patients with complex and very-early-onset *ATL1*-related spastic paraplegia offer insights on genotype/phenotype correlations and support for autosomal recessive forms of SPG3A

Angélique Hamamie-Chaar[1], *Mathilde Renaud*[2], *Pinar Gençpinar*[3], *Ange-Line Bruel*[1], *Christophe Philippe*[1], *Julien Maraval*[1], *Caroline Racine*[1], *Nawale Hadouiri*[1], *Laetitia Lambert*[4], *Emmanuelle Schmitt*[4], *Guillaume Banneau*[5], *Armand Hocquel*[2], *Christel Thauvin*[1], *Laurence Faivre*[1], ***Quentin Hugo Thomas***[1]

[1]*Dijon Burgundy University hospital, Dijon, France,* [2]*CHRU Nancy, Nancy, France,* [3]*İzmir Katip Çelebi University Department of Pediatric Neurology, Izmir, Turkey,* [4]*INSERM-U1256 NGERE, Université de Lorraine, Nancy, France,* [5]*Sorbonne Université, AP-HP, Paris, France.*

Background: Spastic paraplegia type 3A (SPG3A) is the second most common form of hereditary spastic paraplegia (HSP). This autosomal-dominant-inherited motor disorder is caused by heterozygous variants in the *ATL1* gene which usually presents as a pure childhood-onset spastic paraplegia. Affected individuals present muscle weakness and spasticity in the lower limbs, with symptom onset in the first decade of life. Individuals with SPG3A typically present a slow progression and remain ambulatory throughout their life.

Material and Methods: Here we report three unrelated individuals presenting with very-early-onset (before 7 months) complex, and severe HSP phenotypes (axial hypotonia, spastic quadriplegia, dystonia, seizures and intellectual disability).

Results & Conclusion: For 2 of the 3 patients, these phenotypes led to the initial diagnosis of cerebral palsy (CP). These individuals carried novel *ATL1* pathogenic variants (a de novo *ATL1* missense p.(Lys406Glu), a homozygous frameshift p.(Arg403Glufs*3) and a homozygous missense variant (p.Tyr367-His)). The parents carrying the heterozygous frameshift and missense variants were asymptomatic. Through these observations, we increase the knowledge on genotype-phenotype correlations in SPG3A and offer additional proof for possible autosomal recessive forms of SPG3A, while raising awareness on these exceptional phenotypes. Their ability to mimic CP also implies that genetic testing should be considered for patients with atypical forms of CP, given the implications for genetic counselling.

P11.116.C Clinical characteristics and mutation spectrum of Neurofibromatosis Type 1 in a North Indian cohort

Priyanka Srivastava[1], *Shifali Gupta*[1], *Chitra Bhardwaj*[1], *Roshan Daniel*[1], *Parminder Kaur*[1], *Anupriya Kaur*[1], *Inusha Panigrahi*[1], *Kausik Mandal*[2]

[1]Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Chandigarh, India.

Background: Neurofibromatosis type 1 (NF1) is a unique, highly penetrant neuro-cutaneous disorder with a wide range of manifestations. Though the clinical diagnosis of NF1 is straight forward, there can be other disorders which mimic NF1, especially its cutaneous features which can be a diagnostic dilemma in certain conditions. Here we describe the clinical and mutation spectrum of a series of individuals whose primary diagnosis was NF1 or NF1 related disorders.

Material and Methods: We have screened 31 consecutive unrelated individuals who fulfilled the clinical criteria of NF1. Whole exome sequencing (WES) was done in all individuals except one with suspected microdeletion syndrome with NF1 in whom Cytogenetic microarray (CMA) was done. All the variants were classified as per ACMG guidelines.

Results: Out of 31 suspected patients, 27 had germline pathogenic/likely pathogenic variants involving NF1 gene. Five novel and 22 known variants in coding and non-coding regions were identified, among them 7 variants were deletions (22.6%), 7 nonsense (22.6%), 4 splice-site (12.9%), 4 missense (12.9%), 3 duplications (9.6%) and 2 (6.5%) were contiguous deletions. In those where NF1 variants were not detected, 3 had neurofibromatosis type 2 (NF2) and 1 rare autosomal recessive form of Elher Danlos syndrome.

Conclusion: We hereby present the wide range of manifestations in different age groups and the mutation spectrum ranging from small scale variants to contiguous gene deletion syndromes involving NF1 gene. We highlight the usefulness of molecular testing and its importance in tumor surveillance and genetic counseling in this disorder.

P11.117.D Chromosomal microarray analysis in patients with developmental delay/intellectual disability and autism spectrum disorder: a retrospective study

Ceren Deniz Ceylan, *Kadri Murat Erdogan, Mehmet Berkay Akcan, Merve Saka Guvenc, Ozge Ozer Kaya, Ozgur Kirbiyik, Ozlem Anlas, Selcan Kesan, Tuba Sozen Turk, Yasar Bekir Kutbay, Altug Koc, Taha Resid Ozdemir, Berk Ozyilmaz*

Izmir City Hospital, Izmir, Turkey.

Background: Developmental delay (DD), intellectual disability (ID), and autism spectrum disorder (ASD) are among the most prevalent conditions within the spectrum of rare diseases. Chromosomal microarray (CMA) technology has been widely utilized as a diagnostic tool in patients with DD/ID and ASD. For many years, CMA has been employed as a first-tier genetic test to elucidate the etiology of these disorders and continues to maintain its diagnostic utility. In this study, we aimed to retrospectively evaluate the chromosomal microarray results of 319 patients (age range:6 months to 28 years) with DD/ID and ASD to understand the effectiveness of the CMA testing in clarifying the etiology.

Material and Methods: Chromosomal microarray analysis was performed on 319 patients (216 males, 103 females) using Applied Biosystems CytoScan™ HT-CMA® Assay kit. Identified copy number variations (CNVs) were analyzed using Chromosome Analysis Suite (CHAS 4.5-NetAffx 2024–0101 version) based on the GRCh38 (hg38) reference genome.

Results: 132 CNVs were reported in 32.9% of patients (n = 105). Among the reported CNVs (n = 132), 29.5% (n = 39) were classified as pathogenic or likely pathogenic while 70.5% (n = 93) were considered variant of uncertain significance (VOUS). While 74.3% (n = 29) of the pathogenic/likely pathogenic CNVs were heterozygous deletions, 25.7% (n = 10) were heterozygous duplications.

Conclusion: Our study indicates the ongoing diagnostic value of chromosomal microarray analysis in elucidating the genetic etiology of DD/ID and ASD, demonstrating its continued relevance in medical genetics practice.

P11.118.B CARE4ARID1B: Developmental Trajectories in ARID1B-Related Disorder - a Multi-Method Multi-Site Prospective Natural History Study

Gal Lazarus[1], *Ioulia Ziavrou*[2], *Kristiina Tammimies*[3], *Charlotte Maria Willfors, PhD*[4], *Philippe Campeau*[5], *Gaetano Cantalupo*[6], *Jacopo Proietti*[6], *Annabelle Arlt*[7], *Peter Krawitz*[7], *Vincent des Portes*[8], *Aurore Curie*[8], *Yasemin ALANAY*[9], *Ozlem Akgun Dogan*[10], *Bernis Sutcubasi*[9], *Felix Distelmaier*[11], *Eva Meisenzahl-Lechner*[2], *Dagmar Wieczorek*[12]

[1]*The Hebrew University of Jerusalem, Jerusalem, Israel,* [2]*Heinrich-Heine University Düsseldorf, Düsseldorf, Germany,* [3]*Karolinska Institutet, Solna, Sweden,* [4]*Karolinska Institutet, Stockholm, Sweden,* [5]*CHU Sainte-Justine, Montreal, QC, Canada,* [6]*University of Verona, Verona, Italy,* [7]*University Hospital Bonn, Bonn, Germany,* [8]*Lyon University Hospital, Lyon, France,* [9]*Acibadem Mehmet Ali Aydinlar University, Istanbul, Turkey,* [10]*10Acibadem Mehmet Ali Aydinlar University, Istanbul, Turkey,* [11]*Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany,* [12]*Heinrich-Heine-University Düsseldorf, Dusseldorf, Germany.*

Background: ARID1B is one of the most frequently mutated genes in monogenic neurodevelopmental disorders (NDDs), with an approximate prevalence of one in 9,500 individuals. ARID1B-related disorder (ARID1B-RD) manifests in early childhood as moderate to severe developmental delay while older individuals have intellectual disability (ID) and often autism spectrum disorder alongside other clinical signs. The current understanding of the disorder's developmental trajectories is strikingly limited.

Material and Methods: The project will address this gap by employing a prospective longitudinal multi-method design. Its primary objectives are twofold: to establish a comprehensive, integrative understanding of the development of ARID1B-RD encompassing all relevant functional domains and physiological systems and to characterize traditional and novel clinical endpoints for upcoming targeted clinical trials. To attain these objectives, we will monitor the development of 135 children and adolescents with ARID1B-RD in seven sites, for 30 months. Monitoring will involve bi-annual standardized NDD assessments, caregivers' reports, ARID1B-RD-specific biomarkers (EEG, episignatures, proteomics and facial phenotype), and collection of ecologically valid data based on caregivers' reports and wearables tapping into motor and language development. The project team brings a diverse set of complementary expertise and collaborates with patient advocacy organizations.

Results: We will present the study design, a call for patients, and preliminary data collected from the first participants.

Conclusion: The data will allow identifying and cross-validating clinical endpoints, and serve as an external historical control, thus facilitating the development of effective therapeutics. Moreover,

the methods implemented will serve as an example for future multinational/lingual natural history studies for NDDs.

P11.119.A Identifying clinically meaningful subgroups in Autism Spectrum Disorders: linking phenotypic profiles to genetic insights

Hanane Issa

University of Edinburgh, Edinburgh, United Kingdom.

Background: Autism Spectrum Disorders (ASDs) are highly heterogeneous and complex neurodevelopmental conditions that are challenging to characterize and accurately diagnose.

Identifying clinically meaningful subgroups of ASDs could improve our understanding of the conditions and lead to more personalised approaches in treatment and care. In this study, we explore the existence of distinct ASDs subgroups using phenotypic data and investigate the association between these subgroups and distinct genetic profiles.

Material and Methods: To achieve this, we build a patient similarity network and apply Louvain community detection to stratify participants from the Simons Foundation Powering Autism Research for Knowledge study. We focus on diagnostic questionnaire data from the basic medical screening, and summary scores from the Developmental Coordination Disorder Questionnaire, Social Communication Questionnaire, and the Repetitive Behaviour Scale-Revised. We apply the same methods to the Simons Simplex Collection cohort and compare our stratification results across datasets. We explore the correlation between genetic markers and identified phenotypic profiles.

Results: Our analyses reveal multiple ASDs subgroups with distinct phenotypic and genotypic profiles. Traditional questionnaire summary scores fail to capture the necessary granularity for effective ASDs stratification, while specific questionnaire data and detailed clinical variables offer a more nuanced understanding of ASDs heterogeneity.

Conclusion: The research findings have the potential to refine the characterisation of ASDs, aiding improved diagnosis and supporting the development of targeted interventions. Understanding the phenotypic and genetic underpinnings of these subgroups could ultimately lead to improved outcomes for individuals with ASDs, advancing the shift towards more personalised clinical support for individuals.

P11.120.C Microcephaly and simplified gyral pattern due to compound heterozygous variants in *TUBGCP6*: Prenatal and postnatal findings in a multiplex family

Hagit Shani*, Eran Kassif, Michal Barkenstadt, Efrat Hadi, Omer Bar Yosef, Ben Pode Shakhed*

Sheba Medical Center, Ramat Gan, Israel.

Background: Microcephaly and chorioretinopathy have been associated with bi-allelic variants in *TUBGCP4, TUBGCP6* and *PLK4*, as well as monoallelic variants in *KIF11*. Since the implication of biallelic variants in *TUBGCP6*, in 2012, ~15 affected individuals have been reported, including two unborn fetuses.

Methods: We sought to establish the molecular diagnosis in a family with two pregnancies affected by microcephaly, delayed sulcation and additional findings on brain imaging. Prenatal quatro exome sequencing (ES), and subsequently single genome sequencing of an affected female child, were pursued.

Results: A non-consanguineous couple presented during their first pregnancy due to fetal microcephaly, delayed sulcation, short and thick corpus callosum and small cerebellum. The pregnancy was terminated, and genetic evaluation- including Chromosomal Microarray Analysis (CMA) and fetal trio ES- were nondiagnostic. Upon a subsequent pregnancy, similar findings in the female fetus were noted, and following close and extensive prenatal follow up, including three fetal brain MRIs, the parents decided to complete the pregnancy. Prenatal ES demonstrated a maternally-inherited heterozygous c.1630del, p.Val544CysfsTer10 variant in *TUBGCP6* shared by the two affected fetuses, however a second variant was not detected. At 2 years of age, the female child shows microcephaly (−3.5 SD), however continues to achieve developmental milestones within the normal range. Ophthalmologic exam shows astigmatism and hyperopia, but no chorioretinopathy. Single genome sequencing revealed a second intronic c.2271-125G>A variant in *TUBGCP6*, confirming the diagnosis in the family.

Conclusions: Our experience with this multiplex family expands the current knowledge regarding the mutational spectrum and neurodevelopmental phenotype of *TUBGCP6*-associated tubulinopathy.

P11.122.A In-depth behavioral characterization of a rat model of Schaaf-Yang syndrome

Felix Franke[1]*, Semih Ertürk*[1]*, Tim Schubert*[1]*, Dominik Kamionek*[1]*, Johann G. Maaß*[1]*, Claudia Pitzer*[2]*, Christian P. Schaaf*[1]*, Ferdinand Althammer*[1]

[1]*Institute of Human Genetics, Heidelberg University, Heidelberg, Germany,* [2]*Interdisciplinary Neurobehavioral Core, Heidelberg University, Heidelberg, Germany.*

Background: Schaaf-Yang syndrome (SYS) is a rare neurodevelopmental disorder caused by truncating variants in the maternally imprinted *MAGEL2* gene. It is characterized by autism spectrum disorder, joint contractures, hypotonia and feeding difficulties. This study provides a behavioral characterization of a novel rat model ("*Magel2 P mut* rats") carrying a truncating mutation on the paternal allele of *Magel2*, which offers greater construct validity for SYS compared to previous animal models that focused on complete *Magel2* deletion.

Material and Methods: We conducted a comprehensive battery of eight different behavioral tests including advanced behavioral assessment systems, such as LABORAS, a non-invasive system for monitoring rodent behavior in the home cage, ultrasonic vocalization (USV) measurements, and CatWalk XT, a precise tool for locomotion analysis.

Results: *Magel2 P mut* rats showed several significant alterations in isolation-induced USVs compared to wild-type littermates. Despite lower body weight in early life, *Magel2 P mut* rats spent significantly more time eating and drinking, as revealed by home-cage monitoring. Additionally, *Magel2 P mut* rats displayed decreased anxiety-like behavior in the elevated plus maze test, delayed decision-making in the T-maze spontaneous alternation

task, several phenotypes of abnormal social interaction and irregular gait patterns.

Conclusion: This study provides new insights into the phenotype of a novel rat model for SYS and provides behavioral outcomes relevant for intervention. The observed behavioral alterations, particularly in social interaction, communication, feeding behavior, and locomotion, may reflect symptoms seen in SYS, underscoring the value of this model for preclinical research on SYS pathophysiology and potential treatments.

P11.123.B *KIF11*-related microcephaly masquerading as congenital CMV: a diagnostic journey

Nazli Busra Acikgoz[1], *Gizem Ürel Demir*[1], *Engin Demir*[2], *Ridvan Akin*[3], *Gulen Eda Utine*[1], *Pelin Ozlem Simsek Kiper*[1]

[1]*Hacettepe University Faculty of Medicine, Department of Pediatric Genetics, Ankara, Turkey,* [2]*LÖSANTE Hospital, Department of Pediatric Gastroenterology, Ankara, Turkey,* [3]*LÖSANTE Hospital, Department of Pediatric Neurology, Ankara, Turkey.*

Background: Microcephaly with or without chorioretinopathy, lymphedema, or impaired intellectual development (MCLMR, OMIM #152950) is a microcephaly syndrome presenting with variable phenotypic features. The most common clinical findings are mild to severe microcephaly and chorioretinal anomalies. This disorder is caused by variants in *KIF11* (Kinesin Family Member 11, OMIM *148760), located on chromosome 10q23. In this study, we present a patient who was born with microcephaly and received valganciclovir at 2 months of age due to positive CMV serology, but was later found to have a pathogenic *KIF11* variant through molecular analysis at 15 months of age.

Material and Methods: Whole exome sequencing (WES) was performed, as it was not possible to definitively distinguish between congenital and acquired CMV infection.

Results: WES analysis identified a heterozygous c.2548-1G>A splice-affecting variant in the KIF11 gene. The detected variant was classified as "pathogenic" according to the ACMG guidelines and was not reported in healthy population databases.

Conclusion: This case highlights the importance of considering genetic etiologies in patients with congenital microcephaly, even when an initial infectious cause, such as congenital CMV, has been identified.

P11.124.C A novel de novo *KCND2* variant emphasizes the pathogenic relevance of a three aminoacid mutation hotspot

Maria Franaszczyk, *Małgorzata Rydzanicz, Karolina Rutkowska, Agnieszka Pollak, Grażyna Kostrzewa, Anna Walczak, Piotr Stawiński, Rafał Płoski*

Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.

Background: The *KCND2* gene (MIM*605410) encodes the voltage-gated potassium channel Kv4.2, which facilitates transmembrane potassium transport in excitable membranes, primarily within the brain. To date, only 6 pathogenic *KCND2* variants have been reported, all associated with global developmental delay and variants in specific residues in transmembrane segment S6. Symptoms typically manifest within the first six months of life and include hypotonia, seizures/epilepsy, visual impairments, delayed motor development, speech and cognitive deficits, and autism spectrum disorder.

Material and Methods: We performed whole-exome sequencing trio analysis on a 10-month-old male patient. He was delivered via cesarean section with an Apgar score of 9. His early development was unremarkable; however, by three months of age, his parents reported stagnation in developmental progress, loss of previously acquired skills, absence of object grasping, lack of eye contact and visual fixation, and no response to auditory stimuli despite normal hearing test results. A medical evaluation revealed significant axial hypotonia, suspected decreased visual acuity, nonspecific delayed cerebral myelination on MRI, and abnormal sleep architecture with generalized changes on EEG. No epileptic seizures were observed.

Results: WES trio analysis identified a de novo *KCND2* variant, p.(Pro403Thr) (NM_012281.3:c.1207C>A).

Conclusion: All six previously reported pathogenic *KCND2* variants, along with our identified variant, are missense variants affecting amino acids V402, P403, and V404 - a region critical for channel gating. The findings in our patient further support the association between *KCND2* missense variants within this critical region (specifically at amino acids 402–404) and global developmental delay.

P11.125.D MELAS syndrome in Hungary: insights from clinical characteristics and longitudinal follow-up

Idris J. Jimoh[1,2], *Peter Balicza*[1,3], *Aniko Gal*[1], *Maria J. Molnar*[1,3]

[1]*Semmelweis University, Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary,* [2]*Doctoral School of Interdisciplinary Medicine, University of Szeged, Szeged, Hungary,* [3]*HUN-REN Multiomics Neurodegeneration Research Group, Hungarian Research Network, Budapest, Hungary.*

Background: MELAS (Mitochondrial Encephalopathy, Lactic Acidosis, and Stroke-like Episodes) syndrome is a mitochondrial DNA disease characterized by a systemic disturbance in oxidative phosphorylation. The disease exhibits a wide clinical spectrum and significant phenotypic variability, even within families. The estimated global prevalence of m.3243A>G-associated MELAS varies widely (0.2–236/100,000). Diagnostic and therapeutic challenges are compounded by the broad symptom spectrum and the fluctuating nature of the disease.

Material and Methods: We aimed to describe the clinical characteristics of MELAS patients diagnosed with the rare m.3243A>G variant in Hungary. We investigated intrafamilial phenotypic variability, the correlation between heteroplasmy levels and disease onset, and the relationship between symptom progression and patient outcomes. Data were collected from 27 patients (9 males, 18 females) across 17 families. In addition to deep phenotyping and clinical assessment, longitudinal follow-up data from 18 patients were analyzed over a mean period of 5.99 (±4.41) years.

Results: The mean age of symptom onset was 33 (±13.21) years, with five childhood cases. Genetic diagnosis was confirmed in 24 cases using blood-derived DNA and in three using muscle-derived DNA. The mean heteroplasmy rate from blood-derived DNA was 32.46% (±14.69%). The average diagnostic time was 7.15 (±6.61) years. Apart from primary myopathic symptoms, initial manifestations primarily included well-established comorbidities

such as diabetes and hearing impairment, even in patients with heteroplasmy as low as 15%.

Conclusion: Our cohort's phenotypic spectra, combined with clinical data offer valuable insights to refine diagnostic markers, optimize patient pathways, and long-term prognosis.

P12 Neuromuscular Disorders

P12.001.A From Newborn Screening to Functional Insight: *SMN1* VUS studies in zebrafish supported therapeutic decisions

Brunhilde Wirth[1], *Brett W. Stringer*[2], *Yougang Zhang*[2], *Afsaneh Taghipour-Sheshdeh*[2], *Sebastian Zetzsche*[1], *Valentina Piano*[1], *Nico Fuhrmann*[1], *Jutta Becker*[1], *Mert Karakaya*[1], *Shuxiang Goh*[3], *Heike Kölbel*[4], *Michelle Farrar*[5], *Jean Giacomotto*[2]

[1]*Institute of Human Genetics, University of Cologne, Koln, Germany,* [2]*Institute for Biomedicine and Glycomics, School of Environment and Science, Griffith University, Brisbane, Australia,* [3]*Discipline of Paediatrics and Child Health, UNSW Medicine, UNSW Sydney, Kensington, Australia,* [4]*Department of Pediatric Neurology, Centre for Neuromuscular Disorders, University Hospital Essen, Essen, Germany,* [5]*Discipline of Paediatrics and Child Health, UNSW Medicine, UNSW Sydney, Kensington, Australia.*

Background: Newborn screening (NBS) in spinal muscular atrophy is widely implemented, enabling early detection and immediate treatment for newborns with homozygous *SMN1* deletions, providing significant neurological benefits. A PCR-based NBS assay with dried blood spots, identify ~95% of cases by absence of exon 7 *SMN1* signals, confirmed via MLPA testing, which also determines *SMN2* copy numbers critical for therapy. Remaining cases involve subtle *SMN1* mutations undetected by screening, often diagnosed too late for prevention.

Results: This study highlights two newborns from Germany (P1) and Australia (P2), identified as lacking *SMN1* signals via NBS. However, MLPA revealed each had one *SMN1* copy; moreover, P1 had no *SMN2* copies, and P2 had one *SMN2* copy. Sanger sequencing uncovered two novel *SMN1* variants of unknown significance (VUS) in exon 7, resulting in the same frameshift mutation, p.(Arg288Alafs*5). These novel variants caused false-negative PCR results due to primer annealing issues. The Australian Functional Genomics Network supported us in developing a zebrafish assay to functionally analyze these VUS. In vitro-transcribed mRNAs from 861VUS and 855VUS were tested alongside positive and negative controls. Animals lacking *Smn* or expressing a pathogenic variant developed severe malformations and died by 6 day-post-fertilization. Contrary, both VUS mRNAs, like wild-type and a non-pathogenic variant, rescued zebrafish SMA hallmarks, including morphology, swimming ability, and survival. Both children, now one-year-old, remain asymptomatic.

Conclusion: This study validates zebrafish as a tool for VUS analysis, supporting diagnostic and therapeutic decisions in clinical practice. Most importantly, therapeutic costs exceeding US$2 million per child have been avoided.

P12.002.B In vivo modeling and characterization of a novel *SNUPN*-deficiency-associated muscular dystrophy (Award Candidate)

Hilal Pırıl Saraçoğlu[1,2], *Marwan Nashabat*[1,2], *Burak Sarıbaş*[1,2], *Elanur Yılmaz*[2], *Şeymanur Tur*[1,2], *Duygu Naz Kutlu*[2], *Emre Yakşi*[2,3], *Hülya Kayserili*[4,5], *Nasrinsadat Nabavizadeh*[1,2], *Nathalie Escande-Beillard*[1,2]

[1]*Laboratory of Functional Genomics, Department of Medical Genetics, Koç University, School of Medicine (KUSoM), İstanbul, Turkey,* [2]*Koç University Research Center for Translational Medicine (KUTTAM), Koç University, İstanbul, Turkey,* [3]*Kavli Institute for Systems Neuroscience and Centre for Neural Computation, Norwegian University of Science and Technology (NTNU), Trondheim, Norway,* [4]*Department of Medical Genetics, Koç University, School of Medicine (KUSoM), İstanbul, Turkey,* [5]*Genetic Diseases Evaluation Center, Koç University Hospital, İstanbul, Turkey.*

Background: We recently identified *SNUPN* loss-of-function mutations as the genetic cause of a novel form of muscular dystrophy (MD), expanding the spectrum of limb-girdle MDs (MIM#620793). Snurportin-1 (SPN1), the protein encoded by *SNUPN*, is crucial for the nuclear import of spliceosomal small nuclear ribonucleoproteins (snRNPs), yet its physiological role in muscle homeostasis remains poorly understood. To address this, we developed a *snupn* zebrafish mutant model, leveraging the high evolutionary conservation between humans and zebrafish, the absence of *snupn* duplication in zebrafish and more importantly their similar neuromuscular systems.

Material and Methods: *snupn* mutant zebrafish line was generated using CRISPR/Cas9. Validation and characterization were performed via Sanger sequencing, qPCR, immunofluorescence, histology, electron microscopy, confocal imaging, birefringence, and behavioral analyses.

Results: The *snupn* mutant zebrafish line harbours an 8-bp insertion, resulting in a truncated Spn1 protein (p.Ser116Ter) and reduced *snupn* mRNA levels in larvae and muscle tissue. Histological and ultrastructural analyses revealed muscle fibre abnormalities and subcellular organelle alterations. Reduced birefringence and phalloidin staining indicated impaired muscle fiber integrity, correlating with significantly reduced locomotor activity. Additionally, Spn1 mutants showed marked reduction in laminin and β-DAG, consistent with extracellular matrix disorganization observed in patient muscle samples. Further analyses revealed Spn1 is essential for proper muscle fiber differentiation and specification.

Conclusion: The Spn1-deficient zebrafish model faithfully recapitulates the human disorder, providing a valuable tool for investigating disease pathogenesis and developing therapeutic strategies to mitigate muscle defects in patients.

P12.003.C Mutational screening of myopathy gene ACTN2 reveals an aggregation hot-spot in the actin-binding domain (Award Candidate)

Johanna Ranta-aho[1], *Per Harald Jonson*[1], *Jaakko Sarparanta*[1], *Bjarne Udd*[1], *Marco Savarese*[2]

[1]*Folkhälsan Research Center, Helsinki, Finland,* [2]*Folkhalsan Research Center, Helsinki, Finland.*

Background: *ACTN2* encodes alpha-actinin-2, a structural protein expressed in both cardiac and skeletal muscle sarcomeres. The primary function of the protein is to cross-link actin in the sarcomere Z-disk. The gene has a long-standing association with cardiomyopathy, but recently, it has been shown to cause skeletal muscle disease as well. However, with small number of patients and limited understanding of the underlying molecular mechanisms, variant interpretation in *ACTN2*-related diseases is currently challenging.

Material and Methods: One of the few clearly demonstrated disease mechanisms of *ACTN2* is aggregation of mutated protein. Using a cellular model and over 200 GFP-tagged *ACTN2* constructs, we screened for aggregating variants in various domains of the gene.

Results: We found nearly 20 positions with aggregating variants in the actin binding region, more specifically in the interface between its two calponin homology domains. Additionally, a few positions with aggregating variants were identified in the neck region of the protein. In contrast, no aggregating variants were found in the EF34-domain. These results suggest that the interface between the two calponin homology domains of the actin binding region is susceptible to aggregation causing variants.

Conclusion: The results indicate that aggregation screening may be a useful initial test to assess the pathogenicity of variants of uncertain significance in the actin binding region of alpha-actinin-2. This mutational screening study will, together with further functional work characterizing other possible molecular disease mechanisms, ease *ACTN2* variant interpretation.

P12.004.D Exploring morphological and functional biomarkers in iPSC-derived corticospinal motor neurons of infantile-onset ascending hereditary spastic paralysis

Valentina Alari[1], *Giuseppe Chiantia*[2], *Sara Perego*[1], *Alessandra Sironi*[1], *Roberta Battini*[3], *Valeria Capra*[4], *Antonia Gurgone*[2], *Andrea Marcantoni*[2], *Lidia Larizza*[1], *Maurizio Giustetto*[2], *Silvia Russo*[1]

[1]*Cytogenetic and Molecular Genetics Laboratory, IRCCS Istituto Auxologico Italiano, Milano, Italy,* [2]*Department of Neuroscience, University of Torino, Torino, Italy,* [3]*Department of Developmental Neuroscience, IRCCS Stella Maris Foundation, Pisa, Italy,* [4]*Medical Genetics Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy.*

Background: Infantile-onset Ascending Hereditary Spastic Paralysis (IAHSP, #607225) is a rare (<1:100.000) autosomal recessive Motor Neuron Disease (MND) diagnosed in just over 50 children, characterized by severe spasticity of the lower limbs in early childhood, which worsen to tetraplegia, anarthria, dysphagia, and slow eye movements. IAHSP is due to mutations in the ALS2 gene (MIM#606352, 2q33.1) encoding Alsin, a protein mainly expressed in the central nervous system with a key role in cytoskeleton integrity and neurite outgrowth. ALS2 mutations lead to a loss of function of Alsin, resulting in progressive degeneration of upper motor neurons (UMNs). A human in vitro model from ALS2 patients has never been developed.

Material and Methods: Using induced pluripotent stem cell (iPSC) technology, patient-specific neuronal models were created from four IAHSP cases: two unrelated girls with compound heterozygous mutations (NM_020919.3:[c.4368delG];[c.4831C>T] and NM_020919.3:[c.529G>C];[c.3304G>A]), and a pair of siblings with homozygous mutations NM_020919.3:[c.4368delG];[c.4368delG].

Results: IPSC were differentiated into corticospinal motor neurons (CSMN) expressing Ctip2 and Znf312 (V layer markers). IF and Western blot on IAHSP mature neurons revealed a decrease in Alsin expression. Morphological examination of CSMNs showed a reduced average lengths in patient-derived models compared to controls. Electrophysiological analysis of neurons from one IAHSP patient revealed altered excitability. Specifically, current clamp recordings showed reduced input resistance, increased rheobase, and lower firing frequency. Patch-clamp studies are ongoing for the other IAHSP cases.

Conclusion: These findings identify potential biomarkers and therapeutic targets, offering insight into disease mechanisms and paving the way for personalized treatments.

Background: Glutamic-oxaloacetic transaminase (GOT), also known as aspartate aminotransferase, catalyzes the reversible transamination of oxaloacetate and glutamate to aspartate and α-ketoglutarate. Two isoforms, cytosolic (GOT1) and mitochondrial (GOT2), are integral to the malate-aspartate shuttle (MAS), a key regulator of intracellular redox homeostasis. Recently, five patients with bi-allelic variants in GOT2 were described, presenting with developmental and epileptic encephalopathy.

Material and Methods: We report 11 additional patients with homozygous *GOT2* variants, along with additional data from 4 previously reported patients. Through genetic, clinical and biochemical analyses, we further characterize the phenotypic spectrum of GOT2 deficiency.

Results: Most patients exhibited progressive neurodevelopmental delay, severe to profound intellectual disability, infantile epilepsy, progressive microcephaly, and hypotonia evolving into spasticity with axial hypotonia. Dysmorphic features included narrow foreheads, broad nasal tips, and tall or pointed chins. Neuroimaging revealed two severity groups based on cerebral volume loss and myelination defects. Thinning of the corpus callosum and white matter abnormalities were common. Biochemical profiling identified low aspartate and high glycerol-3-phosphate in dried blood spots as potential biomarkers. Patient fibroblast cells showed reduced serine and glycine biosynthesis, rescuable by pyruvate supplementation.

Conclusion: These findings expand the phenotypic spectrum of GOT2 deficiency, establish it as a cause of DEE, and propose novel biomarkers for diagnosis and treatment.

P12.006.B Long-read sequencing reveals the genetic origins of SMA alleles and excludes whole-blood DNA methylation as an epigenetic biomarker

*Maria Zwartkruis[1], Martin Elferink[1], Demi Gommers[1], Joris Kortooms[1], Laura Blasco Perez[2], Mar Costa-Roger[2], Ilaria Signoria[1], Joyce van der Sel[1], Paul Hop[1], Ramona Zwamborn[1], Ivo Renkens[1], Robin Geene[1], Jared Green[1], Carlo Vermeulen[1], Roy Straver[1], Hanneke van Deutekom[1], Wouter van Rheenen[1], Jan Veldink[1], Fay-Lynn Asselman[1], Eduardo Tizzano[3], Renske Wadman[1], Ludo van der Pol[1], **Gijs van Haaften**[1], Ewout Groen[1]*

[1]UMC Utrecht, Utrecht, Netherlands, [2]Vall d'Hebron Research Institute (VHIR), Barcelona, Spain, [3]HOSPITAL VALL D'HEBRON, Barcelona, Spain.

Background: The complex 2 Mb SMN locus on chromosome 5q13, containing the SMA-causing SMN1 gene and its modifier SMN2, remains unresolved due to segmental duplications. SMN2 copy number, influenced by SMN1-to-SMN2 gene conversion, impacts disease severity but lacks sufficient prognostic value. With newborn screening and SMN-targeted therapies, identifying genetic markers for disease progression and treatment response is critical. SMN2 DNA methylation has been proposed as such biomarker, but methodological limitations have hindered progress.

Material and Methods: We developed HapSMA, a polyploid phasing method for SMN locus analysis, enabling copy-specific assessment of genetic variation and DNA methylation using long-read sequencing. We applied HapSMA on publicly available nanopore sequencing data of 29 healthy controls and performed long-read, targeted nanopore sequencing of the *SMN* locus of 31 patients with SMA. Differential DNA methylation was validated in 365 SMA patients using targeted bisulfite sequencing.

Results: In healthy controls, we identified SMN1- and SMN2-specific SNVs as potential gene conversion markers. Broad phasing including the *NAIP* gene improved our view of *SMN* locus variation. Genetic variation in *SMN2* haplotypes was larger in SMA patients. 42% of *SMN2* haplotypes of SMA patients showed varying *SMN1* to *SMN2* gene conversion breakpoints, serving as direct evidence of gene conversion as a common genetic characteristic in SMA. However, SMN2 DNA methylation showed no correlation with disease severity or treatment response, excluding blood methylation patterns as predictive biomarkers.

Conclusion: Our findings highlight the need for methodological advancements and patient-based analyses to resolve complex genetic loci and address critical clinical challenges in SMA.

Background: Pathogenic variants in the mitochondrial aspartyl-tRNA synthetase 2 (*DARS2*) gene are known to cause leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL). Here we report five individuals from three unrelated families with recessively inherited variants in *DARS2* presenting as isolated axonal Charcot-Marie-Tooth (CMT) phenotype.

Material and Methods: We retrospectively collected clinical information of all individuals and performed functional studies on three affected persons.

Results: All individuals exhibited progressive distal muscle weakness with onset in childhood and absent lower limb deep tendon reflexes. Electrophysiological studies supported an axonal motor and sensory neuropathy. Two pairs of adult siblings had normal cognitive functions, whereas the fifth patient presented with speech delay, moderate intellectual disability, and generalized epilepsy with onset at age eleven. Brain MRI scans showed no white matter abnormalities or elevated lactate in any of the patients. Whole exome sequencing identified compound heterozygous variants in *DARS2* gene (NM_018122.5) across all families (c.713C>T; p.Ser238Phe and c.1006C>T; p.Arg336Cys in family 1; c.74del; p.Ile25Thrfs*38 and c.713C>T; p.Ser238Phe in family 2; and c.492+2T>C and c.1508C>T p.Pro503Leu in family 3). Functional analysis demonstrated reduced DARS2 protein activity (25% for the missense c.1508C>T variant) and altered mitochondrial localization, accompanied by disrupted mitochondrial network morphology. Muscle biopsy from patient five showed marked fibrosis, fatty tissue infiltration, numerous groups of atrophic muscle fibers, and uniformity of type 2 fibers.

Conclusion: We describe a new phenotype of mostly pure axonal CMT in five individuals from three unrelated families, associated with recessively inherited variants in the *DARS2* gene.

P12.008.D Identification of differential expressed serum microRNAs as potential biomarkers for myotonic dystrophy type 1 and facioscapulohumeral muscular dystrophy

***Yunjung Choi**, Soo-Hyun Kim, Hyung Jun Park*

Department of Neurology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of.

Background: Myotonic dystrophy type 1 (DM1) and facioscapulohumeral muscular dystrophy (FSHD) are common adult-onset muscular dystrophies characterized by progressive muscle weakness. Given their prevalence, reliable and easily accessible biomarkers are needed for accurate diagnosis. Recent studies suggest disease-specific microRNAs (miRNAs) expression patterns, which may provide insights into disease pathogenesis and novel diagnostic strategies. This study aims to identify potential miRNA biomarkers through comparative expression analysis in healthy controls, DM1, and FSHD groups.

Material and Methods: Small RNA was extracted from serum using the miRNeasy Serum/Plasma Kit, and library were prepared and sequencing was performed on the Illumina Nextseq2000 platform with 100-bp paired-end reads. Differential expression analysis was conducted using the CLC Genomics Workbench 25.0, modeling read counts with a Negative Binominal distribution. Differentially expressed miRNAs were identified based on an False Discovery Rate (FDR)-adjusted p-value (<0.05) and an absolute | log2(fold change)|≥1.

Results: A total of 93 serum samples, including 22 controls, 34 DM1, and 37 FSHD1 patients, were analyzed for differential mRNA expression. In the DM1 group, 30 miRNAs were significantly differentially expressed, with hsa-miR-1306-5p, hsa-miR-483-3p, and hsa-miR-885-5p demonstrated the most notable changes (FDR < 0.05) after applying a Counts Per Million (CPM) threshold of >10. In the FSHD1 group, 16 miRNAs initially met the criteria for differential expression, with 13 retained after filtering. While none reached FDR, hsa-miR-4307, hsa-miR-206, and hsa-miR-133a-3p exhibited substantial upregulation in FSHD patients compared to controls.

Conclusion: This study identifies showed distinct serum miRNA expression profiles in DM1 and FSHD1 and identified hsa-miR-1306-5p, hsa-miR-483-3p, and hsa-miR-885-5p as potential biomarkers for DM1.

Background: Despite its often characteristic clinical phenotype, diagnosing FSHD remains challenging, with approximately 5% of cases lacking a molecular genetic diagnosis. Distinct methylation profiles have been identified as key biomarkers reflecting the complex genetic basis of FSHD, offering improvements in genetic diagnostics.

Material and Methods: We analysed the methylation profiles of over 150 patients using a bisulfite assay and identified 12 cases that would have received a false-positive or false-negative diagnosis using standard diagnostic methods. To achieve a comprehensive characterization of the genetic and epigenetic parameters, we further examined these 12 patients, along with 8

additional FSHD2 cases, using Nanopore long-read sequencing. This method enabled simultaneous analysis of allelic haplotypes, repeat units (RUs), methylation profiles, single nucleotide variants, structural variations and hybrid alleles.

Results: We identified 10 patients who would have received a false-negative diagnosis using standard diagnostics. These individuals carried either a grey zone allele of 11 RUs or no detectable variant in known epigenetic suppressor genes, despite presenting with global hypomethylation associated with FSHD2. One patient exhibited characteristics of both FSHD1 and FSHD2, while another patient was excluded from an FSHD diagnosis due to the presence of a non-permissive hybrid allele.

Conclusion: Our results reinforce the value of methylation profiling as the most precise biomarker for FSHD diagnostics and suggests the existence of additional unknown factors acting as methylation modifiers. Integrating genetic with epigenetic data using long-read sequencing improves diagnostic accuracy and broadens our understanding of the underlying pathomechanisms of FSHD.

Background: Variants in the TTN gene have been identified in over 25% of all cases of dilated cardiomyopathy, and biallelic TTN truncating variants (TTNtv) are among the most prevalent causes of myopathies. Approximately 1 in 20 individuals carries a rare missense TTN variant (MAF <1%), and the TTN protein has over 600,000 possible amino acid alterations. Nearly all these are currently classified as variants of uncertain significance.

Material and Methods: Patients' clinical and genetic data were collected from various international hospitals. The study includes preliminary in-vitro experimental evidence on selected missense variants. We cloned the sequences encoding wild type (WT) and variant titin domains into a vector for eukaryotic cell expression with an N-terminal GFP-tag. Transfected COS-7 cells were cultured for 2 days, fixed, and then analyzed.

Results: In an overall analysis, we calculated that 33% of all variants absent in GnomAD and 64% of all possible proline substitutions are predicted likely pathogenic by AlphaMissense (score > 0.5). We then identified 15 myopathy patients with a TTNtv in trans with a missense variant. For each missense variant, we assessed pathogenicity score with AlphaMissense, minor allele frequency (MAF) from GnomAD, and the nature of the amino acid substitution. In selected cases of proline substitutions located in beta-strands, experimental results showed an aggregated appearance of the mutated domain.

Conclusion: This study identified likely pathogenic TTN missense variants, highlighting the destabilizing effect of proline substitutions in beta-strand domains. It also offered initial insights into genotype-phenotype correlations in these underinvestigated forms of recessive titinopathies.

P12.011.C From genomes to phenomes: Discovering *DMPK* repeat expansions in Genomics England for future PheWAS

Rezbieara Rahman, *Elijah Behr, Marta Futema, Emma Matthews*

City, St George's University of London, London, United Kingdom.

Background: Myotonic Dystrophy Type 1 (DM1) is an autosomal dominant disorder caused by CTG repeat expansions in the *DMPK* gene. Typically, healthy individuals have 5–37 repeats; those with premutation alleles (38–49 repeats) may be asymptomatic, carry the risk of intergenerational expansion. Pathogenic expansions (>50 repeats) lead to DM1's multisystemic symptoms. Despite well-established clinical features, the population-level impact of *DMPK* expansions, particularly across different genetic ancestries, remains underexplored. Leveraging the Genomics England (GEL) data, we aim to (1) identify and classify *DMPK* expansions, (2) analyse repeat length distributions across ancestries, and (3) establish a genotype-phenotype database linking individuals to Human Phenotype Ontology (HPO) terms. Thus, laying the groundwork for a future phenome-wide association study (PheWAS) utilising this data, representing the first application of an HPO-based PheWAS in a DM1 context.

Material and Methods: We analysed 80,110 GEL whole-genome sequencing samples for *DMPK* expansions using Expansion Hunter, categorising participants into normal (<37 repeats), premutation (38–49 repeats), and pathogenic (>50 repeats) cohorts. Statistical analyses assessed ancestry-based patterns in repeat distributions.

Results: Among 80,110 genomes, we identified 78 participants with pathogenic expansions, 183 with premutation alleles, and 79,849 with normal repeat lengths. Significant ancestry-based differences were observed in comparisons between pathogenic

vs. normal cohorts ($p = 0.038$) and normal vs. premutation cohorts ($p = 0.003$), $p < 0.05$.

Conclusion: This study identified significant ancestry-related differences in *DMPK* expansions with a robust HPO-linked database being developed to support the planned PheWAS. Thus, paving the way for the first HPO-based PheWAS investigating pleiotropic effects of *DMPK* expansions, broadening our understanding of DM1 across populations.

Background: Structural variants in the nebulin gene (*NEB*) are an established cause of recessive nemaline myopathies and related neuromuscular disorders. We present data from 35 families with muscle disorders caused by *NEB* intragenic structural variants, including 18 previously unpublished cases.

Material and Methods: Our cohort consists of 35 families; of these, 12 families have dominantly inherited *NEB*-related distal myopathy phenotypes (10 unpublished) caused by large deletions, and 23 families have recessively inherited myopathies caused by pathogenic gains of the *NEB* triplicate region ($n = 12$, 5 unpublished) or other structural variants ($n = 11$, 3 unpublished) either in a homozygous or compound heterozygous state. Variants were detected using exome or genome sequencing, Droplet Digital PCR, or custom Comparative Genomic Hybridization arrays. Sanger sequencing was used to validate breakpoints in applicable cases.

Results: In families affected by dominant distal myopathy phenotypes, we identified eight unique *NEB* deletions encompassing 51 to 97 exons in heterozygous ($n = 10$) or mosaic ($n = 2$) state. Among the recessive cases, no correlation was observed between the type of variant and the disease severity.

Conclusion: We establish a statistically significant association between large *NEB* deletions and a dominant form of *NEB*-related distal myopathy ($p < 0.001$). Additionally, we provide the most comprehensive overview to date of the spectra of structural variants in *NEB*.

P12.013.A Mutational Spectrum of Hereditary transthyretin-mediated amyloidosis-hATTR in Italian population: results from the Genilam Project

Carla Proserpio, *alessandro Diotallevi, Debora Belperio, Simon Brizi, Elena D'Angelosante, Silvia Antonelli, Martina Di Lullo, Ettore Cotroneo, Rossella Falcone, valeria cacciafesta, Laura Gigante*

Eurofins Genoma, Rome, Italy.

Background: Hereditary transthyretin-mediated amyloidosis-hATTR, caused by heterozygous variant in the transthyretin (TTR) gene, is a potentially life-threatening condition for which targeted therapies dramatically changed the prognosis. Highly variable clinical presentation makes hATTR a diagnostic challenge because of subclinical and non-specific presentation. Since 2019, Italian clinical centres were offered the possibility of TTR testing in the project Genilam

Material and Methods: We retrospectively evaluated results for samples analysed between June 2019 and December 2023. DNA was obtained by buccal swab; TTR testing was performed by Sanger sequencing of exons 2, 3 and 4. TAT: 15 working days.

Results: A total of 7536 samples from >200 specialized medical centres were tested. A total of 372 patients (372/7536; 4.93%) tested positive, including 3 compound heterozygous and 2 homozygous. The most common amyloidogenic variants were Phe84Leu (130/372; 32.3%), Val50Met (80/372; 19.8%), Ile88Leu (68/372; 16.9%), Val142Ile (40/372; 9.9%), Glu109Gln (31/372; 7.7%). Non-amyloidogenic variants were also identified (His110Asn: 17/372, 4.5%; Arg124Cys: 3/372, 0.80%; Ala129Thr: 1/372, 0.26%; Thr139Met: 7/372, 1.88%). Most patients identified as positive were male (220/372; 59.1%). Number of positive results for each region was evaluated according to both location of referring center (RC) and place of birth (PoB). Three regions showed the highest incidence for both parameters: Sicilia (25.5% RC; 26.9% PoB), Lazio (24.5% RC, 18.5% PoB), and Puglia (10.8% RC, 13.2% PoB).

Conclusion: Genilam project allowed rapid diagnosis improving management timely identifying affected individual. The project will also redefine the spectrum of variants in Italy allowing for improvement of genotype phenotype correlation

P12.014.B Detecting distant relatedness between ALS patients to facilitate gene discovery

Daphne van Oosten[1], *Polina Merbaum*[1], *Bi-nan Wang*[1], *Sophie Plasmans*[1], *Floor Munnik*[1], *Project MinE ALS sequencing consortium*[2], *Wouter van Rheenen*[1], *Jan Veldink*[1]

[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]

Background: Amyotrophic lateral sclerosis (ALS) is fatal neurodegenerative disease. The search for underlying pathogenic variants is ongoing. The construction of so-called superpedigrees, extended families with multiple distantly related ALS patients, is highly valuable for the detection of low-frequency genetic variants with large effect but moderate penetrance. Here, we explore bioinformatic pipelines that detect distant relatedness between individuals from genetic data.

Materials and Methods: We applied the methods (TRIBES[1], DRUID[2] and GRAPE[3]) to a dataset of 3,842 Dutch ALS cases and controls from Project MinE, and compared them based on speed, scalability, usability and ability to identify clusters of related individuals.

Results: GRAPE was the most computationally efficient workflow, whereas TRIBES was the most sensitive. All methods detected significantly more relationships (up to the sixth degree) between individuals with the *C9orf72* repeat expansion than would be expected by chance. Furthermore, network analyses revealed higher clustering of ALS patients compared to controls, validating the accuracy of the approach. We discovered three extended pedigrees: 1) linked familial ALS cases with an unresolved pathogenic variant, partially previously found by genealogy; 2) interconnected sporadic ALS cases from an isolated village in the Netherlands; 3) a *C9orf72* positive family with two *C9orf72* positive sporadic ALS cases not previously linked to the family. Unresolved pedigrees are prime targets for haplotype and linkage analysis.

Conclusion: Our findings suggest that the reconstruction of extended superpedigrees through the application of these methods, validated by traditional genealogy, is a promising approach for identifying new ALS risk genes.

P12.015.C Rapid *SMN1* and *SMN2* copy number analysis by digital PCR (dPCR) in 6 hours to facilitate neonatal SMA therapy treatment

Cheryl K. Walsh*, Katrina Newland, Nicholas Silver, Shu Yau*

Synnovis, London, United Kingdom.

Background: Spinal Muscular Atrophy (SMA) is a neuromuscular disorder that affects ~1 in 100,000 live births with ~94% having a homozygous deletion of *SMN1* exon 7. Molecular diagnosis is complicated by the presence of a pseudogene, *SMN2*. Recently, treatments including gene therapy have become available which can improve these patients' outcome but as neurodegeneration occurs at ~34 weeks *in utero*, rapid diagnosis is critical. To facilitate this, we have developed and validated two dPCR assays.

Material and Methods: Two multiplex dPCR assays (A & B) were developed using the same primers and probes for *SMN1* and *SMN2* exon 7 and controls, *RPPH1* and *TERT;* but using different fluorescent dyes for the probes. 71 DNA samples extracted from a variety of tissues and with 0–4 copies of *SMN1* and 0–5 copies of *SMN2*, determined by MLPA, were tested.

Results: 69 of 71 samples with dPCR gave the same genotypes as MLPA analysis. The two discordant samples had a MLPA *SMN2* copy number call of 4/5 and 5, but dPCR (A & B) *SMN2* calls of 5 and 4, respectively. Further testing of these samples are underway. 34 samples were retested using both assays generating the same genotypes, demonstrating the assay's reproducibility. The same genotypes were obtained using final DNA concentrations from 0.3 to 2 ng/µL, defining the limit of detection.

Conclusion: We have designed and validated two dPCR assays for the rapid and accurate diagnosis of SMA patients, enabling them to have earlier access to treatment, significantly affecting their quality of life.

P12.016.D Expanding the *FDXR*-associated disease phenotype and defining the underlining disease mechanisms

Silvia Sabeni[1], *Sara Carli*[1], *Luigi Monti*[2], *Ilaria Pettenuzzo*[3], *Daniele Frattini*[4], *Gaia Tioli*[5], *Luisa Iommarini*[5], *Flavia Palombo*[1], *Chiara La Morgia*[6], *Caterina Garone, Professoressa associata*[1]

[1]*Department of Medical and Surgical Sciences, Alma Mater Studiorum University of Bologna, Bologna, Italy,* [2]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [3]*UOC Neuropsichiatria dell'età pediatrica, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy,* [4]*Child Neurology*

and Psychiatry Unit, Pediatric Neurophysiology Laboratory, Mother and Child Department, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [5]Department of Pharmacy and Biotechnology (FABIT), University of Bologna, Bologna, Italy, [6]Programma di Neurogenetica, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy.

Background: Ferredoxin reductase (*FDXR*) is a mitochondrial flavoprotein crucial for iron-sulfur cluster (ISC) and heme biosynthesis, initiating the electron transport chain (ETC) by transferring electrons from NADPH to cytochrome P450 system. Mutations in *FDXR* cause a rare recessive neurological disorder, characterized by visual and hearing impairment, with onset in first or second decade of life. Disease severity varies, with some cases exhibiting debilitating neurological symptoms. However, the mechanisms underlying the clinical manifestations remain unclear. Here, we investigate clinical, molecular and biochemical data of two patients with novel *FDXR* mutations.

Material and Methods: Patient-derived fibroblasts were used for molecular and functional analysis.

Results: Patient 1 (P.1) presents severe retinal degeneration, acute pancerebellar syndrome, and red-cone dystrophy with no optic atrophy. Patient 2 (P.2) developed progressive visual disturbances with optic atrophy, nystagmus, and mild sensorineural deafness at 16 years. Sanger sequencing revealed an unreported homozygous variant, c.1472G>A (p.R491Q), in P.1 and two compound heterozygous variants, c.1231G>A (p.D411N) and c.1A>G (p.M1V), in P.2. Mitochondrial copy number was increased in *FDXR* patients' fibroblast cell lines. Both P.1 and P.2 showed reduced FDXR steady-state protein levels. In P.2, levels of ETC ISC-containing subunits as Ndufs1 and SDHB were decreased, while oxidative stress-related proteins, Aconitase-2 and SOD2, were dysregulated in both patients. Additionally, P.2 exhibited significant impairment in oxygen consumption rate, with reduced basal and maximal respiration.

Conclusion: Our findings confirm the presence of deleterious oxidative stress in two patients with novel *FDXR* mutations. Future studies will elucidate the pathogenic mechanisms and explore potential therapeutic strategies.

P12.018.B Aminoacyl-tRNA synthetase defects in Charcot-Marie-Tooth (CMT) disease

Angelica Moresco[1,2], *Sarah D P Wilhelm*[3], *Andee Qiao*[4], *Victoria Mok Siu*[1,2], *Ilka Heinemann*[3,2]

[1]*Division of Medical Genetics, Department of Paediatrics, The University of Western Ontario, London, ON, Canada,* [2]*Children's Health Research Institute, London, ON, Canada,* [3]*Department of Biochemistry, The University of Western Ontario, London, ON, Canada,* [4]*Schulich School of Medicine & Dentistry, Western University, London, ON, Canada.*

Background: Charcot-Marie-Tooth (CMT) disease, affecting 1 in 2500 individuals globally, is characterized by progressive peripheral neuropathy. CMT presents significant phenotypic and genetic heterogeneity, with over 150 implicated genes including seven aminoacyl-tRNA synthetases (aaRS) associated with autosomal dominant CMT type 2. These enzymes are essential for protein synthesis by charging tRNA with cognate amino acids. Advancements in genome sequencing have uncovered numerous aaRS variants, often classified as variants of uncertain significance (VUS). We investigated aaRS variants to characterize their pathogenicity and potential response to amino acid supplementation.

Material and Methods: We studied patients with peripheral polyneuropathy and aaRS variants, including two patients with HARS1 variants: p.Y138H (patient 1) and p.L400F (patient 2), initially classified as VUS. Humanized yeast models and biochemical assays were used to assess variant pathogenicity and amino acid supplementation efficacy.

Results: Both patients presented with peripheral polyneuropathy and non-classical symptoms including burning sensations and weakness in the neck, arms, and legs, with exhaustion exacerbated by febrile episodes and exposure to high ambient temperatures. Humanized HARS1 yeast models and biochemical analyses revealed deficient protein dimerization and growth defects, supporting their pathogenicity. Histidine supplementation showed mild but significant improvement for p.Y138H but reduced growth for p.L400F; alternative therapeutic approaches are currently being evaluated for this variant.

Conclusion: Understanding the molecular mechanisms of aaRS variants in CMT is crucial for characterizing VUS pathogenicity and developing targeted therapies. As demonstrated with these HARS1 variants, different alleles may require different therapeutic interventions for advancing personalized treatments.

P12.019.C Family-based gene discoveries in ALS: comprehensive literature review and analysis of Dutch familial ALS cohort

Bi-nan Wang[1], *Rick A.A. van der Spek*[1], *Justus D.A.M. van Nispen tot Sevenaer*[1], *Fabienne L. Kick*[1], *Joke J.F.A. van Vugt*[1], *Mark K. Bakker*[1], *Project MinE ALS Sequencing Consortium*[2], *Leonard H. van den Berg*[1], *Wouter van Rheenen*[1], *Jan H. Veldink*[1]

[1]*University Medical Centre Utrecht, Utrecht, Netherlands,* [2]

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease showing marked locus heterogeneity in familial cases. Family-based studies have been crucial in identifying ALS-associated genes.[1] The recent approval of Tofersen as a treatment for SOD1-linked ALS underscores the significance of elucidating the complete genetic architecture of familial ALS (FALS).[2,3]

Methods: We compiled ALS-associated genes from family-based studies and screened variants in WGS data from FALS cases in our national biobank up to March 2024. Variants were annotated using ANNOVAR, incorporating gnomAD, ClinVar, and refGene data. We excluded non-coding and synonymous variants, and those with MAF $>1.0 \times 10^{-4}$ in Non-Finnish Europeans. Using adapted ACMG guidelines[4–6], we classified variants and assessed pedigrees to identify those with a causal variant.

Results: We analysed 111 pedigrees, including 140 cases, predominantly with ALS (89.3%). Other diagnoses included primary lateral sclerosis, progressive muscular atrophy, and segmental spinal muscular atrophy. We detected C9orf72 repeat expansions and explored SNVs in 38 genes across the cohort. 63 pedigrees (57%) were resolved, with 52 having C9orf72 as the sole causal variant. Other causal genes included TARDBP (5/111), CHCHD10 (1/111), FUS (1/111), SOD1 (1/111), and TBK1 (1/111). Two pedigrees had multiple causal variants: C9orf72 and NEK1 in one, C9orf72 and TARDBP in the other. Among the unresolved pedigrees, 44 had no identifiable causal variant, while 4 contained VUS.

Conclusion: Most pedigrees were resolved, while a causal locus remains unidentified in over 40%. WGS of extended pedigrees where familial and sporadic branches may be connected could help uncover new causative loci.

P12.020.D Prevalence of Late-Onset Pompe Disease-causing variants in the UK Biobank

Delia Gagliardi[1,2], *Chiara Villella*[3], *Stefania Corti*[3,4], *Giacomo Comi*[3,1], *Arianna Tucci*[5,6], *Henry Houlden*[2,7], *Dario Ronchi*[3,1]

[1]*IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, Milan, Italy,* [2]*Department of Neuromuscular Diseases, Institute of Neurology, University College London, London, United Kingdom,* [3]*University of Milan, Dino Ferrari Center, Milan, Italy,* [4]*IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Neuromuscular Unit, Milan, Italy,* [5]*William Harvey Research Institute, Queen Mary University of London, London, United Kingdom,* [6]*Department of Neurodegenerative Disease, UCL Queen Square Institute of Neurology, London, United Kingdom,* [7]*Neurogenetics Unit, National Hospital for Neurology and Neurosurgery, London, United Kingdom.*

Background: Pompe disease (PD), is a disorder due to biallelic pathogenic variants in *GAA*, resulting in the enzymatic deficiency of alpha-1,4-glucosidase. Two clinical forms are recognized: early- (EOPD) and late-onset (LOPD). LOPD manifestation is heterogenous with variable degrees of severity and progression rate. Some LOPD patients remain asymptomatic for decades. The estimate of incidence is around 1/40,000 overall (3/4 as LOPD and 1/4 as EOPD). We aimed to determine the prevalence of LOPD disease in UK Biobank.

Material and Methods: We sought GAA gene variants in exome sequencing data from 470 000 individuals aged 40 years or older). We focused on variants previously established as pathogenetic in the GAA variant database at Erasmus MC in Rotterdam and on Class 4 or 5 variants (ACMG guidelines).

Results: The common variant IVS1-32-13T>G (IVS1) displayed a carrier frequency of 1.3%. 17 subjects were found homozygous for IVS1. 74 subjects presented IVS1 and a second pathogenetic defect with (n = 15) or without (n = 59) conclusive demonstration of pathogenicity: less than 10% of them presented clinical symptoms compatible with LOPD. Additional 8 subjects harbored two (non IVS1) coding variants, reported with a mild-to-moderate pathogenic burden. If biallelic inheritance was proven, the genetic prevalence of LOPD-causing variants in UK Biobank is 1/4700.

Conclusion: The genetic prevalence of LOPD likely exceeds traditional and recent (1/18000, newborn screening programs) estimates. Genotypes observed are likely not associated with a severe course of the disease. Nevertheless, given the existence of therapeutic options, an in-depth follow up of these subjects is advised.

Background: *RYR1*-related diseases are a group of rare genetic disorders caused by variants in *RYR1*, which encodes the ryanodine receptor 1 (RyR1). These manifest as a spectrum of neuromuscular conditions, including well-known phenotypes such as central core disease, multiminicore disease, and malignant hyperthermia susceptibility, as well as viral infection- and exercise-induced hyperCKemia. The study aims to explore the genetic and clinical features of *RYR1*-related diseases in a cohort of affected individuals.

Material and Methods: Seventeen patients (ages 0–69 years) from 16 unrelated families were referred for Whole exome sequencing (WES) due to variable clinical presentations, ranging from asymptomatic hyperCKemia and recurrent rhabdomyolysis episodes to severe muscle weakness. Clinical, genetic, and histopathological data were assessed to allow phenotype-genotype correlations.

Results: Twenty-four, of which 7 novel, distinct pathogenic/likely pathogenic *RYR1* variants were identified, most of them missense, following both autosomal dominant (AD) and autosomal recessive (AR) inheritance. In 3 out of 16 patients with congenital myopathy the previously associated with malignant hyperthermia, c.[4711A>G;10097G>A;11798A>G] haplotype was detected in compound heterozygosity. In five patients, muscle biopsies were available and revealed "Central core" pathology (n = 2), centronuclear pathology (n = 1), congenital fiber-type disproportion (CFTD) (n = 1) and predominance of type I muscle fibers (n = 1) which were concordant with molecular diagnosis.

Conclusion: Identification of seven novel pathogenic *RYR1* variants, further expands the genetic and phenotypic spectrum of *RYR1*-related diseases highlighting the broad genetic heterogeneity and the association between specific variants and clinical phenotypes.

P12.023.C Parallel analysis of repeat expansions: an updated Clin-CATS workflow for nanopore R10 flow cells

Maria Schoedel[1], *Veronika Scholz*[1], *Veronika Schönrock*[1], *Hannes Erdmann*[1,2], *Vitus Prokosch*[1], *Veronika Mayer*[1], *Eva Breithausen*[1], *Inga van Buren*[1], *Christine Dineiger*[1], *Manuela Almus*[1], *Mayra Sauer*[1], *Madeline Golibrzuch*[1], *Minerva Cristina Montero Hernández*[1,3], *Annette Lischka*[4], *Katja Eggermann*[4], *Caroline Heintz*[1], *Ariane Hallermayr*[1,5], *Teresa Neuhann*[1], *Elke Holinski-Feder*[1,5], *Angela Abicht*[1,2], *Anna Benet-Pagès*[1,6], *Morghan C. Lucas*[1,2,5]

[1]MGZ - Medical Genetics Center, Munich, Germany, [2]Friedrich-Baur-Institute, Department of Neurology, Klinikum der Universität, Ludwig-Maximilians-Universität, Munich, Germany, [3]Laboratorio de Genética Médica, Instituto de Biomedicina (IB), Facultad de Medicina de Albacete, Universidad de Castilla-La Mancha (UCLM), Albacente, Spain, [4]University Hospital RWTH Aachen, Institute for Human Genetics and Genomic Medicine, Aachen, Germany, [5]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München Campus Innenstadt, Munich, Germany, [6]Institute of Neurogenomics, Helmholtz Zentrum München GmbH - German Research Center for Environmental Health, Munich, Germany.

Background: Hereditary ataxias caused by short tandem repeat (STR) expansions are difficult to diagnose with conventional PCR and Southern blot methods, which fail to detect complex expansions, repeat interruptions, and methylation. Long-read sequencing, particularly Oxford Nanopore Technologies (ONT) platforms, provides a viable alternative but requires workflow adaptation.

Material and Methods: We present an updated Clinical Nanopore Cas9-Targeted Sequencing (Clin-CATS) workflow optimized for R10 flow cells. The workflow integrates the ONT wf-human-variation pipeline with Straglr for repeat expansion analysis. The number of analyzed genes was expanded from 10 to 27, introducing new panels for neurological disorders. Validation was performed using Coriell reference and clinical samples, and multiplexing, use of Flongle flowcells, and single-gene targeting were assessed.

Results: Protocol modifications achieved an average coverage of 222× across all targets, compared to 439× with R9 flowcells. Mean read quality improved from 15.3 (R9) to 16.5 (R10), reaching 17.5 in Coriell samples. Multiplexed sequencing with 2, 4, and 6 samples yielded only 3–5× coverage and Flongle flowcells 3.2×, failing to meet the 50× diagnostic threshold. Single-gene targeting performed comparably to full-panel sequencing. Integration of Straglr improves repeat expansion analysis and ensures compatibility with all sequencing chemistries as it relies on basecalled data.

Conclusion: The updated Clin-CATS workflow improves diagnostic utility for STR-associated disorders. Although coverage is reduced compared to R9, the updated workflow meets the required diagnostic thresholds and improves repeat expansion detection overall.

Background: Bi-allelic variants in Sigma Nonopioid Intracellular Receptor 1 (*SIGMAR1*) have been associated with distal hereditary motor neuropathy (dHMN) and juvenile amyotrophic lateral sclerosis. Current understanding is based on case reports and small series. We evaluated genotype-phenotype correlations in individuals with biallelic *SIGMAR1* variants.

Material and Methods: Through exome sequencing and international data sharing, we identified 16 affected individuals from 15 families. Phenotypic and genetic data from these cases and available data from previously reported cases were analyzed.

Results: Seventy-seven patients from 37 families were included in the study. Seven novel and eight recurrent *SIGMAR1* variants were identified, including nine missense, four frameshift, and two nonsense changes. Most patients exhibited a uniform phenotype of symmetrical distal weakness, with varying degrees of pyramidal features. Exceptions included three individuals with asymmetrical muscle weakness or atrophy. The disease manifested in the first or early second decade of life, except in three patients harboring different biallelic variants. Lower extremity symptoms preceded upper extremity involvement by an average of 4.8 ± 4.1 years. The mean age was 28.6 ± 18.5 years at the last clinical assessment. Patients remained ambulatory (with or without support) for a mean disease duration of 15.6 ± 11.3 years. Distal weakness were universally observed, while proximal weakness occurred in 7 out of 37 patients with available clinical data. Notably, bulbar features, respiratory dysfunction, and sensory signs were absent in all patients.

Conclusion: This study expands the genotypic spectrum and characterizes the phenotypic presentation of *SIGMAR1*-related dHMN, highlighting its consistent clinical features.

P12.025.A Latin-SEQ: a collaborative network to provide genetic diagnosis to patients with neuromuscular diseases in Latin-America

Ana Topf[1], *Alejandro Gonzalez-Chamorro*[1], *Leonela Luce*[1], *Joel Mannion*[1], *Steven Laurie*[2], *Anastasios Papakonstantinou Ntalis*[2], *Jordi Diaz-Manera*[1], *Latin-SEQ Consortium*[3]

[1]JWMDRC, Newcastle, United Kingdom, [2]CNAG, Barcelona, Spain, [3]

NGS has revolutionized the diagnostic process of patients with neuromuscular diseases (NMDs). However, access to these technologies in less developed regions, such as Latin American countries is highly limited, leaving patient without a diagnosis and therefore no proper counselling, management, or access to therapies or trials. We created a consortium of specialised centers with the objective of providing undiagnosed NMD patients a much-needed opportunity for genetic testing. We will also study disease prevalence, region-specific genotype-phenotype correlation, founder mutations, and novel causative genes.

Results: The Latin-SEQ consortium was stablished and currently comprises >60 centers from 18 countries in Latin America. Biomaterial from NMD patients and their family members is recruited locally and processed and biobanked in Newcastle, currently totally 1230 samples. Detailed phenotypic data is collected in an HPO-based clinical database. Proband-only exome sequencing is performed and the data analysed through the Genome Phenome Analysis Platform. Genetic variants are classified following ACMG guidelines, and individual cases discussed in patient-centered MDT meetings to reach an expert-level consensus. A total of 350 exomes have been so far analysed with a diagnostic yield of 38%. A novel candidate gene has already been identified in the Latin-SEQ cohort. Analysis continues.

Conclusions: After numerous administrative and logistic challenges, the Latin-SEQ consortium continues to grow. The phenotype-driven screening pipeline allowed a diagnosis of ~40% of cases, eight of whom will start life-changing treatment soon. The consortium has also created an international framework for further collaborative research in the region to obtain much needed genetic and epidemiological data.

P12.026.B Abstract ESHG 2025 A multi-omics approach to study monozygotic twins discordant for amyotrophic lateral sclerosis

Martina Tosi[1], *Francesco Favero*[2], *Miriam Zuccalà*[1], *Endri Visha, PhD Student*[1], *Nadia Barizzone*[1], *Nicola Pomella*[1], *Laura Follia*[1], *Lucia Corrado*[1], *Davide Corà*[2], *Loredana Martignetti*[3,4,5], *Maurizio Leone*[6], *Sandra D'Alfonso*[1]

[1]*Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy,* [2]*Center for Translational Research on Allergic and Autoimmune Diseases (CAAD), Università del Piemonte Orientale, Novara, Italy,* [3]*Institut Curie, Université PSL, Paris, France,* [4]*INSERM, U900, Paris, France,* [5]*Mines ParisTech, Université PSL, Paris, France,* [6]*Scientific Direction, Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.*

Background: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder characterized by motor neuron degeneration. The majority of ALS cases are sporadic, while 10% are familial: part of heritability remains unexplained, suggesting the involvement of other genetic and epigenetic factors.

Material and Methods: We used a multi-omics approach in a pair of Italian monozygotic twins discordant for ALS, integrating genome-wide DNA methylation, bulk transcriptomics and whole exome sequencing. Furthermore, we performed a systematic review of the literature on monozygotic twins and sALS, to highlight possible general disease mechanisms.

Results: No pathogenetic variants were observed among twins. Conversely, transcriptomic analysis identified 42 differentially expressed genes (p.adj < 0.1; |log2FC|>1). Functional analyses on DEGs (Metascape) revealed the involvement of adaptive and innate immune system pathways. Moreover, epigenetic analysis identified 250 differentially methylated probes (p.adj < 0.05; $|\Delta\beta| < 0.06$) and 17 regions (padj < 0.05), and enrichment analysis highlighted the involvement of brain related terms. A late integration of the three omics data revealed no shared gene. Notably, we analyzed for the first time the results of all literature studies on discordant ALS twins (45 twins from 6 studies) and of 9 studies on 7046 sALS and 3110 controls, and compared literature data to ours. We confirmed the involvement of immune system and brain related terms, suggesting shared pathogenetic mechanisms across ALS cases.

Conclusion: results obtained by applying a multi-omics approach to a small, well-characterized cohort were confirmed on a higher number of ALS subjects, providing pathological insights into ALS with a focus on neurodegenerative and immune-related processes.

P12.027.C Duchenne muscular dystrophy and delandistrogene moxeparvovec gene therapy in children: a systematic review and meta-analysis

Breno Bopp Antonello[1], ***Sara Hadj Sadok***[2], *Laura Grespan Dill*[3], *Anna Luiza Braga Albuquerque*[4], *Giovanna Giovacchini*[5], *Paulo Victor Zattar Ribeiro*[6]

[1]*Franciscan University, Santa Maria, Brazil,* [2]*Hospital Universitari Joan XXIII/Hospital Vall d'Hebrón, Barcelona, Spain,* [3]*Federal University of Santa Maria, Santa Maria, Brazil,* [4]*Federal University of Minas Gerais, Belo Horizonte, Brazil,* [5]*ABC Medical College, Santo André, Brazil,* [6]*University of São Paulo, Ribeirão Preto, Brazil.*

Background: Duchenne muscular dystrophy (DMD) is a progressive neuromuscular disorder caused by mutations in the *DMD* gene, leading to the absence of functional dystrophin. This results in muscle degeneration, loss of ambulation, respiratory failure, and reduced life expectancy. Current treatments, including corticosteroids and supportive care, offer limited long-term benefits. Delandistrogene Moxeparvovec is a promising gene therapy designed to restore dystrophin expression. This systematic review and meta-analysis assess its efficacy in ambulatory pediatric patients with DMD.

Methods: We searched Cochrane, PubMed, and Embase (January 2025) for RCTs and cohort studies evaluating Delandistrogene Moxeparvovec in ambulatory male children (≥4 to <8 years) with DMD. Primary outcomes included NSAA score changes, 10-meter Walk/Run (10 MWR), and Time To Rise (TTR). Study selection, data extraction, and quality assessment followed PRISMA guidelines. Statistical analyses were performed using R software (Version 4.2.3). PROSPERO registration: CRD42025635605.

Results: We included 276 patients from three studies (two RCTs). Follow-up ranged from 48 to 52 weeks. All had confirmed *DMD* mutations (exons 18–79) and received corticosteroids for ≥12 weeks. Delandistrogene Moxeparvovec (1.33×10^{14} vg/kg) was given to 104 patients; 174 were in placebo or external control groups. TTR improved significantly (MD: −0.85s, 95% CI: −1.23 to −0.47, P < 0.01). NSAA (MD: 1.52, P = 0.06) and 10 MWR (MD: −0.27s, P = 0.57) showed no statistical significance.

Conclusion: Delandistrogene Moxeparvovec may improve functional outcomes in DMD patients aged ≥4 to <8 years. Therefore, Delandistrogene Moxeparvovec may be a therapeutic

option for patients with DMD. However, further RCTs with longer follow-ups are needed to confirm long-term efficacy.

P12.028.D Assessment of an explainable AI model for variant classification in neuromuscular disorders

Laura Martinez Gomez[1], *Nooshin Bayat, PhD*[1], *Raul Valin*[1], *Kristina Ibañez*[1], *Rajiv Sangle*[2], *Abe Shuya*[3], *Fuji Masaru*[3], *Serban Georgescu*[4]

[1]*Fujitsu Research of Europe Limited Sucursal en España, Madrid, Spain,* [2]*Fujitsu Research of India, Bangalore, India,* [3]*Fujitsu Laboratory, Fujitsu Ltd, Kawasaki, Japan,* [4]*Fujitsu Research of Europe Limited, Slough, United Kingdom.*

Background: Neuromuscular disorders (NMDs) are a diverse group of inherited conditions caused by genetic mutations, many of which remain classified as Variants of Uncertain Significance (VUS). This classification creates significant challenges in providing patients with a definitive genetic diagnosis. Reclassifying these variants using up-to-date evidence is essential to improve diagnostic outcomes. In recent years, artificial intelligence (AI) has emerged as a promising approach for tackling this challenge. Here, we evaluate the performance of an AI-based meta-predictor designed to classify novel NMD variants with high accuracy.

Material and Methods: The meta-predictor [1] was trained on ClinVar 2023 data. The variants selected for evaluation have been described in a multi-national study [2], consisting of 33 variants with clear clinical significance for testing and 34 VUS to explore potential reclassifications. Notably, 95% of these variants were absent from ClinVar, making this a challenging benchmark for assessing the tool's accuracy. ACMG guideline-based classifications done by experts have been used as the ground truth for validation [2].

Results: The AI model accurately classified 90% of the pathogenic variants in the test dataset. It also provided reclassifications for 86% of VUS, suggesting that many of these variants may eventually achieve clinical significance as more evidence becomes available.

Conclusion: This study demonstrates the effectiveness of an AI-based meta-predictor for classifying different types of variants associated with NMDs. By addressing the challenges of VUS, our tool shows promise for improving genetic diagnostics and supporting clinical decision-making. Continued validation will be important to ensure its broader application in real-world settings.

P12.029.A Using patient-derived iPSC lines for calpainopathy research and therapy development

Janis Stavusis[1], *Karina Goluba*[1], *Inna Inashkina*[2], *Vadims Parfejevs*[1], *Baiba Lace*[3,1], *Una Riekstina*[1]

[1]*Department of Pharmaceutical Sciences, Faculty of Medicine and Life Sciences, University of Latvia, Riga, Latvia,* [2]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [3]*Riga East Clinical University Hospital, Riga, Latvia.*

Background: Calpainopathy is a progressive autosomal recessive limb-girdle muscular dystrophy (LGMDR1) caused by calpain 3 (*CAPN3*) gene variants. We previously identified a hypomorphic intronic variant, c.1746-20C>G, common in Latvia (MAF 0.24) and other Eastern European countries, classified as having conflicting interpretations of pathogenicity. We showed it causes aberrant splicing, likely due to a disrupted branch point, and contributes to disease phenotype when in a compound heterozygous state with another pathogenic variant in the gene.

Materials and Methods: Fibroblasts from patient skin biopsies were transduced with Sendai virus to generate iPSC clones. Colonies were screened for virus clearance, and pluripotency was assessed via marker expression and trilineage differentiation (immunofluorescence, TaqMan hPSC scorecard). Genetic stability was evaluated using CMA assay and G-banded karyotyping. STR profiling was conducted on both iPSCs and the original fibroblasts. iPSCs were differentiated using the appropriate differentiation media and validated through marker expression.

Results: Three patient-specific iPSC lines were established, exhibiting PSC-like morphology and expressing Oct-4, Nanog, Sox2, SSEA-4, and Tra-1-60. Trilineage differentiation potential was confirmed, and STR analysis verified the identity of iPSCs. All lines showed genetic stability at p.11 and were successfully differentiated into myoblasts and myotubes. The cell lines are registered in the hPSCreg registry.

Conclusion: These cell lines provide a valuable in vitro model to study calpainopathy-affected muscles, offering an animal-free platform for future investigations of disease mechanisms and therapeutic strategies, including muscle-on-chip approaches.

P12.031.C A Machine Learning approach to investigate digenic inheritance in Amyotrophic Lateral Sclerosis using Whole Genome Data

Benedetta Bartilomo[1], *Fjorilda Caushi*[1], *Maurizio Grassano*[2], *Alessio Bottrighi*[3], *Nicola Pomella*[1], *Davide Cerotti*[3], *Marzio Pennisi*[3], *Anna Sapienza*[3], *Mirko Lai*[3], *Salvatore Vilella*[3], *Fabiola De Marchi*[4], *Susanna Zucca*[5], *Federica De Paoli*[5], *Andrea Calvo*[2], *Rosario Vasta*[2], *Umberto Manera*[2], *Cristina Moglia*[2], *Maura Brunetti*[2], *Antonia Follenzi*[1], *Patrizia Bossolasco*[6], *Lucia Corrado*[1], *Letizia Mazzini*[4], *Antonia Ratti*[6], *Adriano Chio*[2], *Sandra D'Alfonso*[1]

Background: In 85% of ALS (Amyotrophic Lateral Sclerosis) cases the genetic cause is unknown. Oligogenic/digenic inheritance can explain the ALS missing heritability since 1–13% of cases carry two pathogenic variants in ALS genes.

Aim: To investigate the role of oligogenic/digenic inheritance in ALS using Machine Learning (ML) tools, either with in-house developed pipeline or utilizing DIVAs tool (Engenome s.r.l.), on WGS data.

Methods: From a pilot cohort of WGS from 60 patients, we used DIVAs to predict digenic gene pairs through an unbiased genome-wide investigation, assigning them a pathogenicity score ranging from 0 to 1. Moreover, we developed a semi-automatic pipeline for digenic data analysis with VarCoPP-HOP software through which we compared the DIVAs data of the pilot cohort and perform a discovery analysis prioritizing gene pairs from a larger WGS cohort of 4,090 ALS patients and 775 controls.

Results: In the pilot study using DIVAs we prioritized digenic combinations with a score higher than 0.6 and predicted to be Variants of Unknown Significance (VUS), Likely Pathogenic (LP) or Pathogenic (P). As an example, we found enriched heterozygous missense LP variants in *SPG7*, causative of autosomal recessive Spastic Paraplegia 7, paired with VUS in ALS genes, namely *TBK1* and *SQSTM1* gene. These digenic combinations were priotitized either by DIVAs and VarCoPP-HOP tools. The discovery analysis with VarCoPP-HOP on the larger case-control WGS is ongoing.

Conclusions: We successfully implemented a workflow capable of selecting digenic pairs from WGS data whose demostration on the involvement in ALS pathogenesis requires replication in a large cohort.

Background: Bethlem myopathy (BM) is the mild end of the spectrum of diseases caused by molecular alterations in *COL6A1*, *COL6A2*, *COL6A3* or *COL12A1*. Here, we present a three-generation familial case of BM, where six affected members presented childhood onset of symptoms, slow progressive proximal muscle weakness of upper and lower limbs, joint contractures, difficulty walking, and a typical collagenopathy CT pattern.

Material and Methods: A proband's DNA sample was initially analysed by whole exome sequencing, but no variants were identified in the *COL6* and *COL12* genes. Exome data was re-analysed applying a pipeline for copy number and structural variants as part of the Solve-RD project. Candidate variants were segregated. Collagen6 immunostaining and RNAseq was performed on proband's fibroblasts.

Results: Re-analysis of exome data detected a large heterozygous insertion in exon 10 of *COL6A2*. It was characterised as a ~321 bp insertion between positions c.989_990 (hg19:chr21:47536717), 10 bp before the 3' end of exon 10. The presence of a target site duplication and the conserved A5TACA6 motif indicate that the inserted sequence stems from an ALU element. The insertion co-segregates with the presence of clinical symptoms, being absent in non-affected family members. RNAseq analysis identified an alternative transcript lacking exon 10, leading to an in-frame deletion. Proband's fibroblast showed a collagen6 immunostaining pattern similar to BM control.

Conclusion: We confirmed the clinical diagnosis of BM by the insertion of an ALU element in COL6A2. To our knowledge, this constitutes the first report of a COL6-related myopathy caused by an ALU mobile element.

Binaghi Hospital, Local Public Health and Social Care Unit (ASSL), Cagliari, Italy,* [5]*University of Sassari, Department of Biomedical Sciences, Sassari, Italy,* [6]*University of Cagliari, Department of Medical Sciences and Public Health, Cagliari, Italy.*

Background: Hereditary peripheral neuropathies (HPN) comprise a heterogeneous group of disorders that cause progressive degeneration of peripheral nerves. Genetic testing is the gold standard for diagnosis, although many families remain unresolved. The genetic homogeneity of the Sardinian population reduces the overall heterogeneity. However, it makes interpreting the results more difficult due to a high prevalence of variants of uncertain significance (VUS), which do not have a well-defined framework for classification.

Material and Methods: We performed WES on 50 unrelated Sardinian patients with a confirmed or suspected diagnosis of HPN.

Results: Following filtering and classification, WES identified significant bi-allelic variants in two distinct patients in the PXN and MFN2, respectively. Heterozygous variants in the MME and MPZ genes associated with Charcot-Marie-Tooth neuropathy were also detected. Notably, we observed heterozygous variants in voltage-gated sodium channel (VGSC) genes, including SCN9A, SCN1A, and SCN4A, suggesting their potential role in phenotype as well as pain modulation. In one family with negative WES results, we identified a bi-allelic AAGGG repeat expansion in the RFC1 gene in three affected siblings. In the remaining 21 families, we detected VUS in potentially causative genes, whose pathogenic relevance will need to be clarified through in silico analysis and/or functional studies.

Conclusion: A reverse phenotyping approach aids in reassessing variant significance based on emerging clinical features, refining atypical phenotypes and VUS classification. In Sardinia, overcoming diagnostic challenges necessitates advanced in silico analyses, cellular studies, comprehensive phenotyping, and integrated genomic techniques like long-read and RNA sequencing, ultimately enhancing diagnosis and personalised medicine.

P12.034.B Comprehensive molecular characterization of eight families with FSHD2

Darya Sherstyukova, *Aysylu Murtazina, Anna Kuchina, MD, Alexandra Filatova, Daria Akimova, Dmitrii Subbotin, Valentina Yakushina, Nikita Beskorovainiy, Maria Orlova, Olga Shatokhina, Shchagina Olga, Mikhail Skoblov, Head of the Department*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Facioscapulohumeral muscular dystrophy type 2 (FSHD2) represents about 5% of all FSHD cases, highlighting its rarity and clinical significance. The complex digenic pathogenesis of this condition poses significant challenges for both research and diagnostics.

Material and Methods: The clinical presentation of the patients was evaluated through physical examination, including the use of the FSHD-CCEF. The lengths and haplotypes of D4Z4 4q alleles were determined using a qPCR-based approach. Pathogenic variants in chromatin modifier genes were identified through WES/WGS. DNA methylation was analyzed using bisulfite conversion assays with PCR targeting three loci (4qAS, 4qAL, and DUX4), followed by deep sequencing. RT-PCR analysis for splicing variants was performed on cDNA derived from PBMCs of heterozygous probands and healthy controls.

Results: From 357 individuals in the Russian FSHD Patient Registry, we identified 8 probands lacking a contracted permissive 4qA allele. Genetic analyses of these probands revealed various variants in the *SMCHD1* gene, including missense, nonsense, splicing, deep intronic variants, and one extended deletion. Comprehensive molecular analysis was performed on 6 probands and their available healthy and affected relatives (11 individuals). In one family, the diagnosis of FSHD2 was excluded based on the collective data. In three distinct families, the analysis unequivocally confirmed the diagnosis of FSHD2. Two families exhibited ambiguous methylation values, complicating the diagnosis of FSHD2. Certain analyses remain pending for two families (8 individuals).

Conclusion: In total, we studied 8 families by comprehensive FSHD diagnostic approach, revealing better understanding of the connections between molecular data, clinical presentation, and disease prognosis.

Background/Objectives: Autosomal recessive limb-girdle muscular dystrophy type R28 (LGMDR28; OMIM #620375) is a recently identified subtype of limb-girdle muscular dystrophy with 15 individuals from six unrelated families carrying biallelic variants in the *HMGCR* gene reported to date. Here, we describe 10 individuals from five unrelated Middle Eastern families diagnosed with LGMDR28, all carrying homozygous *HMGCR* variants.

Methods: Using genome and exome sequencing, we identified the *HMGCR* variants. The family members were screened by Sanger sequencing.

Results: Beyond the previously characterized clinical features of LGMDR28, we report congenital onset in two unrelated families and liver failure in three affected individuals. Because of the new disease association, *HMGCR* is rarely included in panel tests. Using genome and exome sequencing, we identified two novel homozygous missense variants, c.2519G>A p.(Arg840Gln) and c.1784G>A, p.(Arg595His); and a homozygous in-frame deletion (c.1522_1524del, p.(Ser508del)) that has been previously reported in a compound heterozygous state with a second HMGCR variant.

Conclusion: Our findings strengthen the evidence for the pathogenic role of *HMGCR* variants and expand the phenotypic spectrum of LGMDR28.

Background: Primary muscle disorders are clinically and genetically heterogeneous. The achievement of a reliable molecular diagnosis can improve clinical management, provides appropriate genetic counseling and testing of relatives, and enables potential therapeutic options. We reviewed the molecular findings obtained by using diagnostic next generation sequencing protocols at Dino Ferrari Center.

Material and Methods: In the last 5 years, 230 patients with the suspect of primary muscle disease underwent NGS-based molecular testing consisting of i) custom targeted gene panels (n = 84) or ii) clinical exome sequencing (n = 146) followed by diagnostic interpretation of variants in genes associated with matched clinical phenotypes.

Results: Disease-causing variants were identified in 82 patients (36%: definitive diagnosis). Furthermore, likely pathogenic variants and/or variants of uncertain significance were found in 34 additional probands (15%: probable diagnosis). Diagnostic yield of the two approaches was similar (50.0% versus 50.7%). This rate tends to increase in patients affected with muscular dystrophies (54%) and congenital myopathies (61%) while it falls to 33% in patients with a suspect of metabolic myopathy. The simultaneous analysis of two affected members from the same family facilitated the establishment of a diagnosis (88%). Muscle biopsy was available for 143 patients (47% presenting a positive genetic reports) and resulted crucial for the interpretation of uncertain results.

Conclusion: Clinical exome sequencing allowed the analysis of additional OMIM genes leading to unexpected diagnosis or the enlargement of the clinical spectrum of known disease-related genes. Whole exome sequencing contributed to identify 3 novel disease genes in the last two years.

Medicine, Umeå University, Umea, Sweden, [43]Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology, London, United Kingdom.

Background: TTR amyloidosis is caused by mutations in the TTR gene, leading to misfolded proteins forming toxic amyloid deposits in the peripheral nerves and heart. There is striking variability across countries and within single families on age-of-onset (AOO) and clinical features, which cannot be entirely explained by the specific gene variant. Therefore, a contribution of additional genetic factors has been hypothesized. This work aimed at identifying genetic modifiers of AOO by a genome-wide association (GWA) approach.

Material and Methods: DNA from ATTRv patients was been genotyped by Infinium TM Global Clinical Research Array-24v1.0 (Illumina, standard backbone of ~1,204,769 SNPs) customized with ~3,000 additional SNPs. Demographic and clinical variables were collected through a standardized form by all participating centres.

Results: 2441 ATTRv patients were enrolled from 38 centres, including 1604 symptomatic individuals. 910 carried a common Val50Met mutation, while 694 carried a different pathogenic variant in TTR gene. 64 percent of patients were males (1024/1604) with Caucasian ancestry (1283/1546, 83%). Median AOO was 56.5 ± 15.1 years, (range 18–87 years). 1403 DNA samples have been already genotyped and 1313 passed quality control (call rate 0.95). A preliminary analysis on 1000 samples did not disclose any GWA significant locus associated with variable AOO outside TTR locus itself, but additional analyses on the entire cohort are ongoing.

Conclusion: These are the baseline features of the largest ATTRv cohort, including different ethnicities, mutations and AOO. Ongoing GWA analyses will aim at identifying genetic modifiers of the onset and phenotype of these highly heterogeneous conditions.

[1]*Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [2]*CENTOGENE GmbH, Rostock, Germany,* [3]*Department of Neurology, King Abdulaziz Medical City, Ministry of National Guard-Health Affairs, Riyadh, Saudi Arabia,* [4]*University of Milan, Department of Pathophysiology and Transplantation (DEPT), Neuroscience Section, Dino Ferrari Centre, Milan, Italy,* [5]*Istituto Italiano di Tecnologia, Genoa, Italy,* [6]*Neuroscience Center, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia,* [7]*Department of Translational Genomics, Genomic Medicine Centre of Excellence (GMCOE), King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia,* [8]*Lifera Omics, Riyadh, Saudi Arabia,* [9]*Genetics and Precision Medicine Department, King Abdullah Specialized Children Hospital (KASCH), King Abdulaziz Medical City, Ministry of National Guard Health Affairs (MNGHA), Riyadh, Saudi Arabia,* [10]*King Saud Bin AbdulAziz University, Health Science, Riyadh, Saudi Arabia,* [11]*King Abdullah International Medical Research Center, Riyadh, Saudi Arabia.*

Background: Non-dystrophic myotonias include several autosomal dominant or recessive skeletal muscle channelopathies. Myotonia congenita is the most common and is caused by pathogenic variants in the *CLCN1* gene. Pathogenic variants induce the hyperexcitability of skeletal muscle fibers and cause myotonia. Genomes evolve and acquire new functions using different mechanisms, one of these is retrotransposition. Processed pseudogenes are transposable elements derived from the retrotransposition of mRNAs that insert into the genome contributing to its plasticity.

Material and Methods: Genetic diagnosis of non-dystrophic myotonias is usually achieved by targeted gene sequencing or whole exome sequencing. Using genome sequencing and a synergistic application of bioinformatic tools, we analyzed myotonic patients from 5 Saudi families in which standard genetic analysis did not reveal the genetic cause of myotonia.

Results: A deep intronic homozygous insertion located in intron 14 of the *CLCN1* gene was detected in the probands. Analysis of the inserted sequence revealed that it was a novel transmissible processed pseudogene, originating from the *UQCRH* gene. Its sequence presented all the typical features of these transposable elements: sequence similar to the parent gene, lack of all or most introns, presence of a poly-A tail and target site duplications at both ends. Patients with the pseudogene insertion showed a common haplotype suggesting a founder effect in the Saudi population.

Conclusion: The insertion of this non-reference processed pseudogene into intron 14 of *CLCN1* is likely a novel pathogenetic mechanism causing Becker recessive myotonia congenita that is not detected by conventional genetic testing.

Background: Duchenne muscular dystrophy (DMD) is an X-linked disorder caused by mutations in the *DMD* gene, 11% of which are duplications. Exon 2 duplication (Dup2) is the most common, typically associated with a severe phenotype.

Materials and Methods: Whole Genome Sequencing was performed on DNA from 21 DMD Dup2 patients, by Illumina DNA-PCR-Free-Prep-Kit and NovaSeq6000 platform. Full-length *DMD* isoforms transcriptional profile was evaluated in 12 DMD Dup2 muscle biopsies using 2100Bioanalyzer-High-Sensitivity-DNA-Kit.

Results: Genomic analysis showed that 20 of the Dup2 rearrangements were *in-tandem*, while 1 was anti-oriented. In 16 Dup2 cases, the 5' duplication breakpoint was in Purkinje intron 1, while in 5 cases it was in muscle intron 1. In 11 Dup2 rearrangements, breakpoints at the 5' or 3' ends were clustered, suggesting a potentially unstable genomic region. Transcriptional analysis revealed four splicing variants, of which the most represented was the exon 2 duplicated *out-of-frame* transcript. This splicing variant was driven by both brain (B) and muscle promoters in *in-tandem* Dup2. Notably and differently the main anti-oriented Dup2 transcript skipped both exons 2. Interestingly, 7 muscles revealed a moderate increase in B isoform expression, while one muscle displayed 51% of *wild-type* B transcript amount. The Purkinje isoform was undetectable in both DMD and control muscles.

Conclusion: All rearrangements are private and likely result from non-homologous-DNA-repair mechanisms. Transcription profile points out a possible role of *DMD* promoters in determining Dup2 splicing choices. This study enhances understanding of Dup2's impact on the *DMD* transcriptional pattern and may suggest new therapeutic strategies.

P12.040.D Search for the causes of Duchenne/Becker muscular dystrophy in Russian patients without molecular diagnosis using whole genome sequencing

Elena Zinina, *Maria Bulakh, Oksana Ryzhkova, Olga Shchagina, Alexander Polyakov*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: It is estimated that approximately 2–6% of cases Duchenne/Becker muscular dystrophy (DMD/BMD) are caused by complex structural rearrangements or deep intronic changes that are undetectable by routine diagnostic tests.

Material and Methods: WGS was performed on 16 unrelated Russian probands. The main inclusion criteria are an increase in the level of creatine phosphokinase (>6000 U/l), an established clinical diagnosis DMD/BMD, absence of molecular cause of the disease in previous conducted studies: MLPA and custom NGS panel

Results: In 81.2% (13/16) of patients, the cause of the disease was found. Variants in the *DMD* gene were detected in 53.8% (7/13): 2 probands had duplications missed earlier during diagnosis, 3 had pathogenic deep intron variants, 1 patient had a pericentric inversion of the chromosome X segment with a breakpoint in intron 7 of the *DMD* gene, and 1 patient had a balanced translocation between chromosomes 1 and X with a breakpoint in intron 48. In 46.2% (6/13), pathogenic variants in other genes responsible for muscular dystrophies were identified: *TK2, MICU1, SGCA, DYSF, ACTN2*.

Conclusion: This study showed an expansion of the diagnostic capabilities of muscular dystrophy using whole genome sequencing. Identification of pathogenic variants in the *DMD* gene is important in the aspect of application of etiotropic therapy.

P12.041.A Etiology of a CHKB-deficient mouse model of muscular dystrophy: A platform for gene therapy development

M. Tavasoli[1], *M. Alkandari*[1], *E. Hoffman*[2], *C. McMaster*[1];

[1]*Dalhousie University, Halifax, NS, Canada,* [2]*Binghamton University, Binghamton, NY*

Background: Megaconial congenital muscular dystrophy (OMIM: 602541) is an autosomal recessive disorder caused by CHKB variants resulting in decreased choline-kinase-β activity, a key enzyme in phosphatidylcholine (PC) biosynthesis via the Kennedy pathway. Patients present with congenital or adolescent-onset limb-girdle muscular dystrophy, with some developing dilated cardiomyopathy and intellectual disability. Understanding disease pathogenesis and developing effective therapies require robust preclinical models.

Results: We investigated Chkb−/− mice as a disease model and therapeutic testing platform. Despite Chkb deficiency, PC levels

remained stable, while significant lipid metabolic disruptions occurred. Affected muscles exhibited impaired mitochondrial β-oxidation, leading to fatty-acyl-carnitine accumulation and subsequent fatty acid shunting into triacylglycerol and storage as lipid droplets. This metabolic shift correlated with reduced Ppar signaling. Ppar agonists restored fatty acid utilization, prevented triacylglycerol buildup, and upregulated Chka, a compensatory choline kinase isoform, in Chkb −/− myoblasts in vitro. Muscle integrity analysis showed an intact dystrophin-glycoprotein complex but disruption of the vinculin-talin-integrin system due to a-actinin detachment, impairing actin-sarcolemma connectivity. Choline kinase inhibition in U2OS cells induced PI(4,5)P2 internalization and reduced vinculin localization, reversible by Chkb overexpression. Chkb−/− mice exhibited cardiac hypertrophy, reduced left ventricular size, and arrhythmia susceptibility, mirroring patient phenotypes. Lipidomic analysis of heterozygous and homozygous Chkb−/− hearts identified elevated acylcarnitine, a known arrhythmogenic factor.

Conclusion: The Chkb−/− mouse recapitulates key aspects of CHKB-mediated muscular dystrophy and cardiac dysfunction, providing novel mechanistic insights into how defective PC synthesis drives disease pathology. These findings establish Chkb−/− mice as a valuable preclinical platform for developing therapeutic interventions for CHKB-mediated muscular dystrophy

P12.042.B Genetic Findings in Over 500 Individuals Tested with a Spastic Paraplegia Gene Panel

Uxia Saraiva Esperon Moldes, *Allison Sluyters, Kirsi Alakurtti, Mònica Segura Castell, Åsa Hagström, Heli Kuisma, Eija Seppälä, Kim Gall, Mikko Muona, Inka Saarinen, Lotta Koskinen, Pertteli Salmenperä, Samuel Myllykangas, Juha Koskenvuo*

Blueprint Genetics, Espoo, Finland.

Background: Hereditary spastic paraplegia (HSP) is genetically heterogenous, with over 80 types identified to date. Despite the increasing knowledge, few studies have evaluated the yield of broad genetic testing in a large heterogenous cohort. We evaluated the yield of genetic testing in a cohort of individuals with suspected HSP.

Material and Methods: We performed a retrospective review of findings in a gene panel which included sequencing and copy number variant (CNV) analysis of up to 75 nuclear genes associated with spastic paraplegia.

Results: A total of 533 individuals underwent testing and 28.3% of them received an informative result. Adults were significantly more likely to receive a diagnostic result. Disease causing variants were reported in 25 different genes. Autosomal dominant inheritance was observed in 67.5% of the individuals, autosomal recessive inheritance in 29.1% and X-linked recessive inheritance in 3.3%. *SPAST* was the most frequent autosomal dominant gene and 17% of the variants in this gene were CNVs. *ABCD1* and *PLP1* accounted for all the X-linked cases. Variants in *CTNNB1*, *PAH*, and *C19orf12* were only seen in individuals tested at age 17 or younger. Overall, 11.3% of cases involved a CNV and non-coding variants contributed to <1% of informative results.

Conclusion: An informative result was received in approximately 28% of individuals. Adults were more likely to be given an informative result. Variants in *SPAST, SPG7*, and *SPG11* were the most common, in line with previous reports. The frequency of *SPAST* variants in autosomal dominant HSP cases was higher than previously reported.

P12.043.C Identification, characterization and segregation analysis of DM1 alleles containing non-CTG variant repeats (VRs) in a two-generation Italian family

Virginia Veronica Visconti[1], *Maria Rosaria D'Apice*[1], *Federica Centofanti*[1], *Marco Carlomagno*[2], *Simone Maestri*[2], *Alfonso Esposito*[2], *Marzia Rossato*[2,3], *Massimo Delledonne*[2,3], *Mariangela Goglia*[1], *Giulia Greco*[1], *Erika Frezza*[1], *Roberto Massa*[1], *Annalisa Botta*[1], *Giuseppe Novelli*[1,4,5]

[1]*University of Rome "Tor Vergata", Rome, Italy,* [2]*University of Verona, Verona, Italy,* [3]*Genartis, Castel D'azzano, Italy,* [4]*Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Neuromed, Pozzilli, Italy,* [5]*University of Nevada, Reno, NV, USA.*

Background: Myotonic dystrophy type 1 (DM1) is an autosomal dominant multisystemic disease caused by a CTG repeat expansion in the 3′-UTR of *DMPK* gene. In the last years, an increasing proportion of DM1 alleles containing non-CTG variant repeats (VRs) have been identified, with still unclear molecular and clinical consequences. In this study, we analyzed a two-generation DM1 Italian family of DM1 patients carrying VRs in relation to phenotype, transmission and the methylation level of the DM1 locus.

Material and Methods: DM1 patients have been deeply analysed to assess DM1 mutation and phenotypes. VRs were characterized by a combination of TP-PCR, LR-PCR, Sanger and PacBio long-read sequencing (LRS).

Results: The two-generation family is composed by two brothers and their respective asymptomatic daughters carrying *DMPK* expanded alleles with VRs at 3′ end of the CTG expansion. The expanded alleles of the two daughters (248 CTG and 298 CTG) were fully sequenced and showed 4–5.3% of VRs consisting of CCGCTGCTG and CCG motifs. LRS sequencing is now ongoing to characterize the entire DM1 locus in both fathers (669 CTG and 729 CTG) also carrying CCGCTG and CCG motifs. A decrease in the methylation levels downstream of the CTG repeat tract has been observed across generations (from 26–38% to 8–17%), consistently with a contraction of paternally derived DM1 expansions.

Conclusion: Understanding the genetic and epigenetic variabilities of *DMPK* expanded alleles containing VRs in DM1 patients could implement clinical phenotype stratification and genotype-phenotype correlations, representing a useful tool in the DM1 genetic testing and counselling.

P12.044.D Unraveling the complexity of mitochondrial DNA disorders: insights into Primary Mitochondrial Myopathies

Alberto Pietro Pasti[1], *Claudio Fiorini*[1], *Andrea Legati*[2], *Danara Ormanbekova*[1], *Marco Barresi*[2], *Rossella Izzo*[2], *Michele Todisco*[1], *Santino Blando*[1], *Francesco Casadei*[1], *Nadia Zanetti*[2], *Eleonora Lamantea*[2], *Maria Lucia Valentino*[1,3], *Costanza Lamperti*[2], *Chiara La Morgia*[1,3], *Valerio Carelli*[1,3], *Daniele Ghezzi*[4,5], *Leonardo Caporali*[1]

[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy, [2]IRCCS Istituto Neurologico Carlo Besta, Milan, Italy, [3]Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna, Bologna, Italy, [4]Foundation IRCCS Neurological Institute, Milano, Italy, [5]Department of Pathophysiology and Transplantation (DEPT), University of Milan, Milan, Italy.

Background: A complex spectrum of phenotypes is associated with the plethora of mitochondrial DNA (mtDNA) pathogenic variants, going from isolated optic neuropathies to severe systemic encephalomyopathies. Among those, primary mitochondrial myopathies (PMM) are a relevant disease for both children and adults, affecting an average of approximately 5.5 in 100,000 people across Europe. The mtDNA variants leading to a PMM phenotype can be both SNVs and large somatic deletions/duplications. Moreover, a subset of the MM patients shows multiple deletions/duplications due to nuclear genes defects encoding enzymes of the mtDNA replisome.

Material and Methods: We analysed mtDNA from skeletal muscle biopsies derived from 100 patients with suspected mitochondrial dysfunction, through NGS sequencing at high coverage depth. We detected SNVs using the MutServe suite and large deletions/duplications with the MitoSAlt tool.

Results: We were able to identify several novel and already described pathogenic variants, located in both coding genes and tRNA sequences of mtDNA, as well as single and multiple macro-rearrangements. As expected, the most common genetic defects in our cohort are the m.3243A>G/*MT-TL1* and the single somatic deletions of mtDNA. This analysis also allowed us to assess the diagnostic yield of mtDNA sequencing across the cohort. Noteworthy, an increased yield is then achieved through analysis of WES or WGS in these patients.

Conclusion: Given their primarily mitochondrial etiology, we emphasize the outmost importance of in-depth analysis of mtDNA on the target tissue of PMM, especially using recent NGS approaches that can precisely define even the structural variants.

P13 Multiple Malformation/Anomalies Syndromes

P13.001.A A distinct de novo frameshift variant in the last exon of *SATB1* causes Hyper-IgM syndrome with a neurodevelopmental phenotype (Award Candidate)

Yasmin Hamzavi-Abedi[1], ***Elke de Boer***[2], *Joery den Hoed*[3], *Maud Tusseau*[4], *Sandra von Hardenberg*[5], *Mathieu Fusaro*[6], *Caspar I. van der Made*[2], *Ulrich Baumann*[5], *Vincent Barlogis*[7], *Nicolas Chatron*[4], *Alexander Hoischen*[2], *Lisenka E.L.M. Vissers*[2], *Vincent R. Bonagura*[8]

[1]AllerVie Health, Fairfax, VA, USA, [2]Radboudumc, Nijmegen, Netherlands, [3]Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands, [4]Hospices Civils de Lyon, Lyon, France, [5]Hannover Medical School, Hannover, Germany, [6]Centre Hospitalier Universitaire de Toulouse, Toulouse, France, [7]University of Lyon - Université Claude Bernard Lyon 1, Lyon, France, [8]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY, USA.

Background: Hyperimmunoglobulin M (HIGM) syndrome includes rare primary immunodeficiencies, characterized by defective class-switch recombination. This leads to normal or increased serum IgM, reduced or absent levels of IgG, IgA, IgE, and recurrent sinopulmonary infections. In approximately 25% of individuals the genetic cause remains unknown. SATB1 is a transcription factor that causes two overlapping neurodevelopmental disorders (NDD) through distinct pathophysiological mechanisms. In addition to neurodevelopment, SATB1 is crucial for immune function and lymphoid development.

Material and Methods: Through international collaborations, clinical and immunological data were collected from medical files of individuals with a distinct de novo frameshift variant in the last exon of *SATB1*, who presented with HIGM and syndromic NDD.

Results: Four unrelated individuals were identified, carrying the same de novo variant in *SATB1* (NM_002971.6:c.1877del;p.(Pro626-Hisfs*81)), who presented with NDD, seizures, dysmorphism and increased susceptibility to infections. All exhibited IgG and IgA deficiencies, with elevated IgM levels in three, and normal IgM in one. CD40L expression on activated CD4+ T cells as assessed by flow cytometry in three individuals was reduced. B cell phenotyping, performed in three individuals, showed deficiency in switched memory B cell numbers.

Conclusion: These cases implicate the c.1877del variant in *SATB1* in HIGM, which has not been described for any other *SATB1* variant so far. We propose *SATB1* as a cause for HIGM syndrome and suggest including *SATB1* in genetic diagnostic workup for primary immunodeficiencies. Further studies are needed to disentangle the pathophysiological complexity of the c.1877del variant, to elucidate its molecular consequences leading to immunological dysfunction.

P13.002.B RENOVO-NF1 accurately predicts NF1 missense variant pathogenicity

Emanuele Bonetti[1], *Serena Pellegatta*[2], *Nayma Rosati*[2], *Marica Eoli*[2], ***Luca Mazzarella***[1]

[1]Istituto Europeo di Oncologia IRCCS, Milan, Italy, [2]Istituto Neurologico Besta IRCCS, Milan, Italy.

Background: Identification of a pathogenic variant in NF1 is diagnostic for neurofibromatosis, but is often impossible at the moment of variant detection due to many factors including allelic heterogeneity, sequence homology, and the lack of functional assays. Computational tools may aid in interpretation but are not established for NF1.

Material and Methods: We optimized our random forest-based predictor RENOVO for NF1 variant interpretation. RENOVO was trained and tested using an approach of "database archaeology": by comparing versions of ClinVar over the years, we defined "stable" variants that maintained the same pathogenic/likely pathogenic/benign/likely benign (P/LP/B/LB) classification over

time (n = 3579, the *training set*), and "unstable" variants that were initially classified as Variants of Unknown Significance (VUS) but were subsequently reclassified as P/LP/B/LB (n = 57, the *test set*). This approach allows to retrospectively measure algorithm accuracy on prediction with insufficient information, reproducing the scenario of maximal clinical utility. We further validated performance on: i) *validation set 1*: 100 NF1 variants classified as VUS at the time of RENOVO development and subsequently reclassified as P/LP/B/LB in ClinVar; ii) *validation set 2*: 15 de novo variants discovered in a prospective clinical cohort and subsequently reclassified per ACMG criteria.

Results: Accuracy was 98.6% on the training test, 96.5% in the test set, 82% in validation set 1 (but 96.2% for missense variants) and 93.7% on validation set 2.

Conclusion: RENOVO-NF1 accurately interprets NF1 variants for which information at the time of detection is insufficient for ACMG classification, and may overcome diagnostic challenges in neurofibromatosis.

P13.003.C Classification of missense DNMT3A variants using a newly derived blood DNA methylation signature for Tatton-Brown Rahman syndrome

Zain Awamleh[1], *Anthony Chen*[1], *Sanaa Choufani*[1], *Jill Kiernan*[2], *Kit Church*[2], *Maria Irene Palafoll*[3], *Eduardo Tizzano*[3], *William Gibson*[4], *Stephen Scherer*[1], *Andrew Jackson*[5], *Rosanna Weksberg*[1]

[1]*The Hospital for Sick Children, Toronto, ON, Canada,* [2]*TBRS Community, Stanfordville, NY, USA,* [3]*HOSPITAL VALL D'HEBRON, Barcelona, Spain,* [4]*BC Children's Hospital, Vancouver, BC, Canada,* [5]*The University of Edinburgh, Edinburgh, United Kingdom.*

Background: Pathogenic variants in *DNMT3A* are causative of Tatton-Brown-Rahman syndrome (TBRS), a disorder characterized by overgrowth, distinctive facial dysmorphia, and intellectual disability. Our previous work has shown that syndromic conditions caused by pathogenic variants in epigenetic regulatory genes have identifiable patterns of DNA methylation (DNAm) change termed: DNAm signatures. Given the role of *DNMT3A* as a de novo DNA methyltransferase, we investigated whether variants underlying TBRS are associated with a DNAm signature.

Methods: We profiled whole-blood DNAm for 45 individuals with DNMT3A variants and 71 typically developing individuals using Illumina's Infinium MethylationEPIC v2.0 microarray.

Results: We identified a robust DNAm signature of 443 CpG sites (FDR < 0.05; $\Delta\beta > 20\%$) in 7 individuals with TBRS and validated it in an additional 20 individuals with TBRS. To demonstrate the diagnostic utility of the signature we classified the DNAm profiles of 9 individuals with variants of uncertain significance in DNMT3A. We found that TBRS-causing variants in DNMT3A result in different magnitudes of methylation change, with 7 individuals exhibiting mild hypomethylation and 3 individuals exhibiting severe hypomethylation. We also classified the DNA methylation profiles of 7 individuals with Heyn-Sproul-Jackson syndrome also caused by pathogenic variants in DNMT3A.

Conclusion: In this study we generated a TBRS specific DNAm signature and demonstrated its diagnostic utility in classifying uncertain variants in *DNMT3A*. Our findings also highlight the complex genotype-phenotype-epigenotype relationships underlying TBRS. Future work is focused on elucidating these relationships and expanding our understanding of the epigenetic landscape underlying disease causing variants in *DNMT3A*.

Background: The *LSM1* gene encodes a subunit of the conserved LSM1-7 protein complex involved in mRNA metabolism. Variants in *LSM1* gene have been described in two separate case reports. The first published report identified the homozygous splice-site variant c.231+4A>C, while the second reported a homozygous missense variant. Nevertheless, variation in *LSM1* has yet to be established as disease-causing in humans.

Material and Methods: Through exome sequencing and detailed phenotyping, we report six syndromic pediatric patients with the homozygous c.231+4A>C variant in the *LSM1* gene, collected via GeneMatcher. GestaltMatcher was used to analyze facial feature similarity and real time quantitative PCR (RT-qPCR) confirmed the splice defect caused by the variant. Haplotype analysis assessed whether this variant resulted from independent occurrences or a common ancestral haplotype.

Results: Patients presented with dysmorphic facial features, developmental delay, and multi-systemic involvement, including urological, cardiac, and skeletal manifestations, showcasing the phenotypic spectrum of this syndrome. RT-qPCR confirmed that the c.231+4A>C variant causes exon 3 skipping, producing negligible *wild-type LSM1* mRNA expression. Elevated mutant isoform expression confirmed pathogenicity according to the ACMG guidelines. We identified this variant in the Muslim Arab and Ashkenazi Jewish populations and determined that it represents a hotspot variant through haplotype analysis.

Conclusion: Our findings establish *LSM1*, and specifically the c.231+4A>C homozygous variant, as causative for a novel autosomal recessive syndromic neurodevelopmental disorder. These results expand the understanding of *LSM1*-related diseases and provide a foundation for further investigation of its molecular mechanisms.

Background: Neurodevelopmental disorders are a group of conditions characterized by manifestations of brain dysfunction, leading to impairments in social, behavioral, and cognitive functioning.

Material and Methods: Here, we studied five patients from three unrelated families originating from Yemen, Germany, and Spain. Variants were identified by exome-sequencing and homozygosity mapping and their consequences were investigated using immunofluorescence, immunoblotting, pulldown assay, and RNA-sequencing.

Results: The affected individuals manifested global developmental delay, variable degrees of microcephaly, and hypotonia. Genomic analyses revealed the biallelic variants in *ZFTRAF1*, encoding a protein of unknown function to date. We detected two frameshift variants in two families and an intronic splice site variant in the third family. We investigated ZFTRAF1, the poorly characterized protein, at the cellular level and signified it as a nucleocytoplasmic protein in different human cell lines. We also investigated the ZFTRAF1 interactome by pulldown assays and identified 110 interacting proteins that are crucial components of the mRNA-processing machinery and autophagic mechanism. ZFTRAF1 was completely absent in primary fibroblasts derived from two independent patients. Profiling of autophagy markers, as well as whole-transcriptome and whole-proteome analyses, revealed dysfunctional autophagy in patient-derived fibroblasts. Another evidence of impaired autophagy was the fact that attempts to reprogram patient fibroblasts got stuck in the pre-iPSCs phase.

Conclusion: Thus, our findings suggest that biallelic variants of *ZFTRAF1* cause a severe neurodevelopmental deficiency syndrome. En masse, the loss of its function leads to inoperative autophagy and mRNA processing, both of which are known to have crucial roles in normal human brain development.

P13.006.B Single-cell multi-omics RNA-seq analysis provides new insights into pathomechanisms of Mulvihill-Smith-syndrome

Cristiana M. Roggia, *Angelika Riess, Antje Schulze-Selting, Vladislav Lysenkov, Stephan Ossowski, Nicolas Casadei, Olaf Riess, Yogesh Singh*

Institute of Medical Genetics and Applied Genomics, University Hospital Tübingen, University of Tübingen, Tuebingen, Germany.

Background: Mulvihill-Smith-syndrome (MSS) is a nano-rare genetically unsolved progeroid disorder with only few patients described so far. We report preliminary data on immunological and gene expression profiles of a 16-year-old MSS patient.

Material and Methods: multi-omics RNA-seq (gene expression, surface protein immune cell markers, TCR, BCR) analysis was applied on single-cell suspensions of PBMCs of the patient and her mother (control). After single cell RNA preparation according to Chromium Next GEM Single Cell 5'-Reagent Kits_v2 (10XGenomics) protocol, gene expression matrices were assessed with the Seurat 5.01 package in RStudio.

Results: The patient showed, compared to control, increased CD4+/CD8+ T cells, expansion of paired αβ TCRs and reduction in naive T cells, indicative of a progressive aging phenotype. Neither diabetes, recurrent infections or cancer were present at the time of the investigation. Pathway analysis revealed a higher inflammatory response of $CD4^+$ EM T cells (overexpression of *SOCS2, PTGDS, TNFRSF4, PTGER2)* and increased cell-killing potency of $CD8^+$ EM T cells *(*upregulation of *CD28, GZMK*, and *PDCD1)* in the MSS patient. Moreover, several pathways related to integrin-mediated signaling, response to hormones, fatty acid metabolism, response to toxic substances and transcriptional processes were differentially regulated in $CD4^+$ EM T cells.

Conclusion: Single cell multi-omics RNA-seq analysis confirmed an aged immune system and dysregulation of several pathways in our patient. This technique seems to be a valuable approach to simultaneously study rare diseases at cellular and molecular level. We are interested in further characterizing MSS patients. For potential collaborations please contact olaf.riess@med.uni-tuebingen.de

P13.007.C A reverse phenotyping approach to identify pathogenic *SMARCA4* variants causing Coffin-Siris syndrome through integration of clinical, genomic, and structural data

Gemma Tort[1], *Guerau Fernàndez*[2,3], *Janet Hoenicka*[1,3], *Raul A. Urrutia*[4,5,6], *Michael T. Zimmermann*[4,6,7], *Francesc Palau*[1,3,8]

[1]*Laboratory of Neurogenetics and Molecular Medicine, Center for Genomic Sciences in Medicine, Institut de Recerca Sant Joan de Déu, Barcelona, Spain,* [2]*Department of Genetic, Hospital Sant Joan de Déu, Barcelona, Spain,* [3]*Center for Biomedical Research Network on Rare Diseases (CIBERER), Barcelona, Spain,* [4]*Linda T. and John A. Mellowes Center for Genomic Sciences and Precision Medicine (Mellowes Center), Medical College of Wisconsin, Milwaukee, WI, USA,* [5]*Department of Surgery, Division of Research, Medical College of Wisconsin, Milwaukee, WI, USA,* [6]*Department of Biochemistry, Medical College of Wisconsin, Milwaukee, WI, USA,* [7]*Clinical and Translational Sciences Institute, Medical College of Wisconsin, Milwaukee, WI, USA,* [8]*Division of Pediatrics, Faculty of Medicine and Health Sciences, University of Barcelona, Barcelona, Spain.*

Background: Coffin-Siris syndrome (CSS) is a developmental disorder characterized by distinctive facial features, hypoplasia of the fifth finger, developmental delay, and intellectual disability. CSS is caused by pathogenic variants in subunits of the BAF chromatin-remodeling complex, which are essential for neurodifferentiation. Despite advancements in genetic diagnostics, a significant number of CSS cases remain unresolved, highlighting the need for further research.

Material and Methods: We utilized a reverse phenotyping approach to identify CSS-related variants in BAF complex genes. We first analyzed clinical and whole-exome sequencing data from 6,189 patients. We focused our study on the *SMARCA4* gene. Variants were filtered based on allelic frequency, pathogenicity scores, and read depth. Finally, mechanistic data for how each potentially pathogenicity variant alters the structure, stability, or flexibility of the BAF complex, was evaluated using computational structural genomics. This approach leveraged information from multiple experimental structures to generate a structure-function mapping. In-depth phenotyping is currently being conducted by clinical geneticists and pediatric neurologists.

Results: We identified 56 unique SMARCA4 missense variants in 53 patients. Among patients with a complete clinical record, three were undiagnosed and exhibited facial dysmorphisms along with intellectual disability. Preliminary protein complex-based structural calculations indicated that these variants might disrupt the assembly of the BAF complex, leading to a reevaluation of the clinical phenotype.

Conclusion: Reverse phenotyping may enhance the diagnosis of neurodevelopmental disorders such as CSS. By integrating structural bioinformatics, systems biology, and computational biology, we can improve the interpretation of genomic data in the diagnosis of rare diseases.

P13.008.D Dissecting the clinical variability observed in HNF1β associated phenotypes

Francesco Massaro

Tigem, Pozzuoli, Italy.

Background: HNF-1β is a transcription factor involved in early development of organs as kidney, liver and pancreas. HNF1β mutations have been associated with a broad spectrum of abnormalities including Maturity Onset Diabetes of the Young type 5 (MODY5), Renal Cysts And Diabetes (RCAD), congenital anomalies of kidneys and genitourinary tract, liver only involvement, neoplastic condition.

Material and Methods: We selected three mutations: a missense mutation (c.436A>G, p.Asn146Asp) in a familial case of RCAD; a frameshift mutation (c.712delT, p.Trp238GlyFs*25) in a familial case with only renal cysts and a missense mutation (c.1484T>A; p.Met495Lys) in a familial MODY5 case.First, we generated a HNF1β KO in HK2 cells and through lentiviral production we established HA-labelled stable cells expressing selected HNF1β mutations or the wild type gene.

Results: Mutations affect expression and size of the HNF1β protein. Furthermore, HNF1β regulates genes involved in renal cystogenesis and in biogenesis and function of mitochondria. HNF1β mutations lead to increase in ROS production, morphological alterations of mitochondria and change in their membrane potential with a metabolic switch towards glycolysis. Transcriptomic analysis revealed alterations in gluconeogenesis, glycogen synthesis, response to insulin stimuli and branching of epithelial morphogenesis.

Conclusion: Our results indicate that HNF1β mutations cause downregulation of different transcripts according to the phenotype studied. The mitochondrial phenotype was observed in cells expressing the renal cysts only and RCAD phenotypes. We believe that our study will identify the molecular mechanisms underlying the phenotypic variability observed in the HNF1β associated clinical spectrum.

P13.009.A Genotypes heterogeneity in PIK3CA-related overgrowth spectrum (PROS)

Ekaterina V. Bychkova[1], *Natalia Semenova*[1], *Garik B. Sagoyan*[2], *Darya M. Guseva*[1], *Vladimir V. Strelnikov*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Federal State Budgetary Institution "National Medical Research Center of Oncology named after N.N. Blokhin" of the Ministry of Health of the Russian Federation, Moscow, Russian Federation.*

Background: Postzygotic somatic variants in cancer-associated genes drive various overgrowth and vascular malformations syndromes, including PIK3CA-related overgrowth spectrum (PROS). PROS comprises over 20 conditions characterized by asymmetric overgrowth and vascular anomalies. Mutations arise during embryogenesis, leading to mosaic mutation distribution. The clinical variability of PROS is influenced by affected tissue type, mutation timing, PI3K activation and additional factors. The overlap with other syndromes and the complexity of detecting mosaic variants pose significant diagnostic challenges.

Material and Methods: 120 patients from unrelated families clinically diagnosed with PROS underwent molecular genetic testing by deep NGS (>1000x) of a targeted panel of genes associated with overgrowth syndromes and vascular malformations. DNA was extracted from fresh-frozen postsurgical material, skin biopsy or FFPE of the pathological lesion.

Results: Pathogenic or likely pathogenic variants were identified in 75 patients (62,5%). A single variant was detected in 72 patients, primarily in *PIK3CA* (n = 45), followed by *GNAQ* (n = 7), *RASA1* (n = 5), *PTEN* (n = 3), *AKT1* (n = 3), *TEK* (n = 2), *PIK3R1* (n = 2), and one case each in *KRAS*, *NRAS*, *HRAS*, *BRAF*, *AKT3*, *GNA11*, and *MAP3K3*. The coexistence of two clinically significant variants was observed in 3 cases.

Conclusion: Molecular genetic testing is essential for the diagnosis and treatment of PROS. The identification of PIK3CA variants provides the basis for prescribing PI3K-inhibitor alpelisib.

Our findings emphasize the genetic heterogeneity of PROS and related disorders, highlighting the necessity of comprehensive genetic testing for accurate diagnosis and potential targeted therapy selection. In cases where PIK3CA variants are not detected, alternative therapeutic strategies must be considered.

Background: In 2016, Sifrim et al. described the first patients carrying a variant in *CDK13* and with a common clinical picture characterized by congenital heart defects, intellectual disability and peculiar facial dysmorphisms (Congenital Heart Defects, Dysmorphic Facial Features, and Intellectual Developmental Disorder; CHDFIDD. OMIM # 617360) generally referred to as *CDK13*-related disorder. The specific phenotypic spectrum is still under definition.

Material and Methods: We describe 27 patients, hitherto unreported, collected through a multicenter effort, all carrying a pathogenic or likely pathogenic variant in *CDK13*.

Results: Besides the most common features, we found some novel findings: cranyosinostosis and variable skeletal features (e.g. cranio-cervical anomalies). We also describe the ocular phenotype that includes bilateral congenital glaucoma, posterior embriotoxon, buphthalmos and Duane anomaly. Moreover, we observed a case of mother-to-daughter transmission, an exceptional event due to the fact that for affected patients the chance of having a child is generally considered to be low. We also saw a pair of monozygotic twins that shared the same variant and an almost identical clinical picture. Furthermore, we highlight the possible endocrinological issues that comprise obesity with insulin-resistance and delayed puberty.

Conclusion: Our report adds some novel features of *CDK13*-related disorder, whose phenotypical spectrum varies from mild neurodevelopmental disorder and behavioral issues without other recurrent malformations to a more severe clinical picture. We also reviewed the literature and summarizing these data with our clinical findings, we redefined the differential diagnosis and we added some recommendations for the clinical approach and the follow-up care of *CDK13*-related disorder.

P13.011.C Pain of muscle-skeletal origin, muscular fibro-adipose involution and impaired muscle fiber differentiation as crucial features in Costello syndrome

Chiara Leoni[1], *Valentina Trevisan*[1], *Lucrezia Perri*[1], *Germana Viscogliosi*[1], *Maria Luigia Angeli*[1], *Consolato Gullì*[1], *Domenico Marco Maurizio Romeo*[1], *Giuseppe Zampino*[1], *Debora Pajalunga*[2], *Serena Cecchetti*[2], *Elisabetta Flex*[2]

[1]*Fondazione Policlinico Gemelli, Rome, Italy,* [2]*Istituto Superiore di Sanità, Rome, Italy.*

Background: Costello syndrome (CS) is a rare condition belonging to RASopathies characterized by musculoskeletal anomalies and pain, decreased muscle force. Anecdotal papers reports muscle fibers anomalies in in vitro cellular models. Herein, we studied skeletal muscle architecture and fibro-adipose infiltration (FAI) in CS by Ultrasonography (US) and assessed the *HRAS* involvement in skeletal muscle defects using engineered myoblasts cell lines expressing two recurrent *HRAS* variants(p.Gly12Ser and p.Gly13Cys).

Methods: 20 CS individuals were enrolled. Paravertebral and lower limb muscles were studied by US (Samsung RS85 Prestige). FAI was graded according to the Heckmatt scale (I-IV). Myoblasts cell lines expressing CS variants were generated by retroviruses infection and purification by flow-cytometric sorting.

Results: FAI was identified in at least one district in all participants. A grade II-III FAI was detected in lumbar paravertebral muscles (85%) and lower limbs (at least one examined district in 75% indivuduals), with vastus lateralis being the most frequently involved. Myoblast cell lines expressing HRAS variants showed impaired muscle differentiation capabilities due to compromised myoblasts cell cycle, decreased expression of late muscle specific markers, and defective fusion into multinucleated myotubes. Moreover, immunofluorescence analyses performed on these cell lines identified lipid droplets content confirming data obtained on patient's fibroblasts by Carpentieri et.al.

Conclusions: Muscle FAI represents a new feature of CS probably correlated to pain and reduced muscle strength. Considering the high fat content in patient's cells and myoblasts model, we speculate that *HRAS* dysregulation causes a metabolic dysfunction leading to increased adipose generation and storage in CS-skeletal muscles.

P13.012.D Large-scale Simons Searchlight medical & genetic data available across 180 rare genetic neurodevelopmental disorders (NDDs)

Michelle Kowanda[1], *Katina Calakos*[2], *Gerhard Schratt*[1], *Cora M. Taylor*[3], *Wendy K. Chung*[4]

[1]*Swiss Federal Institute of Technology ETH, Zurich, Switzerland,* [2]*Boston Children's Hospital, Boston, MA, USA,* [3]*Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA, USA,* [4]*Boston Children's Hospital, Boston, MA, USA.*

Background: The international Simons Searchlight research program (**SimonsSearchlight.org**) has collected cross-sectional and longitudinal caregiver/participant-provided medical, developmental, and behavioral data and biospecimens for 180 genetic neurodevelopmental disorders. Participants can be re-contacted for additional research participation through SFARI Research Match. Researchers can request data and biospecimens for analysis and publication via SFARI Base (www.base.sfari.org).

Material and Methods: Simons Searchlight has enrolled >3000 affected participants with 156 monogenic and 24 copy number variant conditions from 71 countries. Medical history (n = 2,502), seizures (n = 2,361), development and behavior (n = 2,461), sleep (n = 1,576), quality of life (n = 1,580) data, and more, are available. 120 patient-derived induced pluripotent stem cell lines are available, with 80 more in progress. Here, we investigated the comorbidity of neurodevelopmental issues across genetic conditions.

Results: Linear regression testing of frequencies of select medical issues, calculated per genetic condition group having >5 likely/pathogenic carriers, was conducted using 2,242 medical histories. The results suggest moderate correlations between frequencies of intellectual disability (ID) and a language disorder, autism spectrum disorder (ASD) and ADHD, and movement disorders (eg, ataxia, tremors) and inability to walk. Results suggest a weak relationship between ID and seizures, hypotonia and movement issues, and hypotonia and gastrointestinal issues. Data suggest moderate and weak inverse associations between hypotonia and ASD, and ID and ASD, respectively.

Conclusion: Our analysis suggests relationships between certain diagnoses across a diverse neurogenetic cohort. Researchers can request data and biospecimens, and submit Research Match applications, at www.base.sfari.org.

Linear regression for the frequency of select medical issues across genetic conditions.

Comparison	R2	F(1,72)	p
ID and language	.32	33.72	< .001
ASD and ADHD	.23	22	< .001
Movement issues and inability to walk	.35	37.94	< .001
ID and seizures	.084	6.64	= .012
Hypotonia and movement	.12	9.88	= .002
Hypotonia and gastrointestinal	.068	5.26	= .025
Hypotonia and ASD	.18	16.28	< .001
ID and ASD	.000024	0.0017	= .967

P13.013.A Acute kidney injury and chronic kidney disease in individuals with Down syndrome: A nationwide cohort study

Freja Leonore Uhd Weldingh[1,2], *Morten Krogh Herlin*[3,2], *Ellen Hollands Steffensen*[4,5,2], *Uffe Heide-Jørgensen*[1,2], *Ida Vogel*[3,5,2], *The Danish Central Cytogenetics Registry Study Group*[6], *Christian Fynbo Christiansen*[1,2]

[1]Department of Clinical Epidemiology, Aarhus University and Aarhus University Hospital, Aarhus, Denmark, [2]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark, [3]Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark, [4]Department of Clinical Genetics, Aalborg University Hospital, Aarhus, Denmark, [5]Center for Fetal Diagnostics, Aarhus University, Aarhus, Denmark, [6]

Objectives: In this nationwide cohort study, we investigated the risk of acute kidney injury (AKI) and chronic kidney disease (CKD) in individuals with Down syndrome (DS) compared to the general population.

Material and Methods: We identified a population-based cohort of individuals with cytogenetically confirmed DS from 1961–2021 using the Danish Cytogenetic Central Registry. For each individual with DS we sampled 10 age-and-sex-matched individuals without DS from the general Danish population. We used laboratory data on creatinine to assess AKI and CKD overall and by different stages and computed the cumulative incidence (risk) of AKI and CKD by age. Furthermore, we estimated the risk of AKI and CKD in subjects without congenital heart disease (CHD).

Results: We identified 2,815 individuals with DS with available laboratory data on plasma creatinine measurements. Comparing individuals with DS to the matched cohort, the risk of AKI was 28.9% vs. 1.4% at age 20, 32.8% vs. 5.3% at age 40, and 48.6% vs. 23.8% at age 70. The risk of CKD was 1.2% vs. 0.1% at age 20, 3.9% vs. 0.4% at age 40, and 23.2% vs. 13.8% at age 70. For subjects without CHD the risk AKI and CKD decreased but remained considerably higher for individuals with DS than for matched individuals.

Conclusion: We found that individuals with DS were at increased risk of developing both AKI and CKD compared to the general population. Additionally, co-occurring CHD could not fully explain the increased risk of AKI and CKD in individuals with DS.

P13.014.B Variant spectrum and genotype-phenotype correlations in *HNRNPK*-related disorder (Au-Kline-Okamoto syndrome)

Ping Yee Billie Au[1], *Snezana Plecas-Maricic*[1], *Lindsay Phillips*[1], *Olivia Young*[1], *Kara Murias*[1], *Paul Gordon*[2], *Vanda McNiven*[3], *Sanaa Choufani*[4], *Rosanna Weksberg*[4], *Christopher L. Ricupero*[5], *Jennifer Bain*[5], *Meena Balasubramanian*[6], *Madelyn Gillentine*[7], *HNRNPK International Consortium*[8], *Antonie D. Kline*[9]

[1]University of Calgary, Alberta Children's Hospital Institute, Calgary, AB, Canada, [2]University of Calgary, Center for Health Genomics and Informatics, Calgary, AB, Canada, [3]Division of Genetics, Department of Pediatrics, McMaster Children's Hospital, Hamilton, ON, Canada, [4]The Hospital for Sick Children, Toronto, ON, Canada, [5]Columbia University, New York, NY, USA, [6]Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom, [7]HNRNP Family Foundation, Seattle, WA, USA, [89]Harvey Institute for Human Genetics, Greater Baltimore Medical Center, Baltimore, MD, USA.

HNRNPK-related disorder, also known as Au-Kline syndrome or Okamoto syndrome (AKS, OMIM 616580) is a multiple malformation syndrome associated with intellectual disability and recognizable dysmorphic features. The first individuals described had de novo loss of function variants in *HNRNPK*. Pathogenic missense variants are now also reported, with the previously identified genome-wide methylation signature supporting variant classification. *HNRNPK* encodes for heterogeneous ribonucleoprotein K (hnK), which is implicated in RNA metabolism. HnK has two N-terminal KH domains and a C-terminal KH domain, which are implicated in RNA binding. We report on the spectrum of clinical features of over 60 individuals with likely pathogenic or pathogenic variants in *HNRNPK*. We include more comprehensive characterization of prenatal phenotypes as provide an update on the frequency of malformations and emerging health issues. We identify several recurrent missense variants (eg. p.Glu85Lys; variants at p.Arg46) and observe pathogenic missense variants cluster in N-terminal KH domains and predicted truncating variants cluster in the C-terminal region. Missense variants correlate with lower malformation burden when compared to predicted truncating variants. We also report a significant association with earlier attainment of motor milestones for individuals with missense variants. We describe a potentially distinct phenotype for 2 individuals with variants at the G-X-X-G nucleic acid binding motif in the KH1 domain. Future work includes an expanded natural history study with longitudinal data collection to better understand the impact of genotype on outcomes as well as cell-based functional work to understand the impact of variants on HnK functional domains and RNA binding.

P13.015.C Burden of common clinical conditions in adults with 22q11.2 microdeletion

Anne S. Bassett[1], *Christina Blagojevic*[1], *Erik Boot*[2], *Tracy Heung*[3], *Sarah Malecki*[1]

[1]University of Toronto, Toronto, ON, Canada, [2]3Advisium, 's Heeren Loo Zorggroep, Amersfoort, Netherlands, [3]Toronto General Hospital, Toronto, ON, Canada.

Background: Limited information is available on adults with rare genetic diseases. We investigated the clinical burden of commonly associated conditions in adults with a 22q11.2 microdeletion.

Material and Methods: In a cohort of 405 adults with 22q11.2 microdeletion (52% female, median age 30.6, IQR 24.8–41.2, years) we evaluated lifetime health records to identify conditions present in ≥5% that required assessment by a specialist and/or significant/ongoing management in adulthood. We used regression modelling to identify predictors of the number of conditions per individual, accounting for age, sex, ancestry, and conditions likely to affect burden: major congenital heart disease (CHD), schizophrenia, and moderate/severe intellectual disability (ID).

Results: We identified 66 conditions from 12 organ systems to be common in 22q11.2 microdeletion, with a median of 12 (range 1–31) conditions involving 7 systems per individual. Those with shorter proximal nested deletions had fewer conditions overall than those with typical 2.5–3.0 Mb 22q11.2 microdeletions ($p = 0.02$). Transmitting parents had more conditions. Older age ($p < 0.0001$), schizophrenia ($p < 0.0001$), major CHD ($p = 0.0005$) and moderate/severe ID ($p = 0.02$), but not sex or ancestry, were significant independent predictors of clinical burden (model R2 0.30, $p < 0.0001$). Most individuals ($n = 346$, 85%; median age 32.1) had one or more of 11 conditions associated with aging.

Conclusion: By early adulthood, the global burden of multisystem conditions associated with 22q11.2 microdeletion is apparent, emphasizing the need for multidisciplinary care for this population, and confirming full penetrance. The results suggest that the 22q11.2 microdeletion can be seen as a model for premature aging.

P13.016.D Size matters: phenotypes associated with nested chromosome 22q11.2 deletions

Donna McDonald-McGinn, *Bekah Wang, Audrey Green, Lydia Rockart, Oanh Tran, Elaine H. Zackai, Beverly S. Emanuel, Daniel E. McGinn, Terrence Blaine Crowley*

Children's Hosp Philadelphia and Perelman School of Med U of PennsylvaniaDept of Pediatrics, Divisio, Philadelphia, PA, USA.

Background: 22q11.2 deletion syndrome (22q11.2DS) results from non-allelic homologous recombination due to low copy repeats (LCRs) A, B, C, and D. Most deletions extend from LCR22A-LCR22D (A-D) and include FISH probes within A-B and important developmental genes *TBX1* (within A-B) and *CRKL* (within C-D). Here we report deletion size and associated features in a large cohort towards establishing genotype-phenotype correlations.

Methods: Findings in 1667 patients with 22q11.2DS were examined under IRB approval. 328 diagnosed by FISH were excluded.

Results: 82% had A-D deletions (1095/1339). 4.7% were not mediated by LCRs. 6.6% would be missed by FISH. Prevalence of congenital heart disease in those deletions including *TBX1* was statistically significantly higher compared to those not including *TBX1* ($p < .01$): **A-D** deletions ($n = 1095$; 66%); **A-B** ($n = 69$; 73%); **A-C** ($n = 24$; 76%); **B-D** ($n = 57$; 26%); **C-D** ($n = 31$; 38%). Hypocalcemia was present in: A-D (52%), A-B (27%), A-C (42%), B-D (2%), C-D (0%). Chronic infection was equal across deletions. Patients with C-D deletions had no palatal nor structural brain anomalies, likewise scoliosis (8%), idiopathic seizures (3%), and ADHD (3%) were uncommon. Mean FSIQ by deletion type revealed: A-D (77.3; $n = 312$), A-B (87.8; $n = 16$); A-C (81.0; $n = 6$); B-D (78.3; $n = 5$); and C-D (87.7; $n = 3$) but numbers were small across nested deletions and standard deviations wide-ranging. 14% (397/461) of A-D deletions were familial, compared with A-B (22%), A-C (17%), B-D (71%), and C-D (67%).

Conclusions: Deletion size significantly impacts phenotypes and is key in providing personalized healthcare guidance, identifying causative genes, and providing recurrence risk counseling.

Departmento de Farmacología-Psicología y Medicina Legal, Facultad de Medicina, Universidad de Zaragoza, CIBERER-GCV02 y IIS-Aragón, Zaragoza, Spain,* [5]*Department of Internal and Pediatric Nursing, Institute of Nursing and Midwifery, Medical University of Gdańsk, Gdańsk, Poland,* [6]*Unidad de Genética Clínica, Servicio de Pediatría, Hospital Universitario 'Lozano Blesa', Facultad de Medicina, Universidad de Zaragoza, CIBERER-GV02, Zaragoza, Spain,* [7]*Medical Genetic Unit, Italian Hospital of Lugano, Lugano, Lugano, Switzerland.*

Background: Cornelia de Lange syndrome (CdLS) is a rare neurodevelopmental disorder primarily caused by mutations in various subunits or regulators of the cohesin complex. However, 30% of patients remain without a molecular diagnosis. In line with the role of cohesin in genomic integrity and DNA accessibility, CdLS falls within the category of transcriptomopathies, a group of disorders characterized by global transcriptional dysregulation.

Material and Methods: Trio whole genome sequencing was performed to investigate 15 unsolved individuals with CdLS-like phenotypes. For all patients, germline or mosaic variants in known CdLS-associated genes had been previously excluded.

Results: Putative disease-causing variants in non-CdLS genes were identified in six patients: two heterozygous missense variants (*DDX23, CSNK1G1*), one hemizygous nonsense variant (*CDK16*), two heterozygous in-frame deletions (*MAU2*, *CREBBP*), and one homozygous missense substitution in *TMTC3*. Additionally, one intragenic deletion affecting *USP7* and one intragenic duplication of *AFF2* were detected. A subsequent episignature study conducted on the remaining unresolved cases identified a CdLS-specific methylation profile in one patient. Re-analysis of the genome data of this patient revealed a de novo deep intronic single nucleotide exchange in *NIPBL*. Blood RNA analyses confirmed aberrant splicing of the *NIPBL* transcript. The genome data of the six remaining unsolved cases are still under investigation. Systematic screening for alterations in repeat expansions identified a possible expansion within the *AFF3* gene promoter for one patient.

Conclusion: The newly identified variants affect proteins involved in transcriptional regulation, confirming the genetic heterogeneity of CdLS and supporting its classification as transcriptomopathy.

P13.018.B Dissecting Pitt-Hopkins syndrome into independent molecular categories, and first evidence of genetic heterogeneity of the condition: analysis of a large cohort of patients

Giuseppe Marangi[1], *Domizia Pasquetti*[2], *Federica Francesca L'Erario*[1], *Anna Gloria Renzi*[1], *Marina Carapelle*[1], *Daniela Orteschi*[1], *Paolo N. Doronzio*[1], *Giorgia Quattromini*[1], *Giordana Di Mario*[1], *Elena Sonnini*[1], *Annalisa Gazzellone*[1], *Clarissa Modafferi*[1], *Chiara Veredice*[3], *Ilaria Contaldo*[3], *Antonio Novelli*[4], *Marcella Zollino*[1]

[1]*Institute of Genomic Medicine, Università Cattolica del Sacro Cuore, Roma, Italy,* [2]*Institute for Maternal and Child Health-IRCCS "Burlo Garofolo", Trieste, Italy,* [3]*Pediatric Neurology Unit, Policlinico Universitario A. Gemelli IRCCS, Roma, Italy,* [4]*Bambino Gesù Children Hospital, Rome, Italy.*

Background: Pitt-Hopkins syndrome (PTHS) is a neurodevelopmental disorder with a distinctive clinical phenotype including severe intellectual disability (ID), absent speech, breathing anomalies and typical facial features. The only known causative gene is *TCF4*. Recently, both a wider spectrum of *TCF4*-associated phenotypes and a possible genetic heterogeneity for PTHS have emerged.

Material and Methods: We present a cohort of 53 patients with a clinical diagnosis of PTHS and a detected genomic defect, affecting mainly *TCF4*, but also other genes. Including literature revision, we aimed to define an intragenic syndromology of *TCF4*,

and to explore the hypothesis that other genes may be responsible for classical PTHS. Genetic analyses included array-CGH, MLPA and NGS; standard karyotyping, optical genome mapping and cDNA studies in selected cases.

Results: We observed a full PTHS phenotype, as per consensus clinical score, in 47 patients: 45 with variants disrupting the coding sequence between exons 9 and 19 of *TCF4*, including a 2 Mb inversion; 2 with pathogenic variants in *SOX11* and *HECW2*. The remaining 6 patients presented with milder ID and good language ability (atypical/intermediate PTHS?), caused by truncating variants in exons 7–8, by some missense variants, or by variants limited to exons 1–6 of *TCF4* but associated with deletions of the upstream regulatory region.

Conclusion: Molecular pathology of the *TCF4* gene leading to different phenotypes in the spectrum of PTHS and definite evidence of genetic heterogeneity of the classical PTHS are discussed here for the first time.

P13.019.C Abnormal growth in Epigenetic Machinery diseases: Energy Expenditure reveals an unexplored metabolic link

Tiziano Palazzotti[1], *Camilla Meossi*[2], *Alessandra De Franco*[1], *Denise Pires Marafon*[3], *Alessandra Mazzocchi*[1], *Elisabetta Prada*[4], *Giulietta Scuvera*[5], *Lidia Pezzani*[5,6], *Carlo Agostoni*[5,7], *Donatella Milani*[5]

[1]*Department of Health Sciences, University of Milan "Università degli Studi di Milano", Milan, Italy,* [2]*Department of Molecular Medicine, IRCCS Stella Maris Foundation, Pisa, Italy,* [3]*Specialization School in Medical Statistics and Biometry, Department of Public Health and Infectious Diseases, Università Sapienza di Roma, Rome, Italy,* [4]*Azienda Socio Sanitaria Territoriale Lariana, Como, Italy,* [5]*Fondazione IRCSS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [6]*SS Malattie rare, ASST Papa Giovanni XXIII, Bergamo, Italy,* [7]*Department of Clinical and Community Sciences, Università degli Studi di Milano, Milan, Italy.*

Background: Mendelian disorders of the epigenetic machinery (MDEMs), include a large number of conditions. Their main clinical findings are multiple congenital anomalies and intellectual disability together with growth dysregulation, that can be variably up- or down-regulated. In addition, in several MDEMs a predisposition to metabolic syndrome and childhood obesity has been reported.

Material and Methods: A heterogeneous pool of 35 patients affected by MDEMs was engaged in this study. The most frequently represented syndromes are Rubinstein-Taybi and Sotos ones. We divided our cohort into 2 subgroups: those exhibiting growth failure (A) and those displaying an overgrowth (B). For each patient we collected physical data and performed indirect calorimetry as a measure of Resting Energy Expenditure (REE). A comparison of REE was made between the two subgroups and versus age-, sex-, height-matched healthy controls.

Results: Notably, the Group B demonstrated a significantly higher REE compared to both Group A both controls. This difference was height-independent. On the other hand, REE measured in Group A presented no significant differences compared to the controls.

Conclusion: A first analysis of energy expenditure in MDEMs was performed, its results demonstrate the presence of an impaired metabolism in patients diagnosed with chromatinopathy characterized by overgrowth. They also suggest an etiopathogenetic mechanism that may go beyond overgrowth itself, paving the way to future studies that will deepen the knowledge about energy metabolism andinvestigate the metabolic bases of this abnormal growth.

P13.020.D Optimizing Cornelia de Lange syndrome diagnosis through clinical scoring and next-generation phenotyping integration

Beatriz Carvalho Nunes[1], *Thainá Vilella*[1], *Hannah Klinkhammer*[2], *Isabel Furquim Pinheiro*[3], *Hiromi Aoi*[4], *Rie Seyama*[5,4], *Naomichi Matsumoto*[5,6,7], *Fernanda Bellucco*[1], *Chong Kim*[3], *Peter Krawitz*[2], *Tzung-Chien Hsieh*[2], *Maria Isabel Melaragno*[1]

[1]*Genetics Division, Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, Brazil,* [2]*Institute for Genomic Statistics and Bioinformatics, University Hospital Bonn, Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn, Germany,* [3]*Genetics Unit, Instituto da Criança, Universidade de São Paulo, São Paulo, Brazil,* [4]*Department of Obstetrics and Gynecology, Juntendo University Faculty of Medicine, Tokyo, Japan,* [5]*Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan,* [6]*Department of Clinical Genetics, Yokohama City University Hospital, Yokohama, Japan,* [7]*Department of Rare Disease Genomics, Yokohama City University Hospital, Yokohama, Japan.*

Background: Cornelia de Lange Syndrome (CdLS) is a rare multisystemic developmental disorder with variable phenotype and overlapping features with multiple syndromes. This study combines the CdLS clinical score with a facial phenotype-based score generated through next-generation phenotyping (NGP) to evaluate the phenotypic spectrum of CdLS patients.

Methods: Molecular testing was performed for 85 patients with CdLS diagnosis hypothesis: 48 were diagnosed with CdLS, 18 had other syndromes, three had variants of uncertain significance (VUS), and 16 remained undiagnosed. The clinical score classified patients' phenotype as classic, non-classic, or only indicative of molecular testing for CdLS. The GestaltScore used GestaltMatcher's evaluation of patients' photos to quantify the likelihood that a genetic variant was pathogenic, assigning evidence to the ACMG PP4 criterion.

Results: All patients diagnosed with CdLS had at least a moderate evidence level of PP4 assigned by the GestaltScore. Among these, those with classic or non-classic phenotypes had at least moderate PP4. Interestingly, the ones with only molecular indication for CdLS testing had strong or very strong PP4. One VUS had very strong evidence for PP4 and was reclassified as likely pathogenic. Among the patients diagnosed with other syndromes, the ones with only indicative molecular testing for CdLS had a moderate or lower PP4 evidence level. Undiagnosed patients' phenotypes ranged across the three clinical categories and had at least moderate PP4.

Conclusion: Combining clinical scoring with NGP enhances clinical accuracy for CdLS, particularly in milder phenotypes, and facilitates reclassification of VUS, supporting further decisions on molecular testing in challenging cases.

P13.021.A Clinical delineation and genotype-phenotype correlation in 104 pediatric patients with Kabuki syndrome: a Large longitudinalCohort from a Single Center in China

W. Yirou;

Shanghai Children's Medical Center, Shanghai, China

Background: Kabuki syndrome is a monogenic genetic disorder affecting multiple systems, with an incidence rate of 1 in 32,000 to 1 in 86,000. This study provides a detailed genotype and phenotype analysis of a large longitudinal cohort of Kabuki Syndrome (KS) from a single center in China.

Material and Methods: From July 2017 to July 2024, participants were enrolled at Shanghai Children's Medical Center. Variants in KMT2D or KDM6A were identified through whole exome sequencing. Phenotype data included prenatal and perinatal history, neonatal, childhood and adolescence evaluations.

Results: A total of 104 KS individuals fullfiled 362 outpatient visits, with an average follow-up of 2.58 years. Growth curves were plotted based on 545 follow-up height data points. Among the patients, 27.08% had congenital heart defects (CHD), and 3 patients were identified with anomalous pulmonary venous connection as a new KS phenotype. KS patients showed facial feature heterogeneity, patients with atypical facial features associated with a older diagnosis age and a more diverse and severe phenotype. The Face2gene software correctly identified the facial photographs of all 85 KS patients.

Conclusion: This study offered a comprehensive description of a Chinese KS cohort. And provided the first growth curves for Chinese KS patients and a detailed CHD phenotype spectrum. Our findings also suggest that artificial intelligence (AI) -assisted facial diagnostic criteria will be a valuable in the clinical diagnosis of KS.

San Gerardo, Monza, Italy, [12]Service of Medical Genetics, Oncologic Institute of Southern Switzerland, EOC, Lugano, Switzerland, [13]Universita di Milano; Department of Health Sciences, Milano, Italy, [14]Laboratory of Molecular Genetics IRCCS San Raffaele Hospital, Milan, Italy, [15]Unit of Genomics for Diagnosis of Human Disease IRCCS San Raffaele Hospital, Milan, Italy, [16]Biostatistics and Clinical Epidemiology, Fondazione IRCCS San Gerardo Dei Tintori, Monza, Italy, [17]Bicocca Bioinformatics Biostatistics and Bioimaging Center, School of Medicine and Surgery, Università di Milano-Bicocca, Milan, Italy, [18]Universita della Campania, Naples, Italy, [19]Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy.

Background: Pierre Robin Sequence (PRS) defines the association of micrognathia, glossoptosis, and respiratory difficulties. Recent European guidelines (ERN CRANIO 2024) suggest that even in apparently isolated PRS, genetic testing should be included in the diagnostic process, although the etiological cause remains unknown in most cases.

Material and Methods: 50 subjects diagnosed with PRS were enrolled and studied clinically and molecularly. For subjects without an etiological identified cause, WGS or reanalysis of WES data was performed. Virtual gene panels for novel candidate genes, based on animal models or function, were applied and non-coding regions on either side of *SOX9* were investigated.

Results: At birth, 25 subjects were classified as isolated PRS, but 13 were later reclassified as non-isolated during follow-up. 25 subjects presented a complex phenotype from birth. A genetic cause was identified in 20 out of 50 subjects (40%). No pathogenic variants in novel candidate genes were found. ArrayCGH showed a detection rate (DR) of 6%, while WES and WGS had higher DRs (34% and 40%, respectively). Among the 25 cases initially classified as isolated PRS, WES and WGS would have had a DR of 16%, identifying early two cases of Stickler Syndrome and two of Campomelic Dysplasia.

Conclusion: Genetic characterization of PRS, even in isolated cases, is essential for identifying rare genetic causes, refining prognosis, optimizing treatment, and improving family counseling. WES/WGS as a first-line diagnostic tool is recommended. The DR of WGS is expected to increase, enhancing the interpretation of intronic variants and further improving diagnostic accuracy.

P13.023.C Diagnostic analysis through genome sequencing of a cohort of 69 Patients with syndromic or recurrent neural tube defect

Marie Faoucher[1,2], *Christèle Dubourg[1,2], Boris Keren[3,4], Tania Attie-Bitcha[5,4], Pierre Blanc[4], Nicolas Chatron[6,7], Julien Thevenon[8,7], Christine Vinciguerra[9,7], Valérie Dupé[2], Lucie Guilbaud[10], Jean-Marie Jouannic[10], Sylvie Odent[11]*

[1]Laboratory of molecular genetics and genomics, Rennes University Hospital, Rennes, France, [2]Univ Rennes, CNRS, INSERM, IGDR (Institut de Génétique et Développement de Rennes) -UMR 6290, ERL U1305, Rennes, France, [3]Department of Genetics, La Pitié-Salpêtrière Hospital, APHP, Sorbonne University, Paris, France, [4]Laboratoire SeqOIA-PFMG2025, Paris, France, [5]Unité d'Embryofoetopathologie, Service d'Histologie-Embryologie-Cytogénétique, Hôpital Necker-Enfants Malades, APHP, Paris, France, [6]Department of genetics, Hospices Civils de Lyon, Lyon, France, [7]GCS AURAGEN, Lyon, France, [8]Department of genetics, CHU de Grenoble, Grenoble, France,

[9]Service d'hématologie, Centre de Biologie et de Pathologie Est, Hospices Civils de Lyon, Bron, France, [10]Department of Fetal Medicine, Armand-Trousseau Hospital, AP-HP Sorbonne University, Paris, France, [11]Service de Génétique Clinique, Centre de Référence "Anomalies du Développement et Syndromes Malformatifs" de l'Inter-région Ouest, FHU GenOMedS, CHU Rennes, Rennes, France, Univ Rennes, CNRS, INSERM, IGDR (Institut de Génétique et Développement de Rennes, Rennes, France.

The France Genomic Medicine Plan 2025 allows for the sequencing of genomes from patients with rare diseases in France, through 77 pre-indications, including dysraphisms, particularly syndromic dysraphisms or those with intra-familial recurrence.

A total of 69 cases were analyzed using genome sequencing. In this cohort, there is a female predominance (40/69, 58%), as reported in the literature. 59.4% (41/69) were fetuses, while 40.1% (28/69) were children or adults. In 24.5% (17/69) of cases, a family history was observed. Most of the neural tube defects were lumbar (53/69, 79.7%), 14.5% (12/69) involved the cephalic pole, and 5.8% (4/69) were craniorachischisis or inencephalies. In 78.9% (54/69) of cases, associated malformations were present. The most common were vertebral anomalies (24.6%), renal anomalies (17.4%), and limb anomalies (17.4%).

Regarding molecular results, a 22q11.2 microdeletion and a truncating inherited variant in *TBXT* were identified, both of which correspond to risk factors for dysraphism. A likely pathogenic missense variant was found in *WBP11* in a patient with a VACTERL-like syndrome. A candidate variant was also identified in *PRICKLE1*, which is involved in planar cell polarity. Additionally, variants were found in candidate genes such as *ZIC1*, *ZMYM3*, and *KIAA0556*.

The exploration of these genomes was conducted within a diagnostic framework aimed at identifying monogenic events that could explain the phenotype. The multifactorial nature of the disease requires a deeper exploration of patient genomes and case-control studies in large cohorts. However, in cases of syndromic forms or familial recurrences, pathogenic variants and known risk factors can be identified.

P13.024.D From Case Reports to Comprehensive Understanding: Nearly a Decade of Witteveen-Kolk Syndrome

Javiera Vildoso Salinas[1], *Jonathan Husserman*[2], *Mariana Aracena*[1]

[1]Sección de Genética y Errores Congénitos del Metabolismo, División de Pediatría, Escuela de Medicina, Pontificia Universidad Católica de Chile, Santiago, Chile, [2]Servicio de Pediatría, Centro de Responsabilidad del Niño y la Niña, Hospital Base San José de Osorno, Osorno, Chile.

Background: Witteveen-Kolk syndrome (WITKOS) is a rare neurodevelopmental disorder characterized by craniofacial dysmorphism, neurodevelopmental abnormalities, and short stature, caused by loss-of-function variants in the *SIN3A* gene. Since 2016, less than 80 cases have been described. This study focuses on three new Chilean cases and review of the 72 patients with *SIN3A* variants or CNVs known up to date.

Methodology: Detailed genetic analyses were performed for the Chilean cases, including whole exome sequencing and CNV analysis. A comprehensive literature review identified 13 publications with 69 previously reported cases, with data collected on craniofacial dysmorphisms, neurodevelopmental abnormalities and types of variants in *SIN3A* gene or CNVs that include this gene.

Results: Among the 72 patients, 76% were full-term newborns, 80% with normal birth weight. Developmental delay and intellectual disability were seen in 77% of cases, while 51% had psychiatric or behavioural issues, where autism spectrum disorder being the most common. Dysmorphic features are present in 72%, such as high forehead(63%) and elongated face(58%). Other findings are microcephaly, feeding difficulties, short stature, and low weight which were less frequent(less than 50%). Additional anomalies included CNS abnormalities(34%), skeletal(20%), cardiovascular(11%) and urogenital(7%). Most of the molecular findings were variants(76%), the majority of cases(78%) were classified as de novo.

Conclusion: Diagnosing WITKOS based on clinical presentation is challenging due to subtle facial features. The *SIN3A* gene's crucial role in cortical development may explain the syndrome manifestations. This study broadens the phenotype, understanding of WITKOS and emphasizes the importance of knowing its natural history for an effective long-term follow-up.

P13.025.A Novel pathogenic mechanism in Rubinstein-Taybi Syndrome: alternative translation initiation in*CREBBP*

Enora Le Tallec, *Caterina Marconi, Thomas Rio Frio, Panasenko Olesya, Marc Abramowicz, Henri Margot*

Hôpitaux Universitaires de Genève, Geneva, Switzerland.

Background: Rubinstein-Taybi syndrome (RTS) is a rare genetic disorder characterized by distinctive facial features, broad and often angulated thumbs and halluces, short stature, and moderate-to-severe intellectual disability. It is caused by loss of function variant or large deletions in ubiquitary expressed *CREBBP* (cAMP response element-binding protein-binding protein), which encodes a transcriptional coactivator critical for gene expression regulation through chromatin remodeling. Haploinsufficiency of *CREBBP* disrupts normal cell growth, differentiation, and survival. We describe the case of a young woman with a clinical presentation highly suggestive of RTS, in which the carrier status of a novel heterozygote, de novo variant in the 5'UTR of *CREBBP* was detected using whole genome sequencing. This variant creates a 195 bp *open reading frame* upstream to the physiologic translation initiation site that do not overlap with *CREBBP* protein sequence**. Hypothesis**: this variant generates a new competing initiating translation site which may lead to aberrant translation of a non-functional protein and disruption of normal *CREBBP* translation or transcription, fostering haploinsufficiency and RTS.

Material and Methods: we investigated our postulate through episignature analysis, protein and RNA expression assays, Ribo-sequencing, and in vitro translation assays.

Results: this study's findings reveal a new mechanism of pathogenicity associated with RTS and underscores the importance of translational regulation in *CREBBP* function.

Conclusion: our results highlight the necessity of whole genome sequencing to uncover elusive variants

P13.026.B Familial recurrence of a Multilocus Imprinting Disturbance resulting in Beckwith-Wiedemann syndrome with Angelman features in a family with maternal NLRP2 mutation

Hippolyte Menou[1], *Cyril Mignot*[1], *Raffaella Moretti*[2], *Boris Keren*[1], *Laurence Cuisset*[3,4], *Frederic Brioude*[5,6,7]

[1]Department of Genetics, La Pitié-Salpêtrière Hospital, APHP, Paris, France, [2]Département de Génétique, Hôpital Trousseau, APHP, Paris, France, [3]Service de Médecine Génomique des Maladies de Système et d'Organe, Département Médico-Universitaire BioPhyGen, Hôpital Cochin, APHP, Paris, France, [4]Université Paris Cité, Paris, France, [5]Explorations Fonctionnelles Endocriniennes, Hôpital Trousseau APHP, Paris, France, [6]Pierre and Marie Curie-Paris VI University (UPMC) Université Paris 06, Paris, France, [7]INSERM UMR_S938 Centre de Recherche Saint-Antoine (CRSA), Paris, France.

Background: Imprinting disorders are congenital diseases characterized by abnormal methylation patterns in differentially methylated regions. They are generally sporadic, but rare instances of familial recurrence raise suspicions of underlying contributing genetic factors. While these disorders typically involve single-locus defects, some cases exhibit methylation abnormalities across multiple loci, a phenomenon known as Multilocus Imprinting Disturbance (MLID), resulting in overlapping syndromes depending on the affected loci. Recurrent MLID is rare and may be due to maternal trans-acting genetic variants in genes involved in embryonic epigenetic reprogramming

Material and Methods: A patient was referred to our center with suspected Beckwith-Wiedemann Syndrome (BWS) with additional symptoms of severe neurodevelopmental delay with absent speech and behavioral disorder reminiscent of Angelman Syndrome (AS). His brother had been previously diagnosed with BWS. We performed methylation assays, genomic microarrays and trio (proband and parents) whole-genome sequencing.

Results: Methylation analysis identified widespread abnormal unbalanced methylation patterns across multiple loci, including the regions associated with Beckwith-Wiedemann and Angelman syndromes (KCNQ1OT1/11p15.5 and SNRPN/15q21). Trio-WGS did not reveal any sequence variant associated with neurodeveloppemental disorder in the proband but the homozygous NM_017852.5:c.1177del p.(Gln393Serfs*16) frameshift variant in maternal NLRP2.

Conclusion: Bi-allelic variants in NLRP2 have been reported in two families with MLID: one family with two children with BWS-MLID and delayed development, one family with a Silver-Russel-MLID. Six additional families with history of early embryonic arrest have also been recorded. We describe the third family with biallelic maternal NLRP2 variant resulting in recurrent MLID and Beckwith-Wiedemann and Angelman syndromes in the same patient.

Background: Alazami syndrome (AS) (MIM 615071) is a rare autosomal recessive disorder caused by pathogenic variants in LARP7, leading to severe intellectual disability, growth retardation, craniofacial dysmorphisms, and skeletal abnormalities. While the clinical spectrum of AS has been well described, the potential involvement of impaired telomere maintenance in the disease pathogenesis reported in two pedigrees, remains unclear. This study aims to expand the phenotype of AS and investigate the correlation between telomere length and clinical manifestations.

Materials and Methods: Following a multicentric collaborative initiative, we identified 22 individuals from 15 families with genetically confirmed AS. Clinical, radiographic, and molecular data were systematically collected. Telomere length were measured by quantitative PCR and flow cytometry-based methods.

Results: All individuals presented with severe intellectual disability, short stature, and characteristic craniofacial anomalies. Skeletal abnormalities, particularly delayed bone age, joint contractures, and scoliosis, were frequently observed. Additional features included feeding difficulties, recurrent respiratory infections, and genitourinary anomalies. Neurodevelopmental assessments revealed profound cognitive impairment with absent or very limited speech development. Behavioral abnormalities, including autistic traits and hyperactivity, were also reported. Telomere length analysis on blood performed in three individuals showed no significant shortening.

Conclusion: This study expands the phenotypic spectrum of AS and provides a comprehensive characterization of its clinical manifestations. The findings highlight the multisystem involvement in AS, emphasizing the importance of early diagnosis and multidisciplinary management. Although the number of cases analyzed is still limited, shortening of telomere length in blood cells has not been confirmed.

Background: *TMEM17* encodes a transmembrane protein that is part of the cilium's transition zone; however, its exact function and structure remain unknown. Three cases have been published involving a primary ciliopathy phenotype associated with biallelic variants in *TMEM17*: NM_198276.2:c.306C>A p.(Asn102Lys) in two brothers with orofaciodigital syndrome and NM_198276:c.302G>T p.(Gly101Val) in a patient with Joubert syndrome. Here, further evidence for the role of the TMEM17 gene in cases of ciliopathies, including Meckel-Gruber syndrome (MGS) is provided.

Material and Methods: CENTOGENE Biodatabank containing information from over 800,000 individuals was queried for biallelic, rare variants in TMEM17 and related phenotypes. Human phenotypes are recorded as Human Phenotype Ontology terms. The gene-disease relationship (GDR) was evaluated according to the ClinGen recommendations.

Results: Four unrelated patients were identified in the Biodatabank with a diagnosis of MGS and novel homozygous variants in *TMEM17:* NM_198276.3:c4del p.(Glu2Serfs*58) in two cases, and NM_198276.3:c:366dup p.(Pro123Thrfs*9) and NM_198276.3:c.368C>G p.(Pro123Arg) in one case each. This allowed the upgrade of the GDR level of evidence from "limited" to "moderate". In contrast to the published patients, the newly identified cases presented prenatally with a very severe phenotype consisting of encephalocele, polycystic kidney dysplasia and polydactyly, with early lethality.

Conclusion: Biallelic variants in *TMEM17* are associated with ciliopathies, showing moderate evidence of a gene-disease relationship. This gene should be considered in the differential diagnosis of patients with a phenotype compatible with a primary ciliopathy. Additionally, the utility of bio-databanks in medical genetics is highlighted.

P13.030.B Genetic and phenotypic spectrum of KBG syndrome: an Australian case series of 21 individuals

***Sinead O'Sullivan**, Chirag Patel, Megan Higgins, Jonathan Rodgers, Christopher Richmond, Carla Smerdon, Di Milnes, Sophie Manoy, Julie McGaughran*

Genetic Health Queensland, Royal Brisbane & Women's Hospital, Brisbane, Australia.

Background: Heterozygous pathogenic loss of function *ANKRD11* variants or chromosome 16q24.3 deletions involving *ANKRD11* can cause KBG syndrome. This multi-system disorder has variable impacts on organ system development, learning, behaviour and growth. We describe a further 21 cases of KBG syndrome, not previously reported.

Material and Methods: Retrospective chart review was undertaken to document relevant clinical features and genetic testing results. Patient consent was obtained for publication of clinical photographs.

Results: 62% of the cohort were male. Age at time of diagnosis ranged from 0–20 years with a mean age of 8 years (SD = 5.2), including one antenatal case. 48% of genetic causes were determined to be de novo and 20% of cases were proven familial. 16q24.3 deletions with partial *ANKRD11* gene deletion were evident for 19% of the cohort, with one parent identified to be mosaic. Genetic variants included frameshift (48%), nonsense (24%), and missense (9%). Macrodontia, a triangular shaped face, synophrys, a distinctive nasal tip, long philtrum and thin upper lip were frequently reported. All patients had developmental delay, in particular speech delay. 52% had learning difficulties and 14% had verified intellectual impairment. 33% had hearing loss, 38% had musculoskeletal anomalies, 33% had short stature (<3rd centile), 33% had seizures and 24% had congenital heart disease. Novel findings for individual cases included anorectal malformation, bicornuate uterus and choanal atresia.

Conclusions: This case series demonstrates the wide spectrum of KBG syndrome and contributes further to the literature about the frequency of associated clinical features.

P13.031.C Complete pseudoanodontia resulting from genomic rearrangement of the *SHH* locus

***Kristjan A. Ragnarsson**[1], Helga Hauksdottir[1], Edda M. Elvarsdottir[1], Erla Sveinbjornsdottir[1], Eirikur Briem[1], Jon J. Jonsson[2]*

[1]Dept. of Genetics and Molecular Medicine, Landspitali University Hospital, Reykjavik, Iceland, [2]Dept. of Genetics and Molecular Medicine, Landspitali University Hospital, Dept. of Biochemistry and Molecular Biology, Faculty of Medicine, Univ. of Iceland, Reykjavik, Iceland.

Background: A mother-daughter pair presented with an unusual phenotype of mild developmental delay, distal arthrogryposis, exostosis of manubrium sterni, eruption failure of deciduous and adult teeth, and amblyopia. Family history negative. Chromosome analysis identified a de novo t(7;22)(q36.2;q13.32) balanced reciprocal translocation in both patients. We characterized the translocation with novel methods and identify a new phenotypic association with the *SHH* gene.

Material and Methods: Clinical laboratory genomics workup. Optical Genome Mapping (OGM), ONT long-read whole-genome sequencing (LRS) and RNA-seq. were performed.

Results: aCGH and short-read WGS were negative. LRS determined the precise breakpoint location (hg38 chr7:156,946,076 and chr22:45,309,078) and revealed a genomic rearrangement of the *SHH* locus. The *SHH* gene remains on derivative chr. 7 while its enhancers are translocated onto derivative chr. 22. The chr. 22 breakpoint is in the *FAM118A* gene, which has no known disease associations. RNA-seq. did not detect chimeric *FAM118A* fusion transcripts or abnormal expression of *FAM118A*. OGM did not detect any other structural variants that could explain their phenotype.

Conclusion: We elucidated the breakpoints of this de novo translocation in patients and identified a genomic rearrangement of the SHH locus. The rearrangement presumably results in disruption of the topologically associating domain of the *SHH* locus. This is the first reported case linking teeth eruption failure in humans to the *SHH* gene. This is supported by published mouse studies that showed total suppression of tooth eruption in neonatal mice following treatment with an Shh inhibitor. Hi-C pending.

P13.032.D Genetic analysis in Rubinstein-Taybi syndrome

Rika Kosaki[1], *Tomoko Kawai*[2], *Kazuhiko Nakabayashi*[3]

[1]*National Center for Child Heatlh and Development, Tokyo, Japan,* [2]*Division of Fetal Development, National Research Institute for Child Health and Development, Tokyo, Japan,* [3]*Department of Maternal-Fetal Biology, National Research Institute for Child Health and Development, Tokyo, Japan.*

Background: Rubinstein-Taybi syndrome (RTS) is characterized by distinctive facial appearance, broad thumbs, short stature, and intellectual disability. RTS is caused by heterozygous pathogenic variants or re-arrangements in the genes *CREBBP* and *EP300*, typically leading to haploinsufficiency. The diagnosis of RTS is made by the characteristic clinical findings and /or molecular genetic testing of a heterozygous pathogenic variant in *CREBBP* or *EP300*.

Material and Methods: Diagnostic approach of molecular genetic testing in RTS: Genomic DNA was extracted from peripheral blood. Targeted analysis of *CREBBP* and/or *EP300* was performed by Sanger sequencing and Multiplex Ligation-dependent Probe Amplification (MLPA) or array Comparative Genomic Hybridisation (aCGH).Whole-exome sequencing (WES), genome-wide methylation pattern (epigenetic signature) were also performed. Written informed consents were obtained from the parents of the patients in accordance with Institute Review Board and Ethics Committee.

Results: Ten patients with RTS were analyzed. Two nonsense variants, two frameshift variants, one splice donor variant, three small deletions, one small intragenic insertion/deletion in *CREBPP* and one nonsense variant in *EP300* were identified. The epigenetic signature was analyzed, as individuals with RTS showed a specific pattern.

Conclusion: RTS demonstrates significant phenotypic overlap with other Mendelian disorders, referred to as chromatinopathies, which affect chromatin structure on genome-wide scale. The identification of a pathogenic variant and genome-wide methylation pattern provides great support to confirm the clinical diagnosis.

P13.033.A Novel deletion of *ATAD3* gene cluster as a cause of lethal pontocerebellar hypoplasia, hypotonia, and respiratory insufficiency syndrome

Helena Paszekova[1], *Vaclava Curtisova*[2], *Ivana Markova*[3], *Renata Michalovska*[1]

[1]*GHC GENETICS, Prague, Czech Republic,* [2]*Ustav lekarske genetiky-Fakultni nemocnice Olomouc, Olomouc, Czech Republic,* [3]*G-CENTRUM Olomouc s.r.o, Olomouc, Czech Republic.*

Background: Neonatal lethal pontocerebellar hypoplasia, hypotonia, and respiratory insufficiency syndrome (PHRINL) is an autosomal recessive multisystem disorder with onset in utero and death in the neonatal period. We have found a homozygous deletion involving exons 6–16 of the *ATAD3B* gene and exons 1–2 of the *ATAD3A* gene in a newborn who died after birth and whose mother was pregnant at the time of the analysis.

Methods: We performed massive parallel sequencing on the NextSeq550 Illumina platform using the Clinical Exome Solutions v3 and Whole Exome Solutions v2 gene panels from Sophia Genetics.

Results: The full-term newborn was severely impaired in consciousness, unresponsive to painful stimuli, unable to open eyes, had hypertonicity, hypotrophy, encephalopathy, sepsis, pneumonia, respiratory failure, heart failure, petechiae, coagulopathy, cryptorchidism. We performed exome sequencing on a deceased newborn, mother, father, and amniotic fluid from an ongoing pregnancy. Deletions in the *ATAD3* gene cluster were detected in this family. The father has a heterozygous deletion including exons 4–16 of the *ATAD3B* gene and exons 1–4 of the *ATAD3A* gene and the mother has a heterozygous deletion including exons 10–12 of the *ATAD3C* gene, the entire *ATAD3B* gene (exons 1–16) and exons 1–2 of the *ATAD3A* gene. In the current pregnancy, the maternal variant was inherited and the second child is a healthy carrier.

Conclusion: We were able to identify new, previously undescribed deletions in the *ATAD3* gene cluster that were present in both parents and whose overlap was the cause of the homozygous deletion in the first deceased offspring.

P13.034.B In-vitro targeting of esophageal atresia candidate pathways with small molecules to investigate rare variant burden

Bianca Miranda de Graaf, *Rebecca Pulvirenti, Frank Magielsen, Rene MH Wijnen, Manon CW Spaander, Erwin Brosens*

ErasmusMC, Rotterdam, Netherlands.

Background: Esophageal atresia (EA) and tracheoesophageal fistula (TEF) arise after defective tracheoesophageal separation. Half of the patients have additional anomalies. Parents are usually unaffected, making de novo or recessive DNA alterations a plausible explanation. Patients with a more complex phenotype (including VACTERL) are known to be enriched for de novo variants. We hypothesize that part of the missing heritability is due to this subgroup of patients. Moreover, a substantial locus heterogeneity contributes to the low diagnostic yield. Our prior studies indicate disrupted actin cytoskeleton organization, BMP-signaling, disrupted cell adhesion, motility, and migration in TEF. We aim to investigate rare variants impacting these pathways by inhibiting and stimulating patient fibroblasts with small molecules.

Material and Methods: We selected twenty complex EA/TEF patients for short- and long-read genome sequencing, of which some have also been subjected to RNA-sequencing. We examine differences in transcriptomes, DNA damage response and cell morphology and behavior in patient versus control fibroblasts. Subsequently, we evaluate the contribution of deleterious de novo and inherited genetic changes in identified affected pathways.

Results: We identified several rare inherited variants in candidate pathway genes. We have determined IC50 values of small molecules in control fibroblasts and are currently investigating the differences of inhibiting and stimulating candidate pathways on patient vs control transcriptomes.

Conclusion: Further evaluation of pathway alteration in vitro should highlight the effect of the variants found. Combined, these results and a pathway-focused approach may improve our understanding of EA/TEF etiology and increase the diagnostic yield of NGS based approaches.

Background: Miller syndrome (MIM #263750) is a rare autosomal recessive acrofacial dysostosis caused by biallelic variants in *DHODH*, a key enzyme in pyrimidine biosynthesis. Since its identification in 2010, case reports have highlighted its variable phenotype, emphasizing the need to refine the clinical spectrum.

Material and Methods: We present a cohort of ten individuals from seven families, aged from prenatal diagnosis to 46 years, identified through national collaboration. Molecular analyses were performed via gene panel, exome, or genome sequencing. Clinical data were collected through standardized forms during routine care.

Results: This is the largest Miller syndrome cohort to date, revealing a broad phenotypic spectrum. We describe a novel finding of optic atrophy in multiple members of one consanguineous family. Typical postaxial limb defects, including 5th digit absence, were consistent with prior reports, but we also noted thumb and tibial hypoplasia, suggesting broader preaxial involvement. A higher prevalence of camptodactyly and facial hemangiomas in two patients were notable findings. Congenital heart defects, mainly atrial septal defects, were common, while neurodevelopment remained normal in all living individuals.

Conclusion: Our findings expand the Miller syndrome phenotype, particularly regarding preaxial limb anomalies and facial hemangiomas. The optic atrophy observed in one family warrants further screening to assess its association with the syndrome. Early prenatal diagnosis, especially in cases with limb and cardiac malformations, is crucial for management and genetic counseling.

P13.036.D Unravelling the molecular basis of Xia-Gibbs syndrome

Aurora Mazzetti[1], *Silvana Bochicchio*[1], *Lorenzo Graziani*[1], *Gloria Ros*[2], *Elisa D'Acunto*[3], *Diego Vozzi*[4], *Lucia Perone*[5], *Stefano Gustincich*[2], *Nicola Brunetti-Pierri*[5], *Remo Sanges*[1]

[1]*Neuroscience Area, International School for Advanced Studies (SISSA), Trieste, Italy,* [2]*Centre for Human Technologies (CHT), Central RNA Laboratory, Istituto Italiano di Tecnologia (IIT), Genova, Italy,* [3]*University of Naples Federico II, Napoli, Italy,* [4]*Genomics Facility (GEFA), Istituto Italiano di Tecnologia (IIT), Genova, Italy,* [5]*The Telethon Institute of Genetics and Medicine (TIGEM), Napoli, Italy.*

Background: Xia-Gibbs syndrome (XIGIS; OMIM #615829) is a rare neurodevelopmental disorder, characterised by various physical and neurological features, including cognitive impairment, motor delays, mild dysmorphism, and autism spectrum traits. XIGIS is associated with heterozygous mutations in the *AT-Hook DNA Binding Motif Containing 1* (*AHDC1*) gene, though the pathogenic mechanisms remain unclear. Preliminary evidence suggests that AHDC1 is involved in transcriptional regulation during differentiation and retinoic acid response.

Material and Methods: To investigate the effects of *AHDC1* mutations, we established lymphoblastoid cell lines in collaboration with the Italian Xia-Gibbs Society. After confirming the *AHDC1* expression, we performed polyA RNA-sequencing of three families to identify differentially expressed genes (DEGs) in the probands compared with their parents. Additionally, we developed a custom antibody targeting the AHDC1 N-terminal region to detect wild-type and potential truncated mutant protein forms via western blot (WB).

Results: RNA sequencing revealed several DEGs in the probands, involved in RNA processing and extracellular organisation. No significant reduction in *AHDC1* mRNA levels was observed in the probands compared with their parents, and mutant transcripts were detected in all XIGIS subjects. Additionally, the custom antibody was validated, and analysis of truncated AHDC1 forms is ongoing.

Conclusion: Our initial findings suggest that *AHDC1* mutations may lead to a gain-of-function mechanism. The identification of DEGs provides insight into potential molecular pathways involved in XIGIS. The successful validation of the custom antibody paves the way for detecting truncated AHDC1 protein forms, further refining our understanding of the molecular mechanisms underlying the syndrome.

P13.037.A Dual diagnosis of two overgrowth conditions in the same individual: Sotos and Tatton-Brown-Rahman syndromes. What is the cancer risk?

Chiara Sciarretta[1,2], *Giovanna Traficante*[2], *Francesco Marco Parodo*[1,2], *Marco Tellini*[3], *Carla Fonte*[3], *Annarita Giliberti*[2], *Lucia Tiberi*[2], *Giulia Gori*[2], *Elia Dirupo*[2], *Rosangela Artuso*[2], *Angela Peron*[1,2]

[1]Department of Clinical and Experimental Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy, [2]Division of Medical Genetics, Neuroscience and Medical Genetics Department, Meyer Children's Hospital IRCCS, Florence, Italy, [3]Neuro-Oncology Unit, Meyer Children's Hospital IRCCS, Florence, Italy.

Material and Methods: We report on a 10-year-old female, third-born to Moroccan consanguineous (first cousin) parents. She was evaluated for classic medulloblastoma (diagnosed at 5 years of age), chronic renal insufficiency, CMV-blindness, and panhypopituitarism. She presented with macrosomia, advanced bone age and joint hyperlaxity with motor impairment.

Results: Trio whole exome sequencing (WES) identified two heterozygous de novo variants: c.6455G>A,p.(Arg2152Gln) in *NSD1* and c.2644C>T,p.(Arg882Cys) in *DNMT3A*, both classified as pathogenic (ACMG).

Previous genetic analyses (karyotype, array-CGH and methylation study of the 11p15.5 region) were normal.

Conclusion: We present a dual diagnosis of two distinct de novo overgrowth conditions in a patient born to consanguineous parents. The co-occurrence of two genetic disorders is a growing phenomenon with the advent of next-generation technologies.Our patient shows variable features of both Sotos and Tatton-Brown-Rahman (TBRS) syndromes, as well as some distinctive facial features reminiscent of Sotos (evident in the childhood photos shown by the family at first genetic evaluation) before the cancer diagnosis and treatment. Furthermore, our case adds some novel features that include pericardiac effusion, which has only been reported in another patient with TBRS. Given the patient's history, the oncological risk associated with both syndromes and the lack of consensus guidelines regarding cancer screening for both conditions, this dual diagnosis represents a new challenge for healthcare professionals in terms of planning personalised surveillance.

Background: *TLK2* is a gene encoding a protein forming homo- and hetero-dimers involved in DNA replication,cell cycle checkpoint recovery and chromatin remodeling.It is responsible for a neurodevelopmental disorder(NDD)(#618050) characterized by developmental delay(DD)/intellectual disability(ID),behavioral issues,microcephaly,gastro-intestinal problems and dysmorphisms.

Material and Methods: Here, we report two children with two different de novo, not yet reported, pathogenic variants (PVs) in *TLK2*:c.878delinsAAGC;p.Arg293delinsGlnAla and c.2117_2118dup;p.Arg707Thrfs*103 (NM_006852).They both had microcephaly,short stature,DD,hypotonia and dysmorphisms.One child also presented IUGR,monocoronal synostosis,joint hypermobility and constipation.We also reviewed literature debating TLK2-NDD clinical and molecular characteristics.

Results: Forty-three other patients were identified.The features of all known TLK2 children are summarized in table. Penetrance is complete, the phenotype variable. Only one homozygous patient (c.163 A>G; p.Lys55Glu) has been reported with a more severe phenotype and healthy carriers' parents.The forty-four PVs reported were distributed along the entire gene.Truncating variants were 38,6%, missense and splicing 29,5% each,and indels 2,3%.

Conclusions: We confirm that the key features of TLK2-NDD are DD/ID, microcephaly, hypotonia, short stature and behavioral issues.Yet *TLK2* can be even a rare cause of syndromic craniosynostosis.Given the extreme rarity of the disorder,the lack of hotspot PVs, the definition of genotype-phenotype correlation is still an object of research.Even haploinsufficiency seems to be the most likely pathogenetic mechanism, dominant negative effect for at least some missense variants has been suggested.Regulation and dimeric structure of *TLK2* warrant further investigation.Description of additional cases, the parallels with other overlapping genetic disorders due to chromatin regulation might offer insights for further studies.

	Affected/Total	%
Speech delay/Developmental delay	42/45	93
Intellectual disability	36/45	80

P13.039.C Further clinical delineation of a *MED13L* recurrent missense variant at codon Pro866 expands the *MED13L*-related syndrome beyond haploinsufficiency

Anne Guimier[1,2], *Charlotte Guillouet*[2], *Thomas Courtin*[1], *Caroline Michot*[3], *Marie Hully*[4], *Sophie Rondeau*[1], *Giulia Barcia*[1], *Chris Gordon*[2], *Jeanne Amiel*[2,1]

[1]*Service de Médecine Génomique des Maladies Rares, Hôpital Necker-Enfants Malades, AP-HP, Paris, France,* [2]*Laboratory of Embryology and Genetics of Malformations, INSERM U1163, Université Paris Cité, Institut Imagine, Paris, France,* [3]*Reference Center for Skeletal Dysplasias, INSERM UMR1163, Paris Descartes - Sorbonne Paris Cité University, Imagine Institute, Necker-Enfants Malades Hospital, Paris, France,* [4]*Département de Neurologie Pédiatrique, Necker Enfants-Malades Hospital, APHP Centre, Université Paris Cité, 75015 Paris, France; AP-HP, Necker Enfant Malade Hospital, Unité de Médecine Physique et de Réadaptation, Paris, France.*

Background: *MED13L* encodes a subunit of the CDK8 kinase module of the Mediator complex. *MED13L* haploinsufficiency leads to syndromic intellectual disability (ID) with minimal or absent speech, hypotonia, behavioral symptoms, seizures and musculoskeletal malformations, with facial features including upslanted and/or short palpebral fissures, broad forehead and large open mouth appearance. Several missense variants have been reported, some of which are recurrent and clustered in exons 15–17 and 25–31. Clinical details and photographs are available for one individual reported with the p.Pro866Leu variant and three with the p.Pro869Ser variant (both within exon 15). These individuals are more severely affected than those with truncating variants.

Methods/Results: Here, we report three unrelated individuals harbouring the recurrent de novo p.Pro866Leu variant and sharing a strikingly similar presentation including pre- and/or post-natal progressive microcephaly, moderate to severe ID, poor/absent speech, hyperlaxity, brachytelephalangy of fingers with fetal pads, severe scoliosis, coxa valga, gracile bones, osteoporosis and fractures. Facial features include stiff skin with a facial mask appearance, metopic ridge, long and everted lower eyelids and thin upper lip. Interestingly, previously reported individuals with the p.Pro866Leu and p.Pro869Ser variants share the same gestalt, in contrast to patients presenting truncating variants. Microcephaly and slender habitus are at odds with the frequent stocky habitus of individuals with classic *MED13L*-related syndrome.

Conclusion: These three cases strengthen the hypothesis of dominant-negative or gain-of-function mechanism for this cluster of missense variants affecting highly conserved residues (Pro866 and Pro869) and leading to a novel and recognizable clinical presentation.

P13.041.A WGS identifies compound heterozygous deep-intronic variant and complex rearrangement in VPS13B in a patient with Cohen syndrome

Lies Hoefsloot[1], *Frank Sleutels*[2], *Camilla Calandrini*[1], *Hannie Douben*[1], *Rachel Schot*[2], *Adriana Iglesias*[3], *Martha J.H. Tjon Fo Sang*[4], *Anneke Kievit*[5], *Tjakko van Ham*[6]

[1]*Erasmus MC, University Medical Center RotterdamDept Clinical Genetics, Rotterdam, Netherlands,* [2]*ErasmusMC, Rotterdam, Netherlands,* [3]*Erasmus MC, Department of Clinical Genetics, Rotterdam, Netherlands,* [4]*Rotterdam Eye Hospital, Rotterdam, Netherlands,* [5]*Dept. of Clinical Genetics; Erasmus MC, Capelle Aan Den Ijssel, Netherlands,* [6]*Erasmus MC, Rotterdam, Netherlands.*

Background/Results: Recently, we implemented diagnostic whole genome sequencing (WGS) to replace exome sequencing. For a patient with high myopia, rod-cone dystrophy, mild cataract, intellectual disability, short stature, microcephaly, central obesity, small hands and feet, hyperlaxity and dysmorphic features this allowed us after ten years to obtain a diagnosis. The family history was negative for vision loss problems, but her brother had intellectual disability and Duchenne muscular dystrophy due to a maternal *DMD* deletion, which the patient did not inherit. Exome analysis with a vision-loss panel did not identify abnormalities, so we expanded the search with a broad gene panel (clingenV1). Two variants were detected in the *VPS13B* gene: a maternal complex rearrangement causing a partial exon 14 deletion, and a deep intronic variant (NM_017890.5(VPS13B):c.4042+258C>G) on the paternal allele, predicted to strengthen a deep-intronic cryptic splice site. Subsequent analysis on RNA from blood cells using RT-PCR and Sanger sequencing showed the inclusion of a pseudo-exon, leading to a predicted frameshift, and nonsense-mediated mRNA decay: NM_017890.5(VPS13B):r.4042_4043ins4042+172_4042+257, p.(Glu1348Glyfs*2). Together, this confirmed the diagnosis Cohen syndrome. Subsequent analysis of 10 WGS datasets revealed 5–21 rare deep-intronic variants per patient (average 11.8), with specific panels reducing this to 0–6 (average 2.1), suggesting the feasibility of analysis of deep-intronic variants.

Conclusion: In this case the availability of WGS data showed the superiority in detecting structural variants and the capacity to directly prioritize relevant deep-intronic variants.

P13.042.B Expanding the PTEN Mutational Spectrum: Identification of Eight Novel Variants and Genotype-Phenotype Correlations in a Multicenter PHTS Cohort

Silvia Cali[1,2], *Valeria Capra*[1], *Andrea Chiaro*[3], *Francesca Mercadante*[2], *Francesca Madia*[4], *Consiglio Valeria*[2], *Pasquale Striano*[5,6], *Maria Stella Vari*[6], *Francesca Faravelli*[1], *Maria Piccione*[7,2]

[1]*IRCCS Giannina Gaslini Institute, Genomics and Clinical Genetics, Genova, Italy,* [2]*AOOR Villa Sofia-Cervello Hospitals, Medical Genetics Unit, Palermo, Italy,* [3]*IRCCS Giannina Gaslini Institute, Pediatric Gastroenterology and Endoscopy Unit, Genova, Italy,* [4]*IRCCS Giannina Gaslini Institute, Medical Genetics Unit, Genova, Genova, Italy,* [5]*Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genova, Genova, Italy,* [6]*IRCCS Giannina Gaslini Institute, Pediatric Neurology and Muscular Diseases Unit, Genova, Italy,* [7]*Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, University of Palermo, Palermo, Italy.*

Background: PTEN Hamartoma Tumor Syndrome (PHTS) is an autosomal dominant disorder characterized by macrocephaly, neurodevelopmental abnormalities, hamartomatous growths, and increased cancer risk. Despite its clinical heterogeneity, genotype-phenotype correlations remain poorly understood. This study investigates PTEN mutational profiles and associated clinical features in a multicenter cohort, expanding the mutational

spectrum with the identification of 8 novel variants.

Methods: Thirty-eight patients were recruited from Cervello Hospital (Palermo) and IRCCS Giannina Gaslini (Genoa). Genetic sequencing identified 29 PTEN variants, classified as pathogenic (P) or likely pathogenic (LP) according to ACMG guidelines. Clinical, neuroimaging, and gastrointestinal data were systematically reviewed to assess phenotypic variability and age-related manifestations.

Results: A total of 29 distinct variants were identified (14 missense, 8 nonsense, 4 frameshift, 3 splice-site), including 8 novel mutations (3 missense, 1 nonsense, 3 frameshift, 1 splice-site). Macrocephaly was present in 89.4% of cases, frequently associated with neurodevelopmental disorders (42.1%) and autism spectrum disorder. Thyroid pathology was observed in 26.3%, including carcinoma in 3 patients. Gastrointestinal polyposis was found in 15.8%, with mixed and hamartomatous histology. Neuroimaging abnormalities were detected in 31.6%, including hydrocephalus (13.2%) and Chiari I malformation (7.9%). Missense mutations were predominantly associated with neurodevelopmental disorders, while truncating mutations showed unexpected links to these phenotypes, suggesting a broader PTEN-related neurodevelopmental impact.

Conclusion: This study expands the PTEN mutational spectrum with 8 novel variants, refining genotype-phenotype correlations and highlighting the need for early genetic diagnosis and personalized follow-up strategies. A multidisciplinary approach is essential to optimize clinical management and long-term surveillance in PHTS patients.

P13.043.C A clinical study of Japanese patients with ReNU syndrome

Nobuhiko Okamoto[1], *Eriko Nishi*[1], *Yuiko Hasegawa*[1], *Kumiko Yanagi*[2], *Tadashi Kaname*[2], *Yuri Uchiyama*[3,4], *Naomichi Matsumoto*[3,4,5]

[1]*Department of Medical Genetics, Osaka Women's and Children's Hospital, Izumi, Japan,* [2]*Department of Genome Medicine, National Center for Child Health and Development, Tokyo, Japan,* [3]*Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan,* [4]*Department of Rare Disease Genomics, Yokohama City University Hospital, Yokohama, Japan,* [5]*Department of Clinical Genetics, Yokohama City University Hospital, Yokohama, Japan.*

Background: ReNU syndrome, also known as neurodevelopmental disorder with hypotonia, brain anomalies, distinctive facies, and absent language (NEDHAFA), is characterized by hypotonia, global developmental delay, intellectual disability (ID) with poor or absent speech, delayed motor development, feeding difficulties, short stature, seizures, and dysmorphic features. Neuroradiological abnormalities including ventriculomegaly, hypoplasia of corpus callosum, and decreased white matter volume are observed. Most of the individuals have the same highly recurrent single base insertion (n.64_65insT) in *RNU4-2*. *RNU4-2* encodes the U4 small nuclear RNA (snRNA), which is a critical component of the U4/U6.U5 tri-snRNP complex of the major spliceosome.

Material and Methods: We reviewed patients with neurodevelopmental disorders that matched the clinical features of ReNU syndrome and performed hotspot analysis using Sanger method. Whole-exome sequencing did not identify any variants that could explain the symptoms in all cases. A recurrent variant was identified in 6 cases, while a novel variant, n.66A>G, was detected in one case.

Results: The 7 patients were aged between 4 and 27 years. All patients showed severe developmental delay and/or ID. Independent walking was achieved in 4 cases. In 5 cases, meaningful words had not been acquired even after the age of 5 years. All patients showed a distinctive pattern of dysmorphic features, including hooded upper eyelid, full cheeks, tented philtrum, and mouth constantly open with an everted lower lip vermilion. All patients showed neuroradiological abnormalities.

Conclusion: The identification of 7 patients at a single institution reaffirmed that ReNU syndrome is an important cause of ID. We identified a novel variant in *RNU4-2*.

P13.044.D Pile on many more layers: a case of neurodevelopmental and hormonal disorder illustrating the complexity of multiple diagnoses

Stefano Giuseppe Caraffi[1], *Gianluca Contrò*[1], *Chiara Sartori*[1], *Carlotta Spagnoli*[1], *Roberta Zuntini*[1], *Maria Amato*[1], *Susanna Rizzi*[1], *Tommaso Pippucci*[2], *Daniele Frattini*[1], *Carlo Fusco*[1], *Livia Garavelli*[1]

[1]*Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy,* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: About 10% of cases with a complex rare condition are actually expected to have multiple Mendelian diseases. Ascertainment can be hindered by their overlapping effects, as illustrated by the triple diagnosis in this case report.

Material and Methods: Imaging, laboratory tests and specialistic evaluation according to good clinical practice; WES (SNV +CNV analysis) filtered for neurodevelopmental disorders.

Results: The proband, a 12 year old boy, is the third child of healthy nonconsanguineous parents. At age 1 year, trigonocephaly due to early closure of the metopic suture was detected. During childhood he showed language delay and was diagnosed with mild to moderate intellectual disability. At age 9 years premature pubarche and high levels of 17-hydroxyprogesterone were noted, and *CYP21A2* gene testing confirmed homozygous pathogenic variant NM_000500.9:c.[844G>T];[844G>T], p.[Val282Leu];[Val282Leu], associated with late-onset adrenal hyperplasia syndrome (NC-CAH). At age 10 years onset of epilepsy with focal impaired awareness seizures prompted neuropsychiatric evaluation at our hospital and WES analysis, which detected a 47,XXY karyotype and a de novo variant in the *ZMYM2* gene: NM_003453.6:c.[3976del];[=], p.[(Tyr1326Ilefs*35)];[(=)] (ACMG/AMP class 4).

Conclusion: NC-CAH may explain the trigonocephaly and apparently offsets the hypogonadism associated with Klinefelter syndrome; a follow-up throughout puberty will elucidate this effect. The presentation is complicated by a neurodevelopmental disorder likely caused by a hypomorphic frameshift alteration of transcriptional regulator *ZMYM2*. Recognition of the multiple diagnosis will aid in addressing each aspect appropriately.

P13.045.A Mosaic *KMT2D* variant in Kabuki syndrome - importance of DNA methylation profiling in diagnostics

Simona Jakovchevska, *Mirjana Gusic, Anna Schossig, Konstanze Hörtnagel*

MVZ Martinsried GmbH, Martinsried, Germany.

Background: Pathogenic variants in *KMT2D* gene cause autosomal dominant Kabuki syndrome (KS), a rare congenital neurodevelopmental disorder characterized by intellectual disability, visceral malformations, persistence of fetal fingertip pads, short stature, skeletal anomalies and combination of specific facial features. In recent years more than 11 individuals with mosaic pathogenic *KMT2D* variants have been reported, with variant allele frequency (VAF) 10%–37%, suggesting that the presence of the variant even in just mosaic form can lead to an almost fully penetrant phenotype. In addition, a distinctive and similar epigenetic signature has been identified in blood of both mosaic and heterozygous patients, proposing the DNA methylation profiling as a diagnostic tool for better interpretation of *KMT2D* variants.

Material and Methods: A four-year old male with hypotonia, unilateral renal agenesis, short stature, downslanted palpebral fissures, microcephaly, premature birth, motor delay, and mild global developmental delay was referred to singleton whole exome sequencing (WES).

Results: WES and subsequent Sanger sequencing analysis revealed a nonsense variant c.8311C>T p.(Arg2771*) in the *KMT2D* gene in mosaic form (VAF 12–19%). This variant has been previously reported in KS patients, but only in heterozygous form. Methylation studies are ongoing.

Conclusion: We report a rare case of *KMT2D* mosaic variant leading to Kabuki syndrome. It highlights the need for variant testing in alternative tissues as well as DNA methylation profiling to better interpret WES results, especially for Mendelian disorders caused by defect in epigenetic machinery.

P13.046.B Molecular and phenotypic characterization of 21 Polish patients with *CREBBP/EP300* mutations: from Rubinstein-Taybi to Menke-Hennekam syndromes

Agata Maria Cieslikowska[1], *Elzbieta Ciara*[1], *Dorota Wicher*[1], *Agnieszka Madej-Pilarczyk*[1], *Maria Jedrzejowska*[1,2], *Katarzyna Iwanicka-Pronicka*[1], *Iwanowski Piotr*[1], *Dorota Jurkiewicz*[1], *Marzena Gawlik*[1], *Dorota Piekutowska-Abramczuk*[1], *Paulina Halat-Wolska*[1], *Justyna Bucher*[1], *Izabela Mendrek*[1], *Krystyna Chrzanowska*[1], *Malgorzata Krajewska-Walasek*[1,3], *Marlena Mlynek*[1], *Piotr Stawinski*[4], *Joanna Kosinska*[4]

[1]*Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland,* [2]*Department of Medical Genetics, Institute of Mother and Child, Warsaw, Poland,* [3]*Imagene.Me SA, Warsaw, Poland,* [4]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.*

Background: Rubinstein-Taybi syndrome (RSTS) is characterized by distinctive facial dysmorphia, broad thumbs/halluces, short stature, hearing loss, heart/renal defect, cryptorchidism and intellectual disability. RSTS is associated with heterozygous mutations in *CREBBP* or *EP300* genes, with expected detection rates of 88% for *CREBBP* SNV, 12% for *CREBBP* CNV, and 8–10% for *EP300* mutations. Variants in 30–31 exons of *CREBBP* or in the homologous regions of *EP300* are associated with Menke-Hennekam syndrome, characterized by developmental delay, distinctive facial features, short stature and behavioral problems.

Material and Methods: The study included 21 patients with a clinical suspicion of either RSTS or an unspecified neurodevelopmental-dysmorphic syndrome (in line with the 'from genotype to phenotype' approach in case of the latter), diagnosed through comprehensive genetic testing (NGS and MLPA/aCGH, where applicable).

Results: Molecular analysis revealed mutations in *CREBBP* (15 patients, 71%) and *EP300* (6 patients, 28%), including frameshift indels(24%), missense(29%) / nonsense(14%) / splice site(5%) variants, or larger deletions(24%). The distribution of variant types shows slightly higher proportion of deletions compared with expected rates. Remarkably, 48% of identified variants were novel (*CREBBP*: c.-49_12del, c.289C>T, c.1094A>G, c.4133+2T>G, c.5028_5029dup, c.7174G>A; *EP300*: c.1093_1096del, c.3044_3045del, c.3205G>A, c.4713_4722del), with 8/10 occurred de novo. Most patients displayed typical RSTS phenotype. Notably, two patients with a *CREBBP* variant in exon 30(c.5028_5029dup) or 31(c.5614A>G) presented clinical features distinct of RSTS, but consistent with Menke-Hennekam syndrome.

Conclusion: This cohort significantly expands the known mutation spectrum of RSTS and highlights the importance of careful genotype-phenotype correlation in patients with variants in exons 30–31 of *CREBBP*.

P13.047.C Mosaic*KMT2D*Mutation in a Patient with Subtle Kabuki Syndrome Facial Dysmorphisms, Aortic Carctation and Mild Neurobehavioral Features: Case Report and Review of Clinical and Molecular data

Maria Lisa Dentici[1], *Federica Lo Bascio*[1,2], *Maria Gnazzo*[3], *Lorenzo Sinibaldi*[1], *Andrea Bartuli*[1], *Antonio Novelli*[3], *Digilio Maria Cristina*[1]

[1]*Rare Diseases and Medical Genetics Unit, Ospedale Pediatrico Bambino Gesù, Rome, Italy, Rome, Italy,* [2]*Department of Biomedicine and Prevention, University of Rome "Tor Vergata", Rome, Italy., Rome, Italy,* [3]*Translational Cytogenomics Research Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy., Rome, Italy.*

Background: Kabuki syndrome (KS) is a rare genetic disorder characterized by multiple congenital anomalies, variable intellectual disability and distinct facial features. Most cases are caused by variants in KMT2D and, less frequently, in KDM6A. Up to now, mosaic KMT2D variations have been documented in 12 individuals with allele frequencies ranging from 10% to 37% in blood cells.

Material and Methods: We report on a 7-year-old boy clinically suspected for KS because of mild facial features including elongated palpebral fissures, sparse lateral eyebrows, large anteverted ears, prominent fetal fingertip pads, fifth digit brachymesophalangy. Stature was in the low-normal range and he presented congenital heart disease (CHD) including aorta coarctation, surgically corrected at 2 months, bicuspid aortic valve, parachute mitral valve dysplasia. He also showed neurodevelopmental delay (speech delay, hyperactivity).

Results: Next-generation sequencing (NGS) panel including KMT2D, KDM6A, RAP1A, RAP1B and HNRNPK genes identified a previously reported KMT2D nonsense variant resulting in a premature stop codon (p.Arg5501Ter) at a low allele fraction of 20% in peripheral blood as the molecular defect underlying the trait.Analysis of available records of *KMT2D* mosaic cases was performed to outline the possible distinguishing features in comparison with the germline KS clinical spectrum. The majority of these patients display milder craniofacial and growth phenotypes and do not have CHD.

Conclusion: Consistent with previous data, we provide evidence that mosaic *KMT2D* mutations may result in subtle KS facial dysmorphisms and mild neurobehavioral features. Additionally, our report emphasizes that tipycal CHD (including aorta coarctation) of constituional KS can also be present in a low rate mosaicism.

P13.048.D Beyond a single syndrome: the importance of comprehensive genetic analysis in complex cases

Iglika Sotkova-Ivanova[1,2], *Hristo Ivanov*[1,2], *Iliana Pacheva*[3], *Ralica Vasileva*[3], *Vili Stoyanova*[1], *Margarita Panova*[3]

[1]*Medical University Plovdiv, Department of Medical Genetics, Plovdiv, Bulgaria,* [2]*Medical center Neuro Ped Gene LTD, Plovdiv, Bulgaria,* [3]*Medical University Plovdiv, Department of Pediatrics, Plovdiv, Bulgaria.*

Background: Genetic disorders often present with complex and overlapping phenotypes, making accurate diagnosis challenging. The assumption that all symptoms arise from a single syndrome can lead to misdiagnosis or incomplete understanding of a patient's condition. We present the case of a 2-month-old female infant born via in vitro fertilization, complicated by maternal hypertension, and delivered at term with an optimal APGAR score and a birth weight of 3010 g. Postnatally, she exhibited skin blistering, nail loss, and mucosal involvement. Due to developmental delay and suspected seizures, further investigations were conducted, leading to the identification of two distinct genetic disorders—Epidermolysis Bullosa (EB) and Beta-Ureidopropionase Deficiency (BUPD).

Material and Methods: A whole exome sequencing with a panel for EB was performed, and reanalysis of the initial NGS data was conducted due to additional symptoms.

Results: An NGS panel identified a homozygous pathogenic variant in LAMB3 (c.727C>T, p.Gln243Ter), confirming Junctional EB, which explained the dermatological manifestations. Subsequent reanalysis revealed a homozygous likely pathogenic variant in UPB1 (c.917-1G>A), associated with Beta-Ureidopropionase Deficiency, explaining the neurological symptoms. This case underscores the importance of considering multiple genetic diagnoses when clinical findings do not align with a single disorder.

Conclusion: Clinicians must remain vigilant to the possibility of dual diagnoses rather than attributing all symptoms to one condition. While targeted panel testing is cost-effective and time-efficient, it may overlook pathogenic variants in genes not included in the panel. Comprehensive genomic analysis should be considered in complex cases, supporting ACMG guidelines advocating for reanalysis when clinical suspicion persists.

P13.050.B A de novo *MYRF* pathogenetic variant in a patient with Cornelia de Lange syndrome

Elisabetta Di Fede[1,2], *Milena Mariani*[3], *Donatella Fossa*[4], *Marzia Giagnacovo*[5], *Silvia Scupilliti*[3], *Maura Masciadri*[6], *Laura Pezzoli*[7], *Maria Iascone*[7], *Cristina Gervasini*[1,2], *Valentina Massa*[1,2], *Angelo Selicorni*[3]

[1]*Dept. Health Sciences, Univeristy of Milan, Milan, Italy,* [2]*"Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, University of Milan, Milan, Italy,* [3]*Dept. Pediatrics, Sant'Anna Hospital, ASST Lariana, Como, Italy,* [4]*Maternal-Fetal Medicine, Gynecology Unit, Sant'Anna Hospital, ASST Lariana, Como, Italy,* [5]*Genetics Laboratory, Sant'Anna Hospital, ASST Lariana, Como, Italy,* [6]*Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milan, Italy,* [7]*Medical Genetics Laboratory, Papa Giovanni XXIII Hospital, Bergamo, Italy.*

Background: Cornelia de Lange syndrome (CdLS) is a rare neurodevelopmental disorder characterized by peculiar features and caused by variants in genes encoding for components of cohesin complex or related proteins (OMIM #122470, #300590, #610759, #614701, #300882, #620568). These genes account for 75–80% of patients, whether some patients remain without molecular diagnosis and several other genes have proposed as causative.

Material and Methods: A patient with fetal diaphragmatic hernia was referred to our prenatal diagnosis clinic and karyotype and SNP array were performed. After birth, targeted gene sequencing and MLPA on patient's sample and trio-whole exome sequencing (WES) were carried out. Bioinformatic analyses were performed exploiting databases for assessing pathogenicity of the variant. Then, protein prediction tools were used for protein interactions analysis.

Results: The newborn had no vital signs at birth, and he showed clinical features of classic CdLS (clinical score evaluation > 11). A de novo frameshift variant in *MYRF* was identified by trio WES: c.1276delC, p.(Leu426Serfs*6). Our patient showed overlapping features with Cardiac-urogenital syndrome (CUGS, OMIM# 618280), caused by de novo variants in *MYRF*, encoding for a transcription factor which regulates CNS myelination and embryonic development. In addition, pathogenicity of the identified variant was sustained by protein prediction tools which show MYRF disruption and a correlation with members of the cohesin complex causative of CdLS was suggested by predicted protein interactors.

Conclusion: These findings expand CdLS molecular range and suggest a possible role for MYRF in this context. Its molecular interactions in genetic disorders should be further addressed.

P13.051.C Unraveling a blended phenotype through reverse phenotyping, a case of prolidase deficiency and epiphyseal dysplasia

Alp Peker[1], *Ayça Aykut*[1], *Işıl Karaarslan*[2], *Haluk Akın*[1], *Asude Durmaz*[1]

[1]*Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey,* [2]*Ege University Faculty of Medicine, Department of Dermatology, Izmir, Turkey.*

Background: A 25-year-old patient with chronic, painful skin ulcers on the lower extremities and epiphyseal dysplasia presented to our clinic. The patient had been experiencing skin lesions for 10 years and was previously diagnosed with vasculitis. However, the lesions remained unresponsive to treatments, including prednisone, colchicine, and cyclosporine. Additionally, the patient had bilateral avascular necrosis, with a history of left hip surgery. After being advised to undergo right hip surgery, but with persistent skin lesions, the patient was referred to our clinic by the dermatology department for further evaluation.

Material and Methods: Genomic DNA was extracted from a peripheral blood sample of the patient for clinical exome analysis. Exons and exon-intron transition regions of 4490 genes were investigated by next-generation sequencing. Variants were analyzed using the Genomize SEQ platform.

Results: A homozygous pathogenic variant of *PEPD* (NM_000285.4) c.549-1G>A, and a heterozygous likely pathogenic variant, *COMP* (NM_000095.3) c.819C>A (p.Asp273Glu), were observed in the patient's genomic data, and were correlating with the patient's clinical findings.

Conclusion: This case demonstrates the value of reverse phenotyping in clarifying a blended phenotype resulting from two distinct genetic disorders. The identification of a homozygous pathogenic *PEPD* variant redefined the patient's treatment-resistant skin ulcers as prolidase deficiency, rather than vasculitis. Additionally, the heterozygous *COMP* variant explained the musculoskeletal complications, including epiphyseal dysplasia and bilateral avascular necrosis. By integrating genomic and clinical data, reverse phenotyping enabled a more accurate diagnosis, highlighting the importance of comprehensive genetic analysis in cases with atypical or overlapping phenotypes, ultimately improving patient management.

P13.052.D Expanding the phenotype: long-QT associated with *EMC1* compound heterozigosity

Inês Beleza[1], *Alice Porto Vasconcelos*[1], *Carla Ramalho*[2,3,4], *João Antunes Sarmento*[5,3], *Luísa Sampaio*[6,7], *Ricardo Rêgo*[8], *João Parente Freixo*[9], *Renata D'Oliveira*[1]

[1]*Serviço de Genética Médica, Hospital de São João (ULS S. João), Porto, Portugal,* [2]*Serviço de Obstetrícia, Hospital de São João (ULS S. João), Porto, Portugal,* [3]*Departamento de Ginecologia-Obstetrícia e Pediatria, Faculdade de Medicina da Universidade do Porto, Porto, Portugal,* [4]*Unidade de Investigação RISE-Health, Faculdade de Medicina da Universidade do Porto, Porto, Portugal,* [5]*Serviço de Cardiologia Pediátrica, Hospital de São João (ULS S. João), Porto, Portugal,* [6]*Serviço de Neurorradiologia, Hospital de São João (ULS S. João), Porto, Portugal,* [7]*Departamento de Medicina, Faculdade de Medicina da Universidade do Porto, Porto, Portugal,* [8]*Unidade de Neurofisiologia, Serviço de Neurologia, Hospital de São João (ULS S. João), Porto, Portugal,* [9]*Centro de Genética Preditiva e Preventiva, Instituto de Biologia Molecular e Celular (CGPP-IBMC), Porto, Portugal.*

Background: Biallelic pathogenic variants at *EMC1* are associated with "Cerebellar atrophy, visual impairment, and psychomotor retardation" (MIM #616875), an ultrarare autosomal recessive neurodegenerative disorder with neonatal presentation of hypotonia, other neurological features, brain abnormalities (namely thin *corpus callosum* and cerebellar atrophy), and craniofacial dysmorphisms.

Methods: Clinical description of severe unusual presentation of *EMC1*-related disorder.

Results: We describe a male infant, born to healthy non-consanguineous parents, with prenatal presentation of sinus bradycardia and premature atrial contractions. He was admitted at birth in the Neonatal Intensive Care Unit with respiratory distress and hypotonia. This infant was subsequently diagnosed with long-QT and dilated cardiomyopathy with progressive heart failure. He maintained progressive global developmental delay, with poor eye contact, severe hypotonia, and facial hypomimia. Seizures were suspected at 5-months-old (right oculocephalic version and bilateral arm flexion), with EEG disclosing bilateral temporo-parietal interictal epileptiform discharges and an abnormal background. Brain imaging showed mega cisterna magna and a small *corpus callosum*. The boy had sudden death at 7.5 months of age, likely due to long-QT-related dysrhythmia. Trio Whole Exome Sequencing identified two compound heterozygous variants in *EMC1* gene, classified as likely pathogenic.

Conclusion: To the best of our knowledge, biallelic *EMC1* pathogenic variants are rarely associated with long-QT and neurodevelopmental delay with seizures. Recently, a case report of two infant siblings linked a similar cardiac phenotype with compound heterozygosity in *EMC1*. These findings show the importance of expanding the current phenotypic knowledge on *EMC1*-related disorders, possibly associating high cardiac risk due to potentially lethal QT-long-related arrythmias.

P13.053.A Atypical presentation of Beckwith-Wiedemann syndrome revealed coexistence of Snijders Blok-Fisher syndrome in a 4-year-old male patient

Sinem Kocagil, *Emre Akbaş, Oğuz Çilingir*

Eskişehir Osmangazi University, Eskişehir, Turkey.

Background: Snijders Blok-Fisher syndrome (SBF, OMIM #618604) is a rare, autosomal dominant neurodevelopmental disorder characterized by mild-severe intellectual disability, dysmorphism, hypotonia, seizures, and central nervous system abnormalities. The clinical presentation is variable in severity and is associated with de novo pathogenic variants in *POU3F3* gene. Beckwith-Wiedemann syndrome (BWS, OMIM #130650) is a rare imprinting disorder characterized by macrosomia, macroglossia, hemihypertrophy, abdominal wall defects, and predisposition to embryonal tumors. BWS is primarily caused by alterations in the imprinted gene cluster on chromosome 11p15.5. This imprint locus consists of imprinting center 1 (IC1) that regulates the expression of IGF2 and H19 genes and imprinting center 2 (IC2) regulates the expression *of CDKN1C, KCNQ10T1*, and*KCNQ1* genes.

Results: Here we report a 4-year-old male patient who was referred to our outpatient clinics for macroglossia, neurodevelopmental delay and seizures. MS-MLPA analysis was done initially to evaluate methylation status of IC1/IC2 locus and hypomethylation of IC2 was detected. Since the patient had neurodevelopmental delay and IC2 hypomethylation, additional MS-MLPA analyses of *PLAGL1* and *SNRPN/UBE3A* locus were performed to exclude multilocus imprinting defects, and the results were normal. Additionally, whole-exome sequencing was done and a de novo pathogenic variant was detected at *POU3F3* gene.

Conclusion: To our knowledge, this is the first reported case of a dual diagnosis of Beckwith-Wiedemann and Snijders-Blok-Fisher syndromes in a patient. In cases where clinical findings are inconsistent with the primary diagnosis, it is essential to consider the possibility of concurrent involvement of two relatively common or rare inherited genetic conditions.

S. Kocagil: None. **E. Akbaş:** None. **O. Çilingir:** None.

P13.054.B The benefit of staying active in a foreign environment

Zaránd Némethi, *Eszter Györgyi Jávorszky, Árpád Ferenc Kovács, Irén Haltrich, Kálmán Tory*

Semmelweis University, Pediatric Centre, MTA Centre of Excellence, Budapest, Hungary.

Background: In X-autosome translocations, the spread of X-inactivation plays a critical role in determining the expression of autosomal genes. In addition, the parental origin of a de novo deletion may also have clinical significance. Our aim was to identify the etiology of severe hypotonia, cleft palate, macrocephaly, craniosynostosis, corpus callosum dysgenesis and cerebral atrophy in a female newborn.

Material and Methods: G-banded karyotyping, fluorescence in situ hybridization, array comparative genomic hybridization (aCGH), haplotype analysis and Sanger sequencing of heterozygous coding variants (rs2899642; rs3027875) in *RNF111* (15q22.1) and *HCFC1* (Xq28) genes in PBMC derived cDNA were performed.

Results: The karyotype was 45, X, der(X) t(X;15)(q28;q15),-15. The X chromosome involved in the translocation was intact, but a 10-Mb region on chromosome 15 with breakpoints at 15q11.2q13.3 containing the Prader-Willi/Angelman critical region was deleted. The deletion was paternal in origin. The cDNA Sanger sequencing of rs2899642 (*RNF111*, 15q22.1) and rs3027875 (*HCFC1*, Xq28) variants revealed skewed X-inactivation: 75–80% of cells expressed the involved X and both distal 15q regions.

Conclusion: The child's symptoms were attributed to the paternal 15q11.2q13.3 deletion, larger than typical in Prader-Willi syndrome. While in unbalanced X-autosome translocations there is a preferential silencing of the abnormal X, a skewed inactivation of the normal X allowed here the expression of the distal 15q22.1 region, consistent with the survival advantage. <!--EndFragment-->The phenotype of the child was thus strongly influenced by both the parental origin of the translocation and the skewed X-inactivation pattern.

P13.055.C Clinical and anthropometric characterization of 100 brazilian patients with 22q11.2 deletion syndrome

Caroline Brandão Piai[1], Diogo Cordeiro Soares[1], Gabriela Yumi Goto Salti[1], Marcella Cardoso Allegro[1], Elisa França Chaves[1], Eder Alencar Moura[1], Rachel Sayuri Honjo[1], Debora Romeo Bertola[1], Leslie Domenici Kulikowski[1], Vera Lúcia Gil-da-Silva-Lopes[2], Társis Antônio Paiva Vieira[2], Maria Isabel Melaragno[3], ***Chong Ae Kim***[1]

[1]*Instituto da Criança e do Adolescente do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo (ICr – HC/FMUSP), Sao Paulo, Brazil,* [2]*Departamento de Genética Médica e Medicina Genômica, Faculdade de Ciências Médicas, Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil,* [3]*Universidade Federal de Sao Paulo (UNIFESP), Sao Paulo, Brazil.*

Background: The 22q11.2 deletion syndrome is a multisystem genetic disorder resulting from a hemizygous microdeletion, with a prevalence of approximately 1:4,000 live births. This study provides a comprehensive clinical and anthropometric profile of Brazilian patients, offering insights into the phenotypic diversity and health challenges associated with this condition.

Material and Methods: We conducted a retrospective review of medical records spanning 2000–2024 from a single specialized genetic center in Brazil. Clinical data, confirmed primarily via MLPA and occasionally by FISH, were analyzed according to CDC growth standards. Anthropometric parameters and clinical findings were systematically evaluated.

Results: Among the 100 patients analyzed (58% male, 42% female), the average age at clinical diagnosis was 6.46 years old. The majority (84%) presented with the common 3 Mb deletion. Key findings included short stature (26%, mean height z-score: −1.2), weight variability (28% underweight, 7% overweight), and microcephaly (19%). Cardiovascular anomalies were the predominant feature (76%), with ventricular septal defects (53%) and tetralogy of Fallot (30%) being most prevalent. Developmental challenges were common, including speech delay (69%), motor delay (57%), and intellectual disability (65%). Notably, 17% of cases lacked congenital anomalies at birth, with symptoms manifesting later in life.

Conclusion: This cohort represents the largest single-center dataset on 22q11.2 deletion syndrome in Brazil, highlighting phenotypic consistencies and unique regional patterns. These findings contribute to the global understanding of this syndrome, emphasizing the need for early diagnosis and tailored management strategies.

P13.056.D Comprehensive reanalysis of septo-optic dysplasia supports more specific inclusion and exclusion criteria

Isabelle Bacchi[1,2]*, Bradley Miller[3], Charles J. Billington, Jr[2], William B. Dobyns[2]*

[1]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy,* [2]*Division of Genetics and Metabolism, Department of Pediatrics, University of Minnesota, Minneapolis, MN, USA,* [3]*Division of Endocrinology, Department of Pediatrics, University of Minnesota Medical School, MHealth Fairview Masonic Children's Hospital, Minneapolis, MN, USA.*

Background: Septo-optic dysplasia (SOD) was defined by combined absent septum pellucidum (ASP) and optic nerve hypoplasia (ONH) by De Morsier (1956). Later reports expanded the brain features to "midline prosencephalic" defects and eye anomalies to microphthalmia and colobomas. Pituitary insufficiency was added by Hoyt et al (1970), but diagnostic criteria comprising any 2 of 3 features were not stated until 2005.

Material and Methods: We studied a comprehensive review of the literature and a new cohort at our institution to re-construct features that clustered together.

Results: Early studies relied on limited understanding of brain development and limited brain imaging, assuming that isolated ASP shared pathogenesis with callosal defects and holoprosencephaly. We found that individuals with midline brain anomalies other than ASP or eye anomalies other than ONH were always atypical. And subjects with putative SOD and sequence variants in genes such as *HESX1* were also atypical. By focusing on typical features observed in most affected individuals, we propose new inclusion criteria consisting of any 2 of the following 4 abnormalities: (1) ASP, (2) ONH, (3) pituitary hypoplasia, and (4) malformations of cortical development (polymicrogyria, heterotopia). And importantly, we add new exclusion criteria comprising midline brain defects other than ASP (i.e. callosal defects), eye anomalies other than ONH, and pituitary insufficiency with normal pituitary structure.

Conclusion: Our new criteria will select a more homogenous group of individuals with low to nil yield from genetic testing, and better developmental outcome as other major brain malformations and genetic disorders will be excluded.

P13.057.A Microcephalies with recognizable phenotypes, although wide variable expressivity - a microtubule problem (case-series)

Alexandra Ţopa[1,2], *Jesper Ottosson*[1,2], *Carl-Johan Törnhage*[3,4]

[1]*Dep. of Clinical Genetics and Genomics, Sahlgrenska University Hospital, Gothenburg, Sweden,* [2]*Institution of Biomedicin, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden,* [3]*Dep. of Pediatrics, Skaraborg Hospital, Skövde, Sweden,* [4]*Institute of Clinical Science, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.*

Background: Here we present four unrelated families with *KIF11*-variants and one family with a *TUBB*-variant to illustrate the variable expressivity of kinesinopathies and tubulinopathies.

Patients and Methods: Four index patients were children with progressive microcephaly and variably present chorioretinopathy and lymphoedema. In one of the children, the diagnosis of *KIF11*-related microcephaly was clinically suspected based on the presence of chorioretinal atrophy and lymphedema. The fifth index patient was a woman referred to our clinic after she experienced two pregnancies with fetal anomalies and intrauterine fetal death. She was clinically diagnosed with Noonan syndrome in childhood based on the association of short stature with heart defect. The diagnosis was dismissed at the clinical genetic evaluation and Circumferential skin creases Kunze type (OMIM#156610) was strongly suspected based on her phenotype. WGS or WES Trio was performed in four families and a targeted analysis of a microcephaly-related gene panel was done in the patient with suspected *KIF11*-related microcephaly.

Results: In two out of four families, the *KIF11*-variants were inherited from parents with small head circumference without significant retinal changes, while de novo occurence was shown in the remaining two families. In the fifth family, the clinically suspected diagnosis was molecularly confirmed by the detection of a novel variant in *TUBB* by WES Trio in both the woman and the affected fetuses.

Conclusion: This case-series illustrates the importance of a specific phenotype-genotype association for the clinical interpretation of novel missense variants as well as the wide intrafamilial phenotypic variability of microtubule disorders.

P13.058.B A case of a de novo *GRIK2* pathogenic variant mimicking a mild Cornelia de Lange phenotype

Daniele Vitale[1,2], *Milena Mariani*[1], *Alessia Carrer*[2], *Andrea Biuso*[1,3], *Maura Masciadri*[4], *Laura Pezzoli*[5], *Daniela Marchetti*[5], *Maria Iascone*[5], *Angelo Selicorni*[1]

[1]*Centro Fondazione Mariani per il Bambino Fragile – S.C. Pediatria, ASST Lariana, Como, Italy,* [2]*Università degli Studi di Milano, Milano, Italy,* [3]*Buzzi Children's Hospital, Department of Biomedical and Clinical Sciences, University of Milan, Milano, Italy,* [4]*Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy,* [5]*Medical Genetics Laboratory, Papa Giovanni XXIII Hospital, Bergamo, Italy.*

Background: Kainate receptors (KARs) are glutamatergic channels that are involved in multiple functions in the central nervous system. Mono-allelic pathogenic variants in *GRIK2* recently emerged as a cause of nonsyndromic neurodevelopmental disorder.

Material and Methods: Clinical assessment of a patient with a de novo *GRIK2* variant presenting with a clinical phenotype mimicking mild Cornelia de Lange spectrum.

Results: A 6-year-old boy presented with global developmental delay and dysmorphic features, consistent with a clinical diagnosis of Cornelia de Lange spectrum according to the scoring system proposed in the 2018 Consensus Statement. NGS-based gene panel for coesinopathies, performed both on blood and buccal swab, identified a variant of unknown significance (VUS) of maternal origin in *NIPBL*. Whole Exome Sequencing identified an heterozygous de novo variant in *GRIK2* [c.1969G>A, p(.Ala657Thr)], previously reported in patients with neurodevelopmental disorder and proven to alter the receptor kinetics via in vitro assays.

Conclusion: To our knowledge this represents the first case of a *GRIK2* pathogenic variant associated with a "syndromic" presentation. Whereas the neuronal expression of GRIK2 has been linked to brain development, little is known about the extra-cerebral functions of this receptor. No crosstalk between GRIK2 and coesinopathies molecular pathway has been established. Conversely, once considered a specific condition, recent clinical and genetic assessment have described a Cornelia de Lange spectrum, with classical and non-classical forms, and conditions with a phenotypic overlapping caused by variants in non-cohesin genes. Further investigation is needed to verify a causal link between *GRIK2* variants and the dysmorphological aspects herein described.

P13.060.D Identification of a de novo Pathogenic Variant in *SET* in an Individual with Intellectual Disability and Dysmorphic Features

Eriko Nishi[1], *Kumiko Yanagi*[2], *Tadashi Kaname*[2], *Nobuhiko Okamoto*[1]

[1]*Osaka Women's and Children's Hospital, Osaka, Japan,* [2]*National Center for Child Health and Development, Tokyo, Japan.*

Background: The *SET* gene encodes a nuclear protein involved in chromatin remodeling and histone acetylation regulation. It has recently been identified as the cause of Intellectual Developmental Disorder, Autosomal Dominant 58 (#MIM: 618106) (Stevens et al., 2018). Previously reported cases demonstrated mild dysmorphic features, including facial asymmetry, high palate, and prominent ears, though these features are not considered syndrome-specific. We present a 7-year-old boy whose phenotype aligns closely with prior descriptions.

Material and Methods: The proband, born at 40 weeks and 1 day (3622g), was first evaluated at 2 years and 5 months due to developmental delays, including head control at 5 months, walking at 24 months, and first words at 22 months. Growth parameters and head circumference were within normal ranges. Brain MRI showed no abnormalities. Chromosomal G-banding and microarray analyses were normal. Trio-based whole exome sequencing (WES) was performed using the Twist Comprehensive Exome, Mitochondrial DNA Panel Spike In and NovaSeq6000 platform.

Results: A de novo frameshift pathogenic variant in *SET* (NM_003011.4: c.128_131del: p.(Arg44Leufs*10)) was identified. This variant, registered as pathogenic in ClinVar and classified as pathogenic by ACMG guidelines, shares phenotypic features with previous reports, including mild ID, a prominent forehead, deep-set eyes, thin upper lip, a wide mouth, and noticeable dental gaps. Additionally, a cheerful and sociable personality was observed.

Conclusion: The phenotype overlaps with prior cases, suggesting *SET* variants may constitute a recognizable syndrome. Further accumulation of cases will expand the phenotypic spectrum and refine diagnostic frameworks.

P13.061.A A new case of a non-mosaic *PORCN* mutation in two male siblings with severe congenital anomalies overlapping Goltz-Gorlin syndrome

Lucía Miranda-Alcaraz[1], *Mónica Mora-Gómez*[1], *Natalia Gallego-Zazo*[1], *Inmaculada Guillén*[2], *Alejandro Cruz-Utrilla*[3], *Nuria Ochoa-Parra*[3], *Alejandro Parra*[1], *Mario Cazalla*[1], *Valeria Vásquez-Amell*[1], *Juan A. Jiménez-Estrada*[1], *Manuel Rodríguez-Canó*[1], *Cristina Silván*[1], *Pedro Arias*[1], *Julián Nevado*[1], *Pablo Lapunzina*[4], *Pilar Escribano-Subías*[3], *Jair Tenorio-Castano*[4]

[1]*Institute of Medical and Molecular Genetics (INGEMM), Madrid, Spain,* [2]*Hospital Infantil Virgen del Rocío, Sevilla, Spain,* [3]*Hospital 12 de Octubre, Madrid, Spain,* [4]*Hospital Universitario La Paz, Madrid, Spain.*

Background: Variants in the *PORCN* gene cause the X-linked dominant condition Goltz-Gorlin syndrome or focal dermal hypoplasia (FDH). Features of FDH include striated pigmentation of the skin and ocular and skeletal malformations. This condition mainly affects females, as in non-mosaic males it usually causes lethality during fetal development. Most male cases reported to date have mosaicism, which is due to de novo mutations occurring after fertilization in the *PORCN* gene. Two cases of surviving male siblings with an inherited mutation in this gene have been described.

Material and Methods: Whole exome sequencing (WES) was performed in two male siblings with malformations including skeletal, ocular, renal defects and pulmonary hypertension.

Results: We report a novel non-mosaic variant, *PORCN*: c.1315T>G; p.(Trp439Gly), in two male siblings with malformations overlapping with Goltz-Gorlin syndrome. The phenotype of one of the brothers matches with one of the already described cases of a male with a non-mosaic variant, *PORCN*: c.749C>T; p.(Ser250Phe), presenting bilateral pyelocaliceal and ureteral hydronephrosis, bilateral vesico-ureteral reflux grade IV-V, coloboma, congenital pseudoarthrosis of the right clavicle, umbilical hernia and pulmonary hypertension.

Conclusion: While the pathogenicity of this variant remains to be further investigated, the presence of non-mosaic *PORCN* variants in males suggests that these are functionally mild mutations leading to an X-linked recessive mode of inheritance.

P13.062.B Detection of a deep intronic variation in *ZEB2* by genomics studies thanks to the clinical expertise of the biologist, a case report of a familial recurrence

Johanne Piotrowski, *Elise Schaefer, Aurélie Gouronc*

Hôpitaux Universitaire de Strasbourg, Strasbourg, France.

Background: A poly-malformation syndrome including agenesis of the corpus callosum, hypospadias, and bilateral ureterohydronephrosis in a 26-week-old fetus, leads to medical termination. The feto-pathological analysis revealed retinal dysplasia and polysplenia. The second child, whose pre-natal ultrasounds were normal, presented with a severe neurodevelopmental delay, microcephaly, growth retardation, facial dysmorphia, a short corpus callosum on MRI, and asplenia.

Material and Methods: Full Genomic study in a quartet with the mother, father, terminated fetus, and sister followed by RNA sequencing.

Results: The facial dysmorphia of the fetus and its sister led the geneticist to suspect Mowat-Wilson syndrome. This allowed the identification of a deep intronic variation whose predictions favored a modification of the canonical splicing of the transcript. The fetus and its sister carry this variation (NM_014795.4 (ZEB2):c.808-572T>G) in the heterozygous state, and it is inherited from their mother in whom the variation was found at a frequency of 9%. She presented with no sign of Mowat-Wilson syndrome. RNA sequencing confirmed an alternative splicing, leading to an additional exon including a STOP codon, with truncating consequences.

Conclusion: The genome can detect intronic variations not covered by sequencing of gene panels or the complete exome, which are more difficult to identify and classify. The clinician as well as the biologist's expertise are essential for their interpretation. Four cases of recurrence of Mowat-Wilson syndrome were previously reported, and one case reported somatic mosaicism in a father. Clinical studies are currently underway in France to specify the fetal phenotype of Mowat-Wilson syndrome.

P13.063.C Exome sequencing in the diagnosis of a complex pediatric case: from unclear prenatal findings to a definitive postnatal genetic diagnosis

Margarita Panova[1], *Hristo Ivanov*[2,3], *Iglika Sotkova-Ivanova*[2,3]

[1]*Medical University Plovdiv, Department of Pediatrics, Plovdiv, Bulgaria,* [2]*Medical University Plovdiv, Department of Medical Genetics, Plovdiv, Bulgaria,* [3]*Medical center Neuro Ped Gene LTD, Plovdiv, Bulgaria.*

Introduction: We present a complex pediatric case involving a 7-month-old female with congenital ventriculomegaly, microcephaly, facial dysmorphism, and cerebral palsy characterized by frequent dystonic episodes.

Materials and Methods: Prenatal testing using Chromoseq was conducted due to ultrasound findings of ventriculomegaly. This test identified four copy number variations (CNVs) classified as variants of uncertain significance (VUSs). However, no further genetic testing was pursued due to the absence of counseling with a medical geneticist. Postnatally, whole exome sequencing (WES) was performed to investigate the underlying genetic etiology.

Results: WES identified a heterozygous de novo missense variant in the DDX3X gene: c.976C>T (p.Arg326Cys). This variant is absent from the gnomAD population database and is classified as pathogenic. It affects a highly conserved residue within the helicase domain of the DDX3X protein, which is crucial for RNA metabolism and neurogenesis during fetal cortical development. The identified mutation correlates with DDX3X-related neurodevelopmental disorder, a condition associated with intellectual disability, speech and language impairments, and motor abnormalities.

Conclusion: This case underscores the diagnostic utility of exome sequencing in complex pediatric cases where prenatal genetic tests fail to provide a definitive diagnosis. The identification of a pathogenic DDX3X variant facilitated a precise diagnosis, guiding clinical management and genetic counseling. Our findings emphasize the need for adequate genetic counseling and advanced genomic testing during the prenatal period to reduce missed opportunities for early intervention and personalized care.

P13.064.D Clinical and molecular findings in a novel 4q duplication syndrome, a case report

Edanur Bulut[1], *Zeynep Esener*[1], *İlkay Can*[2]

[1]*Balikesir University, Faculty of Medicine, Department of Medical Genetics, Balikesir, Turkey,* [2]*Balikesir University Faculty of Medicine, Department of Dermatology, Balikesir, Turkey.*

Background: 4q duplication syndrome is a rare chromosomal abnormality characterized by the variable duplication sizes in long arm of chromosome 4. Syndrome manifests with a broad spectrum of phenotypic features, depending on the size and specific location of the duplication. Here, we present a case from Turkiye with a distinctive phenotype with a novel ~ 42.318 kbp duplication in 4q22.3q28.3 (95517323-137835086).

Material-Methods : Detailed family history and clinical examination were evaluated. The diagnosis was achieved through SNP-Array analysis.

Results: A 8-year-old girl was referred to our medical genetics outpatient clinic by dermatology due to skin findings and dysmorphic facial features. She was the second-born child from healthy non-consanguineous parents. She had postnatal growth retardation, global developmental delay, mild intellectual disability, hypotonia, constipation, attention deficit hyperactivity disorder, delayed speech and lisping and a developmental dysplasia of the hip. On physical examination, she had facial dysmorphism, microcephaly, localized hypopigmented hair strands, hypopigmented macules and xerosis on arms, hypertrichosis especially on extremities, left thumb hypoplasia and sacral dimple. SNP-Array revealed a 4q22.3q28.3(95517323-137835086) duplication with 16068 marker.

Conclusion: In the literature, 4q duplication syndrome has been reported with varying duplication sizes and associated with a broad spectrum of phenotypes. Through our novel case, we aim to contribute to the understanding of genotype-phenotype correlations and highlight the significance of phenotypic and genotypic variability in 4q duplication syndrome. This underscores the critical role of early intervention, precise genetic counseling, personalized management strategies, and long-term follow-up in optimizing patient outcomes.

P13.065.A Complex phenotypic syndromic obesity: Co-occurrence of Roifman Syndrome and Weyers Acrofacial Dysostosis

Yusuf Can Dogan, ***Mehmet Mert Topaloglu****, Türkan Turkut Tan, Zehra Burcu YILMAZ, Pediatric Specialist pre-doc genetics researcher, Tahir Atik, Ozgur COGULU, Esra Isik*

Ege University, Izmir, Turkey.

Background: Syndromic obesity is a rare condition involving obesity, short stature, dysmorphic features, neurodevelopmental delay, and systemic anomalies. Clinical evaluation and family history may be insufficient for diagnosis. We present a child with syndromic obesity carrying two distinct rare disorders, highlighting their combined effects on phenotype.

Material and Methods: Syndromic obesity is a rare condition involving obesity, short stature, dysmorphic features, neurodevelopmental delay, and systemic anomalies. Clinical evaluation and family history may be insufficient for diagnosis. We present a child with syndromic obesity carrying two distinct rare disorders, highlighting their combined effects on phenotype.

Results: Born to consanguineous parents at term with low birth weight (1850 g, <3rd percentile), she had recurrent infections requiring IV immunoglobulin. Walking was achieved at age 5, and speech was limited to two-word sentences. Examination revealed short stature (−5.26 SDS), obesity (BMI 20.2, 95th percentile), coarse facial features, synophrys, midface hypoplasia, conical canines, multiple frenula, brachydactyly, joint laxity, small extremities, simian creases, and partial toe syndactyly. WES identified a heterozygous *EVC* gene variant (c.1750del, p.Gln584ArgfsTer4), associated with Weyers acrofacial dysostosis, and a homozygous *RNU4ATAC* gene variant (n.16G>A), linked to Roifman syndrome. Retrospective phenotyping revealed that Weyers syndrome contributed skeletal and dental anomalies, while Roifman syndrome accounted for growth restriction, immunodeficiency, neurodevelopmental delay, and ocular findings. Their interplay created a diagnostically complex phenotype.

Conclusion: This case underscores the importance of detailed phenotyping and genetic analysis in syndromic obesity, particularly in consanguineous populations where multiple rare genetic disorders may co-segregate.

P13.066.B Developmental defect of the urogenital tract, genua recurvata, hypotonic syndrome; using WES familial *CAV3* associated hyperCKemia was diagnosed

Dagmar Grecmalova[1], *Andrea Hladikova*[1], *Lenka Noskova*[2], *Marie Zikanova*[2], *Stanislav Kmoch*[2]

[1]*University Hospital Ostrava, Ostrava, Czech Republic,* [2]*Research Unit for Rare Diseases, Department of Pediatrics and Inherited Metabolic Disorders, First Faculty of Medicine of the Charles University and General University Hospital, Prague, Czech Republic.*

Background/Objectives: The girl was examined after birth for a congenital developmental defect of the urogenital system: renal agenesis, cystic malformation in retroperitoneum, uterus bicornis, genua recurvata and an orthopedic defect of the limbs. SNP microarray, karyotype, NGS for rare disease and WES were done. The cause of congenital defects was not found. Subsequently, with an interval of 1 year, she comes for a hypotonic syndrome and an increased level of CK, hepatal enzymes in the serum, the neurologist sends to rule out a rare neuromuscular disease. After supplementing the anamnesis and clinical examination of the child and her mother (calf hypertrophy, negative EMG, hyperCK in both mother and child), the geneticist indicated a reanalysis of the whole-exome sequencing data.

Material and Methods: The patient was ascertained from a series of patients with paediatric-onset rare diseases with unknown genetic bases who underwent whole-exome sequencing at the Research Unit for Rare Diseases. Genomic DNA extracted from leukocytes of patient, her parents and healthy sibling was used for whole-exome sequencing on Novaseq 6000 platform (Illumina).

Results: Significant deleterious variant c.344A>G p.(Gln115Arg) in *CAV3* gene was detected; both mother and daughter carry it heterozygously, the DNA findings correspond to the phenotypic unit "Creatine phosphokinase elevated serum levels" OMIM (#123320).

Conclusion: A detailed evaluation of the patient´s phenotype and family history led to the discovery of the disease in the family. Authors highlight important reanalysis of WES data in a newly emerging clinical problem, segregation of the allele with the disease in the family.

D. Grecmalova: None. **A. Hladikova:** None. **L. Noskova:** None. **M. Zikanova:** None. **S. Kmoch:** None.

P13.067.C Identification of Homozygous Variants in *PTK7* and *HSPG2* in a Neonate with Neural Tube Defect and Skeletal Anomalies

Tilbe Hakçıl Öz[1], *Gülsüm Kayhan*[1], *Nuriye Ebru Ergenekon*[2], *Ismail Akdulum*[3], *Meral Toker*[4]

[1]*Gazi University, Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [2]*Gazi University, Faculty of Medicine, Department of Neonatology, Ankara, Turkey,* [3]*Gazi University, Faculty of Medicine, Department of Radiology, Ankara, Turkey,* [4]*Gazi University, Faculty of Medicine, Department of Pathology, Ankara, Turkey.*

Background: Neural tube defects (NTDs) are among the most common congenital malformations, resulting from the failure of neural tube closure between days 18–26 of embryonic development. The etiology involves both genetic and non-genetic factors, with folate metabolism and planar cell polarity signaling being key genetic pathways.

Material and Methods: Despite periconceptional folate supplementation, a newborn with meningomyelocele, born to consanguineous parents, was referred to our clinic. The infant presented with additional anomalies, including respiratory distress, costovertebral anomalies, intestinal malrotation, and cerebellar hypoplasia. The family history included a previous fetus with NTD and abdominal wall defect. Chromosomal microarray (CMA) and whole exome sequencing (WES) were performed from the patient's blood samples.

Results: CMA was normal. WES identified rare homozygous missense variants in the *HSPG2* (NM_005529.7: c.11648C>T, p.Ser3883-Leu) and *PTK7* (NM_002821.5: c.2648T>C, p.Leu883Pro) genes.

Conclusion: The clinical significance of the variants in *HSPG2* and *PTK7* remains uncertain. Although the patient's phenotype shares some similarities with *HSPG2*-associated conditions, such as neural tube defects (NTDs) and skeletal anomalies, it does not align with the typical *HSPG2* related phenotypes. The *PTK7* variant, involved in planar cell polarity and the Wnt signaling pathway, has not been previously reported in the homozygous state. Mouse studies suggest that biallelic *PTK7* loss-of-function variants lead to phenotypes resembling those observed in this patient and the fetus, including NTDs, abdominal wall defects, and costovertebral anomalies. Ongoing efforts to isolate DNA from autopsy tissues of the affected fetus for Sanger analysis may elucidate the role of observed phenotype.

C.O.I. Disclosure:

T. Hakçıl Öz: None. **G. Kayhan:** None. **N.E. Ergenekon:** None. **I. Akdulum:** None. **M. Toker:** None.

P13.068.D Clinical heterogeneity of the *GBE1* gene associated diseases

Sabina Nagieva[1], *Natalia Semenova*[1], *Aysylu Murtazina*[1], *Viktoriia Zabnenkova*[1], *Victoria Bezverbnaya*[1], *Olga Shchagina*[1], *Andrey Zubovich*[2], *Zumrud Abdulmanapova*[2], *Natalia Taran*[2], *Tatyana Strokova*[2], *Ekaterina Zakharova*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Research Centre of Nutrition and Biotechnology, Moscow, Russian Federation.*

Background: Biallelic pathogenic variants in the *GBE1* gene are implicated in two distinct clinical conditions: Glycogen Storage Disease Type IV (GSD IV; OMIM: 232500) and Adult Polyglucosan Body Disease (APBD; OMIM: 263570). GSD IV is characterized by a range of symptoms, involving the hepatobiliary or neuromuscular systems, with early childhood occurrence. APBD is primarily associated with the upper and lower motor neurons lesions, with clinical manifestations emerging after the age of 40.

Material and Methods: Clinical data analysis, Whole Exome Sequencing (WES) and Sanger sequencing for variants validation.

Results: An 11-year-old boy was referred for genetic counseling due to gait disturbance symptoms present since the age of 7. The patient had cirrhosis and underwent liver transplantation at age 4. Transaminase levels remained elevated even after transplantation, and electromyography was normal. Examination revealed signs of spastic paraplegia. Genetic analysis identified a previously reported pathogenic variant in the GBE1 gene (NM_000158.4: c.1543C>T p.(Arg515Cys)) and an unreported variant (NM_000158.4: c.1240G>A p.(Val414Ile)) in a compound-heterozygous state. The second patient, a 15-year-old boy, presented with similar complaints. Retrospective data revealed delayed motor development from birth, cirrhosis since age 3 followed by liver transplantation, and spastic paraplegia since age 9. The proband also had elevated transaminase levels after transplantation, along with cholestasis and low glucose levels. Electromyography showed a muscular type of peripheral neuromotor damage. WES identified the same variant as in the first patient (GBE1: c.1240G>A p.(Val414Ile)) in a homozygous state.

Conclusion: These cases demonstrate a novel combined presentation of two *GBE1*-associated phenotypes in children.

P13.069.A Two novel cases with *PIGQ*-related GPI-anchor deficiency: expanding of the genotype and phenotype spectrum

Katarína Kušíková[1], *Tzung-Chien Hsieh*[2], *Mateja Pfeifer*[3], *Christiane Fauth*[4], *Yoshiko Murakami*[5], *Franco Laccone*[3], *Daniela Karall*[6], *Walter Bonfig*[7], *Denisa Weis*[8]

[1]*Department of Pediatric Neurology, Medical School, Comenius University and National Institute of Children's Diseases, Bratislava, Slovakia,* [2]*University Hospital Bonn, Bonn, Germany,* [3]*Institute of Medical Genetics, Medical University of Vienna, Vienna, Austria,* [4]*Institute of Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [5]*Laboratory of Immunoglycobiology Research Institute for microbial diseases Osaka University, Osaka, Japan,* [6]*Department of Pediatrics I, Inherited Metabolic Disorders, Medical University of Innsbruck, Innsbruck, Austria,* [7]*Department of Pediatrics, Klinikum Wels-Grieskirchen, Wels, Austria,* [8]*Department of Medical Genetics, Kepler University Hospital, School of Medicine, Johannes Kepler University, Linz, Austria.*

Background: The glycosylphosphatidylinositol (GPI)-anchor is a glycolipid that anchors proteins to the eucaryotic cell surface. An anchoring process is a posttranslational modification of at least

150 molecules with various functions. Biallelic causal variants in the PIGQ gene (OMIM: *605754) are associated with the type of GPI-anchor deficiency called Multiple congenital anomalies-hypotonia-seizures syndrome 4 (MCAHS4, OMIM: #618548).

Material and Methods: We present two novel cases of MCAHS4 with two novel variants in the *PIGQ* gene, detailed phenotyping, and a review of all published cases so far. For deep gestalt analysis, we used GestaltMatcher and investigated its potential use in diagnosing MCAHS4 patients.

Results: We found two novel variants in the *PIGQ* gene: frameshift c.1092dupC, p.(Phe365LeufsTer78) and VUS missense c.1370T>G, p.(Leu457Arg), which pathogenicity was proved by a functional study on Chinese hamster ovarian cells. After reviewing all 13 already diagnosed MCAHS4 patients, we found that attacks of rhabdomyolysis induced by a febrile infection were documented only in our patient. Facial dysmorphia (coarse features, anteverted nares, and open mouth) seen in all analyzed MCAHS4 patients seems specific. Moreover, GestaltMatcher proved that MCAHS4 patients shared a similar facial phenotype.

Conclusion: In the presented work, we expand the genotype spectrum by describing two novel causal *PIGQ* variants. In MCAHS4 patients, it is appropriate to consider attacks of rhabdomyolysis because of their life-threatening complications. GestaltMatcher seems to be an effective diagnostic tool in MCAHS4.

P13.070.B An atypical form of Peters Plus syndrome without Peters anomaly: Expanding the *B3GLCT*-related phenotype with skeletal involvement

Victoria Granier[1], *Olivier Patat*[1], *Bertrand Chesneau*[1], *Christelle Bonifas*[2], *Nicolas Chassaing*[1], *Guillaume Banneau*[1], *Marion Aubert Mucca*[1]

[1]*Department of Medical Genetics, University Hospital Centre Toulouse, Toulouse, France,* [2]*Pediatric Ophthalmology and Adult Strabismus unit, Clinique Rive Gauche, Toulouse, France.*

Background: Peters Plus syndrome (PTRPLS) is an autosomal recessive disorder caused by *B3GLCT* variants [MIM* 610308], characterised by Peters anomaly, neurodevelopmental impairment, short stature, limb anomalies and/or cleft palate. Extraocular manifestations, especially skeletal defects, remain largely understudied.

Material and Methods: We present the case of an individual with a homozygous pathogenic variation in *B3GLCT*, exhibiting syndromic features, including skeletal involvement, neurodevelopmental disorder and atypical ocular manifestations in the absence of Peters anomaly.

Results: A 37-year-old case of unrelated parents presented with severe intrauterine growth restriction, ocular anomalies (bilateral iris chamber atrophy, severe myopia, glaucoma, retinovitreal degeneration, unilateral macular coloboma, nystagmus), skeletal involvement (short and broad hands and feet with brachydactly and brachymecarpia/tarsia, early-onset severe osteoarthritis, and narrow cervical canal) with short stature (137 cm), cerebral malformations (partial agenesis of corpus callosum, triventricular hydrocephalus), intellectual disability, autism spectrum disorder, and hearing loss. Trio exome sequencing identified the recurrent pathogenic variant in *B3GLCT*, NM_194318.4:c.660+1G>A at homozygous state.

Conclusion: While *B3GLCT* variants are linked to PTRPLS, extraocular features, particularly skeletal involvement, remain underreported. This case highlights an expanded phenotype with significant skeletal abnormalities, reinforcing the need to refine PTRPLS clinical delineation. We call for collaborative efforts to identify additional cases and better characterize skeletal manifestations associated with *B3GLCT* variants.

P13.071.C Frontonasal dysplasia with creased nasal ridge (FNDCN): a member of the Recurrent Constellation of Embryonic Malformations (RCEM) group? Report of four new patients

Daphne Lehalle[1], *David Genevieve*[2], *Marjolaine Willems*[3], *Benedicte Demeer*[4], *Christel Depienne*[5], *Laurence Faivre*[6], *Guillaume Captier*[7], *Delphine Heron*[1]

[1]*AP-HP Sorbonne University, Genetic Department, Hospital Trousseau and Pitié Salpêtrière, Paris, France,* [2]*CHU MontpellierMedical Genetics, Montpellier, France,* [3]*CHU de MONTPELLIER, Hopital Arnaud de Villeneuve, Montpellier Cedex 05, France,* [4]*Amiens University Hospital, Amiens, France,* [5]*Institute of Human Genetics, University Hospital Essen, University of Duisburg-Essen, Essen, Germany,* [6]*CHU DijonGenetique, Dijon, France,* [7]*Pediatric Orthopedic and Plastic Surgery, University of Montpellier, Montpellier University Hospital, Montpellier, France.*

Background: we reported frontonasal dysplasia with creased nasal ridges (FNDCN) as a distinct entity among frontonasal dysplasia in 2017. This publication described the phenotype of eleven patients, including three discordant monozygous or dizygous twins. The etiology is unknown so far. In 2020, the concept of "recurrent constellation of embryonic malformations (RCEM)" has been suggested for a group of recurrent malformations without genetic basis, including the more frequent VACTERL and oculo-auriculo-vertebral syndrome, characterized among others by an excess of discordant monozygotic twins. RCEM are believed to share a common pathogenesis, as supported by the recent identification of a common DNA methylation episignature.

Material and Methods: following our publication describing FNDCN, we were contacted by colleagues from Maxillofacial or Genetics teams to report on four novel patients. Trio genome sequencing (GS) was performed in one patient.

Results: four unrelated individuals, aged 2 to 39 years, presented with the typical and recognizable facial aspect of FNDCN, including characteristic creased nasal dorsum, absent or bifid tip and hypertelorism. Abnormal olfactory bulbs and dehiscent basal skull were present in one individual each. Three patients were issued from twin pregnancies, all co-twins being unaffected. GS performed in one patient was non-contributive.

Conclusion: FNDCN is a rare entity, in which is observed an excess of twins (6/15 in total, 40%) and no familial recurrence. This report raises awareness on this condition and suggests its belonging to the recently conceptualized RCEM group. The identification of more patients will pave the way to the understanding of their common pathophysiology.

P13.072.D Trio-Wes Analysis of Two Goldenhar Families and Two Candidate Genes

Cekdar Kapazan, *Esra Saliha Olgun, Bilgen Bilge Geckinli*

Marmara University Medical Genetic Department, Istanbul, Turkey.

Background: Goldenhar syndrome or Oculo-auriculo-vertebral spectrum (OAVS) is due to an abnormal development of first and second branchial arches during embryogenesis.OAVS is characterised by hemifacial microsomia associated with 3 main clinical findings auricular, ocular and vertebral malformations.In this study, we examined two OAVS patients with Trio-WES analysis.

Material and Methods: After DNA isolation from peripheral blood lymphocytes with the QIAampDNA mini kit, WES was done with the illumina NovaSeq Platform.Raw data was analyzed using the Sophia DDMR data analysis platform.

Results: Clinical findings of Patient 1 showed unilateral microtia and external auditory canal atresia, mandibular hypoplasia, facial asymmetry and macrostomia.Patient 2 had hydrocephalus in prenatal period.He had unilateral anophtalmia, unilateral microtia and external auditory canal atresia, mandibular hypoplasia, syringomyelia, unilateral hand polydactyly, AVSD, epilepsy, persistent pneumonia.In cranial MRI corpus callosum dysgenesis, polymicrogyria was detected.Both patients' chromosomal and aCGH analysis were normal.As a result of the trio-WES analysis, we have found *ARID3B* c.1523-1G>T and *FBLN1* p.Cys248Serfs*56 heterozygous novel de-novo variants in patient 1 and patient 2, respectively.

Conclusion: Recent studies have shown that FBLN1 and ARID3B are associated with FGF pathway and its functions include embryonic development and neural crest cell (NCC) maintenance, NCC migration as well as patterning of structures formed from NCC such as branchial arches and cranial nerves.ARID3B has been associated with OAVS in a genomewide association study.Knockout ARID3B animal modelling studies have shown that branchial arch, neural tube and otic vesicle development were disrupted.-Further studies are needed to uncover the relationship between these two genes and OAVS

P13.073.A Refining the ALKAS phenotype: first evidence of reproductive tract anomalies

Ayse Gurel[1], *Aysenur Buz Yasar*[2], *Aysegul Danis*[3], *Semih Bolu*[4]

[1]*Department of Medical Genetics, Bolu Abant Izzet Baysal University, Izzet Baysal Training and Research Hospital, Bolu, Turkey,* [2]*Department of Radiology, Faculty of Medicine, Bolu Abant Izzet Baysal University, Bolu, Turkey,* [3]*Pediatric Neurology Unit, Department of Pediatrics, Faculty of Medicine, Bolu Abant Izzet Baysal University, Bolu, Turkey,* [4]*Pediatric Endocrinology Unit, Department of Pediatrics, Faculty of Medicine, Bolu Abant Izzet Baysal University, Bolu, Turkey.*

Background: Al Kaissi syndrome (ALKAS, #617694) is a rare developmental disorder characterized by developmental delay, growth retardation, facial dysmorphism and spinal malformations. Biallelic mutations in *CDK10*, encoding cyclin-dependent protein kinase-10 (#603464) causes this disorder. CDK10 forms a heterodimer with Cyclin M, a complex critical for cell proliferation and regulation of ciliogenesis. Here, we present the first adolescent female with ALKAS, expanding the clinical spectrum to include reproductive tract anomalies.

Methods and Results: The proband, 16-year-old female born to consanguineous parents, presented with microcephaly, intellectual disability, attention-deficit/hyperactivity disorder, articulation defects, wide-based gait and hearing loss. Facial dysmorphism was notable for telecanthus, hypertelorism, narrow palpebral fissures, posteriorly rotated ears, high and narrow palate, pointed chin and single palmar transverse creases. Skeletal abnormalities included torticollis, kyphoscoliosis, C2-C3 vertebral fusion and sphenoid fibrous dysplasia. Cranial magnetic resonance imaging revealed corpus callosum dysgenesis. Intriguingly, the proband exhibited menstrual irregularities and polymenorrhea, with an enlarged uterus relative for age and endometrial hyperplasia observed on suprapubic ultrasonography. Genetic workup demonstrated a 46,XX karyotype and no pathogenic copy number variation on microarray analysis. Whole exome sequencing identified a homozygous frameshift mutation in *CDK10* (c.520_521del, p.Lys174Glyfs*34), classified as disease-causing.

Conclusion: Recent studies indicate that CDK10/Cyclin-M deficiency disrupts ciliogenesis, leading to abnormal primary cilia morphology. This report, presenting the 12th known ALKAS family, suggests that reproductive tract anomalies may be a novel phenotypic feature of ALKAS, mirroring features of certain ciliopathies. Recognizing ALKAS as a potential ciliopathy could refine clinical management, uncover underlying molecular mechanisms and pave the way for targeted therapeutic strategies.

P13.074.B *PIK3CA* Related Overgrowth: a diverse case series from Romania

Adela Chirita-Emandi[1,2], *Catalin Vasile Munteanu*[3,4], *Nicoleta Andreescu*[1,5]

[1]*Department of Microscopic Morphology, Genetics Discipline, Center of Genomic Medicine, "Victor Babeș" University of Medicine and Pharmacy, TIMISOARA, Romania,* [2]*Regional Center of Medical Genetics Timiș, Clinical Emergency Hospital for Children "Louis Țurcanu, Timisoara, Romania,* [3]*Regional Center of Medical Genetics Timiș, Clinical Emergency Hospital for Children "Louis Țurcanu, TIMISOARA, Romania,* [4]*"Victor Babeș" University of Medicine and Pharmacy, Timisoara, Romania,* [5]*Regional Center of Medical Genetics Timiș, Clinical Emergency Hospital for Children, Timisoara, Romania.*

Background: *PIK3CA*-Related Overgrowth Spectrum (PROS) refers to a heterogeneous group of overlapping syndromes characterized by segmental excessive growth and other clinical features such as brain abnormalities, vascular malformations, cutaneous manifestations and skeletal dysplasia.

Material and method: Herein we report 4 patients with PROS diagnosed using next generation sequencing gene panels from skin biopsy or buccal swab.

Result: Concise clinical description and variants identified were as follows: (1) a 4 year-old female patient with neurodevelopmental delay, obesity, hypothyroidism and postaxial polydactyly (*PIK3CA* NM_006218.4:c.2740G>A,p.Gly914Arg, Pathogenic), (2) a 13 year-old male with facial dysmorphic features, neurodevelopmental delay, macrocephaly, obesity and right lower limb hypertrophy (c.3061T>C,p.Tyr1021His, Pathogenic), (3) a 23 years old female with verrucous lymphovascular malformation of lower right limb (c.1625A>T,p.Glu542Val, Pathogenic)-treated with Sirolimus, and (4) a 4 years old male with right hemihypertrophy and mild meurodevelopmental delay (c.1412C>T,p.Pro471Leu, Likely Pathogenic). Clinically significant missense variants in *PIK3CA* gene were identified with variable variant allele frequency in studied tissues. Family history was negative for all.

Conclusion: PROS disease burden is significant, most patients presented neurodevelopmental delay aside from overgrowth. In the light of treatment options acting on the PI3K-AKT-mTOR pathway, somatic molecular diagnosis is crucial.

P13.075.C Phelan-McDermid 22q13.31 deletion originating from a maternal balanced translocation

Faidon-Nikolaos Tilemis[1], *Nicoletta Selenti*[1], *Nikolaos M. Marinakis*[1], *Konstantina Kosma*[1], *Vasileia Christodoulaki*[1], *Periklis Makrythanasis*[1,2,3], *Christalena Sofocleous*[1]

[1]*Laboratory of Medical Genetics, School of Medicine, "Aghia Sophia" Children's Hospital, National and Kapodistrian University of Athens, Athens, Greece,* [2]*Department of Genetic Medicine and Development, Medical School, University of Geneva, Geneva, Switzerland,* [3]*Biomedical Research Foundation of the Academy of Athens, Athens, Greece.*

Background: Phelan-McDermid syndrome (PMS) is a rare genetic disorder characterized by developmental delay, hypotonia, absent/delayed speech, congenital heart defects and urogenital malformations. PMS is usually caused by telomeric deletions (from 160 Kb to 9 Mb) on the long arm of chromosome 22 either arising de novo or, because of inherited unbalanced translocations detected after parental conventional karyotyping.

Material and Methods: An 1-year-old female referred with hypotonia, absent speech, hydronephrosis, joint hypermobility and mitral valve prolapse underwent Whole Exome Sequencing (WES) and chromosome analysis. WES used xGen Exome Research v2 kit (IDT) for library preparation and NextSeq-500 system (Illumina) for sequencing. Bioinformatic analysis, with VarSome Clinical and ExomeDepth softwares, enables detection of both nucleotide and copy number (CNVs) variants, classified according to the ACMG and ClinGen recommendations. Further investigation included conventional karyotype on the patient and her parents.

Results: Heterozygous CNVs, comprising a 6.3 Mb pathogenic deletion (DEL:chr22:44892717-51220722, hg19) on chromosome 22q13.31-q13.33 and a 690.2 Kb duplication (DUP:24796957-25487163, hg19) of unknown significance (VUS) on 13q12.12, were detected by ExomeDepth. Subsequent chromosome analysis confirmed the deletion, and a diagnosis of PMS, in the patient, and indicated that the apparently unaffected mother carries a balanced translocation involving chromosomes 13 and 22 [46,XX,t(13;22)(q12.12;q13.3)].

Conclusion: Combined molecular and chromosomal analysis allowed case resolution and PMS diagnosis. Unbalanced segregation of reciprocal translocations generates CNVs in offsprings with rare genetic diseases and, despite the obvious benefits of WES, conventional karyotype can still contribute valuable information towards elucidation of escaping events and underlying mechanisms.

P13.076.D Microcephaly Represented with Deletion of *SHH* and *DPP6* Genes on Unbalanced Segregation of Translocation t(7;11)(q34;q24.1)

Ilknur Sunar

Metagentech Center for Genetic Diseases, Istanbul, Turkey.

Background: Microcephaly affects one in every 30,000 to 250,000 births globally where the brain size and volume are less than the 3rd percentile. As a structural birth defect, it is commonly accompanied by a genetic component resulting in developmental delay and intellectual disability.

Material and Methods: Patient was born at 36 weeks; she was consulted for genetic examination at newborn intensive care unit. She had a head circumference of 32 cm (2nd percentile) with narrow forehead, frontal bossing, downslanting palpebral fissures, narrow nose root and tip, retrognathia, short neck, large ears and cutis marmaratus. She developed seizures and acute brain infarct at left parietooccipital lobe on MRI at one month. Karyotyping, whole exome analysis (WES) and microarray analysis were offered.

Results: Prenatal screening with non-invasive prenatal test (NIPT) revealed a microdeletion on chromosome 7 (7q34-q36.3) of 17,6 Mbp in size at 11th week of gestation. USG screening at 22 weeks was normal. The first microcephalic evaluation was reported at 32nd week on obstetric controls.Karyotyping results were 46,XX. WES analysis did not reveal any pathogenic variants except copy number analysis confirmed the NIPT results with additional duplication on chromosome 11 (11q24.1-q25). Microarray analysis result was arr[GRCh38] 7q34q36.3 (141,927,349_159,327,017)x1; arr[GRCh38] 11q24.1q25 (122,584,812_135,068,576)x3 which includes deletion of *SHH* and *DPP6* genes.

Conclusion: When there is a result of NIPT test with deletion/duplication, CNV or microarray analysis is mandatory for proper segregation analysis and correct prenatal/postnatal diagnosis of underlying translocation. Here we present a novel case of *DPP6 and SHH* haploinsufficiency with microcephaly.

P13.077.A Renal Complications in a Patient with ITPR1-Related Spinocerebellar Ataxia

Tomoko Takamatsu[1,2], *Hironobu Okuno*[1], *Gaku Yamanaka*[1], *Noriko Miyake*[3], *Hironao Numabe*[2]

[1]*Department of Pediatrics and Adolescent Medicine, Tokyo Medical University Hospital, Nishi-Shinjuku, Shinjuku-ku, Japan,* [2]*Department of Pediatrics, Tokyo Yamate Medical Center, Shinjuku-ku, Japan,* [3]*Department of Human Genetics, Research Institute, National Center of Global Health and Medicine, Shinjuku-ku, Japan.*

Background: Spinocerebellar ataxia type 29 (SCA29) is a non-progressive cerebellar ataxia with autosomal dominant inheritance. It is characterized by childhood-onset hypotonia, delayed motor development, and cognitive impairment. Affected individuals exhibit cerebellar dysfunction, often with cerebellar atrophy on neuroimaging. A missense variant in *ITPR1* was determined to be responsible.

Patient: The patient is a 2-year-old girl. She is noted for cerebellar hypoplasia, hypoplasia of the right kidney, left renal hydronephrosis, psychomotor developmental delay, and characteristic facial features. The Family history is unknown. Chromosomal microarray analysis did not reveal any significant variants. Because of the presence of cerebellar hypoplasia, the patient was suspected to have spinocerebellar ataxia and was referred to our hospital for whole exome sequencing.

Results: We obtained blood samples from the patient and her parents and performed whole exome sequencing. We found that the patient had a previously reported de novo heterozygous pathogenic variant in the *ITPR1* gene. The variant is identified as follows: NM_002222(*ITPR1*): c.7604T>A p. (Ile2535Asn). The variant has been confirmed by Sanger sequencing. The patient had kidney hypoplasia and hydronephrosis, which were not typically associated with SCA29. Exome sequencing did not reveal any other variants. The *ITPR1* gene has been reported to be associated with renal abnormalities, and it is possible that renal malformations may have occurred due to its effect on the kidney during the embryonic period.

Conclusion: We concluded that a pathogenic variant of *ITPR1* may cause renal malformations associated with SCA29.

P13.078.B Clinical and genetic variability in two Armenian patients with DiGeorge syndrome features

Arpine Mkrtchyan[1], *Susanna Midyan*[2,1], *Seda Hakobyan*[2], *Anzhela Yervandyan*[1], *Natella Kostandyan*[2,1], *Aline Aywaz*[2,1]

[1]*Yerevan State Medical University after Mkhitar Heratsi (YSMU), Yerevan, Armenia,* [2]*Center of Medical Genetics and Primary Health Care of Armenia, Yerevan, Armenia.*

Background: In this report we present two cases with DiGeorge clinical features[1], but different genetic results. The 1st patient in the 39th week of gestation, was born via cesarean section. At the age of 1,5 months, a ventricular septal defect with high pulmonary artery pressure was detected. At the time of the latest consultation: 3,5 months, weight 0%, height 0%, head circumference 0%. He has prominent ears, a round nose, retrognathia, and syndactyly on the right foot. The 2nd patient was born in the 39th week of gestation. During pregnancy limb shortening was detected via ultrasound. At the age of 13 days old, the weight was at 0.9%, height 1.2%, and head circumference 7.2%. The facial features include a narrow forehead, upslanting palpebral fissures, hypertelorism, flat nose with an upturned tip, long philtrum, thin lips, downturned corners of the mouth, short neck, and shortening of the limbs. The patient has tetralogy of Fallot.

Methods: For DiGeorge syndrome, the first patient underwent karyotyping[2] and FISH[3], whereas for the second patient an array CGH was performed.

Results: Studies of the 1st patient revealed 46,XY, t(17,22)(q21.3;q13.2) ish22q13.3(D22S75, TBX1, Tuple)x2. During FISH testing no deletions were detected in D22S75, TBX1, and Tuple genes. The results of the 2nd patient were arr[GRCh38] 8q24.22q24.3(132180770_145076860)x3, 20p13q11.23(68448_38132166)x3.

Conclusion: To our knowledge, there are no described cases of DiGeorge syndrome with such genetic changes. However, as the patients had characteristic phenotypical features, DiGeorge syndrome can't be excluded. Further investigation such as WES is needed to find the pathogenic variation.

P13.079.C A rare case of de novo mosaicism of isochromosome 18q and 18p deletion

Jihane Ahmidi[1,2], *Khawla Zerrouki*[1,2], *fatimazahra Smaili*[1,2], *Fatima Ezzahra Aouni*[1,2], *Sara Meziane*[1,2], *Kaoutar Ahmidouch*[1,2], *Mariam Tajir*[1,2]

[1]*Medical Genetics Laboratory, Central Laboratory, Mohammed VI University Hospital Oujda, Oujda, Morocco,* [2]*Faculty of Medicine and Pharmacy of Oujda, Mohammed First University, Oujda, Morocco.*

Background: Cellular mosaicism involving an isochromosome 18q and a deletion 18p is an extremely rare chromosomal anomaly, with only nine reported cases, including four in a prenatal context and five in living children. Isochromosome 18q results from duplication of the long arm of chromosome 18, leading to trisomy 18q and monosomy 18p. Deletion 18p corresponds to partial or complete loss of the short arm of chromosome 18. In this work, we report the 10th case of i(18q)/del(18p) mosaicism diagnosed in a Moroccan girl and propose a hypothesis explaining its mechanism of formation.

Methods: A 4-year-old Moroccan girl, born to non-consanguineous parents, was referred to our medical genetics consultation for a dysmorphic syndrome associated with psychomotor developmental delay. A constitutional karyotype was performed in our laboratory using cultured lymphocytes obtained from patient's venous blood.

Results: The karyotype revealed i(18q)/del(18p) mosaicism, with 80% of cells carrying an isochromosome 18q and 20% of cells showing an 18p deletion. The parental karyotype, performed to investigate a possible balanced translocation, showed no abnormalities. Clinical analysis revealed phenotypic features similar to those described in isochromosome 18q syndrome, although with a milder expression of the typical trisomy 18q characteristics.

Conclusion: Mosaicism associating an 18q isochromosome and an 18p deletion represents an extremely rare chromosomal anomaly. The clinical phenotype is similar to that seen in i(18q) syndrome, although it expresses few of the typical features of 18q trisomy. Diagnosis relies on cytogenetic analysis, which is essential for guiding genetic counseling and adapting treatment.

P13.080.D Valve insufficiency and aortic root dilatation: new signs in Non-FLHS SRCAP-related neurodevelopmental disorder

Alessandra Spano[1], *Marco Spada*[1], *Marta Della Croce Di Dojola*[1], *Elena Banaudi*[2], *Elisa Biamino*[3]

[1]*University of Turin, Turin, Italy,* [2]*SC Cardiologia- Ospedale Infantile Regina Margherita, Turin, Italy,* [3]*Ospedale Infantile Regina Margherita, Turin, Italy.*

We present the case of a 12-year-old boy who came to our attention due to intellectual disability and motor dyspraxia. At phisical examination he presented a slender physique with marfanoid habitus (height +2 SD, BMI 16.6), arachnodactyly, bilateral cavus feet, ogival palate, scoliosis, and left inguinal hernia. Cardiological evaluation with echocardiography disclosed mitral valve prolapse associated with mild insufficiency, bicuspid aortic valve with mild insufficiency and aortic root dilatation (z-score +3.7). Whole Exome Sequencing (WES) in trio identified a de novo heterozygous variant in exon 25 of *SRCAP* gene (c.5368_5371dupTTGA, p.Ser1791fs). The variant was not reported in dbSNP, ClinVar, GnomAD databases and was considered pathogenetics. *SCARP* truncating variants were originally associated with Floating-Harbor Syndrome (FLHS). More recently has been defined a new entity, called non-FLHS SRCAP-related neurodevelopmental disorder, linked to truncating variants outside FLHS region (ie exon 33 and 34) and characterized by developmental delay/intellectual disability, psychiatric symptoms, hypotonia and musculoskeletal abnormalities. The patients generally exhibit normal or tall stature and marfanoid habitus has been specifically reported in only one patient. To the best of our knowledge, cardiac abnormalities have never been reported in these patients but they haven't been precisely ruled out by echocardiography. Aortic root dilatation, bicuspid aortic valve and mitral valve could represent new features of non-FLHS SRCAP-related neurodevelopmental disorder, suggesting to carry out cardiological investigations in these patients.

C.O.I. Disclosure:

P13.081.A Expanding the phenotypic spectrum of 17q12 microdeletion syndrome: liver hemangioma as a novel feature

Elif Kubar, *Ekin Cemre Bayram Tokaç, Ayça Aykut, Asude Durmaz, Haluk Akın, Erhan Parıltay*

Ege University Department of Medical Genetics, Izmir, Turkey.

Background:17q12 microdeletion syndrome is a rare disorder primarily associated with renal cystic disease, maturity-onset diabetes of the young type 5 and neurodevelopmental disorders. Beyond these common features, the syndrome manifests a wide phenotypic spectrum, including liver abnormalities, gastrointestinal features, and congenital heart diseases, which are rarely reported as components.

Material and Methods: Four patients were clinically evaluated to expand the phenotypic spectrum of 17q12 microdeletion syndrome. Three of the patients were children diagnosed with **renal cystic disease**. Along with this diagnosis, additional clinical features were identified: Case1 had **transposition of the great arteries**, which was surgically treated in infancy, along with **mild intellectual disability**; Case2 displayed **unusual dental development, liver hemangioma**, and **accessory spleen**; Case3 showed **macrocephaly** and **growth retardation**. Case4 was an adult patient diagnosed with **diabetes mellitus, sensorymotor neuropathy, liver hemangioma, elevated transaminase levels**, and **bipolar disorder**. Patients' genomic DNA was extracted from blood samples. The oligonucleotide microarray analysis was performed using Affymetrix Cytoscan Optima Array. Copy number variants (CNVs) were analyzed using ChAS4.2. CNV pathogenicity was interpreted based on ACMG guidelines.

Results: The array results of the patients, evaluated as patogenic, are presented in Table 1.

Conclusion: Due to the rarity of 17q12 microdeletion syndrome, it is important to evaluate patients systematically to prevent uncommon findings from being overlooked. In the literature, only one patient with 17q12 microdeletion syndrome has been reported to have liver hemangioma. Combined with our data, liver hemangioma may represent a newly identified phenotypic trait.

Table 1: Array results of the patients

CASE1	arr[GRCh38]17q12(36,466,620_38,254,553)x1
CASE2	arr[GRCh38]17q12(36,467,352_37,924,067)x1
CASE3	arr[GRCh38]17q12(36,134,106_38,214,937)x1

P13.083.C Thyroid analytical screening: a case-report emphasizing added-value in patients with intellectual disability

Ana Miguel Pinto Capela[1], *Carla Carmona*[1,2], *Ana Maria Fortuna*[1,2], *Cláudia Falcão Reis*[1,2,3]

[1]*Unidade Local de Saúde de Santo António, Porto, Portugal,* [2]*Unidade Multidisciplinar de Investigação Biomédica, Instituto de Ciências Biomédicas Abel Salazar (UMIB/ICBAS), Universidade do Porto and Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal,* [3]*Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal.*

Background: The *SECISBP2* gene encodes a key factor for incorporating selenocysteine into selenoproteins, essential for cellular redox regulation, thyroid hormone metabolism, and immune function. Biallelic deleterious variants in *SECISBP2* cause Abnormal Thyroid Hormone Metabolism 1 (THMA1, MIM #607693), a multisystemic condition with varying degrees of endocrine, metabolic, and neurological features. With fifteen patients reported to date, we describe a new case, aiming to expand knowledge regarding this ultra-rare condition.

Material and Methods: Case file consultation and literature review.

Results: A 21-year-old male, born to non-consanguineous parents with unremarkable family history. He presented microcephaly (3rd centile), dysmorphic features, hypotonia, moderate intellectual disability (ID), hearing loss, and proportionate short stature (1,61m). *FMR1* testing, array-CGH, and myopathy NGS gene panel were negative. Biochemistry blood-work showed persistently elevated CKs (ranging from 287 to 1473, for reference 24–204) and thyroxine (T4) (ranging from 14 to 17.3, for reference 5,91-13.2), with low triiodothyronine (T3) (ranging from 0.4 to 0.6, for reference 0,92-2.18). WES disclosed two novel truncating *SECISBP2* variants. Segregation studies confirmed the likely pathogenic variants were biallelic, establishing the diagnosis of THMA1 in our patient.

Conclusion: While the minor thyroid function abnormalities were acknowledged, their syndromic nature only became clear after WES analysis. This confirms the consensus benefit of high-throughput diagnostics in patients presenting complex multisystem features and in their re-appreciation. The combination of increased T4 with low T3 is an uncommon feature that provides an important etiology clue and shows added utility, beyond hypo/hyperthyroidism, of thorough thyroid assessment in ID patients.

P13.084.D Novel Genitourinary Anomalies and Facial Dysmorphisms in a Patient with a Large Mosaic Duplication of Chromosome 11p

Alison Eaton[1], *Baril Rebecca*[2], *Maisa Yoshimoto*[3], *Joan Knoll*[3], *Georges Maire*[3]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Department of Pediatrics, University of Alberta, Edmonton, AB, Canada,* [3]*Genetics and Genomics, Alberta Precision Laboratories, Edmonton, Edmonton, AB, Canada.*

Background: Duplications of chromosome 11p15 encompassing the BWS critical region have been associated with Beckwith-Wiedemann and Russel Silver Syndrome phenotypes, depending on parent-of-origin. Larger duplications may be associated with additional anomalies/comorbidities, but few duplications larger than 6 Mb have been reported in living individuals.

Results: We describe a 58-year-old female patient with a very large (>15 Mb) high-level mosaic duplication of 11p associated with an unbalanced derivative chromosome 21 (46,XX,der(21)t(11;21)(p15.2;p13)[24]/46,XX[6], arr[GRCh37] 11p15.5p15.2 (198510_15319228)x3) in peripheral blood. MS-MLPA to determine parent of origin is pending. Clinically, the patient clinically has striking facial dysmorphisms including short palpebral fissures/blepharophimosis, frontal upsweep, bulbous nasal tip, simple low set ears, and cranial nerve palsies (reminiscent of Nablus syndrome). She additionally has significant short stature (−5.7SD), rhizomelia and mild leg-length discrepancy, as well as striking genitourinary anomalies including underdeveloped,

hypoplastic external genitalia with a large, cavernous outlet. Imaging confirmed presence of a uterus. History includes natal teeth, epilepsy, and moderate intellectual disability, but she is otherwise well.

Conclusion: To our knowledge, this represents the oldest reported patient with a duplication of 11p of this magnitude. Moreover, this is the first report of substantial genitourinary malformations associated with 11p duplications in a female, and of facial features reminiscent of Nablus Mask-Like Facies Syndrome. Parent-of-origin is not yet known, but she does not clearly fit within either the BWS or RSS spectrums, and anomalies are much more significant. Mosaicism and/or position effect from adjacent chromatin at the translocation site may be contributing to viability and lack of life-limiting comorbidities.

P14 Cytogenetics, Genome Variation and Architecture

P14.001.A Reclassification of splicing variants of uncertain significance

Natalie J. Wood, *Sam Nalty, Miranda Durkie, Florentina Sava*

Sheffield Diagnostic Genetics Service, Sheffield Children's Hospital, Sheffield, United Kingdom.

Background: Variants in +/−1,2 canonical splice sites and other variants, such as splice region, missense, or synonymous variants can alter constitutive splicing. Such variants may produce (multiple) aberrant functional and/or non-functional transcripts. Furthermore, it can be time consuming for Clinical Scientists to revisit previously identified variants of uncertain significance (VUS).

Material and Methods: We perform an evaluation of spliceogenic variants in genes related to Gastrohepatology and Inherited Cancers in a cohort of NHS patients. We targeted VUS that are more likely to be reclassified following the Walker *et al*., 2023 ClinGen splicing SVI and the latest ACGS 2024 variant classification guidelines. Using a variety of in silico tools we compared the predicted splicing impact of variants within the same splice region. Finally, we fill a gap by creating new resources, such as a gene specific PVS1 decision tree, to aid splicing variant interpretation in NHS laboratories.

Results: Out of 7533 variants, we identified over 400 spliceogenic VUS. Applying PS1 classification criteria enabled us to reclassify 11 out of 24 VUS to likely pathogenic. We also show that different in silico tools can complement each other and we generated a *PKD1* PVS1 decision tree to ease variant interpretation.

Conclusion: Reclassification of 46% of the splicing variants will impact patient management, for example by allowing familial predictive testing. Production of resources on splicing variant classification will aid variant interpretation for clinical scientists. We also illustrate that the use of PS1 brings additional weight when assigning pathogenic criteria.

Background: Complex structural variants (SVs) are linked to regions containing DNA palindromes, motifs that can form hairpin structures predisposing to double-strand breaks.

Materials and Methods: We identified a novel, severe and recognisable neurodegenerative disorder associated with triplication of part of chromosome 16p13.3. Clinical and neuroradiological studies were undertaken to delineate the phenotypic spectrum. Analysis of data from microarray, short and long-read genome sequencing, constellation read technology and RNAseq was undertaken to fully characterise the molecular basis of the condition.

Results: Eleven affected individuals from nine families presented with progressive early-onset ataxia (10–23 years) and cerebellar atrophy. Additional variable features included intellectual disability, neurodevelopmental regression, peripheral neuropathy and scoliosis. In all families where genome sequencing and/or high-resolution array data were available (7/9), a triplicated segment was identified within the duplication, with central inversion in five cases. Parental segregation data, available for 7/8, showed the SVs to have occurred de novo or inheritance from a mosaic parent, with one additional multiplex family (three individuals). While nineteen duplications were identified in UK Biobank (500,000 individuals), no triplications were detected. The minimal overlap region included *ATP6V0C* and *AMDHD2*, both highly expressed in the cerebellum and RNAseq in blood showed a 4-fold increase in *ATP6V0C* expression. The proximal breakpoints of these SVs lie within a 144 kb palindromic repeat, which likely mediates the rearrangements.

Conclusion: We describe a novel neurodegenerative disorder caused by triplication of a region containing *ATP6V0C*/*AMDHD2*, likely mediated by a palindromic repeat. This is the second distinct neurodevelopmental disorder linked to this locus.

P14.003.C Unravelling the diagnostic power of whole-exome sequencing for copy number variant detection

*Athina Theodosiou[1], **Constantia Aristidou**[2], Angelos Alexandrou[1], Ioannis Papaevripidou[1], Paola Evangelidou[1], Ludmila Kousoulidou[1], Sofia Ourani[3], George A. Tanteles[2,4], Carolina Sismani[1]*

[1]Department of Cytogenetics and Genomics, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [2]Department of Clinical Genetics and Genomics, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [3]Clinical Genetics Department, Archbishop Makarios III Hosptital, State Health Services Organization, Nicosia, Cyprus, [4]Department of Basic and Clinical Sciences, University of Nicosia Medical School, Nicosia, Cyprus.

Background: Whole-exome sequencing (WES) has emerged as a powerful tool for detecting single nucleotide variants (SNVs) and insertions/deletions (indels). Recent studies have shown that WES, paired with advanced computational methods, can also provide high-resolution copy number variant (CNV) detection, often surpassing traditional techniques in terms of accuracy and efficiency. Here we present four cases of CNV detection by WES in patients with various neurodevelopmental disorders and/or congenital anomalies, who remained undiagnosed after karyotyping and array-CGH (resolution 100 kb).

Material and Methods: WES was performed on Illumina NextSeq 2000 platform using Illumina DNA Prep with Exome Enrichment. Bioinformatic analysis, annotation and interpretation were performed on Franklin by Genoox platform using the human genome assembly hg19. Array-CGH results were retrospectively re-evaluated and quantitative Real-Time PCR (qRT-PCR) was used to validate WES findings.

Results: In 4/136 family trios, pathogenic or likely pathogenic CNVs, consistent with the patients' phenotype, were identified from WES: i) a ~6.15 kb copy number gain in *SLC12A3* (exons 9–14) found in trans with a pathogenic missense SNV, ii) a de novo heterozygous ~793 bp deletion in *POGZ* (exons 11–12), iii) a homozygous ~140 bp deletion in *IFT74* (exon2), and iv) a homozygous ~84 kb deletion in *PGM2L1* (exons 6–14). None of the CNVs were detectable by array-CGH, but all were successfully confirmed by qRT-PCR.

Conclusion: This study supports that detection of CNVs <100 kb yields an additional ~3% of resolved cases. Hence, CNV analysis incorporation into WES diagnostic pipelines is of outmost importance for comprehensive evaluation of patients and discovery of novel disease-associated variants.

P14.004.D Spreading of X-chromosome inactivation into autosomal sequences in unbalanced X-Autosome translocations: predicting silencing and escape

***Bianca P. Favilla**[1], Ahmed Al-Rikabi[2], Danielle C. F. Bruno[3,4], Paula Asprino[5], Eduardo Perrone[1], Danilo Moretti-Ferreira[6], Vera Meloni[1], Pedro A. F. Galante[5], Iscia Lopes-Cendes[3,4], Fernanda Bellucco[1], Thomas Liehr[2], Maria Isabel Melaragno[1]*

[1]Genetics Division, Universidade Federal de São Paulo, São Paulo, Brazil, [2]Institute of Human Genetics, Jena University Hospital - Friedrich Schiller University, Jena, Germany, [3]Department of Medical Genetics and Genomic Medicine, School of Medical Sciences, University of Campinas, Campinas, Brazil, [4]Brazilian Institute of Neuroscience and Neurotechnology, Campinas, Brazil, [5]Molecular Oncology Center, Instituto de Ensino e Pesquisa (IEP) - Hospital Sírio-Libanês, São Paulo, Brazil, [6]Department of Chemical and Biological Sciences, Biosciences Institute, Universidade Estadual Paulista, Botucatu, Brazil.

Background: Unbalanced X-autosome translocations are rare structural abnormalities that present unique challenges due to skewed X-chromosome inactivation and its spread into translocated autosomal regions. Assessing silencing in these regions aids phenotypic characterization and helps uncover genomic and epigenetic features that could predict silencing and escape.

Material and Methods: We studied three patients with unbalanced X-autosome translocations involving chromosomes 13, 15, and 21, confirmed by G-banding karyotype and chromosomal microarray. Using Long-read Sequencing and RNA-seq, we assessed haplotype-resolved DNA methylation and allele-specific gene expression profiles from peripheral blood samples. This allowed classification of autosomal genes as active/inactive. In silico, we annotated 43 genomic and epigenetic features in human embryonic stem cells for 101 active and 101 inactive translocated genes to develop a Random Forest Model (RFM) with RFM-based clustering that identifies and prioritizes underlying predictors of silencing and escape.

Results: Variable silencing was observed in 24–26% of autosomal genes across translocated regions, with allele-specific hypermethylation identified near promoters of some clinically relevant genes. The RFM (mean accuracy = 75%, p[accuracy>non-information rate] <0.05) revealed reduced genomic distance from XIST and association of polycomb features as predictors of silencing. Conversely, increased ALU density and gene density were associated with escape. Validation on an independent dataset of six unbalanced X-autosome translocations (N = 904 genes) yielded 80% predictive accuracy.

Conclusion: Our findings emphasize the interplay between genomic and epigenetic elements in predicting silencing and escape in unbalanced X-autosome translocations. Moreover, the RFM could be applied to predict inactivation status of clinically relevant genes in similar translocations.

Background/Objectives: Deletions and pathogenic variants in *SET* and *SPTAN1*, included in 9q34.11 locus, are associated with neurodevelopmental disorders (NDDs) and intellectual disability. To date, duplications of the 9q34.11 region have not yet been reported as pathogenic. We report 11 individuals with overlapping 9q34.11 microduplications presenting with NDD and recurrent facial dysmorphic features.

Methods: Pediatric individuals with NDD were evaluated by Chromosomal Microarray Analysis. Cases were collected through DECIPHER and the ITHACA European Reference Network. Nine unaffected parents of children with NDDs were analyzed as controls.

Results: Eleven individuals aged 4 to 21 years with overlapping 9q34.11 microduplications exhibited NDD (11/11), intellectual disability (8/11), and autism spectrum disorder (4/11). The minimal region of overlap (chr9: 128679215-128770807 on GRCh38/hg38) encompasses *SET* and *ZER1*, with 10/11 cases also involving *SPTAN1*. Two individuals developed epilepsy; mild dilatation of the renal pelvis was noted (3/11). Dysmorphic features including midface hypoplasia and thin lips, were observed in most cases. Among unaffected controls, 8/9 carried a partial duplication of *ZER1* and 1 carried a whole duplication of *SET*.

Conclusion: We report 11 individuals with 9q34.11 microduplications encompassing *SET* and *ZER1* in all cases and *SPTAN1* in 10/11 cases. The only case without *SPTAN1* duplication also carried a pathogenic 16p11.2 deletion. Altogether, these results suggest that increased gene dosage of *SPTAN1* is responsible for a novel 9q34.11 microduplication syndrome presenting with NDD and recurrent dysmorphisms.

P14.007.C Hi-C and RNA-seq analyses on hiPSC-derived astrocytes allow to further decipher pathomechanisms in Autosomal Dominant adult-onset demyelinating LeukoDystrophy (ADLD)

Anna Basile[1], *Ingrid Battistella*[2], *Mariia Zadorozhna*[1,3], *Malte Spielmann*[4,5,6], *Luciano Conti*[2], *Elisa Giorgio*[1,3]

[1]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [2]*Laboratory of Stem Cell Biology, Department of Cellular, Computational and Integrative Biology-CIBIO, University of Trento, Trento, Italy,* [3]*Neurogenetics Research Centre, IRCCS Mondino Foundation, Pavia, Italy,* [4]*Institute of Human Genetics, Universitätsklinikum Schleswig Holstein, University of Lübeck and University of Kiel, Lübeck, Germany,* [5]*Max Planck Institute for Molecular Genetics, Human Molecular Genomics Group, Berlin, Germany,* [6]*Institute of Human Genetics, Universitätsklinikum Schleswig Holstein Campus Kiel and Christian-Albrechts-Universität, Kiel, Germany.*

Background: ADLD is a rare neurodegenerative disorder caused by LMNB1 overexpression due to gene duplications (classical ADLD) or noncoding deletions in the locus (atypical ADLD). Our group collected > 20 families worldwide carrying structural variants (SVs) in the *LMNB1* locus and reported strong clinical variability, even among patients carrying duplications of the entire *LMNB1* gene, ranging from classical and atypical ADLD to asymptomatic carriers. We performed Hi-C and RNA sequencing on ADLD fibroblasts, providing preliminary insights into ADLD pathomechanisms and the genotype/phenotype correlation of SVs at the *LMNB1* locus. Here, we aim to validate these findings in disease-relevant cellular models, namely hiPSC-derived astrocytes.

Material and Methods: We generated hiPSC-derived astrocytes from four subjects carrying a SV in the *LMNB1* locus (a classical ADLD and two atypical ADLD patients, and an asymptomatic carrier) and a healthy control. Hi-C and RNA seq were performed on 1 million astrocytes per sample following standard protocols.

Results: We validate that: classical ADLD is due to an intra-TAD duplication, resulting in a simple gene dose gain; atypical ADLD is caused by *LMNB1* forebrain-specific misexpression due to SVs encompassing a TAD boundary. Finally, in the asymptomatic subject we identified an inter-TAD duplication, which extends centromerically and crosses two boundaries.

Conclusion: These results emphasize the critical role of TAD structure in mediating the pathogenicity of SVs in the *LMNB1* locus and further show that a duplication encompassing the *LMNB1* gene is not sufficient per se to diagnose ADLD, with implications for ADLD diagnosis and genetic counseling.

Molecular Medicine, University of Pavia, Pavia, Italy, [4]Neurogenetics Research Centre, IRCCS Mondino Foundation, Pavia, Italy, [5]Max Planck Institute for Molecular Genetics, Development and Disease Group, Berlin, Germany, [6]Institute of Human Genetics, University Hospitals Schleswig-Holstein, University of Lübeck and University of Kiel, Lübeck, Germany, [7]DZHK (German Centre for Cardiovascular Research) Germany, partner site Hamburg, Lübeck, Kiel, Lübeck, Germany.

Background: Ring14 syndrome (R14S) is a rare neurodevelopmental disorder with a complex phenotype, including drug-resistant epilepsy. R14S is caused by the rearrangement of chromosome 14 into a ring-shaped structure formed by two breakpoints fused with terminal deletions. This genetic loss doesn't explain some clinical features, e.g., individuals with similar 14q linear deletions don't exhibit epilepsy[1]. Our project aims to characterize the molecular pathogenesis of R14S using genome-wide chromosome conformation capture (Hi-C) and define R14 breakpoints and ring-associated rearrangements with long-read sequencing (LRS), exploiting the complete T2T-CHM13 human genome assembly[2] where acrocentric chromosomes are resolved.

Methods: We analyzed cell lines from 10 R14S patients and 5 parents from the Telethon Network of Genetic Biobanks. We performed Hi-C on the entire cohort and whole-genome LRS with Oxford Nanopore Technology (ONT) on a subset of samples. Hi-C data were processed using HiCPro[3] and FitHiC2[4]. LRS reads were aligned with Minimap2[5] and variant calling was performed with Sniffles[6] and Spectre[7]. PEPPER-Margin-DeepVariant pipeline[8] was applied for haplotag.

Results: Using Hi-C, we reconstructed ring contacts between 14p and 14q ends and detected terminal 14q deletions (100 Kb-5 Mb) identified by a-CGH. LRS confirmed the intra-chromosomal junctions observed with Hi-C, showing circularization involved genetic rearrangement at both chromosomal ends.

Conclusion: Our study highlights the innovative use of Hi-C and LRS to characterize Ring14 chromosomes. These techniques, while well-established for genome assembly, have not been applied to human ring chromosomes. By combining Hi-C's structural resolution with LRS, we offer a novel approach for studying chromosomal alterations in R14S.

P14.009.A Cohort of 90 patients mainly affected by neurodevelopmental delay analyzed using optical genome mapping (OMG) technique in constitutional cytogenomics

Martine Doco-Fenzy[1], Emma N. Benbakir[2], Wallid Deb[2], Bertrand Isidor[2], Olivier Pichon[3], Emilie Landais[1], Tony Yammine[1], Celine Poirsier[1], Faezeh Vasheghani[2], Mathilde Nizon[2], Nathalie Bednarek[4], Sandra Mercier[2], Marie Vincent[5], Sylvie Jaillard[6], Sylvie Odent[7], Sylvie Bernard[8], Nicolas Gruchy[9], Mylene Dexheimer[10], Celine Bonnet[10], Nathalie Ledu[11], Noemie Celton[11], Paul Gueguen[11], Vincent Jauffret[8], Clemence Jacquin[1], Jonathan Levy[12], Agnes Guichet[13], ***Stephane Bezieau***[2]

[1]CHU-Reimsgenetics, Reims, France, [2]Nantes Université, CHU de Nantes, Service de Génétique médicale, Nantes, France, [3]Nantes Université, CHU de Nantes, Service de Génétique médicale, Reims, France, [4]CHU-Reims Pediatrics, Reims, France, [5]CHU Nantes, NANTES cedex 1, France, [6]CHU-Rennes Genetics, Rennes, France, [7]CHU de Rennes Hosp SUDService de genetique Clinique, RENNES cedex 2, France, [8]laboratory Cytogen, Saint Herblain, France, [9]CHU-Caen Genetics, Caen, France, [10]CHU-Nancy genetics, Nancy, France, [11]CHU-Tours Genetics, Tours, France, [12]AP-HP CHU Paris, Paris, France, [13]CHU-Angers Genetics, Angers, France.

Optical genome mapping (OGM) is an innovative technology based on automated fluorescence optical imaging of ultra-long DNA molecules. This whole-genome approach enables a rapid analysis of structural variants (SV) and their spatial organization. Ninety patient samples, including 85 peripheral blood and 5 amniotic fluids, were collected between 2022 and 2024 and analyzed using OGM in the cytogenetics department. Among these, 30 cases with SVs previously identified by routine diagnostic methods (karyotyping, CMA, genome sequencing) were reanalyzed using OGM. Additionally, 60 cases with undiagnosed neurodevelopmental delay were investigated to identify any potential pathogenic SV. Except for two families analyzed as duo/trio cases, the analyses were performed as solo studies. In our cohort, OGM demonstrated a 97.1% concordance with the SVs identified by prior diagnostic methods. Furthermore, OGM contributed to a better spatial understanding of these chromosomal aberrations in 65% of cases. Candidate SVs were discovered in 33% of cases including eight patients with at least one likely pathogenic or pathogenic SV. Overall, we analyzed a broad spectrum of chromosomal abnormalities such as aneuploidies, deletions, duplications, inversions and insertions, triplications, translocation-derived chromosomes, ring chromosomes and markers, inversion-duplication-deletion and complex rearrangements. We compared them with other techniques in order to validate the protocol using OGM. The results of other techniques will be reported in comparison. Furthermore, no pathogenic variants were identified in 29 cases. This study enhances our knowledge of OGM useful applications in constitutional rare diseases, highlighting its ability to perform high-resolution SV characterization as well as its advantages and limitations.

P14.010.B Chromosome 17q12 deletion and duplication in the Irish population

Yuxin Woon[1,2]*, Linda McArdle[1], Juan Trujillo[2], Andrew Green[1]*

[1]Department of Clinical Genetics, Children's Health Ireland at Crumlin, Dublin, Ireland, [2]Paediatrics and Child Health, Cork University Hospital, Cork, Ireland.

Background: The recurrent chromosomal region 17q12 is linked to diverse clinical manifestations, particularly neurodevelopmental issues and organ-specific abnormalities. Deletions of 17q12 are strongly associated with renal and genitourinary anomalies, as well as maturity-onset diabetes of the young type 5. In contrast, duplications exhibit variable phenotype ranging from normal to severe intellectual disabilities, developmental delays, and neuropsychiatric conditions. This study explores the clinical phenotypes associated with 17q12 deletions and duplications in an Irish cohort.

Material and Methods: 36 cases were identified through the cytogenetic and clinical database of the Department of Clinical Genetics, Children's Health Ireland, searching between 2013 and 2024: 20 with deletions and 16 with duplications. Array comparative genomic hybridization (Array-CGH) and next-

generation sequencing-based copy number variant (CNV) analysis were utilized. Platforms included 120 kb and 180 kb CGH arrays (Agilent) and Illumina NovaSeq6000. Ethical approval was obtained (REC-503-24).

Results: Findings showed that 75% of deletion cases had antenatal findings, predominantly renal anomalies (85%), compared to only one duplication case with antenatal findings. Developmental delays were more pronounced in duplications than deletions, with significant differences in gross motor, fine motor, and speech delays. Neurodiversity and intellectual disabilities were observed in both groups, while more severe autism appeared more frequently with deletions, influencing school placement. Parental testing revealed that 80% of duplications were inherited compared to only 6% of deletions and parental phenotype were explored respectively.

Conclusion: This study highlights the multisystem and neurodevelopmental impact of 17q12 deletions and duplications. It also emphasizes the importance of parental segregation studies in guiding clinical management.

P14.011.C Exploring Chromosome Instability: the DEB test beyond the diagnosis of Fanconi Anemia

Cláudia Oliveira[1,2,3], *Nádia Neto*[1,2,3], *Pedro Oliveira*[4,3], *Beatriz Porto**[1], *Paula Jorge**[1,2,3]

[1]*Cytogenetics Laboratory, Department of Microscopy, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal,* [2]*UMIB - Unit for Multidisciplinary Research in Biomedicine, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal,* [3]*ITR - Laboratory for Integrative and Translational Research in Population Health, Porto, Portugal,* [4]*EPIUnit, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal.*

Background: Fanconi anemia (FA) is a rare genetic disorder characterized by chromosome instability (CI), particularly following exposure to DNA crosslinking agents, such as 1,2:3,4-Diepoxybutane (DEB). The DEB test, sensitive and specific, remains the gold standard for FA diagnosis due to its non-overlapping separation between positive and negative CI values. However, a subset of patients referred to our Laboratory for this test exhibited intermediate CI levels, i.e., between FA and control values, suggesting potentially reduced DNA repair capacity.

Material and Methods: A retrospective study was performed using CI levels from a cohort of patients evaluated for suspicion/exclusion of FA between 1993 and 2025. The study included three groups: healthy controls (n = 244), FA patients (n = 83), and non-FA patients, with molecular exclusion of FA (n = 813). CI assays were conducted using different concentrations of DEB. Statistical analyses were employed to compare CI levels across the groups.

Results: Within the non-FA group, we identified a subset of patients exhibiting intermediate CI levels. These included individuals diagnosed with inherited bone marrow failure syndromes (IBMFS), mostly Shwachman-Diamond syndrome, as well as patients without a definitive diagnosis.

Conclusion: Our findings demonstrate a spectrum of CI levels in non-AF individuals, emphasizing the clinical relevance of precise CI analysis beyond FA diagnosis. Further investigation is crucial to understand the underlying mechanisms of CI and its clinical implications. Of particular clinical significance are the IBMFS, where pre-transplant conditioning regimens for HSCT may require careful tailoring to minimize the risk of toxicity due to their potentially compromised DNA repair capacity.

P14.012.D Integration of Long-Read Genome Sequencing with Prenatal Testing to Resolve Structural and Epigenetic Consequences of an X;1 Chromosomal Translocation

Mark Drost, *Federico Ferraro, Dmitrijs Rots, Herma Zondervan-van der Linde, Malgorzata Srebniak, Tjitske Kleefstra, Tjakko van Ham*

ErasmusMC, Rotterdam, Netherlands.

Background: Resolving complex chromosomal anomalies traditionally requires multiple techniques, such as karyotyping, microarray, FISH, short-read genome sequencing and, if needed, epigenetic assays for X-chromosome inactivation (XCI). Long-read genome sequencing (LR-GS) provides a comprehensive, single-platform alternative. We present a case where LR-GS alone provided a complete genomic and epigenomic assessment of an unbalanced X;1 translocation in a prenatal sample initially detected by non-invasive prenatal testing (NIPT).

Material and Methods: NIPT identified a chromosome 1q gain. Conventional follow-up methods suggested an unbalanced translocation between chromosomes X and 1. Instead of using multiple assays, we performed nanopore LR-GS and used sniffles2 and spectre to resolve the precise structure of the translocation, and in house scripts to evaluate methylation alterations on chromosome 1 and X.

Results: LR-GS precisely delineated the breakpoints of the unbalanced X;1 translocation, identifying both a terminal Xq loss and terminal 1q gain. Additionally, direct DNA methylation analysis demonstrated skewed XCI, showing inactivation exclusively of the derivative X;1 chromosome (carrying the 1q gain), providing functional insight without the need for separate XCI testing. As the 1q gain derivate chromosome is inactivated, the possible effect of this gain remains unknown. This integrated approach allowed for characterization of both complex structural and epigenetic variant evaluation in a single experiment.

Conclusion: This case illustrates the potential of LR-GS as a single-platform alternative to conventional cytogenetic and molecular techniques. By integrating structural variant detection with direct XCI assessment, LR-GS streamlines genomic analysis, with the potential to improve diagnostic efficiency in (prenatal) genetic testing.

P14.013.A An Emirati pangenome incorporating a diploid telomere-to-telomere reference

Michael Roland Olbrich[1], *Mira Mousa*[1], *Inken Wohlers*[1], *Amira Al Aamri*[1], *Aisha Abdalla Saleh Hanaya Alsuwaidi*[1], *Hima Vadakkeveettil Manoharan*[1], *Nour al dain Marzouka*[1], *Sanjay Ramachandran*[1], *Anju Annie Thomas*[1], *Mohamed AlAmeri*[2], *Guan Tay*[3], *Rifat Hamoudi*[4], *Saleh Ibrahim*[1], *Noura AlGhaithi*[2], *Habiba Alsafar*[1]

[1]*Khalifa University, Abu Dhabi, United Arab Emirates,* [2]*Department of Health Abu Dhabi, Abu Dhabi, United Arab Emirates,* [3]*University of Western Australia, Perth, Australia,* [4]*University of Sharjah, Sharjah, United Arab Emirates.*

Background: Reference data on genomic variation is at the basis of genetics research. To date, global pangenomes do not include

genomes from the Middle Eastern Region. To address this shortcoming, we provide an Emirati genome reference.

Material and Methods: The core of the reference is a diploid assembly with a QV of 60 that includes ten telomere-to-telomere chromosomes. This assembly is incorporated into a pangenome graph constructed of 52 additional high-quality, trio-based assemblies, half of which are trio-based. Advancements in sequencing technologies enabled chromosome-level accuracy, and all assemblies were evaluated for coverage, consistency, and structural integrity to ensure robust representation of challenging genomic regions.

Results: The Emirati pangenome reveals a similar level of genomic variation compared to the Human Pangenome Reference Consortium, thus filling a critical gap by including a Middle Eastern genome component. Its telomere-to-telomere chromosomes permit reliable detection of complex genomic regions, enhancing the identification of both global and population-specific variants. This resource offers improved insights into regional genetic diversity, an area often underrepresented in existing references. The successful assembly pipeline highlights the feasibility of producing similarly comprehensive pangenomes for other underserved populations.

Conclusion: Our Emirati pangenome provides an essential reference for global genomics research while emphasizing the importance of diverse ancestries. This high-quality, diploid assembly supports personalized medicine initiatives in the United Arab Emirates and beyond, paving the way for broader, more inclusive genomic discovery and application.

P14.014.B De novo assembly of the H9 cell line

Erika Souche[1], *Marta Sousa Santos*[1], *Senne Meynants*[1], *Wim Meert*[2], *Wouter Bossuyt*[2], *Jonas Demeulemeester*[3], *Joris Vermeesch*[1]

[1]*KU Leuven, Department of Human Genetics, Leuven, Belgium,* [2]*Genomics Core, UZ Leuven, Leuven, Belgium,* [3]*KU Leuven, Department of Oncology, Leuven, Belgium.*

Background: Human embryonic stem cell (hESC) lines such as the H9 cell line are widely used in research due to their differentiation potential making them an optimal platform for genome editing and developmental studies. The H9 cell line has been genome sequenced using short read sequencing but a full genome assembly is not yet available, hampering editing and precluding the study of repetitive regions.

Material and Methods: To generate a telomere to telomere (T2T) H9 assembly, we performed both PacBio and Oxford Nanopore Technology (ONT) long read sequencing. Assemblies have been generated using hifiasm and flye for PacBio and ONT, respectively. Verkko has been used to assemble PacBio reads with ultra long ONT data. The Nanopore-only T2T protocol consisting of two ultra long runs, one pore-C run and one assembly polishing run has also been tested.

Results: A regular ONT run leads to the assembly of 91% of the genome in 1,280 haploid contigs while a single PacBio run covers 93% of the genome with 322 and 318 haploid contigs. The use of ONT read correction and pore-C as well as nanopore only T2T are promising to further improve the de novo assembly and decrease the number of haploid contigs. We will present and compare those assembly results.

Conclusion: Long read sequencing allowed the full assembly of the H9 cell line, including the assembly of repetitive regions.

P14.015.C Alternative splicing site events in Arrhythmogenic Cardiomyopathy-related genes using in silico predictions and minigene assays

Giulia Tosato, *Rudy Celeghin, Serena Pinci, Francesca Dalla Zanna, Maria Bueno Marinas, Marco Cason, Cristina Basso, Kalliopi Pilichou*

University of Padua - Department of Cardio-Thoraco-Vascular Sciences and Public Health, Padua, Italy.

Background: Splicing site variant (SSV) data and associated computational tools often exhibit limited sensitivity and specificity, offering only probabilistic estimates and imprecise evidence weighting for splicing findings. Arrhythmogenic cardiomyopathy (ACM) [OMIM#107970, ORPHA247], a rare inherited cardiac disorder, is predominantly caused by pathogenic variants in desmosomal genes, with 10–15% affecting noncanonical splice sites, auxiliary splice sites, and deep-intronic regions. This study sought to generate and apply minigene splicing assay for a prioritized set of splicing variants to refine their classification in accordance with ClinGen recommendations, ultimately improving diagnostic accuracy.

Material-and-Methods: Selected variants from 112 consecutive ACM patients were cloned into the pSPL3 plasmid to create a minigene, which was transfected into HEK-293T cells. Aberrant RNA transcripts were analyzed via reverse transcription and direct sequencing. When available, frozen tissue was used to confirm results.

Results: Among 15 rare SSVs identified in ACM-related genes, including *desmoplakin, plakophilin-2, desmoglein-2, desmocollin-2*, and *filamin-C*, 4 were located in canonical splice sites, while 11 were in non-canonical regions. Minigene assays detected alternative splicing events in 9 of these variants. Canonical variants predominantly resulted in exon skipping, whereas non-canonical variants led to alternative intron retention or abnormal exon deletion, revealing previously unrecognized molecular mechanisms. RNA analysis on frozen tissue confirmed the concordance between in vitro assay and natural splicing processes.

Conclusion: Approximately one-third of rare SSVs were reclassified based on in vitro loss-of-function evidence, enabling appropriate PVS1-assignment. Integrating functional validation with bioinformatics significantly improved pathogenicity assessment of splicing variants, enhancing diagnostic accuracy and clinical management of ACM patients.

P14.017.A Breakpoint mapping in balanced chromosomal rearrangements allows insights into the molecular underpinnings of rare diseases

Michael Wendel Da Silva[1], *Bruna Burssed*[1], *Bart van der Sanden*[2], *Kornelia Neveling*[3], *Alexander Hoischen*[4], *Marco Antônio Ramos*[1], *Chong Kim*[5], *Maria Isabel Melaragno*[6]

[1]*Universidade Federal de São Paulo, São Paulo, Brazil,* [2]*Radboud university medical center, Nijmegen, Netherlands,* [3]*Radboud university medical center,Department of Human Genetics, Nijmegen,*

Netherlands, [4]Radboud University Nijmegen Medical CentreDepartment of Human Genetics, Nijmegen, Netherlands, [5]Instituto da Crianca HC-FMUSPPediatrics, Sao Paulo, SP, Brazil, [6]Universidade Federal de Sao Paulo, Sao Paulo, Brazil.

Background: Balanced chromosomal rearrangements can often lead to the dysfunction of multiple genes located at or near the breakpoints. Among individuals with balanced rearrangements, approximately 6% exhibit phenotypic abnormalities attributed to various pathogenic mechanisms, including copy number variations (CNVs) undetectable by karyotyping, gene disruptions, gene fusions, position effects, alterations in topologically associated domains (TADs), and disrupted genomic interactions.

Material and Methods: Six patients presenting phenotypic abnormalities with balanced chromosomal rearrangements identified by karyotyping and the presence of CNVs excluded by chromosomal microarray analysis were investigated using optical genome mapping (OGM) to explore the underlying pathogenic mechanisms. Further analyses of altered TADs and gene-protein interactions were conducted through in silico approaches. Genotype-phenotype correlation studies were performed for all selected patients.

Results: Initial OGM findings revealed potential overlapping mechanisms with gene disruptions identified in five of the six patients, CNVs in two of the six, and TAD disturbances affecting candidate genes in three of the six. Disruption of the *TCF4* gene was found in a patient with t(14;18)(q13.2;q21.2), representing one of the few documented translocations associated with Pitt-Hopkins syndrome, which is characterized by motor delay, stereotypic movements, breathing abnormalities, and other clinical features. In a patient with t(5;17)(p13.2;q11.2), disruption of the *PRLR* gene, along with TAD impairment involving the *NF1* gene, may be associated with phenotypes such as osteopenia, amenorrhea, and microcephaly, among others.

Conclusion: OGM demonstrated significant value in uncovering pathogenic mechanisms, advancing etiological understanding, guiding diagnoses, and shortening the diagnostic odyssey for patients with balanced chromosomal rearrangements.

P14.018.B Long-Read Sequencing for Structural Variant Detection and Analysis: Mechanism Characterization

Jade Fauqueux[1], Jean-Pascal Meneboo[2], Emilie Ait-yahya[3], Caroline Thuillier[4], Céline Villenet[2], Martin Figeac[2], Jamal Ghoumid[5,1], ***Thomas Smol****[4,1]*

[1]ULR 7364 RADEME, University of Lille, Lille, France, [2]Univ. Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, US 41-UAR 2014-PLBS, Lille, France, [3]CHU Lille, Cellule de Bioinformatique, Plateau Commun de Séquençage, CHU Lille, Lille, France, [4]CHU Lille, Institut de Génétique Médicale, Lille, France, [5]CHU Lille, Clinique de Génétique, Lille, France.

Background: Accurate characterization of Structural Variants (SVs) is crucial for precise diagnosis. While conventional and molecular cytogenetic techniques provide partial insights, they have limitations in resolving SVs within complex rearrangements and repetitive regions. These challenges can be addressed by third-generation sequencing technologies.

Material and Methods: We analyzed ten patients with SVs previously identified by CGH-array and classified as variants of uncertain significance or likely pathogenic based on clinical presentation. Long-read DNA sequencing (LRS) using Nanopore technology was employed to enhance the characterization of these variants and to develop hypotheses regarding their underlying mechanisms of formation.

Results: The analysis identified the following structural variants: 1 DUP-TRP/INV-DUP, 1 DUP-NML-DUP/INV, 6 tandem duplications, 1 tandem triplication, and 1 inversion. LRS enabled precise breakpoint characterization and provided insights into their underlying mechanisms of formation. Among the tandem duplications, five were likely mediated by Fork Stalling and Template Switching or Microhomology-Mediated Break-Induced Replication, both associated with microhomologies. The remaining tandem copy-gain variants were likely mediated by the classical Non-Homologous End Joining mechanism, as evidenced by insertions at the breakpoints. Both complex rearrangements appeared to involve two distinct mechanisms. Lastly, the inversion was likely mediated by Non-Allelic Homologous Recombination, with segmental duplications observed at its breakpoints.

Conclusion: LRS enables the precise detection and reconstruction of complex variants that were not fully characterized by CGH-array, as well as the identification of previously undetected variants. It provides base-pair resolution of breakpoint sequences for all structural variants, facilitating the determination of the specific mechanisms underlying their formation.

P14.019.C Not just Turner, rare X chromosome rearrangements causing infertility

Ayat Farhan Khalaileh

Rambam Medical Center, Haifa, Israel.

Background: Premature ovarian failure (POF) is heterogeneous and could be caused by a variety of etiologies. Here, we present three patients diagnosed with POF and rare rearrangements on chromosome X.

Material and Methods: We clinically evaluated three patients with POF and performed chromosomal microarray (CMA) and Karyotype.

Results: Patient#1 was a 26-year-old referred for abnormal fragile X testing suggestive of triple X syndrome. The initial Karyotype was reported as normal, but the CMA revealed a deletion of 30 Mb in Xq25q28 and duplication of 36 Mb in Xp22.33p21. On revision, the duplicated segment was located in the deletion area, thereby masking this finding. On clinical evaluation, the patient was healthy with normal height but had infertility and elevated FSH levels. Patient #2 was a 16-year-old girl with secondary amenorrhea and increased levels of FSH. The Karyotype and CMA revealed a large de novo 54 Mb deletion on Xq13.2q25 that includes *MECP2*. She was healthy with a normal height and physical examination but with suspected borderline intelligence. Patient #3 was 35 years old with severe oocyte quality after ovum aspiration. CMA revealed a pathogenic 110 kb deletion at Xq27.3 including FMR1 and FMR1-AS genes. She had short stature with suspected borderline intelligence.

Conclusion: We describe ultra-rare chromosome X rearrangements associated with apparently isolated POF. We found scarce data in the literature on these abnormalities. A full medical history and physical examination together with Karyotype and CMA, should be performed in such cases to fully understand the phenotype and genetic diagnosis.

P14.020.D Supernumerary heterochromatic marker in fetus with balanced translocation 11,15

Angelina Pranteda[1], *Roberta Leone*[1], *Carla Lori*[1], *Nadia Messina*[1], *Valentina Arista*[1], *Serena Torricelli*[1], *Emilia Morrone*[1], *Valeria Maselli*[1], *Stefania Napoletano*[1], *Ester Sallicandro*[2], *Antonio Novelli*[3], *Mariateresa Sessa*[1], *Ettore Cotroneo*[1], *Laura Gigante*[4]

[1]*Eurofins Genoma Group, Cytogenetic Lab, Rome, Italy,* [2]*Laboratory of Medical Genetics, Translational Cytogenomics Research Unit, "Bambino Gesù" Children Hospital, IRCCS, Rome, Italy,* [3]*Bambino Gesù Children Hospital, Rome, Italy,* [4]*Department of Genetic Counseling, Eurofins Genoma Group, Rome, Italy.*

Background: Small supernumerary marker chromosomes (sSMCs) are abnormal chromosomes with unclear origins, often not detectable through traditional karyotyping. Techniques like aCGH and FISH provide more precise characterization of sSMCs, identifying their chromosome origin and gene content. However, aCGH may have limitations in detecting balanced translocations and regions with repetitive sequences, complicating data interpretation.

Material and Methods: We present a case of a 35-year-old pregnant woman with a history of recurrent miscarriages, carrying a balanced translocation between chromosomes 11 and 15. Chorionic villus sampling (CVS) was performed, and aCGH was used to analyze fetal DNA. Short tandem repeat (STR) markers were analyzed to exclude Uniparental Disomy (UPD). Traditional karyotyping and FISH were also employed to assess the fetal chromosomal profile.

Results: aCGH revealed a female genomic profile without chromosome rearrangements. STR analysis excluded UPD on chromosomes 11 and 15. Karyotyping identified a 47,XX,+mar,t(11;15)(q21;q26)mat karyotype, confirming the presence of a sSMC and the maternal translocation. FISH analysis localized the sSMC to the pericentromeric region of chromosome 15, excluding involvement of the Prader-Willi/Angelman syndrome critical region.

Conclusion: The sSMC detected in the CVS sample was found to be heterochromatic, which explains why it was not detected by aCGH. This case represents a rare occurrence of a sSMC originating from one of the chromosomes involved in a balanced translocation. The origin of the sSMC in this fetus may be linked to a chromosomal rescue mechanism associated with the maternal translocation.

P14.021.A The value of regions of heterozygocity metrics for predicting morbidity: insights from a large cohort of chromosomal microarray analyses

Lena Sagi-Dain[1], *Michal Levy*[2], *Reut Matar*[2], *Sarit Kahana*[2], *Ifaat Agmon-Fishman*[2], *Cochava Klein*[2], *Merav Gurevitch*[2], *Lina Basel-Salmon*[2], *Idit Maya*[3]

[1]*Carmel Medical Center, Haifa, Israel,* [2]*The Raphael Recanati Genetic Institute, Rabin Medical Center, Petach Tikva, Israel,* [3]*The Raphael Recanati Genetic Institute, Rabin Medical Center, Petah Tikva, Israel.*

Background: This study aimed to define the optimal Regions of Homozygosity (ROH) size cut-offs for prediction of morbidity, based on a large cohort of Chromosomal Microarray Analyses (CMA).

Material and Methods: This retrospective cohort study analyzed data from 13,483 CMA tests conducted between April 2017 and December 2023. Receiver operating characteristic (ROC) curves were generated, and area under the curve (AUC) was used to assess the predictive capability of total ROH percentage (TRPS), ROH number and ROH segment size in distinguishing between healthy ($n = 6,196$) and affected ($n = 6,839$) cohorts.

Results: ROH segments were identified in 13,035 samples (96.7%), encompassing 66,710 ROH segments. Significant differences in TRPS and ROH segment size were observed between healthy and affected cohorts ($p = 0.012$ and $p < 0.001$, respectively). In addition, both telomeric and interstitial ROH segments exhibited greater sizes in the affected cohort. However, no clinically significant thresholds could be established based on ROC curves for TRPS and ROH number per sample, as well as for ROH size (AUC 0.64, 0.55 and 0.62, respectively). The same was noted for telomeric vs. interstitial locations, various origins, as well for several subcategories of TRPS.

Conclusion: This study highlights the complexity of ROH interpretation and emphasizes the importance of tailored reporting strategies in clinical practice, particularly in populations with notable consanguinity.

Table 1. Regions of Homozygosity (ROH) and total ROH percentage (TRPS) metrics - comparison between healthy and affected cohorts.

	Healthy (6196 samples)	Affected (6839 samples)	p	AUC
TRPS per sample (%)	0.59 (0.37–0.91)	0.60 (0.36–1.00)	0.01163	0.640

P14.022.B Optical genome mapping and long-read sequencing unravel the mechanisms and phenotypic implications of constitutional complex chromosomal rearrangements

Bruna Burssed[1,2], *Bart van der Sanden*[2], *Kornelia Neveling*[2], *Wolfram Hops*[2], *Eveline Kamping*[2], *Ronald van Beek*[2], *Amber den Ouden*[2], *Ronny Derks*[2], *Raoul Timmermans*[2], *Eduardo Perrone*[1], *Marco Antonio Ramos*[1], *Fernanda Teixeira Bellucco*[1], *Alexander Hoischen*[2,3], *Maria Isabel Melaragno*[1]

[1]*Universidade Federal de São Paulo, Department of Morphology and Genetics, São Paulo, Brazil,* [2]*Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands,* [3]*Radboud University Medical Center, Department of Internal Medicine, Nijmegen, Netherlands.*

Background: Complex chromosomal rearrangements (CCRs) are structural variants (SVs) that involve at least three breakpoints. Their complete characterization allows for mechanism of formation inference and phenotype correlation.

Methods: Six patients had their constitutional CCRs fully characterized through karyotyping, chromosomal microarray, optical genome mapping (OGM), and 10-fold coverage long-read genome sequencing (LRS).

Results: Three patients presented multiple-chromosome CCRs while the other three involved a single chromosome. The fewest breakpoints (four) were detected in a patient with duplication-inverted/triplication-duplication in chromosome 2, while the most (47) were identified in a patient with a six-chromosome CCR. Given its higher resolution, LRS could detect more breakpoints (136 versus 116) than OGM, which presented a breakpoint uncertainty of ~5,853 base pairs on average. OGM's ultra-long reads and de novo assembly maps, however, achieved the best contiguity of complex SVs and guided the visual inspection of chimeric LRS reads, which especially proved valuable in the ~60% of the CCR junctions for which no automatic SV call was made. Two patients with breakpoints in previously unmapped regions, such as the acrocentric chromosomes' short arms, were resolved using the T2T reference genome. Non-homologous end-joining and chromoplexy were the most prevalent mechanisms of formation since most junctions exhibited break-end joining and insertions. Gene dosage alterations and regulatory context disruptions were associated with the patients' phenotypes.

Conclusion: The combination of OGM and LRS allowed us to assess CCRs at nucleotide resolution for all cases, helping to determine the mechanism of formation of complex SVs and to correlate them with patients' phenotypes.

P14.024.D Cytogenomic characterization of karyotypes with additional autosomal material and the genomic features around breakpoints

Priscila S. Rodrigues[1], *Bruna Burssed*[1], *Fernanda T. Bellucco*[1], *Débora C. Rosolen*[2], *Chong A. Kim*[2], ***Maria I. Melaragno***[1]

[1]*Universidade Federal de Sao Paulo, Sao Paulo, Brazil,* [2]*Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Chromosomal rearrangements involving additional material in individuals with phenotypic alterations usually result in partial trisomy, often accompanied by partial monosomy.

Objective: To characterize chromosomal rearrangements and analyze genomic characteristics in the breakpoint regions in 31 patients with additional material on an autosomal chromosome.

Methods: Different tests were performed to characterize these patients, such as karyotyping, chromosomal microarray analysis (CMA), and fluorescent in situ hybridization (FISH). In silico analyses were used to evaluate A/B chromosomal compartments, segmental duplications, and repetitive elements at breakpoints.

Results: The 31 rearrangements resulted in 47 copy number variations (CNVs) and a range of structural aberrations were identified, including six tandem duplications, 19 derivative chromosomes, two intrachromosomal rearrangements, one recombinant, two dicentric chromosomes, and one triplication. A deleted segment was associated with the duplication in 16 of the 19 patients with derivative chromosomes from translocation. Among the trios whose chromosome rearrangement origin could be investigated, 54,5% were de novo, 31,9% were maternally inherited, and 13,6% were paternally inherited from balanced translocations or inversion. Breakpoint analysis revealed that 22 were in the A compartment (euchromatin), 25 were in the B compartment (heterochromatin), and five were in an undefined compartment. Additionally, 14 patients had breakpoints in regions of segmental duplications and repeat elements.

Conclusion: Through various cytogenomic methodologies, different chromosomal rearrangements were described in patients with additional material, and it was possible to highlight the effects of parental origin in their rearrangements, also the genomic architecture of breakpoint regions could be elucidated and better characterized.

P14.025.A CNVs in the imprinted 11p15.5 regions: Frequency, anticipation, heterogeneity and unpredictability

Thomas Eggermann[1], *Matthias Begemann*[1], *Katja Kloth-Stachnau*[2], *Ingo Kurth*[1], *Miriam Elbracht*[1], *Katja Eggermann*[1], *Florian Kraft*[1]

[1]*Center for human genetics and genome medicine, Aachen, Germany,* [2]*Amedes group, Hamburg, Germany.*

Background: Disturbances of the imprinting centres IC1 and IC2 in 11p15.5 are associated with Beckwith-Wiedemann and Silver-Russell syndrome (BWS, SRS). Among the different molecular

disturbances are copy number variants (CNVs), which represent a challenge for clinical management and genetic counselling, due to different sizes and variable functional consequences. Advances of diagnostic methods have improved the sensitivity to identify and characterise these CNVs, but their interpretation is still difficult.

Material and Methods: In a cohort of more than 2000 patients referred for diagnostic BWS or SRS testing, the diagnostic yield for the key molecular disturbances was determined by MS-MLPA. Additionally, the contribution of CNVs in 11p15.5 to the spectrum of variants was delineated. Molecular methods were used to precisely determine their sizes and contents The obtained data were compared with cases from an extensive literature and database search.

Results: The detection rate in the cohort was ~20%, CNVs contributed to ~2% of the cases with a positive testing result. In addition to the common 11p15.5 CNVs comprising both ICs and additional genes, smaller CNVs affecting only one IC were identified both in the cohort and in the literature. The phenotypes of the CNV carriers differed markedly, ranging from patients with BWS or SRS features to unaffected.

Conclusion: The heterogeneous clinical outcome of carriers of CNVs affecting 11p15.5 represent a challenge in respect to prognosis, clinical management and genetic counselling. A decision tree to address these aspects in patients with 11p15.5 disturbances will be presented.

P14.026.B Hunting for the Y chromosome in a 45,X boy - when cytogenetics fails, novel approaches come to aid

Malgorzata Ponikowska[1], *Magdalena Wójcik*[2], *Agnieszka Maciejewska*[3], *Magdalena Koczkowska*[2], *Agnieszka Ulenberg*[4], *Ryszard Pawlowski*[3], *Maciej Jankowski*[1], *Natalia Filipowicz*[2], *Kinga Drezek-Chyla*[2], *Edyta Rychlicka-Buniowska*[2], *Dorota Birkholz-Walerzak*[4], *Jan P. Dumanski*[2,5], *Malgorzata Mysliwiec*[6,4], *Beata S. Lipska-Zietkiewicz*[1,7]

[1]*Department of Biology and Medical Genetics, Medical University of Gdansk, Gdansk, Poland,* [2]*3P-Laboratory Medicine, Medical University of Gdansk, Gdansk, Poland,* [3]*Department of Forensic Medicine, Medical University of Gdansk, Gdansk, Poland,* [4]*Department of Pediatrics, Diabetology and Endocrinology, University Clinical Center, Gdansk, Poland,* [5]*Department of Immunology, Genetics and Pathology and Science for Life Laboratory, Uppsala University, Uppsala, Sweden,* [6]*Department of Pediatrics, Diabetology and Endocrinology, Medical University of Gdańsk, Gdansk, Poland,* [7]*Rare Diseases Center, Medical University of Gdansk, Gdansk, Poland.*

Background: An 8-year-old phenotypic male presented with coarctation of the aorta, short stature, and dysmorphic features. Physical examination showed descended testes and glanular hypospadias. Cytogenetic analysis of peripheral blood lymphocytes revealed a 45,X[11].nuc ish(SRY-)[203] karyotype, and skin fibroblasts showed 45,X[11].ish Xp11.1(DXZ1x1),(DYZ1-),(SRY-)[12]. To clarify the mechanism of male sex differentiation and assess gonadoblastoma risk, we employed highly sensitive methods to detect Y chromosome material in various tissues.

Material and Methods: DNA was isolated from peripheral blood, buccal swabs and urine. ddPCR was designed to target *AMELX* and *AMELY* (blood, buccal swabs, urine) and *SRY* in a separate assay (blood, buccal swabs) with the QX200 Droplet Digital PCR System (Bio-Rad). Data analysis used QuantaSoft. STR analysis (blood, buccal swabs, urine) employed the PowerPlex® Y23 System (Promega) for 23 Y chromosome loci with the detection of products by ABI 3130 Genetic Analyzer (Applied Biosystems) and analysis in GeneMapper ID.

Results: ddPCR revealed presence of the *SRY* gene in the buccal swab, but not in the blood, and *AMELY/AMELX* signal ratios of 0.01 (blood), 0.60 (buccal swab), 0.15 (urine). STR analysis confirmed the presence of 18/23 Y chromosome loci in the buccal swab and urine, but revealed no Y chromosome signal in the blood.

Conclusion: Presence of Y chromosome comprising *SRY* gene was confirmed at varying levels of mosaicism across tissues, explaining the male phenotype. The absence of 5 STR loci at Yq11.22 (AZFc), suggestive of partial Y loss, points to the driving genomic aberration at the origin of the chromosomal abnormality.

Background: Short fragment genome sequencing (sfGS) is the gold standard for molecular diagnosis of neurodevelopmental disorders. However, the identification of certain structural variants (SV) can be difficult to identify using this technique. In such cases, long fragment genome sequencing (lfGS) can be used as an alternative, which facilitates de novo genome assembly, SV identification and haplotype phasing. Optical genome mapping (OGM) can also be utilized as it identifies SV and constructs high resolution genome maps.

Material and Methods: We performed sfGS abd lfGS alongside OGM in a male proband that presents with isolated neurodevelopmental delay.

Results: The initial analyses of sfGS did not identify any variant that could explain the patient's phenotype. An MRI spectroscopy was subsequently performed which showed the absence of a creatine peak, and was in favour of a creatine transporter deficiency due to loss of function of the *SLC6A8* gene. Direct visualization of the sfGS sequences with IGV software led to the suspicion of intra-exonic chromosomal rearrangement involving this gene, present in the hemizygous state in the patient and in

mosaic form in his mother. In combining lfGS and OGM, we confirmed the presence of a mitochondrial insertion in the *SLC6A8* gene. Currently, mitochondrial DNA insertions in nuclear DNA have rarely been reported as being responsible for human constitutional pathologies.

Conclusion: This finding illustrated the importance of combining genome sequencing techniques to achieve accurate molecular diagnoses where previous analyses remained non-conclusive and the rarely observed possibility of mitochondrial DNA insertion as a novel pathological mechanism.

P14.028.D Split-read analysis of short-read genome sequencing data identifies a de novo congenital chromosome 13 chromothripsis event contributing to bilateral retinoblastoma

Lubomir Balabanski[1,2], *Maya Atanasoska*[1,3], *Slavyana Yaneva Staykova*[1,2], *Irena Bradinova*[1,4,5], *Daniela Mircheva*[1], *Radoslava Vazharova*[1,6], *Draga Toncheva*[1,7]

[1]*Genetic and Medical Diagnostic Laboratory "CellGenetics", Sofia, Bulgaria,* [2]*Genetic Laboratory, Polymed Hospital, Sofia, Bulgaria,* [3]*Laboratory of Reproductive OMICs Technologies, Institute of Biology and Immunology of Reproduction, Bulgarian Academy of Sciences, Sofia, Bulgaria,* [4]*National Genetic Laboratory, University Hospital for Obstetrics and Gynaecology "Maichin Dom", Sofia, Bulgaria,* [5]*Medical University - Sofia, Faculty of Medicine, Department of Obstetrics and Gynaecology, Sofia, Bulgaria,* [6]*Sofia University "St. Kliment Ohridski", Faculty of Medicine, Department of Biology, Medical Genetics and Microbiology, Sofia, Bulgaria,* [7]*Bulgarian Academy of Sciences, Sofia, Bulgaria.*

Chromothripsis is an extreme type of complex chromosomal rearrangement that arises when a chromosome is shattered in many fragments in a single, catastrophic event and is then repaired in a random pattern not directed by homology. We performed short-read (150-bp) whole-genome sequencing on a 33-year-old man who had had bilateral retinoblastoma as a child and was planning to have children. Analysing the *RB1* gene we discovered a large 1.3-Mb deletion encompassing the whole gene. Interestingly, when we analysed the split-reads at the apparent breakpoints flanking *RB1* we established that the reads mapped reliably at distant coordinates along the long arm of chromosome 13. We went on to perform sequence analysis of all split-reads around potential breakpoints along chromosome 13. In total, we detected 15 high-confidence breakpoints that had led to four large deletions and multiple intrachromosomal translocations in inverted or non-inverted orientation that most likely arose after chromothripsis. MLPA analysis confirmed the hemizygous deletion of *RB1*, and long-read sequencing validated all the breakpoints detected. The patient was found to carry the low-penetrance pathogenic variant Ile157Thr in *CHEK2* that could have potentially contributed to the rearrangement event, as has been suggested for other DNA repair genes like *TP53*. Preimplantation genetic testing was performed on one embryo based on rare informative SNPs located on the functional *RB1* copy of the father. This embryo had not inherited the rearranged chromosome 13 but was unfortunately chaotic. This case illustrates how application of different bioinformatic algorithms could detect even complex structural variation resulting from chromothripsis.

L. Balabanski: None. **M. Atanasoska:** None. **S. Yaneva Staykova:** None. **I. Bradinova:** None. **D. Mircheva:** None. **R. Vazharova:** None. **D. Toncheva:** None.

P14.029.A Pathogenic complex genomic rearrangements in rare diseases: mechanisms, clinical implications, and diagnostic strategies

Jesper eisfeldt[1], *Anna Lindstrand*[2]

[1]*Karolinska institutet, Solna, Sweden,* [2]*Karolinska institutet, Stockholm, Sweden.*

Background: Complex genomic rearrangements (CGRs) are underrecognized contributors to genetic disorders due to the limitations of routine diagnostic methods. These structural variants, often involving multiple breakpoint junctions alongside copy-number changes and inversions, can disrupt gene function, alter regulatory landscapes, and contribute to disease phenotypes. However, their detection and characterization require advanced sequencing technologies capable of resolving structural complexity at nucleotide resolution

Material and Methods: In this study, we analyzed in house data from 64 CGRs, including both previously published (n = 48) and newly identified cases (n = 16), encompassing 536 breakpoint junctions (BPJs) mapped at single-nucleotide resolution. Genome sequencing data were generated using short-read (n = 52) and long-read (n = 33) technology. The CGRs were classified into two groups: intrachromosomal events (n = 53) and complex translocations involving multiple chromosomes (n = 11).

Results: The distribution of BPJs between the groups were 255 BPJs in intrachromomal events (range 2–26) and 274 BPJs in complex translocations (range 2–132). Of note, inversions were observed in 78% of the CGRs, with no significant difference between the two groups.

Conclusion: Our findings highlight the need for long-read sequencing, the telomere-to-telomere reference genome to fully resolve CGRs implicated in neurodevelopmental disorders, autism, Alzheimer's disease, and congenital malformations. The high prevalence of inversions in CGRs suggests specific mechanistic pathways driving structural complexity, with implications for mutational processes and disease risk. These insights reinforce the value of advanced sequencing technologies in identifying previously undetected structural variants, pinpointing disease-causing events, and improving rare disease diagnostics and personalized medicine.

P14.030.B Can long-read sequencing replace current cytogenetic methods in clinical genetic diagnostics?

Emilie B. Lester[1], *Christina Fagerberg*[2], *Caroline H. Baekgaard*[1], *Charlotte B. Andersen*[1], *Morten B. Engelund*[3], *Steffen M. Boettger*[1], *Martin J. Larsen*[1]

[1]*Odense University Hospital, Odense C, Denmark,* [2]*Sygehus Lillebaelt, Vejle, Denmark,* [3]*Odense University HospitalDepartment of Clinical Genetics, Odense C, Denmark.*

Background: Detection of structural variants and complex chromosomal rearrangements is a challenge with current methods used for molecular diagnostic of genetic disorders. Balanced translocations are one example of structural variants

where traditional cytogenetic methods is the only method used for detection, which have a low resolution. Long-read sequencing in genetic diagnostics holds great potential as it combines the advantages of traditional cytogenetic methods with the base-pair-level resolution of newer molecular methods. This study wants to explore the capability of long-read sequencing to detect structural variants and fine map the involved breakpoints for future use in genetic patient diagnostics.

Material and Methods: To obtain a broad variety of variants both blood samples from patients with known disease-causing variants and Coriell lymphoblastoid cell lines are included in the project. A broad spectrum of variants has been sequenced, including balanced and unbalanced translocations, duplications, deletions, inversions and complex chromosomal rearrangements. Long-read whole genome sequencing was preformed using Oxford Nanopore Technologies PromethION (p24) platform for all samples.

Results: Results from more than 30 samples have demonstrated that long-read sequencing data enables fine mapping of break points that are inaccessible by current methods. However, for some arears of the chromosome there are still challenges to overcome before detecting all variants with long-read sequencing.

Conclusion: The research to date supports the potential future use of nanopore sequencing in genetic patient diagnostics. The next step prior to implementation would be to validate the method, before using the method for patient diagnostic.

P14.031.C Familial segregation of a 2q23.1 deletion in the *MBD5* Gene: Reevaluation of pathogenicity based on asymptomatic carriers

Yarin Hadid[1,2], *Jasmin Levitaz*[1,2], *Adel Shalata*[1,3]

[1]*Bnai Zion, Haifa, Israel,* [2]*The Simon Winter Institute for human genetics, Bnai Zion Medical Center, Haifa, Israel,* [3]*The Simon Winter Institute for human genetics, Bnai Zion Medical Center, The Bruce-Rappaport faculty of Medicine, the Technion Inst. of technology, Israel, Haifa, Haifa, Israel.*

Background: The *MBD5* gene, located on chromosome 2q23.1, encodes a protein involved in DNA methylation and chromatin remodeling. Disruption of *MBD5* through heterozygous deletions or point mutations leads to *MBD5*-associated neurodevelopmental disorder (MAND), characterized by autosomal dominant inheritance. MAND manifests with universal intellectual disability, alongside common features such as seizures, dysmorphic traits (short stature, microcephaly), sleep disturbances, ataxia, aggressive behavior, and hyperactivity. *MBD5* deletions are relatively rare, detected in approximately 0.05% of 17,477 individuals undergoing clinical microarray analysis. The majority of these cases are de novo, although rare instances of inheritance from mildly affected or mosaic parents have been described

Material and Methods: We report a family that underwent prenatal diagnosis without a specific medical indication

Results: Chromosomal microarray analysis (CMA) revealed a 172 kb deletion at the 2q23.1 locus encompassing exons 3 and 4 of *MBD5*. Due to the potential clinical risk, the pregnancy was terminated. Subsequent parental testing identified paternal inheritance of the deletion. Family segregation analysis, including ten paternal relatives, revealed two additional asymptomatic carriers (the paternal grandfather and a brother) who harbor the same deletion

Conclusion: Segregation analysis documented three unaffected individuals carrying the 2q23.1 deletion. This evidence suggests that in this family, the deletion may not lead to the severe phenotypic presentation typically associated with *MBD5* deletions, although a pathogenic effect cannot be definitively excluded. Consequently, the variant classification was revised from 'Likely Pathogenic' (LP) to 'Variant of Uncertain Significance' (VOUS)

P14.032.D Detection of a rare 46,XXX,t(13;14)(q10;q10) karyotype in a patient with primary infertility and recurrent pregnancy loss

Lilit Ohanyan, *Ruben Ter-Melikyan, Eduard Hambardzumyan, Tatevik Hambardzumyan, Anna Hovhannisyan*

"Fertility Center" Reproductive Center, Yerevan, Armenia.

Background: Robertsonian translocations, particularly t(13;14), are associated with reproductive challenges such as infertility and recurrent pregnancy loss. Triple X syndrome (47,XXX) is a sex chromosome aneuploidy that may also impact fertility, though many individuals remain asymptomatic. The co-occurrence of 47,XXX and a Robertsonian translocation is rare, with limited literature on its clinical and reproductive implications.

Material and Methods: A 44-year-old female with 4 years of primary infertility, a history of a terminated distal ectopic pregnancy (cervical), and a failed insemination attempt was referred to the "Fertility Center" Reproductive Center. Cytogenetic analysis was performed using G-banding karyotyping on peripheral blood lymphocytes. Fluorescence in situ hybridization (FISH) was used to confirm the translocation and exclude cryptic rearrangements. Hormonal profiling and ovarian reserve testing were conducted to assess reproductive health. Biological parents were unavailable for study, and the origin of the chromosomal findings could not be determined.

Results: Karyotype analysis revealed a 46,XXX,t(13;14)(q10;q10) chromosomal complement, confirming the presence of a balanced Robertsonian translocation in conjunction with triple X syndrome. FISH analysis validated the translocation breakpoints and ruled out additional structural abnormalities. Hormonal testing indicated diminished ovarian reserve, consistent with the patient's reproductive history.

Conclusion: This case highlights the rare coexistence 47,XXX and a Robertsonian translocation, t(13;14)(q10;q10), and its potential impact on reproductive health. The findings emphasize the importance of comprehensive cytogenetic evaluation in individuals with infertility and recurrent pregnancy loss. Further studies are needed to elucidate the mechanisms underlying the reproductive challenges in such cases.

Medical City, Department of Laboratory Medicine, RIYADH, Saudi Arabia, [5]King Khalid University Hospital, King Saud University Medical City, Department of Laboratory Medicine, RIYADH, Saudi Arabia, RIYADH, Saudi Arabia, [6]Medical Genetic Division, Pediatrics Department, King Khalid University Hospital, King Saud University Medical City, RIYADH, Saudi Arabia

Background: Triplication and tetraplication of chromosome 15q is a rare developmental genetic disorder that may be presented with variable presentation of developmental delay, hypotonia, intellectual disability and autistic behavior.

Material and Methods: Patient's physical examinations, conventional chromosomal analysis, fluorescence in situ hybridization (FISH) analysis and array-CGH were performed as a standard genetic care.

Results: Here, we reported four newborns with various congenital anomalies and autistic spectrum disorder with chromosome abnormality of interstitial duplication (partial Trisomy) of 15q11q13 in two cases verses a unique epilepsy and other findings with an extra supernumerary marker (Partial tetrasomy) chromosome 15 in the two other cases. Subsequently array CGH and FISH analysis were confirmed the de novo finding of triplication and tetraplication imprinting of 15q11-q13 region.

Conclusion: The 15q imprinting syndrome is a rare genetic disorder that may presented with variable unique clinical presentation according to the size of triplication or tetraplication of the Prader-Willi/Angelman Critical Region. Furthermore an extensive genetic analysis with array CGH and FISH may provide a robust diagnostic methodology that improve early diagnosis and better patient counseling.

P14.034.B Single-molecule long-read sequencing provides fine characterization of 22q12 microdeletions in NF2 patients unravelling specific patho-genetic and -epigenetic mechanisms

Viviana Tritto[1], *Micol Pozzi*[1], *Eleonora Mangano*[2], *Roberta Bordoni*[2], *Rosina Paterra*[3], *Serena Redaelli*[4], *Marica Eoli*[3], *Paola Riva*[5]

[1]*University of Milan, Department of Medical Biotechnology and Translational Medicine, Segrate (Milan), Italy,* [2]*National Research Center (CNR), Institute of Biomedical Technologies (ITB), Segrate (Milan), Italy,* [3]*IRCCS Foundation Carlo Besta Neurological Institute, Unit of Molecular Neuro-Oncology, Milan, Italy,* [4]*University of Milano-Bicocca, School of Medicine and Surgery, Monza (MB), Italy,* [5]*University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy.*

Background: Neurofibromatosis type 2 (NF2) is an autosomal dominant tumor-prone disorder, mainly due to point mutations or intragenic deletions of the tumor suppressor gene *NF2*. Rarely, 22q12 microdeletions have been identified in NF2 patients showing variable phenotypes. Due to the lack of hot spot recombination, few of them have been genetically characterized. We studied two 22q12 microdeletions by a new approach identifying the role of patho-genetic/epigenetic mechanisms to the patients' complex phenotype.

Material and Methods: We carried out aCGH analysis to ascertain the deletion extent, Nanopore long-read sequencing (LRS) to identify the deletion breakpoints, Sanger Sequencing to validate the junction fragment, and in silico analysis of gene content and breakpoints' sequences. To study a possible position effect generated by chromatin alteration, we performed in silico analysis of 22q12 TADs and regulatory elements, expression analysis by qPCR on 12 genes flanking patients' deletions, and LRS DNA methylation study. The role of detected gene variants in the onset of patients' phenotypes was also evaluated.

Results: Patients 568 and 690 show deletions spanning 3.08 and 2.35 Mb, respectively, involving 44–47 genes and 5–6 TADs. The position effect on specific flanking genes was detected by qPCR, according to abnormal DNA methylation profiles. Genotype-phenotype correlation studies revealed possible associations between *AP1B1* gene haploinsufficiency and cognitive impairment in PT568, and the *EVC* pathogenic variant and congenital heart defects in PT690.

Conclusion: The LRS approach is an effective advancement for studies of pathomechanisms in NF2 microdeletion patients, improving the identification of prognostic markers, counselling, and patient management.

P14.035.C De novo deletion in *NCKAP1* and monosomy 18 mosaicism in a 6-year-old boy with developmental delay and autism

Anna Sophia J C Mueller[1], *Bianca Greiten*[1], *Vincent Arriens*[2], *Maj-Britt Salewski*[2], *Rebecca Gembicki*[1], *Anna-Sophie Liegmann*[1], *Lara Mellinger*[1], *Britta Hanker*[1], *Malte Spielmann*[1,2], *Yorck Hellenbroich*[1], *Eva M. Murga Penas*[1,2]

[1]*Institute of Human Genetics, University Hospital Schleswig-Holstein/ University of Lübeck, Lübeck, Germany,* [2]*Institute of Human Genetics, University Hospital Schleswig-Holstein/Christian-Albrechts University Kiel, Kiel, Germany.*

Background: Loss-of-function variants in *NCKAP1* have been associated with complex neurodevelopmental delay. Two cases of monosomy 18 (−18) in mosaic form have been reported, one with severe neurological symptoms [1], and another with a cleft lip and palate and mild behavioural problems [2]. We report a new case of a 6-year-old boy with developmental delay, autism, and intellectual disability, with a pathogenic variant in *NCKAP1* and mosaic -18.

Materials and Methods: The proband was born at term to non-consanguineous parents. Global developmental delay, mild intellectual disability, and autism were diagnosed at age four. Sleep EEG showed asymptomatic abnormalities. On examination, he had a long face with downslanted palpebral fissures, anteverted nares, and low-set ears as well as hypertrichosis with strong eyebrows and long eyelashes. Cytogenetic, FISH, array-CGH, and exome analysis were performed.

Results: GTG-banding of two different cultures showed the karyotype mos 45,XY,-18[5]/46,XY[17], confirmed by FISH. Mosaic -18 was not detected by array-CGH or FISH analysis of saliva. Exome sequencing revealed the de novo variant c.3161_3164del; p.(Arg1054Leufs*13) in *NCKAP1*.

Conclusion: This case enriches the sparse landscape of *NCKAP1*-associated developmental delay and mosaic -18. So far, several patients with truncating variants in *NCKAP1* have been reported with neurodevelopmental and behavioral symptomatology consistent with this case. Two previous cases of mosaic -18 have been reported, the phenotypes of which overlap with our case. While this patient's phenotype can be primarily attributed to the *NCKAP1* variant, the significance of the -18 mosaicism detected remains unclear and further investigations are ongoing.

P14.036.D Effects of prolonged exposure to Ionizing radiation on structural variants in the human germline

Fabian Brand, *Alexej Knaus, Peter Krawitz*

Universitätsklinikum Bonn, Bonn, Germany.

Background: Prolonged paternal exposure to low dose ionizing radiation (IR) is known to cause a wide variety of DNA changes in humans. These range from small changes on the single-bp scale to structural changes, including large Insertions, Deletions and Translocations, mediated by the interaction of IR with DNA and different mechanisms of DNA repair. For our previous works, we recruited a cohort of soldiers of both german armies which were likely exposed to IR during their military service.

Materials and Methods: We analyze de-novo structural variation in whole-genome sequencing (WGS) data from a cohort of 110 offspring of exposed soldiers of both german armies and 1275 children born to parents with no known non-natural exposure to IR. Structural variants (SVs) are detected using an ensemble approach using information from four different structural variant calling algorithms.

Results: DNA repair mechanisms and selection and survivorship biases inherent to the human germline introduce important confounders in our analysis. Only damage to human DNA that is not within a narrow band of large-enough to be inherited by the next generation but small enough to not cause fatal damage to the cell or human embryo is detectable in the trio-WGS data of our cohorts. We aim to find SVs associated with the increased paternal exposure to IR, while addressing the aforementioned and other confounders. Our previous small scale studies suggested increased numbers of balanced Translocations and similar SVs as a potential observable biomarker in the offspring of Radar soldiers.

P14.037.A Molecular cytogenetic analyses of two cases of constitutional non-supernumerary ring chromosomes: r(2) and r(7)

Keiko Wakui[1,2], *Tatsuya Sakashita*[2], *Yoshimitsu Fukushima*[1,2], *Tomoki Kosho*[1,2]

[1]*Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan,* [2]*Center for Medical Genetics, Shinshu University Hospital, Matsumoto, Japan.*

Background: Human ring chromosomes (RCs) are rare and unique chromosomal abnormalities, reported in all chromosomes. These RCs are generally classified into complete, incomplete, or complex rings.

Here, we report and discuss the results of chromosomal microarray (CMA) and fluorescence in situ hybridization (FISH) performed on two cases of constitutional non-supernumerary RCs, detected by G-banding.

Case 1: r(2)(p25.3q37.3)

Previous subtelomeric FISH showed signals at both 2pter and 2qter on the r(2), leading to its initial classification as a 'complete ring' without deletions at either end (Kosho et al., 2005). However, subsequent CMA analysis revealed a ~200 kb copy number loss at 2pter. We then confirmed the presence of the deletion in the r(2) by metaphase FISH using a BAC clone that mapped to the deleted region.

Case 2: r(7)(p22q36)

CMA analysis revealed a 7pter loss (~1.0 Mb) and a 7qter gain (~2.4 Mb). Metaphase FISH using selected BAC probes specific to each CNV region confirmed the presence of both CNVs in the r(7). To further investigate whether either parent was a carrier of the pericentric inversion of chromosome 7, metaphase FISH analyses were performed with selected BAC probes and the mBAND7 probe, revealing normal chromosomes 7 patterns in both parents.

Conclusion: CMA analysis is effective in detecting CNVs, particularly microduplications, which are difficult to identify by G-banding. However, CMA cannot specify which homologous chromosome carries each CNV. Metaphase FISH, performed after CNV detection with appropriate probe selection, is an essential method to identify chromosomal rearrangements associated with one or more CNVs.

P14.038.B Heterochromatin Dynamics: Unraveling its Role in Phenotypic Modulation

Fatma MAAZOUN[1], *Aziza LEBBAR*[1], *Khaled POCATE*[2], *Virginie QUEST*[1], *Nadine DEBUSSY*[1], *Pascale AUVINET*[1], *alimha GODIN*[1], *Thierry BIENVENU*[1], *Jean-michel DUPONT*[1]

[1]*Department of Genomic Medicine of System and Organs Diseases, Cochin Hospital, APHP Center, University Paris Cité, Paris, France,* [2]*Department of Histology, Embryology, and Reproductive Biology, Cochin Hospital, Paris, France.*

Background: We report the case of a 40-year-old male patient presenting with oligo-astheno-teratozoospermia which led to the prescription of cytogenetic analyses.

Material and Methods: A constitutional karyotype was performed. This analysis was complemented by chromosomal microarray analysis (CMA) and fluorescence in situ hybridization (FISH).

Results: The karyotype revealed an abnormal chromosome 7, with a long arm larger than its homolog, suggesting an insertion or duplication at 7q11. CMA subsequently identified a 22.8 Mb copy gain in the 2q11.1q14.1 region. This CNV has never been previously reported in literature. FISH analysis demonstrated a direct insertion of the duplicated 2q segment into the centromere of one chromosome 7. The optical mapping of the genome found the duplication but did not show its centromeric insertion as expected. This 22 Mb (7;2) insertion caused no significant phenotypic abnormalities in the patient, except for reproductive impairments. Our hypothesis to explain this attenuated phenotype is that the inserted chromosomal segment may be inactivated by the pericentromeric heterochromatin of chromosome 7. To validate this heterochromatinization phenomenon, we are employing various techniques, including immunofluorescence staining with antibodies against trimethylated histone H3, heterochromatin protein 1, 5-methylcytosine and the centromeric marker CENPA. We also performed RNA sequencing to refine the expression profiling of the inserted region.

Conclusion: If our hypothesis regarding heterochromatin-mediated inactivation is confirmed, this case would illustrate the pivotal role of heterochromatin in the epigenetic regulation of gene expression. It would also emphasize its capacity to mediate heterochromatinization of large chromosomal segments.

P14.039.C Defining breakpoint regions with Optical Genome Mapping (OGM)

Hui Yi Yon, *Xin Yi Boo, Yimin Hu, Lin Hui Ng, Mui Li Tan, Min-Hwee Yong, Sylvia Pei Rong Kam, Hai Yang Law, Nikki Wen Yan Fong, Teck Wah Ting, Angeline Hwei Meeng Lai*

KK Women's and Children's Hospital, Singapore, Singapore.

Background: A 11-month-old baby was investigated for global developmental delay, hypotonia, short stature and strabismus. Chromosomal Microarray Analysis (CMA) was performed and as part of ongoing validation studies, Optical Genome Mapping (OGM) was also done.

Material and Methods: CMA was performed using Agilent Technologies SurePrint G3 ISCA CGH+SNP 4 × 180K and analyzed with Cytogenomics software. Extraction of ultra-high-molecular-weight genomic DNA and DNA labelling was carried out as per Bionano's instructions. Analysis was performed using Bionano Access, comparing the results of the sample with the GRCh38/hg38 reference genome map.

Results: CMA showed a female profile with a gain of 0.506 Mb at 6q24.3, arr[GRCh38] 6q24.3(145792859-146299000)x3. The gain results in the partial gene gain of 1 OMIM gene associated with phenotype, *GRM1*. OGM found that this gain was directly inserted into *GRM1*, disrupting the gene.

Conclusion: Heterozygous pathogenic variants in *GRM1* are associated with Spinocerebellar ataxia 44 (MIM: 617691), and biallelic pathogenic variants in *GRM1* are associated with Spinocerebellar ataxia autosomal recessive 13 (MIM:614831). CMA analysis cannot determine if the duplicated segment of *GRM1* is located within the gene (causing gene disruption) or inserted elsewhere in the genome. However, OGM revealed a direct insertion of the gain into 6q24.3, which is predicted to disrupt the gene *GRM1*. We will discuss possible implications of this heterozygous *GRM1* disruption in relation to the patient's phenotype. This example illustrates the utility of OGM in defining breakpoint regions and how the integration of OGM into the clinical workflow can help clinicians gain better understanding of structural variants.

P15 Genomics of rare diseases

P15.001.D Genome screening for mobile element insertions in undiagnosed rare diseases

Stefanie Beck-Wödl[1], *Joohyun Park*[1], *German Demidov*[1], *Tizia Matthäus*[1], *Luise Hackenbruch*[1], *Martin Kehrer*[1], *Ingrid Bader*[1], *Heike Losch*[2], *Christiane Kehrer*[3], *Marc Sturm*[1], *Olaf Rieß*[1,4], *Stephan Ossowski*[5,4], *Tobias B. Haack*[1,4]

[1]*Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tuebingen, Germany,* [2]*Children's Hospital Elisabeth, University of Oldenburg, Oldenburg, Germany,* [3]*Department of Neuropediatrics, University Children's Hospital Tübingen, Tuebingen, Germany,* [4]*Center for Rare Diseases, University of Tübingen, Tübingen, Germany,* [5]*Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tubingen, Germany.*

Background: Detection and interpretation of point mutations, small deletions, insertions, and even copy number variants are well established in clinical genome sequencing. In contrast, mobile elements insertions (MEIs) are technically difficult to detect and rarely reported. Our objective was to establish a MEI detection tool in routine diagnostics to solve undiagnosed cases and assess its impact on diagnostic yield.

Methods: In this study, we applied the Mobile Element Locator tool (MELT) for the detection of MEIs and screened our in-house database of 5000 clinical genome datasets of undiagnosed rare disease patients. Detected MEIs in coding, splicing and near-splice regions were prioritized for phenotype-based filtering strategies.

Results: The analysis demonstrated that reanalyzing genomes for the detection of MEIs located in exons or near splice sites and with rare allele frequency identified unsolved cases. Disease-causing MEIs, e.g. LINE- and Alu-elements were found in the genes *SLC17A5*, *PTEN* and *CTNNB1*, compatible with the patients phenotype. Following segregation and transcriptomics analysis a firm genetic diagnosis was made for three patients.

Conclusions: MEIs very rarely occur in coding regions of the human genome, however this study shows that the bioinformatic MELT tool can lead to additional diagnosis in routine work, here concerning mental retardation and neurological disorders.

Carter*[1,4], *Roberto Mendoza-Londono*[5,6], *Christine Armour*[1,4], *Tugce Balci*[7], *James Dowling*[5,6], *Mark Tarnopolsky*[8], *Care4Rare Canada Consortium*[9], *Christian R. Marshall*[5,6], *Kristin D. Kernohan*[1,10], *Kym M. Boycott*[1,4]

[1]*CHEO Research Institute, Ottawa, ON, Canada,* [2]*Centre for Computational Medicine, The Hospital for Sick Children, Toronto, ON, Canada,* [3]*Pacific Biosciences of California, Inc, Menlo Park, CA, USA,* [4]*Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,* [5]*The Hospital for Sick Children, Toronto, ON, Canada,* [6]*University of Toronto, Toronto, ON, Canada,* [7]*London Health Sciences Centre, Western University, London, ON, Canada,* [8]*McMaster Children's Hospital, McMaster University, Hamilton, ON, Canada,* [910]*Newborn Screening Ontario, Ottawa, ON, Canada.*

Background: Long-read genome sequencing (LR-GS) is emerging as a useful tool to identify the genomic causes of unsolved rare diseases (RDs). It can accurately detect a range of genomic variants and overcome some limitations of short-read genome sequencing (SR-GS) including improved structural variant detection and sequencing highly repetitive, highly similar, or low-complexity regions. We therefore aimed to apply LR-GS to identify disease-associated variants in our unsolved RD cohort.

Materials and Methods: Families enrolled in the Care4Rare Canada research project with a suspected monogenic disorder without definitive molecular diagnoses following clinical testing and research SR-GS, or those requiring LR-GS to clarify a previously identified variant(s), were sequenced on the PacBio Sequel IIe or Revio systems. Data was processed using the PacBio Human WGS workflow and in-house pipelines.

Results: To date, 51 families (139 participants) with unsolved RDs have been sequenced and 25 have initial analyses complete. LR-GS revealed a new disease-associated variant in two families (8%), including an intronic retroelement insertion and a novel chromoanasynthesis event. In another four families (16%), LR-GS clarified previously identified variants to establish their association with disease. In one family (4%), a previously identified duplication was revealed to be a more complex structural variant, however this requires further investigation to confirm disease-association. Seventeen families (68%) remain unsolved.

Conclusion: LR-GS contributed to solving 24% of unsolved RDs in our cohort so far. LR-GS was most useful to discover/clarify complex genomic rearrangements, tandem repeat expansions, or other challenging variants for SR-GS (e.g. retroelement insertions), and for variant phasing.

P15.003.B Stanford Center for Undiagnosed Diseases: a decade of advancing genetic diagnosis and discovery

Devon Elaine Bonner[1,2], *Jennefer Carter*[1,2], *Chloe Reuter*[1,2], *Shruti Marwaha*[1,2], *Elijah Kravets*[1,2], *Jason Hom*[1,2], *Jacinda Sampson*[1,2], *The Undiagnosed Diseases Network*[3], *Paul Fisher*[1,2], *Euan Ashley*[1,2], *Holly Tabor*[1,2], *Meghan Halley*[1,2], *Matthew Wheeler*[1,2], *Jonathan Bernstein*[1,2]

[1]*Stanford Center for Undiagnosed Diseases, Palo Alto, CA, USA,* [2]*Stanford University, Palo Alto, CA, USA,* [3]

Background: Despite the rapid progress in clinical genetic testing, most patients with a suspected rare disease remain undiagnosed after extensive medical evaluation. The Stanford Center for Undiagnosed Diseases (CUD) was established in 2015 and is a clinical site of the National Institutes of Health supported Undiagnosed Diseases Network. At the CUD, we developed an approach that integrates phenotyping, genomics, other omics assays, and model organism studies to improve diagnosis and care for patients with rare diseases.

Material and Methods: We evaluated patients with undiagnosed diseases who were referred to the CUD between 2015 and 2025. We determined the diagnostic rate and highlighted genetic discoveries facilitated by the program.

Results: A total of 283 patients were evaluated by the CUD, of which 53% were female, 61% were pediatric and 59% were non-Hispanic White. Patients primarily had neurological (42%), musculoskeletal (13%), immunological (12%), and cardiovascular (7%) symptoms. Patients underwent short read exome or genome sequencing (95%), RNA-seq (68%), metabolomics (21%), immunomics (19%) and long read genome sequencing (10%). Overall, 36% of patients (102) received a likely or candidate diagnosis including 97 molecular, 4 clinical, and 1 antibody-mediated phenocopy of a Mendelian disease. Seven patients received multiple molecular diagnoses. We described 22 novel candidate genes/loci, expanded the phenotype or mode of inheritance for 8 known disease genes, and identified 64 novel causative variants.

Conclusion: Here we present a comprehensive and integrated clinical and multi-omic approach to advance diagnosis and discovery, shorten the diagnostic odyssey, and improve care for patients impacted by rare diseases.

P15.004.C Germline variants in coagulation genes underlying hereditary unclassified bleeding disorders

Francesca Tettamanzi[1,2], *Valeria Rimoldi*[1,2], *Samin Mohsenian*[3,4], *Marzia Menegatti*[3,4], *Giulia Soldà*[1,2], *Rosanna Asselta*[1,2], *Flora Peyvandi*[3,4]

[1]*Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy,* [2]*Humanitas Clinical and Research Centre – IRCCS, Rozzano, Italy,* [3]*Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy,* [4]*Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center and Fondazione Luigi Villa, Milan, Italy.*

Background: Hereditary bleeding disorders are a rare and heterogeneous group of diseases characterized by genetic defects that impair normal hemostasis. Despite bleeding tendency about 30% of patients present normal hemostatic tests with no identifiable cause, remaining lastingly undiagnosed, sometimes with severe and even fatal consequences. The identification of genetic variants in these unclassified bleeding disorders (UBD) can be essential for providing patients with accurate diagnosis and better disease management, as well as for uncovering new pathophysiological mechanisms.

Material and Methods: Sixteen families reporting a history of UBD (thirty-two affected and fifteen healthy members) underwent whole-exome sequencing. Germline mutation burden was assessed in 425 genes related to coagulation, platelet activation, and endothelium adhesion, selecting non-synonymous variants, with minor-allele frequency <0.01, and not reported as benign in ClinVar. Phenotype and altered genes relationship was analyzed using mixed effect models.

Results: Patients carried 406 variants falling in coagulation (38%), endothelium (34%) and platelet activation (27%) genes. An increased frequency of variants in coagulation genes was associated with UBD ($p = 0.048$). Most frequently mutated genes were *MADCAM1*, *SH2B2*, *DCT* (84–62%), *IL6ST*, and *COL18A1* (28%). In "core" coagulation genes, variants were detected in *VWF* (16%), *F5*, *FGA* (12%), *FGG* (9%), *F2*, *F7*, *F13A1*, *F13B* (6%). Among altered genes, two metalloproteinases involved in hemostatic balance, *ADAMTS18* and *MMP8*, displayed a suggestive association with phenotype ($p = 0.045$; $p = 0.077$).

Conclusion: UBD patients harbored increasing numbers of variants in coagulation genes compared to healthy family members. Alterations in genes *ADAMTS18* and *MMP8* might also play a role in UBD development.

P15.005.D Results from Rapid Whole Genome Sequencing (rWGS) in patients presenting with Neonatal and Pediatric Hypotonia

Lucia Guidugli[1], *Shimul Chowdhury*[1], *Meredith Wright*[1], *Edwin Juarez Rosales*[1], *Stacey Huynh*[1], *Shareef Nahas*[1], *Stephen Kingsmore*[2], *Katarzyna Ellsworth*[1]

[1]*Rady Children's Institute for Genomic Medicine, San Diego, CA, USA,* [2]*Rady Children's Institute for Genomic Medicine, San Diego, CA, USA.*

Background: Whole Genome Sequencing (WGS) represents a complete testing approach to rapidly identify an underlying molecular defect in children with hypotonia by simultaneously assessing multiple variant types. We report the results from clinical WGS at Rady Children's Institute for Genomic Medicine (RCIGM) between 2017 and 2024 in patients with hypotonia at the time of testing.

Material and Methods: WGS was performed at CAP/CLIA RCIGM via PCR-free WGS. Alignment and variant calling were done using the Illumina DRAGEN software. Annotation, variant prioritization and clinical reporting were performed using Fabric Enterprise. Genomic variation assessed spanned SNVs, Indels, CNVs, Aneuploidies, SMN1 and SMN2 copy number, mitochondrial variants, repeat expansions and UPD15.

Results: A total of 5708 patients were evaluated (age median = 50 days). 591 patients had hypotonia or neonatal hypotonia at the time of testing (10.4%), and most underwent rapid or ultra-rapid WGS. A molecular diagnosis was made in 268 cases (45.3%). Recurrent diagnoses included SNVs/Indels affecting GLDC (n = 9), MTM1 (n = 6) KCNQ2 (n = 5), Trisomy 21 (n = 10), CNVs encompassing the 15q11.2q13.1 imprinted region (n = 7), deletions affecting SMN1 (n = 5) and DMD (n = 2). The median TAT for reporting preliminary results was 4 days.

Conclusion: The clinically validated fast WGS pipeline at RCIGM has proven utility in diagnosing patients with hypotonia. This exhaustive testing approach detects a wide range of genomic alterations in a time-effective manner, thus enabling optimal management. Additional refinements and improvements of the technology and breath of identifiable variation will further enhance the diagnostic yield of the RCIGM WGS pipeline in patients with hypotonia.

P15.006.A Single-Cell RNA Sequencing Demonstrates Specific Sex Hormone Responses of Alveolar Type 2 Epithelial Cells to Profibrotic Exposure

Jisha Jasmin, *Anja Schweikert, Mari Ozaki, Cormac Murphy, Gianpiero L. Cavalleri, Killian Hurley*

Royal College of Surgeons in Ireland, Dublin, Ireland.

Background: Pulmonary fibrosis (PF) is a progressive, fatal lung disease characterised by tissue scarring. A recent mouse study highlights a potential protective role of estrogen against PF, suggesting that sex hormones influence the development and progression of PF.

Material and Methods: Here we set out to detail sex hormone responses of alveolar type 2 epithelial cells to profibrotic exposure, using scRNA approach. We generated AT2 cells from induced pluripotent stemcells (iAT2) to examine the effects of sex hormones on gene expression using single-cell RNA sequencing. iAT2 cells were treated with estrogen and testosterone for 14 days, with subsequent profibrotic cocktail (PFC) exposure in the final 72 hours. Single live cells were encapsulated using a 10X-Genomics Core machine and RNA libraries were generated, followed by sequencing. scRNA-seq analysis was conducted using Seurat after identifying the highest-quality cells. Dimensionality reduction techniques were employed to visualise clustering, followed by cluster annotation and pathway enrichment analysis. Heatmaps, violin plots, and feature plots were also generated.

Results: Cluster annotation revealed that estrogen-treated cell clusters exhibited senescence markers following PFC-exposure, whereas testosterone-treated cell clusters demonstrated TGF-β activation and aberrant-basaloid markers. RNA velocity indicated a transition towards aberrant basaloid cells from other clusters, including the TGF-β cluster. Overall, these analysis suggests that testosterone is linked to a potential transition to recognised profibrotic cell states after PFC-exposure.

Conclusion: Our findings suggest distinct roles of sex hormones in modulating AT2 cells, offering insights into understanding PF and its treatment. However, additional laboratory validation is necessary to confirm these observations.

P15.007.B Reclassification of genomic duplication variants of uncertain significance using nanopore adaptive sampling

Veronika Schönrock[1], *Florentine Scharf*[1], *Bianca Goldschmidt*[1], *Veronika Mayer*[1], *Eva Breithausen*[1], *Simone Rost*[1], *Christina Sofeso*[1], *Melanie Locher*[1], *Mayra Sauer*[1], *Maria Schödel*[1], *Caroline Heintz*[1], *Andreas Risch*[1], *Jan Henkel*[1], *Andreas Laner*[1], *Anna Benet-Pagès*[1,2], *Ariane Hallermayr*[1,3], *Barbara Klink*[1], *Teresa Neuhann*[1], *Angela Abicht*[1,4], *Elke Holinski-Feder*[1,3], *Morghan C. Lucas*[1,4,3]

[1]*MGZ - Medical Genetics Center, Munich, Germany,* [2]*Institute of Neurogenomics, Helmholtz Zentrum München GmbH - German Research Center for Environmental Health, Munich, Germany,* [3]*Medizinische Klinik und Poliklinik IV, Klinikum der Universität München Campus Innenstadt, Munich, Germany,* [4]*Friedrich-Baur-Institute, Department of Neurology, Klinikum der Universität, Ludwig-Maximilians-Universität, Munich, Germany.*

Background: Genomic duplications classified as variants of uncertain significance (VUS) pose a challenge in clinical diagnostics due to their unclear pathogenicity. Short-read sequencing can detect copy number variations (CNVs) but lacks the resolution to define breakpoints accurately. This study aimed to evaluate the feasibility and diagnostic yield of Oxford Nanopore Technologies (ONT) adaptive sampling (AS) for resolving VUS duplications.

Material and Methods: A cohort of 49 patients with VUS duplications identified through short-read sequencing was analyzed using ONT AS. The protocol was optimized to improve sequencing accuracy and coverage, including DNA input and library preparation adjustments. Long-read sequencing data were assessed for breakpoints, reading frame integrity, and variant classification according to ACMG/AMP guidelines.

Results: Tandem duplications were detected in 28 samples (57%), with 7 reclassified as likely pathogenic (18%) or pathogenic (7%), resulting in a 25% reclassification rate. The remaining 75% of cases retained their VUS classification due to insufficient supporting evidence. The optimized protocol improved sequencing efficiency, achieving higher coverage (>24X) and more reliable variant detection.

Conclusion: ONT AS is a feasible approach for detecting structural variants and reclassifying VUS duplications, offering improved resolution for clinical variant interpretation. Its bioinformatics-driven, targeted sequencing strategy eliminates the need for specialized library preparation for specific genes, making it scalable, automatable, and adaptable for routine diagnostics. While additional validation is needed, ONT AS presents a cost-effective and flexible solution for integrating long-read sequencing into clinical practice, ultimately enhancing genetic analysis and patient care.

P15.008.C Diagnostic yields of exome sequencing, short-read genome sequencing, and long-read genome sequencing in neurofibromatosis type 1

Wuttichart Kamolvisit[1,2], *Chalurmpon Srichomthong*[1,2], *Vorasuk Shotlersuk*[1,2]

[1]*Excellence Center for Genomics and Precision Medicine, King Chulalongkorn Memorial Hospital, The Thai Red Cross Society, Bangkok, Thailand,* [2]*Center of Excellence for Medical Genomics, Medical Genomics Cluster, Department of Pediatrics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*

Background: Neurofibromatosis Type 1 (NF1) is primarily diagnosed using NIH criteria, however molecular testing is increasingly important. The diagnostic yields of exome sequencing (ES), short-read genome sequencing (SR-GS), and long-read genome sequencing (LR-GS) remain unclear due to NF1's complexity.

Material and Methods: Patients meeting NIH criteria for NF1 were recruited from King Chulalongkorn Memorial Hospital between 2019 and 2023. A stepwise sequencing approach was utilized, beginning with ES on the Illumina NovaSeq 6000 platform. For unresolved cases, SR-GS was performed using the BGI DNBSEQ-T7 platform, followed by LR-GS on the PacBio HiFi platform. Variants were classified according to ACMG/AMP guidelines.

Results: Among 94 patients (87 families), ES identified 71 (likely) pathogenic *NF1* variants in 77 patients (71 families) (82%; 71/87), including nonsense (41%, 29/71), frameshift (30%, 21/71), splice-site (17%, 12/71), missense (7%, 5/71), large deletions (4%, 3/71), and large duplications (1%, 1/71). In unresolved cases, SR-GS detected one deep intronic variant in 1 patient (1 family) (1.2%; 1/87), while LR-GS further identified 3 pathogenic structural variants: 2 deletions and 1 inversion, in 3 patients (3 families) (3.5%; 3/87). The combined diagnostic yield was 86% (75/87). The remaining 13 unresolved cases (12 families) may involve somatic mosaicism or variants with uncertain pathogenicity.

Conclusion: ES is an effective molecular diagnostic tool for NF1, with SR-GS and LR-GS serving as a valuable complement to resolve complex cases.

Background: Massive sequencing techniques have enabled unprecedented progress in diagnosing rare diseases. Exome and genome sequencing have great capacity to reliably identify point variants and small insertions and deletions. However, due to the use of short reads, these methodologies do not efficiently identify structural variants (SV) of moderate-large size. The Optical Genome Mapping (OGM) strategy uses long DNA molecules to identify structural variations throughout the genome, hardly detected with short-read sequencing. SpainUDP program has applied OGM and evaluated the diagnostic success of adding this technology in still undiagnosed cases.

Material and Methods: OGM was done in 42 undiagnosed cases analyzed in trios, including a subset of 10 cases performed in the European Solve-RD project. High molecular weight DNA was extracted from blood samples and OGM was made using the Saphyr system (Bionano) and initially analyzed with Access software for detection of de novo SV.

Results: By OGM we could find candidate de novo SV in 10 cases (23%) and managed to definitively diagnose 3 cases (7%), identifying complex de novo SV in patients, including an inversion in *PTH* gene, a retrotransposon insertion in *USP9X* (confirmed with LR-WGS) and a complex case with multiple SV pointing to chromotripsis events. In the other seven cases, we found SV affecting candidate genes, 4 of them associated with syndromes, which are being validated.

Conclusion: By de novo analysis of OGM we expect between 7–14% diagnostic success in cases that remained unexplained. The OGM results highlight the complexity of the structural variation of our genome.

P15.010.A Targeted long-read sequencing: a cost-effective approach to overcome limitations of short-read sequencing in routine diagnostics (Award Candidate)

Xavier Vanhoye, *Pascal Mouty, Melanie Eyries, Boris Lipinski, Vincent Gassend, Thibaut Benquey, Rizk Bennani, Vanna Geromel, Alice Bedois, Alexia Zelus, Nishta Thacoor, Marine Serveaux Dancer, Benedicte Gerard, Mederic Jeanne, Laure Raymond*

Eurofins Biomnis, Lyon, France.

Background: Short-read sequencing (SRS) is the gold standard in genetic diagnostics but remains inconclusive in over 50% of cases. Challenges such as pseudogenes, variants phasing, and structural variations contribute to this diagnostic gap. Whole-genome long-read sequencing (WGLRS) has the potential to overcome these issues but remains costly, data-intensive, and challenging to implement in routine diagnostics. To overcome these limitations, we implemented targeted long-read sequencing (TLRS) as a complementary approach.

Material and Methods: Long-range PCR (amplicons up to 30 kb) was followed by Nanopore sequencing and in-house bioinformatics analysis. We analyzed 200+ cases where SRS was inconclusive but suggested single-gene involvement.

Results: Our analysis demonstrated the utility of TLRS across several challenging scenarios. In 40% of cases TLRS differentiates pathogenic variants from pseudogene artefacts (*PMS2*, *PKD1*, *CYP2D6*) preventing misdiagnoses from short-read sequencing. In 20% of cases, when parental/related samples were not available, it successfully determined the phase of heterozygous variants in recessive genes, allowing accurate interpretation. Another 20% of cases involved the resolution of SRS-suspected copy number variants or indels in complex regions. Nine structural variants were precisely characterized and reclassified, including deletions, inversions, and duplications. Additionally, our approach resolved two WES-negative cases of clinically suspected monogenic disorders (*APRT* compound heterozygosity; *GBA1* variants undetected due to pseudogene interference).

Conclusion: TLRS offers a high-yield and cost-effective alternative to WGLRS. This approach is a powerful complement to SRS, resolving challenges due to pseudogenes, variant phasing, and structural variants characterization. It strengthens diagnostic certainty by providing definitive variant confirmation, exclusion and reclassification.

Background: Despite advances in massive parallel sequencing, up to 60% of rare disease patients remain undiagnosed after whole-genome sequencing (WGS), partly due to incomplete phenotype data and challenges in detecting the full spectrum of pathogenic variants. The Undiagnosed Diseases Network (UDN Sweden) unites clinicians, genetic counselors, clinical laboratory geneticists, bioinformaticians, and researchers to improve rare disease diagnostics. Our goal is to enhance genomic technologies in healthcare and ensure equitable precision diagnostics for undiagnosed children with rare syndromes involving intellectual disability and/or congenital malformations.

Methods: Since 2023, 171 children have been enrolled through Wilhelm Foundation and the seven Swedish university hospitals. All remained undiagnosed despite extensive clinical and genetic evaluations. After collecting structured phenotype data using the phenotype tool tip2toe, we performed systematic analyses of short-read WGS (singleton, trio, or quartet), RNA-sequencing (138 participants), and PacBio HiFi long-read WGS (130 participants).

Results: To date, short-read WGS reanalysis has provided definitive genetic diagnoses for eleven individuals, uncovering pathogenic variants in *CKLD5*, *TUBB4A*, *SCN2A, TCF4, RNU4-2, TBCE*, *NF1*, *U2AF2*, and *CUX2*, as well as duplication of *MYT1L* and a 16p12.2 microdeletion. Candidate variants have been identified in three additional cases. Data analysis of the entire cohort is ongoing. In addition, a national hackathon is planned to analyze 12 selected cases.

Conclusion: These preliminary results demonstrate the potential of an integrated phenotype-genomics-transcriptomics approach and a coordinated network of clinical, laboratory, and research expertise to improve diagnostic yield, streamline clinical workflows, and ultimately enhance outcomes for children with rare genetic neurodevelopmental disorders.

P15.012.C Whole Genome Sequencing as a last-tier test: wouldn't it be better to do it sooner?

Camilla Lucca[1], *Sara Mingotti*[1], *Erica Rosina*[1], *Laura Pezzoli*[1], *Daniela Marchetti*[1], *Lucrezia Goisis*[1], *Francesca Cappuccini*[1], *Chiara Mongodi*[1], *Nunzia Della Malva*[1], *Loredana Perego*[1], *Riccardo Rubini*[1], *Anna Rita Lincesso*[1], *Matteo Bellini*[1], *Agnese Scatigno*[2], *Lidia Pezzani*[2], *Maria Iascone*[1]

[1]Laboratory of Medical Genetics, ASST Papa Giovanni XXIII, Bergamo, Italy, [2]Rare Disease Unit, ASST Papa Giovanni XXIII, Bergamo, Italy.

Background: Children with rare and non-critical genetic diseases often face a multi-stage diagnostic strategy that sometimes lasts years. This path has a socio-economic impact on the family and the health system. Achieving a diagnosis is essential for the best clinical management and family counseling. This study evaluated the utility of whole genome sequencing (WGS) as a last-line test.

Material and Methods: We retrospectively analyzed data from 147 outpatients with a suspected genetic condition who underwent trio-WGS after at least array-CGH and multigene panels or whole exome sequencing (WES) in the past two years.

Results: The age of patients covers a wide range (from 0 to 47 years, mean age 10.2 years), although the clinical manifestations were present from birth or early childhood. Most cases had a neurodevelopment disorder (47.6%), followed by malformation syndromes (34%). Most patients (64.1%) had two or more tests performed before WGS. Trio-WGS added a genetic diagnosis to 27.2% of patients. In 13 cases, WES has been previously performed. Three cases had a double diagnosis, causing a compound phenotype. Considering the type of identified variants, ranging from deep intronic variants to complex rearrangements, 30.4% (17/56) would have been missed with other techniques, including WES.

Conclusion: In our experience, genome sequencing has been a resolutive technique for almost a third of cases. These data highlight that using trio-WGS as a first-tier test would shorten the time for a diagnosis, reducing the diagnostic odyssey and health system costs and improving the patients' management.

P15.013.D Accurate Phasing and Imputation of Rare Variants in Diverse Chinese Subpopulations Using 22,374 Deeply Sequenced Genomes

Fengxiao Bu*, Fandi Ai, Jing Cheng, Yu Lu, Huijun Yuan*

West China Hospital, Chengdu, China.

Background: Reference panels are critical for improving genotype imputation accuracy in underrepresented populations, yet existing resources often lack diversity in non-European and non-Han Chinese ethnic groups. Addressing this gap is essential for advancing equitable genomic research and precision medicine initiatives.

Material and Methods: The GSRD-100K^{WCH} reference panel was constructed using high-coverage whole-genome sequencing (WGS) data from 22,374 individuals, including 17,514 Han Chinese and 4,860 individuals from 45 non-Han Chinese ethnic groups. Imputation performance was evaluated using simulated and

empirical HGDP array datasets, benchmarking against leading reference panels (e.g., TOPMed). Metrics included precision, sensitivity, aggregate R^2 (genotype concordance), and non-reference discordance (NRD) rates.

Results: The panel comprises 321,365,014 variants, with 34,016,043 (10.58%) unique to non-Han populations. In simulated analyses, GSRD-100K^{WCH} imputed 72.56% more variants than comparator panels (excluding TOPMed), 49.79% of which were panel-specific. It achieved high precision (0.9831) and sensitivity (0.9802), with improved aggregate R^2 and reduced NRD across Chinese subpopulations. While performance was robust in most groups, slight accuracy reductions occurred in admixed populations (e.g., Turkic and Indo-Iranian groups). The panel also outperformed existing resources in imputing Asian-relevant GWAS and polygenic score (PGS) catalog variants.

Conclusion: The GSRD-100K^{WCH} reference panel enhances imputation accuracy in diverse Chinese populations, addressing critical gaps in non-Han genetic representation. Its inclusion of underrepresented ethnic groups advances equitable genomic research and precision medicine. Future efforts should prioritize ancestral diversity to optimize global applicability.

P15.014.A Exploring Mosaic NLRP3 Variations: From Chronic Urticaria to Neonatal Autoinflammatory Disease

Aphrodite Daskalopoulou[1], *Eman Assrawi*[2], *Farah Diab*[1], *Camille Louvrier*[1,2], *William Piterboth*[2], *Marie Legendre*[1,2], *Dan Lipsker*[3], *Serge Amselem*[1,2], *Sonia Karabina*[1], *Irina Giurgea*[1,2]

[1]*Sorbonne Université, Inserm, Maladies génétiques d'expression pédiatrique, F-75012 Paris, France,* [2]*Sorbonne Université, APHP, Hôpital Armand-Trousseau, F-75012 Paris, France,* [3]*Université de Strasbourg et Clinique dermatologique, Strasbourg, France.*

Background: NLRP3-associated autoinflammatory diseases (NLRP3-AIDs) encompass a range of inflammatory disorders driven by germline or somatic mosaic variations in the *NLRP3* gene, which cause dysregulated inflammasome activation and systemic inflammation. The clinical manifestations of *NLRP3*-AIDs vary from isolated conditions such as chronic urticaria to more complex, syndromic forms associated with severe systemic inflammation. This study investigates the phenotypic and molecular characteristics of *NLRP3* mosaic variations in patients with systemic autoinflammatory diseases (SAIDs).

Material and Methods: A cohort of 1,000 patients with clinical features ranging from isolated chronic urticaria to syndromic forms of autoinflammatory diseases was evaluated using conventional or high-depth (1,500X) next-generation sequencing (NGS) targeting a panel of SAID genes. Functional assays, including NF-κB pathway activation and ASC speck formation, were performed to assess the gain-of-function (GOF) effects of the identified *NLRP3* variations.

Results: Mosaic *NLRP3* variations were identified in nine patients, with allele frequencies as low as 2–3%, undetectable by conventional NGS. Clinical presentations ranged from isolated late-onset chronic urticaria to neonatal syndromic SAID. Functional studies confirmed a GOF effect in all mutations, activating the NF-κB pathway and/or promoting inflammasome activation (ASC speck formation). Anti-IL-1 therapy led to significant clinical improvement, with earlier initiation preventing severe complications.

Conclusion: This study underscores the importance of high-depth sequencing for detecting low-level mosaic *NLRP3* variations underlying a broad spectrum of chronic inflammatory conditions. Early and accurate diagnosis is crucial for timely anti-IL-1 therapy, significantly improving patient outcomes and preventing complications in NLRP3-AID.

Background: Beckwith-Wiedemann syndrome (BWS) is a genetic overgrowth disorder associated with DNA methylation anomalies in the 11p15.5 region, particularly affecting ICR1 and ICR2. These regions regulate key genes like IGF2 and CDKN1C, essential for growth and development. Multilocus imprinting disturbances (MLID) in BWS, are characterized by aberrant methylation in regions beyond 11p15.5 or other regions, are found in some BWS cases and are relevant for diagnosis and management.

Material and Methods: The methylation status of 101 BWS patients was analyzed by both MS-MLPA and methylation microarrays. All selected patients had previously been diagnosed with BWS due to abnormal methylation in the 11p15.5 chromosomal region and compatible phenotype, using the SALSA MS-MLPA probemix ME030 BWS/RSS kit, while methylation microarrays (Infinium MethylationEPIC v2.0 BeadChip) provided genome-wide CpG site data, identifying additional methylation patterns. Raw data were processed in R and analyzed for differential methylation. Clinical feature differences were evaluated using statistical tests, including Chi-square and Fisher's exact, with significance set at $p < 0.05$.

Results: ICR2 hypomethylation was prevalent in MLID cases (15.84% by MS-MLPA, rising to 26.73% using microarrays). Novel hypomethylated loci (DIRAS3, FAM50B, ZNF331) were detected, expanding the spectrum of epigenetic abnormalities in BWS. Significant loci like GNAS and PLAGL1 were frequently altered, consistent with previous reports.

Conclusion: ICR2 hypomethylation is a diagnostic hallmark of MLID in BWS. Advanced methylation techniques improve diagnostic precision, revealing novel loci. These findings emphasize genome-wide approaches for comprehensive MLID analysis and suggest potential targets for future research and therapy development.

Background: Charcot-Marie-Tooth disease is the most common inherited peripheral neuropathy, with more than 100 associated genes identified to date. Among these, the *GDAP1* gene is particularly noteworthy due to its dual inheritance patterns—autosomal recessive and autosomal dominant —and its association with both demyelinating (CMT4A or AR-CMTde-*GDAP1*) and axonal forms (CMT2H/AR-CMTax-*GDAP1* and CMT2K/AD-CMTax-*GDAP1*), corresponding to distinct electrophysiological characteristics of the associated neuropathies.

Material and Methods: Our study aimed to analyze a large cohort to better understand the genetic characteristics of *GDAP1*-related Charcot-Marie-Tooth disease. The cohort included 167 individuals, of whom 110 were index cases.

Results: *GDAP1* variants were inherited in an autosomal recessive manner in 58% of cases and an autosomal dominant manner in 42%. In our cohort, we identified 60 distinct variants, among which 25 have never been described in the literature. Consistent with existing literature, the most frequent alterations were p.(Arg120Trp) in dominant cases and p.(Ser193*) in recessive cases. The pathogenicity of the newly identified variants was assessed according to the ACMG guidelines.

Conclusion: This comprehensive analysis of a large *GDAP1* cohort offers valuable insights into the genetic diversity underlying *GDAP1*-associated CMT, enhancing our understanding of this complex disorder.

P15.017.D Using whole-genome sequencing and related technologies to resolve cases of suspected autosomal recessive rare genetic disease

Emma H. Gillesse[1,2], *P.Y.Billie Au*[1,2], *Francois P. Bernier*[1,2], *Jillian Parboosingh*[1,2], *Care for Rare Canada Consortium*[3], *Ryan E. Lamont*[1,2], *A Micheil Innes*[1,2]

[1]*Dept. of Medical Genetics, University of Calgary, Calgary, AB, Canada,* [2]*Alberta Children's Hospital Research Institute, Calgary, AB, Canada,* [3]

Background: In genetic testing for rare diseases, it is a recurring scenario that a single heterozygous pathogenic variant is identified in a gene associated with an autosomal recessive disorder, but no second variant is identified in trans. It is hypothesized that this second variant may be present, however cannot be detected due to the technical limitations of capture-based NGS methods.

Materials and Methods: 17 individuals were identified for whom previous panel testing or exome sequencing identified a heterozygous pathogenic variant in a gene felt to be a good fit for their clinical presentation. All individuals and available parents underwent WGS. Data analysis first prioritized interpretation of variants in the locus of interest. If no second compound variant was identified, a genome wide analysis was performed to identify alternative explanatory variants.

Results: Of the genomes analyzed, WGS identified a second variant in the initial gene of interest for four individuals. An additional four individuals were found to have candidate pathogenic variants in an alternative gene. Additional functional work is currently being undertaken to confirm the pathogenicity of certain variants identified. The remaining 9 are currently unsolved and have been sent for additional investigations including RNAseq and long-read genome sequencing.

Conclusions: These results show the efficacy of short-read WGS to provide a molecular diagnosis in these specific cases of suspected autosomal recessive inheritance. It also highlights the benefit of looking beyond the initial region of interest, especially when an individual's clinical presentation is genetically heterogeneous.

P15.019.B Investigating rare diseases through multiomic nanopore sequencing approaches

Edmund Day[1], ***Heather Jeffery***[1], *George Dodd*[1], *Tatiana Dvorkina*[1], *Rachel Martin*[1], *Philipp Rescheneder*[1], *Phillip James*[1], *Sissel Juul*[2]

[1]*Oxford Nanopore Technologies, Oxford, United Kingdom,* [2]*Oxford Nanopore Technologies Plc, New York, NY, USA.*

Rare diseases often require multiple individual assays to understand their aetiology. The additional time, cost, and complexity associated with complex genetic and epigenetic disorders creates a high barrier of entry into research of these systems. Here we explore the technical abilities of nanopore sequencing to address the complexity of rare diseases using a multiomic approach. We analysed 9 cell lines derived from traditional and non-traditional trios of healthy individuals and probands with rare genetic and epigenetic disorders including Rett syndrome, Friedreich's ataxia and alpha-thalassemia. We investigated phased genetic, transcriptomic, and epigenetic variation, as well as higher order structural changes associated with disease state. We performed whole genome sequencing to more than 30x coverage per sample and N50's of 10–20 kb. Using a multiomic approach encompassing phased SNP, SV and methylation calling in combination with chromatin accessibility, chromatin conformation and long read cDNA analysis we demonstrate that skewed X-inactivation and crossing over events are the primary drivers of phenotypic differences between a healthy mother and affected daughter, both with an underlying genetic variant associated with Rett syndrome. In addition we explore how long read sequencing can help resolve challenging medically relevant genes (CMRGs) including characterising the length and composition of repeat expansions, as found in the *FXN* gene, and differentiating

homologous regions of the genome, for example *HBA1/2*. In summary, we present a nanopore-based multiomic approach that leverages information from genetic, epigenetic, transcriptomic and structural components to gain a deeper insight into the mechanisms underpinning complex and difficult to resolve disorders.

P15.020.C Disordered genome methylation in the Beckwith-Wiedemann syndrome associated with Multi-Locus Imprinting Disturbance

Andrea Riccio[1,2], *Francesco Cecere*[2], *Laura Pignata*[1], *Emilia D'Angelo*[1], *Bruno Hay Mele*[3], *Abu Saadat*[1], *Subham Saha*[1], *Jair Antonio Tenorio-Castaño*[4], *Claudia Angelini*[5], *Pablo Lapunzina*[4], *Flavia Cerrato*[1]

[1]*DiSTABiF, University of Campania Luigi Vanvitelli, Caserta, Italy,* [2]*Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Napoli, Italy,* [3]*Dpt. of Biology, University of Naples Federico II, Napoli, Italy,* [4]*Instituto de Genética Médica y Molecular (INGEMM), Hospital Universitario La Paz, Madrid, Spain,* [5]*Istituto per le Applicazioni del Calcolo (IAC) "Mauro Picone", CNR, Napoli, Italy.*

The monoallelic expression of the imprinted genes is under the control of germline-derived Differentially Methylated Regions (gDMRs). The Beckwith-Wiedemann syndrome (BWS) is an overgrowth and tumor-associated disorder characterized by deregulation of chromosome 11p15.5 imprinted genes. The most frequent molecular defect is loss of methylation (LoM) of the KCNQ1OT1-TSS gDMR (aka IC2). Approximately one-third of the IC2 LoM BWS patients display multi-locus imprinting disturbance (MLID). However, in most of these studies investigation was rather limited and the impact of MLID on the whole genome is unknown. By employing the Infinium Epic methylation array, we investigated the whole epigenome in 65 BWS patients with IC2 LoM. By comparing these patients with 33 control subjects, we identified differentially methylated CpGs within all gDMRs that allowed to separate 30 cases with MLID from 35 cases with only IC2 LoM by hierarchical clustering. By extending the analysis outside of the imprinted loci, we also found that the MLID cohort exhibited higher methylation variation in a consistent fraction of CpGs with respect to the control and non-MLID groups. By whole exome-sequencing, we further demonstrated the presence of maternal-effect pathogenic variants of the Sub-Cortical Maternal Complex genes in 50% of the MLID cases but not in the non-MLID group. In conclusion, these findings support the hypothesis that MLID in BWS is a disorder caused by variants of maternal-effect genes affecting CpG methylation maintenance in the whole genome, including all the imprinted and thousands of further genomic loci, whose impact on the clinical phenotype needs to be evaluated.

P15.021.D Long-read genome sequencing in pediatric cohort with rare genetic disorders: evaluating diagnostic rates in a Qatari population

Amal Abdulsalam Ibrahim[1], *Elbay Aliyev*[2], *Najeeb Syed*[2], *Aljazi Al-Maraghi*[2], *Waleed Aamer*[2], *Khalid Fakhro*[2]

[1]*Hamad Bin Khalifa University, Doha, Qatar,* [2]*Sidra Medicine, Doha, Qatar.*

Background: Despite wide adoption of next-generation sequencing in diagnosing rare genetic diseases, over 50% of cases remain unresolved. This diagnostic gap is potentially due to limitations of short-read sequencing (SRS) in resolving complex genome regions. The emerging application of long-read sequencing (LRS) addresses these limitations by generating longer reads (10–500 kb), which enhances detection of structural variants (SVs) and other complex genome regions. This study aims to investigate the utility of LRS in improving diagnostic yield in patients that remained undiagnosed by SRS.

Material and Methods: We performed whole-genome LRS using ONT's PromethION on 68 pediatric patients with genetic diseases at Sidra Medicine. Of these, 48 cases had negative or inconclusive findings from microarray and SRS, while 20 cases served as positive controls with known variants identified using SRS. Sequencing was performed at 20x depth, and data processed with wf-human variation workflow, which includes Sniffles2 for SV calling.

Results: LRS confirmed all variants in the positive cohort (20/20 cases). Additionally, LRS identified four SVs not detected by SRS, leading to an 8.3% increase in diagnostic yield (4/48 cases). These included deletions in TTN and KCNQ2, a duplication in SCNNB1, and a novel de novo inversion in SMARCC2, associated with Autism Spectrum Disorder (ASD).

Conclusion: Our findings highlight the potential of LRS to improve diagnostic yield in cases unresolved by SRS. Future integration of methylation analysis and other complex genomic regions could enhance its utility in rare disease diagnostics.

P15.022.A An expanded view of uORF variants as causes of mendelian disorders

Dan Haritonov[1], *Alexandra Filatova*[1], *Rostislav Skitchenko*[2], *Yury Barbitoff*[3], *Mikhail Skoblov, Head of the Department*[1]

[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Almazov National Medical Research Centre, St. Petersburg, Russian Federation, [3]Bioinformatics Institute, St. Petersburg, Russian Federation.

Background: Interpretation of variants in upstream ORFs (uORFs) is a significant and complex task in medical genetics. This challenge arises from the limited understanding of how these variants influence downstream CDS translation, especially when variants do not lead to overlap with it.

Material and Methods: We used a previously created uORF_annotator tool to identify and assess the impact of nucleotide variants from HGMD and ClinVar (P/LP/VUS) on uORFs structure and the subsequent change in main CDS translation. Next, we conducted detailed analysis of the identified variants using publicly available databases (GWIPS-viz, TRIPS-viz, gnomAD, CAGE data, etc.).

Results: uORF_annotator revealed 83 variants altering ATG-started uORFs by their elongation or shortening. Among these, 57 variants were found in non-overlapping uORFs, while 26 affected uORFs that initially overlapped with CDS. We classified variants in non-overlapping uORFs based on their potential impact on downstream CDS: (1) uORF elongation resulted in out-of-frame CDS overlapping (most pathogenic variants and eight VUS); (2) four variants elongate uORF in-frame with main CDS, leading to N-terminal protein extension; (3) 45 VUS variants altered uORF length without affecting CDS. These variants may exhibit varying effects on uORF length and distance to the CDS start codon, resulting in diverse impacts on CDS translation. Several groups were also identified among variants in overlapping uORFs. The most interesting included uORF shortening with overlap removal, which may enhance main CDS translation.

Conclusion: Our bioinformatic analysis suggests mechanisms by which uORF variants may influence CDS translation. These hypotheses will be tested in future experimental studies.

P15.023.B The puzzle of OFD1: one gene, several disorders

N. Pezzella[1,2], *L. Ferrante*[1], *F. Cifarelli*[1,3], *D. Migliorati*[4], *F. Massaro*[1,5], *R. Tammaro*[1], *M. Cesana*[1,6], *L. Fava*[4], *B. Franco*[7];

[1]TIGEM, NAPLES, Italy, [2]Scuola Superiore Meridionale, Naples, Italy, [3]Università degli Studi Federico II, Naples, Italy, [4]Armenise-Harvard Laboratory of Cell Division, Department of Cellular, Computational and Integrative Biology-CIBIO, Trento, Italy, [5]Scuola Superiore Merdionale, Naples, Italy, [6]Department of Biology, University of Naples Federico II, Naples, Italy, [7]TELETHON FOUNDATIONTIGEM, Pozzuoli, Italy

Background: The complex structure of the gene *OFD1* reflects the functional complexity of this pleiotropic protein; involved in biogenesis and maintenance of primary cilia, DNA repair and regulation of protein balance. Four different X-linked ciliopathies have been associated with *OFD1* mutations: OFD syndromes type I, Joubert type 10, Retinitis Pigmentosa 23 and Primary Ciliary Dyskinesia. This evident clinical and genetic heterogeneity suggests different underlying molecular events, that we aim to identify.

Material and Methods: We selected representative variants for the four ciliopathies and generated HK-2 mutant stable cell lines. Their characterization by super-resolution microscopy and OMICs techniques led us to identify specific phenotypes that we are defining with functional assays.

Results: Mutant lines expressing JBS10 and PCD phenotypes exhibit a significant hyper-elongation of the cilium; this suggested a compromised sensorial function of the cilia, which Transcriptomics analyses confirmed. Transcriptomics analyses also revealed up-regulation of genes involved in mitochondrial functions. Indeed, by performing TMRE and mito-stress assays, we found that mitochondria parameters are particularly compromised in the RP23 mutant. This finding is consistent with the emerging correlation between ciliary length and mitochondrial function. In the PCD mutant, we observed the loss of OFD1-interactors with critical roles in actin-mediated movement of cellular substructure, while the OFD1 mutant showed endoplasmic reticulum defects, which we are dissecting by EM analysis.

Conclusion: This experimental approach will shed light on the pathogenetic mechanisms underlying the clinical heterogeneity associated with *OFD1* mutations and could be also applied to other difficult-to-study disease genes in the field of ciliopathies.

P15.025.D Selective exome screening of newborns: first results of the pilot project

Alina Dokshukina, *Jekaterina Shubina, Ekaterina Tolmacheva, Nadezhda Pavlova, Dmitriy Trofimov*

National Medical Research Center for Obstetrics, Gynecology, and Perinatology named after Academician V.I. Kulakov, Moscow, Russian Federation.

Background: 3.5–5.9% of the population suffers from rare diseases, often manifesting in childhood. Only 10% of genetic disorders have pathognomonic signs in the neonatal period with deterioration in the first year of life, but the genetic disease can be suspected by indirect clinical manifestations and the neonate can be placed in the risk group for selective exome screening (SES).

Material and Methods: Neonatologists and geneticists in 7 perinatal centers selected newborns based on 128 clinical parameters. Whole exome sequencing (WES) was performed on blood samples. Inclusion required ≥2 clinical features; some cases with one feature were analyzed at physicians' discretion.

Results: Of 1306 neonates screened, 174 (13.3%) had causative findings. On average 4 criteria (median) were noted, maximum number of features was noted in 1 child (19), 1 feature - in 47 neonates. The detection rate with 1 feature was 8.5%, dropping to 2.5% if "neonatal screening risk" was excluded. With ≥3 features, the rate was 14.1%. Detection varied by organ systems: 16% for gastrointestinal/neuromuscular issues and lab changes; 22–33% for musculoskeletal, urinary, and facial dysmorphisms. Potentially it makes possible to use these features as the sole for inclusion in the SES. Notably, 41.3% of cases would have been missed without WES. Increasing the number of clinical criteria had minimal impact on detection rates.

Conclusion: SES is effective, achieving a 13.3% detection rate overall. High-yield clinical features could serve as standalone criteria, optimizing inclusion and reducing reliance on multiple indicators.

P15.026.A Long-read sequencing increases the diagnostic rate for rare diseases

Hannah Titheradge[1], *Lorraine Hartles-Spencer*[2], *Luke Ames*[3], *Jo Stockton*[3], *Derek Lim*[4], *Kai Ren Ong*[1], *Emma Douglas*[1], *Madhura Chandrashekara*[1], *Ataf Sabir*[1], *Deborah Osio*[1], *Mary O'Driscoll*[1],

Denise Williams[1], Helen Brittain[1], Joanna Jarvis[1], Esther Kinning[1], Helen Cox[1], Rebecca Igbokwe[1], Adrian Shields[3], Scott Hackett[5], Abhijit Dixit[6], Claire Searle[6], Andrew Beggs[3]

[1]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom, [2]West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom, [3]University of Birmingham, Birmingham, United Kingdom, [4]Clinical Genetics Unit, Birmingham Women's Hospital, Birmingham, United Kingdom, [5]University Hospitals Birmingham, Birmingham, United Kingdom, [6]Nottingham University Hospital NHS Trust, Nottingham, United Kingdom.

Background: We aim to evaluate the utility of Nanopore long-read sequencing (LRS) as a tool to increase the diagnostic rate of suspected monogenic rare disorders for those patients who have no molecular diagnosis despite maximal standard-of-care genomic testing.

Material and Methods: We identified 27 individuals highly likely to have a monogenic disorder, who have no molecular genetic diagnosis, despite reaching the ceiling of investigation as defined by the NHS England within the National Genomic Test Directory. They were recruited as trios and quads (affected patient(s), and their parents). Whole genome sequencing was performed using the Oxford Nanopore Promethion P24 instrument. We have used a range of existing software packages to study participants' genomes for potentially disease-causing variants including, sequence, copy number, methylation variants, and tandem repeats.

Results: We have identified the underlying molecular aetiology in an additional 11% of patients and their families so far including a diagnosis of Coffin Siris syndrome, Familial Adenomatous Polyposis and Roifman syndrome. We will discuss the clinical phenotypes of these patients, the bioinformatic pipeline and downstream analysis tools utilised. We will explore why these variants were not previously identified on genomic testing as well as the characteristics that seem to optimise the diagnostic yield from LRS. Finally, we will consider the feasibility of implementation of Nanopore sequencing into diagnostic testing pathways.

Conclusion: Nanopore LRS has increased the diagnostic rate for patients with likely monogenic disorders in families who have reached the ceiling for investigation in the NHS.

P15.027.B Long-read genome sequencing for diagnosis of rare diseases

Médéric Jeanne[1], *Mehmet Bugrahan Duz[1], Tina K. Truong[1], Wanqing Shao[1], Bryan Leland[2], Kshitij Amar[3], Nathaniel Edisis[1], Pratiksha Pradhan[1], Priyesh Rughani[2], Rebecca Stubbs[2], Kenney Tuyen[2], Talia Tzadikario[3], Carly Tyer[2], Scott Hickey[2], Sissel Juul[2], Shira Rockowitz[1], Piotr Sliz[1], Catherine A. Brownstein[1], Miten Jain[3], Alan H. Beggs[1], Wendy K. Chung[1]*

[1]Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, [2]Oxford Nanopore Technologies Inc, New York, NY, USA, [3]Northeastern University, Boston, MA, USA.

Background: Overcoming the limitations of traditional short-read sequencing, long-read genome sequencing (LRGS) allows variant phasing, methylation analysis, detection of structural variations (SVs), copy number variations (CNVs), and short tandem repeat expansions, while maintaining accurate single nucleotide variants (SNV) and small indel detection. To explore the utility of LRGS, we conducted nanopore sequencing in a cohort of undiagnosed patients.

Material and Methods: We selected probands with rare diseases who consented to research-based genomic analysis. DNA was sequenced on Oxford Nanopore Technologies' PromethION instruments. The EPI2ME-wf-human-variation workflow was employed for variant calling, methylation analysis and phasing.

Results: The BEACON Project aims to apply LRGS sequencing to 500+ samples. Here, we assessed 52 participants (33 affected individuals), including 21 singletons, 1 duo, and 10 trio cases with congenital diaphragmatic hernia (6), esophageal atresia (21), and other rare conditions (6). LRGS informed the diagnosis in nine individuals (28%), including two with congenital diaphragmatic hernia, six with esophageal atresia, and one with another rare condition. Findings included three CNVs and six SNVs or indels. In an overgrowth case, LGRS identified a 6 kb 3'UTR deletion of *HMGA2*, a known overgrowth gene, and methylation analysis was suggestive of overexpression, supporting its pathogenicity. Additionally, in a case of esophageal atresia, LRGS identified a truncating deletion in *ZZZ3*, a candidate gene involved in chromatin remodeling.

Conclusion: LRGS is an effective tool for identifying a wide range of variants including SVs, CNVs, methylation abnormalities, as well as SNVs and indels with the potential to be an effective diagnostic tool.

Background: Few autosomal recessive genetic disorders are more frequent in the Saguenay-Lac-Saint-Jean (SLSJ), Charlevoix (Cx), and Haute-Côte-Nord (HCN), three regions of the Province of Quebec, Canada, well known for their shared founder effect. Since 2010, a provincial carrier screening program covers the four most common disorders, with carrier rates between 1/19 and 1/23. Recently published clinical data suggested that additional disorders should be considered in the carrier screening program[1]. This study aimed to identify missing diseases and pathogenic variants eligible for inclusion in the carrier screening program.

Material and Methods: We used clinical data and variants identified in a recent unbiased study[2] to identify pathogenic variants causal of recessive disorders presenting as more frequent in the SLSJ, Cx and HCN populations. Their carrier frequencies were confirmed in an independent and randomly selected cohort of 1000 reporting at least one grandparent from the SLSJ, Cx, or HCN regions using specific TaqMan real-time PCR Assays. A carrier rate threshold of 1/200 to assess potential eligibility for carrier screening was determined taking in consideration the recommendations of multiple regulatory bodies.

Results: A total of 23 disorders and 31 variants were identified and selected for carrier rate assessment and confirmation. Among them, 23 variants (21 disorders) reached a carrier frequency of 1/200 or higher.

Conclusion: We have identified 23 novel pathogenic variants with a carrier rate of 1/200 or higher. These are causal of very severe recessive diseases for which no curative treatment is available. They should be considered for carrier screening program.

P15.030.A Genetic newborn screening by TREAT panel targeted sequencing in a large European cohort: pipeline design and first output results from the Screen4Care EU project

*Emanuele Agolini[1], **Leslie Matalonga**[2], Moshe Einhorn[3], Fernanda Fortunato[4], Gabriele Macari[5], Luciana Caforio[5], Michela Zuccolo[6], Maria Martinez-Fresno[7], Kathrin Freyler[8], Raul Tonda[2], Claire Morgan[2], Alice Margutti[4], Silvia Montanari[4], Vittoria Nagliati[4], Martina Mietto[4], Emeline Davoine[9], Frédéric Tran-Mau-Them[9], Laurence Faivre[9], Kaja Zarakowska[10], Rita Selvatici[4], Screen4care data flow and analysis subgroup[11], Ivo Gut[2], Antonio Novelli[12], Enrico Bertini[12], Stefaan Sansen[13], Janbernd Kirschner[8], Alessandra Ferlini[4], Sergi Beltran[2]*

[1]Ospedale Pediatrico Bambino Gesu (OPBG), Roma, Italy, [2]Centro Nacional de Análisis Genómico (CNAG), Barcelona, Spain, [3]GENOOX, Tel Aviv, Israel, [4]Università degli Studi di Ferrara, Ferrara, Italy, [5]GenomeUP, Rome, Italy, [6]Roche, Basel, Switzerland, [7]Illumina, Madrid, Spain, [8]Universitätsklinikum Freiburg, Freiburg, Germany, [9]CHU Dijon Bourgogne, Dijon, France, [10]Union Chimique Belge (UCB), Brussels, Belgium, [1112]Ospedale Pediatrico Bambino Gesu (OPBG), Rome, Italy, [13]Sanofi, Brussels, Belgium.

The EU Screen4Care initiative has developed a 245-gene panel of treatable disorders for genetic newborn screening (gNBS). This study outlines the data flow and analysis strategy, from patient recruitment to research report. The TREAT panel, designed using Roche technology, is supported by GenomeUP software for metadata collection and an Illumina BaseSpace account for secure raw data transfer. Recruitment materials, including multilingual videos and flyers, were distributed at participating maternity centers from Italy, Germany, and France. Samples are collected on custom dried blood spot cards developed for the project. The cards are periodically shipped to the sequencing center for panel sequencing. Validation of the panel using 24 positive control cases addressed complex variants, including short deletions, large deletions, duplications, and variants in pseudogenes (e.g. SMN1). Gene coverage assessments identified challenges in reporting certain genes, such as CBS. Results showed high accuracy and a very low false positive rate. Based on those, a standard procedure was established for automated filtering. This includes identifying (likely) pathogenic variants based on ACMG criteria and integrated databases, including ClinVar. Filtering parameters were tailored to each gene's inheritance pattern and specific variant types. Protocols involving European Reference Networks have been set up to evaluate variants of uncertain significance. The initial results from validation and first enrolled samples highlight challenges in implementing gNBS at scale. Over the coming months, the workflow will expand to screen up to 18,000 newborns, improving our understanding of gNBS, early diagnosis and treatment of rare genetic disorders.

P15.031.B Identifying molecular diagnoses using an RNA-guided workflow to interpret variants of unknown significance and candidate genes with gene network analysis to accelerate rare disease diagnostics

***W. T.K. Maassen**[1], C. C.E.T. Pape[1], C. G. Urzua-Traslavina[1], T. Niemeijer[1], Tijs van Lieshout[1], M. van der Molen[1], L. Johansson[1], K.J. van der Velde[1], L.H. Franke[1], M.E. van Gijn[2], M.A. Swertz[1]*

[1]University Medical Center Groningen, Groningen, Netherlands, [2]Amsterdam University Medical Center, Amsterdam, Netherlands.

Current genome diagnostics provides a molecular diagnosis for 20–80% of patients. Interpreting variants remains a challenge, as WGS delivers 4 to 5 million variants per individual, most of them non-coding, which can be of unknown significance or are not linked to a specific gene.Within the long-loving MOLGENIS project, the variant interpretation pipeline (VIP) is widely used to annotate variants with best-in-practice algorithms and protocols from routine diagnostics, supporting the usage of ACMG guidelines. Newly emerging methods like sequence-based models are able to prioritise variants with likely functional consequences, while gene outlier analysis can identify genes that are aberrantly expressed. Combining these new tools with standardised workflows, like VIP, could increase diagnostic yield.Here, with the expertise of clinical geneticists, clinical genetic laboratory specialists and bioinformaticians, we combined VIP, OUTRIDER and FRASER into a single simplified workflow to pinpoint variants causing deregulated gene expression and splicing in whole blood (WB) and fibroblasts (FB). Additionally, Borzoi and Pangolin are used, zooming in deeper on expression and splicing altering variants and GADO to identify new candidate genes. This workflow provides stand-alone interactive reports for immediate clinical interpretation on a patient level.We studied WB and FB RNA sequencing data, germline WGS and HPO data for 300 undiagnosed cases from the the American Undiagnosed Disease Network (UDN) with clinical diagnoses ranging from rare neurological and neurodevelopmental to haematological diseases. By leveraging the new toolings together with expertise from clinical geneticists, we identified 8 strong candidate variants explaining the clinical phenotype of the patient.

P15.033.D Investigating the genotype-phenotype relationshipfor TSC1 and TSC2pathogenic variants in a population cohort; implications for genomic newborn screening

James Fasham[1], Anna McPhater[1], Michael Weedon[2], Caroline Wright[2], ***Leigh Jackson***[1]

[1]University of ExeterMedical School, EXETER, United Kingdom, [2]University of Exeter, Exeter, United Kingdom.

Background: Despite the inclusion of tuberous sclerosis genes *TSC1* and *TSC2* in genomic newborn screening programs worldwide the penetrance of pathogenic variants in these genes in general populations remains unknown.

Materials & Methods: We analysed genome sequencing data on 500,000 UK Biobank participants, identifying individuals with high confidence, loss-of-function or previously reported pathogenic variants (ClinVar 2-star or above) in *TSC1* and *TSC2*. These were appraised according to ACMG criteria retaining likely pathogenic and pathogenic variants. In individuals with these variants phenotypic data, including ICD10, ICD-9, self-reported disease and primary care read codes, were interrogated for symptoms indicative of Tuberous Sclerosis.

Results: 13 *TSC1* and 9 *TSC2* variants were identified, in 13 and 12 participants, respectively. Only 5 had a diagnosis of tuberous sclerosis (4 *TSC1*, 1 *TSC2*), whilst a further 4 showed at least one feature of tuberous sclerosis. Notably, 16/25 (64%) individuals identified, all aged ≥55 years, had no recorded features of tuberous sclerosis. Despite analysis of all rare coding / splice variants in TSC1 and TSC2, 10/18 individuals self-reporting as having Tuberous Sclerosis had no explanatory variant.

Conclusion: Our findings challenge the previously reported near-complete penetrance of tuberous sclerosis, revealing a substantial number of asymptomatic variant carriers are present in the general population. While penetrance may be affected by healthy cohort bias, the existence of these individuals has important implications for newborn screening programs, clinical counselling and variant interpretation. Additionally, our finding of errors in clinical and self-reported diagnosis has wider implications to similar studies.

P15.034.A Applications of the new tool: VUS Notifier

Milan Domazet, Milena Ugrin, Marina Andjelkovic, Kristel Klaassen, Anita Skakic, Jovana Komazec, Vesna Spasovski, Sasa Todorovic, Maja Stojiljkovic

Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia.

Background: More than 300 million people worldwide are affected by a genetic rare disease (RD). Currently, comprehensive genetic testing, including whole-exome and whole-genome sequencing, has become the first-tier approach for determining the molecular genetic basis of these conditions. However, many genetic variants identified through these tests lack sufficient data for definitive classification as either pathogenic or benign and are therefore designated as variants of uncertain significance (VUS). Over time, as new scientific evidence emerges, these VUS may be reclassified as either pathogenic or benign.

Material and Methods: VUS Notifier tool facilitates the search for specific genetic variants by integrating data from four publicly available databases: ClinVar, VEP, LOVD and PubMed. More importantly, users can save variants of interest, and the system provides notifications when new information about these variants becomes available in the databases or scientific literature. Tool was developed using Python for backend and Next.js for frontend.

Results: Novel freely available tool, VUS Notifier, was developed and it is available at https://www.vusnotifier.app/

Conclusion: The VUS Notifier addresses the challenge of delivering timely updates on VUS and other genetic variants, offering a range of applications. First, it autonomously searches for new information, eliminating the need for manual monitoring by patients, geneticists, or clinicians. Additionally, it can facilitate the re-analysis of unresolved RD cases. Furthermore, the tool could be used to systematically collect published data, aiding in the selection of the most attractive genetic targets for pharmacochaperones. Notably, this is the first tool to integrate multiple resources while providing automated notifications.

P15.035.B Polyadenylation-Disrupting Variants in Rare Disease: A Genome-Wide Analysis and Experimental Validation

Yaroslav Kainov*, Cristina Dias, Tim Hubbard*

King's College London, London, United Kingdom.

Background: Cleavage and polyadenylation of mRNAs is essential for transcription termination and gene expression, yet variants disrupting conserved sequences essential to this process are often overlooked as putative causal variants in individuals with rare Mendelian disorders.

Material and Methods: Here, starting with variant effect predictions from advanced machine learning models, we conducted a systematic genome-wide analysis of germline variants inferred to impact cleavage and polyadenylation in mRNA 3'-untranslated regions (3'UTRs) in individuals with rare diseases in the Genomics England 100,000 Genomes Project.

Results: We identified enrichment of ultrarare alleles predicted to disrupt polyadenylation in a large cohort of undiagnosed probands with rare disease disorders from the Genomics England 100k dataset. These alleles are predominantly located in the 3' UTRs of genes where protein-coding variants have previously been identified as causal in rare diseases. Experimental validation of a putative causal variant predicted to disrupt polyadenylation of SLC16A2 in a proband with intellectual disability, confirmed the allele's deleterious impact on gene expression.

Conclusion: These results demonstrate that variants affecting cleavage and polyadenylation can have functional consequences and should be considered in the genetic diagnosis of rare disorders.

P15.036.C Genotype-Phenotype Correlations of Rare SCHEMA Variants: Insights into Cognitive, Demographic, and Neuroimaging Features from the UK Biobank

Xinmu CHEN, *Andrew McQuillin, Nick Bass*

Division of Psychiatry, University College London, London, United Kingdom.

Background: Genetic studies have established the role of rare variants in schizophrenia aetiology. The Schizophrenia Exome Sequencing Meta-Analysis (SCHEMA) consortium identified 32 genes significantly associated with schizophrenia risk. This project examines rare variant carriers of SCHEMA genes in the UK Biobank and compares their phenotypic traits with non-carriers.

Material and Methods: Genotypic analyses were conducted using the UK Biobank Research Analysis Platform. Variant carriers that passed quality control were extracted from population-level exome OQFE data in PLINK format, with an allele frequency threshold of <0.000005.Phenotypic comparisons were performed across three groups: (1) carriers of the top ten SCHEMA genes ($n = 652$), (2) carriers of genes ranked 11 to 32 ($n = 1506$), and (3) all SCHEMA gene carriers ($n = 2074$) versus the rest of the UK Biobank population.

Results: Across all groups, rare variant carriers exhibited significantly greater socioeconomic deprivation ($p = 2.87e-04$, $p = 5.622e-07$, $p = 1.566e-10$), lower fluid intelligence scores ($p = 0.001336$, $p = 2.91e-08$, $p = 1.308e-09$), and poorer performance on cognitive tasks, including prospective memory ($p = 0.0001215$, $p = 0.003548$, $p = 8.743e-06$). Carriers in groups 1 and 3 took longer to correctly identify matches ($p = 0.001701$, $p = 0.001698$), while groups 2 and 3 showed a higher likelihood of perceiving unreal visual stimuli ($p = 0.04121$, $p = 0.03141$). Imaging analyses revealed significantly smaller ventricular cerebrospinal fluid volumes in carriers ($p = 0.04376$), normalised for head size. However, no significant associations were found with ICD-10 mental and behavioural disorders or schizophrenia related diagnoses.

Conclusion: While rare SCHEMA variant carriers show disadvantages in cognitive and demographic factors, these do not translate into a significantly increased risk of psychiatric disorders.

P15.037.D Answering the unmet need of rare disease diagnosis through high throughput functional genomics

Teresa Zhao[1,2,3], *Daniella H. Hock*[4,1], *Tanavi Sharma*[4], *Susan M. White*[1,2,3], *Tiong Yang Tan*[1,2,3], *Michelle G. de Silva*[1,3], *Rosie Brown*[1], *David R. Thorburn*[1,2,3], *David A. Stroud*[4,1], *John Christodoulou*[1,2,3]

[1]*Murdoch Children's Research Institute, Royal Children's Hospital, Melbourne, Australia,* [2]*Department of Paediatrics, University of Melbourne, Melbourne, Australia,* [3]*Victorian Clinical Genetics Services, Melbourne, Australia,* [4]*Department of Biochemistry & Pharmacology, Bio21 Molecular Science and Biotechnology Institute, Melbourne, Australia.*

Background: A major challenge in diagnostics is that true causative variants often require functional evidence to be reclassified from variants of uncertain significance (VUS). Clinically validated, accessible functional methods are needed to fulfill this purpose. Untargeted mass spectrometry (MS)-based proteomics has gained attention as a functional genomic technology due to its increasing ability to detect changes in thousands of proteins in common clinical sample types and its high-throughput nature.

Material and Methods: A retrospective study was conducted on lymphoblast or fibroblast cells from 23 randomly selected rare disease patients with their diagnosis blinded to investigate the utility of MS-based proteomics. Relevant HPO terms and 1–2 candidate genes were provided for each case. The untargeted proteomics results were reviewed with respect to candidate proteins based on 1) abundance, 2) protein complex association, and 3) interacting or binding partners noted in published literature.

Results: We observed a similar number of recessive and dominant cases, de novo, homozygous, and compound heterozygous variants and a range of variant types (missense, frameshift, splicing) in our cohort. Nearly 50% of the cases showed a significant reduction in protein abundance, providing direct evidence of likely pathogenicity for the candidate variants. The candidate proteins exhibited an 80% mean reduction in recessive conditions compared to 20% in dominant conditions. Protein complex and interaction analyses were explored for the remaining cases.

Conclusion: Proteomic analyses will likely provide evidence to support variant pathogenicity in a high proportion of monogenic disorders and across all inheritance patterns and for all common variant types.

P15.038.A Beyond *CFTR*: Unraveling the Genetic Basis of Elevated Neonatal IRT in Non-CF Newborns

Francesca Rosamilia[1], *Ummara Sarfraz*[1,2], *Giovanni Fiorito*[1], *Carola Di Meo*[1], *Maria Baffico*[3], *Giulia Camisassi*[4], *Michela Cassanello*[5], *Elvira Sondo*[5], *Vito Terlizzi*[6], *Laura Barrocu*[7], *Dorota Sands*[8,9], *Katarzyna Zybert*[8,9], *Mohamad Maghnie*[5], *Isabella Ceccherini*[10], *Paolo Uva*[1], *Carlo Castellani*[4]

[1]IRCCS Istituto Giannina Gaslini - Clinical Bioinformatic Unit, Genova, Italy, [2]University of Pavia - Department of Biology and Biotechnology, Pavia, Italy, [3]IRCCS Istituto Giannina Gaslini - UOC Human Genetic, Genova, Italy, [4]IRCCS Istituto Giannina Gaslini - Cystic Fibrosis Center, Genova, Italy, [5]IRCCS Istituto Giannina Gaslini - LABSIEM-Laboratory for the Study of Inborn Errors of Metabolism, Genova, Italy, [6]Azienda Ospedaliero-Universitaria Meyer - Centro Regionale Toscano per la Fibrosi Cistica, Firenze, Italy, [7]Ospedale Infantile Regina Margherita – Sant' Anna – S.C. Pneumologia, Torino, Italy, [8]Institute of Mother and Child - Cystic Fibrosis Department, Warsaw, Poland, [9]Pediatric Hospital - Cystic Fibrosis Centre, Dziekanów Leśny, Poland, [10]IRCCS Istituto Giannina Gaslini - UOSD Area Aggregazione Laboratori della Ricerca, Genova, Italy.

Background: Cystic Fibrosis (CF) is the most common severe autosomal recessive disease in Europe, affecting the respiratory tract and exocrine pancreas, also involving altered lipid metabolism. Measurement of the pancreatic enzyme immunoreactive-trypsinogen (IRT) is the first tier of screening even if it implies the identification of False Positives (FP), i.e. non-CF infants with elevated IRT. However, the reasons behind the raised >IRT levels in FP newborns remain unclear and could suggest a genetic contribution.

Material and Methods: Whole Exome Sequencing (WES) was performed on three groups of screened newborns: true positives (TP i.e.CF-confirmed), true negatives (TN, i.e. CF-negative with normal IRT), and FP. Two complementary statistical approaches have been applied: a Bayesian method for rare variants and a logistic regression model for common variants.

Results: WES from 293 CF Newborn samples were investigated: in detail 40 TP, 103 FP, 119 TN and 31 SPID (Borderline Cases). The combination of the Bayesian and logistic approach enables to highlight the contribution of both common and rare variants in such a complex phenotype. The comparison between FP and TN, using both methods, suggested a polygenic risk model, where multiple markers contribute to elevated IRT phenotype. *CFTR* was causative only in TP, while additional genetic factors may underlie elevated IRT in FP.

Conclusion: The present findings improve non-CF detection and enhance NBS positive predictive value. Identifying risk alleles could refine the management of uncertain cases, enabling personalized follow-up. Validation of the results is ongoing and will be presented at the meeting.

Background: Hereditary neuropathies pose a significant diagnostic challenge due to their clinical and genetic heterogeneity. Thanks to the national program Plan France Médecine Génomique 2025, whole genome sequencing (WGS) is now available as part of clinical care in France. This study evaluates the impact of WGS on the diagnosis of hereditary neuropathies before the age of 50.

Material and Methods: From February 2023 to December 2025, 186 WGS requests were received for patients with suspected hereditary neuropathies after prior gene panel testing. 97 cases underwent the Auragen pipeline and 89 SeqOIA. Of these, 109 analyses were completed, 26 are ongoing and 51 are pending.

Results: Of the 109 cases processed, 35 (32%) yielded a definitive genetic diagnosis, identifying pathogenic variants in known neuromuscular genes. Six cases (6%) revealed variants of uncertain significance requiring further validation. Sixty-eight cases (62%) were inconclusive, reflecting the genetic complexity of inherited neuropathies. WGS identified several new candidate genes, and in some cases, this analysis led us to revise the initial diagnosis and suggest appropriate management.

Conclusion: This study highlights the role of WGS in reducing the number of undiagnosed patients with inherited neuropathies. A molecular diagnosis was established in 32% of cases, a high proportion given that all had previously undergone gene panels, thus reducing the number of patients in a diagnostic odyssey. In addition, WGS has proved invaluable in identifying novel disease-associated genes. In conclusion, our nationwide French experience strongly supports WGS as a diagnostic tool for hereditary neuropathies, especially for young patients.

P15.040.C Using zebrafish model to investigate complex hereditary spastic paraplegia caused by EPT1 variants

Shige Wang, *Siddharth Banka, Martin Lowe, anna nicolaou*

University of Manchester, Manchester, United Kingdom.

Background: Hereditary Spastic Paraplegia (HSP) comprises a broad and heterogeneous group of inherited neurodegenerative disorders. Among the identified spastic paraplegia genes, 19 are involved in membrane phospholipid metabolism. The Kennedy

pathway is a major biosynthetic route for phosphatidylethanolamine (PE), in which *EPT1* encodes ethanolaminephosphotransferase converting CDP-ethanolamine to PE. Biallelic loss-of-function mutations in *EPT1* have been associated with SPG81.

Material and Methods: To investigate the role of ept1 in HSP, we generated ept1 exon 5 (ex5) knock-out mutants and crispants using the CRISPR-Cas9 system. Phenotypic characterization, RNA sequencing, and lipidomic profiling were performed in these zebrafish models.

Results: The *ept1* ex5 knock-out mutants harbored an 8-bp deletion in the catalytic domain and were viable, exhibiting a 60% reduction in *ept1* mRNA levels. Compared to wildtypes, homozygous knockouts displayed significant impairments in locomotion, reduced body length and head width. Transcriptomic analysis revealed downregulation of genes involved in light response, synaptic activity, and lipid metabolism, whereas genes associated with immune signaling and neuroinflammation were upregulated. Lipidomic profiling showed a reduction in total PE and PC levels in knockouts, with plasmenyl-PE being most severely affected. Through crispant analysis, we found that both *ept1* and *cept1b* crispants exhibited significantly impaired locomotion; however, only *ept1* crispants displayed reductions in body length and head width.

Conclusion: The *ept1* knock-out mutants and crispants recapitulate movement disorder and developmental delay observed in SPG81 patients, making them valuable models for disease research. Moreover, our findings suggest that neuroinflammation may play a crucial role in HSP pathogenesis and could serve as a potential therapeutic target.

P15.041.D Identification and genotyping of pathogenic short tandem repeat expansions using long-read sequencing

*Johannes Lenz[1], Helene Faust[1,2], Patricia Duffek[1], Eva-Maria Kraus[1], Rami Abou Jamra[1], **Denny Popp**[1]*

[1]Institute of Human Genetics, Leipzig, Germany, [2]Institute of Human Genetics, Kiel, Germany.

Background: Movement disorders such as ataxia and myotonic dystrophy are frequently caused by short tandem repeat (STR) expansions. These expansions can extend up to several kilobases in length and exhibit complex motif variations, making them difficult to detect using state-of-the-art approaches.

Material and Methods: Nanopore long-read whole genome sequencing (lrWGS) was performed on positive controls with prior known pathogenic repeat expansions in the genes *ATN1, ATXN1, ATXN2, ATXN8OS, CNBP, C9orf72, DAB1, DMPK, FGF14, FMR1, FXN, HTT, NOP56* and *RFC1*. Repeat loci were evaluated and manually genotyped using IGV (Integrated Genome Viewer) as well as automatically genotyped with tools such as Straglr. Subsequently, lrWGS was applied to a cohort of unsolved ataxia cases.

Results: Even long and complex repeat expansions in the available positive controls could be accurately analyzed manually using lrWGS. However, exact genotyping was complicated by variable motifs and repeat sizes as for some STRs like in *NOP56* a high somatic variability occurs. Hitherto, this also impedes the automatic genotyping of *ATN1, CNBP, DAB1, FGF14* and *NOP56* by Straglr. So far, seven patients from our cohort were subjected to lrWGS and two of them were found to have a clinically relevant repeat expansion (*ATXN8OS* and *FGF14*).

Conclusion: Nanopore lrWGS is a suitable method for genotyping various disease-associated STRs. However, somatic variability remains a challenge that can be addressed by increasing the sequencing coverage.

P15.042.A Human sex determination and associated pathologies as a model to understand developmental gene regulation

***Estelle Talouarn**[1,2,3], Maëva ElZaiat-Munsch[1,2,4], Somboon Wakanit[1,2,4], Laurène Schlick[1,2,4], Anu Bashamboo[1,2,4], Kenneth McElreavey[1,2,4]*

[1]Human Developmental Genetics, Paris, France, [2]Institut Pasteur, Paris, France, [3]Université Paris Cité, Paris, France, [4]CNRS UMR3738, Paris, France.

Background: Our analysis of patients with sex-reversal has identified many genes involved in mammalian sex-determination (SD). Despite extensive exome studies >50% of cases remain idiopathic. We hypothesize that unexplained cases are due to variants in gene regulatory elements (GREs) that may define gene regulatory networks (GRNs). Recently, we defined a novel *SRY* enhancer and identified SNVs in it, associated with 46,XY sex-reversal (PMID: 38555298). We have developed a multi-omic genome-wide approach to identify functional GREs in human SD and predict GRNs.

Material and Methods: Single-cell RNAseq and ATACseq data from human fetal gonad atlas (PMID: 35794482) was reanalysed by Scenic+, to define candidate GREs (cGREs). Transcription factor (TF) binding-site enrichment and mutational constraint in cGREs were determined using pycistarget and Gnocchi respectively. We defined cGREs corresponding to human accelerated regions (HARs, PMID: 27667684). Rare/novel variants from genome sequences of >160 individuals with unexplained sex-reversal were mapped to cGREs and functional variants prioritized using CADD, FinSurf and Fabian.

Results: We defined 18,932 and 18,200 cGREs in Sertoli and pre-granulosa cells with a mean Gnocchi score of 7.90 and 7.88 respectively. Using our pipeline, we observed an enrichment of binding-sites for known SD TFs in cGREs: e.g: SOX9 (Normalized Enrichment Score (NES) = 12.95), NR5A1 (NES = 10.98) in Sertoli and LHX9 (NES = 5.66) in pre-granulosa cells. As proof of principle, we identified a previously reported *SOX9* GRE (eSR-A (PMID: 30552336)).

Conclusion: Our approach dissects the role of GREs and GRNs in SD providing a unique model to further understand developmental gene regulation.

P15.043.B Investigating the interplay between prematurity and genetic variation in the context of developmental disorders

***Patrick Campbell**[1], Olivia Wootton[2], Sarah Richardson[3], Sarah J. Lindsay[2], Qin Qin Huang[2], Erwan Delage[2], Sana Amanat[2], Michael A. Simpson[1], Elizabeth J. Radford[2], Hilary C. Martin[2]*

[1]King's College London, London, United Kingdom, [2]Wellcome Sanger Institute, Hinxton, United Kingdom, [3]Oxford Centre for Genomic Medicine, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom.

Background: Rare damaging genetic variation accounts for a large proportion of the risk of rare developmental disorders, but common genetic variants, as well as environmental factors such as prematurity, also contribute. Little is known about the interplay between genetic factors and preterm birth in rare developmental disorders, particularly in influencing phenotypic outcomes.

Methods: We use phenotypic and genetic data from 21,712 patients with developmental disorders recruited for clinical sequencing, 16% of whom were born prematurely.

Results: In line with past work, we show that common variants associated with higher educational attainment are associated with longer gestational duration. We advance existing knowledge by demonstrating that this association is likely to be the result of genetically-influenced parental traits or confounders, rather than direct genetic effects, and that the presence of a monogenic diagnosis modifies this association. We identify genes and gene sets enriched for diagnostic mutations amongst preterm probands. In our sample, pathogenic de novo mutations account for a greater proportion of developmental disorder cases among term probands compared to preterm probands, consistent with a liability-threshold model of aetiology. However, we find an excess of likely damaging de novo variants in genes that are not currently associated with developmental disorders among preterm and term undiagnosed probands. In a phenotype analysis, we find that prematurity is associated with more severe clinical presentations and that prematurity and monogenic diagnoses contribute independently and additively to severity.

Conclusions: Our findings emphasise the importance of considering prematurity in understanding and predicting outcomes in rare developmental disorders.

P15.044.C Evaluating the Utility of Face2Gene in 290 Molecularly Diagnosed Cases: Insights from the Telethon Undiagnosed Disease Project

Giulia De Riso[1,2], *Alberto Budillon*[3], *Nadia Mehrdad*[1], *TUDP*[4], *Vincenzo Nigro*[3,5], *Michele Pinelli*[1,2], *Annalaura Torella*[3,5]

[1]*Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples, Italy,* [2]*Unit of medical Genetics, AOU Federico II, Naples, Italy,* [3]*Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy,* [45]*Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli, Naples, Italy.*

Background: Face2Gene (FDNA, Inc.), an AI-driven tool designed to analyze facial features for syndrome identification, incorporates two main components: DeepGestalt, trained on 300 rare genetic syndromes, and GestaltMatcher, developed for the identification of ultra-rare and novel syndromes. DeepGestalt can be combined with Human Phenotype Ontology (HPO) analysis to enhance diagnostic accuracy.This study evaluates the utility of Face2Gene's tools in a cohort of 290 molecularly diagnosed cases from the Telethon Undiagnosed Disease Project.

Material and Methods: Frontal facial photographs of patients with confirmed molecular diagnoses were analyzed. Predictive performance was assessed by comparing the software's top-30 ranked diagnoses against the known molecular diagnoses.

Results: DeepGestalt correctly identified the molecular diagnosis within the top-30 predictions for 83 cases (including 51 cases in the top 3). Incorporating HPO terms alongside image-based predictions removed 9 patients from and added 7 to the top-30 list, slightly reducing overall performance while expanding the range of potential diagnoses (n = 90). Predictions based solely on GestaltMatcher confirmed 13 diagnoses, with minimal overlap (n = 3) between the two algorithms.

Conclusion: In our cohort, the largest from an Undiagnosed Disease Project study, the three tools collectively identified diagnoses in 100 out of 290 patients (34%), with the majority relying on facial feature-based predictions.

Background: Genomic technologies are revolutionising rare disease diagnosis and enabling precision child health. However, there remain significant gaps in our ability to interpret genomic findings and understand their biological impact. Rare Diseases Now (RDNow) is a multifaceted, clinically integrated rare disease program utilising multi-omic analyses to boost diagnostic yield.

Material and Methods: Individuals who remain undiagnosed after clinical exome/genome sequencing are enrolled on referral from genetics or other medical subspecialties. A personalised testing strategy is designed from a suite of technologies including transcriptomics, proteomics, deep sequencing, long-read sequencing or other functional analyses depending on clinical phenotype and genomic findings.

Results: Of the 392 families recruited, sequencing and analysis is complete for 170 families and for 92 of them we have identified the genetic cause for their condition (54% diagnostic yield). Multi-omics was necessary in 16/92 (17.4%) of diagnosed cases and required comprehensive interdisciplinary collaboration. Other approaches included data reanalysis, deep sequencing, and global matchmaking and functional studies for novel gene discoveries.- Transcriptomics and proteomics were especially useful in refuting pathogenicity of variants of uncertain significance.

Conclusion: We demonstrate that a personalised multi-omic approach informed by clinical deep phenotyping is increasingly important for the diagnosis of patients with undiagnosed rare diseases. Understanding the optimal deployment of these complementary technologies and scalability remain ongoing priorities to deliver integrated multi-omics for rare disease diagnostics.

P15.046.A Genetic and immunological features in patients with MHC class II deficiency

Y. Meddour[1], *R. Djidjik*[2], *N. Messaoudani*[2];

[1]Mother & Children Hospital Algiers, Algiers, Algeria, [2]Immunology Departement. CHU Beni Messous, Algiers, Algeria

Background: Major histocompatibility complex (MHC) class II molecules are master key in antigen presenting process during CD4+ lymphocytes priming. MHC class II genes transcription is regulated by four transcription factors: CIITA, RFXANK, RFX5 and RFXAP. Defects in these factors result in major histocompatibility complex class II expression deficiency, a primary combined immunodeficiency frequent in North Africa. Autosomal recessive mutations in the RFXANK gene have been reported as being the principal defect found in North African patients with this disorder.

Material and Methods: Here, we describe genetic, immunological and clinical features of 11 unrelated Algerian patients whose monocytes display a total absence of MHC class II molecules. They shared mainly the same clinical picture which included protracted diarrhoea and respiratory tract recurrent infections.

Results: Genetic analysis revealed that 9 of the 11 patients had the same RFXANK founder mutation, a 26 bp deletion (named I5E6-25_I5E6+1, also known as 752delG26).

Conclusion: Genetic and Immunological findings in our series may facilitate genetic counselling implementation for Algerian consanguineous families. Further studies need to be conducted to determine 752delG26 heterozygous mutation frequency in Algerian population.

Background/Objectives: Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL, OMIM 125310) is an adult-onset, inherited small vessel disease caused by NOTCH3 mutations and characterized by a high phenotype variability. We have studied a large and multigenerational sample of individuals (connected in a 17-generation pedigree) from a founder population of South Italy carrying the widespread p.Arg1231Cys mutation to assess the phenotype variability in this sample and to identify additional genetic factors that could modulate CADASIL phenotype.

Methods: Clinical data were compared between p.Arg1231Cys mutation carriers (CILCAD) and the NON-Carriers from the same population; also, MRI features in CILCAD were compared to those detected in UK-population samples. NOTCH3-region haplotypes were analyzed to define the minimum haplotype shared by the CILCAD and identify novel genetic contributions to the disease phenotype.

Results: We found an increase in neurological manifestations in the CILCAD compared to NON-Carriers from the same population; however, our data suggest a milder disease phenotype associated with the p.Arg1231Cys mutation in the CILCAD. Moreover, we found that CILCAD subjects have lower total cholesterol and LDL levels than the rest of the population. Indeed, NOTCH3-region haplotype sharing analysis revealed that the haplotype carrying the p.Arg1231Cys mutation in CILCAD also carries lowering cholesterol alleles.

Conclusions: We hypothesize that additional genetic and/or environmental factors could contribute to a milder phenotype observed in CILCAD. We also believe that this sample could represent a useful resource for identifying novel genetic and environmental factors implicated in the disease, contributing to an improved understanding of CADASIL pathogenesis.

P15.048.C Whole-exome Sequencing Reveals Mutational Profiles Associated with Medulloblastoma

D. Han*, L. Sang, J. Wang, X. Chen, Z. Wang, Y. Gao;*

BGI research, Shenzhen, China

Background: Relapse is the leading cause of death in patients with medulloblastoma (MB), the most common malignant pediatric brain tumor. Understanding the mechanisms underlying recurrence could lead to more effective therapies targeting tumor relapses.

Material and Methods: To investigate the mutational differences between primary and recurrent MB across four molecular subtypes, we recruited 28 patients with primary MB who experienced tumor recurrence, collecting paired samples from a total of 56 cases for whole-exome sequencing (WES). We analyzed differential mutational events at the levels of variants, copy number variations (CNV), genes, and SNP loci for each subtype between primary and recurrent tumors.

Results: In the G3 tumor, recurrence-specific alterations were observed in the driver genes *CTNNB1* and *IDH1*. Different CNV segments showed amplification or deletion across the subtypes, and Genome-Wide Association Studies (GWAS) revealed significant SNP loci in the G3 and G4 subtypes. Recurrent tumors exhibited a higher mutational load compared to primary tumors.

Conclusion: This study enhances the understanding of the mutational differences between primary and recurrent MB across different molecular subtypes. Identifying these molecular alterations can aid in developing more effective therapeutic strategies for targeting tumor relapses in MB.

Background: Neurodevelopmental disorders (NDDs) are complex conditions with a strong yet not completely understood genetic component. NDDs genetic architecture in under-represented communities is poorly studied. We present a comprehensive whole-genome sequencing (WGS) analysis to investigate the genetic basis of NDDs in 298 individuals from 100 families resident in Valle d'Aosta, Italy. This study is part of the "5000genomes@VdA" project, which aims to characterize the genomic landscape of the healthy population and residents affected by various conditions.

Material and Methods: We used a comprehensive computational pipeline, rigorous filters and extensive manual curation to detect both de novo and inherited short variants (SNVs and indels) as well as several classes of structural variants.

Results: We identified likely pathogenic variants in 26 out of 110 of our probands, for a diagnostic rate of 23.6%. Additionally, we detected 44 VUS potentially contributig to the probands phenotypes. Notably, four likely gene-damaging variants affected genes not previously robustly implicated in specific NDDs: *KALRN, BAZ2B, ALDH18A1, SYTL4* and *COL6A1*. Additionally, the examination of rare inherited and de novo copy number variants (CNVs) suggested a role for *PRDM16, DOCK8, NPAS1, NECTIN3*, and *GLRA1;* as well as multiple CNVs located in the 15q13.2-q13.3 and 15q11.2 *loci*. These variants may primarily function as susceptibility factors with incomplete penetrance.

Conclusion: This comprehensive approach highlights the utility of WGS in uncovering complex genetic factors and suggests new candidate genes and variants for further investigation.

P15.050.A Automated Uniparental Disomy Detection: Insights from a Large Rare Disease Cohort

***Anett Marais**, Matthias Bieg, Jorge Pinto Basto, Peter Bauer, Krishna Kumar Kandaswamy*

Centogene GmbH, Rostock, Germany.

Uniparental disomy (UPD) is a copy-neutral genetic anomaly where both copies of a chromosomal pair, or segments, originate from a single parent. This alteration can have significant clinical consequences, yet detecting UPD is challenging due to its rarity and limited understanding of its phenotypic presentation. We report a large UPD cohort analysis after integrating automated UPD detection methods into our routine rare disease diagnostic DNA sequencing pipeline, using solo/trio Exome- and solo Genome Sequencing. Solo UPD analyses utilized regions of homozygosity (ROH), while trio UPD detection employed Mendelian inheritance error principles with Bayesian machine learning methods. Among 88,624 analyzed samples, 47 previously undiagnosed potential UPD cases were identified and CNVs excluded. Of these, 37 were confirmed as true UPD cases by either MLPA or CMA, four were reported as ROH regions (chr 1, 2, 21), and six were considered potential UPD without available confirmatory methods (chr 1, 2, 6, 9, 21). Additionally, 34 UPDs associated with established imprinting disorders[1], including chromosomes 6 (one patient), 7 (six Silver-Russell Syndrome patients), 14 (one Kagami-Ogata Syndrome and two Temple Syndrome patients), 15 (13 Angelman Syndrome and eight Prader-Willi Syndrome patients), and 20 (three GNAS disorders). Of the 47 suggestive UPDs, trio analyses detected five isodisomies and one heterodisomy. Among solo samples were 29 likely isodisomies, based on confirmatory results, and 12 ambiguous calls. Our study demonstrates the reliable application of automated UPD detection in a diverse patient cohort, enhancing diagnostic accuracy and understanding of UPDs, including potential novel and previously underexplored associations.

P15.051.B Using GPT-4 chatbot for genomic data interpretation in monogenic disorders

***Avi Fellner**[1], Marina Lifshitc-Kalis[1], Lily Bazak[1], Lina Basel-Salmon[1,2,3]*

[1]The Raphael Recanati Genetics Institute, Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel, [2]Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [3]Felsenstein Medical Research Center, Tel-Aviv University, Tel-Aviv, Israel.

Background: Artificial intelligence technologies are increasingly being used in medicine. We investigated the use of GPT-4, a generative large language model-based chatbot, in exome sequencing variant prioritization.

Material and Methods: For each case, the exome analysis platform (Emedgene variant interpretation software; Emedgene Technologies, an Illumina company) suggests a list of approximately 10 "most likely" (ML) variants to solve the case. We retrospectively applied GPT-4 in 43 solved exome sequencing cases. For each case, we used the ML variant list that included the

true diagnosis (as identified by the exome analysis platform and manually confirmed by the variant interpretation team) to generate a GPT-4 query, asking which variant from the ML variant list causes the patient's phenotype based on the Human Phenotype Ontology terms originally used in the exome analysis.

Results: GPT suggested the true diagnosis in 30/43 (69.8%) of cases. Correct and incorrect diagnoses by GPT did not differ significantly in the presence of causative truncating/splice variants compared to missense/in-frame/synonymous variants ($p = 0.33$) or in the total number of gene publications in Pubmed ($p = 0.79$). However, correct diagnoses were associated with an earlier year of the first publication of gene association with human disease (median year: 2005 vs. 2015.5; $p = 0.0067$).

Conclusion: Our results support the use of GPT-4 as an added assistive tool in variant prioritization, yet its current limitations should be taken into consideration. Additional studies are needed to further characterize the advantages and limitations of GPT and other large language model-based tools in genomic medicine.

P15.052.C Genomic approaches for solving rare and undiagnosed diseases through Rareboost project: results and insights

Ayça Yigit[1,2], *Ravza Nur Yildirim*[2], *Mert Pekerbas*[2], *Emre Ozzeybek*[1,2], *Ece Sonmezler*[3,1], *Yavuz Oktay*[1,2,4], *Mehmet Baysan*[2,5,6], *A. Okay Caglayan*[7,2], *Ugur Ozbek*[2]

[1]*İzmir International Biomedicine and Genome Institute (IBG-İzmir), Dokuz Eylül University, Izmir, Turkey,* [2]*Rare and Undiagnosed Diseases Platform (RUDiP), Izmir Biomedicine and Genome Center, Izmir, Turkey,* [3]*Izmir Biomedicine and Genome Center, Izmir, Turkey,* [4]*Department of Medical Biology, Faculty of Medicine, Dokuz Eylul University, Izmir, Türkiye, Izmir, Turkey,* [5]*Health Institutes of Turkey, Istanbul, Turkey,* [6]*Department of Computer Engineering, Istanbul Technical University, Istanbul, Turkey,* [7]*Department of Medical Genetics, Faculty of Medicine, Dokuz Eylul University, Izmir, Turkey.*

Background: Rare diseases (RDs) impact millions worldwide, compounded by diagnostic uncertainties and limited treatment options. Many individuals endure years-long diagnostic odysseys, with some remaining undiagnosed. The RareBoost Project aims to bridge this gap by focusing on individuals with suspected but undiagnosed rare genetic diseases, leveraging translational research to enhance diagnostic accuracy and outcomes.

Material and Methods: The study cohort comprises 57 unresolved or undiagnosed cases selected from Rare and Undiagnosed Disease Advisory Board meetings, which bring together a multidisciplinary team of IBG researchers and clinicians from healthcare partners. Initial WES reanalyses on available data were performed on 39 of these cases, while WES, WGS, and/or RNA-Seq were conducted on 25 cases that remained without a definitive diagnosis.

Results: NGS analyses were conducted on 57 unresolved cases from 46 families enrolled in the RareBoost cohort. Genomic data reanalysis was performed for 39 patients, while WES (10/57), WGS (13/57), and RNA-Seq (3/57) were applied to the remaining undiagnosed cases to identify potential causative variants. Seven families (12%) achieved a definitive diagnosis based on pathogenic or likely pathogenic variants. Two cases involving synonymous variants were resolved through RT-PCR analysis and RNA-Seq analysis, respectively. Additionally, clinically relevant variants of uncertain significance (VUSs) were identified in 21 families (36.8%), with ongoing functional studies to assess their clinical relevance.

Conclusion: Our findings underscore the effectiveness of genomic approaches in diagnosing rare and undiagnosed cases, demonstrating their potential to enhance diagnostic accuracy and improve patient care.

Background: The role of the digenic model in rare disorders has been relatively underexplored, mostly due to both the difficulties of statistically supporting these associations to disease and the limitations of generating experimental models. We have developed an approach based on the analysis of genomic data from hundreds of thousands of individuals available from large biomedical projects to detect or validate pathogenic digenic interactions.

Material and Methods: We analyzed genotyping data for 70 autoinflammatory disorder genes in UK Biobank for 467,000 European ancestry individuals based on PCA analyses. We compared the expected and observed frequencies of co-carriers for all possible pairs of variants from different genes.

Results: The analysis revealed candidate digenic interactions among AID genes, evidenced by deviations from neutrality of the genotypes distribution. One of the interactions, validated in an independent patient cohort, may provide insight into the incomplete penetrance of Familial Mediterranean Fever (FMF) where heterozygous individuals carrying pathogenic variants in the *MEFV* gene may or may not develop the disease. Specifically, we suggest that a genetic variant in a functionally related gene acts as a modifier, influencing disease expression by conditioning the action of the primary pathogenic variant in *MEFV*.

Conclusion: Our approach can identify digenic and modifier interactions in rare diseases. We have identified a candidate modifier gene that may explain incomplete penetrance in FMF.

P15.054.A A combination of short-read and long-read sequencing elucidating the complex mechanism behind the gross genomic insertions in a variety of genetic disorders

Kornelia Tripolszki, *Mandy Radefeldt, Vasiliki Karageorgou, Javier Francisco Martini, Antonio Romito, Lígia Almeida, Arun Raj, Andreia Pinto, Rocio Garcia Jimenez, Anne-Kathrin Langenberg, Sabine Schröder, Isabel Sánchez Guiu, Marta Hervas Garcia, Matthias Bieg, Krishna Kumar Kandaswamy, Jorge Pinto Basto, Aida Bertoli-Avella, Peter Bauer*

CENTOGENE GmbH, Rostock, Germany.

Background: Structural variants (SVs) are defined as genetic variants greater than 50 base pairs and include insertions, deletions, duplications, and rearrangements. SVs are a major source of genetic diversity associated with different diseases and phenotypes. The detection of gross insertions is challenging because the mutant allele exceeds standard NGS technologies read length.

Material and Methods: To identify the causative variants in rare disease patients, short-read sequencing methods (panel, exome, and genome sequencing) were applied in diagnostic setting. In cases where gross insertions were detected, confirmatory analysis comprising PCR and Sanger sequencing of the insertion/breakpoints was performed. Long-read sequencing (Nanopore) was applied in all confirmed cases to characterize the inserted sequence.

Results: Using short-read sequencing methods as first-tier, we identified gross insertions in 11 different genes (*SLC37A4, CLCN1, ATP7A, BCKDHB, ITGB3, NAGLU, LDLR, NF1, SLC26A3, PKLR* and *COL6A1*). The sequence of origin of the insertions was found to be: intron of another gene (1 gene), processed pseudogene (1 gene), mobile element (8 genes), and mitochondrial sequence (1 gene). The phenotype of the patients were matching to the genes associated disorders in which the insertions were found.

Conclusion: Our study underscores the utility of combined sequencing approaches in rare disease diagnostics. The results show that gross insertions can be detected in various genetic disorders and this mechanism is to be considered especially in previously unsolvable cases. Short-read sequencing plays a crucial role as first-tier in detecting these variants and long-read sequencing is a complementary method to characterize the mechanism of disease-causing insertions.

P15.056.C Piloting BadgerSeq: A decentralized AI-assisted model for ultra-rapid long-read diagnostic genome sequencing

M Stephen Meyn[1], *Jessica M. Chen*[1], *Derek Pavelec*[2], *Brian Ross*[1], *Jadin Heilman*[1], *Leah A. Frater-Rubsam*[3], *Hieu T. Nguyen*[4], *Xiang-Qiang Shao*[3], *Vanessa Horner*[5], *Bryn D. Webb*[1], *April L. Hall*[1]

[1]*UW Center for Human Genomics and Precision Medicine/University of Wisconsin School of Medicine, Madison, WI, USA,* [2]*Biotechnology Center, University of Wisconsin School of Medicine, Madison, WI, USA,* [3]*State Laboratory of Hygiene, University of Wisconsin - Madison, Madison, WI, USA,* [4]*State Laboratory of Hygiene/University of Wisconsin - Madison, Madison, WI, USA,* [5]*Nationwide Childrens Hospital, Columbus, OH, USA.*

Background/Objectives: Rare genetic disorders affect >20% of patients in level IV NICUs, where rapid genome sequencing is becoming the genetic test of choice. BadgerSeq is designed to improve availability, quality, and speed of sequencing, with a goal of 96 hours from clinical presentation to laboratory results.

Methods: BadgerSeq selects patients for sequencing prior to a genetics consult by evaluating all NICU patients daily using artificial intelligence (AI) software. FastHPOCR software text mines their EMR for HPO terms, which are input into the Mendelian Phenotype Search Engine, which ranks patients for sequencing. Infants whose scores exceed a threshold are offered rapid trio long-read Nanopore genome sequencing followed by AI-assisted tertiary variant analysis.

Results to Date: We are testing BadgerSeq's patient selection workflow on a retrospective cohort of 339 NICU patients, of whom 33% had genetic consults and 20% underwent rapid exome/genome testing. Initial results indicate that the workflow runs efficiently in a secure computing environment on a single virtual PC. We are piloting BadgerSeq's sequencing workflow using trios (proband + parents) from our Undiagnosed Disease Program. The first 10 cases averaged 46–48 hours from DNA to completion of initial tertiary analysis. The workflow correctly identified pathogenic SNVs and structural variants in the 3 positive controls and suggested candidate variants for 3 of 7 unknowns.

Conclusions: Our initial results demonstrate the feasibility of BadgerSeq's AI-assisted ultra-rapid sequencing workflow, a workflow that will offer hospitals a faster, more comprehensive long-read alternative to the current model of centralized high volume rapid short-read genome sequencing.

Background: Structural variants (SVs) are a common cause of human diseases and contribute to inter-individual variability.

However, their detection remains challenging, especially when relying on short-read sequencing. To investigate and overcome these challenges, we combined an exhaustive selection of sequencing technologies in a cohort of nine individuals.

Material and Methods: We created a comprehensive SV detection benchmark to evaluate how each sequencing technology and SV caller perform across various settings as a guide for clinicians and researchers. Guided by our comparison, we designed a short-read-based machine learning model, dicast, to accurately identify true-positive (TP) SVs and demonstrate its applicability for clinical diagnostics.

Results: Our benchmark dataset includes 122,133 insertions, 104,099 deletions, 9,664 duplications, and 5,877 inversions. Dicast outperforms five leading short-read SV callers and consensus methods, identifying 79% more true-positive SVs than manta with comparable precision. It reduces false positives by 65% compared to the union of tested SV callers and increases true positives by 200% over consensus calling. We further demonstrate the clinical applicability of improved SV calling in three cohorts of rare disease patients with congenital limb malformations, neuromuscular disorders as well as atrial fibrillation.

Conclusion: While long-read-sequencing exhibits superior SV detection performance, short-read-sequencing remains more accessible, scalable, and less costly. We demonstrate that machine learning can push the boundaries of current short-read-based methods and dramatically reduces the need for time-consuming manual inspection of variants in the context of clinical diagnostics.

P15.058.A Mapping global innovations in genomic newborn screening: A comparative review of technology and implementation

N. Shah[1], *R. Heald*[1], *R. Reimers*[2], *N. Encina*[1], *D. Bick*[3], *R. Green*[4], *International Consortium on Newborn Sequencing;*

[1]*International Consortium on Newborn Sequencing, Boston, MA,* [2]*Rady Children's Institute of Genomic Medicine, San Diego, CA,* [3]*Genomics England, London, United Kingdom,* [4]*Brigham and Women's Hospital, Boston, MA*

Background: There are now over 30 research programs in genomic newborn screening (gNBS) worldwide, reflecting diverse strategies in approach, design, technology and implementation.

Project Name	Headquarters	Recruitment Goal	Status (Feb 2025)	Operational Model	Gene Content (Technology Backbone)	Sample	Genomic Test as first tier?
Anatolian Newborn Screening Program	Istanbul, Turkiye	10,000	Enrolling	Academic Multicenter	1393 (WGS)	Blood	Yes
Australian Targeted Genomic Newborn Screening Research Collaborative phase 2	Brisbane, Australia	60,000	Enrolling	Regional Public Health-Academic Multicenter	99 (Panel)	tNBS blood spot	Yes
BabyDetect	Liège, Belgium	40,000	Enrolling	Academic Single Center	405 (Panel)	Blood spot separate from tNBS	Yes
BabyScreen+	Melbourne, Australia	1000	Enrolling	Regional Public Health-Academic Multicenter	605 (WGS)	tNBS blood spot	Yes
BabySeq2	Boston, MA, USA	1000	Enrolling	Academic Multicenter	4299 (WGS)	Micropipette sample separate from tNBS	Yes
BeginNGS	San Diego, CA, USA	1,000,000	Enrolling	Academic Multicenter	>1500 (WGS)	Blood spot at same time, but separate from tNBS blood spot	Yes
Chen et al 2023	Shanghai, China	29,601	Post-enrollment	Academic Multicenter	142 (Panel)	tNBS blood spot	concurrent with tNBS
CRADLE	Bilthoven, Netherlands	under development	Pre-enrollment	National Public Health-Academic Multicenter	105 (Panel)	under development	Yes
EarlyCheck	Durham, NC, USA	10,000	Enrolling	State Public Health-Private-Academic Multicenter	188 (WGS)	tNBS blood spot	Yes

Project Name	Headquarters	Recruitment Goal	Status (Feb 2025)	Operational Model	Gene Content (Technology Backbone)	Sample	Genomic Test as first tier?
EpiGNs	Melbourne, Australia	100,000	Enrolling	Regional Public Health-Academic Multicenter	9 conditions (MS-QMA, methylation, WGS)	tNBS blood spot	No, low pass WGS as 3rd tier
EXAMEN	Moscow, Russia	7000	Post-enrollment	Academic Single Center	2350 (WES)	Umbilical cord blood sampling	Yes
FirstSteps	Athens, Greece	100,000	Enrolling	National Public Health-Private-Academic Multicenter	385 (WGS)	tNBS blood spot	Yes
Fecarotta et al 2025	Campagnia, Italy	108	Post-enrollment	Regional Public Health-Academic Single Center	105 (Panel)	tNBS blood spot	No, sequencing concurrent with confirmatory biochemical assay as 2nd tier
Generation Study	London, United Kingdom	100000	Enrolling	National Public Health Multicenter	463 (WGS)	Umbilical cord blood sampling	Yes
GenomaPuglia	Bari, Italy	3000	Enrolling	Regional Public Health-Academic Multicenter	407 (Panel)	tNBS blood spot	Yes
gnSTAR	Hangzhou, China	125,000	Post-enrollment	Academic Multicenter	154 (Panel)	tNBS blood spot	Yes
GUARDIAN Study	New York City, NY, USA	100,000	Enrolling	State Public Health-Academic Multicenter	450 (WGS)	tNBS blood spot	Yes
Lee et al 2019	Seoul, Korea	48	Post-enrollment	Academic Single Center	198 (Panel)	Blood spot separate from tNBS	Yes
NeoExome	Shanghai, China	3423	Post-enrollment	Academic Multicenter	601 (WES)	tNBS blood spot	Yes
NeoScreen	Queensland, Australia	under development	Pre-enrollment	Regional Public Health-Academic Single Center	under development	under development	Under development
NeoGen	Torino, Italy	4000	Post-enrollment	Academic Single Center	521 (WES)	tNBS blood spot	Yes
NeoSeq	Changzhou, China	196	Post-enrollment	Academic Single Center	136 (MTA-Seq)	tNBS blood spot	Yes
NESTS Phase 2	Beijing, China	11,484	Post-enrollment	Academic Single Center	465 (Panel)	Blood spot separate from tNBS	concurrent with tNBS
NewbornsInSA	Adelaide, Australia	1,000	Enrolling	Regional Public Health-Academic Multicenter	613 (WGS)	tNBS blood spot	concurrent with tNBS and Metabolomics
NEWBORN GEN SEQ TRAIL: NEWborn GENomic SEQuencing in	Sydney, Australia	1500	Enrolling	Regional Public Health-	605 (WGS)	Blood spot separate from tNBS	Yes

Project Name	Headquarters	Recruitment Goal	Status (Feb 2025)	Operational Model	Gene Content (Technology Backbone)	Sample	Genomic Test as first tier?
Screening: Therapy Ready And Information for Life Study				Academic Multicenter			
NEW LIVES: Genomic NEWborn screening programs - Legal Implications, Value, Ethics and Society	Heidelberg, Germany	under development	Pre-enrollment	National Public Health-Academic Multicenter	under development	under development	under development
PERIGENOMED Phase I	Dijon, France	2,500	Pre-enrollment	National Public Health-Private-Academic Multicenter	801 (WGS)	Blood spot at same time, but separate from tNBS blood spot	Yes
PREDiSPOSED Phase 1	Copenhagen, Denmark	2304	Pre-enrollment	Academic Multicenter	580 (Panel - Double Batch Sequencing Approach)	tNBS blood spot	Yes
Qataf Blooms	Doha, Qatar	4000	Pre-enrollment	Academic Single Center	114 (WGS)	Umbilical cord blood sampling	yes
Qingdao Newborn Genome Screening Program Phase 2	Qingdao, China	10,000	Post-enrollment	Academic Multicenter	234 (WGS)	Blood spot separate from tNBS	Yes
ScreenPlus	Bronx, NY, USA	100,000	Enrolling	State Public Health-Academic Multicenter	14 (Panel)	tNBS blood spot	No, sequencing of relevant gene only as 3rd tier
Screen4Care	Ferrara, Italy	25,000	Enrolling	National Public Health-Private-Academic Multicenter	245 (Panel)	dried blood spot (separate from tNBS)	Yes
Wang et al 2023	Nanjing, China	10,334	Post-enrollment	Academic Single Center	164 (Panel)	Blood spot at same time, but separate from tNBS blood spot	concurrent with tNBS

We highlight key regional initiatives and methodological differences.

Material and Methods: We compare and contrast the different approaches undertaken in implementing gNBS, including operational models, gene content, technology backbone and methodologies for consent, returning results and long-term follow up. Data have been compiled from personal communications, International Consortium on Newborn Sequencing conference proceedings and published literature.

Results: For the 33 programs with information available, genes assessed vary from 14 to 4299 (median 405; mean 592) on varied technology backbones [WGS = 13, targeted NGS panel = 13, WES = 3, other = 2, under development = 2], with majority using genomic testing (28) as a first-tier test. Some programs are focused on developing companion digital tools for education and consent (7), and studying metabolomics (1) and epigenomics (1). Operational models include Academic (16), Public Health (1), Public Health-Academic (12) and Public Health-Private-Academic (4).

Conclusion: The global landscape of gNBS is marked by a rich diversity of scientific approaches, technologies, operational models and implementation strategies. Each region's approach reflects its unique healthcare priorities, resource availability, and ethical considerations, clearly indicating that one size does not fit all. The current scarcity of gNBS outcome data, essential for defining best practices, also explains the diverse approaches. Future research and policy development should prioritize the creation of flexible, sustainable models that allow for localized modifications and drive equitable health outcomes.

P15.059.B Deciphering the expression signature in Kleefstra Syndrome by RNAseq

Laura Pezzoli[1], *Camilla Lucca*[1], *Matteo Bellini*[1], *Daniela Marchetti*[1], *Francesca Cappuccini*[1], *Lucrezia Goisis*[1], *Silvia Castiglioni*[2], *Chiara*

Baldo[3], Alessia Arado[3], Michela Mura[4], Camilla Meossi[5], Giulia B. Marchetti[4], Donatella Milani[4], Valentina Massa[2,6], Cristina Gervasini[2], Maria Iascone[1]

[1]Laboratorio Genetica Medica, ASST Papa Giovanni XXIII, Bergamo, Italy, [2]Dipartimento di Scienze della Salute, Università Degli Studi di Milano, Milano, Italy, [3]Laboratorio di Genetica Umana IRCCS Istituto Giannina Gaslini, Genova, Italy, [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milano, Italy, [5]Medicina Molecolare, IRCCS Fondazione Stella Maris, Pisa, Italy, [6]"Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, Università Degli Studi di Milano, Milano, Italy.

Background: Haploinsufficiency of *EHMT1* is the leading cause of Kleefstra syndrome (KLEFS, OMIM #610253), a rare condition characterized by severe neurodevelopmental disorder and multisystemic involvement. Large or intragenic deletions, splicing, and truncating variants are the most common causes of KLEFS, but pathogenic missense variants are also reported and tentatively associated with a milder phenotype. We aim to characterize the expression pattern of *EHMT1* and related pathways in patients with KLEFS to deepen our understanding of the pathogenetic mechanism and attempt a genotype-phenotype correlation.

Material and Methods: Patients were enrolled in the setting of a multicenter study. Genetic data and blood samples were collected. Lymphoblastoid cell lines (LCLs) were obtained from blood cells of patients with different pathogenetic variants and used to perform RNAseq. We obtained and analyzed 18 KLEFS LCLs and compared them to 10 healthy controls. Relative *EHMT1* expression was calculated by comparing the normalized TPM (transcripts per million) value of *EHMT1* and housekeeping genes. Edger and DESeq2 assessed differential expression patterns, and enrichment analysis was performed using the ORA (over-representation analysis) method.

Results: The expression levels of *EHMT1* are significantly reduced in KLEFS LCLs, with slight differences among different types of mutations. We identified three impaired pathways involved in neuronal homeostasis and extracellular matrix interaction.

Conclusion: Our preliminary results catch a glimpse on the biological effects of different *EHMT1* defects, possibly unravelling new genotype-phenotype correlations and identifying novel candidate targets for future therapies.

P15.060.C Development of iPSC-derived vascular smooth muscle cell-model for Loeys-Dietz syndrome type V aortic phenotype

Lucia Buccioli[1], *Melanie Perik[1], Laura Rabaut[1], Lotte Van Den Heuvel[1], Maaike Bastiaansen[1], Joe Davis Velchev[1], An Wouters[2], Erik Fransen[1], Lut Van Laer[1], Aline Verstraeten[1], Bart Loeys[1,3]*

[1]Center of Medical Genetics, University of Antwerp and Antwerp University Hospital, Antwerp, Belgium, [2]Center for Oncological Researchn University of Antwerp, Antwerp, Belgium, [3]Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands.

Background: Thoracic aortic aneurysm and dissection (TAAD) is a hallmark of Loeys-Dietz syndrome (LDS) and a prominent cause of sudden death. Unfortunately, the pathophysiology of TAAD remains largely elusive which complicates therapy development. A human in vitro model that closely recapitulates the disease phenotype is required to gain better insight into the pathomechanisms underlying TAAD as well as to expedite the development of new treatments.

Material and Methods: In this preliminary study, induced pluripotent stem cell (iPSC)-derived neural crest-vascular smooth muscle cell (NC-VSMC) lines from two TAAD-presenting LDS type V (LDS-V) patients carrying a likely pathogenic p.(Asp263His) variant in TGFB3 and a healthy control were generated and characterized at transcriptional and translational levels.

Results: Consistent with previous biochemical analysis of LDS-V aortic tissue, we observed a trend towards reduction in contractile marker expression along with reduced contractility and calcium flux upon stimulation with the thromboxane A2 receptor agonist U46619 in patient versus control NC-VSMCs. Additionally, we observed upregulation of the transforming growth factor beta (TGFβ) pathway, a well-known contributor to syndromic TAA. Interestingly, the cellular phenotype differed between the NC-VSMCs of the two patients, with one patient exhibiting a more deteriorated cellular phenotype, aligning with his more severe TAAD phenotype.

Conclusion: For the first time we describe iPSC-VSMC modelling of LDS-V. The obtained data suggest that iPSC-derived NC-VSMCs from LDS-V patients recapitulate at least part of the disease phenotype. Upon consolidation of our findings in additional NC-VSMC clones, we deliver the TAAD community a novel tool for preclinical LDS-V research.

P15.061.D The homozygous *FICD* p.(Arg371Ser) variant causes a syndrome of neonatal diabetes, cataracts and developmental delay through a variant-specific mechanism

Suhel Ahmed, *Matthew Johnson, Kashyap Patel, Andrew Hattersley, Sarah Flanagan, Elisa De Franco*

University of Exeter, Exeter, United Kingdom.

Background: Variant-specific disease mechanisms, where different variant(s) in the same gene cause different disorders, are increasingly being identified in human monogenic disease. We recently identified a homozygous *FICD* variant, p.(Arg371Ser), in 5 individuals with neonatal diabetes (NDM), cataracts and developmental delay (DD). We hypothesised that this phenotype was variant-specific as a different recessive *FICD* variant, p.(Arg374His), causes spastic paraplegia-92. The clinical features of spastic paraplegia-92 did not overlap with those in our 5 cases. Biochemical studies predicted both variants to similarly affect *FICD*'s function. It is therefore unclear how these variants cause distinct phenotypes. Here, we further explore whether the *FICD* p.(Arg371Ser) variant causes NDM in a variant-specific manner.

Material and Methods: We screened for rare (GnomAD MAF <0.01%) biallelic *FICD* variants in 384 probands with diabetes diagnosed <3years of unknown genetic cause using genome sequencing.

Results: We identified four additional individuals homozygous for the *FICD* p.(Arg371Ser) variant, taking the total to 9. 8/9 (including 5/5 original cases) had the same nucleotide change (NM_007076.2:c.1113G>C). Importantly, the ninth case harboured a different nucleotide change (NM_007076.2:c.1113G>T). Clinically, age at diabetes onset ranged between 12 weeks and 2 years (median = 29.5 weeks). Early-onset cataracts (4/9) and DD (5/9)

were common features. No spastic paraplegia-92 features were reported.

Conclusion: Identification of the *FICD* p.(Arg371Ser) variant in nine individuals, including one with a different nucleotide change, strongly supports that this variant causes NDM, cataracts and DD via a variant-specific mechanism. Further studies are needed to understand the mechanisms underlying the specific phenotypes caused by *FICD* variants.

P15.062.A CLINICAL, DEMOGRAPHIC AND GENOTYPE SPECIFIC ASSOCIATIONS IN HERITABLE TP53-RELATED CANCERS

Alexandre Dias[1,2], *Rita Matos*[1], *Rita Quental*[3], *Luis F. Maia*[4], *Carla Oliveira*[1,5]

[1]*i3S - Institute for Research and Innovation in Health, Porto, Portugal,* [2]*ICBAS - Instituto de Ciências Biomédicas Abel Salazar, University of Porto, Porto, Portugal, Porto, Portugal,* [3]*Human Genetics Department, Centro Hospitalar Universitário São João, (CHUSJ), Porto, Portugal, Porto, Portugal,* [4]*Department of Neurology, Centro Hospitalar Universitário de Santo António, ULSdSA, Porto, Portugal,* [5]*Faculty of Medicine, University of Porto, Porto, Portugal.*

Background: Heritable *TP53*-related cancer (h*TP53*rc) syndrome is an autosomal dominant disorder caused by germline *TP53* variants, leading to the early onset of multiple cancers. Essential genotype-phenotype data is missing to improve h*TP53*rc management guidelines. This study aims to provide a comprehensive genotype-phenotype analysis to deliver clinical-, demographic- and genotype-specific associations.

Material and Methods: We curated the germline dataset from International Agency for Research on Cancer TP53 database (R20). For genotype-phenotype analysis, we: (1) considered families with at least one confirmed germline carrier; (2) standardized phenotypes; (3) classified variants regarding pathogenicity (ACMG) and predicted functional impact (dominant-negative effect [DNE] and loss-of-function [LOF]). Statistical analysis were performed with RStudio.

Results: The curated dataset comprised 2.733 phenotypes from 2.071 individuals (62.7% females), from which 34.3% developed the first cancer between 0–17 years, while 14.5% were diagnosed after 50. Phenotypes were grouped into 24 cancer-types associated with 202 pathogenic/likely-pathogenic variants (55.4% DNE_LOF, 13.7% notDNE_LOF, and 30.9% unkownDNE_-LOF). Three major female cancer-susceptibility profiles were identified: **(1)** variants in codon-133 were associated with breast carcinomas between 18–49 years ($OR = 3.8$, $p = 0.010$); **(2)** c.824G>A variant was associated with soft-tissues sarcoma ($OR = 6.5$, $p < 0.001$); **(3)** c.1010G>A variant was associated with adrenal gland carcinomas, between 0–17 years ($OR = 23.4$, $p < 0.001$). Additionally, patients carrying DNE_LOF variants with a first diagnosis between 0–17 years were 2.3-fold more likely to develop multiple malignancies than notDNE_LOF ($p = 0.007$). Lastly, variants c.659A>G and c.844C>T were significantly associated with lower age-of-diagnosis.

Conclusion: This genotype-phenotype analysis provides the rationale and context to prioritize intensive surveillance and/or prophylaxis across hTP53rc patients.

P15.063.B A prediction of the economic impact of whole-genome sequencing on the diagnostic pathway of paediatric rare genetic diseases: a multi-centre analysis

Maria Palomares Bralo[1], *Antonio Novelli*[2], *Dario Cocciadiferro*[2], *Fe Amalia García Santiago*[1], *Fernando Santos-Simarro*[3], *Marta Pacio Míguez*[4], *Carmen Rodríguez Jiménez*[1], *Mª de los Ángeles Gómez Cano*[1], *Anna Baggi*[5], *Victoria Lucia Rabsiun Aramburu*[5], *Maria Antonietta Magno*[5], *Lidia Pezzani*[6], *Erica Rosina*[6], *Laura Pezzoli*[6], ***Maria Iascone***[6]

[1]*Instituto de Genética Médica y Molecular (INGEMM) Hospital Universitario La Paz, Madrid, Spain,* [2]*Bambino Gesù Children Hospital, Rome, Italy,* [3]*Unidad de Diagnóstico Molecular y Genética Clínica (UDMGC). Hospital Universitari Son Espases, Palma de Mallorca, Spain,* [4]*Servicio de Genética del Hospital Universitario Ramón y Cajal, Madrid, Spain,* [5]*Business Integration Partners S.p.A, Milan, Italy,* [6]*ASST Papa Giovanni XXIII, Bergamo, Italy.*

Background: Diagnosing rare genetic diseases in children involves prolonged, costly pathways with low diagnostic yield (DY). This analysis evaluates comprehensive genomic testing versus traditional diagnostic approaches in paediatric rare diseases.

Material and Methods: Data were collected in 2023–24 at two Italian and one Spanish centres through semi-structured interviews mapping and costing two patient settings: hypotonic inpatients in Intensive Care Units (ICUs) receiving genetic testing, outpatients with suspected neurodevelopmental disorders facing prolonged diagnostics. Incremental costs for diagnosed patient (IC: cost to reach a diagnosis divided by DY of technique used) were compared across past (without clinical exome sequencing [CES], Whole-Exome Sequencing [WES] or WGS), current (CES, WES, WES+Chromosomal Micro Array), and future (WGS) scenarios.

Results: Across centres, ICU costs (limited to pre-diagnosis ICU days) constituted up to 99% of pre-diagnosis inpatients expenses in all scenarios, while genetic testing was a minor component. As diagnostic techniques advanced, DY increased (e.g., past-15%, current-50% predicted-65%) while pre-diagnosis days in ICU and relative costs-to-diagnosis decreased (e.g., from 180 to 20 and 12 days, from € 297k to € 32.2k and €19.8k). For outpatients, DY similarly rose (e.g., from 19% to predicted 60%) with expected moderate cost increases in future. Overall, IC is expected to decrease as techniques evolve (e.g., inpatients: €2,007k to €72.4k and €38.4k; outpatients: €27.6–19.9k to €9.5k and €8.5k).

Conclusion: CES and WES are routine in all centres, with WGS anticipated to follow. WGS is predicted to improve DY, reduce IC, shorten diagnostic time, improving care for children with rare genetic diseases.

P15.064.C Phenotypic and genotypic comparison between severe forms and microform of holoprosencephaly in a cohort of 173 individuals with pathogenic variants in *SHH* gene

Ophélie Boutfol[1,2], *Paul Rollier*[1,2,3], *Valérie Dupé*[3], *Artem Kim*[4,5], *Alinoé Lavillaureix*[1,3], *Wilfrid Carré*[2], *Christèle Dubourg*[2,3], *Sylvie Odent*[1,3]

[1]Rennes university hospital - clinical genetic department, Rennes cedex 2, France, [2]Rennes University Hospital, Molecular Genetics and Genomics Laboratory, Rennes, France, [3]Rennes University, Rennes Institute of Genetics and Development (IGDR), CNRS INSERM-UMR6290 ERL U1305, Rennes, France, [4]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA, [5]Center for Genetic Epidemiology, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA.

Background: Holoprosencephaly (HPE) is a congenital condition caused by incomplete cleavage of the cerebral hemispheres during embryonic development, resulting in a range of cerebral and craniofacial abnormalities. This study compares the differences between severe (alobar, semilobar, lobar) forms and microforms of HPE in individuals with pathogenic variants in the most frequently gene implicated in HPE, *SHH*.

Material and Methods: The data of 173 individuals (77 probands, 96 relatives) were collected from HPE database which lists patients suffering from HPE in Europe and for which advice has been requested in Rennes University Hospital, France.

Results: 47.4% of individuals exhibited microforms of HPE, while 18.5% had alobar forms, 9.2% semilobar forms, 5.2% lobar forms, and 9.8% were asymptomatic (relatives). The analysis showed that severe forms of HPE were significantly associated with higher rates of brain, adrenal and craniofacial anomalies compared to microforms ($p < 0.05$). In contrast, dental malformations and nasal cavity abnormalities were more frequent in microforms ($p < 0.01$). Importantly, in a specific region of the *SHH* gene (amino acids 275–330), we didn't found any pathogenic variants, although benign variants have been described, which suggests that variant in this area may not be pathogenic.

Conclusion: These findings emphasize the distinctive clinical features of microforms compared with severe forms and broaden the spectrum of malformations associated with HPE related to *SHH* (adrenal malformations, over-representation of dental and nasal cavity abnormalities in microforms). The study highlights the complexities of genetic counseling in HPE: intra- and inter-familial variability, intellectual disability even in microforms (38%), and oligogenism.

P15.065.D Telomere biology disorders- clinical service, dilemmas and challenges

Noa Hourvitz[1,2], *Dan Lichtental*[2], *Riham Smoom*[2], *Monica Neustadter*[2], *Avraham Untermann*[3,4], *Alina Kurolap*[1], *Adi Mory*[1], *Uri Hamiel*[1,4], *Yael Hoffman*[1,4], *Hagit Feldman Baris*[1,4], *Yehuda Tzfati*[2], *Daphna Marom*[1,4]

[1]The Genetic Institute and Genomics Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Tel Aviv, Israel, [2]Department of Genetics, The Silberman Institute for Life Sciences, The Hebrew University of Jerusalem, Jerusalem, Israel, Jerusalem, Israel, [3]Pulmonary Fibrosis Center of Excellence, Tel Aviv Medical Center, Israel, Tel Aviv, Israel, [4]School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel, Tel Aviv, Israel.

Background: Germline variants affecting telomere maintenance cause Telomere Biology Disorders (TBDs). Adult-onset TBDs include pulmonary fibrosis, bone marrow and liver diseases. Lack of clinical guidelines may delay diagnosis and tailored management in late-onset TBDs. We describe our experience in a novel TBD clinic.

Material and Methods: Cohort analysis of patients referred to the TBD clinic at the Genetics Institute at the Tel-Aviv Medical Center from February to December 2024. Indications for referral, phenotypes and diagnostic tests, including telomere length and sequencing results, are reviewed.

Results: Twenty-four probands were referred to our clinic. Average age at first visit was 56 years (range 3–81 years), 17/24 (70.8%) were familial and 7/24 (29.2%) were simplex cases. Ethnic origin was Jewish in 22/24 (91.7%). Two probands were from consanguineous non-Jewish families. Phenotypes included pulmonary fibrosis in 20/24, (83.3%), myelodysplasia in 2/24 (8.3%), liver fibrosis in one (4.2%), and multisystem disease in one (4.2%). Compared to controls, 20/21 (95%) showed short telomeres, 4 of whom measured in the extremely short range. Variants in TERC, TERT and MDM4 confirmed TBD in 5/7 (71.4%), who performed genetic testing. Diagnostic challenges and management dilemmas included negative next-generation-sequencing in familial pulmonary fibrosis, variant interpretation, selection of bone marrow donors in a familial TERT-related TBD, and follow-up of first-degree relatives in TERC-related TBD.

Conclusion: TBDs are complex disorders. A collaborative multidisciplinary approach is vital in management of patients. The advent of available precision medicine mandates their early diagnosis. Further studies will help to establish clinical guidelines and healthcare public funding.

P15.066.A Concordant epigenetic and discordant clinical iPPSD3 manifestations in two monozygotic adolescent twins

Africa Manero-Azua[1], *Gustavo Perez-Nanclares*[2], *Arrate Pereda*[3], *Gema Grau*[2], *Yerai Vado*[1], *June Corcuera*[4], *Itxaso Rica*[2], *Alejandro Garcia-Castaño*[4], *Ainhoa Camille Aranaga-Decori*[4], *Luis Castano*[2], ***Guiomar Perez de Nanclares***[1]

[1]Bioaraba Health Research Institute, Araba University Hospital, Vitoria-Gasteiz, Spain, [2]Biobizkaia Health Research Institute, Cruces University Hospital, Cruces, Barakaldo, Spain, [3]Bioaraba Health Research Institute, Vitoria-Gasteiz, Spain, [4]Biobizkaia Health Research Institute, Cruces, Barakaldo, Spain.

Background: iPPSD3, formerly pseudohypoparathyroidism 1B, is characterized by PTH resistance, hypocalcemia, hyperphosphatemia and, sometimes, TSH resistance. It is caused by epigenetic variants occurring in one or more *GNAS*-DMRs, with consistent hypomethylation at *GNAS A/B*:TSS-DMR. We describe monozygotic 14-year-old twins, one with clinical features suggestive of iPPSD3 and the other with unaltered phosphocalcic metabolism.

Material and Methods: Analysis of the *GNAS* locus by MS-MLPA (ME031 kit; lot: C1-0523) was performed on saliva and blood samples from both twins. Uniparental disomy of chromosome 20q was assessed through SNParray, a custom MS-MLPA (targeting *GNAS, L3MBTL1, NNAT* and *MCTS2P* DMRs) and microsatellite typing. Finally, genome-wide by long-read sequencing was performed on blood and saliva samples.

Results: MS-MLPA revealed similar partial methylation disturbance for all *GNAS*-DMRs in both twins´ blood samples, whereas the healthy sister´s saliva suggested fewer epigenetic alterations. The long-read sequencing study, which does not modify or digest the DNA, and performs control-independent analysis, revealed the same methylation pattern in both blood samples, but different at maternal alleles in saliva (Table).

Methylation percentages detected by long-read sequencing									
		GNAS-NESP:TSS-DMR		*GNAS-AS*:TSS-DMR		*GNAS-XL*:TSS-DMR		*GNAS A/B*:TSS-DMR	
		Blood	Saliva	Blood	Saliva	Blood	Saliva	Blood	Saliva
Control	Paternal allele (%)	100	100	0	0	0	0	0	0
	Maternal allele (%)	0	0	100	100	100	100	100	100
Affected twin	Paternal allele (%)	100	100	0	0	0	0	0	0
	Maternal allele (%)	40	65	40–50	0–25	50	25	50	25
Healthy twin	Paternal allele (%)	100	100	0	0	0	0	0	0
	Maternal allele (%)	25	50	25–50	75	50	75	50	50

Conclusion: Given the clinical discordance and the epigenetic findings, we postulate that the epigenetic alteration occurred postzygotically, but before zygote cleavage. Probably, the altered cells in each of the sisters migrated to different embryonic cell lines, involving those related with phosphocalcic metabolism in the affected twin but not in her sister.

P15.067.B Application of polygenic risk scores for Latvian hypercholesterolemia patient differentiation

Ivanna Atava[1], *Monta Briviba*[1], *Janis Klovins*[1,2], *Gustavs Latkovskis*[3,2,4]

[1]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [2]*Faculty of Medicine and Life Sciences, University of Latvia, Riga, Latvia,* [3]*Institute of Cardiology and Regenerative Medicine, University of Latvia, Riga, Latvia,* [4]*Latvian Center of Cardiology, Pauls Stradins Clinical University Hospital, Riga, Latvia.*

Background: Polygenic hypercholesterolemia (PH) comprises about 30% of patients with a clinical diagnosis of familial hypercholesterolemia (FH). In our recent study, we applied the published LDL-C PRS (PGS000115) to explore the genetic background of Latvian patients with clinical FH diagnosis. The chosen score had overall good discriminatory ability. Nevertheless, despite the availability of pre-existing PRS models for the LDL-C trait, selecting the most fitting score for a specific population, even with European origin, remains a challenge.

Material and Methods: The DNA from 329 adults with clinical FH diagnosis and 515 controls from the Latvian reference cohort was sequenced using the MGI DNBSEQ-T10×4RS platform. The PRS was calculated using 118 publicly available LDL-C PRS models from the PGS Catalog.

Results: Ninety-seven PRS met the minimum match rate threshold of 0.75. The PGS004793 model reached the highest area under the curve (AUC = 0.82) among models developed in European ancestry cohorts and the third highest overall. There was a positive correlation between the number of SNPs included in a model and AUC ($p = 0.006$). The PGS000115 and PGS004793 differentiated FH and non-FH groups, but PGS004793 showed stronger discriminatory ability and less variability in PRS distributions. The proportion of FH patients decreased with higher PRS percentiles, with PGS004793 displaying more pronounced differences between LDL-C PRS quartiles.

Conclusion: The number of SNPs positively correlated with PRS model performance. While both models performed well, PGS004793 explained 40.08% of PH inheritance in non-FH cases, compared to19.84% by PGS000115, making it more effective model.

P15.068.C miRNA expression profile in symptomatic and presymptomatic genetic FTD

Chiara Fenoglio[1], *Maria Serpente*[2], *Marina Arcaro*[1], *Tiziana Carandini*[2], *Luca Sacchi*[2], *Manuela Pintus*[2], *Emanuela Rotondo*[2], *Giulia Giudici*[2], *Laura Ghezzi*[1], *Andrea Arighi*[1], *Daniela Galimberti*[1], *GENFI group*[3]

[1]*University of Milan, IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [2]*IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [3]

Background: Frontotemporal dementia (FTD) is a neurodegenerative disease characterized by significant clinical and genetic heterogeneity, with approximately 40% of cases linked to hereditary genetic mutations, including MAPT, GRN, and C9ORF72. Recently, microRNAs (miRNAs) have emerged as key regulators of cellular processes related to neurodegeneration and as potential biomarkers for FTD. However, their relevance in presymptomatic stages remains poorly understood.

Material and Methods: We conducted a miRNA expression analysis using TaqMan OpenArray® panels on blood samples collected from 171 individuals, including symptomatic mutation carriers (SMC), presymptomatic carriers (PMC) and healthy non carriers (NC). Dysregulated miRNAs were validated and further investigated.

Results: In C9ORF72, miR-20b-5p and miR-223-5p were significantly upregulated in SMC (fold regulation over NC: 2.418 $p = 0.0336$ and 7.829 $p < 0.0264$ respectively), and PMC (5.518, $p < 0.0001$ and 3.941, $p < 0.0001$ respectively). In GRN mutation carriers, miR-28-3p was altered in both SMC and PMC (fold regulation over NC: 1.484 $p < 0.050$ and 3.287, $p < 0.050$). In MAPT mutation carriers, miR-28-5p, miR-192-3p, miR-25-3p, and miR-532-3p were altered only in SMC (fold regulation over NC: 1.496 $p < 0.050$, 1.911 $p = 0.006$, 1.468 $p < 0.05$ and 0.728 $p < 0.05$). Bioinformatic analysis revealed enrichment of pathways related to neurodegeneration and synapse impairment.

Conclusion: These results suggest that miRNA expression levels are de-regulated in mutated SMC, and also in *C9ORF72* and *GRN* PMC. Notably, miR-20b-5p, miR-223-5p, and miR-28-3p were increased in preclinical stages of the disease, supporting their role as early biomarkers for *C9ORF72*-FTD and *GRN*-FTD. Conversely, alterations in *MAPT* carriers appeared only in symptomatic stages, suggesting a different involvement in disease progression.

P15.071.B Proteomics analysis in a diverse cohort of 50 unsolved cases with suspicion of a rare genetic disorder

Kaisa T. Oja[1,2], *Dmitrii Smirnov*[3,4], *Robert Kopajtich*[4,3], *Lea D. Schlieben*[4], *Tiia Reimand*[2,1], *Karit Reinson*[2,1], *Laura Roht*[2], *Kai Muru*[2,1], *Piret Merstina*[2,1], *Sander Pajusalu*[1,2], *Holger Prokisch*[3], *Katrin Ounap*[2,1]

[1]*University of Tartu, Department of Genetics and Personalized Medicine, Tartu, Estonia,* [2]*Tartu University Hospital, Genetics and Personalized Medicine Clinic, Tartu, Estonia,* [3]*Klinikum rechts der Isar der Technischen Universitat Munchen, Munich, Germany,* [4]*Helmholtz Zentrum München, Munich, Germany.*

Background: Rare diseases, approximately 80% of which are genetic, pose a significant burden on the healthcare system. Despite advancements in diagnostic methods, particularly next-generation sequencing, many cases remain unsolved.We aimed to use a multi-omics approach, mainly transcriptomics and proteomics, to investigate unsolved cases with a suspicion of a genetic disorder.

Material and Methods: Our cohort consisted of 50 unsolved cases with heterogeneous phenotypes, including neurodevelopmental disorders with variable severity (31/50, 62%), epilepsy (7/50, 14%), suspicion of mitochondrial disorder (7/50, 14%), and other clinical presentations. The median age of individuals was 8 years, ranging from 1 to 63 years. The male-to-female ratio was roughly equal, with 28 (56%) male participants. All patients had undergone exome sequencing (mostly trios 44/50, 88%) but remained unsolved. For the proteomics, we used cultured skin fibroblasts, and the results were bioinformatically analyzed using the PROTRIDER pipeline. We combined different multi-omics results manually.

Results: Overall, the PROTRIDER pipeline identified 442 proteins with aberrant expression (adjusted p-value < 0.1), of which 256 (57.9%) showed reduced expression (fold-change <1). Among the proteins with significantly low expression, three cases were particularly relevant to the phenotype, but no corresponding DNA variants were identified.

Conclusion: Despite employing a multi-omics approach, no definitive disease-causing variants were identified in our unsolved patients' cohort after proteomics analysis. We believe proteomics is more effective in cases with well-defined and specific phenotypes. The diversity and ambiguity of our cohort may have limited the approach's effectiveness.

P15.072.C Uniparental isodisomy as a mechanism of inheritance of autosomal recessive diseases

Anna Stepanova*, Elena Zinina, Natalya Ogorodova, Vitaly Kadyshev, Lyudmila Bessonova, Inna Sharkova, Oxana Ryzhkova, Olga Schagina, Alexander Polyakov*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Uniparental disomy (UPD) is a rare pathology in which diploid offspring carry a chromosome pair from one parent. We report cases of uniparental disomy leading to diseases with a traditionally autosomal recessive type of inheritance.

Material and Methods: Sequencing of targeted panels "Ophthalmo", "Limb-Girdle Muscular Dystrophies", "Clinex", including genes responsible for various hereditary pathologies. Validation of variants was performed by Sanger sequencing of the *RPE65, SGCD, PREPL* genes. Analysis of the copy number of the corresponding genes using MRC-Holland kits. Relationship was confirmed by analyzing microsatellite markers on 12 different chromosomes. Microsatellite marker analysis of the studied gene region on chromosomes 1, 2 and 5.

Results: In four patients with referral diagnoses of LCA (2 probands), limb-girdle muscular dystrophy and congenital myasthenia, pathogenic variants were identified in the *RPE65, SGCD* and *PREPL* genes, respectively, in a homo-/hemizygous state. When determining zygosity, it was found that one of the patient's parents did not have a pathogenic variant in the studied gene. Two copies of the corresponding genes were detected in the probands and their parents. Relationship was confirmed in all families. To prove the hypothesis of UPD, an analysis was performed using polymorphic markers from the studied gene region. It was found that each of the probands lacked alleles of one of the parents, which indicates UPD for the chromosomal region containing the studied genes.

Conclusion: The established mechanism of inheritance is an important step towards accurate medical genetic counseling.

P15.073.D Individualized genetic testing of patients with renal and cardiac diseases at the University of Debrecen

Orsolya Nagy[1], *Katalin Koczok*[1], *Eszter Kovács*[1], *János Mátyus*[2], *Tamás Szabó*[3], *Attila Borbély*[4], *Beáta Bessenyei*[1], *László Madar*[1], *István Balogh*[1,5]

[1]*Division of Clinical Genetics, Department of Laboratory Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary,* [2]*Division of Nephrology, Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary,* [3]*Department of Pediatrics, Faculty of Medicine, University of Debrecen, Debrecen, Hungary,* [4]*Department of Cardiology, Faculty of Medicine, University of Debrecen, Debrecen, Hungary,* [5]*Department of Human Genetics, Faculty of Medicine, University of Debrecen, Debrecen, Hungary.*

Background: Inherited renal and cardiac diseases are clinically and genetically heterogeneous. Next-generation sequencing (NGS) studies have previously described several mutated genes in the background of these diseases. Therefore, two targeted NGS gene panels have been established in our department to identify mutations in the affected patients.

Patients and Methods: We have tested patients with suspected genetic kidney (n = 33) and heart (n = 49) diseases. The nephrology (n = 33) and cardiology (n = 43) genes were sequenced using NGS method. All small-scale mutations were confirmed by Sanger sequencing. Copy number variations (CNVs) were confirmed using multiplex ligation-dependent probe amplification (MLPA).

Results: NGS gene panel analysis showed 39% positivity rate (n = 13) in case of patients with renal disorders and 18% diagnostic efficiency (n = 9) in patients with cardiac diseases, which correlates with the international data. We found genetic alterations most frequently in the *PKHD1* (n = 5) and *COL4A3* (n = 4) genes using Nephrology NGS gene panel. Four patients had mutation in other genes. The most common mutation type was missense (n = 9), followed by three cases of CNVs and nonsense mutations (n = 2). The most prevalently mutated gene was *TTN* (n = 2) in the patients with hereditary cardiac disease. In addition, causative mutations were detected in the following genes: *ACTC1*, *DSG2*, *FLNC*, *KCNQ1*, *MYBPC3*, *PLN* and *TNNI3*. In these, we identified mainly missense (n = 3), nonsense (n = 2),

frameshift (n = 2), splicing (n = 1) and synonymous (n = 1) mutations.

Conclusion: The early indication of genetic testing in patients with unusual or progressive renal and cardiac disease can improve the diagnostic efficiency, and may influence the therapeutic decision making.

P15.074.A The potential utility of WES in newborn screening workflow

Diana Postorivo, Cristina Montrasio, Alessandra Vasco, Simona Lucchi, Andrea Meta, Elisa Pratiffi, Alessia Mauri, Francesca Fiumani, Joranda Ceku, Carola Sanguinazzi, Clarissa Berardo, ***Stephana Carelli****, Cristina Cereda*

Center of Functional Genomics and Rare diseases Department of Pediatrics Buzzi Children's Hospital, Milan, Italy.

Background: Newborn Screening(NBS) is a major Italian public health program to screen all newborns to prevent the long-term consequences of inborn errors of metabolism (IEMs). Immunochemistry and tandem-mass spectrometry are currently the gold-standard methods for NBS, but false-positive cases are still common (0.3%/year). We evaluated the feasibility of including next-generation sequencing(NGS) in NBS workflow to reduce the number of false positives.

Material and Methods: We perfomed Whole Exome Sequencing(WES) on genomic DNA extracted from dried blood spots(DBS) of 39 newborns positive to biochemical first-tier-test of NBS and referred to clinical evaluation. Libraries were prepared with "Illumina DNA Prep with Exome 2.5 Enrichment" and sequenced on NextSeq2000 (Illumina). Analysis was performed first using a virtual panel of 125 genes related to IEMs. Whole exome was analyzed in negatives or heterozygous cases. Variants were classified according to ACMG criteria.

Results:20/39(51.3%) cases had no variants in genes implicated in metabolic diseases; 13/39(33.3%) were heterozygous and 3/39(7.7%) compound heterozygous,3/39(7.7%) were homozygous for variants in ACADVL, ACADS and GALE genes. Variants in ACADVL and ACADS are pathogenic, while GALE variant is likely benign, more common among African-American populations and associated with a mild-form of epimerase deficiency galactosemia.

Conclusion: These results show that WES introduction in NBS workflow reduce the number of false positives and then patient's number monitored by clinicians. Only 2/39 cases, with this approach, would have been referred to clinical centers, while heterozygous could have followed another clinical pathway, without the need for immediate intervention, reducing costs and parental anxiety and allowing more efficient care management.

P15.075.B Expanding the diversity of genetic mechanisms in rare diseases through Long-Read sequencing

Belén de la Morena-Barrio[1]*, Pedro Garrido-Rodriguez*[1]*, Maria Eugenia de la Morena-Barrio*[1]*, Maria Llamas-López*[1]*, Esther Navarro-Manzano*[1]*, Jose Padilla-Ruiz*[1]*, Juan Jose Rojo-Carrillo*[1]*, Carlos Bravo-Pérez*[1]*, Ana Zamora-Cánovas*[1]*, Mari Luz Morales*[1]*, María Elena Fernández Suárez, PhD*[2]*, Nina Borràs*[3]*, Francisco Vidal*[3]*, María González-del Pozo*[4]*, Jose Rivera*[1]*, Francisca Ferrer-Marin*[1]*, Vicente Vicente Garcia*[1]*, Maria Luisa Lozano Almela*[1]*, Javier Corral de la Calle*[1]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Pascual Parrilla, CIBERER, Murcia, Murcia, Spain, [2]Hospital Universitario Virgen del Rocío, Sevilla, Spain, [3]Laboratori Coagulopaties Congènites, Banc de Sang i Teixits, Barcelona, Spain; Medicina Transfusional, Vall d'Hebron Research Institute, Universitat Autònoma de Barcelona (VHIR-UAB),CIBERCV, Barcelona, Spain, Barcelona, Spain, [4]Department of Maternofetal Medicine, Genetics and Reproduction, Institute of Biomedicine of Seville (IBiS), University Hospital Virgen del Rocío/CSIC/University of Seville, Center for Biomedical Network Research on Rare Diseases (CIBERER) Seville, Spain, Sevilla, Spain.

Background: Next-generation sequencing methods have revolutionized genetic diagnosis, although they present certain limitations due to short reads. We explored the strengths of long-read sequencing with nanopore in rare diseases.

Material and Methods: Long-range (LR) PCRs were barcoded and sequenced in MinION. Whole genome or targeted sequencing of unmanipulated DNA was done in MinION or PromethION. Sniffles, Clair3 and modkit, were used to identify structural variants (SVs), SNVs or epigenetic changes.

Results: 1) Identification of founder effect. LR-PCRs and sequencing of *SERPINC1* in 14 patients with antithrombin deficiency revealed a common intragenic haplotype with 13 SNVs linked to the p.Thr147Ala variant. 2) Characterization of SVs. Nanopore sequencing fully characterized 12 SVs affecting *SERPINC1* or *F11* in patients with antithrombin or FXI deficiency, regardless their size (198 bp-5 Mb), or type (deletion, duplication, inversion, insertion). It defined the length and the breakpoints, which involved repetitive elements, and resolved complex SVs, which were incorrectly classified by other methods. 3) Identification of the molecular basis. Inversions, complex rearrangements or retrotransposon insertions were identified in candidate genes of 12 patients lacking a molecular diagnosis for 7 different rare diseases. 4) Identification of new mechanisms. Expansion of a ***CALR*-mutated** myeloid clone with epigenetic silencing of the wild-type allele in a woman heterozygous for the *PGK1*^{Ser320Asn} variant explained her anemia.

Conclusion: Nanopore sequencing opens new perspectives in the genetic diagnosis of rare diseases, enabling: 1) rapid and cost-effective haplotype resolution; 2) identification and characterization of SVs; and 3) detection of new pathogenic mechanisms (retrotransposon insertions, inversions, and epigenetic modifications).

P15.077.D Real-world genetic prevalence estimates of Factor V deficiency using large-scale genomic data

Giulia Solda[1]*, Andrea Caricasole*[2]*, Rosanna Asselta*[3]

[1]Humanitas University, Pieve Emanuele (Milan), Italy, [2]Kedrion Biopharma S.p.A, Gallicano, Italy, [3]Humanitas University Department of Biomedical Sciences, Pieve Emanuele, Italy.

Background: Factor V (FV) deficiency is a rare autosomal recessive bleeding disorder characterized by reduced levels and/or activity of FV coagulation factor in blood. Its estimated prevalence is 1:10^6. Currently, >220 causative mutations have been identified throughout the *F5* gene.

Material and Methods: We explored exome/genome data from >800,000 subjects in the genome Aggregation Database (gnomAD v.4.1). Worldwide and ethnic-specific prevalences were calculated with the Genetic Prevalence Estimator (GeniE, https://genie.broadinstitute.org/).

Results: A total of 6,228 *F5* variants were identified in gnomAD; of these, the number labelled as disease-causing depended greatly on the specific criteria used for selection. Three datasets were generated: a "GeniE recommended/default" dataset, consisting of 377 variants, and two custom datasets, in which pathogenic missense variants were defined either on REVEL >0.773 or AlphaMissense score. These included 656 and 742 variants, respectively. The GeniE default dataset gave a worldwide prevalence estimate similar to what expected (1:10^6), whereas the custom datasets both gave higher prevalence (5:10^6 and 5.8:10^6). Interestingly, by using as benchmark 226 known FV deficiency-causing variants annotated in the Human Gene Mutation Database (HGMD), we found that the custom datasets both had a much similar distribution to HGMD set in terms of representation of different variant types compared to the default GeniE dataset ($p = 0$), which is inflated with loss-of-function variants.

Conclusion: We provide a critical assessment of methods to select potentially pathogenic variants from population data, which can be adapted to other rare diseases. Our results suggest that FV deficiency prevalence might be higher than previously thought.

P15.078.A Bridging gaps in diagnosis: the high impact of gene-disease relationship evaluation

Mariana Ferreira, *Emir Zonic, Boodor Al-Kawlani, Ismet Duranovic, Javier Francisco Martini, Maria Eugenia Rocha, Ruxandra Aanicai, Alejandra Reyes, Peter Bauer, Jorge Pinto Basto, Aida Bertoli-Avella*

Centogene GmbH, Rostock, Germany.

Background: One of the primary challenges faced by diagnostic laboratories is evaluating the clinical significance of genetic variants. A crucial part of this process involves establishing gene-disease relationships (GDR). In this study, we summarize our experiences over the past two years using the ClinGen framework in the daily operations of a diagnostic laboratory.

Material and Methods: The ClinGen Clinical Validity Framework was used for evaluating GDR. We systematically assessed genes without OMIM entries or those with provisional entries. Gene selection was based on specific variants identified during routine diagnostic evaluations of patients' genomic data. The internal CENTOGENE biodatabank, containing exome/genome data from previously tested individuals, alongside data from literature and public databases, was utilized for gene classification. The framework allows for classification into definitive, strong, moderate, limited, or no known disease relationships.

Results: Over 700 genes were assessed, resulting in a strong/definitive level of evidence for 22% of genes, moderate for 25%, limited for 44%, and no known disease relationship or disputed for 9% of the genes. A total of 104 genes (14%) without OMIM entries achieved moderate or strong GDR.

Conclusion: Our findings highlight the importance of thoroughly assessing gene clinical validity data and utilizing genetic data repositories. The implementation of the ClinGen standardized scoring system for routine gene-disease association assessments is straightforward to apply and highly relevant in a clinical diagnostic context, providing benefits for patients, families, and healthcare providers.

P15.079.B Diagnostic yield of whole exome sequencing versus whole genome sequencing in pediatric patients with rare phenotypes: a systematic review and meta-analysis

Anna Luiza B. Albuquerque[1], *Giovanna G. dos Santos*[2], *Antonio Mutarelli*[3], *Breno B. Antonello*[4], *Maria Eduarda A. de Carvalho*[5], *Lorena Melo de Jesus*[6], *Sara H. Sadok*[7], *Paulo Victor Zattar Ribeiro*[8]

[1]*Federal University of Minas Gerais, Belo Horizonte, Brazil,* [2]*Faculty of Medicine of ABC, Santo André, Brazil,* [3]*Massachusets General Hospital - Cardiology Clinical Research, Boston, MA, USA,* [4]*Franciscan University, Santa Maria, Brazil,* [5]*State University of Minas Gerais, Passos, Brazil,* [6]*Federal University of Amazonas, Manaus, Brazil,* [7]*Hospital Universitari Joan XXIII, Tarragona, Spain,* [8]*State University of São Paulo, Ribeirão Preto, Brazil.*

Background: Rare diseases affect 6% of Western societies and are a leading cause of pediatric mortality. The popularization of Next Generation Sequencing technologies, specially whole exome sequencing (WES), revolutionized the diagnosis of children with rare disease. Still, most patients face extensive diagnostic odysseys and remain undiagnosed. Recently, whole genome sequencing (WGS) emerged in hope that its broader coverage could improve diagnostic yield compared to WES. This study aims to systematically review and meta-analyze the diagnostic power of WES versus WGS in pediatric populations with rare diseases.

Methods: A systematic review of PubMed, Cochrane, and Embase databases was performed on December 11, 2024, for non-randomized studies comparing WGS diagnostic yield with WES or WES reanalysis in pediatric populations with rare disease. Statistical analyses were performed in R software version 4.3.2. and the study was registered on PROSPERO (CRD42024619640).

Results: In a cohort of 1,767 patients from 12 studies, WGS-specific diagnostic yield was 8.2% (95% CI: 5.1%–13.0%; $p < 0.0001$). Subgroup analysis revealed that WES reanalysis and WGS provided statistically similar diagnostic yields in patients with prior negative WES due to overlapping confidence intervals. The diagnostic rate of WES reanalysis was 14.3% (9.1%–21.7%; $p < 0.0001$), while WGS was 7.8% (5.3%–11.3%; $p < 0.0239$).

Conclusion: This meta-analysis showed that WGS could establish molecular diagnoses in 8.2% more patients after negative WES. However, similar diagnostic yields from WES

reanalysis and WGS emphasize the importance of periodic reanalysis and variant reinterpretation in diagnostic workflows.

P15.080.C Unraveling the Genetic Landscape of Progressive Familial Intrahepatic Cholestasis: Novel Variants and Functional Insights

Anna Monica Rosaria Bianco[1], *Michela Zorzi*[1], *Ronald Moura*[1], *Mariateresa Di Stazio*[1], *Ilaria Ziccardi*[2], *Saveria Lory Crocè*[2], *Angelo Di Giorgio*[3], *Rachele Rapetti*[4], *Mauro Giuffrè*[5], *Adamo Pio d'Adamo*[1]

[1]*IRCCS BURLO GAROFOLO, Trieste, Italy,* [2]*Medical, Surgical and Health Sciences Department, Medical, Surgical and Health Sciences Department, Trieste, Italy., Trieste, Italy,* [3]*Pediatric Hepatology Gastroenterology and Transplantation, Hospital Papa Giovanni XXIII, Bergamo, Italy., Bergamo, Italy,* [4]*Internal Medicine, Azienda Ospedaliero-Universitaria "Maggiore Della Carità", Novara, Italy, Novara, Italy,* [5]*Medical, Surgical and Health Sciences Department, Medical, Surgical and Health Sciences Department, Trieste, Italy, Trieste, Italy.*

Background: Progressive Familial Intrahepatic Cholestasis (PFIC) encompasses a heterogeneous group of rare, inherited liver disorders characterized by impaired bile flow due to genetic defects affecting hepatocellular transporters, bile canaliculi structure, or cholangiocyte function. Despite the identification of 13 PFIC types (ATP8B1, *ABCB11*, and *ABCB4*, while more recently discovered causative genes include *TJP2*, *NR1H4/FXR*, *SLC51A*, *USP53*, *KIF12*, *ZFYVE19*, *MYO5B*, *SEMA7A*, *VPS33B* and *PSKH1*), primarily linked to mutations in genes regulating bile acid homeostasis, approximately 30% of cholestatic cases remain genetically undiagnosed, highlighting the need for advanced investigative approaches.

Material and Methods: We analyzed 40 pediatric patients (average age of onset 0.8 years) with intrahepatic cholestasis through whole exome sequencing (WES). Clinical manifestations included hepatomegaly, jaundice, pruritus, and various extrahepatic signs. We performed comprehensive genetic analysis through trio-based WES, extending analysis beyond established PFIC genes.

Results: Beyond identifying variants in known PFIC genes (*ATP8B1*, *ABCB4*, *MYO5B*), we discovered novel variants in previously unreported genes, including *PLEC* (affecting BSEP targeting), *NEK8* (associated with bile duct paucity). Functional studies validated the pathogenicity of identified variants and their impact on bile acid transport pathways.

Conclusion: This multi-faceted approach will advance our understanding of cholestatic disorders by combining genetic discovery with functional validation, potentially leading to improved diagnostic strategies and personalized therapeutic approaches.

P15.081.D Whole Genome and RNA sequencing, a double approach to complex clinical cases: the Shwachman-Diamond example

Lucrezia Goisis[1], *Camilla Lucca*[1], *Lidia Pezzani*[2], *Laura Pezzoli*[1], *Daniela Marchetti*[1], *Matteo Bellini*[1], *Francesca Cappuccini*[1], *Chiara Mongodi*[1], *Loredana Perego*[1], *Nunzia Della Malva*[1], *Riccardo Rubini*[1], *Annarita Lincesso*[1], *Agnese Scatigno*[2], *Erica Rosina*[1], *Luigina Spaccini*[3], *Maria Iascone*[1]

[1]*Laboratory of Medical Genetics, ASST Papa Giovanni XXIII, Bergamo, Italy,* [2]*Rare Disease Unit, ASST Papa Giovanni XXIII, Bergamo, Italy,* [3]*Clinical Genetics Unit, Department of Obstetrics and Gynecology, Vittore Buzzi Children's Hospital, University of Milan, Milano, Italy.*

Background: Shwachman-Diamond syndrome (SDS) is caused by biallelic variants in the SBDS gene, which shares 97% sequence homology with the pseudogene SBDSP1. Both genes are expressed in different tissues. Gene conversion is a known disease mechanism, which may lead to unexpected inheritance and failure to detect pathogenic variants by enrichment-based approaches.

Material and Methods: We performed genome analysis of the proband and parents for family 1 and of two fetuses and parents for family 2 on DNA extracted from peripheral blood or amniocytes. As a validation, we performed RNA sequencing from PAXgene blood samples from family 1 and control samples.

Results: WGS analysis detected in the family 1 the known variants c.258+2T>C on the maternal allele and c.183-184TA>CT and c.201A>G de novo and with a low VAF on the other allele, and c.258+2T>C and c.428C>T in both fetuses of the second family, inherited from the mother and father, respectively. The presence of the pseudogene SBDSP1 can lead to misalignment during genome analysis. Therefore, we performed RNA analysis since the two transcripts present different exon-intron structures, ensuring the exclusive analysis of the SBDS gene. In this way, we characterized the identified variants: the c.258+2T>C causes the production of several aberrant transcripts and the apparently de novo variants c.183-184TA>CT and c.201A>G are due to a postzygotic gene conversion event.

Conclusion: WGS analysis is a practical approach for diagnosing SDS and many other diseases caused by complex genomic rearrangements. In addition, RNA sequencing is a proper complementary method to deepen ambiguous genetic alterations.

P15.082.A A system for RNA analysis of the *CFTR* splicing variants identified in patients with cystic fibrosis

Ksenia Davydenko, *Olga Kachanova, Anna Efremova, Alexandra Filatova, Mikhail Skoblov, Head of the Department*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Cystic fibrosis (CF) is caused by pathogenic variants in the *CFTR* gene, approximately 10% of which are splicing errors. Understanding the pathogenetic mechanisms of splicing variants is crucial for clarifying gene-phenotype correlations and developing gene therapies.

Material and Methods: Total RNA was isolated from patient-derived samples, followed by RT-PCR analysis. PCR-products were sequenced using various NGS platforms and processed via an in-house pipeline.

Results: To analyze splicing variants in the *CFTR* gene, we developed a system for RNA analysis. Since *CFTR* expression is low in commonly available clinical tissues, such as primary skin fibroblasts or blood, we used intestinal organoids and cultured nasal epithelium for RNA isolation. We developed and tested primers that enable the amplification of the entire *CFTR* coding

region as a single locus from cDNA (4608 bp). Next, we performed NGS of the obtained PCR product, achieving an average coverage of ~100,000× across the *CFTR* CDS. This allowed us to detect minor splicing events (subject to NMD degradation or residual expression of the reference isoform) and the quantification of allele expression disbalances. The system underwent validation using healthy control samples and the known splicing variant as well as the established missense variant. In addition, we analyzed several patient-derived samples stored in the SRC "Biobank" of the Research Centre for Medical Genetics and determined the pathogenic mechanisms of these variants.

Conclusion: This study highlights the complexity of splicing defects and improves our understanding of CF pathogenesis, which is key to the development of new therapeutic strategies.

P15.083.B Multiple Endocrine Neoplasia and Sporadic Insulinomas

Klaus Brusgaard[1], *Kirstine Andersen*[2], *Henrik T. Christesen*[2], *Evgenia Globa*[3], *Sönke Detlefsen*[2], *Maria Malikian*[4]

[1]*Vejle Sygehus, Vejle, Denmark,* [2]*Odense University Hospital, Odense, Denmark,* [3]*Ukrainian Research Center of Endocrine Surgery and Transplantation of Endocrine Organs and Tissues, Kyiv, Ukraine,* [4]*Yerevan State Medical University, Yerevan, Armenia.*

Background: Functional pancreatic neuroendocrine tumors (PNETs) can be hereditary or sporadic. Hereditary forms are often associated with MEN1 mutations, while most insulinomas are sporadic, solitary, and low-grade. However, the tumorigenesis of sporadic insulinomas remains poorly understood. This study investigates secondary events following the first-hit MEN1 variant and the mutational profiles of both MEN1-associated insulinomas and sporadic tumors.

Materials and Methods: Tissue samples were collected from 4 patients with MEN1 syndrome and 12 patients with sporadic PNETs. Analyses included NGS exome sequencing, transcriptomics, histology, and immunohistochemistry (IHC). Variant calling utilized the GATK pipeline with variant filtering in Varseq software. CNV and LOH analyses were conducted using Varseq, employing Z-scores, ratio plots, and VAF metrics. RNA was extracted and hybridized to Clariom S arrays, with data processed in the Transcriptome Analysis Console (TAC) and refined using R scripts. IHC staining was performed for insulin, glucagon, synaptophysin, islet-1, and Ki67 across all insulinoma specimens.

Results: This study represents the first to evaluate MEN1 second-hit occurrences in PNETs from young MEN1 patients at DNA, RNA, and protein levels. Sporadic insulinomas exhibited significant genetic heterogeneity with few recurrent alterations among candidate genes.

Conclusion: Findings provide novel insights into beta-cell pathophysiology and insulin secretion, offering a framework for future research on therapeutic targets in diabetes and hyperinsulinism. Results were further corroborated through meta-analysis with published exome and genome sequencing data of well-differentiated MEN1 and sporadic PNETs.

P15.084.C In-depth molecular analysis of *TSC1* and *TSC2* genes in 76 Polish tuberous sclerosis complex probands, with a focus on detecting low-level mosaicism in blood

Justyna Prokopiuk[1], *Urszula Ławrynowicz*[1], *Agnieszka Tarasewicz*[2], *Izabella Kuźmiuk-Glembin*[2], *Kinga Drężek-Chyła*[1], *Monika Horbacz*[1], *Piotr Skrzypczyk*[3], *Anna Wabik*[3], *Michał Szyszka*[3], *Małgorzata Pańczyk-Tomaszewska*[3], *Piotr Madanecki*[4], *Irene Tiemann-Boege*[5], *Jan P. Dumanski*[6], *Maria Alicja Dębska-Ślizień*[2], *Arkadiusz Piotrowski*[1], *Beata S. Lipska-Ziętkiewicz*[7], *Magdalena Koczkowska*[1]

[1]*3P-Medicine Laboratory, Medical University of Gdansk, Gdansk, Poland,* [2]*Department of Nephrology, Transplantology and Internal Diseases, Medical University of Gdansk, Gdansk, Poland,* [3]*Department of Pediatrics and Nephrology, Medical University of Warsaw, Warsaw, Poland,* [4]*Department of Biology and Pharmaceutical Botany, Medical University of Gdansk, Gdansk, Poland,* [5]*Institute of Biophysics, Johannes Kepler University, Linz, Austria,* [6]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,* [7]*Centre for Rare Disease and Clinical Genetics Unit, Medical University of Gdansk, Gdansk, Poland.*

Background: Tuberous sclerosis complex (TSC) is a rare tumor predisposition syndrome caused by the inactivation of the *TSC1/TS2* genes, leading to the development of hamartomas in multiple organs. Early diagnosis is crucial for effective clinical management and genetic counseling; however, it is often hindered by the challenge of detecting low-level mosaicism. Here, we demonstrate that implementing duplex sequencing alongside standard diagnostic approaches can increase the sensitivity of *TSC1/TSC2* variant detection, potentially up to 92%.

Material and Methods: We performed targeted next-generation sequencing (NGS), complemented by multiplex ligation-dependent probe amplification (MLPA) analysis, on blood-derived DNA from 76 probands with a definitive clinical diagnosis of TSC according to the current diagnostic criteria. To identify low-level mosaicism, we implemented duplex sequencing, an ultra-sensitive NGS modification that significantly reduces the sequencing error rate, enabling the detection of pathogenic variants at extremely low frequencies.

Results: A total of 85.5% (65/76) likely pathogenic or pathogenic variants were identified in *TSC1/TSC2* using the standard diagnostic approach, including twelve mosaic variants with allele frequencies (AF) ranging from 5.1% to 32.7%. Samples from the remaining 11 individuals, initially classified as negative results, were subjected to duplex sequencing, leading to the detection of *TSC1/TSC2* pathogenic variants in five additional individuals, with the lowest detected AF being 0.3%.

Conclusion: Duplex sequencing emerges as a promising complementary tool that increases the detection rate of previously undiagnosed cases of low-level mosaicism in TSC-related patients. This approach could facilitate TSC diagnosis and enable the timely implementation of appropriate medical surveillance.

P15.085.D HiFi long-read sequencing of repeat expansions: applications for precision genetics in a clinical setting

Marinella Corbetta, *Viviana Pensato, Elisa Sarto, Elena Rizzo, Daniela Di bella, Cinzia Gellera, Franco Taroni, Stefania Magri*

Fondazione IRCCS Istituto Neurologico Carlo Besta, Unit of Medical Genetics and Neurogenetics, Milan, Italy.

Background: The Unit of Neurogenetics at the Carlo Besta Institute is a major Italian referral center for the clinical and genetic diagnosis of neurodegenerative diseases caused by Repeat Expansions (RE). The aim of this study was to exploit the power of HiFi single-molecule sequencing technology (Pacific Biosciences, PacBio) to elucidate the architecture of complex REs and validate the data obtained by routine laboratory techniques.

Material and Methods: Thirteen subjects previously diagnosed with RE (n = 7 SCA8/*ATXN8OS*, n = 1 FXTAS/*FMR1*, n = 1 FRDA/*FXN*, n = 3 FTDALS1/*C9orf72*, n = 1 CANVAS/*RFC1*) underwent long-read sequencing (LRseq) on a PacBio Sequel IIe sequencer with the PureTarget RE panel kit.

Results: We obtained an average coverage of ~433X in the 20 regions analyzed. RE lengths were concordant with those estimated by PCR, except for a systematic discrepancy of +3(CAG) in *ATXN1* detected by LRseq. Sequencing of *RFC1* RE revealed the complexity of this region, characterizing one carrier of a pathogenic AAGGG expansion and various short alleles with alternate motifs. Sizing and sequencing of the *C9orf72* RE was inefficient in 1 patient, likely due to the RE length causing allele drop-out. Moreover, PacBio sequencing allowed to distinguish between CTA and CTG tracts in the challenging *ATXN8OS*/SCA8 RE, thus making it possible to size exclusively and precisely the disease-causing CTG repeat.

Conclusion: HiFi PacBio sequencing allows to improve definition of RE, contributing to reduce systematic errors of fragment analysis and to elucidate the complex architecture of critical REs. Extension of the study to a larger number of patients and conditions is ongoing.

P15.086.A Relative gene expression and translation efficiency of *CALM1*, *CALM2*, and *CALM3* may contribute to variation in severity of calmodulinopathy

Steffan Noe Niikanoff Christiansen[1], *Stine Bøttcher Jacobsen*[2], *Jeppe Dyrberg Andersen*[2], *Michael Toft Overgaard*[1], *Mette Nyegaard*[1]

[1]*Aalborg University, Aalborg, Denmark,* [2]*University of Copenhagen, Copenhagen, Denmark.*

Background: Ultra-rare missense variants in the *CALM1*, *CALM2*, and *CALM3* genes, which encode identical calmodulin proteins, can cause calmodulinopathy, a spectrum of various clinical manifestations, including ventricular arrhythmias and sudden cardiac death. However, disease-causing variants are not observed with equal frequency among the three calmodulin encoding genes in clinical studies. This observation may be explained by distinct roles of the three genes. Consequently, the phenotypic severity may depend on which of the calmodulin encoding genes that is affected by a missense variant.

Materials and Methods: We used data from cardiac tissues of 466 individuals to compare the gene expression levels and translation efficiency of *CALM1*, *CALM2*, and *CALM3*.

Results: In the human heart, *CALM2* displayed the highest expression level with a median expression level 15.2% higher than *CALM1* and 90.1% higher than *CALM3*. Furthermore, the translation efficiency of *CALM1* and *CALM2* was 139.5% and 105.4% higher than that of *CALM3*.

Conclusion: These differences in expression levels and translation efficiencies indicate that missense variants in *CALM3* may be less severe than those in *CALM1* and *CALM2*. Consequently, gene-specific variant interpretation may be required in the clinical management of calmodulinopathy.

P15.087.B Advancing Genome Sequencing for Neurodevelopmental Disorders: integrating structural variant calling, classification, and prioritization

Emanuela Iovino[1], *Francesca Montanari*[2], *Giulia Severi*[2], *Ettore Rocchi*[1,3], *Francesca Bisulli*[4], *Raffaella Minardi*[4], *Laura Licchetta*[4], *Andrea Cavalli*[5], *Federica Vita*[6], *James Guevara*[7], *Gastone Castellani*[8,3], *Jonathan Sebat*[7], *Tommaso Pippucci*[1], *Marco Seri*[8]

[1]*Computational Genomics IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [2]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [3]*Department of Medical and Surgical Sciences – DIMEC, Alma Mater Studiorum, Bologna, Italy,* [4]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Epilepsy Center (Reference Center for Rare and Complex Epilepsies-EpiCARE), Bologna, Italy,* [5]*Computational and Chemical Biology, Italian Institute of Technology, Genoa, Italy,* [6]*Istituto di Biofisica, Consiglio Nazionale delle Ricerche, Genoa, Italy,* [7]*Department of Psychiatry, University of California San Diego, La Jolla, CA, USA,* [8]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: GS is increasingly used as a first-line diagnostic test for patients with rare genetic diseases such as neurodevelopmental disorders (NDDs). Its clinical applications require a robust infrastructure for processing, storage and analysis. Moreover, Structural Variants detection and interpretation remain challenging, and a prioritization system is needed to facilitate downstream clinical analysis. Here, we present the results of a clinical application of WGS in a cohort of 54 families with NDDs.

Methods: We developed portable workflows for GS data-processing and SNV/SV/STR calling. A benchmark of state-of-art SV detection tools identified the most accurate combination for SV calling, and a machine-learning model was trained to assess reliability of SV detection combining calls from different state-of-art tools. Additionally, a gene-based prioritization system was implemented to support variant interpretation.

Results: Our benchmark analysis optimized SV detection by selecting the most accurate tools combination and integrating them into a dedicated pipeline. An xGBoost was trained (within a 10-fold cross-validation, repeated 10 times) to assess SV reliability, achieving robust AUROC on test set (0.869 ± 0.014). The prioritization system supported downstream analysis leading to a molecular diagnosis in 21.8% of patients, with SV accounting for 16%. Additionally, it suggested a potential diagnosis in up to 14.5% of cases, mainly consisting of non-coding variants.

Conclusion: Our findings highlight that integrating SNV/SV analysis significantly enhances the diagnostic yield of GS, although potential finding may need additional layers of analysis to be thoroughly interpreted. Moreover, implementing a dedicated pipeline improves variant detection, classification and interpretation, supporting more accurate molecular diagnoses.

P15.088.C Challenges in prioritising disease-causing variants in recessive monogenic diseases observed in homozygous state in population databases

Sukumaran Sija[1], *Sheeba Farooqui*[1], *Rosario C do Michelle*[1], *Mayuri Yeole*[1], *Prashanth Rao*[1], *Meher Vangara Mounika*[1], *Periyasamy Radhakrishnan*[2], *Dhanya Lakshmi Narayanan*[1], *Katta Mohan Girisha*[1,3], *Vivekananda Bhat*[1], *Purvi Majethia*[1], *Anju Shukla*[1]

[1]*Kasturba Medical College and Kasturba Hospital, Manipal, India,* [2]*Department of Clinical Research and Department of Biomedicine, University Hospital Basel and University of Basel, Basel, Switzerland,* [3]*Department of Genetics, College of Medicine &Health Sciences, Sultan Qaboos University Muscat 112, Muscat, Oman.*

Background: Allele frequencies from population databases are crucial for prioritizing and interpreting rare variants associated with Mendelian disorders in genomic analysis.

Material and Methods: A retrospective analysis was conducted on data from individuals with a molecular diagnosis at our centre to identify probands carrying variants associated with rare genetic disorders, observed in a homozygous state in the gnomAD (v4.1.0) population database.

Results: We herein report five individuals from four unrelated families with three distinct autosomal recessive disorders. In family 1, we identified, c.193G>T p.(Gly65Trp) and c.956A>G p.(Tyr319Cys) in compound heterozygous state in GALC (NM_000153.4), causing later-onset Krabbe disease (MIM #245200). The variant c.956A>G p.(Tyr319Cys) is reported in 14 individuals in a homozygous state in gnomAD (Allele frequency:0.0007902). In family 2, we identified c.275-2A>G and c.680G>A p.(Arg227Lys) in compound heterozygous state in MECR (NM_016011.5) causing optic atrophy 16 (MIM #620629) in two similarly affected siblings. The variant c.680G>A is reported in 12 individuals in a homozygous state (Allele frequency:0.001979). In family 3 and family 4, c.2179G>A p.(Val727Met) in compound heterozygous state with c.1505G>A p.(Gly502Asp) and c.1664C>T p.(Ala555Val) were noted, respectively in GNE (NM_001128227.3), causing Nonaka myopathy (MIM #605820). The variant c.2179G>A is reported in 12 individuals in a homozygous state (Allele frequency :0.0007453).

Conclusion: The likely explanations for the presence of disease-causing variants for recessive monogenic diseases in population databases include possible hypomorphic variants, late-onset disorders, and non-penetrance. An integrated clinical and genomic approach to variant interpretation is likely to result in improved identification of these variants in genomic testing pipelines.

P15.089.D Population prevalence of postzygotic variants at preclinical frequency in the *UBA1* gene

Jaume Reig Palou[1,2], *Juan I. Aróstegui*[3,4], *Ferran Casals*[1,5,6]

[1]*Departament de Genètica, Microbiologia i Estadística, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain,* [2]*Institut de Biomedicina de la Universitat de Barcelona (IBUB), Barcelona, Spain,* [3]*Departament d'Immunologia, Hospital Clínic–Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain,* [4]*Escola de Medicina, Universitat de Barcelona, Barcelona, Spain,* [5]*Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain,* [6]*Institut de Recerca Sant Joan de Déu (IRSJD), Esplugues de Llobregat, Spain.*

Background: Increasing evidence supports that somatic variants contribute to non-cancer diseases, mostly monogenic but also complex disorders. Notably, gene mosaicism plays a relevant role in the pathogenesis of inborn errors of immunity, especially in the group of autoinflammatory diseases (AIDs). Clinical manifestations in certain AIDs appear later in life, suggesting the expansion of preexisting mutant clones through clonal hematopoiesis. Herein we aim to characterize the mutational load of somatic variants at subclinical frequencies in *UBA1* causing the VEXAS syndrome and other AIDs genes.

Material and Methods: We have analyzed whole-genome sequences from 490,000 individuals aged 40–70 years in the UK Biobank repository. A bioinformatic pipeline with GATK and Variant Effect Predictor was applied to detect low-frequency variants, combined with a set of filters based on mapping quality, minimum reads supporting the alternative allele, strand bias and proximity to read ends and indels, was applied to reduce false positives.

Results: We have identified carriers of pathogenic variants in *UBA1* and *NLRP3*, some of them previously reported as pathogenic in AIDs. These results have enabled to establish a characterization of the load of somatic variants in these genes for males and females, as well as performing a spatial distribution analysis of the germline and somatic variants.

Conclusion: The genetic load of somatic variants in unaffected individuals is informative on the number of individuals at risk of developing an AID of postzygotic origin, which can be of relevance for physicians visiting patients with late-onset inflammatory disorders.

Background: Kleefstra syndrome (KLEFS, OMIM #610253) is a rare genetic disorder, characterized by moderate-to-severe intellectual disability, hypotonia and distinctive gestalt, variably associated to seizures and congenital defects. Causative alterations, both single nucleotide- or copy number- variants, affect *EHMT1*, an euchromatin histone methyltransferase.

Materials and methods: This project develops on three synergic paths. *Clinical study* Clinical reports have been collected, reviewed and compared to literature, in order to better define study population and build a dedicated registry. *Molecular study* All molecular tests were revised to define population genotypes and to correctly label individuals harbouring *EHMT1* uncertain

variants. In vitro *study* Starting from patients' blood cells, personalized in vitro models were created, aiming to investigate etiopathological processes and to test novel therapeutic approaches.

Results: Exhaustive clinical and genetic data were gathered for 38 patients, including pregnancy history, auxological parameters, cardiological and neuropsychiatric evaluations. All patients were also re-evaluated from a gestaltic point of view.The cohort phenotypical and mutational repertoire will be described generating a comprehensive overview of this rare condition. The results of genome wide scanning on mislabelled cases will help to acquire a critical viewpoint when facing a variant in *EHMT1*. In collaboration with the Gaslini Telethon Genetic Bank service, we generated 36 lymphoblastoid cell lines. Preliminary results of in vitro studies will be presented.

Conclusion: This innovative holistic bench to clinic study on KLEFS provides a deeper knowledge of this rare disorder, of its genotypic and phenotypic landscape with the final aim to develop targeted therapies.

P15.092.C Clinical Application of Whole Genome Sequencing in a Russian Cohort: Insights from 3600 Genomes

*Oxana Ryzhkova[1], Viktoriia Zabnenkova[1], **Dmitry V. Pustoshilov**[2], Timofei Vizerov[1], Philipp Sviridov[1], Maria Bulakh[1], Maria Orlova[1], Kseniya Zabudskaya[1], Tatiana Milovidova[1], Ekaterina Nikolaevna Solodovnikova[1], Anna Orlova[1], Tatiana Markova, MD[1], Olga Shchagina[1], Olga Mironovich[1], Ekaterina Zakharova[1], Galina Matiushchenko[1], Aleksandr Poliakov[1], Sergey Kutsev[1]*

[1]FSBSI Research Centre For Medical Genetics, Moscow, Russian Federation, [2]Biotech Campus LLC, Moscow, Russian Federation.

Background: Whole genome sequencing (WGS) is the most comprehensive molecular diagnostic tool, yet its clinical adoption remains limited despite declining costs outpacing whole exome (WES) and panel sequencing. While WGS is predominantly utilized in research and population studies, it is rarely first-line in clinical practice due to persistent cost and infrastructure barriers. This study evaluates the diagnostic utility of WGS in a large Russian cohort with unresolved genetic conditions.

Material and Methods: WGS was performed on 3,646 DNA samples (patients and relatives) using PCR-free enzymatic fragmentation (MGI) and the DNBSEQ-T7 platform (paired-end 150 bp reads). Collaborative efforts under the national "100,000+ Me" initiative enabled sequencing and analysis of 1,876 families over one year. Trio/quadro analysis comprised 50% of cases.

Results: Causative/likely pathogenic (P/LP) variants were identified in 34% of cases (2,088 unique variants; 65% novel). Despite prior targeted testing, WGS provided an 8.2% incremental diagnostic yield. Variant distribution included SNPs (85%), deep intronic (11%), CNVs (3%), and rare mitochondrial/STR/structural variants (common <1%). The diagnostic yield varied across disease groups, ranging from 18% for epilepsy to 67% for Rubinstein-Taybi syndrome. The cohort exhibited selection bias, as part patients underwent prior panel/WES testing per diagnostic protocols.

Conclusion: While WGS incurs costs beyond sequencing (data storage, infrastructure, security), its clinical adoption is rising, particularly for ultra-rare disorders. This study underscores WGS's unique capacity to resolve complex cases, urging a paradigm shift in diagnostic workflows for rare diseases.

P15.094.A Integrating phenotype data and de novo filtering to prioritise non-coding variants in clinical whole genome sequencing

***Sophie Ellis**[1,2], Sam Nalty[1], Michael Spiller[1]*

[1]Sheffield Diagnostic Genetics Service, Sheffield, United Kingdom, [2]University of Manchester, Manchester, United Kingdom.

Background: Whole genome sequencing (WGS) has become the first-line diagnostic test for severe paediatric rare diseases in the NHS England Genomic Medicine Service (NHSE GMS). However, current analysis is limited to coding regions, due to challenges in prioritising and interpreting non-coding variants. Increasing evidence for the role of non-coding variation in rare disease underscores the need for effective analysis strategies. This study examines whether filtering de novo single nucleotide variants (SNVs), in genes from the NHSE GMS R27 Paediatric Disorders expertly curated gene panel, can effectively identify clinically relevant non-coding variants.

Material and Methods: Variant call format (VCF) files were obtained from local GMS cases with no causative variants reported. Filtering criteria included de novo SNVs in autosomal dominant or X-linked R27 "green" genes and absence from gnomAD. Variants with a coding consequence, autosomal recessive inheritance and all indel variants were excluded. Variants were annotated using Ensembl Variant Effect Predictor v113.0 with gnomAD v4.1 and SpliceAI delta scores.

Results: A total of 172 cases were analysed, yielding 484 autosomal dominant de novo non-coding variants. Of these, 246 variants across 116 cases were determined to be potentially phenotypically relevant. Stringent assessment of patient HPOs narrowed this down to 16 variants for further analysis. Full results will be presented at the conference.

Conclusion: This approach demonstrates the feasibility of expanding current WGS analysis to include non-coding regions. Robust filtering and prioritisation strategies are required to incorporate phenotype and in silico prediction tools to allow identification of clinically relevant variants.

P15.095.B Regional Clustering of the COL7A1 c.5047C>T Variant in Recessive Dystrophic Epidermolysis Bullosa Patients in Brazil

***Michele Patricia Migliavacca**, Marina de Franca Basto Silva, Antonio Victor Campos Coelho, Tatiana Almeida, Joao Bosco de Oliveira Filho*

Hospital Israelita Albert Einstein, SÃO PAULO, Brazil.

Background: Recessive dystrophic epidermolysis bullosa (RDEB) is a severe inherited skin disorder characterized by recurrent blistering beneath the cutaneous basement membrane, leading to scarring, contractures, and gastrointestinal strictures. Diagnosis is confirmed by clinical findings and biallelic pathogenic variants in the COL7A1 gene. Emerging therapies, such as COL7A1-targeted gene therapy, show promise. Guide et al. (2022) demonstrated significant wound healing in RDEB patients treated with topical B-VEC (beremagene geperpavec), a herpes simplex virus-based gene therapy.

Material and Methods: Brazil's diverse, admixed population provides a unique setting to evaluate COL7A1 variants. We analyzed whole-genome sequencing data from the BRGP (Brazilian Rare Genomes Project), a PROADI-SUS consortium with the Israelita Albert Einstein Hospital, encompassing 7,375 patients with rare diseases across 28 centers.

Results: Among the 7,375 probands analyzed, 37 patients (0.50%) were found to carry pathogenic bi-allelic variants in the COL7A1 gene. Of these, 18 (48.6%) harbored the loss-of-function variant c.5047C>T; p.(Arg1683Ter). Within this group, 4 patients (22.2%) were compound heterozygous, and 14 (77.8%) were homozygous. Remarkably, all 18 patients originated from Bahia State, indicating a potential founder effect.

Conclusion: Our findings reveal a significant clustering of RDEB patients in Brazil, particularly in Bahia linked to the c.5047C>T variant in COL7A1. This regional concentration highlights the importance of targeted diagnostic and therapeutic strategies, including emerging treatments like B-VEC, and tailored genetic counseling to address the unique genetic landscape and healthcare needs of this population.

P15.097.D A novel GPR143 mutation in a large Iranian family with X-linked nystagmus

H. Motamed[1], *D. D.Farhud*[1,2,3], *M. Zarif-Yeganeh*[1];

[1]*Dr. Farhud Genetic Clinic, Tehran, Iran, Islamic Republic of,* [2]*School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [3]*Department of Basic Sciences, Iranian Academy of Medical Sciences, Tehran, Iran, Islamic Republic of*

Background: Congenital Nystagmus syndrome is a genetic disorder characterized by involuntary oscillation of the eyes starting within the first six months of life. While many genes associated with this condition have been identified, the objective of this study is to discover a new mutation contributing to this syndrome.

Material and Methods: This family-based study investigated a 4-generation Iranian family with nystagmus. Whole exome sequencing, Sanger sequencing for mutation confirmation, segregation analysis, bioinformatics tools, and in silico protein modeling were utilized.

Results: A rare hemizygous missense variant in the G-protein coupled receptor 143 (GPR143) gene was identified in affected males. The mothers of the affected individuals were heterozygous carriers, and unaffected males did not carry the mutation. Protein modeling revealed that the p.Ala2Asp mutation is located near the Beta-1 adrenergic receptor interaction site, likely causing structural instability.

Conclusion: This study identifies a novel X-linked recessive missense mutation in the GPR143 gene associated with congenital nystagmus. These findings may have implications for genetic studies in the Iranian population and beyond.

Background: Biliary atresia (BA) is a rare, rapidly progressive cholangiopathy exclusive to newborns, characterized by fibro-obliterative destruction of the bile ducts. As one of the most common causes of neonatal cholestasis and treatable through timely surgical intervention, BA requires prompt diagnostic evaluation. The first-line surgical treatment, Kasai portoenterostomy (PE), aims to restore bile flow and prolong survival with the native liver. However, despite PE, 70–80% of BA patients eventually require liver transplantation (LT) before adulthood, making them the largest group (40–50%) of pediatric LT recipients worldwide. The advent of genetic testing has transformed the evaluation of neonatal cholestasis, providing opportunities for accurate molecular diagnoses. Despite this, only a limited number of BA-linked genetic variants have been identified to date.

Material and Methods: Whole-exome sequencing (WES) was conducted to identify rare genetic single nucleotide and copy number variants, while genome-wide association study (GWAS) analysis was performed to investigate common SNP associations across the cohort of 48 BA patients. To further validate the functional impact of selected candidate variants, immunostaining and flow cytometry were performed on patients' skin biopsy or PBMC.

Results: While GWAS did not reveal significant SNP associations, WES identified plausible rare candidate variants in 11 patients, including a copy number gain in chromosome 22 in one case. However, for the majority (77%) of patients, no plausible rare disease-causing variants were detected.

Conclusion: Our findings highlight the genetic complexity of biliary atresia, supporting the hypothesis that BA is primarily a multifactorial disease.

P15.099.B Robust and accurate genome analysis with SOPHiA DDM™ WGS solutions

Izabela Matyszczak, *David Fast, Tommaso Coletta, Tomas Zimmermann, Bita Khalili, Dmitri Ivanov, Loc Tran, Amjad Alkodsi, Yuanlong Liu, Yohann Nedelec, Jaume Bonet Martinez, Mark Laver, Christian Pozzorini Pozzorini, Alex Tuck, Zhenyu Xu*

SOPHiA GENETICS SA, Rolle, Switzerland.

Background: Whole-genome sequencing (WGS) provides unparalleled insights into the genetic basis of rare diseases. To fully leverage WGS, accurate, scalable, and comprehensive genomic analytic solutions are crucial.

Material and Methods: We developed two WGS solutions integrating proprietary algorithms with public tools for variant detection, annotation, and reporting; SOPHiA DDM™ low-pass WGS (lpWGS) solution offers an alternative to chromosomal microarray analysis (CMA) for CNV and RoH detection, while the 30xWGS solution analyses all variant types. Their performance was evaluated using the Genome in a Bottle (GIAB) and 1000 Genomes Project (1KGP) reference materials, and simulated data. The lpWGS solution was compared to CMA, while 30xWGS was benchmarked against leading solutions.

Results: The 30xWGS solution achieved >99% sensitivity, precision, and F1-score for SNV/indel detection. Mitochondrial variant calling reached >97% accuracy with a heteroplasmy threshold of 5%. Structural variant detection showed 75% sensitivity and 94% precision, outperforming other leading SV callers. CNV benchmarking achieved 94% recall and 77% precision, surpassing established CNV detection tools. Analysis of simulated CNV data demonstrated 95% sensitivity for detecting constitutional CNVs ≥10 kb and mosaic CNVs ≥5 Mbp at 30% mosaic fraction. The lpWGS solution achieved >95% sensitivity for constitutional CNVs ≥30 kb and mosaic CNVs ≥5 Mbp at 30% mosaic fraction. RoH detection with both pipelines showed >99% sensitivity for events ≥5 Mbp.

Conclusion: The SOPHiA DDM™ lpWGS and 30xWGS solutions demonstrated high sensitivity and precision across all variant types surpassing established gold standards. Their robust performance and scalability make them powerful tools for comprehensive genomic analysis.

P15.100.C SH2D1A-Related X-Linked Lymphoproliferative Disease goes beyond Epstein-Barr Virus: Varicella-Zoster as an Atypical Trigger

Natali Valcheva[1], *Slavena Atemin*[1], *Mila Sleptsova*[1,2], *Zornitsa Pavlova*[1], *Tihomir Todorov*[1], *Albena Todorova*[1,2]

[1]*GMDL "Genica" and IMDL "Genome Center Bulgaria", Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria.*

Background: The SH2D1A gene encodes the SLAM-associated protein (SAP), a key regulator of T-cell signaling critical for effective immune responses. Mutations in SH2D1A are the primary cause of X-linked lymphoproliferative disease (XLP), a rare immunodeficiency marked by abnormal responses to Epstein-Barr virus (EBV), autoimmune manifestations, lymphomas, and internal bleeding complications due to herpes family virus infections. Understanding the genetic basis of such conditions is essential for early intervention and family counseling.

Material and Methods: Two male patients, aged 11 and 19, were evaluated for immune dysregulation. Whole Exome Sequencing (WES) identified pathogenic variants in SH2D1A. Parental testing via Sanger sequencing clarified inheritance patterns. The clinical data was analyzed to help correlate genotype with phenotype.

Results: The 11-year-old patient presented with eosinophilic colitis, chronic mucositis, dermatitis, pneumonitis with granulomatous lesions, and intermittent fever. A c.137+5G>A variant in SH2D1A was detected, leading to a 22 bp deletion in exon 1 and loss of SAP function. This maternally inherited variant disrupts splicing, emphasizing the need for genetic counseling. The second patient, a 19-year-old male, exhibited multiple aneurysms and iron deficiency anemia. WES revealed a maternally inherited c.313_315del, p.(Lys105del) variant, previously associated with thrombotic vasculopathy and aneurysms in EBV-infected patients. While EBV is the typical trigger in SH2D1A-related immune dysregulation, this patient's disease was initiated by herpes zoster from varicella-zoster virus (VZV). Notably, the spleen and kidney aneurysms in the reported case required surgical removal due to hemorrhage.

Conclusion: SH2D1A mutations lead to severe immune dysregulation and varied systemic complications without clear targeted therapies.

P15.101.D Combining bio-informatic tools to facilitate implementation of non-coding variant analysis in genome diagnostics

Sanne Jansen, Bart Charbon, Lennart Johansson, Dennis Hendriksen, Wilhelmina Kerstjens-Frederikse, Morris Swertz, Birgit Sikkema-Raddatz, Jan Jongbloed, Kristin M. Abbott

University Medical Center Groningen, Groningen, Netherlands.

Background: Diagnostic yield for solving rare genetic diseases remains around 30–40%. Current analyses are focused on variants of the coding genome and ignore most non-coding (nc) variants in important regulatory regions. Our aim is to develop a diagnostic-proof filter strategy for non-coding variant analysis, to augment current NGS testing.

Material and Methods: WGS data from 1 positive case (known deep-intronic splicing variant) and 10 unsolved cases, previously analyzed for neurodevelopmental phenotypes, were examined. Two filter strategy tools (VariantInterpretationPipeline (VIP, in-house) and GREEN-VARAN (G-V, open-source)) were used to identify variants in promoter/enhancer, intronic and UTR regions

using FATHMM-MKL, ReMM and ncER algorithms. In VIP, SpliceAI and UTRAnnotator algorithms were used to identify splice and 5'UTR variants. Finally, filtering for 5045 (mainly) neurodevelopmental associated genes was applied. The two filter strategies were compared and clinical review was performed.

Results: The two filter strategies resulted in varying variants of interest (VOI): VIP = 1321 ± 323 and G-V = 138 ± 46. Application of gene panel filtering reduced the number of VOIs to 21–51 for VIP, and 4–14 for G-V. The VIP/G-V overlap (including splice and 5'UTR variants) reduced the number of VOIs to 5–17, and clinical review led to 0–3 variants per individual. Notably, the positive control splice variant was prioritized in VIP. Follow-up includes parental inheritance control and functional testing: RNAseq to confirm spicing of VOI in *TLK2*, and methylation pattern testing for *ZEB2* enhancer VOI.

Conclusion: Our results demonstrate that applying a diagnostic-aimed filter strategy incorporating existing bio-informatic tools makes diagnostic non-coding variant analysis feasible.

P15.102.A Whole Genome Sequencing-based Identification of a Novel Frameshift Mutation in the *STK11* Gene in Peutz-Jeghers Syndrome

Malgorzata Marcinkowska-Swojak[1], *Pawel Wojciechowski*[2], *Jacek Blazewicz*[2], *Marek Figlerowicz*[1], *Luiza Handschuh, professor*[1]

[1]*Institute of Bioorganic Chemistry PAS, Poznan, Poland,* [2]*Poznan University of Technology, Poznan, Poland.*

Background: Peutz-Jeghers syndrome (PJS) is a rare autosomal dominant disorder characterized by gastrointestinal polyposis and mucocutaneous pigmentation, typically caused by *STK11* mutations. However, some patients exhibit PJS features without these mutations. Here, we report the case of a 30-year-old man with suspected PJS, partial symptoms, and an unknown genetic background. He and his asymptomatic parents participated in a study aimed at creating the Genomic Map of Poland.

Material and Methods: Whole genomes were sequenced at 30x coverage using DNBSEQ (MGI platform). To identify potentially pathogenic variants, we analyzed SNPs and indels using five approaches: i) *STK11* gene only, ii) HIGH-impact variants determined by Variant Effect Predictor (Ensembl), iii) variants from ClinVar database, iv) COSMIC database variants, and v) pathogenic and likely pathogenic variants determined by eVai (enGenome).

Results: Based on the whole genome sequencing (WGS), we identified a heterozygous frameshift mutation in the *STK11* gene, not reported previously. This variant is a single nucleotide deletion (c.171delA) that alters the amino acid sequence in the N-terminal part of the protein (p.Gly58fs). The mutation was found exclusively in the patient and absent in both parents, indicating de novo origin. WGS results were confirmed by Sanger sequencing of the affected *STK11* gene fragment.

Conclusions: Our findings, combined with medical examinations, strongly suggest that the identified novel frameshift mutation in *STK11* may be responsible for the patient's phenotype. This case underscores the importance of comprehensive genetic analysis in the diagnosis of PJS and other rare diseases, particularly in patients lacking typical disease-related phenotypes.

P15.103.B Multi-Omics Approach Reveals the Impact of Prognosis Model-Related Genes on the Tumor Microenvironment in Medulloblastoma

D. Han, *Z. Wang, X. Jin, Y. Gao, X. Chen, J. Li;*

BGI research, Shenzhen, China

Background: The tumor microenvironment (TME) significantly impacts the progression and prognosis of medulloblastoma (MB). This study aimed to develop a TME-associated risk score(TMErisk) model using RNA sequencing data to predict patient outcomes and elucidate biological mechanisms.

Material and Methods: RNA sequencing data from 322 Tiantan and 763 GSE85217 MB samples were analyzed. Key gene modules related to immune and stromal components were identified using Weighted Gene Co-expression Network Analysis (WGCNA). Significant genes were screened using LASSO-COX and COX regression models. Single-cell RNA sequencing (scRNA-seq), single-cell ATAC sequencing (scATAC-seq), and spatial RNA analyses validated the findings.

Results: Differential expression analysis identified 731 upregulated and 15 downregulated genes in high vs. low immune score MB patients, and 686 upregulated and 43 downregulated genes in high vs. low stromal score patients. Eight key genes (*CEBPB*, *OLFML2B*, *GGTA1*, *GZMA*, *TCIM*, *OLFML3*, *NAT1*, and *CD1C*) were included in the TMErisk model, which demonstrated strong prognostic power. High TMErisk scores correlated with poorer survival, distinct immune cell infiltration patterns, and lower tumor cell stemness. Single-cell analyses revealed the expression dynamics of TMErisk genes across cell types, including macrophages, T cells, and NK cells, and identified key regulatory transcription factors. Spatial transcriptomics showed significant clustering of TMErisk genes in tumor regions, highlighting spatial heterogeneity and the formation of immune hubs.

Conclusion: The TMErisk model enhances our understanding of the MB tumor microenvironment, serving as a robust prognostic tool and suggesting new avenues for targeted therapy.

P15.105.D Polygenic Risk Scores (PRS) and Pharmacogenetic Card Profiling Analysis in a Cohort of 35 Patients with Wolff-Hirschhorn Disease

Julian NEVADO[1,2,3], *Mario Cazalla*[4], *Jair A. Tenorio-Castaño*[1,2,3], *Manuel J. Rodríguez Canó, Predoctoral Research*[1], *Sandra Ferreiro*[5], *Jorge Blom-Dahl*[5], *Guillermo Perea-Solero*[5], *Pablo D. Lapunzina*[1,2,3]

[1]*INGEMM(HULP), Madrid, Spain,* [2]*CIBERER, Madrid, Spain,* [3]*ITHACA Research Network, Madrid, Spain,* [4]*INGEMM (HULP), Madrid, Spain,* [5]*ADNTRO Genetics, Madrid, Spain.*

Background: Wolf-Hirschhorn syndrome (WHS) is a rare genetic disorder characterized by a deletion of the distal short arm of chromosome 4p16.3. Clinically, WHS presents with developmental delay, intellectual disability, distinctive craniofacial features, and seizures. Interestingly, WHS shows a great variability in the epilepsy management among patients. Despite advances in genetic characterization, the role of polygenic influences and pharmacogenetics in WHS remains underexplored.

Materials and Methods: We analyzed polygenic risk scores (PRS) for 130 traits in 35 WHS patients to investigate potential correlations with phenotype, by using WGS. PRS values were extracted, and traits with percentile scores above 90 and 95 were examined systematically. Additionally, pharmacogenetic profiling for 49 medications was

performed using PharmCat, focusing on gene-drug interactions and clinical recommendations. Data were categorized by patient with a specific emphasis on antiepileptic drugs.

Results: The traits "Insomnia," "COVID susceptibility" "Irritable bowel syndrome" and "periodontitis" exhibited PRS values exceeding the 90th percentile suggesting potential commonalities in polygenic influences within this cohort. Pharmacogenetic analysis revealed that 28 patients (and nine unique genes) had specific recommendations for at least one of the 49 medications studied. However, no recommendations for antiepileptic drugs were identified. The results highlight variability in pharmacogenetic profiles within the cohort, emphasizing the need for personalized medicine approaches.

Conclusion: This study provides a comprehensive overview of polygenic and pharmacogenetic influences in WHS. The pharmacogenetic analysis further emphasizes the clinical relevance of genetic profiling in optimizing therapeutic strategies. Future research should aim to explore the integration of PRS and pharmacogenetics in patient care.

Background: Methylation arrays are a high-throughput technique for evaluating unique DNA methylation patterns, known as episignatures. An increasing number of rare disorders have been linked to specific episignatures, providing quick and accurate diagnoses across a wide range of clinical applications.

Material and Methods: This retrospective study analyzes the first group of Portuguese patients who underwent DNA methylation testing from January 2023 to June 2024 using Illumina Infinium Methylation EPIC BeadChip arrays and the EpiSign assay. Testing was conducted by national Medical Genetics Departments, which defined the criteria. The study included two groups: 1 - subjects with variants of unknown clinical significance in genes with known episignature and clinical overlap; 2 - subjects with inconclusive genetic results but a diagnosis aligning with syndromes that have established episignatures.

Results: In our cohort of 48 cases, 44% showed positive results for episignature or imprinting changes, with highly reliable results. In Group 1, 50% of cases tested positive for a episignature compatible with the previously identified genetic variant, allowing us to label it as likely pathogenic and achieve a clear diagnosis. In Group 2, 41% of patients had an episignature that confirmed clinical diagnosis, strengthened it and guided individual recommendations for further testing.

Conclusion: Our study found a high rate of positive results, likely due to careful patient selection. A combined clinical and laboratory approach was crucial for accuracy. We believe episignature testing is useful for clinical practice and that genetics departments in Portugal are ready to use it regularly and expand its applications.

P15.107.B Uncovering population-specific pathogenic variants in recessive monogenic diseases: insights from North Macedonia

Predrag Noveski, *Ivana Maleva Kostovska, Natalija Jovanovska, Gjorgji Bozhinovski, Emilija Shukarova Stefanovska, Aleksandar Dimovski, Dijana Plaseska-Karanfilska*

Research Centre for Genetic Engineering and Biotechnology "Georgi D. Efremov", Macedonian Academy of Sciences and Arts, Skopje, North Macedonia, The Republic of.

Background: Massive parallel sequencing (MPS) has enabled comprehensive testing for carrier status in recessive monogenic diseases (RMDs) and has revealed that variant frequency differences necessitate population-specific adjustments in RMD carrier screening. Our aim was to identify population-specific pathogenic variants in RMDs from MPS data in North Macedonia.

Materials and Methods: We analyzed exome sequencing data from 1,269 patients referred to our laboratory for genetic testing for rare diseases. We searched for ClinVar pathogenic variants (version 06-Jan-2025) in 1,283 genes linked to childhood-onset RMDs (panelapp.agha.umccr.org/panels/3139). Filtering criteria included variant quality, allele frequencies, and ClinVar review status. Alleles causing the patients' clinical phenotypes were excluded from the count.

Results: A total of 2,086 alleles, including 918 distinct pathogenic variants in 482 genes, were identified, of which 92 variants (679 alleles in 86 genes) showed significantly higher allele frequencies compared to gnomAD exomes v.2.1 after applying Bonferroni correction, and were designated as population-specific variants. As expected, cystic fibrosis and phenylketonuria were among the top-ranked genes with the highest gene carrier frequencies. However, similar allele frequencies were observed for other genes/diseases, revealing a discrepancy between the expected and observed disease incidence in North Macedonia (internal data). This discrepancy may result from prenatal lethality associated with highly deleterious variants (e.g., CPLANE1:c.1819-del;7871T>A, DHCR7:c.452G>A, DDX11:c.1403dup) or mild

phenotypes due to hypomorphic variants (e.g., MKS1:c.1476T>G), leading to potential underdiagnosis.

Conclusion: MPS from genetic testing can be further utilized to inform national health policies by highlighting potential clinical underdiagnosis and guiding the design of preconception carrier screening programs.

Background: DNA-methylation analysis is increasingly playing a crucial role in diagnosing neurodevelopmental disorders(NDDs) by identifying specific episignatures, now associated with over 90 conditions. This study aimed to evaluate DNA-methylation patterns in NDD patients as part of a multicentric project.

Material and Methods: A subset of 16 deeply phenotyped cases was examined, which previously tested negative for fragile-X-syndrome, chromosomal microarray and trio-exome sequencing. Methylation profiling was performed with Infinium-MethylationEPIC v2.0 BeadChips and data were analyzed using the Episign v4.0 platform.

Results: We detected known episignatures in six out of 16 patients. A *SETD5*-associated pattern for Mental Retardation, Autosomal Dominant 23 was found in a child with severe growth delay. However, the causative variant was also present in the mildly symptomatic mother but with an uncertain associated methylation pattern. A second pathological condition was suggested in a mother-child pair correlated to the *SMARCA2*:c.3313C>G,p.(Arg1105Gly) variant. The proband showed developmental delay and seizure while the mother was milder. Identified conditions also included Kleefstra-syndrome-1 in one of two clinically similar siblings, later confirmed by the de novo *EHMT1*:c.1384_1385del,p.(Lys462ValfsTer7) variant. Sotos-syndrome was diagnosed in a child with a paternally inherited *NSD1*:c.3004_3005del,p.(K1002EfsTer8) variant. Nicolaides-Baraitser-syndrome was suggested in another case with subsequent identification of causative variant already present in the mother in a mosaic state. Lastly, a patient initially suspected of Cornelia de Lange syndrome(CdLS) exhibited a KBG-syndrome methylation pattern, but no apparent variant was found in CdLS genes.

Conclusion: Our findings underscore the diagnostic value of episignatures, particularly when conventional genetic tests yield inconclusive results.

P15.109.D Identification of the molecular mechanism underlying the involvement of mutations in the MYO5B gene and cholestasis

Mariateresa Di Stazio[1], *Cecilia Del Vecchio*[2], *Anna Monica Rosaria Bianco, Researcher*[1], *Francesco Giambuzzi*[1], *Cristina Bellarosa*[3], *Adamo Pio d'Adamo*[1,2]

[1]*Institute for Maternal and Child Health IRCCS Burlo Garofolo, Trieste, Italy,* [2]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy,* [3]*Italian Liver Foundation, Trieste, Italy.*

Background: Progressive Familial Intrahepatic Cholestasis (PFIC) comprises rare genetic disorders presenting in infancy with severe itching, hepatosplenomegaly, steatorrhea, and liver failure. While MYO5B mutations have been recently identified in PFIC patients, their pathogenic mechanism remains controversial. Previous studies suggested that mutated MYO5B protein disrupts canalicular protein localization, leading to altered bile salt secretion and cholestasis.

Material and Methods: We analyzed six PFIC patients with MYO5B mutations through genetic analysis and performed protein expression assays on available liver biopsies to investigate canalicular protein localization.

Results: Immunohistochemical analysis of liver biopsies from two patients revealed normal BSEP expression and localization at the canalicular membrane, contrasting with previous hypotheses about MYO5B's role in protein trafficking.

Conclusion: Our findings, along with other unpublished studies, demonstrate preserved BSEP localization in MYO5B-related cholestasis, challenging current understanding of its pathogenic mechanism. Further investigation of MYO5B in cholestasis is crucial to for developing targeted therapies. In vitro models, including induced hepatocytes 2D cells culture and organoids, offer promising platforms to study canalicular protein trafficking and understand the cholestatic phenotype associated with MYO5B mutations.

P15.110.A An integrated approach to analyze RNA-seq data in the context of rare disorders

Felix Brechtmann, *Christian Mertes, Vicente Yépez*

OmicsDiscoveries GmbH, Planegg, Germany.

Background: Multi-omics data provide complementary insights that improve the diagnosis of rare genetic disorders. Experience from several international projects has shown that integration of all results into a unified view significantly accelerates interpretation by clinical geneticists.

Materials and Methods: We observed different approaches to analysing RNA-seq alongside DNA data in many projects, including different approaches to reporting RNA results to

researchers interpreting the data, ranging from plotting capabilities using dedicated software to per-family reports in Solve-RD. Analysis of the requirements from these projects led to the development of novel best practices and a user interface.

Results: Here we present our best practices for joint analysis of multiple omics datasets and RNAvision, a novel platform for reporting results. Our pipeline detects approximately 10 outlier genes per sample, significantly reducing the number of dubious findings compared to DROP. The novel user interface includes a summary table of all outlier genes and a common visualisation of all findings and their position within the gene, including variants.

Conclusion: Multi-omics visualisation allows geneticists to seamlessly interpret whole transcriptome data and integrate it into the analysis of rare disease cases. This pipeline can accelerate the adoption of RNA-seq as a complementary assay in human genetics.

P15.111.B Advancing splicing variant analysis in neurological disorders with targeted long-read RNA sequencing

Ilaria Quartesan[1], *Ricardo Parolin Schnekenberg*[1], *Stefano Facchini*[1,2], *Riccardo Currò*[1,2], *Arianna Manini*[3], *Arianna Ghia*[2], *Alessandro Bertini*[4], *Enrico Bugiardini*[1], *Matilde Laura*[1], *Henry Houlden*[1], *Mary M. Reilly*[1], *Andrea Cortese*[1]

[1]*Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology, London, United Kingdom,* [2]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy,* [3]*UNIVERSITY OF MILAN, CUSANO MILANINO, Italy,* [4]*Unit of Rare Neurological Diseases, Department of Clinical Neurosciences, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy.*

Backgrond: Short-read whole-genome sequencing (srWGS) has increased the identification of non-coding variants, underscoring their role in hereditary disorders. Yet interpreting these variants without functional validation is difficult. Amplicon-based long-read RNA sequencing (Amp-lrRNAseq) provides a cost-effective approach to analyze splicing in full-length transcripts while retaining phasing. This study evaluated Amp-lrRNAseq in predicting splicing consequences of non-coding variants.

Material and Methods: Variants in five patients with hereditary neurological disorders were identified by srWGS and prioritized by phenotype and in silico splicing predictions. Amp-lrRNAseq was performed on fibroblasts or whole blood. Quantitative PCR (qPCR) was used to assess variant impact on gene expression.

Results: In a patient with CMT2, we identified a homozygous *GDAP1* variant (c.311-23A>G), previously reported. We confirmed the mutation activates a cryptic splice site, causing the inclusion of intronic nucleotides into exon 2. We also validate previous observations of aberrant splicing caused by a known heterozygous *POLR3A* mutation (c.1909+22G>A) in a spastic ataxia patient. In a patient with Behr syndrome, a novel homozygous deletion in *OPA1* (c.4_5+2del) resulted in skipping of the final exon, with reduced *OPA1* expression in patient fibroblasts. A patient with early-onset myopathy carried a biallelic *PYROXD1* variant (c.85-5A>G) that promotes inclusion of four intronic nucleotides, likely introducing a premature stop codon (p.Gln29fs). Lastly, in an HSP patient, a novel *SPG11* variant (c.2068-498T>G) caused exonization of intron 11.

Conclusion: Amp-lrRNAseq clarifies how genetic variants disrupt splicing and lead to disease, offering a cost-effective, versatile option for variants that match the clinical phenotype but lack definitive pathogenicity evidence.

Background: Genetic diseases are a leading cause of mortality among neonates and pediatric patients in intensive care units (ICUs). Rapid whole genome sequencing (rWGS) has the potential to revolutionize the diagnosis and treatment of rare diseases, advancing precision medicine in ICU settings. Baby Fox is a prospective multicenter study conducted in neonatal and pediatric ICUs of four tertiary hospitals in Czechia, evaluating the feasibility, diagnostic yield, and clinical utility of rWGS. Here, we present the first findings three months after the study's initiation.

Material and Methods: Patients suspected of monogenic diseases were enrolled following multidisciplinary case discussions. Trio rWGS with phenotype-driven analysis was performed. Demographic data, Human Phenotype Ontology (HPO) terms, rWGS turnaround time, sequencing results, and their actionability (C-GUIDE^{TM}) were analyzed.

Results: Between October and December 2024, 6 newborns (median age 22 days [range 1–90]) and 7 pediatric patients (median age 8 years [range 1–17]) underwent trio rWGS. The median turnaround time was 6 days (range 4–7), with a median of 11 HPO terms per patient (range 4–23). Disease-causing variants, including one non-coding and one structural variant, were identified in 7 patients (3 newborns, 4 pediatric), yielding a diagnostic rate of 54%. Clinical management was modified in 4 patients with molecular diagnoses (57%), including changes in medication and referral to relevant ERN centers.

Conclusion: Despite the project's multicenter nature and logistical challenges, these preliminary findings demonstrate the feasibility of a 7-day turnaround time and expected diagnostic yield, substantiating the clinical utility of rWGS in critically ill children.

P15.113.D Deciphering the pathogenicity of missense variants in the giant protein Nesprin-1

Jordi Pijuan[1,2], *Guerau Fernàndez*[1,2,3], *Anna Altisent-Huguet*[1], *Javier Aparicio*[4], *Beatriz Beseler-Soto*[5], *Alba Gabaldón-Albero*[5,6], *Miguel Tomás-Vila*[5], *Janet Hoenicka*[1,2], *Francesc Palau*[1,2,7]

[1]*Laboratory of Neurogenetics and Molecular Medicine, Center for Genomic Sciences in Medicine, Institut de Recerca Sant Joan de Déu and Hospital Sant Joan de Déu, Barcelona, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Barcelona, Spain,* [3]*Department of Genetics, Hospital Sant Joan de Déu, Barcelona, Spain,* [4]*Epilepsy Unit, Department of Pediatric Neurology, Hospital Sant Joan de Déu, Barcelona, Spain,* [5]*Neuropediatrics Unit, University and Polytechnic Hospital La Fe, Valencia, Spain,* [6]*Translational Research Group in Genetics, La Fe Health Research Institute, Valencia, Spain,* [7]*Division of Pediatrics, Faculty of Medicine and Health Sciences, University of Barcelona, Barcelona, Spain.*

Background: Predicting the pathogenicity of missense genetic variants poses a significant challenge, especially in undiagnosed rare diseases. This report describes a patient with early-onset spinocerebellar ataxia carrying two recessive missense variants in the *SYNE1* gene, which encodes Nesprin-1, the second-largest known protein. Initial predictions deemed these variants were benign and VUS, leading to the dismissal of *SYNE1* as a potential candidate. Nevertheless, we experimentally demonstrated a dramatic impact on the Nesprin-1 and the Linker of Nucleoskeleton and Cytoskeleton (LINC) complex function.

Material and Methods: Gene expression studies were conducted using RT-PCR, Western blotting, and immunostaining. Additionally, reverse phenotyping for *SYNE1* was performed in a cohort of 6,189 pediatric patients from our hospital.

Results: Functional studies showed in the patient's fibroblasts a significant decrease in Nesprin-1, changes in nuclear morphology and LINC complex defects. Reverse phenotyping revealed 22 undiagnosed patients with two or more *SYNE1* missense variants, and 10 additional undiagnosed patients with at least one of the variants from the index case. All patients exhibited epilepsy-associated features or neurodevelopmental phenotypes.

Conclusion: This study highlights the current limitations for predicting how missense variants affect both protein function and their potential pathogenicity. These challenges are particularly pronounced in large proteins like Nesprin-1, where it is difficult to investigate the structural implications, especially given the multiple isoforms expressed from the *SYNE1* gene. Prioritizing the patient's phenotype/genotype correlation and conducting functional studies have been crucial for reaching an etiological diagnosis. Furthermore, understanding the effect of *SYNE1* missense variants would potentially identify novel associated phenotypes.

Gemelli IRCCS, Rome, Italy,* [11]*Universita Cattolica del Sacro Cuore, Rome, Italy.*

Background/Objectives: Vascular malformations define a heterogeneous group of conditions characterized by a wide spectrum of clinical phenotypes ranging from mild forms such as isolated capillary malformations to severe forms involving multisystemic districts and vital organs such as lymphatic malformations[1]. While molecularly targeted therapies can be lifesaving, identifying the molecular cause is often challenging due to complex access to affected tissue samples, mosaicism, or insufficient sequencing depth[2,3,4].

Methods: Among 28 patients, DNA was extracted from affected tissue (fresh biopsy or formalin fixed paraffin embedded (FFPE)) in 16 individuals. The analysis was performed on DNA extracted from fresh biopsy (4/16), on FFPE 11/16 and from cystic fluid (CF) in one. Tissue somatic libraries were prepared with Myriapod® NGS Cancer Panel DNA (Diatech Pharmacogenetics s.r.l.) and sequenced in platform Mi-Seq® System (Illumina), ensuring average coverage per sample of 3000X.

Results: Pathogenic *PIK3CA* variants were identified in 11/16 patients, with VAF ranging from 1.16% to 7%. Variants in multiple targetable genes (*BRAF and PIK3CA*) were found in one individual. The test was negative in 5/16 patients: one screening failure, three not informative results and one with only CF available.

Conclusion: In total, we identified druggable variants in 68% of patients with low level of mosaicism using a multi-tier genetic approach. Given the recent advances in treatment, targeted therapy was applied with beneficial outcome in three challenging patients not responding to previous treatment. Our study confirms that identification of the molecular cause for complex vascular anomalies is fundamental and needs to be prioritized whenever possible.

Science for life laboratory, Uppsala University, Uppsala, Sweden, [4]National Genomics Infrastructure, Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [5]Department of Clinical Genetics and Genomics, Sahlgrenska University Hospital, Göteborg, Sweden, [6]Department of Laboratory Medicine, Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Göteborg, Sweden.

Background: Precise detection of pathogenic variants in genes implicated in hereditary cancer is important for accurate diagnosis and patient management. This study evaluates the efficacy of targeted long-read sequencing (TLRS) with a custom designed panel, including genes relevant for inherited cancer diagnostics and variants that make up an established poly-genic risk score (PRS) for inherited breast-cancer. The targets include *PMS2*, a gene that is challenging to sequence with short reads due to pseudogene interference.

Material and Methods: A custom sequencing panel was developed, covering both the 313 variants of the PRS and the whole gene segments (+/− 5 kb) around 31 genes (Twist Bioscience). Ninety-six individuals with suspected hereditary cancer were included in a pilot study to assess the performance of the panel. Sequencing libraries were constructed using the Twist long read library preparation and standard hyb v2 enrichment and sequenced on the PacBio Revio system. An inhouse bioinformatics pipeline was developed and identified variants were interpreted using Alissa Interpret software (Agilent Technologies).

Results: Benchmarking analysis showed high F1-scores for both SNVs (99.96%–99.83%) and indels (93.47%–93.01%) in NA12878 and NA24385 GIAB samples. The TLRS panel had good coverage depth and uniformity across all targets. Reads were able to align accurately and reproduce variants across all genes including *PMS2*. The long-read approach also allows for variant phasing.

Conclusion: TLRS provide great sensitivity for targeted gene panels, it helps resolve complex regions and provides information on compound heterozygosity. Our findings support the integration of TLRS in the clinical routines.

P15.117.D The clinical utility of ultra-long Nanopore Adaptive Sampling for rare disease investigation including NGS intractable regions

Aleksandr Jestin[1], *Siying Lin*[2], *Theresa Erlenbach*[3], *Omar Mahroo*[2], *Michel Michaelides*[2], *Andrew Webster*[4], *Gavin Arno*[3]

[1]*University College London, London, United Kingdom,* [2]*Moorfields Eye Hospital, London, United Kingdom,* [3]*Greenwood Genetic Center, Greenwood, SC, USA,* [4]*UCL, London, United Kingdom.*

Background: Many rare disease patients remain usolved after current comprehensive genetic testing, partly due to the complexity of certain genomic regions and limitations in current detection technologies. The opsin array on Xq28 represents one such region, and patients affected by X-linked cone-dysfunction have limited access to effective testing. Advances in nanopore long-read sequencing and computational approaches provide new opportunities to address these challenges. We investigated the utility of nanopore adaptive-sampling for variant detection across an inherited retinal dystrophy (IRD) gene panel including the opsin array.

Methods: Ten affected or carrier individuals (3 females) were recruited from Moorfield's Eye Hospital either with a known opsin array mutation or prior inconclusive testing. Fresh or frozen EDTA blood derived DNA was subjected to ultralong-read sequencing targeting a custom panel of 309 IRD genes by adaptive-sampling on the Oxford Nanopore Technologies PromethION platform. Sequencing runs were typically 12h and yielded 2.6–4.8 Gb of data with N50 ranging 33–61 kb.

Results: This approach enabled detailed characterization of single nucleotide variants (SNVs), the array composition, and hybrid gene combinations. Ten pathogenic mutations in 10 individuals were identified including SNVs, complete array deletion, and known pathogenic mis-splicing haplotypes in exon 3 including phased variant detection in three female carriers.

Conclusion: Ultra-long-read sequencing enables unambiguous read-through of large multi-copy gene arrays, with variant detection and phasing. Adaptive-sampling adds an effective targeting method avoiding complex enrichments. This study demonstrates the utility of our method for use in a diagnostic pipeline for patients and families with rare genetic disorders.

Background: In 2022, ACURARE launched ISTisNA Platform (https://istisna.org), a national initiative to improve the diagnosis and management of rare and undiagnosed diseases in Istanbul. Undiagnosed Diseases Program (UDP-IST), was implemented in 2024 as the first structured workflow for patients who remain undiagnosed despite previous evaluations. This study assesses the program's workflow, diagnostic strategies, and early outcomes.

Material and Methods: UDP-IST follows a structured approach where referring clinicians submit clinical and genomic data through an online portal. The ACURARE expert panel reanalyzes genomic data using an in-house bioinformatics pipeline and collaborates with referring clinicians for deep phenotyping. If cases remain unresolved, WGS and transcriptome analyses are performed. A dedicated team manages data analysis and case tracking.

Results: Between January-December 2024, 45 unsolved referrals were reviewed in biweekly multidisciplinary meetings. WES reanalysis solved 27% (12/45) of submissions without further testing. Repeated WES due to data quality solved 1 patient. WGS

provided diagnoses in five additional cases where WES was inconclusive. Two families underwent WGS for the index and WES for the parents, revealing a candidate variant in a novel gene in one family. Solved or unsolved, all families received a written report, and face-to-face genetic counseling was provided. Functional validation studies, including RNA sequencing and episignature analysis are ongoing for unsolved patients with VUS or negative results.

Conclusion: UDP-IST is an inaugurational model for Istanbul and Turkey. Successful integration of genomic reanalysis, expert case discussions, and functional studies are fundamental components. We hope our model paves the way for a nationwide implementation.

P15.119.B Chromatinopathies: on the trail of the wheel

Giulia Bruna Marchetti[1], *Michela Mura*[1], *Camilla Meossi*[2], *Lidia Pezzani*[3], *Erica Rosina*[1,4], *Federica Gaudioso*[1], *Sara De Matteis*[5], *Elisabetta Di Fede*[5,6], *Valentina Massa*[5,6], *Cristina Gervasini*[5,6], *Carlo Agostoni*[7,1], *Laura Pezzoli*[4], *Maria Iascone*[4], *Donatella Milani*[1]

[1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy,* [2]*Molecular Medicine, IRCCS Fondazione Stella Maris, Pisa, Italy,* [3]*SS Malattie rare, ASST Papa Giovanni XXIII, Bergamo, Italy,* [4]*Laboratorio di Genetica Medica, ASST Papa Giovanni XXIII, Bergamo, Italy,* [5]*Department of Health Sciences, Università Degli Studi di Milano, Milan, Italy,* [6]*"Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, Università Degli Studi di Milano, Milano, Italy,* [7]*Department of Clinical and Community Sciences, Università degli Studi di Milano, Milan, Italy.*

Background: Chromatinopathies (CPs) are an expanding group of rare genetic disorders affecting epigenetic machinery. Beside an intricated genotypical spectrum, these conditions are also merged by overlapping phenotypes characterized by neurocognitive impairment, growth defects and distinctive, but often convergent, facial features. Due to their complexity and rarity, accurate diagnosis and management pose significant difficulties. Our goal is to gain a deeper understanding of this complex spectrum of conditions, aimed to ameliorate our diagnostic and managing approach to them and, prospectically, to identify novel therapeutic targets.

Material and Methods: We conducted a retrospective chart review of all patients diagnosed with CP seen at our Clinic before December 31st, 2024. Clinical data, including growth parameters, neurodevelopmental assessments, and facial photographs, were collected and analyzed.

Results: 235 individuals affected by 31 distinct CPs, mainly Sotos Syndrome, Rubinstein-Taybi Syndrome and Kleefstra Syndrome were enrolled. We compared diagnostic tests, analyzed growth parameters, deepen neurocognitive profiles and facial traits. Our data globally confirm the complexity of this spectrum of conditions, suggest the absence of pubertal peak in CPs and underline the burden of convergent phenotypes in this spectrum. Well-trained medical geneticists and tight collaboration with Laboratory play a key role to avoid diagnostic odyssey in CPs and to set up tailored health care.

Conclusion: This study represents the largest collection of CPs patients to date. Our data provide valuable insights into the clinical spectrum of these rare disorders, leading to improved diagnostic, therapeutic, and counseling strategies, paving the way for the development of personalized care plans.

P15.120.C Deciphering the Genetic Enigma: The Paradox of Zero Phenotype-Genotype Correlation in ABCD1 Gene Mutations

S. Kumar;

Maulana Azad Medical College, New Delhi, India

Background: X-linked adrenoleukodystrophy (X-ALD), caused by pathogenic variants in the **ABCD1 gene**, presents a perplexing clinical heterogeneity, where individuals harboring identical mutations exhibit **discordant phenotypic outcomes**, ranging from severe neurological impairment to an asymptomatic state. This **lack of genotype-phenotype correlation** complicates risk stratification and clinical management. Emerging evidence suggests that secondary molecular regulators may **modulate disease expressivity**. This study investigates the potential role of **SIRT1, PGC1α, GLUT21, RAGE, ABCD2, and GDF15** as candidate modifiers in individuals with **ABCD1 mutations**.

Material and Methods: A cohort of **eight genetically confirmed individuals** with **ABCD1 mutations** was recruited, comprising **four symptomatic and four asymptomatic individuals**. Peripheral blood mononuclear cells (PBMCs) were analyzed using **flow cytometric assays** to quantify the expression levels of **SIRT1, PGC1α, GLUT21, RAGE, ABCD2, and GDF15**. Statistical analyses were performed to assess differential expression between symptomatic and asymptomatic groups.

Results: A significant **downregulation** of **SIRT1, PGC1α, GLUT21, RAGE, ABCD2, and GDF15** was observed in symptomatic individuals compared to asymptomatic carriers ($p < 0.05$). The reduced expression of these markers implicates a dysregulation in **mitochondrial function, metabolic homeostasis, oxidative stress response, and cellular signaling**, which may contribute to the variable disease phenotypes.

Conclusion: These findings suggest that **SIRT1, PGC1α, GLUT21, RAGE, ABCD2, and GDF15** act as potential **phenotypic modifiers** in X-ALD, influencing disease severity independently of ABCD1 mutation status. Understanding these molecular pathways may provide insights into **biomarker-based risk assessment** and **targeted therapeutic strategies**, refining precision medicine approaches for X-ALD management.

Département de Génétique and Centre de Référence Déficiences Intellectuelles de Causes Rares, Paris, France, [6]Medical University of South Carolina, Charleston, SC, USA, [7]APHP.Sorbonne Université, Service de Neuropédiatrie, Hôpital Armand Trousseau, Paris, France, [8]Istituto G.Gaslini, Genova, Italy, [9]Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Università Degli Studi di Genova, Genoa, Italy, [10]Medical Genetics Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy, [11]Clinical Genetics Unit, Department of Women and Children's Health, University of Padova, Padova, Italy, [12]Genomed Ltd., Moscow, Russian Federation, [13]Research centre for medical genetics, Moscow, Russian Federation.

Background: Pathogenic missense variants in the *MORC2* gene are associated with two distinct disorders: Charcot-Marie-Tooth disease type 2Z (CMT2Z), a hereditary neuropathy, and DIGFAN syndrome, which has a broader and more variable clinical spectrum.

Material and Methods: Clinical and imaging data from 12 patients with DIGFAN and 3 patients with CMT2Z were collected. For functional analysis, a MORC2 expression vector with a C-terminal Flag tag was constructed and transfected into HEK293T cells. Twelve missense variants were introduced into the wild-type vector, and Western blot analysis was performed to assess protein stability.

Results: A total of 10 different missense variants in the *MORC2* gene were identified in our cohort, including five novel variants. The analysis of clinical data revealed a potential correlation between specific *MORC2* variants and predominant clinical features. For example, the S87L and R132C variants were frequently associated with diffuse hypotonia and muscle weakness, while the E27K variant was linked to ataxic gait and other disturbances without severe muscle weakness. Protein expression levels of MORC2 were lower in DIGFAN patients compared to CMT2Z cases; however, this difference was not statistically significant and did not account for the observed clinical variability.

Conclusion: This study enhances the phenotypic understanding of DIGFAN syndrome. Although Western blot analysis showed no significant differences in protein expression between the two phenotypes, our findings suggest that specific *MORC2* variants may influence clinical manifestations. Further research is needed to elucidate the mechanisms underlying the phenotypic variability in *MORC2*-associated disorders.

P15.122.A The minigene assay as a tool for evaluating the pathogenicity of genetic variants in hearing loss patients

Nina Sara Gan[1,2], *Dominika Oziębło*[1], *Marcin L. Leja*[1], *Natalia Bałdyga*[1], *Henryk Skarżyński*[3], *Monika Ołdak*[1]

[1]*Department of Genetics, Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*Doctoral School of Translational Medicine, Centre of Postgraduate Medical Education, Warsaw, Poland,* [3]*Oto-Rhino-Laryngology Surgery Clinic, Institute of Physiology and Pathology of Hearing, Warsaw, Poland.*

Background: The next generation sequencing (NGS) is becoming a common tool in clinical setting. It allows for quicker and more accurate diagnosis, especially in genetically heterogenous diseases as hearing loss (HL). This technique generates a huge number of variants, which creates a need for their functional verification. One such tools is the minigene assays, which allows for the assessment of the possible effect on splicing.

Material and Methods: Ten variants detected in HL patients from the Genetic Clinic of Institute of Physiology and Pathology of Hearing were selected to assess their pathogenicity using the minigene assay: *EYA1* c.1475+1G>T, *EYA4* c.1282-12T>A, *GSDME* c.991delT, *GSDME* c.1127A>G, *MYO6* c.816+1G>A, *MYO6* c.1984-1G>A, *MYO6* c.3281-13A>G, *MYO7A* c.2829G>A, *MYO15A* c.9230-4A>T, *SLC26A4* c.1001+1G>A. All variants were detected using a dedicated panel of HL genes (237 genes). The fragments of genes of interest were amplified from patients' DNA and cloned into the expression vector pDEST-pCI-Neo-RHO using the Gateway system and transfected into HEK293T cells. The transcripts were analyzed using RT-PCR and Sanger sequencing.

Results: Most of the studied variants (9 out of 10) affected splicing. The most commonly observed effects were exon skipping and intron exonization, mostly resulting in the creation of premature stop codon.

Conclusion: Performing the minigene assay allowed for the verification of the pathogenicity of all studied variants. Splicing may be affected not only by variants disrupting the canonical splice sites but also coding variants and those located deeper within the intron sequence. Both syndromic and isolated HL can be caused by splicing affecting variants.

P15.123.B Autosomal recessive *TTN*-related disease: evaluating the need for partner screening

Maxime C.G. van Keulen[1], *Marlies N. van Lingen*[1], *Jessica van Setten*[1], *Fenne L. Komdeur*[2], *J. Peter van Tintelen*[1], *Saskia N. van der Crabben*[2], *Karin Y. van Spaendonck-Zwarts*[1,3], *Arjan C. Houweling*[2], *Dennis Dooijes*[1]

[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Amsterdam University Medical Center, Amsterdam, Netherlands,* [3]*University Medical Center Groningen, Groningen, Netherlands.*

Background: Heterozygous truncating *TTN* variants (TTNtv) are a common cause of autosomal dominant dilated cardiomyopathy, while autosomal recessive (AR) titin related diseases are rare and associated with severe early-onset cardiac and skeletal muscle phenotypes. Variant interpretation is challenging due to a carrier frequency of 1% in the general population. This study explores the need for partner screening of TTNtv carriers to guide reproductive planning.

Material and Methods: A literature review was conducted using PubMed and Embase to identify studies describing patients with biallelic *TTN* variants. Additionally, we analyzed TTNtv in UK Biobank participants.

Results: The literature review encompassed 28 articles, identifying four AR phenotypes: congenital titinopathy, Salih myopathy, proximal titinopathy, and distal titinopathy. A total of 114 unique *TTN* variants were reported in 112 patients (38% frameshift, 38% nonsense, and 24% splice site). The I-band was most frequently affected (42%). Despite comprising only 6.7% of *TTN* coding sequence, the M-line accounted for 36% of reported variants. Analysis of 200,643 UK Biobank exomes identified 2,443 TTNtv, corresponding with a population carrier frequency of 1 in 82 (1.2%). The carrier frequency of TTNtv specifically within the I-band and M-line regions was approximately 1 in 106.

Conclusion: The high carrier frequency of TTNtv in the general population combined with uncertainty regarding their clinical

relevance do not support routine partner screening for all TTNtv. We propose to limit partner screening to carriers of known AR related *TTN* variants, in case of a familial history of TTNtv related disease or for TTNtv consanguineous couples.

P15.124.C DoAggregate: a pipeline for aggregation testing for rare-variants on a gene and pathway level

Simon Boutry[1,2,3], *Cédric Van Marcke*[4], *Nisha Limaye*[5], *Guillaume Smits*[3], *Pascal Brouillard*[6], *Martina De Bortoli*[7], *Eleonore Pairet*[8], *Ali Saadat Varnosfaderanii*[1], *Raphaël Helaers*[2], *Jacques Fellay*[1], *Tom Lenaerts*[3,9,10], *Miikka Vikkula*[11,12]

[1]*Global Health Institute, School of Life Sciences, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland,* [2]*Human Molecular Genetics, de Duve Institute, UCLouvain, Brussels, Belgium,* [3]*Inter-university Institute of Bioinformatics in Brussels, Université Libre de Bruxelles-Vrije Universiteit Brussels, Brussels, Belgium,* [4]*Cliniques Universitaires Saint-Luc, Brussels, Belgium,* [5]*de Duve Institute, UCLouvain, Brussels, Belgium,* [6]*de Duve Institue - UCLouvain, Brussels, Belgium,* [7]*de Duve Insitute, Brussels, Belgium,* [8]*de Duve Institute, Brussels, Belgium,* [9]*Machine Learning Group, Université Libre de Bruxelles, Brussels, Belgium,* [10]*Artificial Intelligence laboratory, Vrije Universiteit Brussel, Brussels, Belgium,* [11]*de Duve Institute, University of LouvainHuman Molecular Genetics, Brussels, Belgium,* [12]*WELBIO department, WEL Research Institute, Wavre, Belgium.*

Background: Aggregation tests address the limitations inherent to the analysis of rare variants in cohort studies by allowing for the combination of multiple genetic markers within a genomic region. However, choosing the appropriate statistical test remains a challenge, as existing tools often fail to provide a comprehensive solution that encompasses automatic data processing, gene-level testing, and exploration of broader genetic regions such as pathways.

Material and Methods: To address these questions, we developed DoAggregate, an innovative, scalable pipeline designed for high-performance computing environments. DoAggregate processes lists of annotated genetic variants in TSV or GVCF formats, supporting tasks ranging from data filtering through pathway analysis to identification of regions of interest, including genes and pathways. It incorporates Excalibur, an ensemble method combining 36 aggregation tests, enhancing analysis by presenting detailed results in Excel format with annotations and plots for nuanced interpretation. The pipeline supports parallelization via Slurm, requires minimal input, and provides extensive resources for data preparation and analysis.

Results: DoAggregate is a comprehensive pipeline for aggregation testing that facilitates in-depth exploration of genetic regions across genomes and exomes. By combining detailed annotations, robust statistical frameworks and user-friendly outputs, DoAggregate improves the interpretation of genomic data.

Conclusion: Our results demonstrate its effectiveness in uncovering disease-related genetic architectures, accelerating biomarker discovery and paving the way for new therapeutic targets, making it an indispensable tool for genomic researchers.

P15.125.D Genetic basis of internal tumors in Xeroderma pigmentosum

S. Nikolaev, *A. Iurchenko, F. Rajabi, A. Sarasin;*

Gustave Roussy, 94800 - VILLEJUIF, France

Xeroderma pigmentosum (XP) is a rare, autosomal recessive genodermatosis caused by Excision Nucleotide Repair deficiency. These patients are sensitive to sunlight, leading to an increased frequency of skin cancers. Recently, it was found that some XP patients are at a very high risk of developing internal tumors, including central nervous systems, hematological malignancies, gynecological and thyroid cancers. We analyzed four published, clinically well-defined XP cohorts (from the States, France, England and Brazil) and assessed the cancer risk of these patients. The Odds Ratio (OR) are very high for young XPs (more than a thousand times higher than for the general population) for the 0–20-year-old French XPs. Very high OR are also observed for English, French, and American XPs for developing brain tumors, hematological malignancies, and thyroid tumors. We analyzed, by whole genome sequencing, 18 internal tumors from XP patients, mainly hematological malignancies. Results demonstrated a dramatic increase in mutation rates in XP-C tumors versus sporadic tumors. A strong mutational asymmetry with respect to transcription and level of gene expression demonstrated the existence of transcription-coupled repair in vivo in humans. Mutations appeared to be caused by unrepaired bulky guanine lesions on the untranscribed strands of DNA. The mutational profiles of internal XP-C tumors are specific to NER- deficiency and nearly identical between all XP-C internal tumors regardless of the tumor type. Physicians following XP patients should be aware of the high risk of internal tumors. Prevention and early detection of leukemia and brain, gynecological and thyroid tumors are needed.

S. Nikolaev: None. **A. Iurchenko:** None. **F. Rajabi:** None. **A. Sarasin:** None.

P15.126.A Frequency of Bardet-Biedl syndrome variants in a population with early-onset obesity

Jesús Argente[1], ***Giuseppina Rosaria Umano***[2], *Melek Yildiz*[3], *Lior Carmon*[4], *Patrick Sleiman*[5], *Charles Savoie*[5], *Carel W. le Roux*[6], *Anthony P. Goldstone*[7]

[1]*Department of Pediatrics & Pediatric Endocrinology, Universidad Autónoma de Madrid, University Hospital Niño Jesús, CIBER "Fisiopatología de la obesidad y nutrición" (CIBEROBN), Instituto de Salud Carlos III, IMDEA Institute, Madrid, Spain,* [2]*Department of Woman, Child and of General and Specialized Surgery, University of Campania "Luigi Vanvitelli", Naples, Italy,* [3]*Department of Pediatric Endocrinology, Istanbul University Faculty of Medicine, Istanbul, Turkey,* [4]*Department of Pediatric Endocrinology, Soroka University Medical Center, Beer-Sheva, Israel,* [5]*Rhythm Pharmaceuticals, Inc, Boston, MA, USA,* [6]*Diabetes Complications Research Centre, University College Dublin, Dublin, Ireland,* [7]*PsychoNeuroEndocrinology Research Group, Division of Psychiatry, Department of Brain Sciences, Imperial College London, London, United Kingdom.*

Background: The melanocortin-4 receptor (MC4R) pathway is crucial for hunger regulation, energy balance, and weight control. In patients with Bardet-Biedl syndrome (BBS), dysfunctional primary cilia impair the MC4R pathway, causing symptoms like vision loss, learning difficulties, renal dysfunction, hyperphagia, and early-onset obesity. The Rare Obesity Advanced Diagnosis (ROAD)™ program aims to improve genetic testing access for

suspected rare MC4R pathway diseases in Europe and the Middle East.

Methods: Genes (*BBS1-BBS22*) from individuals with early-onset obesity were sequenced. Variants were classified as pathogenic/likely pathogenic/variants of uncertain significance (P/LP/VUS).

Results: Among 5,051 individuals, 16 individuals had a P/LP biallelic variant and 72 had a VUS biallelic variant, with *BBS14*, *BBS20*, and *BBS9* variants most frequent. For individuals <18 years, mean BMI z-score was 3.8; for ≥18 years, BMI was 41.6 kg/m^2. Age of obesity onset was 4.8 years and hyperphagia onset was 3.1 years. Individuals with P/LP/VUS variants were from Türkiye (5.82% of all individuals tested in the country), Spain (1.09%), Italy (1.08%), UK (2.25%), Israel (0.60%), Ireland (0.80%), and Germany (1.32%). Only 25 (28%) had a BBS suspicion at testing.

Conclusion: Among tested individuals, 1.74% with early-onset obesity had a biallelic variant in one of 22 BBS genes, with higher frequencies of *BBS14* and *BBS20* variants versus literature and a high frequency in Türkiye due to consanguinity. Not all patients had a clear BBS phenotype at diagnosis, indicating the need to include all BBS genes in early-onset obesity panels to improve disease understanding and early diagnosis for potential novel treatments.

P15.127.B Investigating the molecular function of *THAP12* in neurodevelopment

Bryce Rampal[1,2], *Katarzyna Ochenkowska*[1,2], *Meijiang Liao*[2], *Eric Samarut*[1,2]

[1]*Université de Montréal, Montréal, QC, Canada,* [2]*Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montréal, QC, Canada.*

Background: Lennox-Gastaut Syndrome (LGS) is a severe epileptic encephalopathy presenting significant diagnostic and therapeutic challenges, with approximately 30% of cases remaining undiagnosed. These cases offer an opportunity to explore novel biological mechanisms underlying LGS. Whole genome sequencing in two patients with severe LGS revealed biallelic variants in *THAP12*, a gene encoding a zinc finger protein involved in DNA binding and transcriptional regulation. However, *THAP12* has not been previously associated with any neurological disorder, and its molecular function, particularly in neurodevelopment, is poorly understood. We hypothesize that THAP12 functions as a transcription factor regulating genes critical for neurodevelopment.

Materials and Methods: In our first objective, we will generate *THAP12*-KO in HEK293FT cells to understand the general role and function of THAP12 in-vitro. We will perform chromatin immunoprecipitation (ChIP-seq) followed by whole transcriptomic analysis (RNA-seq), to understand how target genes are differentially regulated by THAP12. We will identify potential interacting partners of THAP12 using co-immunoprecipitation (Co-IP) coupled with liquid mass spectrometry. In our second objective, we will repeat these experiments in neural progenitor cells to identify target genes and interacting partners of THAP12 contributing to its role in neurodevelopment.

Results: Our preliminary results from RNA-seq on *THAP12*-KO HEK293FT cells have revealed a significant dysregulation of genes involved in neurodevelopment and transcription regulation. We have also identified several candidate interacting partners of THAP12 involved in cell cycle progression, neurodevelopment, and neurometabolism.

Conclusion: Our findings will shed light on *THAP12*'s role in neurodevelopment, offering insights into potential therapeutic targets for LGS.

[1]*Laboratory of Medical Genetics, ASST Papa Giovanni XXIII, Bergamo, Italy,* [2]*Rare disease unit, ASST Papa Giovanni XXIII, Bergamo, Italy,* [3]*Unit of Pediatric Neurology, COALA Center for Diagnosis and Treatment of Leukodystrophies, V. Buzzi Children's Hospital, Milano, Italy,* [4]*Department of Biomedical and Clinical Sciences, University of Milan, Milano, Italy,* [5]*Dept of Pediatrics, Rhumatology clinic, V. Buzzi Children's Hospital, Milano, Italy.*

Background: We report on a 16-year-old female third child from consanguineous parents (first degree cousins). The patient's mother was affected by systemic lupus erythematosus and hypothyroidism and the patient brother had chilblain lupus. The sister and the father were reported healthy. The patient presented at 15 years old with chilblain lupus, mitral valve insufficiency. Interferon signature was tested positive.

Material and Methods: We analyzed the patient-parents trio by PCR-free 2 × 150 bp Whole Genome sequencing; bioinformatics analysis was performed with Dragen version 3.9.5. As a validation, we performed RNAseq from PAXgene samples of peripheral blood and Sanger sequencing after RT-PCR.

Results: From trio-WGS data we suspected the presence of a homozygous duplication of the region chr20(GRCh38):g.36930231-36932015, encompassing exon 5 of the *SAMHD1* gene. Indeed, the bioinformatic pipeline called a 1784 bp heterozygous duplication within a run of homozygosity in proband and both parents, but visual inspection of the BAM files suggested the duplication would be homozygous in the proband and heterozygous in both parents. By RNAseq we confirmed the tandem duplication of *SAMHD1* exon 5, but we needed to perform RT-PCR and Sanger sequencing to confirm the homozygosity in the proband and heterozygosity in

parents. The duplication is predicted to generate a frameshift and is classified as likely pathogenic.

Conclusion: We highlight a main limitation of alignment tools in identifying homozygous duplications and we would suggest paying particular attention to isolated heterozygous calls within runs of homozygosity, since they could represent the only alert to address the right finding.

P15.129.D Artificial Intelligence and Facial Analysis for Diagnosing and Genotype Phenotype Correlation in RASopathies

Louise Lecat[1], *thomas courtin*[1], *Marlène Rio*[2], *valerie cormier daire*[1], *Caroline Michot*[1], *Genevieve Baujat*[1], *stanislas lyonnet*[1], *jeanne amiel*[1], *anne guimier*[1], *Sandrine marlin, MD PhD*[1], *ahmed zaiter*[3], *olivier lienhard*[3], *quentin hennocq*[4]

[1]*Paris Descartes-Sorbonne Paris Cité Université, Imagine Institute, 75015 Paris, France; Département de Génétique, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris (AP-HP), Paris, France., Paris, France,* [2]*Paris Descartes-Sorbonne Paris Cité Université, Imagine Institute, 75015 Paris, France; Département de Génétique, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris (AP-HP), Paris, France, Paris, France,* [3]*Université de Paris, Imagine Institute, Data Science Platform, INSERM UMR 1163, Paris, France; Centre de Recherche des Cordeliers, Sorbonne Université, INSERM, Université de Paris, Paris, France., Paris, France,* [4]*Laboratoire Forme et Croissance du Crâne, Hôpital Necker-Enfants Malades, Assistance Publique Hôpitaux de Paris, Paris, France., Paris, France.*

Background: RASopathies are a group of developmental syndromes caused by germline mutations in genes belonging to the Ras/MAPK pathway. Common features include intellectual disability, congenital heart defects, skin abnormalities, and craniofacial abnormalities. Due to their high genetic variability, establishing a genotype-phenotype correlation can be challenging. We aim to assist in diagnosis and genotype-phenotype correlation by using artificial intelligence and facial images.

Material and Methods: We tested AIDY (Artificial Intelligence for Dysmorphology), an artificial intelligence tool developed at Institut Imagine, Necker-Enfants Malades Hospital. We retrospectively included all frontal and lateral pictures of patients with a molecular diagnosis of RASopathies. We tested AIDY's ability to provide an accurate diagnosis.

Results: In total, we identified 197 patients in our local database with molecularly confirmed RASopathy and facial pictures. Of these, 73% (N = 143) had Noonan syndrome, 11% (N = 22) had neurofibromatosis-Noonan syndrome; 7.6% (N = 15) had Costello syndrome; 3% (N = 6) had an indistinguishable phenotype between Noonan syndrome and cardiofaciocutaneous syndrome, 2.5% (N = 5) had cardiofaciocutaneous syndrome, 2% (N = 4) had Noonan syndrome with multiple lentigines. Computational analysis is still ongoing, and we are hoping to have results soon.

Conclusion: Next-Generation Phenotyping using artificial intelligence could be a real benefit for patients, helping establish a precise diagnosis and genotype-phenotype correlation. Indeed, some genes are more associated with certain features; for example, RIT1 and RAF1 are associated with cardiomyopathy, and PTPN11 and KRAS with the risk of cancer.

P15.130.A Application of Nanopore sequencing for CNVs characterization in paediatric patients with genetic epilepsies

Simona Virdò[1], *Elena Cellini*[1], *Flavia Fineschi*[1], *Valentina Cetica*[1], *Aurelia Iuliana Timis*[1], *Dalila De Vita*[1], *Domenico Rutigliano*[1], *Daniela Pucatti*[1], *Claudia Mandorlini*[1], *Renzo Guerrini*[1,2], *Elena Parrini*[1], *Davide Mei*[1]

[1]*Neuroscience and Medical Genetics Department, Meyer Children's Hospital - IRCCS, Florence, Italy,* [2]*University of Florence, Florence, Italy.*

Background: Genetic epilepsies (GEs) represent a group of conditions caused by heterogeneous genetic aetiologies. Long-read sequencing enables precise detection and characterization of copy number variants (CNVs) and complex rearrangements, increasing diagnostic yield in unsolved cases. We utilized Oxford Nanopore Technologies (ONT) long-read sequencing on a cohort of paediatric GE patients with pathogenic CNVs, previously identified using conventional methods, to enhance their molecular characterization.

Material and Methods: We re-analysed the DNA of patients carrying CNVs previously detected by Multiplex ligation-dependent probe amplification (MLPA) or NGS sequencing. We performed whole genome or adaptive sampling sequencing, a software-based enrichment targeting the regions of interest during sequencing, using PromethION or MinION flow cells.

Results: Nanopore sequencing allowed to confirm and better characterize two intragenic deletions involving the DEPDC5 and STXBP1 genes. An alleged duplication, including four SCN1A exons detected by MLPA, was reclassified as a complex intragenic rearrangement resulting from a flanking duplication with multiple deletions. We also defined the exact breakpoints of two deletions involving the SCN1A gene; in one patient, we unravelled the additional involvement in the deletion of a gene located upstream SCN1A.

Conclusion: ONT long-read sequencing has proven to be diagnostically and research-wise useful, enabling the validation of known CNVs, allowing a precise identification of breakpoints, and improving the refinement and characterization of complex rearrangements in GEs. Our findings demonstrate the effectiveness of this platform in the diagnostic workflow for characterizing genomic abnormalities and elucidating their role in the disease pathogenesis, providing significant clinical insights.

P15.131.B Understanding the role of a protein subunit in an undiagnosable neurodevelopmental disorder

Shalini Roy Choudhury[1], *Christopher Geoff Woods*[2]

[1]*Cambridge Institute for Medical Research, Cambridge, United Kingdom,* [2]*Clinical Genetics Department, Addenbrooke's Hospital, Cambridge, United Kingdom.*

Background: We report a consanguineous Pakistani family where a male and female cousin had an undiagnosable neurodevelopmental disorder. Both had a similar phenotype; severe

developmental delay, cerebellar anomalies, insensitivity to pain, and a progressive sensory and motor peripheral neuropathy that affected arms more than the legs. We aimed to identify the genetic cause and molecular mechanisms underlying this disease.

Material and Methods: We undertook whole exome sequence analysis and identified a potential mutation in the *RPP30* gene. RPP30 is a subunit of the ubiquitous ribonuclease P complex. We carried out cellular and molecular studies to understand the contribution of this mutation in this disorder.

Results: The mutant RPP30 forms aggregates in the nucleus unlike the wild-type protein which is diffused. The mutant protein has an overall reduced cellular expression, and is degraded by the proteasomal pathway. The mutant RPP30 still interacts with a second partner protein, which, along with several other proteins, forms a functional ribonuclease P complex. Curiously, in the presence of this second protein, the mutant RPP30 forms less cellular aggregates.

Conclusion: We identified a new gene, *RPP30*, as a novel cause of a rare neurodevelopmental disorder. Functional studies indicate that the mutation identified in the patient likely disrupts the protein structure and function, leading to the disease.

P15.132.C Implementation of rare diseases registry into hospital

Kristi Tael[1,2], *Elis R. Tars Hurt*[1], *Saara M. Laidre*[1], *Tiiu Laud*[3], *Jarno Raid*[3], *Katrin Ounap*[1,2]

[1]*Tartu University Hospital, Genetics and Personalized Medicine Clinic, Tartu, Estonia,* [2]*Institute of Clinical Medicine, University of Tartu, Tartu, Estonia,* [3]*Tartu University Hospital, Informatics Administration, Tartu, Estonia.*

Background: In the European Union, a rare disease (RD) is defined as one affecting fewer than 5 out of 10,000 members of the general population. Only approximately 350 RD have an ICD-10 diagnosis code, which is why patients cannot be identified in patient information systems and thus RD prevalence and patients' numbers cannot be estimated.Tartu University Hospital (TUH) is the only university hospital in Estonia and in certain fields the only center of expertise. The Rare Disease Competence Centre (RDCC) is established at the TUH IN 2021. The RD registry (RDR) is part of the TUH's e-health system, data about RD patients is registered here.

Material and Methods: TUH is the first hospital to implement RDR in Estonia from April 1st 2023. Data about RDCC patients' were registered retrospectively from the year 2012 and prospectively. The data is collected according to the Set of Common Data Elements for RD Registration. The information collected refers to ORPHA-code, ICD10 code, disease history and information about the laboratory analysis on the basis of which the diagnosis has been confirmed.

Results: To January 26th 2025, the registry includes 2746 entries of patients with all cytogenetically and molecular-genetically confirmed RD. 832 different ORPHA-codes have been used. Among them, 37% of patients (997) are pediatric <10 years, and 14.% (390) of them are hereditary cancer syndrome patients.

Conclusion: The systematic collection of data on patients with RD provides important information on both the prevalence of diseases and the number of patients.

P15.134.A Novel Illumina 5-base NGS approach can bring genomic and epigenomic findings using single assay

Fiona Kaper[1], *Ev Chekalin*[1], *Oscar Murillo*[1], *Danielle Goldberg*[1], *Emily Parker*[1], *James Baye*[2], *Joshua Beytebiere*[1], *Kayla Busby*[1], *Eric Brustad*[1], *Bridget Dorsey*[1], *Sophie Fertel*[1], *Stephen Gross*[1], *Rebekah Karadeema*[1], *Huy Lam*[1], *Valerie Montel*[1], *June Pais*[1], *Suzanne Rohrback*[1], *Angelica Schalembier*[1], *David Tse*[1], *Kat Tzeng*[1], *Richard Wang*[1], *Lisa Watson*[1], *Allison Yunghans*[1], *Ali Crawford*[1]

[1]*Illumina, San Diego, CA, USA,* [2]*Illumina, Cambridge, United Kingdom.*

Multiomics studies provide an integrated approach to identify complex biomolecular fingerprints that may indicate disease. For example, the analysis of genomic variants in combination with epigenetic signatures allows the interrogation of a wide spectrum of disease-associated loci for a variety of conditions such as Rare Undiagnosed Genetic Diseases (RUGD) diagnostics and cancer classifications. This approach typically employs individual, disparate assays that provide single-omic information, creating a barrier that is often costly and time-consuming. A single platform that provides a readout of both genomic and epigenomic analysis could substantially simplify our ability to collect and analyze complex multiomic information.Here we present novel, single-step methyl-conversion library-prep technology capable of simultaneous genome variant detection and DNA methylation profiling in a single experiment. It is a simplified workflow compared to commercially available conversion technologies, resulting in a less than seven-hour turnaround time, while also requiring as little as 50 ng of genomic DNA input.We evaluated our solution against current methods for DNA sequencing and methylation analysis including: Whole Genome Sequencing, Enzymatic Sequencing (EM-Seq) and Illumina Methylation arrays. We show that the single 5-base solution presented can produce results that can be used for disease cases resolution.

P15.135.B Genome sequencing (GS) vs targeted gene panel next generation sequencing (panelNGS) for paediatric and syndromic cardiomyopathy in the diagnostic setting:

resolution, reanalysis, and review

Phillipa May[1], *Matthew Edwards*[1], *Lizi Briggs*[1], *Maha Younes*[1], *Andrew Fleming*[1], *Renata Gomes*[1], *Anna Lockhart*[1], *Sally Walsh*[1], *Krunal Mahida*[1], *Sam Wilkinson*[1], *Amy Slater*[1], *Katie Williams*[1], *Steven Muller*[1], *Tahni-Ann Wilson*[2], *Ellie Quinn*[2], *Tessa Homfray*[1], *Deborah Morris-Rosendahl*[1]

[1]*Clinical Genetics & Genomics Laboratory, Royal Brompton Hospital, London, United Kingdom,* [2]*Clinical Genetics, Royal Brompton Hospital, London, United Kingdom.*

Background: We present a two-year retrospective analysis of genetic diagnostic testing for paediatric or syndromic cardiomyopathy, to determine the 'added value' of GS.

Material and Methods: Patients were referred for a custom NGS panel (n = 100+ probands) or singleton/duo/trio GS performed in the NHSE Genomic Medicine Service (80+ probands). Both approaches use a bioinformatically-applied gene list (119–160 genes in PanelApp), however panelNGS was mostly restricted to protein-coding regions.

Results: GS identified a genetic aetiology fully explaining the patient's cardiac phenotype (likely pathogenic or pathogenic variants) consistent with the inheritance pattern, in 41% of cases versus 18% of panel NGS cases. The panelNGS yield was increased to 20% following further testing such as parental testing. The GS approach resulted in fewer follow up tests and quicker resolution. We dissect the reasons for this difference, breaking down resolution rates in families versus singletons, and the location of variants not detectable by panelNGS. Panel App is regularly reviewed and our data show the success of incremental changes. We compare the Tiering approach for filtering variants to Exomiser and examine the effects of the number of Human Phenotype Ontology (HPO) terms submitted with the referral.

Conclusion: In a phenotypically heterogenous patient cohort, GS has advantages over targeted panel testing, allowing analysis of variation outside the standard target: genes not included in the panel, non-coding regions and the identification of structural variants. However, these advantages depend on efficient prioritisation of variants, which requires a well-structured bioinformatic pipeline.

P15.136.C Deploying multiomics and pangenome tools to detect complex variants, validate VUS, and increase testing equity in rare disease

Emmanuèle Colette Délot[1], *Seth I. Berger*[2], *Jean Monlong*[3], *Greta Pitsava*[1], *Shloka Negi*[4], *Brandy McNulty*[4], *Karen H. Miga*[4], *UCI-GREGoR*[5], *Benedict Paten*[4], *Eric Vilain*[1]

[1]*University of California, Irvine, Irvine, CA, USA,* [2]*Children's National Hospital, Washington, DC, USA,* [3]*University of Toulouse, INSERM, Toulouse, France,* [4]*University of California, Santa Cruz, Santa Cruz, CA, USA,* [5]

Background: We evaluated the ability of nanopore-based long-read sequencing (LRS) to detect clinically relevant complex variants in a cohort.

Material and Methods: We targeted outputs practical and cost-effective for a clinical laboratory setting (e.g. no ultra-long reads).

Results: In Y-X translocations, alignment to the T2T reference disambiguated the pseudoautosomal regions and revealed different breakpoints as well as additional X deletions undetected by clinical testing. In 46,XY gonadal dysgenesis caused by 9pter deletions, we show that the terminal deletions are in fact exchanges of telomeric regions with another chromosome. To genotype segmentally duplicated regions, such as the RCCX module associated with Congenital Adrenal Hyperplasia, *TNXB*-associated Ehlers-Danlos syndrome, and susceptibility to schizophrenia and autoimmune disorders, we created a new tool, *Parakit*. Creating an enriched local pangenome, Parakit mapped and phased variants and fusions, counted modules, and made diagnoses in singleton-only cases, beyond the ability of current clinical assays. Diagnosing singleton-only cases is critical to addressing inequity in genetic testing for the millions of families where one or both biological parents are not available. By systematically deploying RNA sequencing in parallel with genome sequencing, we demonstrated non-canonical exon inclusions as a frequent etiology in rare disease. But =, in addition, the CpG methylation status available in the LRS dataset showed an episignature matching that of CSS1 in a proband with a deep intronic VUS in *ARID1B*, leading to a reclassification of the variant to likely pathogenic and a firm diagnosis.

Conclusion: Deploying LRS and multi-omics reveals complexity and hidden diagnoses in rare disease.

P15.137.D Exploring the neurophysiologic and neuropathologic basis of visual deficits in cystinosis

H. Chang[1], *L. Prifti*[1], *A. Solorzano*[1], *H. Sattler*[1], *L. Mac Taggart*[1], *S. Spallina*[1], *C. Canavesi*[2], *E. Freedman*[1], *K. Wang*[1], *J. Foxe*[1];

[1]*University of Rochester School of Medicine and Dentistry, Rochester, NY,* [2]*LighTopTech Corp., Rochester, NY*

Cystinosis is a rare, childhood lysosomal storage disorder caused by mutations in cystinosin, the transporter responsible for cystine from the lysosome to the cytosol. In cystinosis, mutated cystinosin causes cystine crystal accumulation and cell death. Photophobia, or abnormal sensitivity to light, is an early symptom of the disease and can be debilitating for patients. Historically, this photophobia has been attributed to ocular corneal cystine crystal accumulation, but eyedrops prescribed to disrupt these crystals do not fully alleviate symptoms. Furthermore, photophobia is known to have a neurobiological basis that extends beyond eye injury alone. Interestingly, when individuals with cystinosis were presented with a series of visual stimuli, they had increased early, cortical visual evoked responses. Given these data, we hypothesize that photophobia in cystinosis could be due to a central nervous system (CNS) hyperexcitability that results from prolonged corneal cystine accumulation. To explore this, we have developed a cystinosin knockout (*Ctns* $^{-/-}$) mouse model using CRISPR/Cas9. This model has been confirmed to produce a truncated, nonfunctional protein product. Phenotypically, our model recapitulates the human disease and demonstrates corneal eye crystal accumulation. Our model will be used to conduct similar visual electrophysiology studies to those conducted in patients and probe for a mechanism of cortical hyperexcitability using various neuromarkers. By recording similar neurophysiologic signatures across species and correlating them with changes in molecular signatures, we aim to deepen our understanding of the pathophysiology of photophobia in cystinosis and develop new therapeutics for individuals.

P15.138.A Applications of ONT long read sequencing in rare disease research and diagnosis

*Ayla Turgay[1], Dize Deryali[2], Behich Koyutourk[2], **Mahmut Cerkez Ergoren**[1]*

[1]Near East University Hospital, Nicosia, Cyprus, [2]Near East University, Nicosia, Cyprus.

Background: Rare diseases, a diverse group of genetic disorders, affect a small portion of the population and are challenging to study due to their complexity. Traditional short-read sequencing (SRS) has limitations in diagnosing these conditions, especially in resolving genetic variants in repetitive regions. Recently, long-read sequencing (LRS) technologies, like those supported by Oxford Nanopore Technology (ONT), have become vital for addressing these challenges.

Material and Methods: This study employed ONT sequencing to analyze genomic DNA from patients with suspected hereditary cancer predisposition. The WholEx Pro protocol (IVD-CE, 4Bases Switzerland) was used for library preparation and sequencing, ensuring high-quality results. LRS generates reads up to 10 kilobases, enabling the detection of diverse genetic alterations, including point mutations, repeat expansions, large insertions, and structural variations. Results were validated through comparative analyses with data from other diagnostic laboratories, focusing on mutations in repetitive and homologous genomic regions that are difficult for SRS to resolve.

Results: Since October 2024, ONT has been actively utilized in our diagnostic lab. Initial analyses demonstrated the platform's accuracy in identifying pathogenic variants, including complex structural variations and repeat expansions. Cross-validation with external facilities confirmed the reliability of the workflow.

Conclusion: Integrating ONT sequencing has significantly improved variant detection in complex genomic regions, particularly in repetitive sequences. This advancement establishes ONT-LRS as a robust, efficient approach for diagnosing hereditary cancer syndromes, offering clear advantages over traditional short-read methods.

P15.139.B Advancing precision medicine: long-read sequencing in complex variant identification

***Pasquale Di Letto**[1], Mariateresa Zanobio[1], Margherita Scarpato[1], Federica Romano[1], Sarah Iffat Rahman[1], Pasquale Primo[1], Maria Elena Onore[1], Rossella Nicoletta Borrelli[1], Carmine Spampanato[1], Giulio Piluso[1], Annalaura Torella[1,2], Vincenzo Nigro[1,2]*

[1]University of Campania Luigi Vanvitelli, Naples, Italy, [2]Telethon Institute of Genetics and Medicine, TIGEM, Pozzuoli, Italy.

Background: Long-read sequencing technologies have revolutionized genomics by enabling the comprehensive detection of complex genetic variations, such as structural variants, repetitive regions, and intricate genomic rearrangements. Thus, they significantly enhance diagnostic capabilities for genetic disorders.

Material and Methods: Analysis was performed using Oxford Nanopore Technologies (ONT) and validated with Sanger sequencing or array-CGH.

Results: Firstly, we performed long-read sequencing to characterize complex variants for which short-read exome sequencing and bioinformatic analysis had initially suggested the presence of structural rearrangements not further defined. ONT confirmed these rearrangements and provided high-resolution breakpoint characterization. Given this, we present three cases in which long-read sequencing brought definitive diagnoses that conventional techniques overlooked. The first case involves a 447 bp Alu-mediated insertion in the NSD1 gene, resulting in exon 13 skipping, which induces the development of Sotos syndrome. In the second case, a 3 kb Alu-mediated deletion in the DEGS1 gene, associated with hypomyelinating leukodystrophy, was successfully identified after eluding detection by short-read sequencing and array-CGH analysis. The third case highlighted a complex maternal mosaicism in the DES gene resulting in two different deletions and disease manifestations, in an affected mother and child.

Conclusion: The cases presented highlight the transformative impact of long-read sequencing in clinical diagnostics. By uncovering previously undetectable genetic variations, this technology significantly enhances the accuracy of diagnoses, leading to deeper understanding of genetic disorders and more precise, personalized patient care. Its integration into clinical practice is not just beneficial but essential for advancing genomic medicine, improving disease management, and ultimately enhancing patient outcomes.

P15.140.C Towards multiomics in rare disease: long-read and RNA sequencing complement short-read genome sequencing

***Håkan Thonberg**[1,2], Jesper Eisfeldt[2], Daniel Nilsson[1,2], Karl De Geer[1,2], Caroline Graff[3,4], Anna Lindstrand[1,2]*

[1]Department of Clinical Genetics and Genomics, Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden, [3]Division for Neurogeriatrics, Centre for Alzheimer Research, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden, [4]Unit for Hereditary Dementias, Karolinska University Hospital, Stockholm, Sweden.

Background: Short-read genome sequencing (WGS), combined with bioinformatic tools for detecting repeat expansions, structural variants, and copy-number variants, enables high diagnostic yields across rare disease patient groups. However, not all genetic variants can be fully resolved or clinically interpreted using WGS alone. Such cases include structural rearrangements, repeat sequences, and variants located in non-coding regions. We have gathered several examples of these variants and explored the clinical value of complementary multiomic analysis.

Methods: WGS, long-read sequencing, RNA-sequencing.

Results: 1) A patient with clinical phenotype of Mb Osler harbored a variant in *ACVRL1* (MIM 600376). Long-read sequencing detected a 2.2 kb exonic insertion of mitochondrial DNA. The variant was deemed pathogenic as it disrupts an autosomal dominant disease gene matching the clinical phenotype. 2) In a newborn boy blind from birth clinical WGS did not identify any causative variant. RNA-sequencing identified loss of *PRICKLE3* expression. Reanalysis of WGS data on the child and the

unaffected mother revealed a hemizygous deletion in a transcription factor binding motif at the *PRICKLE3*-promoter. The variant is likely to cause the loss of expression but further functional studied are needed to prove causality of *PRICKLE3*. 3) In an individual with frontotemporal dementia but normal ELISA results, clinical WGS detected a likely pathogenic canonical splice-site variant in *GRN* (MIM 607485). Follow-up RNA sequencing revealed aberrant splicing caused by a cryptic splice site and not the typical haplo-insufficiency.

Conclusion: Long-read and RNA-sequencing can provide additional result to clinical analysis and thereby increase diagnostic yield

P15.141.D Individual competence assessment of WGS/WES proportionate variant analysis using the GENie platform

Miranda Durkie[1], *Dave Cregeen*[2], *Angie Kolozi*[2], *Joseph Leslie*[3], *Ian Berry*[4], *Karen Stals*[5], *Martina Owens*[5], *Rachael Mein*[6], *Andrew Parrish*[5], *Sian Ellard*[5,7], *Emma Baple*[8,7,5], *Sandi Deans*[2]

[1]*NHS North East Yorkshire Genomic Laboratory Hub, Sheffield, United Kingdom,* [2]*GenQA Department of Laboratory Medicine, Edinburgh, United Kingdom,* [3]*University of Exeter, Exeter, United Kingdom,* [4]*NHS South West Genomic Laboratory Hub, Bristol, United Kingdom,* [5]*NHS South West Genomic Laboratory Hub, Exeter, United Kingdom,* [6]*NHS England, London, United Kingdom,* [7]*University of Exeter Medical School, Exeter, United Kingdom,* [8]*Peninsula Clinical Genetics Service, Exeter, United Kingdom.*

Background: Genomic diagnostic testing is increasingly expanding to whole exome (WES) and whole genome sequencing (WGS) to improve sensitivity for causative variants. However, the overall burden of variants requiring analysis is increased compared to targeted panels. To maximise variant scientist resource and capacity, proportionate analysis of variants, excluding those with low probability of pathogenicity and focussing on the most likely causative variants is recommended (PMID: 39327040 and https://www.youtube.com/watch?v=vOV_xiccw3U).

Material and Methods: GENie is an online, individual learning and assessment tool from GenQA. To support the genomics workforce, the pilot program included six clinical WES/WGS case scenarios that require variant prioritisation prior to further analysis and reporting. Participants assessed the annotated variants and chose to "exclude from analysis", "definitely report" or flag for "further variant classification". Upon result submission, expected responses by expert advisors were provided. Summary results will be presented at an online webinar prior to the introduction of the full GENie module.

Results: Results of this pilot scheme will be presented, focussing on learning points from difficult cases and variants, as well as participant summary data such as role, experience and time taken to complete each case.

Conclusion: The GENie online training platform allows scientists to showcase their expertise and continuing professional development. It can be used to evidence the competency of individual scientists to accurately and efficiently perform WES and WGS analysis, maximising resources to ensure patients get their results in a timely manner.

P15.142.A Phenotype-driven filtering in whole exome sequencing: Results of Human Phenotype Ontology usage to create patient-specific virtual gene panels in a single center

Mehmet Kocabey[1], *Merve Berfin Aktan Karaca*[1], *Semra GÜRSOY*[2], *Ayfer Ulgenalp*[1], *Ahmet Okay Caglayan*[1]

[1]*Dokuz Eylul University Faculty of Medicine Department of Medical Genetics, Izmir, Turkey,* [2]*Dokuz Eylul University Faculty of Medicine Department of Pediatric Genetics, Izmir, Turkey.*

Background: Whole exome sequencing (WES) is widely used in rare disease diagnostics, yet its diagnostic yield remains suboptimal. Genomic variation must be filtered and analyzed, incorporating phenotypic data. Accurate phenotypic descriptions are essential in this process and the Human Phenotype Ontology (HPO) provides a standardized, hierarchical vocabulary, along with gene-phenotype associations.

Material and Methods: The results of 176 unrelated cases who underwent WES between 2019 and 2024 were retrospectively analyzed. Analyses involving known relatives were excluded. Phenotypic information was obtained from requesting physicians, and corresponding HPO terms were determined by clinical geneticists. Only variants associated with HPO terms were filtered, similar to a virtual panel specific to the patient, and diagnostic yield was examined.

Results: 981 (439 unique) HPO terms were assigned to 176 cases presenting with a broad spectrum of symptoms. The average per case was 5.57, with a median of 5 terms. Among them, 102 cases had ≥5 terms, while 74 cases had four or fewer. A definitive diagnosis was established in 56 cases (31.8%). Every diagnostic variant matched with at least 1 HPO term. There was no statistically significant difference in diagnostic rate between cases with ≥5 terms (31.4%) and with ≤4 terms (32.4%) ($p > 0.05$).

Conclusion: This study demonstrates that HPO-based filtering is highly effective. Unexpectedly, adding more symptoms does not necessarily increase the likelihood of diagnosis, which may be due to cohort size. Remarkably, even a single, well-chosen HPO term can be sufficient for diagnosis, as specificity plays a crucial role in identifying the causative variant.

P15.143.B Targeted long-read sequencing of the RCA cluster to personalise management of aHUS

Giles S. Holt[1], *Inas Natasya*[1], *Lorna Wilkinson*[2], *Nicole van de Kar*[3], *Bert van den Heuvel*[3], *Vicky Brocklebank*[2], *Chris Watson*[4], *Joris Veltman*[5], *David Kavanagh*[2]

[1]*Newcastle University, Biosciences Institute, Newcastle upon Tyne, United Kingdom,* [2]*Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom,* [3]*Radboud University, Nijmegen, Netherlands,* [4]*North East and Yorkshire Genomic Laboratory Hub, Leeds, United Kingdom,* [5]*Newcastle University, Biosciences Institute, Newcastle-upon-Tyne, United Kingdom.*

Background: Atypical haemolytic-uremic syndrome (aHUS) is a rare life-threatening disease caused by genomic variation in the complement region. For approximately 20% of familial and 40% of sporadic cases, a molecular diagnosis is not established using standard sequencing methodologies due to complex surrounding genomic architecture. Accurate diagnosis is important, with drug treatments of £350k per patient/annum, and genetic causes predicting outcomes in transplants and disease relapse after treatment withdrawal.

Material&Methods: Our study aims to combine accurate target-capture and long-read sequencing for improved diagnostics. A hybridization capture panel was designed and optimised to target a 1 Mb genetic region required for aHUS diagnosis. A pipeline was constructed for a bespoke, cost-effective, long-read sequencing approach that would advance analysis of this structurally complex region.

Results: Using multiplexed sequencing on a single PromethION flowcell we demonstrate >90% capture and achieve up to 400x coverage per sample, with high-quality MAPQ 60 mapping versus low-quality MAPQ 0–20 in short-read data of the same region. Early analysis of 120 mutation positive cases confirmed reliable detection of all causal point mutations using the new approach, with improved structural variant interpretation, including precise breakpoints and greater resolution for complex structural rearrangements. Over 500 mutation positive cases and unresolved cases are now being assessed.

Conclusion: This pilot study validates a cost-efficient advancement for aHUS diagnostics. We aim to establish this novel genetic assay for the NHS. Accurate and rapid genetic diagnosis is essential for clinical decision-making and the approach can be easily expanded for other rare diseases caused by variation in complex regions.

P15.144.C Definition of rare mutations involved in the pathogenesis of sporadic brain malformations using whole exome sequencing

Elena Zholdybayeva, *Ayazhan Bekbayeva, Alua Gusmaulemova, Botakoz Kurentay*

National Centar for Biotechnology, Astana, Kazakhstan.

Background: Brain arteriovenous malformations (AVMs) are a significant cause of hemorrhagic stroke in both children and adults. AVMs are classified into hereditary and sporadic forms, with approximately 95% being sporadic and only about 3% hereditary. Despite extensive research, the mechanisms underlying brain AVM formation remain poorly understood.

Material and Methods: The study included a 39-year-old male patient diagnosed with brain AVM, confirmed via magnetic resonance angiography. DNA was extracted from peripheral blood using the QIAamp DNA Blood Mini Kit (Qiagen). Paired-end libraries were obtained by the Twist Library Preparation EF Kit and sequenced on the NovaSeq 6000 Illumina platform. Data analysis and annotation were performed using the GATK workflow, and variant call format (VCF) files were generated. To visualize and functionally group genes with filtered variants, the ClueGO plug-in in Cytoscape software was utilized. Candidate gene prioritization was carried out using ToppGene (https://toppgene.cchmc.org/). Variants were validated by Sanger sequencing.

Results: A total of 45,593,698 reads were obtained, of which 92.82% had a Phred quality score >30. After applying filtering criteria (Missense, nonsense, frameshift, and short indels; MAF <0.01), approximately 316 variants were selected. ClueGO enrichment analysis identified pathways related to cell-cell adhesion, telencephalon cell migration, and forebrain cell migration. Prioritization analysis highlighted key genes involved in biological processes, including aorta morphogenesis (*COL3A1*), BMP signaling pathway (*MAPK*), cellular response to endogenous stimuli (*CTBP2*), and positive regulation of intracellular signal transduction (*RNF31*).

Conclusion: We propose that disruptions in these pathways represent potential mechanisms contributing to the pathogenesis of brain AVMs.

P15.145.D Novel EMC10 Frameshift Variant Detected by Whole Exome Sequencing: EMC10 Related Neurodevelopmental Disorder

Dilan Genç Akdag[1], *Gül Ünsel Bolat*[2], *Hilmi Bolat*[3]

[1]*Department of Medical Genetics, Faculty of Medicine, Balıkesir University, Balıkesir, Turkey,* [2]*Department of Child and Adolescent Psychiatry, Faculty of Medicine, Balıkesir University, Balıkesir, Turkey,* [3]*Department of Medical Genetics, Faculty of Medicine, Balıkesir University, Balıkesir, Turkey.*

Background: The EMC10 gene, located on chromosome 19, encodes one of the 10 components of the endoplasmic reticulum complex (EMC), a highly conserved protein complex involved in membrane protein biology. EMC10-related Neurodevelopmental disorder (NDD) with dysmorphic facies and variable seizures is an autosomal recessive disorder characterized by global developmental delay apparent in early childhood.

Material and Methods: In the first step, peripheral blood samples were analyzed using karyotyping, FMR1 CGG repeats analysis, and microarray analysis. In the subsequent step, the patient underwent whole exome sequencing (WES). To confirm the detected variant and assess family segregation, Sanger sequencing was performed.

Results: Whole exome sequencing (WES) revealed a novel homozygous frameshift pathogenic variant (NM_206538.4) c.431del p.Asp144AlafsTer3 in the EMC10 gene, which was associated with the clinical presentation.

Discussion: A total of 31 cases, including ours, have been reported in the literature with this clinical presentation. In our case, developmental delay, speech delay, intellectual disability, poor weight gain, EEG abnormalities, dysmorphic facial features (long face, triangular face, long forehead, bifrontal narrowing, narrow nasal bridge, crowded teeth, full nasal tip, fifth finger clinodactyly), and microcephaly are present, which align with the characteristics observed in the other reported cases. However, our case does not exhibit kidney cysts, nephrocalcinosis, elevated

parathyroid hormone levels, ataxia, or hypotonia, which have been reported in other patients in the literature

P15.147.B Genotype-phenotype spectrum of FBN1-related fibrillinopathies

Daniela Kostova[1,2], *Kunka Kamenarova*[3,2], *Darina Kachakova-Yordanova*[3,2], *Kalina Mihova*[3,2], *Martin Georgiev*[3,2], *Ivanka Dimova*[4,5], *Maria Sredkova-Ruskova*[6], *Nevyana Veleva*[7], *Radka Kaneva*[3,2]

[1]Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical faculty, Medical University of Sofia, Sofia, Bulgaria, [2]Laboratory of Genome Diagnostics, Molecular Medicine Center, Medical faculty, Medical University of Sofia, Sofia, Bulgaria, [3]Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical faculty, Medical University of Sofia, Sofia, Bulgaria, Sofia, Bulgaria, [4]Laboratory of Genome Diagnostics, Molecular Medicine Center, Medical University of Sofia, Sofia, Bulgaria, [5]Department of Medical Genetics, Medical faculty, Medical University of Sofia, Sofia, Bulgaria, Sofia, Bulgaria, [6]University Pediatrics Hospital, Department of Clinical Genetics, Medical University of Sofia, Sofia, Bulgaria, [7]University Hospital "Aleksandrovska", Department of Ophthalmology, Sofia, Bulgaria.

Background: Marfan syndrome (MFS) is an autosomal-dominant disorder with highly variable clinical manifestations including cardiovascular, ocular, hearing and a series of skeletal anomalies. Mutations in the gene for fibrillin-1 (*FBN1*) cause MFS, and over than 3700 pathogenic/likely pathogenic variants have been published to date. The aim of the present study was to identify the genetic diagnosis in a group of Bulgarian patients with symptoms strongly suggesting for MFS and to determine the contribution of rare *FBN1*-variants in the pathogenesis of the studied phenotypes.

Material and Methods: Thirty patients presenting symptoms, ranging from mild phenotypes, such as isolated ectopia lentis, retinopathy, or hearing impairment, to severe cardiovascular disorders, were recruited from different clinical departments. We performed WES on NovaSeq6000 platform of Illumina. Variants in MFS-associated genes were extracted from the WES data and filtered using systematic bioinformatics analysis and the American College of Medical Genetics and Genomics criteria.

Results: Fourteen disease-causing variants in *FBN1* were found in 16 out of 30 patients analyzed (53%) - 12 known and 2 novel. In 14 patients (47%) genetic cause of the disease was not identified, possibly due to the presence of non-coding mutations or copy number variation in related genes. Predominant clinical phenotype in the studied cohort was MFS/Marfan-like, but also non-syndromic retinopathy, primary open-angle glaucoma, ectopia lentis, and deafness.

Conclusion: *FBN1*-mutations have been found not only in MFS but also in a range of phenotypes, suggesting a role of this gene in the pathogenesis of wide spectrum of seemingly not-related diseases.

[1]Laboratory of Molecular Genetics of Neurometabolic Diseases Department of Neuroscience and Medical Genetics, Meyer Children's Hospital IRCCS, Florence, Italy, [2]Department of NEUROFARBA, University of Florence, Florence, Italy, [3]USL Toscana Centro, Neurology Unit, Ospedale San Giovanni di Dio, Florence, Florence, Italy, [4]Parkinson Unit, AOU Careggi, Florence, Florence, Italy, [5]Neuroscience Department, Meyer Children's Hospital IRCCS, Florence, Florence, Italy, [6]Newborn Screening, Clinical Chemistry and Pharmacology Lab, Meyer Children's Hospital IRCCS, Florence, Florence, Italy, [7]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy, [8]Metabolic and Muscular Unit, Neuroscience Department, Meyer Children's Hospital IRCCS, Florence, Florence, Italy

Background: Common neurodegenerative disorders (NDDs), such as Parkinson's disease (PD), Alzheimer's disease or ataxia of different aetiology, can present with symptoms similar to Lysosomal Storage Disorders (LSDs). A known association exists between *GBA* gene mutations at a heterozygous level and PD. Variants in the galactocerebrosidase (*GALC*), and arylsulfatase A (*ARSA*) genes, causing the autosomal recessive Krabbe disease and metachromatic leukodystrophy respectively, have also been identified as risk factors for NDDs.We defined a study to select undiagnosed neurological patients with symptoms of NDDs that overlap with late-onset LSDs.

Material and Methods: Patients enrolled in this study were analysed using a NGS panel including 64 genes involved in LSDs. Familial analyses, enzyme assays and functional studies were used to characterise patients' defects.

Results: In this study, which included 148 patients with NDDS, we identified a patient affected by the late-onset form of Krabbe disease, and 2 patients with pathogenic variants in the lysosomal *GRN* gene, causing frontotemporal dementia, an autosomal dominant disorder.We also identified 11 patients carrying known *GBA* mutations, 3 patients carrying known *GALC* mutations and 3 patients with pathogenic variants in the *ARSA* gene. These 17 patients carried the pathogenic variants at a heterozygous state.

Conclusion: This study emphasizes the importance of including LSDs in the differential diagnosis of NDDs. In addition, compared to the general population, we identified a high percentage of heterozygous carriers of known pathogenic variants involved in LSDs, which suggests that LSD genetic defects may be at a greater risk of developing NDDs.

P15.149.D Differential coverage of Whole Exome Sequencing commercial kits utilizing DNA derived from diverse tissue sources

Edgard Verdura[1,2], *José-Luis Villanueva-Cañas*[1,3,4], *Aina Montalbán-Casafont*[1], *Xavier Solé*[1,3,4], *Esther Titos*[1,2,4], *Eva Gonzalez-Roca*[1,4,5], *Maria Isabel Alvarez-Mora*[2,3,4], *Laura Gort*[3,4,6], *Meritxell Jodar*[2,3,4], *Irene Madrigal*[2,3,4], *Blai Morales-Romero*[3,4,6], *Abraham José Paredes-*

Fuentes[6], Miriam Potrony[2,3,4], Laia Rodriguez-Revenga[2,3,4], Judit Garcia-Villoria[3,4,6], Celia Badenas[2,3,4], Joan Anton Puig-Butillé[1,2,3]

[1]Molecular Biology CORE, Hospital Clínic de Barcelona, Barcelona, Spain, [2]Division of Molecular Genetics, Biochemistry and Molecular Genetics Department, Hospital Clínic de Barcelona, Barcelona, Spain, [3]Center for Biomedical Network Research on Rare Diseases (CIBERER), ISCIII, Barcelona, Spain, [4]Fundació de Recerca Clínic Barcelona - Institut d'Investigacions Biomèdiques August Pi i Sunyer (FCRB-IDIBAPS), Barcelona, Spain, [5]Immunology Department, Hospital Clínic de Barcelona, Barcelona, Spain, [6]Division of Inborn Errors of Metabolism-IBC, Department of Biochemistry and Molecular Genetics, Barcelona, Spain.

Background: Whole Exome Sequencing (WES) is gaining increasing relevance both as a molecular biology method and standard diagnostic strategy in medical genetics. However, commercial WES library preparation kits vary significantly in design and coverage. Few studies have assessed the impact of the DNA tissue of origin on WES performance, particularly for rare disease diagnoses where preanalytical factors may compromise DNA quality.

Material and Methods: We evaluated three WES commercial solutions using eight DNA samples from distinct tissue types (four from peripheral blood and four from other sources, including amniotic fluid, postmortem tissue, and skin-derived fibroblasts). A second set of 24 previously sequenced samples (12 peripheral blood and 12 non-blood tissues) was resequenced using the highest-performing kit. A comprehensive bioinformatics pipeline was applied to evaluate key metrics such as coverage uniformity, duplication rates, or estimated library size, among other metrics.

Results: Solution (S1) demonstrated the best overall performance, achieving more uniform coverage, lower duplication rates (8% vs 16–17%), and a larger estimated library size (243M vs 102–129M) compared to S2 or S3. Additionally, S1 achieved 93% of regions covered at 38x (compared to ~80% in S2 and S3). Notably, this kit also consistently delivered superior results for DNA extracted from non-peripheral blood tissues.

Conclusion: This pilot study suggests that solution 1 provides robust performance and is particularly well-suited for samples where DNA quality may be compromised due to preanalytical limitations.

P15.150.A A case of FINCA syndrome presenting with neurodevelopmental disorder, interstitial lung disease, recurrent infection, and hemolytic anemia: case report and literature review

***Pattima Pakhathirathien**, Wongsathorn Eiumtrakul, Saisuda Nujarean, Arthaporn Khongkraparn, Duangrurdee Wattanasirichaigoon, Parith Wongkittichote*

Faculty of Medincine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Fibrosis, neurodegeneration, and cerebral angiomatosis (FINCA) syndrome is an ultra-rare autosomal recessive disorder, characterized by infantile-onset, progressive cerebropulmonary disease with variable multisystemic symptoms, including immunologic, and hematologic involvement. Biallelic pathogenic variants of the *NHLRC2* gene have been associated with FINCA syndrome. Here, we described the case of FINCA syndrome presenting with neurodevelopmental disorder, interstitial lung disease with subpleural cysts, recurrent infection, and chronic hemolytic anemia. Clinical exome sequencing revealed compound heterozygous variants in *NHLRC2* designated as c.442G>T (p.Asp148Tyr) and c.1220C>T (p.Ala407Val). The variant p.Asp148Tyr has been previously reported in nearly 80% of all patients with this disease. Interestingly, the patients harboring compound heterozygous of variants of p.Asp148Tyr and another truncating variants exhibit more severe than those with p.Asp148Tyr and missense variants. The systemic symptoms include pulmonary disease, recurrent infections, episodic diarrhea, and chronic hemolytic anemia (85.7%, 100%, 71.4%, and 85.7%, respectively in truncating variants and 88.9%, 88.9%, 77.8% and 33.3%, respectively in other missense variants). Patients with the homozygous p.Asp148Tyr trend to have fewer multiorgan involvement compared to those with compound heterozygous of p.Asp148Tyr with other variants (18% of pulmonary disease, 27% of recurrent infection, and none of hemolytic anemia). In conclusion, we described a new FINCA syndrome patient with one common and one novel variants of *NHLRC2*. According to our analysis, certain genotype-phenotype correlation is suggestive in FINCA syndrome although a larger cohort is needed.

P15.151.B Gene burden testing in a clinical NHS cohort identifies suggestive novel associations with early-onset severe obesity

***Jade Doughty**[1,2], Win Min Tun[3,1,2], Gavin Fuller[1,2], Isabelle Delon[1,2], Kate Downes[1,2], Matthew Garner[1,2], Hana Lango Allen[1,2]*

[1]Cambridge Genomics Laboratory, Cambridge, United Kingdom, [2]NHS East Genomic Laboratory Hub, East, United Kingdom, [3]Synnovis LLP, London, United Kingdom.

Background: Gene-level burden testing of rare variants in sequenced population-based cohorts has identified novel associations with clinically-relevant phenotypes. Routine whole exome sequencing (WES) of NHS patients with rare diseases provides an opportunity to use similar approaches. Genetic testing for young children with severe obesity is commissioned by NHS England through the National Genomic Test Directory and delivered by the NHS East Genomic Laboratory Hub. A virtual panel of 30 genes is applied to WES data; diagnostic yield is low (<4%) suggesting variants in other genes may be involved.

Material and Methods: Gene burden testing was performed exome-wide in a retrospective, case/control, deidentified cohort, using rare (gnomAD AF < 0.1%) and predicted deleterious variants (protein-truncating and missense with REVEL>0.7). Only 11 of 597 cases, referred for early-onset obesity, received a positive diagnosis at the time of clinical reporting (~1.8%); most reported variants were in *MC4R* (n = 8). Controls were patients referred for other indications (n = 3898).

Results: Association with *MC4R* was replicated at p = 0.00030; 4 controls harboured known pathogenic *MC4R* variants, consistent with their observation in the general population. Suggestive novel associations were identified for three genes. Association of these genes with BMI in the UKBiobank cohort and with early-onset obesity in a research cohort is being investigated.

Conclusion: Gene-agnostic statistical approaches can be applied to clinical WES to make scientific discoveries. Key limitations to overcome include limited numbers of rare disease cases in a single testing laboratory, lack of phenotype and genetic

ancestry information, and non-uniform sequencing and data processing steps applied across samples.

P15.152.C Application of HiFi long-read genome sequencing for the diagnostics of genodermatoses

Marie Louise Bondeson[1,2,3], *Padraic Corcoran*[2,3], *Katja Holmgren*[4,5], *Carina Frykholm*[1,2], *Joakim Klar*[1,2,3], *Cecilia Soussi Zander*[1,2], *Torborg Hoppe*[4,5], *Marie Virtanen*[4,5], *Enikö Sonkoly*[4,5], *Adam Ameur*[2,6], *Ida Höijer*[2,3,6], *Claes Ladenvall*[2,3], *Malin Melin*[2,3], *Maria Wilbe*[2]

[1]*Dept of Clinical genetics, Uppsala University Hospital, Uppsala, Sweden,* [2]*Dept of immunology, genetics and pathology, Uppsala University, Uppsala, Sweden,* [3]*Clinical genomics, Science for life laboratory, Uppsala University, Uppsala, Sweden,* [4]*Dept of Dermatology and Venereology, Uppsala University Hospital, Uppsala, Sweden,* [5]*Dept of Medical Sciences, Uppsala University, Uppsala, Sweden,* [6]*National Genomics Infrastructure, Uppsala University, Uppsala, Sweden.*

Background: Genodermatoses are a complex and heterogeneous group of skin disorders characterized by variable expression and clinical and genetic heterogeneity. To date, a diagnosis can be established in about 50% of cases using DNA-based techniques, such as WES. However, certain genes associated with genodermatoses pose particular challenges for short-read sequencing technologies. For example, the *KRT6A, KRT6B*, and *KRT6C* genes share >95% sequence identity in their coding regions. This high level of homology underscores the challenges in genetic diagnostics. In this study, we evaluate the use of HiFi Revio long-read genome sequencing for diagnostics of genodermatoses.

Material and Methods: Eighteen patients with genodermatoses, who previously had undergone genetic testing using WES or WGS were included the study. PacBio SMRTbell library construction was performed using the SMRTbell Template prep kit, and sequencing was conducted on the PacBio Revio system, with each SMRTbell sequenced on a 25M SMRT cell. Bioinformatic analysis was performed using Genomic Medicine Sweden's Nallo pipeline, and the vcf files were analyzed using in silico gene panels and Alissa Interpret (Agilent).

Results: Validation was performed on Genome in a Bottle (GIAB) and clinical samples with previously known variants. Benchmarking analysis showed high F1-scores for both SNVs (99.92%–99.96%) and INDELs (98.46%–98.77%) in NA12878 and NA24385 GIAB samples. Notably, a pathogenic *KRT6C* variant was identified in a patient with suspected pachyonychia congenita, where prior short-read WGS had been inconclusive.

Conclusion: This study highlights the potential of HiFi Revio long-read genome sequencing for improved diagnostics of genodermatoses.

Background: Red blood cell (RBC) disorders are a diverse group of hereditary hemolytic anemias (HHA) characterized by variations in clinical presentation and molecular mechanisms. This study aimed to clarify the diagnoses of patients who remained undiagnosed despite continued clinical follow-up.

Material and Methods: Fourteen index cases that remained undiagnosed through clinical evaluation and routine laboratory tests were analyzed using whole exome sequencing (WES). Candidate variations were confirmed, and familial segregation analyses were conducted using Sanger sequencing.

Results: We identified variants explaining the HHA phenotype in 12/14 cases (85%). Variants in *PKLR* gene (n = 4, 28%) were the most commonly encountered, with two cases homozygous and the other two showing compound heterozygosity. Erythrocyte membrane defects were detected in the *SPTB*, *PIEZO1* and *ABCB6* genes in three cases (21%). In one patient, a compound heterozygous *CDIN1* variation was identified in CDA type 1b, while an *ALAS2* variation was found in another patient with sideroblastic anemia. The diagnosis was revised in one case due to a pathogenic homozygous variation detected in the *SLC29A3* gene. Variations in novel candidate genes involved in erythropoiesis were also identified in three cases. In two cases, the genetic cause could not be clearly identified. There was no overlap in causative variants.

Conclusion: HHA exhibits genetic heterogeneity. Diagnoses may be revised, novel candidate genes can be identified through WES, and the potential for compound heterozygosity in known genes should not be overlooked.

Background: Analyses involving whole-genome or whole-exome sequencing (WGS/WES) inevitably capture data on the entire genome, often revealing secondary findings (SF) beyond the original scope of investigation. Although the decision to disclose SF resulting from research is still debated, the American College of Medical Genetics and Genomics (ACMG) provides guidelines for reporting SF in clinical exome and genome sequencing (Miller et al., 2023).

Methods: In this study, we examined WES data of a cohort of 444 Bulgarian patients, originally recruited to explore the genetic factors influencing COVID-19 severity. Written Informed consents with opt-in SF reporting for actionable genes were obtained. Variations were found in 71 of the genes and their classification was done according to ACMG recommendations criteria version 3.2.

Results: 67 likely pathogenic (LP) or pathogenic (P) variants were detected in 31 genes (7.55% of all studied variants), found across 61 heterozygous carriers. Of these, 58 variants were unique and 39 were also reported as LP/P in ClinVar. The frequencies of SF in genes linked to cardiovascular diseases, hereditary cancers, and metabolic disorders were 3.38%, 2.14%, and 0.68%, respectively (1.35% in other genes). SF in dominantly/recessively inherited alleles were 65.67%/34.33% respectively. The most frequent SF were identified in *MUTYH* (9 cases, 4 variants), *LDLR* (7 cases, 4 variants), and *FBN1* (5 cases/variants).

Conclusion: Our findings reaffirm that WGS/WES uncovers many clinically actionable secondary findings. As genomic research becomes more affordable, careful ethical consideration of SF disclosure will be essential to maximize both scientific value and individual patient benefit.

P15.155.B Assessing the diagnostic yield and clinical utility of whole-exome sequencing in undiagnosed pediatric patients: a single-center study from the Czech Republic

Petra Pokorna[1,2], *Katerina Kozelkova*[1], *Eliska Hlouskova*[1], *Sona Adamcova*[1], *Robin Jugas*[1], *Jana Kubatova*[3], *Pavlina Danhofer*[2,4], *Ondrej Horak*[4], *Petr Jabandziev*[2,5], *Tereza Svatonova*[5,6], *Hana Palova*[1], *Dana Knoflickova*[1], *Ondrej Slaby*[1,2,3], *Katerina Slaba*[2,5,6]

[1]*Department of Biology, Faculty of Medicine and Central European Institute of Technology, Masaryk University, Brno, Czech Republic,* [2]*Center for Precision Medicine, University Hospital Brno, Brno, Czech Republic,* [3]*CREATIC, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [4]*Department of Pediatric Neurology, University Hospital Brno and Faculty of Medicine Masaryk University, Brno, Czech Republic,* [5]*Department of Pediatrics, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [6]*Institute of Medical Genetics and Genomics, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic.*

Background: Rare diseases are clinically heterogeneous, primarily genetic conditions affecting fewer than 1 in 2000 individuals. Despite their low individual prevalence, the cumulative impact is substantial, with many patients remaining undiagnosed and undergoing a prolonged diagnostic odyssey. To address this, we integrated whole-exome sequencing (WES) into the diagnostic workflow for undiagnosed pediatric patients at our center, aiming to evaluate its diagnostic yield and actionability.

Material and Methods: Between 2020 and 2024, 101 undiagnosed pediatric patients (44 females, 57 males) were enrolled in a study at the Outpatient Clinic for Undiagnosed Pediatric Patients, Department of Pediatrics, University Hospital Brno, Czech Republic. All patients underwent singleton WES, with selected cases receiving whole-genome sequencing (WGS). Data were bioinformatically processed and analyzed using a phenotype-driven approach.

Results: WES identified or facilitated the discovery of a causal variant in 44% of cases. In two cases, WES suggested a specific phenotype but detected only a heterozygous variant, requiring further WGS analysis to confirm the diagnosis. In another case, WES indicated a homozygous deletion, subsequently validated using MLPA. Among the positive findings, 40 variants were classified as pathogenic or likely pathogenic, including several previously unreported variants. Additionally, four variants initially categorized as VUS were later confirmed as causative through further testing. The overall actionability, enabling at least one type of change in patient care, was 59%.

Conclusion: Our study demonstrates that WES achieves a high diagnostic yield and clinical utility in undiagnosed pediatric patients, reaching the upper range of outcomes reported in published meta-analyses.

P15.156.C Discrepancy in *CFTR* genotype distribution between cystic fibrosis patient registry and newborn screening data: implications for diagnostic improvement

Oksana Tyshchenko[1,2], *Lyudmyla Bober*[3], *Marta Tyrkus*[4], *Yelyzaveta Polyakova*[2,5], *Oksana Arkhipova*[5], *Halyna Makukh*[1,5]

[1]*Medical Scientific Genetic Center "Leogene, LTD", Lviv, Ukraine,* [2]*Ivan Franko National University of Lviv, Lviv, Ukraine,* [3]*West Ukrainian Specialised Children Hospital, Lviv, Ukraine,* [4]*Institute of Hereditary Pathology of National Academy of Medical Sciences of Ukraine, Lviv, Ukraine,* [5]*Lviv State Regional Clinical Perinatal Center, Lviv, Ukraine.*

Background: *CFTR* mutation distribution varies across populations, impacting cystic fibrosis (CF) diagnosis and treatment eligibility. Ukraine implemented CF newborn screening (NBS) in 2022 as part of a comprehensive screening program for rare diseases. This study compares *CFTR* genotype frequencies between NBS data and the national CF registry, particularly focusing on c.1521_1523delCTT (F508del) allele prevalence, which determines eligibility for elexacaftor-tezacaftor-ivacaftor (ETI) treatment.

Material and Methods: We analyzed *CFTR* variant distribution using the European Cystic Fibrosis Patient Registry (ECFPR) data. The Ukrainian CF-NBS protocol employs immunoreactive trypsin (IRT) measurement followed by DNA testing for 34 common CFTR variants (IRT/IRT/DNA). Next-generation sequencing (NGS) is performed when two pathogenic variants are not initially identified. We compared genotype frequencies between NBS-diagnosed cases and registry data.

Results: The CF registry for 2023 year ($n = 512$) revealed 33% patients were F508del homozygotes, 50% F508del compound heterozygotes, and 17% had other pathogenic variants. The NBS CF-diagnosed cohort showed significantly different distribution ($p = 0.05$): 42% F508del homozygotes, 27% F508del compound heterozygotes, and 31% with other variants. This difference impacts ETI treatment eligibility rates between registry (83%) and NBS (69%) populations.

Conclusion: The discrepancy between registry and NBS genotype distributions suggests potential underdiagnosis of CF patients carrying non-F508del variants, possibly due to milder phenotypes. NBS implementation may provide more comprehensive detection of CF cases across all genotypes.

P15.157.D Unraveling the genetic basis of recessive neurodevelopmental disorders (NDD) and skeletal dysplasias (SKDs) in 80 consanguineous families through exome sequencing

N. Kakar[1], *S. Balachandran*[2], *a. ullah*[3], *M. Shadman*[2], *n. kruse*[2], *J. Pozojevic*[4], *V. Sreenivasan*[4], *S. Malik*[3], *K. Händler*[4], *m. spielmann*[4];

[1]Institut fur Humangenetik, Luebeck, Germany, [2]Institut für Humangenetik, Universitätsklinikum Schleswig-Holstein, University of Lübeck and University of Kiel, Lübeck, Germany, [3]Human Genetics Program, Department of Zoology, Quaid-i-Azam University, Islamabad, Pakistan, [4]Institut für Humangenetik, Universitätsklinikum Schleswig-Holstein, University of Lübeck and University of Kiel, Luebeck, Germany

Background: Monogenic diseases such as neurodevelopmental disorder (NDD) and skeletal dysplasias (SKDs) inherited as autosomal-recessive (AR) traits are common in populations with a high rate of consanguinity. A higher prevalence of these AR diseases is observed in countries such as Pakistan, where consanguineous marriages are culturally favored, exhibit a higher prevalence of AR diseases. This offers the opportunity to identify new disease-causing genes/mutations associated with AR disorders, helping to uncover their genetic and pathophysiological mechanisms. The aim of the study was to identify new disease-causing genes associated with NDD and SKDs. To achieve this, 80 families with recessive diseases were enrolled and investigated for disease-causing genes.

Material and Methods: Exome sequencing (ES) was performed on 112 individuals from 80 families, primarily presenting with NDD and SKDs. Many of these families had multiple affected individuals.

Results: We were able to identify the underlying genetic cause in 48 families, while 26 remained without a strong candidate variant. Six families required further re-analysis. Overall, a strong candidate variant was detected in about 50% of cases, whereas the remaining 50% lacked a definitive molecular diagnosis. Notably, novel disease-associated gene *NAV3* and candidate genes such as *DOCK1*, *IQCG*, and *HOXC10*, were identified, where biallelic variants were linked to recessive NDD, post axial polydactyly and brachydactyly respectively.

Conclusion: In conclusion, these findings expand the genetic landscape NDD and SKDs by identifying novel disease causing-gene and several candidate genes.

P15.158.A Mapping the genetic landscape of rare diseases: Insights from Orphanet gene-disease annotations

Mickaël De Carvalho, *Caterina Lucano, Perrine Renard, David Lagorce, Ana Rath*

INSERM, US14 - Orphanet, Plateforme Maladies Rares, Paris, France.

Background: Orphanet is a rare diseases knowledge base that includes manually curated annotations of gene-disease relationships. These annotations are derived from scientific publications and follow standardized procedures to ensure accurate linkage decisions.

Material and Methods: Orphanet genetic annotations are linked to rare diseases classified by medical domain and aligned to external genetic resources, including OMIM, HGNC, ensembl and Reactome, allowing the retrieval of gene pathway information. By assessing the distribution of disease-associated genes across medical domains we provide insights into the current state of genetic knowledge on rare diseases. Furthermore, a cross-referencing of the Orphanet gene list with external genetic databases will enable the identification of shared genes and pathways involvement across medical domains.

Results: This work will present the distribution of rare genetic disorders with or without a known molecular cause across medical domains. Orphanet currently includes 4,377 unique genes, of which 4,062 are indexed as disease-causing, with germline mutations being the most common association. Overall, 3,250 out of the 4,659 genetic disorders present in Orphanet have at least one known gene disease-association. Rare developmental defects during embryogenesis and rare neurological diseases represent the categories with the highest genetic disease's distribution. Data normalization will also show the average number of genes per disease by medical specialty. Leveraging Orphanet's gene mappings to external databases will allow further exploration of rare disease genetics.

Conclusion: The Orphanet gene-disease annotations combined with disease classification by medical domain and mappings to other gene databases provide a powerful resource for exploring the genetic landscape of rare diseases.

Background: Cholestatic jaundice in infants and adults represents a significant clinical challenge, potentially leading to severe outcomes without prompt treatment. PLEC, encoding plectin a cytoskeletal linker for intermediate filaments - has recently emerged as a candidate gene in cholestasis. While initially identified in siblings with progressive familial intrahepatic cholestasis, PLEC's role in adult cholestasis remains largely unexplored.

Material and Methods: Liver biopsy samples from patients with cholestasis carrying PLEC mutations underwent detailed immunohistochemical and immunofluorescence analysis to assess protein expression patterns and subcellular localization.

Results: Our study identified three distinct cases with PLEC variants: A young woman presenting with severe cholestasis since adolescence, carrying compound heterozygous missense variants, demonstrated significant alterations in both plectin and bile salt export pump protein expression; An adult patient with two in cis heterozygous missense variants exhibited a milder cholestatic phenotype, with immunohistochemical analysis revealing correspondingly less severe protein alterations; A 17-year-old male with obstructive cholestasis harbored a previously unreported heterozygous missense variant.

Conclusion: Our findings provide strong evidence that PLEC mutations may be associated with familial intrahepatic cholestasis phenotype. Immunofluorescence studies offer crucial insights into the molecular mechanisms underlying cholestasis development in

these patients. These newly identified PLEC mutations expand our understanding of cholestasis genetics and highlight the significant phenotypic variability between pediatric and adult-onset presentations, suggesting age-dependent penetrance or modifier effects. Like other PFIC genes where heterozygous mutations result in milder phenotypes, PLEC mutations present on a single allele have been associated with transient episodes of cholestasis.

P15.160.C Diagnostic role of whole exome sequencing in children with medical complexity

Elisa Biamino[1], *Marta Della Croce di Dojola*[2], *Alessandra Spano*[2], *Marco Spada*[1]

[1]*Ospedale Infantile Regina Margherita, Turin, Italy,* [2]*University of Turin, Turin, Italy.*

The aim of this study was to analyse the diagnostic yied of Whole Exome Sequencing (WES) in a cohort of 140 children with medical complexity, and to evaluate the predictive value of specific symptoms and clinical signs. WES identified a pathogenetic or probably pathogenic variant (C5-C4) in 84/140 patients (60%), a variant of uncertain significance (C3) in 37/140 patients (26.4%) and a benign or potentially benign (C2-C1) variant in 19/140 patients (13.6%). Medical history, clinical phenotype and imaging studies (brain, heart, abdomen) were analysed for all patients: consanguinity of the parents had a positive predictive value (PPV) of 78.6%, onset of symptoms <1 year a PPV of 60.4%, clinical signs of regression a PPV of 68.2%, pathological brain magnetic imaging a PPV of 62.5%, pathological echocardiography a PPV of 60.7%, pathological nephro-urologic ultrasound a PPV of 45.4%, pathological ophthalmological examination a PPV of 70.9%, hypotonia or hypertonia a PPV of 68.4% and microcephaly or macrocephaly a PPV of 71.8%. In conclusion, WES led to a rapid, accurate diagnosis in 60% of cases. Consanguineity of the parents increased the diagnostic yields, as expected; furthermore, hypo/hypertonia and micro/macrocephaly emerged as key clinical signs. Further research is warranted to validate these data.

P15.161.D Adult-onset β-thalassemia major is an acquired imprinting disorder

Nicolò Tesio[1], *Francesco Cecere*[2,3], *Teresa Ceglie*[4], *Emilia D'Angelo*[2], *Neha Sanjay Kargutkar*[5], *Flavia Cerrato*[2], *Giorgia Mandrile*[4], *Andrea Riccio*[2,3], *Giovanni Battista Ferrero*[5]

[1]*Department of Public Health and Pediatric Sciences, University of Torino, Torino, Italy,* [2]*DiSTABiF, University of Campania Luigi Vanvitelli, Caserta, Italy,* [3]*Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Napoli, Italy,* [4]*Thalassemia and Rare Hematological Diseases Centre, San Luigi Gonzaga University Hospital, Orbassano, Italy,* [5]*Department di Clinical and Biological Sciences, University of Turin, Orbassano, Italy.*

Background: Adult-onset β-thalassemia major is an extremely rare disorder observed in β-thalassemia carriers, resulting from chromosome 11p15 somatic loss of heterozygosity. We present the case of a man, carrier of the HBB:c.118C>T β^0 globin mutation, who developed progressive anemia, characterized by increased hemolysis, elevated HbF levels (39.8%), and diffuse hematopoietic hyperplasia. Over the years his Hb levels gradually declined from 12 g/dL to 8 g/dL, prompting further evaluations.

Material and Methods: Acquired *HBB* mutation homozygosity was observed in peripheral leukocytes, while heterozygosis was confirmed on a buccal swab. SNP-array on bone marrow DNA revealed a 14.7 Mb pUPD on 11p15.2-11p15.5 (11p15.2-11p15.5, 219089_14922363), explaining the homozygosity for the β-globin mutation. Exome sequencing on peripheral leukocytes and total RNA-seq on bone marrow were performed to explore the biological mechanisms driving pUPD 11p clonal expansion.

Results: RNA-seq demonstrated loss of expression of the *HBB* gene and overexpression of the *IGF2*, *HBG1*, *HBG2*, and *BGLT3* genes. No known HPFH-associated DNA variants were identified.

Conclusion: The propositus inherited the β^0-globin mutation from his father and hematopoietic stem cells developed adult-onset pUPD 11p causing β^0 homozygosity. As observed in Beckwith-Wiedemann syndrome, this pUPD duplicated the paternally inherited active allele of the imprinted *IGF2* gene. RNA-seq confirmed *IGF2* overexpression, which is likely driving the clonal expansion of β^0-homozygous cells. Notably, overexpression of *HBG1* and *HBG2*, along with high levels of HbF, may be explained by increased expression of the lncRNA BGLT3. The molecular mechanisms leading to BGLT3 activation are unknown but presumably related to the UPD event.

P15.163.B Genotype-phenotype correlations in the analysis of *GFAP* Variants in Type I Alexander Disease subtypes

Tiziana Bachetti[1], *Ylenia Vaia*[2,3], *Alice Grossi*[4], *Francesca Rosamilia*[5], *Deianira Bellitto*[1], *Isabella Ceccherini*[4], *Davide Tonduti*[2,3]

[1]*IRCCS Ospedale Policlinico San Martino, Genova, Italy,* [2]*Centro di ricerca in Neuroscienze, Dipartimento di Scienze Biomediche e Cliniche, Università degli Studi di Milano, Milano, Italy,* [3]*Unit of Pediatric Neurology, C.O.A.L.A. (Center for Diagnosis and Treatment of Leukodystrophies), V. Buzzi Children's Hospital, Milano, Italy,* [4]*UOSD Area Aggregazione Laboratori della Ricerca, IRCCS Istituto Giannina Gaslini, Genova, Italy,* [5]*Clinical Bioinformatics, IRCCS Istituto Giannina Gaslini, Genova, Italy.*

Background: Alexander disease (AxD) is a leukodystrophy caused by autosomal dominant gain-of-function mutations in the Glial Fibrillary Acidic Protein (GFAP) gene. AxD presents as Type I AxD and Type II AxD, based on clinical and neuroradiological features. The variability in Type I disease progression led to a subclassification into Ia, Ib, Ic, and Id, and intermediate Ic/Id. This study aimed to deepen the understanding of genotype-phenotype correlations in Type I AxD subtypes

Material and Methods: *GFAP* variants have been deeply analyzed in a cohort of 74 genetically confirmed Type I AxD patients divided in Ia-Ib-Ic-Ic/d-d. Analyses have been performed within each subgroup to identify elements differently stratifying the five groups and, in addition, focusing on the two larger sets based on ability (Ic+Ic/d+Id) or not (Ia+Ib) to acquire autonomous ambulation

Results: 1.progressive decrease in *GFAP* allelic heterogeneity from Ia to Id2.opposite extent of variants detected in exon 1 and in exon 4, directly and inversely correlating with Ia to Id stratification, respectively. 3. p.R239 and p.R79 never detected in Id and Ia, respectively 4.Different p.R79 changes stratify patients with/without autonomous ambulation. 5.CADD scores showed an

inverse correlation with autonomous ambulation 6.Median age of onset: progressive increase from Ia to Id

Conclusion: These results suggest that specific GFAP variants could predict disease progression in Type I AxD, suggesting a refinement of classification and improving patient outcomes. These findings underscore the importance of both genetic and clinical factors in the management of AxD, particularly as therapeutic interventions are being developed

P15.164.C Genetic modifiers influence: A novel *COL4A4* variant delays kidney failure in a homozygous Alport syndrome patient and expedites kidney failure in a heterozygous patient

Christiana Polydorou[1], *Gregory Papagregoriou*[1], *Apostolos Malatras*[1], *Despina Hadjipanagi*[1], *George Michael*[1], *Dionysios Fanidis*[1], *Eirini Moutsouri*[1], *Katerina Stefanou*[1], *Grigoris Konstantinou*[1], *Myria Zachariou*[1], *Chrysoula Pipili*[2], *Charalampos Charalampous*[2], *Maria Kkolou*[3], *Androula Pastelli*[3], *Panagiota Loukaidou*[3], *Lakis Yioukas*[4], *Kypros Constantinou*[5], *Elpida Toumasi*[5], *Isavella Savva*[5], *Andreas Soloukides*[5], *Constantinos Deltas*[6]

[1]*University of Cyprus, Biobank.cy, Nicosia, Cyprus,* [2]*State Health Services Organisation, Department of Nephrology, General Hospital, Ammochostos, Cyprus,* [3]*State Health Services Organisation, Department of Nephrology, General Hospital, Larnaca, Cyprus,* [4]*State Health Services Organisation, Department of Nephrology, General Hospital, Pafos, Cyprus,* [5]*Kidney Transplantation Clinic, Nicosia General Hospital, State Health Services Organisation, Nicosia, Cyprus,* [6]*University of Cyprus, Director of Biobank.cy, Prof. at Medical School of University of Cyprus, Nicosia, Cyprus.*

Background: Patients who are heterozygous for *COL4A3* or *COL4A4* pathogenic variants develop autosomal dominant Alport syndrome (ADAS) generally of milder phenotype than patients with biallelic mutations. A common feature is familial microscopic hematuria (FMH), which may or may not progress to added proteinuria and chronic kidney disease (CKD).

Material and Methods: We studied clinically and genetically nine patients from four families that segregate FMH, proteinuria, and CKD, with clinical suspicion for Alport syndrome.

Results: Molecular and genetic testing revealed the inheritance of a common *COL4A4* variant, substituting arginine for glycine-1248, thus disturbing the protein triple-helical domain (COL4A4:c.3742G>C(p.Gly1248Arg). A homozygous patient had the Alport phenotype, including hearing impairment and ocular findings, but a much later age-at-onset of kidney failure (46 years), compared to the age usually seen in patients with other mutations. Importantly, a relative patient, heterozygous for the variant developed kidney failure at 58 years, without extrarenal findings.

Conclusion: The delayed kidney failure of the homozygous patient could be attributed to the position of the substitution near a natural interruption of the α4-chain collagenous domain. We hypothesize that the disruption conferred during propagation of the collagen-IV triple-helix is less drastic, affecting less severely the protomer configuration, and maintaining residual activity for network formation in the glomerular basement membrane. The heterozygous patient co-inherited a *LAMA5* gene variant that probably acted as a genetic modifier negatively influencing the phenotype. The findings support the notion that collagen-IV nephropathies constitute an Alport spectrum condition with diverse manifestations.

P15.165.D Investigating*TNNC1*gene inheritance and clinical outcomes through a comprehensive familial study

Skevi Kyriakou[1], *Michaella Georgiadou*[1], *Lygia Ioannou*[1], *Styliana Philippou*[1], *Valando Soteriou*[1], *Louisa Constantinou*[1], *Ioanna Neophytou*[1], *Evi Touvana*[1], *Paola Evangelidou*[2], *Carolina Sismani*[2], *Elena Kypri*[1], *Marios Ioannides*[1], *Antonis Jossif*[3], *George Koumbaris*[1], *Philippos Patsalis*[1]

[1]*Medicover Genetics, Nicosia, Cyprus,* [2]*The Cyprus Institute of Neurology and Genetics, Cytogenetics amd Genomics, Nicosia, Cyprus,* [3]*Paedi Center for Specialized Pediatrics, Nicosia, Cyprus.*

Background: Hypertrophic cardiomyopathy (HCM) and restrictive cardiomyopathy (RCM) have significant phenotypic overlap and a similar genetic background. This study focuses on the genetic testing of two interconnected families with four infants diagnosed with fatal RCM associated with bi-ventricular hypertrophy.

Material and Methods: Biological samples of the deceased infants were analyzed with exome sequencing, while direct ancestors and siblings of the deceased infants were analyzed using the Ventrilia Cardiovascular NGS test (Medicover Genetics), that analyzes 292 genes that can cause multiple cardiovascular conditions with complex phenotypes. The rest of the family members were tested using Sanger sequencing.

Results: A pedigree spanning six generations was created, involving 56 individuals participating in this study. Our genetic analysis revealed that homozygosity for NM_003280.3(*TNNC1*):c.23C>T(p.Ala8Val) results in HCM which evolves into a severe RCM phenotype, leading to fatal outcomes during infancy. Identified heterozygous individuals were predominantly asymptomatic or exhibited later onset of HCM, inherited in an autosomal dominant manner.

Conclusion: Our study provides strong evidence that the homozygous expression of A8V TnC exacerbates disease progression, leading to the transition from HCM to RCM, ultimately culminating in death. This indicates that variants in the TNNC1 gene associated with HCM can also lead to severe RCM in infancy, showing different inheritance patterns. Overall, this study underscores the complex nature of genetic inheritance in cardiomyopathies and emphasizes the vital role of genetic testing in providing essential insights crucial for diagnosis, prognosis, early intervention, and the development of potential treatment strategies.

P15.166.A Clinical and Molecular Heterogeneous Pathway Disorders: RASopathy Syndromes

Türkan Turkut Tan, *Durdugul AYYILDIZ EMECEN, Enise Avci Durmusalioglu, Yusuf Can Dogan, Zehra Burcu YILMAZ, Deniz Özalp Kizilay, Tahir Atik, Ozgur COGULU, Esra Isik*

Ege University Faculty of Medicine, Izmir, Turkey.

Background / Objective: RASopathies are a group of multisystem disorders caused by genetic variations that disrupt the RAS/MAPK signaling pathway. These conditions are classified into four main groups: Noonan syndrome (NS) and related disorders, Neurofibromatosis type 1, Non-systemic RASopathies, and Mosaic RASopathies. This study aims to evaluate the clinical and molecular characteristics of patients diagnosed with RASopathies.

Method: Clinical and molecular data of 16 patients diagnosed with RASopathies were retrospectively analyzed at the Department of Pediatric Genetic Diseases, Ege University.

Results: Of the cases diagnosed with RASopathies, 8 are female and 8 are male. Pathogenic or likely pathogenic variants were detected in 93.7% (n = 15) of the cases. Variants in genes related to Noonan syndrome and related disorders (PTPN11 in 5 cases, BRAF in 2 cases, SHOC2 in 1 case, SOS1 in 1 case, KRAS in 1 case) were detected in 10 patients. Craniofacial dysmorphic features were present in all Noonan syndrome cases. In 4 patients with non-systemic RASopathies, three variants were found in the RASA1 gene, two of which were novel. One patient with an NF1 variant was diagnosed with NF-NS based on clinical and molecular findings, and Selumetinib treatment was planned due to extensive plexiform neurofibromas. Another patient with isolated mosaic RASopathy underwent DNA isolation from a skin biopsy, revealing no variants in KRAS, NRAS, or HRAS genes.

Conclusion: This study emphasizes the clinical and molecular heterogeneity of RASopathies. Next-generation sequencing methods have increased diagnostic rates, contributing to genetic counseling, prognosis prediction, understanding pathophysiology, and developing therapeutic approaches.

P15.167.B Genetic variants related to childhood neurodevelopmental disorders in well-characterized Finnish cohort

Fatma Doagu[1], *Alfredo Ortega-Alonso*[1], *Henna Oksanen-Hennah*[2,3,1], *Vanhala Raija*[2], *Hanna Raaska*[2], *Arja Voutilainen*[2], *Laura Timonen-Soivio*[2], *William G Hennah*[1]

[1]*Neuroscience Center, Helsinki Institute of Life Sciences, University of Helsinki, Helsinki, Finland,* [2]*Pediatric Neuropsychiatric Unit, Helsinki University Hospital, Helsinki, Finland,* [3]*Department of Psychology and Logopedics, University of Helsinki, Helsinki, Finland.*

Background: Pediatric neuropsychiatric disorders like Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) have long-term impacts on individuals, families, and the healthcare system. Genomic studies have identified various common, rare, and de novo variants linked to these disorders, raising questions about the role of genetic testing in clinical practice. While genetic testing is not currently used to guide ASD intervention, understanding genetic factors can help families better comprehend the disorder. This study aims to evaluate the clinical significance of genetic variants in a Finnish cohort and identify patterns that predict the presence of clinically relevant variants.

Material and Methods: Twenty-one children (ages 5–8) with complex neurodevelopmental phenotypes were recruited from the Pediatric Neuropsychiatric Unit of Helsinki University Hospital. A multidisciplinary team performed comprehensive clinical assessments, and whole genome sequencing (WGS) was conducted on both patients and their parents. Our data analysis pipeline integrates multiple tools for variant calling, interpretation, and curation, with targeted sequencing to validate relevant findings.

Results: Preliminary findings suggest that most children carry potentially high-impact variants linked to neurodevelopmental disorders, including ASD. This contrasts with prior clinical CMA results, where only four out of twelve children had genetic findings. These results require validation.

Conclusion: WGS identifies potentially clinically relevant variants at a much higher rate than current clinical methods. This suggests that integrating WGS into routine evaluations could lead to more precise, personalized diagnoses for children with complex neurodevelopmental symptoms.

P15.168.C WES analysis of CN-LOH regions increases diagnostic yield in patients with neurodevelopmental disorders and/or congenital anomalies

Anastasios K. Mitrakos[1], *Konstantina Kosma*[1], *Christalena Sofocleous*[1], *Maria Tzetis*[1], *Periklis Makrythanasis*[2]

[1]*National and Kapodistrian University of Athens, Medical School, Laboratory of Medical Genetics, Athens, Greece,* [2]*Medical School, National and Kapodistrian University of Athens, Athens, Greece.*

Background: Regions with Copy-Neutral Loss of Heterozygosity (CN-LOH) occur in human genomes because of parental consanguinity, recombination events or other chromosomal rearrangements, and lead to obligatory homozygosity for variants in autosomal recessive genes. Whole Exome Sequencing (WES) analysis, targeting CN-LOH regions identified by SNP array, can enhance genetic diagnosis through the detection of homozygous pathogenic variants.

Material and Methods: 7 patients with neurodevelopmental disorders and/or congenital anomalies, with extensive regions of CN-LOH were included in the study. Genomic DNA was extracted from peripheral blood samples using the QiaSymphony system (Qiagen, Germany). CMA was performed with the G3 4 × 180K CGH+SNP microarray platform (Agilent Technologies, USA), that contains ~60.000 SNP probes, providing detection of CN-LOH regions larger than 5 Mb across the genome. Consequently, WES was performed with the Human Exome core 2.0 library preparation kit (Twist Biosciences, USA) on a NovaSeq 6000 instrument (Illumina, USA). Alignment and variant calling were performed with GATK (Broad Institute, USA). Variant annotation and interpretation were performed with Franklin (https://franklin.genoox.com).

Results: On average 69 Mb of CN-LOH regions were identified per sample, ranging from 15 Mb to 116 Mb. WES analysis of these regions detected novel homozygous causative variants in 2/7 cases (28%). Specifically, the NM_138701.4:c.238del variant in *MPLKIP*, associated with Trichothiodystrophy 4 (#234050) and the NM_016194.4:c.819C>A variant in *GNB5*, associated with Lodder-Merla syndrome 1 (#617173) were identified in patients 1 and 4, respectively.

Conclusion: WES analysis targeted at CN-LOH regions can enhance the identification of novel rare recessive pathogenic variants and increase diagnostic yield.

P15.169.D Revisiting cold cases: a single center's experience with clinical and bioinformatic re-evaluation of undiagnosed

disorders

Nurit Assia Batzir[1], *Lina Basel-Salmon*[2], *Ranit Jaron*[1], *Nesia Kropach-Gilad*[1], *Efrat Sofrin-Drucker*[3], *Naama Orenstein*[1]

[1]*Schneider Children's Medical Center of Israel, Petah-Tikva, Israel,* [2]*Rabin Medical Center, Petah Tikva, Israel,* [3]*Schneider Children's Medical Center of Israel, Petah Tikva, Israel.*

Background: Despite the growing availability and improved capabilities of genetic testing, some patients remain without a molecular diagnosis, even when physical signs and symptoms strongly suggest an underlying hereditary disorder. We present our experience with cases referred to the Undiagnosed Clinic.

Material and Methods: Cases were discussed by a team of clinical geneticists, including refinement of the clinical phenotype and consideration of potential diagnoses. Reevaluation of exome (ES) or genome sequencing (GS) data was done by the team. Additional clinical or research tests were done as recommended.

Results: 81 cases were evaluated over a period of 40 months. The most common reason for referral was intellectual disability/developmental delay with dysmorphism or additional manifestations (42/81, 52%). A new diagnosis was achieved in eight (10%) cases, including four cases where reanalysis revealed a novel or recently discovered gene, and one deletion that included a novel gene. One variant was identified that had previously been filtered out due to poor sequencing quality. In one case with negative CMA, ES and GS, a karyotype was done revealing a de novo balanced translocation t(X;13) not detectable by the previous methods. In addition, at least four candidate variants were identified in the cohort. In three cases it was decided that previously-detected variants were likely causative.

Conclusion: Clinical reevaluation and reconsideration of the diagnostic approach as well as ES/GS reanalysis were useful in diagnosing cases with a high suspicion for a monogenic etiology. The overall yield is potentially higher given that additional results of tests are pending.

C.O.I. Disclosure:

P15.170.A Genome sequencing in routine clinical care: The good, the bad, and the uglY

Gaby Schobers[1], *Lot Snijders Blok, dr.*[1], *Rolph Pfundt*[1], *David Koolen, dr.*[1], *Aexander Stegmann*[2], *Bert de Vries*[1], *Jeroen van Reeuwijk*[1], *Dineke Westra*[1], *Nicole de Leeuw*[1]

[1]*Radboudumc, Nijmegen, Netherlands,* [2]*MUMC+, Maastricht, Netherlands.*

Background: Genome sequencing (GS), which allows for comprehensive genome analysis, is increasingly part of routine clinical care in rare diseases. It not only leads to new diagnoses but also uncovers pitfalls in structural variant (SV) detection, and challenges with interpreting Y-chromosomal variants.

Material and Methods: Twelve illustrative cases were selected from routine short-read GS gene panel analyses.

Results: GS finally revealed pathogenic variants for clinically diagnosed patients: a large insertion-deletion of an inverted segment from Xp22.33 affecting the *MECP2* gene on Xq28, confirming Rett syndrome; a de novo deletion including the first two exons from the *KANSL1* gene, causing Koolen-de Vries syndrome; and an intragenic deletion in the *EHMT1* gene, justifying the episignature for Kleefstra syndrome. GS also detected cytogenetic abnormalities: a mosaic ring chromosome 18 was identified and confirmed via karyotyping, while an unbalanced translocation, der(20)t(16;20)(q23.3;q13.33) -below the resolution of karyotyping- was confirmed with FISH. Interestingly, in two other cases, subsequent karyotyping did not confirm abnormal findings: a possible reciprocal translocation t(1;22)(p13.3;q12.2) and a suspected translocation t(1;7)(p31.3;p14.3). Additionally, a reciprocal translocation t(8;14)(p23.1;q32.1) and a mosaic 10qter deletion were detected, albeit after extensive inspection. GS data visualization and interpretation of the Y chromosome can be hampered by forced read-alignment of the pseudoautosomal regions to the X chromosome. Nonetheless, with careful inspection and handling of GS data, aberrant Y chromosomes were detected in three cases.

Conclusion: GS enables the diagnosis of genetically unsolved, clinically diagnosed patients. While GS can detect (complex) SVs, interpretation requires caution and cytogenetic expertise.

Background: FLVCR2, a conserved member of the major facilitator superfamily (MFS), transports small molecules across lipid bilayers. Loss of the murine ortholog Mfsd7c leads to brain angiogenic deficiency and lethality. Recessive *FLVCR2* variants cause Fowler syndrome (PVHH), a severe condition with microcephaly, skeletal deformities, and cerebrovascular defects. Despite reported cases, evidence of FLVCR2 variant pathogenicity remains limited.

Material and Methods: We investigated a fetal case of Fowler syndrome using exome sequencing, identifying compound heterozygous FLVCR2 variants: maternal c.1124+3_1124+6del and paternal p.(Arg492Trp). Minigene assay assessed mRNA splicing effects. Protein modeling (Rosetta, DynaMut2) assessed

the structural effect of the p.(Arg492Trp) variant. Radiolabeled-choline and ethanolamine transport assays in HEK 293 cells measured FLVCR2 transport activity.

Results: The c.1124+3_1124+6del variant impaired FLVCR2 exon 5 splicing. The p.(Arg492Trp) substitution caused a 50–60% reduction in FLVCR2 transport activity, resulting in a net activity of 25–30%. These findings indicate that the p.(Arg492Trp) variant significantly impacts FLVCR2 function. Protein modeling confirmed the destabilizing effects of the substitution, while transport assays established a functional deficiency of the FLVCR2 protein.

Conclusion: Our findings suggest that FLVCR2 deficiency may be sufficient to cause PVHH, even without a complete loss of transport activity. These results highlight the potential involvement of extragenetic factors in the pathophysiology of this complex condition, advancing our understanding of Fowler syndrome and FLVCR2-related pathologies.

P15.173.D Transcriptome profiling of patients with brain arteriovenous malformations

Alua Gusmaulemova

National Center for Biotechnology, Astana, Kazakhstan.

Background: Arteriovenous malformations (AVMs) of the brain are pathological tangles of blood vessels where arteries connect directly to veins without intermediate capillaries, leading to the formation of a cluster of abnormal vessels. RNA sequencing enables the identification of genes potentially involved in the mechanism of AVM development.

Material and Methods: The study was conducted on a cohort of three patients from Kazakhstan with brain AVM. RNA extracted from tissue by using RNAqueous™-4PCR Total RNA Isolation Kit. RNA sequencing was performed on the DNBSEQ platform). with an average yield of 8.51G data per sample. The analysis of the obtained data was carried out using the Dr.Tom systems support program (https://www.bgi.com/global/service/dr-tom. To validate the transcriptome data by qRT-PCR assays.

Results: The average alignment ratio of the sample comparison genome was 97.68%, which was comparative. The average alignment of the gene set was 53.76%; a total of 123252 genes were detected. Venn diagram indicates that 8028 DEGs were common to all samples. The bioinformatics analysis showed the biological processes and pathways related to angiogenesis, cell adhesion, signal transduction and signaling molecules and interaction were significantly enriched.

Conclusion: The integration of genomics and transcriptomics data broadens our understanding of key genetic mutations, signaling pathways, and molecular mechanisms involved in the pathogenesis of AVMs.

P15.174.A Whole genome sequencing in unsolved cases of Russian patients affected with inherited retinal diseases

Natalya Ogorodova, *Anna Stepanova, Vitaly Kadyshev, Nikita Beskorovainy, Alexander Polyakov, Olga Shchagina*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Autosomal recessive forms account for more than 55% of all inherited retinal diseases (IRDs). Whole genome sequencing (WGS) offers significant advantages over targeted gene panels.

Methods: We performed WGS on 56 unrelated Russian patients in whom a single pathogenic/likely pathogenic variant in the *ABCA4, CNGB3, USH2A, CRB1, EYS, CNGA3*, and *CEP290* genes had been previously identified by panel sequencing (212 genes).

Results: In 30 out of 56 patients (53.57%) the cause of the disease could be identified. Among them, a pathogenic variant on the second allele in the studied genes was detected in 17 patients (56.67%). In the *EYS* gene in five patients the following alterations were detected: large deletion partially involving exon 19 (2 patients), deletions of exon 1 and exons 3–5, inversion in the 6q12 region with a breakpoint in the 13th intron of the gene. In the *ABCA4* two previously described intronic variants c.4539+2064C>T and c.6817-679C>A were identified in two patients, and one patient had a deletion of exon 30. In the *CEP290* a previously undescribed intronic variant c.2818-955A>G (spliceAI, z-score 0.99) was identified in one patient. Large deletions of exon 4 and exons 22–24 were detected in the *USH2A* gene in two individuals. The remaining 13 patients had variants in other genes: *CWC27, CFAP410, TRPM1, TTLL5, NR2E3, CNGB1, BBS5* and *ALMS1*.

Conclusion: This study emphasized the utility of WGS in the diagnosis of unresolved cases of IRDs.

P15.175.B Primary care implementation of a genetic test for MODY2 screening

Karine Tremblay[1], *Marie-Eve Poitras*[2], *Josianne Leblanc*[3], *Philippe Caron*[4], *Amélie Fournier*[2], *Joanie Bouchard*[1], *Lysanne Girard*[5], *Elizabeth Boivin*[1], *Vanessa T. Vaillancourt*[2], *Catherine Savard*[2], *Nathalie Bettez*[2], *Luigi Bouchard*[3,5], *Samuel Legeay*[6]

[1]*Department of Pharmacology-Physiology, Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, QC, Canada,* [2]*Department of Family Medicine and Emergency Medicine, Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, QC, Canada,* [3]*Department of Laboratory Medicine, CIUSSS Saguenay-Lac-St-Jean, Saguenay, QC, Canada,* [4]*Department of Endocrinology, CIUSSS Saguenay-Lac-St-Jean, Quebec, Canada, Saguenay, QC, Canada,* [5]*Department of Biochemistry and Functional Genomics, Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, QC, Canada,* [6]*Univ Angers, Inserm, CNRS, MINT, SFR ICAT, F-49000, Anger, France.*

Background: Maturity Onset Diabetes of the Young 2 (MODY2) presents with mild hyperglycemia devoid of microvascular (and possibly macrovascular) complications, often mistaken for other diabetes types. Access in primary care genetic testing for MODY2 is a major challenge but needed to realign treatment with the clinical recommendation which consists mainly of lifestyle modification alone. The objective is to evaluate the implementation of a validated genetic test for MODY2 in primary care.

Material and Methods: A developmental evaluation with qualitative and quantitative data sources is being carried out. This evaluation is supported by the RE-AIM model, a conceptual framework to guide our research into patients' and healthcare professionals' experiences of using the MODY2 screening test. Asynchronous online training on MODY2 and genetic testing, with

pre/post questionnaires, is provided to healthcare professionals (HCPs). HCPs propose the study to patients and, with consent, provide them a buccal cell collection kit. To date, 54 HCPs are participating in the project and 70 patients have been collected, including 13 positive for MODY2.

Results: Conditions for the implementation of the genetic test as well as the effects of training on the acquisition of knowledge by HCPs will be presented. This study also document the implementation process of a genetic test in a primary care setting and the essential factors to be considered for widespread deployment in other Canadian primary care clinics.

Conclusion: Evaluation of the implementation will identify facilitating and limiting factors, with the aim of establishing implementation standards for a provincial scaling-up strategy as a next step.

K. Tremblay: None. **M. Poitras:** None. **J. Leblanc:** None. **P. Caron:** None. **A. Fournier:** None. **J. Bouchard:** None. **L. Girard:** None. **E. Boivin:** None. **V.T. Vaillancourt:** None. **C. Savard:** None. **N. Bettez:** None. **L. Bouchard:** None. **S. Legeay:** None.

P15.176.C A novel homozygous splice-site variant in *WDR4* results in rare microcephaly syndrome

Philipp Sviridov[1], *Anait Voskanyan*[1], *Oxana Ryzhkova, MD, PhD*[2]

[1]*FSBSI Research Centre For Medical Genetics, Moscow, Russian Federation,* [2]*Research Centre for Medical Genetics, Moscow, Russian Federation.*

Background: Homozygous/compound heterozygous pathogenic variants in the *WDR4* gene are linked to Microcephaly, growth deficiency, seizures, and brain malformations syndrome (MIM:618346) or Galloway-Mowat 6 (MIM:618347) syndrome. This study identifies a novel homozygous splice-site variant in *WDR4* in two siblings. To date, only 9 patients with 8 pathogenic *WDR4* variants are described, of which only one is a variant in the canonical splicing site.

Material and Methods: Clinical evaluations and pre-test counseling were conducted. Whole exome sequencing (WES) was performed, followed by segregation analysis in family members.

Results: Two siblings exhibited intrauterine growth delay, poor postnatal growth, delayed motor and intellectual development, and minor dysmorphic features. WES identified a novel homozygous duplication at the +2 position of the exon 10 donor splice site in *WDR4* (NM_018669.6:c.1045+2dup). Segregation analysis confirmed the variant in the affected siblings, with parents and one unaffected sibling being heterozygous, and another unaffected sibling homozygous for the normal allele. SpliceAI predicted a donor site loss (Δ score = 0.96), classifying the variant as likely pathogenic. RNA-sequencing is planned to validate splicing impact. The previously described canonical splice-site variant shows only partial phenotypic overlap, with varying severity and clinical manifestations among affected family members. While 3 of 4 patients in the described family had glomerulosclerosis, our patients currently show no renal involvement. Neurologic manifestations also differ in features and severity between the described cases and our patients.

Conclusion: This case contributes to the limited literature on *WDR4* variants, expanding knowledge about phenotypic heterogeneity and the potential for diverse clinical presentations.

P. Sviridov: None. **A. Voskanyan:** None.

P15.177.D Investigation of HS3ST6 mutations in hereditary angioedema

Alessandra Buonfiglio, *Maria Francesca D'Ambrosio, Giorgia Cordisco, Angelica Leccese, Anastasia Ariano, Giovanna D'Andrea, Maria D'Apolito, Rosa Santacroce*

Università degli Studi di Foggia, Foggia, Italy.

Background: Hereditary angioedema (HAE) is a rare autosomal dominant disorder characterized by recurrent episodes of subcutaneous and submucosal edema, which can be life-threatening when affecting the airways. HAE types 1 and 2 are caused by mutations in the C1-inhibitor gene, while type 3 is linked to mutations in Factor XII. Additional genes, including PLG, ANGPT1, KNG1, MYOF, and DAB1P, have been associated with unknown HAE (U-HAE). Bork et al in 2021 identified a novel disease-linked mutation for HAE in **HS3ST6** gene, the **c.430A>**T p.(Thr144Ser). This study aimed to investigate a cohort of 160 U-HAE patients, in whom no mutations were found in other HAE-associated genes, to detect this or other HS3ST6 mutations.

Material and Methods: 160 probands diagnosed with HAE, previously studied with NGS custom panel HaloPlex HS Target Enrichment System (Agilent) for genes ANGPT1 (NM_001146.5), SERPING1 (NM_00006.2), PLG (NM_000301.4), MYOF (NM_013451.4), KNG1 (NM_001102416.3), and F12 (NM_000505.3), were examined via Sanger sequencing for the HS3ST6 gene.

Results: The c.430A>T p.(Thr144Ser) mutation was not detected in any patient. However, three novel variants were found: c.488C>T p.(Ala163Val) (in 65 patients, in 7 in a homozygous condition), c.574G>A p.(Ala192Thr) (in 63 patients, in 12 in homozygous condition) and c.946C>G p.(Leu316Val) (in 2 patients in heterozygous condition)

Conclusion: Although HS3ST6 remains a candidate gene for U-HAE, the identified variants were classified as benign by in silico analysis. Only the c.946C>G p.(Leu316Val) is reported in the database ClinVar as a variant of uncertain significance (VUS). Further investigations with an expanded cohort are necessary.

P15.178.A Identification and genetic analysis of novel mutations in patients with branchial anomalies

Klaudia Cipkova[1], *Marek Sklenar*[1], *Lukas Varga*[1,2], *Miloslav Karhanek*[1], *Miroslav Sabo*[1], *Martina Skopkova*[1], *Lenka Radicova*[3], *Milan Profant*[2], *Daniela Gasperikova*[1], *Silvia Borecka*[1]

[1]*Institute of Experimental Endocrinology, Biomedical Research Center SAS, Bratislava, Slovakia,* [2]*Department of Otorhinolaryngology – Head and Neck Surgery, Medical Faculty of Comenius University and University Hospital, Bratislava, Slovakia,* [3]*Clinic of Pediatric Otorhinolaryngology, Medical Faculty of Comenius University and National Institute of Children's Diseases, Bratislava, Slovakia.*

Background: Branchial cleft anomalies are congenital anomalies that develop from the first to the fourth pharyngeal clefts. They can manifest as preauricular sinuses, cervical cysts, or fistulae and present a diagnostic feature of syndromic diseases, such as Branchio-oto-renal (BOR) syndrome, Branchio-otic (BO) syndrome and Oculo-auriculo-vertebral spectrum (OAVS). The aim of the study was identification and genetic analysis of novel mutations in patients with branchial anomalies.

Material and Methods: Eleven families diagnosed with branchial anomalies were included in this study. Samples were

analyzed by WES, WGS, CNV, MLPA and Sanger sequencing. The minigene assay and Nanopore sequencing of nasopharyngeal swab samples was performed to confirm the potential pathogenic effect of splice site variants.

Results: One novel variant of unknown significance in the *SIX1* gene and a novel dominant pathogenic frameshift variant in the *PAX1* gene were identified in two families. Two heterozygous whole *EYA1* gene deletions and four pathogenic variants in the gene *EYA1* were identified in six families. One novel likely pathogenic variant *EYA1*:c.318G>A, one novel deletion (*EYA1*:c.1051-80_1052del) and a pathogenic variant *EYA1*:c.1360+5G>A were identified in three families. Using minigene assay, we confirmed the shortening or skipping of the affected exons. The subsequent cDNA analysis from nasopharyngeal swabs clarified the results of the minigene assay.

Conclusion: Branchial anomalies are mostly caused by pathogenic variants in the *EYA1* gene, which contribute to the BOR syndrome. Nasopharyngeal swabs are a suitable, easily available material to examine the transcriptional profile of the *EYA1* gene in vivo.

P15.181.D Case studies of diagnostic whole exome sequencing analysis using Franklin Genoox

Jan Kral, *Barbora Honysova, Michala Hrabikova, Stepan Chvojka, Inna Soldatova, Martina Bittoova, Monika Koudova*

GNTLabs by Gennet, Prague, Czech Republic.

Background: We perform diagnostic exome assessment using Franklin Genoox for secondary and tertiary analysis. The combination of the broad range of exome sequencing with Franklin's ability to select relevant variants based on phenotype defined by HPO terms allows for streamlined diagnostic exome assessment.

Material and Methods: We sequence the whole exome using Twist Bioscience panel (Exome 2.0 VCGS) and NovaSeq X Plus (Illumina). Primary analysis is done using DRAGEN software (FPGAtechnology), and secondary and tertiary analysis is performed using Franklin (Genoox). The assessment process focuses on genes associated with the phenotype as defined by HPO terms. We evaluate both SNP and CNV variants. Additionally, we report secondary findings as defined by ACMG recommendations, as well as pathogenic variants in ten most common recessive diseases in our population. Franklin integrates publicly available data from population, disease and sequence databases and published literature. Franklin also uses machine learning to select relevant genetic variants and suggest automated classification based on ACMG classification criteria.

Results: We analyzed 276 whole exome cases, including 72 prenatal and 204 postnatal cases. The majority of the prenatal cases were trio analyses, indicated due to increased nuchal translucency or congenital developmental defects. We identified the genetic cause in 14% of prenatal and 24% of postnatal cases.

Conclusion: The success of finding a causal variant is lower in prenatal cases than in postnatal cases, likely because the phenotype of postnatal cases can be described more specifically. We would like to present some interesting case studies from our diagnostic exome analysis.

P15.182.A Summary of 14-year single-center experience in fragile X syndrome diagnostics in Poland: Is a dedicated test still necessary?

Urszula Zawadzka-Więch, *Danuta Sielska-Rotblum, Marlena Młynek, Sylwia Purwin, Agata Cieślikowska, Dorota Wicher, Monika Kowalczyk, Justyna Pietrasik, Piotr Iwanowski, Agata Skórka, Katarzyna Iwanicka-Pronicka, Maria Jędrzejowska, Agnieszka Madej-Pilarczyk*

Children's Memorial Health Institute, Warsaw, Poland.

Background: Fragile X syndrome (FXS) is one of the most common monogenic causes of intellectual disability (ID) and autism spectrum disorders (ASD), affecting approximately 1 in 4,000 males and 1 in 8,000 females worldwide. Over 99% of FXS cases are due to the expansion of CGG trinucleotide repeats in the *FMR1* gene located on the X chromosome. This study presents a summary of our 14-year experience in FXS diagnostics.

Material and Methods: From 2011 to 2024, 1467 patients with a neurodevelopmental phenotype suggestive of FXS were referred for genetic testing. Until 2023, molecular data from 1260 patients was analysed using a PCR-based screening test with GeneScan and/or Methylation-sensitive Multiplex Ligation Probe Amplification (MS-MLPA). In 2024, 207 patients were tested using screening, MS-MLPA and/or the newly introduced Tripled-primed PCR (AmplideX PCR/CE FMR1 Kit) method.

Results: Between 2011 and 2023, the full mutation in the *FMR1* gene was detected in 17 of 1260 (1.3%) probands. A total of 171 patients (13.6%) did not yield conclusive results. In 2024, among 207 patients, 7 (3.4%) were found to have the full mutation. Family testing identified the full mutation in 1 patient and a mosaic of full mutation/premutation in 2 others.

Conclusion: Complete FXS diagnostics increases the detection rate of FXS and enables carrier status analysis in the patient's relatives. In the era of high-throughput molecular diagnostic methods, such as aCGH/NGS, we recommend initial FXS testing in patients with ID/ASD phenotype, as it can significantly shorten the diagnostic process while being cost-effective.

P15.183.B Combined RNA and genome sequencing identifies a novel homozygous intronic variant in *SNX14* in an individual with autosomal-recessive Spinocerebellar Ataxia (SCAR20)

Melanie Brugger[1,2], *Alice Saparov*[1,3,4], *Diana Ballhausen*[5], *Kevork Derderian*[1], *Ivana Dzinovic*[1,4], *Robert Kopajtich*[1,6], *Elisabeth Graf*[1,2], *Bavarian Genomes Network for Rare Disorders*[7], *Thomas Meitinger*[8,2], *Matias Wagner*[1,2,4], *Holger Prokisch*[9,2,4], *Juliane Winkelmann*[1,4,10], *Michael Zech*[1,4,11]

Germany, [11]Institute for Advanced Study, Technical University of Munich, Garching, Germany.

Background: Performing whole genome sequencing (WGS) in individuals with rare disorders usually leads to the identification of numerous rare or previously undescribed non-coding variants in disease-associated genes. Unbiased analysis of RNA sequencing data can be a vital tool in variant interpretation when performing WGS to increase the diagnostic yield in previously undiagnosed patients.

Material and Methods: We performed short-read WGS of a patient and her healthy parents and RNA sequencing of a patient-derived fibroblast cell line in the frameworks of the research project "Bavarian Genomes". Transcriptomic data was analysed for expression and splicing outliers with OUTRIDER and FRASER tools.

Results: Expression and splicing outlier analysis revealed a significantly reduced RNA expression of Sorting Nexin 14 (*SNX14*; fold change: 0,21; p(adj) = 6,82 × 10-57) in an index case born of consanguineous parents presenting with global muscular hypotonia, developmental delay, movement disorder and cerebellar atrophy. Parallel analysis of WGS data lead to the prioritization of a homozygous intronic variant in intron 12 of *SNX14* (NM_001297614.2:c.1108+28A>G). Transcriptomic data showed an integration of 28 base pairs of intronic sequence into *SNX14* mRNA disrupting the reading frame. This led to the diagnosis of autosomal recessive Spinocerebellar Ataxia 20 (SCAR20) in the index.

Conclusion: By combining expression outliers from transcriptomic data with short read WGS data, we could identify a novel pathogenic intronic variant in *SNX14* as the cause of SCAR20. This example illustrates the benefit of parallel RNA and WGS sequencing in individuals with previously undiagnosed neurodevelopmental disorders, especially in the context of consanguinity.

P15.184.C Exome sequencing enhances diagnosis of hereditary epidermolysis bullosa in tunisian patients

H. El Mabrouk[1], *H. Othman*[2], *L. Bousoffara*[3], *H. Chouk*[1], *M. Gribaa*[2], *M. Denguezli*[4], *C. Has*[5], *D. H'mida*[2];

[1]*Higher Institute of Biotechnology of Monastir, Monastir, Tunisia,* [2]*Laboratory of Human Cytogenetics, Molecular Genetics, and Reproductive Biology, Department of Genetics, Farhat Hached University Hospital of Sousse, Sousse, Tunisia,* [3]*Faculty of Medicine Ibn Eljazzar University of Sousse, Sousse, Tunisia,* [4]*Department of Dermatology and Venerology, Farhat Hached University Hospital of Sousse, Sousse, Tunisia,* [5]*Department of Dermatology and Venerology, Medical Center University of Freiburg, Freiburg, Germany*

Background: Hereditary epidermolysis bullosa (EB) comprises a heterogeneous group of genodermatoses characterized by skin fragility and blistering. The clinical overlap between EB subtypes, coupled with incomplete patient data, complicates classification, prognosis, and management. Genetic analysis can refine diagnoses, particularly in cases with ambiguous phenotypes.

Material and Methods: This study investigated nine Tunisian patients clinically diagnosed with EB, including cases with incomplete data or unclassified subtypes. Exome sequencing (ES) was performed to identify pathogenic variants in EB-associated genes. Bioinformatic analyses assessed variant pathogenicity, facilitating candidate selection for further functional validation.

Results: Eleven pathogenic variants were identified in four genes (COL7A1, LAMA3, DST, and FERMT1), including three novel variants in patients with initially unclassified EB. ES confirmed diagnoses of recessive dystrophic EB and junctional EB in these cases. For patients with incomplete clinical data, genetic findings enabled accurate reclassification, bridging the gap between genotype and phenotype. Bioinformatic predictions validate pathogenicity, reducing the need for extensive functional studies. Integrating ES with bioinformatics significantly streamlined diagnostics, minimizing time and costs compared to traditional serial testing.

Conclusion: ES is an essential tool for EB diagnosis, particularly in cases with incomplete clinical data. Its combination with bioinformatic analyses enhances diagnostic precision, ensuring molecular findings align with clinical phenotypes. This study highlights the importance of integrating genetic approaches into EB diagnostics to improve patient management through early, accurate, and cost-effective classification.

P16 Diagnostic Improvements and Quality Control

P16.001.D Evaluation and optimisation of the variant prioritisation algorithm for whole genome sequencing-based newborns screening in the Generation Study

Prasanth Sivakumar[1], *Joanna Kaplanis*[1], *Dasha Deen*[1], *Arina Puzriakova*[1], *James Skelton*[1], *Paul Quinn*[1], *Andrew Parrish*[2], *Emma Baple*[2], *Katrina Stone*[1], *Amanda Pichini*[1], *David Bick*[1], *Ellen Thomas*[1], *Richard Scott*[1], *Dalia Kasperaviciute*[1]

[1]*Genomics England, London, United Kingdom,* [2]*Royal Devon University Healthcare NHS Foundation Trust, London, United Kingdom.*

Background: The Generation Study explores the benefits, challenges, and feasibility of using whole genome sequencing to screen 100,000 newborns in England for >200 severe, early onset conditions across > 450 genes in which early, equitably accessible interventions could contribute to treatment success. Additionally, the genomes will be used to support research.

Material and Methods: To maximise positive predictive value and minimise downstream manual review requirements, we have developed an automated variant prioritisation pipeline that prioritises reported pathogenic variants from ClinVar, a commercially procured dataset, specialist-curated variant lists, and predicted loss-of-function variants. Testing on 34,410 individuals of mixed ancestry, not enriched for rare disease, identified the highest numbers of prioritised non-reportable variants in genes associated with multiple phenotypes, multiple modes of inheritance, overlapping other disease genes and/or hypomorphic variants. Specificity was then assessed in a 5,855 genome cohort and 1,362 genome cohort with the optimised pipeline for use in the study.

Results: Specificity was estimated at 95–97% across the cohorts, meaning 3–5% of the genomes will need manual review of prioritised variants, while ~1% of cases are expected to have reportable variants. Study-wide sensitivity, assessed in a 546 patient cohort with known diagnostic variants, reached 80%, primarily missing missense variants absent in known variant datasets. Variant callability was assessed using genome alignment quality and coverage per-gene.

Conclusion: In summary, we demonstrate the value of analytical validity assessment of genes screened in the study, and the potential of our bioinformatics pipeline to prioritise the majority of diagnostic variants whilst minimising false positives.

P16.002.A Integrative multi-omics for undiagnosed Rare Diseases (Omics-RD)

Anna Esteve-Codina[1], *Beatriz Martín-Mur*[1], *Marc Dabad*[1], *Estrella López-Martín*[2], *Beatriz Martínez-Delgado*[3,4], *María J.Barrero*[2], *Eva Bermejo*[2], *Antonia Ribes*[5], *Frederic Tort*[5], *Agatha Schlüter*[6], *Aurora Pujol-Onofre*[7], *Gemma Bullich*[1], *Emanuele Raineri*[1]

[1]*CNAG, Barcelona, Spain,* [2]*IIER, SpainUDP, ISCIII, Madrid, Spain,* [3]*CIBERER, Madrid, Spain,* [4]*IIER, SpainUDP, ISCIII, Madrid, Austria,* [5]*IDIBAPS, Hospital Clínic, Barcelona, Spain,* [6]*IDIBELL, Hospital de Bellvitge, Barcelona, Spain,* [7]*IDIBELL, Hospital de Bellvitge, BARCELONA, Spain.*

Background: Over 100 unsolved rare disease (RD) cases with inconclusive WES/WGS results—including leukodystrophies, spastic paraplegias, inherited metabolic disorders, and other complex syndromes—were included in the OMICS-RD project. The goal was to apply complementary omics technologies to prioritize disease-associated genes and causal variants.

Material and Methods: RNA-seq was performed on 83 blood and 28 fibroblast samples. The DROP pipeline was used to detect aberrant gene expression and splicing. Long-read WGS was conducted on 20 trio families (60 individuals total). Variant calling for SNVs, CNVs, SVs, and STRs was performed using the epi2me wf-human-variation pipeline, while methylation call was carried with modkit based on dorado's basecalling.

Results: Multi-omics analysis helped reveal the effects of causal mutations, including a a) homozygous duplication leading to a twofold increase in gene expression, b) SNV affecting splicing, c) a 40 kb deletion disrupting homologous exons of two consecutive genes, resulting in a gene fusion, d) a 50 kb heterozygous deletion causing a 50% reduction in gene expression, e) a rare intronic variant leading to intron retention and a 50% decrease in expression, f) a transposon insertion within an intron, g) a deep intronic variant inducing exon truncation, h) a triplet expansion causing an 80% decrease in expression, and i) a case with probable maternal UPD.

Conclusion: RNA-seq proved invaluable for detecting the functional consequences of previously deprioritized DNA variants, while long-read technologies enabled haplotype phasing, epivariation detection, and the identification of complex structural variants.

Background: Incorporating genomic sequencing into newborn screening (NBS) has the potential to dramatically increase the number of detectable conditions, but raises a range of practical and ethical issues. There is currently limited evidence from prospective cohorts internationally to guide policy and implementation.

Material and Methods: The BabyScreen+ study investigated the feasibility, acceptability and outcomes of clinically accredited genomic NBS (gNBS) in a prospective cohort of 1,000 newborns in Victoria, Australia. Prospective parents enrolled during pregnancy. Newborns were screened for variants in 605 genes associated with early onset, severe, treatable conditions using whole genome sequencing (WGS) on DNA from dried blood spots (DBS). Our semi-automated workflow identified variants for further consideration and reporting. Assay failure rates and causes, turnaround times, and clinical impacts of results were captured. Experiences of participating families were explored using surveys and interviews.

Results: gNBS was performed in 1,000 newborns, of whom 16 (1.6%) were identified as having a high chance of being affected by one of the conditions screened. Of these, only one condition was detectable by standard NBS. Average time to result was 13 days. Challenges with our approach included insufficient DNA yield from DBS (2%), data quality issues (19%), and a high manual review burden (55%). The median decisional regret was low, and >99% of participants believed gNBS should be available to all parents.

Conclusion: We have demonstrated the feasibility of clinically accredited gNBS for over 600 genes, with high accuracy and acceptability. Further work is needed to address issues of scalability and equity.

P16.004.C Performance of short-read whole-genome sequencing (srWGS) for detecting short tandem repeat

expansions: a comparison with standard of care

Markus Svensson, *Sofie Ivarsson, Hans Ehrencrona*

Department of Clinical genetics, Lund, Sweden.

Background: Short tandem repeat (STR) expansions cause several hereditary disorders, including myotonic dystrophy type 1 (DM1), C9orf72-related frontotemporal dementia and/or amyotrophic lateral sclerosis, fragile X syndrome (FXS), and Huntington disease (HD). Standard of care (SOC) diagnostics commonly rely on PCR-based methods and/or Southern blot, but whole-genome sequencing (WGS) is emerging as a potential alternative for high-throughput screening. This work evaluates the performance of short read WGS (srWGS) compared to SOC for STR expansion detection.

Material and Methods: We analyzed 180 STR loci in 142 patients using both srWGS (Illumina platform, in-house pipeline based on ExpansionHunter) and SOC (e.g., PCR-based methods and/or Southern blot). Loci analyzed included *AR, ATN1, ATXN1, ATXN10, ATXN2, ATXN3, ATXN7, ATXN8OS, C9orf72, CACNA1A, CNBP, DMPK, FMR1, FXN, HTT, NOP56, PABPN1, PPP2R2B*, and *TBP*. Concordance was assessed at two levels: (1) whether srWGS correctly classified expansions in clinically relevant categories (e.g., normal, intermediate, premutation, or full mutation), and (2) whether srWGS correctly distinguished normal repeat lengths from any expansion (e.g., intermediate, premutation, or full mutation).

Results: (1) SrWGS was concordant with SOC in 160/180 (88.9%) analyses for clinical classification of expansions. (2) When distinguishing normal repeat lengths on srWGS from any expansion, concordance improved to 97/97 (100%).

Conclusion: SrWGS demonstrates high concordance with SOC in detecting STR expansions and shows promise as a first-tier screening tool. While refinements are needed for precise classification of expansion categories, srWGS reliably rules out clinically significant expansions in the examined loci when repeat length is classified as normal.

P16.006.A Harmonized framework for RNA-seq-based rare disease diagnostics in a pan-continental consortium - Solve-RD (Award Candidate)

Rebeka Luknárová[1], *Anna Esteve-Codina*[2], *Solve-RD Consortium*[3], *Vicente A. Yépez*[1], *Julien Gagneur*[1]

[1]*Technical University of Munich, Munich, Germany,* [2]*CNAG, Barcelona, Spain,* [3]

Background: To enhance the diagnosis of rare disease patients within the European Solve-RD project, multi-omics data, including DNA, RNA-seq, and clinical phenotype, were integrated. Given the complexity of the data and the involvement of multiple analysts and interpreters from five European Reference Networks, the need to optimize and standardize result presentation became evident. Additionally, a structured framework for data interpretation was essential to ensure consistency.

Material and Methods: We detected aberrant expression and splicing in RNA-seq data from 350 affected individuals who were initially undiagnosed after DNA sequencing. These outliers were integrated with variants, clinical phenotype, and segregation data into a per-family report containing annotated result tables and plots. Close collaboration between bioinformaticians and clinical geneticists was essential and performed through regular consultation hours and "Solvathon" workshops. We developed a new framework to standardize the integration and classification of the results within the Solve-RD network.

Results: A median of 10 expression and splicing outliers were reported per sample. Most of them were discarded, mainly due to phenotype incompatibility. Eighteen families received a diagnosis, corresponding to a 7% diagnostic rate—comparable to the 12.6% achieved globally at Solve-RD through DNA analyses. Additionally, over 80 candidate variants were identified, along with five potential new disease genes.

Conclusion: The additional solved cases highlight the value of RNA-seq in rare disease diagnostics. Our framework efficiently filters and classifies RNA outliers, streamlining the diagnostic process. This approach is particularly beneficial for large consortia, such as the UDN and the emerging ERDERA.

Background: Intellectual disability (ID) is the first cause of referral to medical genetic departments in French academic hospitals. Growing evidence of the effectiveness of genome sequencing (GS) compared to reference sequencing strategies (RS) (fragile X expansion testing, chromosomal microarray analysis and 44 ID genes panel) is now well established. However, the value of GS as the first all-in-one test in ID has yet to be confirmed at national level.

Material and Methods: DEFIDIAG is a national prospective pilot study carried out in the framework of the French initiative for genomic medicine which aimed at comparing the diagnostic yield of GS *trio* analysis (GST) with the RS in real-life conditions of clinical and laboratory workflows. Both strategies were applied blindly in 1239 ID probands (50% previously investigated), including 187 patients randomized to undergo GS *solo* in addition to GST and RS.

Results: Overall, 442 class 4/5 SNVs were identified, 171 class 3+ SNVs, 79 class 4/5 CNV and 10 class 4/5 structural variants. The diagnostic yield for class 4/5 variants increased from 17.3% with the RS to 41.9% with GST in the never explored patients, and from 21.9% to 29.9% with GS *solo*. In addition, a prompt data reanalysis led to the identification of a recurrent pathogenic de novo variant in the *RNU4-2* gene in 7 patients.

Conclusion: The DEFIDIAG study demonstrates that GS as the first-line diagnostic test for ID shows a significantly better diagnostic yield, including in *solo* situations, compared to the RS in real-life medical genetic care.

P16.008.C Does quality of whole genome analysis matter?

Ivo Gut[1], *Marta Gut*[1], *Raul Tonda*[1], *Gabriela Aguileta*[1], *Lucia Estelles*[1], *Lidia Sevilla*[1], *Jean-Remi Trotta*[1], *Lidia Agueda*[1], *Matthew Ingham*[1], *Javier Gutierrez*[1], *Jordi Morata*[1], *Joan Gaztelu*[1], *plLC Participating Laboratories*[2]

[1]*Centro Nacional de Analisis Genomico, BARCELONA, Spain,* [2]

Whole-genome sequencing (WGS) using next-generation platforms is widespread and essential for the 1+Million Genomes Initiative. Laboratories performing professional WGS typically seek ISO17025 or ISO15189 accreditation to ensure regulatory compliance which involves verifying and validating their entire process and demonstrating proficiency. Currently, no proficiency testing schemes for the full WGS process exist. Interlaboratory comparisons (ILC) provide an alternative to demonstrate competence.

We conducted an WGS ILC with 19 European laboratories using Illumina NovaSeq6000 short-read sequencing, evaluating 57 quality metrics for laboratory sequencing performance, sample preparation and bioinformatics, with additional investigative metrics for process improvement. To ensure relevance, we distributed blood-extracted gDNA from a healthy donor - closely mirroring the intended use sample type - and alongside, the well-established GIAB reference gDNA. Gold-standard blood-extracted gDNA variant sets for SNVs, indels, and SVs were established using 600x short-read sequencing, orthogonal nanopore sequencing and variant transmission. Results showed blood-derived gDNA provided more uniform coverage than cell-line DNA. PCR-free sample preparation methods reduced indel false positive and negative calls 10-fold. In both testing items, SV calling exhibited shocking discrepancies in true-positive, false-positive, and false-negative calls across pipelines.

These findings highlight the importance of using relevant testing items and favouring PCR-free methods. SV detection with short reads remains challenging and requires substantial improvement. Proficiency testing is crucial to demonstrate competence, maintaining vigilance, pinpoint frailties and improve aspects of sequencing workflows. This ILC challenges the perception that WGS is a solved problem, demonstrating that major pitfalls persist even with common NGS methodologies.

[1]Department of Genetics and Molecular Pathology, Centre for Cancer Biology, an alliance between SA pathology and UniSA, Adelaide, Australia, [2]ACRF Genomics Facility, Centre for Cancer Biology, An alliance between SA Pathology and UniSA, Adelaide, Australia, [3]Adelaide Medical School, University of Adelaide, Adelaide, Australia, [4]Department of Genetics and Molecular Pathology, SA Pathology, Adelaide, Australia, [5]Kids Neuroscience Centre, The Children's Hospital at Westmead, Westmead, Australia, [6]Faculty of Medicine and Health, The University of Sydney, Westmead, Australia, [7]Paediatric and Reproductive Genetics Unit, Women's and Children's Hospital, Adelaide, Australia, [8]Adult Genetics Unit, Royal Adelaide Hospital, Adelaide, Australia, [9]UniSA Clinical and Health Sciences, University of South Australia, Adelaide, Australia, [10]Australian Genomics, Parkville, Australia, [11]Department of Clinical Genetics, Maastricht University Medical Centre +, Maastricht, Netherlands.

Background: Genetic variants altering mRNA splicing contribute up to 9% of variants underlying genetic diseases, which is biased towards canonical splice sites, and likely an underrepresentation. Continued improvements in long-read sequencing technologies promise a sensitive and high-throughput method for identifying multiple RNA transcripts resulting from a single splice altering variant.

Aim: To validate Oxford Nanopore technology (ONT) long-read sequencing as a read-out after RT-PCR for potential splice variants identified in research or diagnostics.

Methods: Targeted RT-PCR was performed on RNA from blood samples of the index patient and at least 2 controls for each variant. RT-PCR cycling conditions were adjusted based on GTEx values in whole blood to reduce PCR bias. These amplicons were sequenced in-house using ONT. Reads were mapped and interrogated using Integrative Genomics Viewer (IGV). Allele specific transcripts were quantitated using informative SNVs and then compared to diagnostic Sanger-determined splicing effects.

Results: Of 102 variants tested by RT-PCR and ONT sequencing, 73 had previously undergone Sanger sequencing. While these approaches were 98.6% concordant in the detection of a splice-effect (only 1 low-abundant mis-splicing event was missed by Sanger), the increased sensitivity of ONT sequencing uncovered additional RNA transcripts in 8 assays. For an additional 7 assays which had failed PCR and/or Sanger sequencing reaction, ONT was successful in generating informative reads for clinical interpretation.

Conclusions: In this ongoing validation study, ONT outperformed the current diagnostic Sanger analysis, simplifying the detection of aberrant transcripts and interpretation of splice-altering variants.

[1]Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy, [2]Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy, [3]Laboratory of Medical Genetics, Translational Cytogenomics Research Unit, Bambino Gesù Children Hospital, IRCCS, Rome, Italy, [4]Neonatal Intensive Care Unit, Bambino Gesù Children Hospital, IRCCS, Trieste, Italy, [5]Laboratory of Medical Genetics, ASST Papa Giovanni XXIII, Bergamo, Italy, [6]Paediatric Unit, ASST Papa Giovanni XXIII, Bergamo, Italy.

Background: Up to 1/3 of critically-ill infants present a genetic disorder and NGS technologies are the best approach to rapidly diagnose these rare and clinically heterogeneous diseases.

Material and Methods: Three NGS-based pilot studies were conducted in the Italian intensive care setting. At (1) IRCCS "Burlo Garofolo" (Trieste), 26 neonates were enrolled; at (2) ASST "Papa Giovanni XIII" (Bergamo), 237 children were analysed; at (3) IRCCS "Ospedale Pediatrico Bambino Gesù" (Rome), 300 paediatric patients were recruited.

Results: At (1), 62% of cases were solved through Whole Exome Sequencing (WES) analysis. For instance, a heterozygous paternally inherited variant in the *ABCC8* gene was identified together with the somatic loss of the maternal 11p15 region: the molecular diagnosis of focal familiar hyperinsulinism was essential to guide the surgical management. At (2), Whole Genome Sequencing achieved a diagnostic yield of 50%, including the identification of a homozygous deletion in the *LIPA* gene in an infant with acute metabolic decompensation, which allowed to promptly start the specific enzymatic replacement therapy. At (3), WES showed a diagnostic yield of 65%: for example, by highlighting a homozygous variant in the *SCYL1* gene and posing a molecular diagnosis of CALFAN syndrome, we provided precise information on the neurological prognosis.

Conclusion: After these promising results, we will launch the "Baby Wolf" study, the first Italian multicentre project that, through a shared WGS-based protocol, aims to achieve a molecular diagnosis in critically-ill NICU/PICU patients, thus providing tailored management plans and appropriate family counselling in a timely and cost-effective manner.

P16.011.B Translational Diagnostics and Therapeutics Program (TDTP): six years of experience in clinical functional genomics

Natàlia Caelles-Gramunt[1], *Jordi Pijuan*[1,2], *Lara Cantarero*[1,2], *María Rodriguez-Sanz*[1], *Gemma Tort*[1], *Berta Estévez-Arias*[1,3], *Mònica Roldán*[1,4], *Guerau Fernàndez*[1,2,5], *Francesc Palau*[1,2,6], *Janet Hoenicka*[1,2]

[1]Laboratory of Neurogenetics and Molecular Medicine, Center for Genomic Sciences in Medicine, Institut de Recerca Sant Joan de Déu, Barcelona, Spain, [2]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Barcelona, Spain, [3]Neuromuscular Unit, Department of Neurology, Hospital Sant Joan de Déu, Barcelona, Spain, [4]Confocal Microscopy and Cellular Imaging Unit, Hospital Sant Joan de Déu, Barcelona, Spain, [5]Department of Genetics, Hospital Sant Joan de Déu, Barcelona, Spain, [6]Division of Pediatrics, Faculty of Medicine and Health Sciences, University of Barcelona, Barcelona, Spain.

Background: Rare diseases pose significant challenges in identifying and interpreting the pathogenicity of genetic variants,

often leading to delayed or missed diagnoses. In our hospital, the Translational Diagnostics and Therapeutics Program (TDTP) addresses these challenges to validate genetic variants in the diagnostic process.

Material and Methods: The TDTP pipeline for diagnostic decision-making includes phenotype assessment and candidate variant analysis by in-silico studies and experimental functional genomics.

Results: The TDTP has assessed 274 cases from different pediatric specialities of which 211 have been evaluated for diagnostic purposes. The diagnostic yield of the concluded cases (n = 175) was 70.28% (n = 123). The high diagnostic rate can be attributed to our precision phenotyping approach, combined with in-silico studies and/or experimental functional genomics. Patients were selected based on nine specific criteria, the most common being carriers of genetic variants of uncertain significance (n = 75). In-silico analyses were the most frequently studies, involving the examination of DNA, RNA, and protein to predict genetic variants pathogenicity and their impact on the function and 3D structure of the encoded proteins (n = 155). In 76 patients, we performed experimental functional genomics using fibroblasts or peripheral blood samples to reach a diagnosis. The experimental methods included RT-qPCR (n = 23), Sanger sequencing (n = 21), Western blotting (n = 22), and computational imaging analysis of immunostained samples (n = 23). Blood samples were adequate for RNA analyses, offering a more practical approach for routine clinical practice and speeding up result delivery.

Conclusion: The program validates the effectiveness of intramural scientific translational approach in addressing diagnostic challenges in rare diseases.

P16.012.C Towards routine modopathy diagnostics: advances and clinical application of direct RNA sequencing by Oxford Nanopore Technologies

Anna Wierczeiko, *Charlotte Hewel*

Institute of Human Genetics, University Medical Center Mainz, Mainz, Germany.

Background: RNA modifications play a crucial role in gene regulation and have been implicated in disease mechanisms (modopathies). The *METTL5* gene encodes a methyltransferase responsible for site-specific rRNA methylation. Pathogenic variants in *METTL5* cause aberrant methylation and are associated with intellectual developmental disorder. However, detecting aberrant RNA modifications in the absence of clear pathogenic variants remains challenging in routine diagnostics. Direct RNA sequencing (DRS) by Oxford Nanopore Technologies enables RNA analysis in its native form, offering full-length isoform detection and unique insights into epitranscriptomic features, with potential applications in modopathy diagnostics.

Material and Methods: We utilized DRS with RNA004 chemistry and novel basecalling models for Ψ and m6A to analyze RNA from human cell lines, synthetic oligonucleotides, and blood samples, comparing performance to earlier sequencing chemistries. As a proof of concept, we analyzed blood-derived RNA from a patient with a truncating pathogenic *METTL5* variant and a potential splice VUS to assess both its splicing effect and impact on RNA methylation.

Results: RNA004 chemistry significantly improved throughput and accuracy, enabling precise site-specific RNA modification detection. For the first time, we demonstrated that DRS can validate a VUS by integrating RNA modification analysis. DRS confirmed aberrant splicing and loss of methylation at the *METTL5*-specific rRNA site, supporting the pathogenicity of the variant combination.

Conclusion: This study highlights the potential of DRS for modopathy diagnostics and VUS validation. By combining splicing analysis with RNA modification profiling, we provided the first functional validation of a VUS, paving the way for routine clinical implementation.

P16.013.D Accurate HBA and SMN genotyping within an integrated NGS workflow: a step toward accessible carrier screening

*Ashley Carroll[1], Vitor Onuchic[1], Jon Albay[1], Dianne Hernandez[1], Jonathan Nery[1], Susanne Angelow[1], Aaron Halpern[1], Shunhua Han[1], Kingshuk Mukherjee[1], Eric Roller[1], Elena Fernández Marcos[2], Maria Berbel Fernandez[2], Claudia Lopez Garcia[2], Carlos Marin[2], Antonio Capalbo[2,3], Chaim Jalas[2], **James Han**[1]*

[1]Illumina Inc, San Diego, CA, USA, [2]Juno Genetics, Valencia, Spain, [3]Unit of Medical Genetics, Center for Advanced Studies and Technology (CAST), "G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy.

Background: The widespread adoption of carrier screening is impeded by high costs and fragmented analytical workflows. Alpha Thalassemia and Spinal Muscular Atrophy (SMA) are among the most prevalent carrier conditions worldwide. Their respective HBA and SMN genes occur in complex genomic regions, necessitating separate analyses, increasing costs and workflow complexity.

Material and Methods: Validation study on targeted callers for SMN and HBA genes implemented in the DRAGEN™ framework along with spike-in panel supplementing the Illumina DNA Prep with Exome 2.5 Enrichment. Positive cell lines for [HBA (α3.7, α4.2, and two copy deletions/duplications)] and SMN1/2 (deletions/duplications) were used to assess repeatability. 71 blinded clinical samples of [7 positive for SMN1 exon7 deletion] and [11 positive for HBA -α3.7,-α4.2, -α20.5] were used to evaluate reproducibility.

Results: Applying the novel solution to a cell line cohort with orthogonally confirmed results for HBA (710 datasets from 203 unique samples) and SMN (728 datasets from 216 unique samples), demonstrated 100% (710/710) concordance for HBA and 97.9% (713/728) concordance for SMN1/2. Discordant results relate to cell line artifacts. In a separate clinical sample cohort (182 datasets from 71 unique samples), the concordance with matched MLPA was 100% (182/182) for HBA and 100% for SMN1 (182/182).

Conclusion: The novel callers and spike-in panel demonstrate a reliable approach for profiling HBA and SMN genes within an integrated NGS workflow. This method has the potential to reduce reliance on orthogonal assays in carrier screening, enhancing cost-effectiveness and accessibility.

For Research Use Only. Not for use in diagnostic procedures.

P16.014.A Integration sites and functional implications of novel processed pseudogenes in mendelian diseases

Artem Borovikov, *Alena Tauseneva, Nikita Beskorovainiy, Andrey Marakhonov*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Processed pseudogenes are genomic elements that arise through the retrotransposition of mRNA molecules. Due to their origin, they lack introns and often contain poly-A tails, reflecting their formation from reverse-transcribed RNA. While CNV caller tools can detect them as multiple intron deletions of their parental genes, their precise genomic integration sites could easily be overlooked in bioinformatic analyses.

Material and Methods: We analyzed 3,655 whole-genome datasets from probands with suspected Mendelian diseases and their healthy relatives. The data were processed using bioinformatic pipelines to identify and annotate processed pseudogenes, with a particular focus on their integration sites and potential functional implications.

Results: We detected 34 processed pseudogenes that are absent in the GRCh38 genome reference, 25 of which are novel and have not been described previously. For 22 of these pseudogenes, we were able to determine the precise Insertion site, while 3 were reclassified as potential mapping errors. Most of the revealed processed pseudogenes have low allele frequency (29 events with a frequency below 0.5%). Notably, we observed that 7 pseudogene integration events occurred within intronic regions, which could lead to potential regulatory or splicing abnormalities in host genes.

Conclusion: Processed pseudogenes are relatively rare genomic events; however, they can contribute to monogenic diseases or serve as valuable markers for population genetics due to their low frequency and unique integration patterns. Further investigation into their functional impact and distribution across populations will enhance our understanding of their role in human health and evolution.

P16.015.B Implementing RNAseq analysis alongside WGS in healthcare, a diagnostic workflow for patients with rare diseases

Lucía Peña-Pérez[1], *Anders Jemt*[2], *Jesper Eisfeldt*[3], *Henrik Stranneheim*[2], *Nicole Lesko*[3], *Daniel Nilsson*[1], *Chiara Rasi*[2], *Anna Wedell*[1], *Valtteri Wirta*[2], *Anna Lindstrand*[1], *Håkan Thonberg*[1]

[1]*Karolinska university Hospital, Stockholm, Sweden,* [2]*SciLifeLab, Stockholm, Sweden,* [3]*Karolinska University Hospital, Stockholm, Sweden.*

Background: RNA-seq has emerged as a powerful complementary technique to whole genome sequencing (WGS) for rare disease diagnostics. While WGS provides extensive genomic information, it often fails to elucidate functional consequences of genetic variants, leaving patients undiagnosed. Performing RNA-seq in combination with WGS enables direct assessment of variant effects on transcripts, potentially increasing the diagnostic yield. Here we report the full implementation of RNA-seq for blood transcriptome analysis. We present the entire workflow from blood-sampling to visualization combined with WGS for interpretation, including a pilot clinical test of 20 patient samples referred for diagnostic analysis.

Material and Methods: Blood samples from 215 rare disease patients were collected in PAXgene tubes and RNA was isolated, sequenced, and processed using our in-house-developed bioinformatic pipeline Tomte. A total of 195 samples were used to create a database for comparing gene expression and splicing events between controls and patients. Tomte performed allele-specific variant calling and annotation, and detected allelic imbalance, aberrant expression, and aberrant splicing. The results were then integrated with previously obtained WGS data and displayed in Scout, our in-house-developed decision support tool for variant interpretation.

Results: Our pilot study of 20 samples revealed an average of five aberrant splicing and eight aberrant expression events per patient. This included cases of reduced exon usage and haploinsufficiency linked to previously identified WGS variants.

Conclusion: The integration of RNA-seq with WGS has the potential to increase the diagnostic yield for rare disease patients by directly showing the functional impact of variants on transcripts.

P16.017.D Diagnostic utility of optical genome mapping in constitutional cases - a single institutional experience

Nicole Park[1], *Kamran Adibi*[1], *Taras Makhnevych*[1], *Ted Young*[1,2], *Kathy Chun*[1,2], *James Stavropoulos*[1,2], *Mary Shago*[1,2], *Afia Hasnain*[1,2]

[1]*Division of Genome Diagnostics, Department of Paediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada,* [2]*Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada.*

Background: Current standard-of-care (SOC) methods to detect structural and copy number variants in constitutional disorders include G-banding, fluorescence in situ hybridization (FISH) and chromosomal microarray. The limitations of SOC methods often require multiple tests to determine the underlying chromosomal rearrangement(s). Optical genome mapping (OGM) can overcome these limitations by being able to detect balanced structural rearrangements, copy number variants, and unbalanced structural variants at a higher resolution in a single assay. Our goal was to evaluate the diagnostic utility of OGM through comparison with traditional cytogenetic methods using samples representing a variety of chromosomal rearrangements.

Material and Methods: OGM was performed using the Saphyr system (Bionano Genomics) on 29 pediatric patients and compared to previously identified variants detected by Cytoscan HD SNP Array (Affymetrix), karyotype and/or FISH results.

Results: Comparison of OGM and previous cytogenetic findings revealed concordance in 25 samples from the validation cohort. Four samples were not included in the validation set, as they had insufficient DNA or failed quality metrics. In total, OGM identified 67 variants, including previously identified inversions, deletions, duplications, dicentrics, and homozygous gains and losses. OGM was able to resolve suspected balanced translocations, identify

inversions, and additional variants that were previously undetected by other methods.

Conclusion: OGM provides a comprehensive higher resolution platform for detecting clinically relevant chromosomal rearrangements. OGM also identified additional variants, suggesting increased sensitivity will result in a higher diagnostic utility for constitutional disorders. Parameters are currently being optimized for integration of OGM into the clinical workflow.

P16.018.A Non-invasive prenatal testing for monogenic disorders using whole-exome sequencing of cell-free DNA

*Kristína Valovicová[1,2], **Maroš Kompas**[2], Iveta Valaskova[3,4], Martin Převorovský[2]*

[1]Section of Genetics and Molecular Biology, Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic, [2]Sophgena a.s., Prague, Czech Republic, [3]Center of Molecular Biology and Genetics, Internal Hematology and Oncology Clinic, University Hospital Brno, Brno, Czech Republic, [4]Institute of Medical Genetics and Genomics, Faculty of Medicine, Masaryk University and University Hospital Brno, Brno, Czech Republic.

Background: Non-invasive prenatal testing (NIPT) has transformed prenatal screening by analyzing cell-free DNA (cfDNA) from maternal plasma to detect common fetal chromosomal aneuploidies. However, many severe postnatal genetic disorders result from dominant de novo pathogenic variants in single genes, which are not detected by standard NIPT procedures. Advances in next-generation sequencing and targeted gene panels have shown technical feasibility of identifying such pathogenic variants with high accuracy. Despite that, NIPT for monogenic disorders has not yet become part of routine clinical practice in Czechia. Expanding NIPT to include monogenic conditions holds a promise of improving early diagnosis and pregnancy management.

Material and Methods: cfDNA was extracted from maternal plasma using the QIAamp Circulating Nucleic Acid Kit. Sequencing libraries were prepared using the Twist cfDNA Library and UMI Adapter System, followed by enrichment with a Twist Exome panel. Sequencing was performed on the Element Biosciences AVITI system using a High Output kit.

Results: A complete workflow for monogenic NIPT analyses was established. Whole-exome sequencing (WES) successfully confirmed dominant pathogenic variants in disease-related genes in cfDNA samples. Estimation of fetal fraction was performed using allele frequency analysis.

Conclusion: Our proof-of-concept study highlights the feasibility and potential of cfDNA-based WES for NIPT of autosomal dominant monogenic disorders, such as achondroplasia. Integrating NIPT of monogenic disorders into routine care could greatly improve early diagnosis, optimize allocation of healthcare resources, and support informed parental decisions. On the other hand, future studies need to focus on the NIPT-related ethical issues as well.

P16.019.B Improvement of management and turnaround time of NGS based genetic testing by using an all in one digital solution

***S. Gambardella**[1,2], G. Macari[3], L. Cafforio[4], R. Ferese[1], R. Campopiano[1], M. Chiaravalloti[1], E. Agolini[5], M. Mattiuzzo[6], M. Lodi[7], M. Dentici[7], S. Gardini[4], B. Dallapiccola[7], A. Novelli[8];*

[1]IRCCS Neuromed, Pozzilli, Italy, [2]Department of Biomolecular Sciences, University of Urbino "Carlo Bo", Urbino, Italy, [3]GenomeUp SRL, Roma, Italy, [4]GenomeUp SRL, Rome, Italy, [5]Ospedale Pediatrico Bambino Gesù, Roma, Italy, [6]Ospedale Pediatrico Bambino Gesù, Rome, Italy, [7]Ospedale Pediatrico Bambino Gesù, Rome, Italy, [8]Bambino Gesù Children Hospital, Rome, Italy

Background: NextGenerationSequencing diagnostic workflows are complex and various challenges related to patient and sample management must be addressed to enhance clinical assessments, laboratory processes and accelerate diagnoses.

Methods: We conducted a pilot study to evaluate the time efficiency of a diagnostic process using an end-to-end digital solution, compared to the traditional workflow. The study involved 80 patients with rare diseases recruited at Bambino Gesù Children's Hospital-Rome and Neuromed Institute-Pozzilli. We performed a swimlane analysis of the following steps: genetic counseling and request submission by clinical geneticists(1), sample check-in and analytical processing by laboratory technicians(2) and variant analysis,interpretation and reporting by biologists(3).

Results: Our results showed that the average turnaround time for the traditional workflow was significantly longer (14d) compared to the digital solution-based workflow (5d). The digital solution streamlined the diagnostic process by incorporating an all-in-one system that facilitated digital genetic counseling, easy submission of genetic requests, digital laboratory operations, sample tracking, NGS data analysis, variant prioritization, automatic generation, validation and delivery of reports.This integration led to an overall 65% reduction in TAT: 15% in phase1, 20% in phase2, and 30% in phase3.

Conclusions: We found that the end-to-end digital solution improved laboratory efficiency and productivity. This approach created a more reliable and scalable laboratory, enhanced patient and sample management, streamlined information sharing, reduced errors, and sped up times. Furthermore, the continuous workflow enabled by the digital solution contributes to the growth of a clinical and biological dataset, facilitating new gene-phenotype association studies, correlation research and enhanced diagnosis.

P16.020.C The Gaslini Genomic Neonatal Screening for the early diagnosis of rare diseases

*Michele Iacomino[1], Concetta Aloi[1], Alessandro Salina[1], Monica Traverso[1], Marta Rusmini[1], Francesca Rosamilia[1], Yeraldin Castillo De Spelorzi[2], Diego Vozzi[2], Francesca Faravelli[1], Mohamad Maghnie[1], Federico Zara[1], **Paolo Uva**[1]*

[1]IRCCS Giannina Gaslini Institute, Genova, Italy, [2]IIT - Center for Human Technologies Genomic Unit, Genova, Italy.

Background: Newborn screening (NBS) is a program aimed at detecting pre-symptomatic newborns with serious yet treatable

disorders. Advances in molecular genomics and gene therapy are expected to expand the spectrum of conditions included in NBS. We evaluated the impact of whole genome sequencing (WGS) in the NBS program for the early identification of infants with potentially treatable diseases or carriers of recessive diseases.

Material and Methods: We performed Illumina PCR-free WGS on DNA extracted from dried blood spots of 200 healthy newborns collected at the Gaslini Institute. Detection of SNVs, indels, CNVs, SVs, and expansions, was performed using Dragen Germline, as well as detection of copy number of SMN1 and SMN2. Variants were annotated and filtered using the in-house BioGeAR pipeline (https://github.com/igg-bioinfo). Analysis focused on ClinVar pathogenic variants within 177 genes associated with disorders potentially included in Italian NBS (e.g., SMA, SCID, CF, Pompe disease). Analyses were automated to reduce turnaround time.

Results: WGS pipeline was validated on 24 individuals with known pathogenic variants. WGS of the first 190 newborns enrolled in the study, with an acceptance rate of 99%, identified homozygous and compound heterozygous clinical Pathogenic/Likely Pathogenic variants in recessive genes (SMN1, CFTR, BTD) in 3 newborns. Gene therapy was administered to the patient with SMA disease.

Conclusion: Our findings indicate that genomic NBS enables the early detection of genetic factors underlying metabolic dysregulation and other disorders, potentially influencing clinical management in the neonatal period. We also identified ethical issues that should be addressed before wider implementation of genomic NBS.

P16.021.D Impact of Gene Specific Guidelines on the Interpretation of Variants of Uncertain Significance

Dina Yagel[1,2], *ofer Isakov*[1,3], *Karin Kfir*[1,3], *Moor Lev*[1,3], *Jordana Kosowsky*[1,3], *Rotem Grinbeerg*[1,2], *Shay Ben Shachar*[1,3]

[1]*Clalit Genomics center, Petach Tikva, Israel,* [2]*Clalit Research Institute, Innovation Division, Clalit Health Services, Rammat Gan, Israel,* [3]*Clalit Research Institute, Innovation Division, Clalit Health Services, Ramat Gan, Israel.*

Introduction: The ClinGen consortium has recently published various gene-specific and disorder-specific variant interpretation criteria, refining the original ACMG guidelines. This study evaluates the impact of applying these criteria on the classification of variants of uncertain significance (VUS).

Methods: Guidelines were extracted from the ClinGen Criteria Specification registry (CSpec) and analyzed for scoring modifications compared to the standard ACMG framework. Variants initially classified as VUS under ACMG guidelines were reanalyzed using the gene-specific criteria to assess changes in classification.

Results: A total of 106 CSpec guidelines were identified. Overall these guidelines applied stricter frequency cutoffs, stringent thresholds for prediction tools, and refined hotspot definitions, generally reducing pathogenic strength. Among 332 VUS analyzed across 14 genes, 196/332 (59%) demonstrated a reduction in pathogenic strength, leading to a downgrade of 68/196 (35%) VUS variants to likely benign (LB) classification. Only 22 VUS (7%) showed increased pathogenicity probability, but none reached a likely pathogenic (LP) classification. For 114/332 (34%) variants, the pathogenicity probability remained unchanged. BRCA1/BRCA2 showed the highest reclassification rate, with 19/20 VUS variants downgraded to LB, while the impact was minimal for PMS2, affecting scores of 15/32 variants, with 3 variants with classification alterations.

Conclusions: Applying CSpec guidelines significantly reduced pathogenicity scores, reclassifying 18% of VUS as LB. This demonstrates the utility of specific guidelines in reducing uncertainty while requires the need for more advanced analytical pipelines for comprehensive assessment.

P16.022.A Enhanced precision in predicting the RNU4-2-related phenotype (ReNU syndrome) by facial image analysis of multiple family members

Aron Kirchhoff[1], *Alexander Hustinx*[1], *Tzung-Chien Hsieh*[1], *Hannah Klinkhammer*[1], *Stefan Barakat*[2,3], *Peter Krawitz*[1], *Annabelle Arlt*[1]

[1]*Institute for Genomic Statistics and Bioinformatics, University Hospital Bonn, Bonn, Germany,* [2]*Department of Clinical Genetics, Erasmus MC University Medical Center, Rotterdam, Netherlands,* [3]*Discovery Unit, Department of Clinical Genetics, Erasmus MC University Medical Center, Rotterdam, Netherlands.*

Background: The introduction of trio genome sequencing (TGS) has revolutionized the identification of de novo mutations in sporadic cases of intellectual disability. In particular, the discovery of non-coding variants underlying the recently delineated ReNU phenotype would not have been possible without TGS. However, as TGS is not widely accessible, there is an increasing demand for scalable and cost-effective screening methods. We therefore fine-tuned GestaltMatcher for this purpose. GestaltMatcher is an artificial intelligence that analyzes phenotypic features of patients with rare diseases.

Material and Methods: GestaltMatcher was trained on over 12k facial photographs including portrait images of 35 unrelated individuals with molecularly confirmed ReNU syndrome. In addition, we analyzed the facial encodings of unaffected family members within this clinical face phenotype space and subtracted their feature embeddings from the patient data. This preprocessing step effectively removes family-specific but non-pathogenic facial traits.

Results: We assessed the rank of the correct diagnosis in GestaltMatcher before and after integrating the embeddings from unaffected family members. We find that including imaging data of additional relatives, ideally taken at a similar age, can be used to increase the signal-to-noise ratio. In average, the rank of ReNU increased from rank 10 to rank 2.

Conclusion: Portrait photos of unaffected family members significantly enhance the accuracy of ReNU syndrome prediction, making computer assisted image analysis a promising screening approach for tiered diagnostics. Through this increased sensitivity towards ReNU, targeted Sanger sequencing of the RNU4-2 locus may serve as a rapid and cost-effective alternative to whole-genome sequencing.

P16.023.B Reasoning with AI: simultaneous HPO extraction and disorder classification for syndromic faces

Alexander Hustinx[1], *Behnam Javanmardi*[1], *GestaltMatcher Database Consortium*[2], *Tom Kamphans*[3], *Peter Krawitz*[1], *Tzung-Chien Hsieh*[1]

[1]University Hospital Bonn, Institute for Genomic Statistics and Bioinformatics, Bonn, Germany, [23]GeneTalk, Bonn, Germany.

Background: Next-generation phenotyping approaches have demonstrated high accuracy in suggesting diagnoses based on dysmorphic facial features. We propose a novel approach using convolutional neural networks (CNNs) to simultaneously infer Human Phenotype Ontology (HPO) terms and classify disorders based on syndromic faces. By integrating HPO extraction and disorder prediction, our method enables cross-validation of results, improving diagnostic robustness. We aim to enhance both diagnostic support and explainability in AI-driven rare disease classification.

Material and Methods: Through GestaltMatcher Database, we set up a large-p effort to annotate the presence and absence of HPO-terms. As annotation of HPO-terms is a subjective process, we allowed multiple experts to annotate the same images to improve the overall robustness. By simultaneously learning to predict disorder and infer HPO-terms, we can cross-reference inferred terms with disorders to (in)validate predictions. Further, since HPO-terms inherently carry spatial information, we can gain new insights into the predicted disorders.

Results: 1000 images, across 10 disorders were annotated with 72 common HPO-terms for the disorders, alongside any term the annotators considered important. We trained several CNNs and compared the performance when predicting HPOs, disorders, and a combination of the two. The latter allowed us to combine the predictions to further improve performance and explainability.

Conclusion: Our proposed approach allows for more and better analyses to be conducted straightforwardly. Further, it inherently improves the explainability of our AI models, improving their usefulness in clinical settings. Additionally, it reduces the subjectiveness of labeling HPO-terms manually and allows clinicians to work more efficiently.

P16.024.C Identification of prognostic miRNA biomarkers from neonatal CSF extracellular vesicles in post-hemorrhagic ventricular dilatation via machine learning approaches

*Priska Bauerstätter[1], Gabriel A. Vignolle[1], Lucia Ciglar[1], Silvia Schönthaler[1], Lisa Klein[2], Angelika Berger[2], Christa Nöhammer[1], Katharina Goeral[2], **Klemens Vierlinger**[1]*

[1]AIT - Austrian Institute of Technology, Wien, Austria, [2]Medical University Vienna, Wien, Austria.

Background: Neonatal post-hemorrhagic ventricular dilatation (PHVD), a serious complication of intraventricular hemorrhage (IVH), is linked to significant neurodevelopmental impairments. Early biomarkers are critical for timely prognosis and intervention. As cerebrospinal fluid (CSF) is routinely drained at the onset of PHVD to reduce the intercranial pressure, we aimed toexplore this understudied, yet accessible biofluid for extracellular vesicles (EVs) isolation and identification of miRNA biomarkers.

Material and Methods: We isolated EVs from 190 CSF samples from 43 neonates diagnosed with PHVD. High-throughput sequencing was used to profile EV-associated miRNAs, generating a novel dataset of miRNA signatures. Machine learning (ML) and artificial intelligence (AI) algorithms were applied to analyze these miRNA profiles and predict neurodevelopmental outcomes at 2 and 3 years of age.

Results: We were able to detect 248 miRNAs consistently in 80% of the samples. Our ML models identified key miRNAs with strong predictive power for cognitive and motor outcomes. These miRNAs showed potential as early, minimally invasive biomarkers for neurodevelopmental prognosis. The identified biomarkers provided insights into the pathophysiology of PHVD and may inform the development of targeted therapies.

Conclusion: This study highlights the potential of EV-associated miRNAs as predictive biomarkers for neurodevelopmental outcomes in neonates with PHVD. Further validation in larger cohorts could establish these miRNAs as valuable clinical tools for early diagnosis and prognosis, offering new avenues for mitigating long-term neurodevelopmental deficits.

P16.026.A Efficacy of universal genome sequencing in critically ill infants on extracorporeal membrane oxygenation

***M. L. Fulmer**[1,2], R. Mao[1,2], C. Rau[3], S. Boyden[4], H. Best[1,2,3], G. McMillin[1,2], A. Mankouski[5], D. Pattison[2], T. Wild[6], L. Brunelli[3,5], N. Carr[5];*

[1]Department of Pathology, University of Utah School of Medicine, Salt Lake City, UT, [2]ARUP Laboratories, Salt Lake City, UT, [3]Department of Pediatrics, University of Utah, Salt Lake City, UT, [4]Utah Center for Genetic Discovery, Department of Human Genetics, University of Utah, Salt Lake City, UT, [5]Intermountain Health, Salt Lake City, UT, [6]Children's Hospital of Philadelphia, Philadelphia, PA

Background: Rapid whole genome sequencing (WGS) in neonatal intensive care units (NICUs) provides fast, actionable diagnostics but lacks clear timing guidelines, especially for infants on extracorporeal membrane oxygenation (ECMO). With growing evidence that early genetic insights could improve outcomes in complex ECMO cases, this study assesses the diagnostic efficacy of universal WGS in this high-risk group.

Material and Methods: We conducted a prospective, multicenter, non-interventional pilot study across eight ICUs within the Children's Hospitals Neonatal Consortium (CHNC) using a single IRB reliance model. The study targeted enrollment of 25 infants (0–12 months) with the primary selection criterion being the need for ECMO. Blood samples were collected prior to cannulation with parental consent. Genome sequencing and variant analysis followed standard research protocols, with no provisions for the timely return of results to clinicians.

Results: The diagnostic rate was 24% (6/25), revealing diverse causal variants including compound heterozygous (1/6), autosomal dominant (1/6), X-linked (1/6), and chromosomal abnormalities (3/6). One positive case carried a second variant of uncertain significance, and another had an ACMG secondary finding. Overall, secondary/incidental findings were reported in 8% (2/25) of infants. Five cases showed potentially pathogenic variants that could not be conclusively assessed due to study setup limitations.

Conclusion: These findings support the potential clinical benefit of universal, first-tier genome sequencing in pediatric ECMO cases. A future multicenter randomized trial is planned to further evaluate the utility of universal ultra-rapid genome sequencing in this population.

P16.027.B Common causes of genotyping error; Trends over time

India Roderick, *Victoria Williams, Weronika Gutowska-Ding, Charlotte Shaw, Simon Patton*

EMQN, Manchester, United Kingdom.

Background: Genotyping errors have potential to cause patient harm. EMQN asks laboratories to complete a Root Cause Analysis (RCA) for errors identified during External Quality Assessment (EQA). Here, we show trends for the most prevalent causes of genotyping errors.

Method: RCA forms received between 2019–2023 from 358 laboratories were analysed to categorise the root cause of genotyping errors and identify trends over time. Results were sub-grouped by field (germline or molecular pathology testing), and error type (false positive or false negative results).

Results: Over 99% of laboratories that submitted forms following a genotyping error successfully identified root causes. Overall, the leading cause of genotyping error was transcription errors, followed by sample swaps and commercial kit performance.

Trends over the five-year period demonstrated consistent decline in errors resulting from suboptimal bioinformatics pipelines and variant misclassification. However, errors associated with NGS quality control (QC), including filtering parameters and insufficient coverage, have increased, highlighting evolving challenges in the field.

Incorrect or incomplete methodological approaches, including use of outdated gene panels, were the main cause of error for laboratories performing germline testing. This comprised entirely of false negative results. Higher rates of sample swaps and commercial kit use errors were associated with molecular pathology testing.

Conclusion: EQA can help identify errors proactively so the root cause can be identified, and services improved. This analysis highlights the importance of caution and checks regarding validation of analytical and bioinformatic QC, report writing and sample processing to ensure the accuracy of test results and prevent patient harm.

P16.028.C Project LANCELOT: A Molecular Newborn Screening of Treatable Conditions

Giovanni Vicidomini[1], *Mariateresa Zanobio*[1], *Pasquale Di Letto, PhD student*[1], *Sarah Iffat Rahman*[1], *Giulio Piluso*[1], *Annalaura Torella*[1,2], *Vincenzo Nigro*[1,2]

[1]*University of Campania Luigi Vanvitelli, Naples, Italy,* [2]*Telethon Institute of Genetics and Medicine, Pozzuoli, Naples, Italy.*

Background: We conceived the Molecular Newborn Screening of Treatable Conditions (LANCELOT) project for the early identification of well-characterised treatable genetic disorders. Our aim is to develop a customised Next Generation Sequencing (NGS) panel-based Newborn Screening (NBS) focused on genomic regions in which druggable disease-causing mutations are located.

Material and Methods: We interrogated the ClinicalTrials.gov database to identify the genes associated with treatable conditions suitable to undergo our NGS-NBS. The 35 selected genes were included in our panel design provided by Agilent SureDesign platform. To assess the project methodology and validate our panel, we conducted a pilot experiment with 60 anonymous newborns. DNA samples were obtained from dried blood spot and enriched with the Agilent SureSelectXT HS Protocol. The libraries were run on the Illumina NextSeq500. Finally, the raw NGS data were analysed using an in-house bioinformatic pipeline.

Results: The data analysis showed a target regions average coverage of 1000X, with an even higher depth for the mitochondrial locus, leading to the identification not only of single nucleotide variants but also copy number variants and mosaicism. This results in a well-characterised, manageable, and cost-effective NGS panel which enables the detection of multiple variant types in a single test.

Conclusion: Performed test proved LANCELOT efficacy, achieving a pivotal milestone towards clinical practice. Following the current evidence-based model for NBS and undergoing continual literature updates, our proposal provides with important technological innovation of high clinical utility and significant economic impact, implementing the diagnostic and therapeutic management of paediatric conditions.

P16.029.D Challenging the use of proxies in genotyping analysis for *DPYD* and *UGT1A1*

Giada Scantamburlo, *Lena-Sophie Helmecke, Abigaile Masiulyte, Charity Nofziger, Simone Vanoni*

PharmGenetix GmbH, Niederalm, Austria.

Background: Dihydropyrimidine dehydrogenase (DPD) and uridine diphosphate glucuronosyltransferase 1A1 (UGT1A1) are metabolic enzymes on whose genes several variants were identified. Both enzymes are involved in the metabolism of common chemotherapeutic drugs namely 5-fluorouracil (5-FU) reduced by DPD and irinotecan active metabolite (SN38) glucuronidated by UGT1A1. Genetic variations decreasing the activity of DPD and expression of UGT1A1 pose an elevated risk for potentially life-threatening fluorouracil/irinotecan toxicity. Preemptive genotyping is therefore considered critical for the correct dosing and tag SNVs are still used as proxies to define the genotype of causative SNVs considered in 100% LD. For *DPYD* c.483+18G>A and c.1236G>A/HapB3 are proxy for c.1129-5923C>G and for *UGT1A1* *80 is proxy for *28.

Material and methods: Genotyping was conducted using OpenArray panels interrogating *DPYD* c.483+18G>A, c.1236G>A, c.1129-5923C>G and *UGT1A1* c.-364C>T (*80). *UGT1A1* c.-54_-39A(TA)6TAA>A(TA)7TAA (*28) was evaluated via targeted PCR amplification and Sanger sequencing. The correlation between the genotype of the causative and the proxy SNVs was studied in 3189 and 171 samples for *DPYD* and *UGT1A1*, respectively.

Results: Concerning *DPYD*, lack of correlation was detected in 11 samples (0,35%) between c.483+18G>A and c.1129 5923C>G, and 1 sample between c.1236G>A and c.1129-5923C>G. The correlation analyses between *80 and *28 on *UGT1A1* identified 1 non matching sample (0,58%).

Conclusions: The use of proxy SNVs has evident limitations even for variants considered in 100% LD and could lead to incorrect genotyping results. Direct genotyping of causative SNVs should be preferred as best molecular diagnostic practice especially for variants clearly associated with severe and life-threatening side effects.

Background: Biallelic loss-of-function (LoF) variants in *ZNF142* underlie a clinically variable neurodevelopmental disorder. *ZNF142* is a zinc-finger transcription factor with potential roles in chromatin organization, implying a possible association of ZNF142 LoF with perturbed genome-wide DNA methylation (DNAm) pattern.

Material and Methods: EPIC array-based DNAm profiling of 27 individuals with biallelic *ZNF142* variants, together with 6 heterozygous carriers and 40 controls was performed. Additional 440 controls were used for discovery and validation analyses. A DNAm signature discovery pipeline was applied, and a machine-learning model was trained to classify individuals carrying *ZNF142* variants of unknown significance (VUS).

Results: We identify a specific DNAm signature for biallelic LoF *ZNF142* variants that was successfully used for VUS reclassification. Analyses directed to explore the genome-wide DNAm landscape in patients revealed a reproducible pattern of large DNAm changes at regulatory regions in a small number of genes. The DNAm signature derived from peripheral blood properly classified individuals carrying biallelic LoF *ZNF142* variants when applied to fibroblasts.

Conclusion: Biallelic LoF *ZNF142* variants result in a specific and robust DNAm signature. The identified DNAm pattern suggests occurrence of a methylation disturbance involving a small number of loci that is shared by multiple cell lineages.

P16.031.B The diagnostic accuracy of FMR1-STR calling from short-read genome sequencing

Paranchai Boonsawat[1], *Alessandra Baumer*[1], *Aude-Annick Suter*[1], *Olga Bürger*[1], *Surema Pfister*[1], *Anaïs Begemann*[1], *Michael Papik*[1], *Angelika Humbel*[1], *Jeannine Villiger*[1], *Anita Rauch*[1,2]

[1]*Institute of Medical Genetics, Schlieren-Zurich, Switzerland,* [2]*Pediatric University Hospital Zurich, Zürich, Switzerland.*

Background: Short-tandem-repeat (STR) expansion is involved in several genetic diseases, including *FMR1*-related disorders with an incidence of 14:100,000, and a female carrier frequency of 1:175. While standard *FMR1* testing is performed using targeted PCR-based assays, *FMR1*-screening from short-read genome sequencing (sr-GS) has been suggested as first-tier tool using e.g. ExpansionHunter but its diagnostic validity has not been fully determined. We therefore analyzed diagnostic accuracy of *FMR1*-STR calling.

Material and Methods: We recruited 130 women seeking preconception carrier screening. After PCR-free Illumina GS, data were aligned using DRAGEN (Illumina), including ExpansionHunter for STR calling. In parallel, the CGG-repeat region in exon 1 of *FMR1* was tested using the Asuragen-Amplidex assay.

Results: With a tolerance of +/−2 repeats, ExpansionHunter and PCR results matched in 78% of samples. The ExpansionHunter does not differentiate between a homozygous allele and an allele drop-out. In 25 cases (19%), the detection of only one allele was based on an allele drop-out, which in one case also included a premutation allele. In ~22% of samples, one or both alleles showed a discrepancy >2 (mean 1.6). There was no clear correlation to the average genome coverage. Overall, there were 2 true positives and 1 false negative, resulting in a 67%-sensitivity [95% CI: 9.43–99.16%] and 100%-specificity [95% CI: 97.14–100.00%].

Conclusion: Due to its limited sensitivity short-read GS data are not suitable to exclude *FMR1*-repeat expansions as a stand-alone test. Nevertheless, if a repeat expansion is suspected from GS as a secondary finding, it has a high positive predictive value.

P16.032.C External Quality Assessment for Hereditary Amyloidosis: Assuring Test Standards to Support the Identification of Patients Eligible for Treatment

Izabela Eden[1], *Rachel Taylor*[1], *Mario Nuvolone*[2,3], *Jan D.H. Jongbloed*[4], *Victoria Williams*[1], *Simon Patton*[1], *Dorota Rowczenio*[5]

[1]*EMQN CIC, Manchester, United Kingdom,* [2]*Amyloidosis Research and Treatment Center, Foundation IRCCS Policlinico San Matteo, Pavia, Italy,* [3]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [4]*Department of Genetics, University of Groningen, University Medical Center Groningen, Groningen, Netherlands,* [5]*National Amyloidosis Centre, Royal Free London NHS Foundation Trust, London, United Kingdom.*

Background: Hereditary amyloidosis is a group of rare conditions characterised by amyloid accumulation impairing organ function. Hereditary transthyretin amyloidosis (ATTRv) - the most common type - is caused by >130 pathogenic variants in *TTR* gene and presents with neurological and/or cardiac manifestations. Several therapies for ATTRv are now available, making proficient diagnosis crucial for improved patient outcomes. We have established a global external quality assessment (EQA) scheme for *TTR* testing to assure diagnostic service quality.

Methods: Thirty laboratories from 21 countries were selected to participate in the pilot EQA. Three DNA samples with corresponding mock clinical referrals were supplied for *TTR* gene analysis. Clinical reports were assessed for genotyping, interpretation, and clerical accuracy by expert assessors.

Results: Twenty-eight laboratories returned clinical reports. All laboratories reported the correct genotype, of these 93% received full marks for genotyping; 87% received full marks for interpretation and 85% received full marks for clerical accuracy. Of note, many laboratories failed to interpret the genotype in the context of the clinical referral.

Conclusion: This pilot EQA scheme has established that the standard of *TTR* testing for hereditary amyloidosis is good. However, areas of improvement, particularly around the accuracy of interpretation of the genotype result, were identified. To date, there are no standardised criteria for genetic analysis and reporting of *TTR* variants in hereditary amyloidosis. This lack of guidance might compromise patient care. We anticipate continued provision of this EQA scheme will improve testing and reporting standards, whilst simultaneously facilitating the development of best practice guidelines.

P16.033.D Improving rare metabolic disease diagnostics: The impact of enzyme assays and RNA-sequencing as primary multi-omics screening tools

Mandy Radefeldt[1], *Erick Alberto Rivera Comparan*[2], *Christian Beetz*[1], *Tobias Boettcher*[1,3], *Sabrina Lemke*[1], *Catarina Pereira*[1], *Sebastian Oppermann*[1], *Claudia Mrosowski*[1], *Susan Zielske*[1], *Peter Bauer*[1,4]

[1]*Centogene GmbH, Rostock, Germany,* [2]*Hospital de Pediatria CMNSXXI, Mexico City, Mexico,* [3]*Medical Faculty, University of Greifswald, Greifswald, Germany,* [4]*Medical Faculty, University of Rostock, Rostock, Germany.*

Background: Conventional genetic diagnostic protocols rely on DNA sequencing as the primary screening method. An alternative strategy - utilizing non-DNA omics as the primary screening tool, followed by DNA sequencing of candidate genes or regions - has remained largely unexplored.

Material and Methods: We re-analyzed a case that had remained negative by conventional 'gene panel sequencing as primary step' approach. We considered the patient's phenotype to define candidate genes, tested the activity of the encoded enzymes and analyzed corresponding transcripts in blood-derived RNA sequencing. We finally Sanger-sequenced a suggestive region and used in silico prediction to interpret the identified variant. All wet lab analyses were done from dried blood spot filter cards.

Results: The clinical information suggested mucopolysaccharidosis (MPS) or a related metabolic disorder. Enzyme activities were normal for *ARSB*, *GUSB*, *IDUA*, *GALNS*, *GLB1*, *MAN2B1*, but below the level of detection for *IDS*. The transcripts for most candidate genes showed no abnormalities, but insertion of an intron 6-derived stretch of 46 nucleotides was observed in the *IDS* transcript. DNA sequencing of this intronic region revealed a hemizygous *IDS* variant (c.880-1180A>T; NM_000202.5), which is predicted to introduce a strong splice donor, ultimately creating a pseudo exon. The variant was classified as likely pathogenic based on ACMG/AMP/ClinGen guidelines.

Conclusion: Our study demonstrates the potential that combining non-DNA primary screening approaches with dried blood spot analysis has for cost-effectively diagnosing rare genetic metabolic disorders. To establish this approach in routine clinical settings, further research involving automated protocols and large-scale validation studies is necessary.

P16.034.A A critical review of the factor 8 intron 22 inversion assay in the setting of prenatal diagnostics

Sunita Biswas, *Abhijit Kulkarni, Sui Yu, Lesley Rawling, Denae Henry*

SA Pathology, Adelaide, Australia.

Background: Accuracy and precision in diagnosis and reporting are the cornerstone of Genetic Pathology, particularly in the setting of prenatal diagnostics. Haemophilia A is an X-linked disorder resulting from Factor 8 (F8) deficiency. Requests looking to interrogate the 50% chance of a male fetus inheriting a pathogenic F8 variant from their heterozygous mother, is therefore a common prenatal request.

Material and Methods: F8 intron 22 inversions, responsible for severe haemophilia A, were identified by long-range PCR followed by nested PCR. Exclusion of maternal cell contamination (MCC), critical in prenatal testing, was performed by short tandem repeat fragment analysis. Recently, this diagnostic method received critical review following release of a false-positive prenatal result.

The male fetus was born without evidence of F8 deficiency; thus, no clinical harm came from this report, however demanded investigation of the testing method.

Results: A two-pronged contribution was identified. Firstly, the pathogenic F8 intron 22 inversion was falsely represented in the fetus due to the high sensitivity of the nested PCR assay in detecting minute traces of MCC. In addition, PCR primers for the wildtype allele were found to overlap a single nucleotide polymorphism in the general population. The wildtype allele, therefore, was not detected due to allelic drop-out.

Conclusion: The nested PCR method used to detect the F8 pathogenic intron 22 inversion is highly sensitive to MCC, and therefore not suitable in the prenatal setting. This case provides an example of how a false-positive result can spur critical review and diagnostic improvement.

P16.035.B Haplotype phasing of biallelic*WNT10B*variants using long-read sequencing in split-hand/foot malformation syndrome

Jelena Pozojevic[1], *Naseebullah Kakar*[1,2], *Henrike Sczakiel*[3], *Nathalie Kruse*[1], *Kristian Händler*[1], *Saranya Balachandran*[1], *Varun Sreenivasan*[1], *Martin A. Mensah*[3], *Malte Spielmann*[1,4]

[1]*Institute of Human Genetics, University Medical Center Schleswig-Holstein, University of Lübeck & Kiel University, Lübeck, Germany,* [2]*Department of Biotechnology, FLS&I, BUITEMS, Quetta, Pakistan,* [3]*Institut fur Humangenetik - Charite Universitatsmedizin Berlin, Berlin, Germany,* [4]*DZHK (German Centre for Cardiovascular Research), partner site Hamburg/Lübeck/Kiel, Lübeck, Germany.*

Background: Whole exome sequencing (WES) is the standard technology in clinical genetics for detecting protein-coding variants. Short-read technologies, while highly accurate, cannot resolve repetitive and GC-rich regions, but long-read sequencing can overcome this problem by resolving difficult sequences and providing epigenetic information. Split-hand/foot malformation syndrome (SHFM) is a congenital limb malformation, clinically and genetically heterogeneous. Variants in *WNT10B* are known to cause an autosomal recessive form of SHFM.

Material and Methods: High molecular weight DNA was freshly extracted from the patient's fibroblasts, and long-read PacBio HiFi sequencing results were visualized in the Geneyx software after bioinformatic analysis. Sanger sequencing confirmed the variants and in silico predictions characterized them as pathogenic.

Results: We report a patient born to unrelated parents who was found to be a compound heterozygote for missense variants in *WNT10B*: c.994C>T, p.(Arg332Trp) and c.638T>G, p.(Phe213Cys). The long-read technology enabled us to phase the reads and show the biallelic nature of the variants, supporting the recessive disease model. The maternally inherited variant p.(Arg332Trp) has been previously reported, whereas the paternally inherited variant p.(Phe213Cys) is novel and not present in gnomAD.

Conclusion: Our findings highlight the utility of long-read haplotype phasing, which provides valuable insights in determining the biallelic nature of variants. This can be particularly informative in recessive disorders when parental DNA is not available, when a variant is de novo, or displays mosaicism. As sequencing costs decrease, high fidelity long-read sequencing might become the preferred technology in clinical genetics, serving as a single diagnostically comprehensive genetic test.

P16.036.C Benchmarking the benchmark: manual revision and high-resolution repeat-structure aware characterisation of 69 clinically relevant tandem-repeat motifs in the GIAB HG002 reference material

Andrej Balaz[1,2], *Ingrid Lojova*[1,3,4], *Marcel Kucharik*[1,3,2], *Tomas Szemes*[3,2,4], *Jaroslav Budis*[3,2], ***Jan Radvanszky***[1,3,4]

[1]*Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*Geneton Ltd., Bratislava, Slovakia,* [3]*Comenius University Science Park, Bratislava, Slovakia,* [4]*Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.*

Background: Tandem repeats (TRs) contribute significantly to human genome variability and have clinical importance. Exact characterisation of these loci is of high importance. Benchmarking TR reference material was, therefore, published recently for the GIAB HG002 individual sample, and is available as mapped sequencing reads and corresponding truth variant set. We performed manual curation of the most common clinically relevant motifs on this reference dataset.

Material and Methods: We downloaded the HG002 TR benchmark v1.0 data (BAM and the VCF). On the BAM files we performed TR genotyping of 69 clinically relevant motifs, by the use of two genotyping tools, Dante and Expansion Hunter. For repeat-motif delineation we used the Dante Clinical TR Database (includes exact HGVS description of the relevant TR motifs referenced for the GRCh38). The results were then cross-compared to the downloaded GIAB-VCF reference, both automatically (using Truvari) as-well-as manually, through the IGV and the alignment visualisation interface of Dante.

Results: We found that validation of genotyping is viable for simple TR motifs. Complex TR motifs, however, represent specific problems which are reflected also in the used conventional VCF files and complicate the automatic comparison of datasets.

Conclusion: To complement the VCF description of the variants, we created an easily readable and interpretable description of the HG002 reference genotypes. This includes not only repeat numbers, but also high-resolution repeat-structure characterisation with HGVS nomenclature and visual depiction of each allele. This material may represent an additional benchmarking dataset for laboratories performing TR genotyping.

P16.037.D Enhancing diagnostic interpretability of GestaltMatcher: Translating facial phenotype distances into probabilities

Hannah Klinkhammer[1], *Tzung-Chien Hsieh*[2], ***Peter Krawitz***[1]

[1]*Institute for Genomic Statistics and Bioinformatics, Bonn, Germany,* [2]*University Hospital Bonn, Bonn, Germany.*

Background: Genetic disorders often present with characteristic facial features. Next-generation phenotyping tools can enhance the diagnostic process by leveraging these phenotypic patterns. GestaltMatcher maps facial images into a high-dimensional clinical face-phenotype space (CFPS), quantifying patient similarities via spatial distances. Prior works demonstrate this clustering approach achieves high top-k syndrome ranking accuracy. However, CFPS distances lack intuitive interpretability. We propose

translating these distances into probabilities, representing the likelihood of a syndrome given a patient's facial phenotype.

Material and Methods: For each syndrome *A* in the GMDB, the distance of each patient to the nearest neighbor with syndrome *A* is computed. A logistic regression model, trained on labeled data, transforms these distances into probabilities for new cases. This framework also provides confidence intervals, estimating uncertainty for each probability.

Results: The derived probabilities are interpretable and align well with expert assessments of facial gestalt distinctiveness. For dual diagnoses, the method assigns high probabilities to multiple syndromes, often yielding cumulative probabilities exceeding 1, as opposed to an overall average below 1. Importantly, converting the scores into probabilities has minimal impact on syndrome ranking, preserving GestaltMatcher's diagnostic accuracy. Confidence intervals offer valuable insights into prediction uncertainty, particularly for rare syndromes.

Conclusion: Translating CFPS distances into probabilities enhances the interpretability and clinical utility of GestaltMatcher's output while maintaining its diagnostic accuracy.

P16.038.A Whole genome sequencing increases the diagnostic yield of neurodegenerative diseases

Lucia Corrado[1], *Nadia Barizzone*[1], *Beatrice Piola*[1], *Fjorilda Caushi*[1], *Martina Tosi*[1], *Giovanni Papagni*[1], *Endri Visha, PhD Student*[1], *Roberta Croce*[1], *Nicola Pomella*[1], *Fabiola De Marchi*[2], *Francesco Favero*[1], *Davide Corà*[1], *Luca Magistrelli*[2], *Marco Pellegrini*[3], *Alfredo Brusco*[4], *Letizia Mazzini*[2], *Sandra D'Alfonso*[1]

[1]*University of Eastern Piedmont, Novara, Italy,* [2]*Clinica Neurologica AOU Maggiore della Carità, Novara, Italy,* [3]*CNR, Pisa, Italy,* [4]*University of Torino, Dept. Neurosciences, Torino, TO, Italy.*

Background: Although WGS is increasingly used in diagnostic contexts, the diagnostic yield often does not exceed 25–30%. This is partly because analysis is often limited to in-silico gene panels, coding regions or focused on SNVs. We test the diagnostic yield in a cohort of patients affected by neurodegenerative diseases (NDD) by exploiting the sequence variations detectable by WGS.

Material and Methods: We analyzed WGS data of 140 NDD patients enriched for a positive family history of the disease and/or early onset. Most of them tested negative for the main causative genes of the disease. We applied a pipeline that allows the comprehensive analysis of all types of variants, (GANgSTR, CNV kit and Delly), to classify SNVs (Intervar) according to ACMG and those with a possible impact on splicing (SpliceAI). Massive in vitro functional assays (MPRA and MAPSY) were performed to evaluate the possible impact of VUS on gene expression or splicing mechanisms.

Results: In 27/140 cases(19%) we identified causative SNVs in NDDs genes. For other 17 cases(12%), we identified pathogenic or likely pathogenic SNVs in genes unrelated to patients' phenotype. Six patients carried repeat expansions in disease-related genes. A 1.2 Mb deletion with unknown significance was found in an ALS patient. Massive in vitro functional analysis identified four variants affecting gene expression and 16 splicing variants whose pathogenic role is still to be demonstrated.

Conclusion: WGS combined with in vitro testing allowed us to identify mutations for 16/140 patients undetectable with WES confirming that WGS can be the first-line genetic test in routine clinical settings.

P16.039.B On flowcell library construction and spatially linked reads provide a novel genome sequencing paradigm to significantly increase the utility of short reads

Niall Lennon*, Sean Hofherr, Mark Fleharty, Gao Yeuyao, Michelle Cippiccio, Katie Larkin*

Broad Institute of MIT & Harvard, Cambridge, MA, USA.

Background: In 2024, scientists at Illumina, informed us of a new capability in early testing: the ability to create adapted library molecules and clusters directly on the surface of a glass flowcell and to use the spatial location of the clusters to link reads that were likely from the same starting DNA molecule.

Material and Methods: We identified 40 samples that we thought would exercise the capabilities of this new technology in our hands. These samples comprised blood and saliva-derived human samples, some with known clinically meaningful challenging variants, as well as 9 cell line derived DNAs with well curated truth data. Samples were prepared with or without a high molecular weight extraction. After dilution to the appropriate loading concentrations, DNA was loaded onto a NovaSeq X 10B flowcell with no library construction.

Results: We observed >90% of genes being fully phased and contig N50s of ~24 Mbp in high molecular weight samples. We observed better performance when the DNA was extracted with high molecular weight methods but still saw performance gains in samples that had been extracted with standard protocols. All 17 clinically meaningful variants in patient samples were found.

Conclusion: This method demonstrates significant improvements over standard short read sequencing, with low input requirements and almost no sample preparation requirements. We report here our findings, our thoughts on where this technology could be applied, current limitations, and considerations for what the final product that will be made available to the community might be.

P16.040.C TRIXi: A high-resolution method for detecting skewed X chromosome inactivation

Dora Goldmann, ***Shadi Jafari****, Johnny Ludvigsson, Colm Nestor*

Linköping University, Linkoping, Sweden.

Females have a higher risk for autoimmune disease and lower risk of mortality from infectious disease than males. While sex steroid hormones do affect immune responses, genetic and epigenetic factors, such as X-chromosome inactivation (XCI), also play critical roles. During embryogenesis, one X chromosome in each female (XX) cell is randomly silenced, resulting in a mosaic of cells with either the paternal (Xp) or maternal (Xm) X chromosome inactivated. However, skewed XCI (sXCI), where one parental X is preferentially silenced, can impact phenotypic variability and disease severity of X-linked disorders in females.Despite its significance, our understanding of sXCI in humans remains

limited. This gap in our knowledge primarily arises from the limitations in detecting sXCI, which continues to depend on methods like the HUMARA assay that lack sensitivity and precision. We introduce TRIXi (Tandem Repeat-based Identification of X-chromosome Inactivation), a novel high-resolution, cost-effective approach that assays XCI at multiple X-linked loci in a single reaction. Having validated the sensitivity and specificity of TRIXi, we assayed sXCI in over 1,000 healthy newborns (via the ABIS biobank) and revealed that extreme skewing of XCI is common (1–3%) at birth, and that constitutional skewing is stably maintained throughout childhood. Our findings are of importance for understanding the likely penetrance of X-linked disorders in human females and for our understanding of the frequency and dynamics of clonal hematopoiesis.TRIXi provides a simple, cheap and robust approach for studying sXCI and its role in female health.

P16.041.D Reclassification of VUS using recommendations specified for sarcomeric genes in hypertrophic cardiomyopathy: resolution rate and technical considerations

Silvia Caroselli[1,2], *Martina Manzoni*[3], *Giulia Corona*[3], *Caterina Micolonghi*[1], *Marco Fabiani*[1], *Camilla Savio*[4], *Aldo Germani*[5], *Stefania Bragliola*[1], *Valeria Maselli*[1], *Speranza Donatella Rubattu*[4,5,6], *Beatrice Musumeci*[4,5], *Giacomo Tini Melato*[4,5], *Simona Petrucci*[4,5], *Valeria Novelli*[3], *Maria Piane*[4,5]

[1]*Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy,* [2]*Juno Genetics, Reproductive Genetics, Rome, Italy,* [3]*Unità di Genetica Cardiovascolare, Centro Cardiologico Monzino IRCCS, Milan, Italy,* [4]*Sant'Andrea University Hospital, Rome, Italy,* [5]*Department of Clinical and Molecular Medicine, Sapienza University of Rome, Rome, Italy,* [6]*IRCCS Neuromed, Pozzilli, Italy.*

Background: Genetic testing most often provides a molecular diagnosis in hypertrophic cardiomyopathy (HCM). However, the presence of VUS remains a critical challenge, complicating the management of patients and their families. In April 2024, the ClinGen Cardiomyopathy Variant Curation Expert Panel adapted the ACMG/AMP guidelines for sarcomeric core genes (*MYH7,-MYBPC3,TNNI3,TNNT2,TPM1,ACTC1,MYL2,MYL3*), providing an opportunity to refine the classification of VUS.

Material and Methods: This study focused on the re-evaluation of 72 VUS originally identified in these genes in HCM patients tested between 2017–2024. Each variant was reassessed by multiple analysts, incorporating the most recent annotation data.

Results: Applying the gene-specific guidelines, we reclassified 18.1% of original VUS. The genes that benefited most were *TNNT2, MYL3, MYBPC3, MYH7*. Specifically, 92.3% of variants was downgraded to benignity (involving 17 patients) and the remaining 7.7% was upgraded to pathogenicity (affecting one patient). In terms of application rate, the leading criteria were population allele frequency (PM2 = 54%, BS1 = 15%), bioinformatic prediction (PP3 = 46%, BP4 = 24%) and definition of specific critical regions per gene (PM1 = 22%). However, most codes suffer from the lack of evidence (segregation data, functional and case-control studies). In addition to combining rules, the scoring system was used significantly (46.1%). Finally, 13.9% of VUS, still thus reported in Clinvar, were reclassified and the mean time to reclassification was 70.9 months.

Conclusion: These gene-specific rules reduce the number of VUS and standardise the interpretation of genetic variants in HCM, improving diagnostic yield and guiding patient management. However, further investigation and continuous updating of guidelines should be encouraged.

P16.042.A Oxford Nanopore Technology (ONT) as an All-in-One Approach in the Diagnosis of Beckwith-Wiedemann Syndrome (BWS)

Federico Rondot[1], *Federica Centofanti*[2], *Luca Angheben*[3], *Matteo Paini*[3], *Federico Fontana*[3], *Niccolò Rossi*[3], *Flavia Cerrato*[4], *Laura Pignata*[4], *Giada Carta*[3], *Chiara Leso*[5], *Barbara Pasini*[1,6], *Alessandro Mussa*[7,8], *Andrea Riccio*[4,9], *Giovanni Battista Ferrero*[10], *Massimo Delledonne*[3], *Alfredo Brusco*[11,1]

[1]*Medical Genetics Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy,* [2]*Department of Biomedicine and Prevention, Medical Genetics Section, University of Rome Tor Vergata, Rome, Italy,* [3]*Biotecnology Department, University of Verona, Verona, Italy,* [4]*Department of Environmental, Biological and Pharmaceutical Sciences and Technologies, Università della Campania Luigi Vanvitelli, Caserta, Italy,* [5]*University of Turin, Department of Clinical and Biological Sciences, Orbassano, Italy,* [6]*Department of Medical Sciences, University of Turin, Turin, Italy,* [7]*Clinical Genetics Unit, Regina Margherita Children's Hospital, Città della Salute e della Scienza University Hospital, Turin, Italy,* [8]*Department of Public Health and Pediatrics, University of Torino, Turin, Italy,* [9]*Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Naples, Italy, Naples, Italy,* [10]*Department of Clinical and Biological Sciences, University of Torino, Orbassano (Torino), Italy,* [11]*Department of Neuroscience, University of Turin, Torino, Italy.*

Background: Beckwith-Wiedemann syndrome (BWS) is a genetic disorder caused by imprinting defects at the 11p15.5 locus. Traditional molecular diagnosis involves multi-step procedures including methylation analysis of Imprinting Centers 1 (IC1) and 2 (IC2), detection of Copy Number Variants (CNVs), Uniparental Isodisomy Paternal (pUPD), and sequencing of CDKN1C. These workflows are resource-intensive and time-consuming.

Material and Methods: ONT-based approaches- Adaptive Sampling with MinION or PromethION (P2), and Genome Sequencing (GS) with P2 - were applied on three clinically and molecularly diagnosed BWS patient samples (IC2 defect, and mosaic pUPD). Performance metrics included SNP, indel, and CNV detection using simplex, simplex corrected with Herro (AI-based tool), and duplex calling aligned on hg38 and T2T assembly.

Results: ONT-AS confirmed all prior molecular diagnoses and showed high sensitivity in detecting pUPD mosaicisms. In terms of Gigabase output, GS-P2 outperformed AS-P2, producing an average of 115.6 Gb vs. 108.3 Gb, while AS-MinION averaged 14.7 Gb. AS-P2, aligned to hg38 and T2T assemblies, achieved superior coverage in regions of interest (ROIs: 167x vs. 168x), IC2 (161x vs. 162x), and IC1 (42x vs. 76.3) compared to other methods. Herro-corrected simplex and duplex calling enhanced SNP and indel detection compared to traditional simplex methods.

Conclusion: AS-ONT is a novel, efficient, and cost-effective method for BWS molecular diagnosis, allowing simultaneous analysis of methylation, CNVs, and sequence variations. Our results also suggest that AS-ONT is an effective method in the identification of pUPD mosaicisms. The integration of this approach into routine diagnostics could transform the landscape of imprinting disorder diagnostics.

P16.043.B Using genome sequencing to improve diagnostic yield for gene panels

Eleni Perraki[1], *Christine Klein*[2], *Tobias Boettcher*[1], *Javier Garcia Planells*[1], *Jorge Pinto-Basto*[1], *Peter Bauer*[1]

[1]*Centogene, Rostock, Germany,* [2]*Institute for Neurogenetics, University of Luebeck, Luebeck, Germany.*

Background: Genome sequencing (GS) is increasingly used as a first-tier test in patient care, with an 8–10% diagnostic yield increase in undiagnosed patients after exome sequencing (ES). Importantly, the exact gain varies by disease. Decreasing costs for GS have accelerated its wider clinical adoption. We evaluated the clinical utility of GS backbone for disease-specific gene panels vs. current ES approach.

Material and Methods: Diseases were categorized into 18 distinct groups and subgroups and were evaluated using genetic data from publicly available databases and our internal database according to defined criteria: 1) types of disease-causing genetic variation (SNV, CNV, repeat expansion, SV, deep-intronic variants, complex genetic events,⋯); 2) ability to detect such variants in ES vs. GS; and 3) groups with diseases caused by pathogenic variants in genes/regions not usually targeted in ES, but covered in GS (e.g. non-coding genes). Clinical utility of GS for each group was determined as the increased sensitivity to detect variants missed by ES and auxiliary assays not being necessary to complement panel design.

Results: Of the defined groups and subgroups, neurological and especially neuromuscular, neurodevelopmental disorders, and reproductive/carrier screening benefit most from GS. Conversely, bone disorders and dermatology benefit the least. Disease group data will be presented in detail per gene and variant type.

Conclusion: We suggest that GS be considered as the backbone of choice for disease-specific gene panels where both diagnostic yield and cost efficiency can be maximized. Furthermore, GS enables re-analysis of genomic data as scientific knowledge advances and new evidence arises.

P16.044.C Standardizing the gene composition of the clinical exome: a semi-automated bioinformatics framework for evaluating gene-phenotype associations

Tiago Carvalho[1], *Filipe Alves*[1], *João Parente Freixo*[1], *Paulo Silva*[1], *Jorge Oliveira*[1,2]

[1]*Centro de Genética Preditiva e Preventiva (CGPP), Instituto de Biologia Molecular e Celular (IBMC), Instituto de Investigação e Inovação em Saúde (i3S), Universidade do Porto, Portugal, Porto, Portugal,* [2]*ICBAS—Institute of Biomedical Sciences Abel Salazar; Universidade do Porto, Portugal, Porto, Portugal.*

Background: The rapid and cost-effective identification of disease-causing variants using whole-exome sequencing (WES) has driven its widespread use in clinical diagnostics, facilitating the concurrent analysis of multiple disease-causing genes. While disease-specific multigene panels are commonly used, a more comprehensive, disorder-agnostic approach may be preferred, incorporating all genes associated with Mendelian diseases, known as the clinical exome (CE). Given the large number of genes comprising the CE, and novel gene-phenotype relationships being continuously discovered, a bioinformatics approach is essential for efficiently creating and updating this panel.

Methodology: An algorithm was developed to generate a disease-associated and clinically relevant genes' list, using an in-house knowledgebase integrating information from several databases such as OMIM, OrphaNet, HGMD, HGNC, NCBI and SFARI. Medical and clinical laboratory geneticists then curate this list to establish a CE panel.

Results: Of 13,076 clinically relevant genes with an HGNC entry, 5,653 were directly added to the CE, and the rest further analyzed. By examining the number of gene-phenotype pairs and HGMD-described disease-causing variants, 3,347 genes were discarded, 3,819 genes included, and the remaining 257 genes subjected to a final manual curation step. Further inclusion of mitochondrial loci and 23 lab-curated genes resulted in a CE panel containing 9,326 genes. These were then further classified according to their analytical effectiveness, by considering their WES-based horizontal coverage.

Conclusion: Optimizing bioinformatic approaches is critical in the fast-evolving clinical diagnostics space. This work presents a new framework to streamline the creation of such complex gene panels, ensuring they remain up-to-date and clinically relevant.

P16.045.D Learnings from five years of External Quality Assessment (EQA) for porphyrias

Michael Woodcock[1], *Michela Barbaro*[2], *Edith Friesema*[3], *Victoria Williams*[1], *Simon Patton*[1], ***Rachel L. Taylor***[1]

[1]*EMQN CIC, Manchester, United Kingdom,* [2]*Karolinska University Hospital, Stockholm, Sweden,* [3]*Erasmus MCDept Internal Medicine-Vascular MedicineOffice Ee814a, Rotterdam, Netherlands.*

Background: Porphyrias (POR) represent eight genetic disorders characterized by the accumulation of porphyrins or their precursors. Affected individuals develop severe cutaneous photosensitivity and/or suffer from attacks of severe abdominal pain. Proficient diagnosis is required for effective clinical management. EMQN established a global EQA scheme in 2005, aimed at ensuring the proficiency of genetic testing for POR.

Material and Methods: Participants received three or four DNA samples with corresponding mock clinical referrals for testing. Participants returned clinical reports which were assessed for genotyping, interpretation, and accuracy (maximum score per category = 2.00). Participant performance was analysed over a 5-year period (2020–2024) to establish trends and understand the impact on reporting quality from continued EQA provision.

Results: Ninety-six participations have been assessed from 32 laboratories in 17 different countries. Genotyping quality was consistently excellent with an average score of 1.93/2.00. However, several laboratories missed a known pathogenic intronic *FECH* variant: NC_000018.10(NM_000140.5):c.315-48T>C p.?. Interpretation quality was also very good, averaging 1.83/2.00 over the period surveyed. In 2023, interpretation performance dropped to 1.63/2.00, due to 55% of laboratories failing to interpret the genotype result in the context of the clinical referral.

Conclusion: These results show POR testing services are consistently of a good standard. However, improvements could

be made in ensuring the scope of testing for rare causes (i.e.-*FECH*) and improving interpretation to ensure reports are informative for the recipient. We anticipate the continued provision of this EQA is crucial for improving testing and reporting standards for POR.

P16.046.A Pioneering study on dd-cfDNA as a rejection biomarker in Kazakhstani transplant population

A. Zhenissova, *M. Bayanova, D. Malik, A. Abdikadirova, M. Sapargalieyva, L. Nazarova, A. Bolatov, Y. Pya;*

"University Medical Center" Corporate Fund, Astana, Kazakhstan

Background: Accurate monitoring of transplant recipients is essential for early rejection detection. Donor-derived cell-free DNA (dd-cfDNA) is a promising biomarker, with digital PCR (dPCR) offering high sensitivity. This study, the first of its kind in Kazakhstan, is also the first to investigate dd-cfDNA using dPCR and Y-chromosome fragment analysis in kidney and heart transplant recipients.

Material and Methods: The prospective study recruited 40 adult and 15 pediatric kidney transplant pairs, along with 30 heart transplant pairs, at the "University Medical Center" CF and the National Research Oncology Center in Astana. Among the recipients, 10 females received organs frommale donors, enabling dd-cfDNA detection through Y-chromosome markers.

Results: Results demonstrated that dPCR accurately quantifies dd-cfDNA, with elevated levels correlating with rejection episodes. This supports dd-cfDNA potential as a diagnostic tool for transplant monitoring. Monitoring of heart transplant recipients revealed an increased level of dd-cfDNA in one patient with clinical signs of allograft rejection. This approach also demonstrated a significantly higher level of dd-cfDNA in a kidney transplant recipient who received an organ from a deceased donor compared to those who received organs from living donors during the first two weeks post-transplantation.

Conclusion: These findings mark the first use of dd-cfDNA as a predictor of transplant rejection in Kazakhstan. Further studies are needed to confirm these results and optimize clinical applications.

P16.047.B Introducing GENie: A two-year journey of discovery and competency

Angie Kolozi[1], *Mark Sales*[1], *Dave Cregeen*[1], *Ros Hastings*[2], *Zandra Deans*[1]

[1]*GenQA, Edinburgh, United Kingdom,* [2]*GenQA, Oxford, United Kingdom.*

Background: As variant classification guidelines and cytogenetic nomenclature are constantly evolving the need for individuals to demonstrate competency for variant classification and report genomic test results following current guidelines has increased. The development of the Genomics Individual Education (GENie) platform is being used to support individual competency demonstration and promote workforce education.

Material and Methods: The GENie platform contains modules for classifying single nucleotide variants (SNVs), copy number variants (CNVs), use of HGVS, and ISCN. The ISCN module provides education and competency assessment for using ISCN 2024 for Constitutional Karyotyping, Neoplasia Karyotyping, Constitutional FISH, and Neoplasia FISH at basic, advanced, and complex levels. The variant classification modules present cases for participants to determine the pathogenic classification and submit supporting evidence. Real-time assessment is provided.

Results: 1,873 individuals have participated in all six nomenclature scenarios, HGVS/ISCN, and completed five-seven cases in each scenario. The expected HGVS/ISCN was submitted by 75% and 60% of participants, respectively. Additionally, there were 1,273 participations for classifications of SNV/CNV, whereby a random set of three-six variants was provided for classification. The expected classifications were submitted by approximately 1,000 participants. All scenarios were generated from a vast bank of cases. The range of these scenarios will be presented.

Conclusion: In the last two years, the GENie platform has been a promising solution for supporting variant classification and nomenclature interpretation practices which is already used by thousands of individuals. By using GENie, individuals can gain the necessary knowledge and skills, which will help them to maintain their competency.

P16.048.C Performance comparison of RNA-seq kits for accurate gene expression profiling across different input levels

Rana Aldisi[1,2], *Nina Ishorst*[1,2], *Matthias Potschka*[1,2], *Stefanie Heilmann-Heimbach*[1,2]

[1]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [2]*NGS Core Facility, Medical Faculty, University of Bonn, Bonn, Germany.*

Background: RNA sequencing (RNA-seq) is a powerful technique for analyzing gene expression and transcript structure. Different kits vary in their methodologies, efficiency, and ability to capture low-abundance transcripts, which can significantly influence data interpretations. In this study, we compare multiple RNA-seq kits to provide researchers with insights into selecting the most appropriate platform for their specific experimental needs.

Material and Methods: Three commercially available RNA-seq kits, Lexogen's QuantSeq 3'mRNA-Seq V2 FWD Kit, New England Biolabs' NEBNext Ultra II Directional RNA Library Prep Kit, and Watchmaker Genomics' mRNA Library Prep Kit, were evaluated using a human **reference RNA and fibroblast-derived RNA**. Libraries were prepared with input amounts of **2.5, 10, 50, 100, and 200 ng**, following each kit's protocol. Quality was assessed using metrics like total sequence, alignment rates, transcript coverage, and differential expression.

Results: All kits produced similar sequencing output and alignment rates. However, the Watchmaker Genomics kit showed better consistency, particularly with lower RNA input. The Lexogen kit yielded fewer protein-coding reads and identified fewer differentially expressed genes compared to the full-length RNA-seq kits from New England Biolabs and Watchmaker Genomics.

Conclusion: In conclusion, while all RNA-seq kits had similar sequencing and alignment results, full-length mRNA sequencing applications showed better consistency, with the Watchmaker Genomics kit showing the highest consistency across different input amounts, and a higher sensitivity in differential expression analysis. Our findings emphasize the importance of kit selection based on input type and research goals and suggest that low-pass full-length mRNASeq outperforms 3'mRNASeq for expression profiling applications.

P16.049.D Are cytogenomic competencies declining?

Mark John Sales, *Fiona Oswald, Melody Tabiner, Sandi Deans*

GenQA, Edinburgh, United Kingdom.

Background: GenQA has provided external quality assessment (EQA) worldwide for cytogenomic testing for over 40 years. Accurate cytogenomic skills are assessed for analytical competence and the cytogenomic knowledge required to correctly interpret the result in the context of the provided case scenario. Cytogenomic training has changed dramatically over the years, with a greater focus on molecular technologies and a move away from traditional cytogenetics. The result is a decrease in the number of trained Cytogeneticists able to deliver accurate analysis and interpretation of chromosomes. GenQA EQA performance therefore provides an opportunity to examine trends over a long period.

Methods: Examination of the cytogenomic EQAs was undertaken. Constitutional EQAs included pre- and postnatal karyotyping, and pregnancy loss G-banding. Review of the haematology EQAs incorporated ALL, CLL, myeloid, lymphoma and mature B&T G-banding. Analytical errors and poor interpretation were addressed.

Results: Incorrect karyotypes and interpretation of cytogenetic abnormalities have been reported in constitutional EQAs, including multiple analytical errors for reporting the incorrect karyotypic sex. For haematological malignancies recurrent interpretation errors include incorrect diagnosis, incorrect prognosis, providing outdated therapeutic information, and failing to include a WHO/ICC classification. There are also errors regarding the counting of chromosome abnormalities (required for determining prognosis). The number and type of errors will be examined in detail.

Conclusion: Numerous errors and recurrent trends have been identified through EQA both for analysis and interpretation. From an EQA perspective, the increasing number of errors demonstrates the decline in cytogenomic competence.

P16.050.A Diagnostic evaluation of Oxford Nanopore Technology in STR screening for neurological diseases

V. L. Race[1], *E. Souche*[2], *S. Meynants*[2], *A. Van Eesbeeck*[1], *L. Budts*[1], *S. Smekens*[1], *M. Taffeiren*[1], *T. Luyten*[1], *R. Vandensande*[1], *L. Keldermans*[1], *A. Goovaerts*[1], *S. Vermeer*[1], *J. Vermeesch*[3];

[1]*UZ Leuven Center for Human Genetics, Leuven, Belgium,* [2]*KU Leuven, Department of Human Genetics, Leuven, Belgium, Leuven, Belgium,* [3]*KU Leuven, Department of Human Genetics/ UZ Leuven Center for Human Genetics, Leuven, Belgium*

Background: Neurogenetic diagnostics standard of care consists of short read whole exome sequencing (WES). While WES performs well for the detection of single nucleotide variants and indels, it is less accurate for the detection of short tandem repeats (STRs). This is definitely a shortcoming in neurogenetic diagnostics since STRs are an important cause of neurological disease such as ataxia, amyotrophic lateral sclerosis/ frontotemporal dementia, myotonic dystrophy. WES is thus currently complemented with a combination of specific repeat-primed PCRs.

Material and Methods: In order to evaluate whether long read sequencing could replace our standard of care, Oxford Nanopore Technology (ONT) sequencing was performed on six patients with known STR expansions (SCA2(ATXN2), CANVAS (RFC1), SCA27B (FGF14), Friedreich (FXN), ALS (C9orf72) and Steinert (DMPK)).

Results: Using a standard DNA extraction, all STRs could be detected by ONT sequencing and the repeat length was concordant with diagnostic results. In addition, new data are also generated from the methylome.

Conclusion: ONT is thus promising since (1) the same DNA extraction can be used for WES and ONT STR analysis while other technologies such as optical genome mapping require a specific DNA extraction methods; (2) the size estimate of all STRs is accurate preventing the need to work with arbitrary cut offs; (3) eventual repeat interruptions can be detected; (4) the methylation status is available, which is not the case with the standard diagnostic tests. The use of ONT for STR screening could improve the diagnosis of neurogenetic diseases and have an impact on patient follow-up/therapy.

P16.051.B A *BRCA2* copy number variant called as a simple duplication turned out to be a rare complex rearrangement

K. Hackmann[1], *T. Hutschenreiter*[1], *A. Glasen*[1], *M. Roa Bravo*[1], *A. Jahn*[1], *C. Meisel*[2], *K. Keller*[2], *P. Wimberger*[2], *J. Porrmann*[1], *E. Schröck*[1,3], *R. Prielipp*[1];

[1]*Institute for Clinical Genetics, University Hospital Carl Gustav Carus at the Technische Universität Dresden, Dresden, Germany,* [2]*Department of Gynecology and Obstetrics, Medical Faculty and University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany,* [3]*Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany*

Background: To identify the underlying pathogenic variant in families with breast and ovarian cancer, germline analysis of potentially affected genes is standard practice. The list of relevant genes has been defined by the German Consortium for Familial Breast and Ovarian Cancer.

Material and Methods: Peripheral blood DNA was enriched using an exon-focused gene panel. Sequencing was performed on an Illumina NextSeq 2000. Read mapping and variant calling was performed in the cloud-based Varvis® software.

Results: In a case of familial breast and ovarian cancer, a simple duplication at the end of exon 11 was reported. Visual inspection of the mapped and soft-clipped reads in the Integrative Genomics Viewer (IGV) revealed a deletion and a translocation by colour coding. Reconstruction of the split reads indicated that the duplicated region was translocated within the exon, with an additional deletion of two nucleotides and insertion of seven nucleotides. Breakpoints of the putative complex rearrangement were verified by specific PCR products followed by sequencing. Theoretically, this should lead to differential splicing, but this could not be accurately predicted. To determine the consequences at the RNA level, cDNA sequencing was performed to apply the correct ACMG criteria and finally to determine the pathogenicity of the variant.

Conclusion: Although duplicated material is usually inserted in tandem next to the original region, there are rare cases of complex rearrangements. These can and should be detected by careful inspection of the mapped reads. The consequences of these rearrangements generally need to be addressed by RNA sequencing.

P16.052.C A phenotype-based approach for prioritizing ASD genetic variants from whole-exome sequencing

Noam Levi[1], *Mor Dekel*[1], *Nadav golden*[1], *Liron Levine*[1], *Michal Ilan*[1], *Gal Meiri*[2], *Analya Michaelovski*[2], *Yair Tsadaka*[3], *Adi Aran*[4], *Ditza Zachor*[5], *Ilan Dinstein*[1], *Idan Menashe*[6]

[1]*Ben-Gurion University of the Negev, Beer-Sheva, Israel,* [2]*Soroka University Medical Center, Beer-Sheva, Israel,* [3]*Ministry of Health IL, Beer-Sheva, Israel,* [4]*Psychology Neuropediatric Unit, Shaare Zedek Medical Center, Jerusalem, Israel,* [5]*The Autism Center, Department of Pediatrics, Shamir (Assaf Harofeh) Medical Center, Zerifin. The Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel,* [6]*Ben-Gurion University, Beer Sheva, Israel.*

Background: Current genetic diagnostic approaches of autism spectrum disorder (ASD) have a relatively low yield of 3%–28%, thus underscoring the need for new methods. Here, we present a novel phenotype-driven approach to identify and prioritize ASD genetic variants.

Material and Methods: We studied phenotype and whole-exome sequencing (WES) data from 115 children with ASD from the Azrieli National Center for Autism and Neurodevelopment Research (ANCAN) database. We used the Human Phenotype Ontology (HPO) nomenclature to group all phenotypes into 41 broad phenotype categories. Then, we used these categories to characterize each participant with an Observed Phenotype Vector (OPV), and each gene in the HPO database with an Expected Phenotype Vector (EPV). Finally, we assessed the EPV-OPV concordance for each detected gene-disrupting variant (GDV) in the WES data.

Results: Overall, 232 HPO terms grouped into 41 broad phenotype categories were identified in our sample. High-confidence ASD genes (from the SFARI database) had significantly higher counts of expected phenotypes than non-ASD genes (15.46 ± 6.6 vs. 7.26 ± 5.96, $p < 2.2e\text{-}16$), hence underscoring a link between the 41 phenotype categories to ASD genes. Of the 593 identified GDVs, 35 showed significant EPV-OPV concordance ($p < 0.05$). Of these 11 variants were found in known ASD genes while another 24 were identified in 22 potentially novel ASD genes.

Conclusion: This phenotype-driven approach shows potential for identifying novel genetic variants linked to ASD, thus substantially increasing the genetic diagnostic yield of the disorder.

P16.053.D Detecting situations that may compromise non-invasive prenatal diagnostic of monogenic diseases

Jean-Louis Blouin[1], *Claudine Rieubland*[2], ***Nouspikel Thierry***[1]

[1]*Hopitaux Universitaires de Geneve HUG, Geneve, Switzerland,* [2]*Hôpital du Valais, Sion, Switzerland.*

Background: Non-invasive prenatal testing for monogenic disorders (NIPD-M) is becoming increasingly popular to detect the presence of known parental mutations in the fetus, without risking miscarriage. However, as the method heavily relies on determining the haplotype balance in cell-free DNA circulating in maternal plasma, it can potentially be confused by various situations, such as aneuploidy of the target chromosome or unrecognized (possibly vanishing) twin pregnancies.

Material and Methods: By mixing DNA from male donors, we generated composite samples with various numbers of different X chromosomes, to simulate a small amount of fetal DNA in maternal DNA (aiming for a 20% fetal fraction). We simulated various challenging situations, like twin pregnancy or aneuploidies, homogeneous or in mosaic.

Results: Examination of the allelic frequency of 5 types of SNPs located on the X chromosome allowed straightforward detection of most abnormal situations, down to a low level of mosaicism. The exceptions were maternal trisomies, for which we had to develop an additional strategy: We informatically reduced fetal fraction by "diluting" data from simulated plasma samples with maternal data and plotted allelic frequency of type-4 (maternal) SNPs against fetal fraction. The linear regression slope proved a powerful indicator to detect maternal trisomies, including mosaics.

Conclusion: We introduce a metric allowing, without additional wet-lab investigations, to reliably detect the presence of anomalies that may compromise NIPD-M results. We show that it can detect twin pregnancies, paternal or maternal trisomies, monosomies and uniparental disomies, down to low fetal fractions and low percentages of mosaicism.

P16.054.A Beyond compliance: how external quality assessment drives laboratory improvement over time

Weronika Gutowska-Ding, *Victoria Williams, Charlotte Shaw, Simon Patton*

EMQN, Manchester, United Kingdom.

Background: External Quality Assessment (EQA) is a crucial tool for monitoring and improving laboratory performance, ensuring the accuracy and reliability of genetic testing. However, the long-term impact of sustained participation in EQA schemes on laboratory performance remains underexplored.

Material and Methods: This study examines laboratory performance trends across EQA schemes over a 10-year period, with a focus on marking changes and the occurrence of poor performance—defined as errors with the potential to cause patient harm. Key performance metrics, including genotyping accuracy, interpretation quality, and clerical precision, were evaluated across multiple EQA cycles. Statistical analysis was conducted to identify patterns in poor and persistent poor performance (characterised as consecutive years of substandard results) and to assess their relationship with the frequency of EQA participation.

Results: A trend emerged, showing that sustained participation in EQA leads to improved laboratory performance. Laboratories with higher participation rates demonstrated a reduction in critical genotyping and interpretation errors. Regular participants showed a marked decrease in poor performance rates and overall accuracy improved compared to first-time participants, with the most notable gains observed in interpretation scores. Despite these improvements, a subset of laboratories continues to experience performance fluctuations, underscoring the need for targeted interventions.

Conclusion: EQA plays a pivotal role in driving continuous improvement in laboratory performance, reducing errors, and enhancing the reliability of genetic testing. While these findings

reinforce the importance of sustained EQA participation, they also suggest that more tailored support strategies may be required for laboratories struggling with persistent poor performance.

P16.055.B DNA sample tracking for diagnostic exome sequencing - a 1-year experience

Peter ND Ceulemans[1], *Matthias De Smet*[2], *Tom Sante*[2], *Gertjan Wils, Scientist*[3], *Thalia Van Laethem*[2], *Mauro Milazzo*[2], *Jo Vandesompele*[1], *Frauke Coppieters*[4], *Lefever Steve*[1], *Brecht Guillemyn*[2], *Kim De Leeneer*[5]

[1]*Pxlence bv, Ghent, Belgium,* [2]*Center for Medical Genetics, Ghent University, Ghent University Hospital, Ghent, Belgium,* [3]*pxlence bv, Gent, Belgium,* [4]*pxlence bv, Ghent, Belgium,* [5]*Center for Medical Genetics, Ghent University, Ghent University Hospital, Gent, Belgium.*

Background: Whole exome sequencing (WES) and other massively parallel sequencing-based tests are well established in clinical diagnostics. However, as these workflows require numerous wet- and dry-lab steps, each increasing the probability of errors, DNA sample tracking throughout the workflow is recommended to identify sample swaps. Here, we report the results of WES sample tracking during a 1-year period in an academic hospital.

Material and Methods: Library preparation for WES and sample tracking was performed in parallel per 96 samples using the KAPA HyperExome V1 (Roche) and the Human Sample ID (HSID, pxlence) kits, respectively. Next, 192 WES and 192 HSID libraries were sequenced together on a NovaSeq 6000 S4 flow cell (Illumina), followed by a Nextflow-based pipeline applying CrosscheckFingerprints (Picard) to compare 43 autosomal SNPs and SampleGender (ngs-bits) to evaluate the X/Y ratio, coverage of the SRY gene and the fraction of heterozygous SNP's on X/Y.

Results: This poster will summarize results of sample tracking performed on >7,500 WES patient samples through HSID kit genotyping of 49 exonic SNPs. Preliminary analysis on a subset of samples revealed an 82.29% index uniformity. On-target coverage is high with 97.92% of samples having over 90% of reads aligning to the regions of interest. Marker coverage uniformity shows that in over 74.48% of samples, over 75% of the autosomal markers attain a coverage within 2-fold of the median coverage.

Conclusion: The HSID kit is an easy-to-use and cost-effective approach for DNA sample tracking in massively parallel sequencing workflows, ensuring quality in accredited laboratory settings.

P16.057.D FrOG - The French OncoGenetics database

Laurent Castéra[1,2], *Sandrine Caputo*[3,4], *Stéphanie BAERT DESURMONT*[5,2], *Safa Allouer*[1], *Simon Fani*[6], *Lamia Ghezali*[7], *Arthur Costil*[7], *Thibaut Lavolé*[1], *Alexandre Atkinson*[1], *Sophie Coutant*[5], *The FrOG consortium*[8]

[1]*Laboratory of Biology and cancer genetics, Centre François Baclesse, FHU G4 Genomics, Caen, France,* [2]*Inserm U1245, Rouen, France,* [3]*Department of Genetics, Institut Curie, Paris, France,* [4]*Université Paris Sciences-Lettres, Paris, France,* [5]*Univ Rouen Normandie, Normandie Univ, CHU Rouen, Department of Genetics, FHU G4 Genomics, Rouen, France,* [6]*Department of Genetics, Institut Curie, Rouen, France,* [7]*Unicancer, Paris, France,* [8]

FrOG is the reference database of genetic variants identified in oncogenetic laboratories in France, the interpretation of these variant is validated by various curation groups of the Groupe Génétique et Cancer (GGC). The mission of FrOG is to guarantee and disseminate a clinically relevant interpretation, harmonised at national level, in order to improve the care of families. FrOG is governed by a consortium agreement, coordinated by UNICANCER, that brings together 24 University Hospitals and Cancer Center healthcare institutions. The laboratories of these institutions, in collaboration with the Groupe Génétique et Cancer (GGC), have an IT tool for collecting, curating and sharing patient data via a website (frog-db.fr). FrOG complies with the requirements of the General Data Protection Regulation (GDPR). A patient information leaflet, validated by the GGC Board, has been distributed to oncogenetic consultations to harmonise discussions on the benefits and even the need for the FrOG programme and to explain patients' rights. An information video can be found at https://youtu.be/tZs6y324GSk?feature=shared. FrOG benefits from an infrastructure hosted by an accredited health data host. New variants and associated phenotypic data are deposited by authorised contributors in pseudo-anonymised form in a secure repository. FrOG-db currently offers interpretation of 17563 variants of 33 genes identified in 52107 patients. FrOG is consulted several hundred times a day as part of molecular diagnostics. This academic project now meets the various regulatory requirements in force and has become an essential tool for diagnosing patients in the French oncogenetics network.

P16.058.A Combinatorial DNA-Pools targeted-Sequencing as a robust cost-effective method to detect rare variants: analysis strategy and application to dilated cardiomyopathy genetic diagnosis

C. PERRET[1,2], *C. PROUST*[3], *F. Ader*[4,1,2], *J. Haas*[5], *J.-F. Pruny*[6], *R. Isnard*[7], *P. Richard*[8,1,2], *D.-A. Trégouët*[9], *P. Charron*[7,1,2], *E. Villard*[1,2];

[1]*Sorbonne Université - INSERM UMRS1166, Paris, France,* [2]*ICAN Institute for Cardiometabolism and Nutrition, Paris, France,* [3]*Université Bordeaux, INSERM, BPH, U1219, Bordeaux, France,* [4]*APHP, UF cardiogénétique et Myogénétique,service de Biochimie métabolique, Paris, France,* [5]*Department of Internal Medicine III, University of Heidelberg, Heidelberg, Germany,* [6]*APHP, Département de Génétique, Centre de Référence Maladies Cardiaques Héréditaires, Paris, France,* [7]*APHP, Cardiology Department, Paris, France,* [8]*APHP, UF Cardiogénétique et Myogénétique, service de Biochimie métabolique, Paris, France,* [9]*Univ. Bordeaux, INSERM, BPH, U1219, Bordeaux, France*

Background: We developed a cost-effective NGS method based on combinatorial DNA pooling to efficiently detect rare variants. The originality of our approach lies in the development of a specific data analysis method that accurately discriminates true rare variants from false positives within pools. The experimental workflow and data analysis were validated by comparison with standard simplex sequencing technology. This method was applied to the genetic diagnosis of dilated cardiomyopathy (DCM).

Methods: 96 non-indexed 8-DNA pools were constituted from 384 DNAs, each being included in a unique pair of concordant pools (sequenced twice though). Exonic regions of a cardiomyopathy gene panel were captured and sequenced by NGS at 500X per pool. Variant calling was performed using Freebayes algorithm, and the resulting QUAL value was compared between variants detected in concordant pools (true variants) and non-concordant pools (false positives) to accurately identify true variants. To benchmark performance, 50 DNA samples were sequenced using standard simplex NGS.

Results: Freebayes parameters QUAL = 12 was found to be discriminative between false-positives and true variants. Using this threshold, our pool-sequencing method successfully detected 96% of rare variants identified in DNA-simplex. Applied to 384 DCM patients, this approach identified 100 pathogenic ACMG class 4 and 5 variants (26%).

Conclusion: We report an innovative, cost-efficient (4-fold cost reduction) NGS pooling method with a dedicated variant analysis strategy that enables accurate detection of rare variants. This approach might be applied more broadly for cost-effective genetic diagnosis in various rare diseases.

P16.059.B Is there anything in the swamp? A credibility assessment of biologic signals from non-secreted low-abundance proteins measured in human plasma

Roberto Spada[1], *Jackie Dennis*[2], *Joe Gogain*[2], *Clare Paterson*[2], *Jessica Kuzma*[2], *Joel Wommack*[2], *Emma Troth*[2], *Stephen A. Williams*[2], *EPIC Study Collaborators*[3]

[1]*Standard BioTools, Strasbourg, France,* [2]*Standard BioTools, Boulder, CO, USA,* [3]

Background: Proteomic multiplexing has expanded and now includes measurement of thousands of non-secreted low-abundance proteins, yet the biological significance of this fraction of the proteome has been questioned. We present here methods to evaluate this question by determining: 1) if proteogenomic associations are present in the non-secreted, low abundance fraction, 2) if this fraction contains other biologically relevant information.

Materials and Methods: We surveyed peer-reviewed publications to determine the number of cis-pQTLs identified on the SomaScan® Assay. Of those, we calculated the proportion of cis-pQTLs in the non-secreted, low-abundance fraction of the proteome. We used data from~15,000 participants in the European Prospective Investigation into Cancer and Nutrition (EPIC) study assayed on SomaScan 7K to determine what proportion of the significant protein biomarkers associated with incident cancers were in the non-secreted low-abundance fraction.

Results: Roughly 2,800 cis-pQTLs identified by SomaScan Assay have been reported in peer-reviewed publications. There are ~5,000 non-secreted low-abundance proteins on the SomaScan 7K menu; 30% (n = 1494) contain a cis-pQTL vs. ~60% of secreted proteins. Of the statistically significant biomarkers for cancer risk, 68% and 60% respectively were found in the non-secreted low-abundance fraction.

Conclusion: Non-secreted proteins comprise a greater proportion of the proteome than known secreted proteins. Despite unclear mechanisms relating to their presence in plasma, they contain important biologic information. Reassurance of correct protein binding in this fraction arises directly from cis-pQTLs and from biomarkers of future cancer diagnosis. Proteomic technologies that can be scaled while maintaining sensitivity and precision will continue to yield useful discoveries.

P16.060.C Detection of Recombinant Alleles in *GBA*Gene Using Short-Read NGS: An Accessible Approach in Routine Genetic Analysis

Gizem Kök[1], *Sezai Arslan*[2], *Serpil Çiftel*[2], *Mahmut Bakır Koyuncu*[3], *Ali Rıza Çalışkan*[4], *Hüseyin Onay*[1]

[1]*Multigen Genetic Diseases Diagnosis Center, İzmir, Turkey,* [2]*Erzurum Bölge Eğitim ve Araştırma Hastanesi, Erzurum, Turkey,* [3]*Medicalpark Mersin Hastanesi, Mersin, Turkey,* [4]*Adıyaman Üniversitesi Eğitim Araştırma Hastanesi, Adıyaman, Turkey.*

Background: Short-read next-generation sequencing (NGS) is widely used in genetic diagnostics due to its low error rate, cost-effectiveness, and accessibility. However, it is generally considered inadequate for detecting complex genomic rearrangements, particularly in genes like *GBA*, which has a highly homologous pseudogene. Long-read NGS is often preferred for identifying such structural variants, but its adoption remains limited. Exonic GBA Sequencing, MLPA, and Whole-Gene GBA Sequencing are performed comprehensively in our diagnostic algorithm. Identifying complex rearrangements is particularly crucial in unresolved cases. This approach enhances our ability to clarify previously unsolved cases.

Material and Methods: we report the detection of recombinant alleles using short-read NGS, relying primarily on IGV visualization, which requires expert interpretation rather than additional computational tools. Since September 2022, 1,790 individuals were analyzed for Gaucher disease. Findings were validated using long-read and Sanger sequencing.

Results: Among the 1,790 individuals analyzed, 373 (20.8%) carried at least one pathogenic or likely pathogenic variant, including 143 patients and 230 carriers. Notably, 17 of these variants (4.6%) were recombinant alleles identified in nine patients and six carriers.

Conclusion: Our analysis revealed that recombinant reads are often misaligned in standard whole-genome alignments, with each recombinant allele exhibiting a distinct fingerprint pattern in either GBAP1 or GBA gene. Our findings challenge the assumption that recombinant alleles in GBA go undetected in routine short-read NGS. We demonstrate that short-read NGS, when combined with careful IGV visualization by an experienced team, can successfully identify complex rearrangements, offering a more accessible and cost-effective alternative for routine diagnostics.

P16.062.A Interesting cases as demonstrator for a one size fits all solution in molecular diagnostics

Ilnaz Sepahi[1], *Jessica Hoffmann*[1], *Björn Schulte*[1], *Florian Battke*[2], *Günter Jäger*[2], *Martin Schulze*[1], *Oliver Bartsch*[3], *Saskia Biskup*[1]

[1]*Zentrum für Humangenetik Tübingen, Tübingen, Germany,* [2]*CeGaT GmbH, Tübingen, Germany,* [3]*Medical Care Center, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany.*

Background: While microarray is the preferred method for detecting copy number variation (CNVs), next-generation sequencing offers greater versatility, detecting single nucleotide variants (SNVs), indels, structural variants and CNVs with high resolution (minimum detectable size of 50 kb in microarray vs. single exon level resolution in NGS) and sensitivity, as well as viral infection specifically in a prenatal setting.

Material and Methods: We aimed to create a platform capable of identifying all type of genetic variations. Therefore, we developed a customized whole exome enrichment method incorporating protein coding regions, over 46,000 non-coding clinically relevant regions, a genome-wide CNV backbone, and targets for certain pathogens that are known to potentially lead to prenatal abnormalities.

Results: Here we summarize the genetic findings detected by whole exome sequencing (WES) in three patients with suspected complex genetic disorder. Genetic variants comprised (i) an unbalanced translocation (breakpoints in 3p25.3 and 5p15.32), (ii) a large de novo structural variant of the X chromosome including a terminal deletion of 1 Mb at Xp22.33 and a terminal gain of 3.2 Mb at Xq28, and (iii) a compound heterozygous identification of a small CNV (deletion of exons 3–5) and an SNV in the *PIGG* gene (4p16.3). In another case, we were able to detect Parvovirus B19 DNA in a fetus with hydrops fetalis.

Conclusion: Our exome design, combined with a robust CNV pipeline and pathogen targets, enables the detection of not only SNVs but also CNVs, structural rearrangements, and viral infections in WES.

P16.063.B Challenges and Pitfalls in diagnosing twins with discordant BWS phenotype

Iacopo Bellani[1], *Valentina Trevisan*[2,3], *Germana Viscogliosi*[2,4], *Maria Grazia Pomponi*[5], *Pietro Chiaruzzi*[6,7], *Alessandro Mussa*[8], *Giuseppe Zampino*[2,9], *Maurizio Genuardi*[6,5], *Chiara Leoni*[2]

Background: Beckwith-Wiedemann syndrome (BWS) is the most common genetic cause of overgrowth, occurring in about 1 in 10,000 live births. It results from imprinting defects in the 11p15 region and presents with a broad range of features, such as hemihypertrophy, macroglossia, abdominal wall abnormalities, hypoglycemia, and an increased risk of embryonal cancers.[1,2] Despite the use of a clinical score to guide molecular diagnosis, BWS shows considerable phenotypic variability, even among individuals with the same genetic defect, as appreciated in monozygotic twins.[3,4]

Material and Methods: Two monochorionic-diamniotic female twins, born from spontaneous pregnancy, with discordant clinical phenotype were assessed at our Rare Disease Unit. The proband, the first-born twin, was tested on suspicion of Silver-Russell syndrome due to intrauterine growth restriction and feedingdifficulties. The second twin showed physiological growth pattern and neurodevelopment with no sign of BWS. Both twins were investigated with multiple ligation-dependent probe amplification (MS-MLPA) of the11p15 region, and the first twin was tested with MS-MLPA in multiple imprinted loci.

Results: Both twins we found sharing the same hypomethylation pattern of the KvDMR/IC2 region. MS-MLPA in multiple imprinted loci of the first twin was negative.

Conclusion: Our report aims to support clinicians facing challenges and pitfalls in diagnosing and managing BWS in twins with discordant phenotype. While waiting for a shared diagnostic algorithm, based on a scoring system, to deal with unexpected results to start the appropriate oncologic surveillance programme, we recommend to always test both twins, exercising caution in data interpretation.[5]

P16.064.C A comprehensive benchmark study of multiple library amplification solutions for NGS

Giulia Corbet[1], *Caitlyn Mendik*[1], *Lee French*[2], *Leo Karamanof*[2], *Meghan Oddy*[2], *Andrew Sutherland*[2], *Philip Benson*[1], *Josh Haimes*[1], *Ross Wadsworth*[2], *Travis Sanders*[1], *Craig Marshall*[1], *Kristina Giorda*[1], *Jen Pavlica*[1], ***Max Boeck***[1], *Rajat Roy*[1], *Thomas Harrison*[1], *Eduard Casas*[1], *Brian Kudlow*[1]

[1]*Watchmaker Genomics, Boulder, CO, USA,* [2]*Watchmaker Genomics, Cape Town, South Africa.*

Background: Precision oncology leverages next-generation sequencing (NGS) to guide decisions based on an individual's genetic profile. As the demand for these applications increases, minimizing errors and biases introduced during library preparation and sequencing becomes essential. PCR amplification is a significant source of potential errors in NGS library preparation, with single-base substitutions, insertions, and deletions (indels), as well as PCR-induced biases in DNA length and GC content, all contributing to data distortion and reduced assay sensitivity and specificity. Enhancing library amplification techniques, coupled with advancements in sequencing technology, will improve NGS assay reliability and performance.

Methods: This study evaluated several commercial library amplification systems, including two from Watchmaker Genomics: Equinox and a newly engineered library amplification mix under development. Using a UMI-powered NGS assay, we assessed base fidelity, indel rates in microsatellite sequences, chimeric reads, and GC-uniformity. Libraries were sequenced on multiple platforms, leveraging the high base quality scores from state-of-the-art sequencing chemistries for precise measurements of polymerase

fidelity. We also examined UMI family depth uniformity, a valuable indicator of template sequence bias and error-correction effectiveness. Additionally, we assess amplification size bias and both SPRI and streptavidin beads compatibility. Finally, we test the ability to generate high terminal library yield, which is important for hybridization capture workflows.

Results and Conclusions: Our findings show that while some products perform well on certain metrics, they underperform in others. Notably, Equinox—especially the newly engineered version—demonstrated consistent, robust performance across all relevant metrics, positioning it as a leading solution for accurate and unbiased library amplification.

P16.065.D Unexpected findings in *MECP2* during genetic workup for cardiological symptoms

***Soheyla Chahrokh-Zadeh**, Laura Frey, Alexander Schreiner*

MVZ Martinsried GmbH, Martinsried, Germany.

Background: A 39-year-old female presented with ventricular tachycardia and syncopes, raising suspicion of a hereditary cardiological disease.

Material and Methods: Singleton exome sequencing was performed, and variants were classified according to ACMG guidelines.

Results: A heterozygous frameshift variant in *MECP2* was identified: NM_004992.3:c.1269_1287del p.(Leu424Profs*52) and initially classified as likely pathogenic (PVS1, PM2_Supporting) according to ClinGen Rett and Angelman-like Disorders Expert Panel Specifications for *MECP2* (Version 3.0.0), although the patient showed no developmental or cognitive abnormalities, nor other symptoms of Rett syndrome. Subsequent targeted analysis of family members revealed that the ten-year-old son (hemizygous) and mother (heterozygous) carried the same variant. Neither displayed clinical symptoms related to *MECP2*-associated disorders, necessitating the reclassification of the variant as uncertain significant (PVS1, PM2_Supporting, BS2).

Conclusion: This raises questions about why this *MECP2* variant does not lead to symptoms of Rett syndrome. Explanations remain speculative unless functional studies may offer valuable insights. Truncating variants escaping nonsense-mediated decay are consistently reported in *MECP2* and have been observed in both Rett syndrome patients and occasionally in population databases (gnomAD), making clinical interpretation challenging. Incomplete penetrance in *MECP2*-related disorders has not been documented in literature. Given the established connection between *MECP2* and cardiac phenotypes, such as long QT syndrome, it is possible that the patient's symptoms are related to this variant, however, isolated cardiac abnormalities are typically not observed in patients with pathogenic *MECP2* variants. This case emphasizes the complexities of genetic counseling in similar cases and highlights the need for more nuanced, evidence-based discussions in variant interpretation.

P16.066.A Cost-effective multiplex digital PCR quantification using universal Rainbow detection probes

***Gertjan Wils**[1], Emma Jacobs[1], Amber Declercq[1], Peter Natividad D Ceulemans[2], Jan Hellemans[1], Frauke Coppieters[3], Steve Lefever[1], Jo Vandesompele[1]*

[1]pxlence, Gent, Belgium, [2]Pxlence BV, Gent, Belgium, [3]pxlence, Dendermonde, Belgium.

Background: While the latest generations of digital PCR instruments enable the quantification of 4 to 8 targets in a single reaction, the design, synthesis, and validation of target-specific probes is a bottleneck. Universal probes are not target-specific and can dramatically speed up the development of multiplex assays while keeping costs and turnaround times under control.

Material and Methods: A Rainbow probe (pxlence), a Rainbow primer (i.e., a tailed primer so that the amplicon gets recognized by the probe; pxlence), and a regular primer were used in asymmetric PCR to selectively amplify and quantify a target on 3 different digital PCR instruments (QX200, Digital LightCycler, and

QIAcuity) using the instrument-specific PCR master mix. For mutation analysis, double-mismatch allele-specific primers were designed according to Lefever et al., 2019 (Scientific Reports); all other applications used a modified primer previously successfully used with a DNA binding dye or target-specific probe.

Results: We will present various digital PCR applications in which Rainbow probes enable straightforward multiplex detection of targets on three different digital PCR instruments. These applications range from 2-plex HER2 copy number quantification in cell-free DNA from breast cancer patients to 6-plex gene copy number quantification in genomic DNA, 2-plex transcript quantification in extracellular vesicles, 5-plex gene expression analysis in differentiating induced pluripotent stem cells, and single nucleotide variant quantification using allele-specific primers (BRAF V600E, ALK F1174L).

Conclusion: The use of universal Rainbow detection probes enables cost-effective multiplexing with short turnaround times, speeding up assay development across a wide range of applications.

P16.067.B Thalassemia panel: a novel diagnostic approach

Valentina Barzon, ***Valentina Favalli****, Stefano Casali*

4bases SRL, Pavia, Italy.

Thalassemia is one of the most heterogeneous diseases, affecting 5–7% of the global population. The most relevant forms are α- and β-thalassemia, caused by mutations in the HBA and HBB genes, respectively. Molecular diagnosis of thalassemia using conventional PCR-based DNA analysis has limitations due to the phenotypic variability and heterogeneity of mutations.

Methods: Next Generation Sequencing data obtained with Thalassemia panel kit (H1090, 4bases Italia), a CE-IVD amplicon-based kit, suggested a more accurate DNA analysis ensuring the identification of single nucleotide variants (SNVs) and the most common Copy Number Variants (CNVs) in a single test, achieving a gain in terms of time and accuracy. The kit validation was performed using 5 commercial standard samples (Coriell Institute), with known and emblematic genotypes: SEA heterozygous (het), FIL het, 3.7del homozygous, SEA-FIL, and Lepore-Baltimore het (3 samples were used as negative controls). Data analysis was conducted with 4eVAR, 4bases proprietary analysis platform, ensuring reliable results through a validated internal workflow.

Results: Thalassemia-causing CNVs represent an analytical challenge due to the overlap and difficulty in mutual discrimination with traditional analysis methods. Validation data showed that all expected mutations have been identified, demonstrating that combined coverage and GAP-PCR analysis helped identify and distinguish frequent overlapping CNVs, with SNVs detected through optimal coverage (>100x) of all panel targets.

Conclusion: The Thalassemia panel kit represents an accurate and fast diagnostic solution for precision medicine, enabling not only the evaluation of mutations related to a thalassemic clinical phenotype, but also family or retrospective studies focused on specific CNVs/SNVs.

P16.068.C A Framework for Efficient Variant Filtering in Whole Genome Sequencing for Improved Diagnostics

Kamila Lee[1], Rivka Birnbaum[2], Shira Yanovski Dagan[1], Michal Chalk[1], Tamar Harel[3], ***Hagar Mor-Shaked****[1]*

[1]Hadassah Medical center, Hebrew university, Jerusalem, Israel, [2]Hadassah Medical Center, Jerusalem, Israel, [3]Hadassah-Hebrew University Medical Center, Jerusalem, Israel.

Background: Rare genetic diseases present significant diagnostic challenges due to genetic diversity and limitations of current sequencing and analysis techniques. Exome Sequencing (ES), which focuses on coding regions, has a limited diagnostic yield of 25–35%. Whole Genome Sequencing (WGS), which includes non-coding regions, structural variants, and intronic sequences may offer higher diagnostic potential. However, the vast number of variants and insufficient annotation of non-coding regions in the global databases only lead to a modest increase in the additional diagnostic yield of WGS on top of ES variant analysis.

Material and Methods: This prospective study evaluated a new filtering method (referred to as smart filtering) on 100 patients with various phenotypes who previously had negative results from ES and conservative WGS analysis. The data was processed with the Geneyx Analysis platform for alignment and variant calling. Pre-filtering step was applied (referred to as smart filtering), followed by automatic filtering and manual analysis to identify clinically relevant variants with a final review by an expert panel for diagnosis confirmation.

Results: The smart filtering method identified clinically significant variants in three cases, validated by additional methods like Sanger sequencing and segregation analysis. This increased the overall diagnostic yield by 3%, supporting the hypothesis that smart filtering can enhance variant detection. In addition, novel variants of unknown significance were identified in 25 cases.

Conclusion: Incorporating non-coding regions using relatively simple filtering criteria in the genomic analysis process demonstrates potential to improve diagnosis rates in rare diseases, especially where conventional methods are unrevealing.

P16.069.D Study of the carrier frequency of *SMN1*-related spinal muscular atrophy in southern India and development of a cost-effective quantitative PCR-based test for SMA carrier screening

Prajnya Ranganath*[1], Roopadarshini Balan[1], Vasantha Rani Sarvade[2], Ashwin Dalal[2]*

[1]Department of Medical Genetics, Nizam's Institute of Medical Sciences, Hyderabad, India, [2]Diagnostics Division, Centre for DNA Fingerprinting and Diagnostics, Hyderabad, India.

Background: Carrier frequency of *SMN1*-related spinal muscular atrophy is reported to be around 1 in 40 to 100 in different ethnic groups, but not well studied in the southern Indian population. This study aimed to determine carrier frequency of SMA in southern India, and to develop a cost-effective quantitative PCR-based strategy for SMA carrier screening.

Material and Methods: Carrier status data of 645 individuals (133 males and 512 females) who underwent routine SMA carrier screening through the standard MLPA method at a medical genetics centre in southern India, was collected prospectively over a period of two years (from January 2023 to December 2024). Further, qPCR was done for 60 randomly chosen individuals from the routine carrier screening cohort and for 51 parents of SMA-affected children with homozygous exon 7/8 deletion.

Results: Sixteen of 645 individuals (2.48%) tested carrier positive. qPCR results for 60 individuals from this cohort showed 100% concordance with MLPA results. Among 51 parents of SMA-affected children, 44 tested positive and 7 tested negative for heterozygous deletion carrier status through both qPCR and MLPA; these 7 presumably have 2+0 carrier status which needs further confirmation. The calculated cost per sample for qPCR-based testing was around half that for MLPA.

Conclusion: Carrier frequency of SMA in our study population was found to be around 1 in 40, similar to world-wide figures. However, being a hospital-based study, this may not truly represent carrier status of the general population. qPCR can be used as a cost-effective strategy for population-based carrier screening.

P16.070.A Utilization of Twist CNV Backbone Spike-in Panel with exome for cytogenetic research

Tina Han, *Alessandro Davassi, Esteban Toro*

Twist Bioscience, South San Francisco, CA, USA.

Background: Array comparative genomic hybridization (aCGH) has been the gold standard for detection of copy number variation (CNV). NGS is becoming a standard tool for clinical lab, enabling platform consolidation into an all-in-one NGS assay to replace aCGH.

Material and Methods: We describe here a method to leverage Twist Bioscience's double-stranded DNA probes that can be individually tuned to enrich regions of interest with exceptional uniformity, reducing the overall cost of sequencing. With a proprietary algorithm we positioned probes in the intergenic and large intronic regions to create a genome-wide backbone of probes that fill the gaps between exome targets. Twist CNV Backbone Spike-in Panels were designed on common and polymorphic SNPs in multiple populations at 3 different probe densities, ranging from highest resolution to lowest at 25 kb, 50 kb, and 100 kb spacing to accommodate various requirements.

Results: We will present data that illustrates target enrichment efficiency using Twist's complete workflow through diverse samples that harbor a clinically significant chromosomal aberration. We will also demonstrate the 100% concordance of CNVs called between NGS and aCGH data. Moreover, we will show how aCGH data output could be replicated using this NGS solution.

Conclusion: The data will demonstrate how Twist's all-in-one assay lets researchers sequence more deeply and more efficiently into each sample. The combination of Twist CNV Backbone Spike-in Panels with Twist Exome Panels enables detection of genome-wide detection of CNVs or LOH, on top of SNVs and small InDels that come with Twist Exome 2.0 plus Comprehensive Exome Spike-in Panel.

P16.071.B The unseen crisis: why genetic testing is failing Greek lung cancer patients

Evmorfia Petropoulou, *Gesthimani Kakavouli, Chrysanthi Bili, Birgitta Vrotsou, Lina Florentin, Nick Spanakis*

A-Lab, Athens, Greece.

Background: Lung cancer (LCa) is the leading cause of cancer-related deaths worldwide and the third leading cause in Greece.[1,2] Currently, there are 11 LCa biomarkers, including *EGFR*, *KRAS*, *ALK*, *MET*, *ROS1*, *BRAF*, *RET*, *HER2*, and *NTRK1/2/3*, that offer opportunities to expand personalised treatment strategies.[3] Unfortunately, in Greece, the identification of actionable variants is not in sync with LCa patients' access to comprehensive genetic testing as national health insurance policies cover testing for only three of them (*EGFR, KRAS, ALK*). This discrepancy leads to healthcare inequalities, ultimately increasing patient mortality rates.

Material and Methods: For 2023 and 2024, variants in the aforementioned genes were identified in-house using either a 3-gene panel (Sanger sequencing and FISH) or a 51-gene panel (Next-Generation Sequencing).

Results: Among 110 LCa patients, 40 opted for the 3-gene panel testing (group A), while 70 chose the 51-gene panel testing (group B). In group A, a clinically significant variant (CSV) was identified in 15% of the cases, whereas in group B, it was present in 48.5%. In group B, approximately 24.2% of the patients had a CSV detected in one of the three genes and a further 24.2% had the CSV identified in the other actionable genes that would have been missed if they had undergone the 3-gene panel testing.

Conclusion: Understanding the importance of expanding the existing genetic panel is essential for providing precise treatment of patients with LCa. Biomarkers are a vital part of personalised medicine, which is an imperative approach to prolonging patients' life.

P16.072.C Diagnosis of myeloproliferative neoplasms: the pivotal importance of Sanger sequencing in the detection of *CALR* gene mutations

Sara Meziane[1,2], *Fatimazahra Smaili*[1,2], *Khawla Zerrouki*[1,2], *Fatima Ezzahra Aouni*[1,2], *Jihane Ahmidi*[1,2], *Kaoutar Ahmidouch*[1,2], *Habiba Alaoui*[3,2], *Mariam Tajir*[1,2]

[1]*Medical Genetics Laboratory, Central Laboratory, Mohammed VI University Hospital Oujda, Oujda, Morocco,* [2]*Faculty of Medicine and Pharmacy, Mohammed First University, Oujda, Morocco,* [3]*Internal Medicine Department, Mohammed VI University Hospital Oujda, Oujda, Morocco.*

Background: The discovery of *CALR* gene mutations represented a major breakthrough in the molecular diagnosis of BCR-ABL-negative myeloproliferative neoplasms (MPN). These mutations are found in approximately 80% of essential thrombocythemia (ET) and primary myelofibrosis (PMF) patients who don't carry mutations in the *JAK2* or *MPL* genes. The objective of our study is to demonstrate the contribution of Sanger sequencing in identifying recurrent mutations of the *CALR* gene and thus in the diagnosis of MPN.

Material and Methods: We report in this study a series of 21 patients referred to our medical genetic laboratory at Mohammed VI University Hospital Center of Oujda for suspected BCR-ABL negative MPN. DNA was extracted from peripheral venous blood. After conventional PCR amplification of the exon 9 of the *CALR*

gene, the DNA fragments were purified and sequenced by the Sanger method on ABI SeqStudio.

Results: The molecular analysis revealed three distinct pathogenic mutations in the *CALR* gene in 6 patients (28.57%). All patients harbored deletion/insertion mutations; two had type 2 recurrent 5 bp insertion (c.1154_1155insTTGTC), one presented type 1 recurrent 52 bp deletion (c.1092_1143del52). The variant c.1099_1150del51 was identified in 3 patients.

Conclusion: The present study underscores the utility of Sanger sequencing-based molecular analysis for the identification of recurrent *CALR* gene mutations in myeloproliferative neoplasms, thereby enabling earlier diagnosis and improved patient management.

The ONTOPREC project advances precision medicine by standardizing socio-health variables relevant to chronic diseases, major contributors to morbimortality and healthcare costs. It leverages ontologies, taxonomies, and standardized electronic health record (EHR) formats to integrate and analyze clinical data. The computation of polygenic risk scores (PRS) through whole genome sequencing (WGS) serves as a use case, demonstrating the benefits of structured data integration and bioinformatic analysis. ONTOPREC aligns with international standards, FHIR and OMOP, and employs natural language processing (NLP) to enhance data interoperability.Through a consensus-driven approach, ONTOPREC has standardized 20 socio-health variables, mapping each to specific ontologies, vocabularies, and synonyms to ensure FHIR and OMOP compatibility. NLP has facilitated variable extraction, mapping, and structuring. A pilot study with 200 WGS samples assessed the feasibility of integrating genetic risk scores into EHRs.ONTOPREC highlights the significance of standardization in precision medicine, providing a scalable framework for chronic disease data integration. The successful consensus on socio-health variables and ontological mapping supports harmonizing datasets for improved patient stratification and decision-making. The project also underscores NLP's role in enhancing unstructured clinical data usability and the importance of genetics in PRS prediction. Future efforts will validate the proposed standards' interoperability across healthcare systems and expand the scope to additional conditions and variables. These findings promote the adoption of standardized EHRs and genetic risk assessments in clinical practice.

P16.074.A Assessing extraction efficiency of DNA for long read sequencing

***Fiona Elizabeth Moon**, Zandra Deans*

GenQA, Edinburgh, United Kingdom.

Background: Increasing numbers of laboratories are looking towards long read sequencing (LRS) to provide more in-depth analysis of DNA. The quality of DNA extraction is a crucial aspect of this process for successful downstream testing. However, there currently is not a way for laboratories to benchmark their extraction process with other diagnostic laboratories.

Material and Methods: GenQA developed an external quality assessment (EQA) to assess the quantity and quality of DNA extracted from blood for LRS. Laboratories were sent a 1ml blood sample from the same source, and were instructed to extract DNA using their routine protocol for LRS and return the sample to GenQA for evaluation.

Results: DNA yield was measured by ddPCR, quality by a reference laboratory using Agilent femto pulse, and volume determined by sample weight.

Sixteen laboratories participated using 8 different extraction methods. One laboratory participated twice, with/without a clean-up step.

The yield of DNA ranged from 4.5 to 29.5 µg. The GQN10kb score, which is the proportion of DNA >10 KB is scored from 0–10. The GQN10kb ranged from 4.6 to 9.6. The laboratory that participated twice had a GQN10kb score of 6.2 for extraction protocol and a score of 9.6 for extraction and clean-up protocol.

Conclusion: The quality of DNA extracted was highly variable, demonstrating the benefit of the EQA for laboratories to identify areas of improvement. The increase in GQN10kb score by the laboratory following the clean-up step highlighted that in some circumstances, it would be beneficial to include this aspect to the extraction protocol.

P16.075.B Could aneurysm and atherosclerosis-associated microRNAs (miR 24-1-5p, miR 34a-5p,miR 126-5p, miR 143-5p, miR 145-5p) also be associated with coronary artery ectasia?

*Zafer Yalım[1], **Serap TUTGUN ONRAT**[2], İbrahim Etem Dural[3], Ersel Onrat[4]*

[1]Afyonkarahisar Health Science University, Faculty of Medicine,Dept of Cardiology, Afyonkarahisar, Turkey, [2]Afyonkarahisar Health Science University, Faculty of Medicine, Medical Genetics, Afyonkarahisar, Turkey, [3]Afyonkarahisar Health Science University, Faculty of Medicine, Dept.of Cardiology, Afyonkarahisar, Turkey, [4]Afyonkarahisar Health Science University, Faculty of Medicine,Dept.of Cardiology, Afyonkarahisar, Turkey.

Background: Coronary artery ectasia (CAE), known for localized or diffuse excessive dilatation of the coronary artery, has an unknown etiology, but it has been reported that the underlying cause may be atherosclerosis and genetic changes that may affect the arterial lumen. MicroRNAs (miRNAs) have been shown to have an effect in aneurysm diseases, and atherosclerosis. The purpose ofthis study was to investigate whether they are also associated with CAE.

Material and Methods: This cross-sectional study consisted of 25 patients with CAE and 25 subjects with normal coronaryarteries. Blood was collected, and miRNA expression was detected using the Rotor-GeneQ real-time poly-merase chain reaction cycler (Qiagen, Dusseldorf, Germany) to investigate expression levels of miR-24-1-5p,miR-34a-5p, miR-126-5p, miR-143-5p, and miR-145-5p.

Results: Demographic variables of CAE (mean age 59.5–1.7; 12 women) and controls (mean age 57.2–2.1; 16 women) were similar. miR-126-5p ($p = 0.014$) and miR-145-5p ($p = 0.003$) levels were found to be less than two fold upregulated in CAE compared with controls; miR-143-5p also showed upregulation, but it was not significant ($p = 0.078$). On the contrary, miR-24-1-5p ($p = 0.032$) levels were downregulated in CAE compared with controls. miR-34a-5p was also downregulated, but this was not considered significant ($p = 0.185$).

Conclusion: According to our study findings, miR-126-5p, miR-145-5p, and miR-24-1-5p may be associated with CAE. We think that these miRNAs could be of therapeutic significance for further studies of CAE involving abnormal angiogenesis and vascular disorders, and potentially serve as useful biomarkers.

P16.076.C Comparative analysis of whole genome sequencing (WGS) diagnostic yield for multiple variant interpretation platforms in genome diagnostics for genetic disorders

***Christophe Debuy**, Rachel Schot, Federico Ferraro, Rick van Minkelen, Adriana Iglesias Gonzalez, Frank Sleutels, Lisette Meerstein - Kessel, Stefan Barakat, Tjakko van Ham*

Erasmus MC, Rotterdam, Netherlands.

Background: Despite the immense impact of exome sequencing (ES) in genetic disorders, still in only 20–50% patients with genetic disorders, the genetic cause is identified. Since 2024, ES has been gradually replaced by WGS with the potential to identify all pathogenic variants but also resulting in an abundance of variants of uncertain significance. To improve the efficiency of genetic diagnostics, it is imperative that reliable and accurate variant interpretation software is used. Here, we will determine and compare the diagnostic yields in our WGS cohort using the previously used Alissa Interpret software and the recently implemented Emedgene variant interpretation software.

Material and Methods: In a retrospective analysis, we compared both variant interpretation software platforms using the same patient cohorts ($N = 297$). This will determine whether causative variants identified using Alissa Interpret, will also be detected and prioritized by AI in Emedgene. Conversely, currently undiagnosed patients analyzed with Alissa Interpret, will be re-analyzed using Emedgene.

Results: In this retrospective analysis, a total diagnostic yield of 22.89% (26.60% including candidate causative variants) was obtained (61/297) using Alissa when WGS was performed first. In patients who had previously undergone WES analysis that yielded no genetic diagnosis, WGS provided an additional diagnostic yield of 8.73% (10.91% including candidate causative variants).

Conclusion: Insights in which analysis platform would uncover more potentially pathogenic variants in unsolved patients, will help improve the diagnostic yield in rare and genetic disorders and the efficacy of genomic medicine in clinical practice.

P16.077.D Streamlining genomic diagnostics: Integration of CNV data into a clinical decision support system for enhanced NGS variant classification at NEYGLH

***Mathew Baines**[1], Joseph Mahon[2], Alistair Jones[1]*

[1]Sheffield Diagnostic Genetics Service, Sheffield, United Kingdom, [2]The Leeds Genetics Laboratory, Leeds, United Kingdom.

Background: NGS results plays a crucial role in the NHS Genomic Medicine Service by diagnosing rare genetic diseases. A key aspect of this service is variant classification, where Copy Number Variants (CNVs) help in identifying the genetic cause of a patient's phenotype. Currently, the Northeast and Yorkshire Genomics Laboratory Hub uses the in-house decision support software VarDB. However, CNV data generated by tools such as DECoN is managed separately, resulting in a fragmented and time-consuming analysis. This project aims to develop a software feature within VarDB that incorporates CNV data alongside existing variant information, streamlining analysis, enabling automated first checks, and facilitating long-term trend analysis.

Material and Methods: An AGILE Software development lifecycle consisting of 3 overarching Epics was used. Epic 1 focused on the system architecture, software design, and gathering user requirements from Clinical Scientist. Epic 2 focused on developing a platform that integrates backend database with filtering algorithms, and a front-end interface for CNV results. Epic 3 consisted of validation and testing, such as performance evaluation using both in-silico and patient data, gathering stakeholder feedback to improve the software.

Results: Design outputs, including system schematics and database models, were created to guide development. These models ensure compatibility with existing VarDB software and future extensibility for additional CNV callers. Preliminary evaluations suggest that the integration reduces analysis turnaround times and complexity.

Conclusion: Final results including validation, impact assessments, and deployment outcomes will be presented at the conference, demonstrating any significant changes in workflow efficiency and patient-focused diagnostic turnaround times.

P16.078.A Overcoming diagnostic challenges: The value of multi-omics approaches for gene-pseudogene constellation

Christian Beetz, Andreia Pinto, Uros Hladnik, Mandy Radefeldt, Sabrina Lemke, Lisa Brandenburg, Jorge Pinto Basto, Peter Bauer

Centogene GmbH, Rostock, Germany.

Background: Pseudogenes complicate the short-read sequencing-based detection of copy number variants (CNV). This is due to read misalignment by gene variants that are representative of pseudogene sequence (or vice versa). Orthogonal MLPA testing is therefore recommended as an aid to confirm the presence of a CNV.

Material and Methods: We analyzed a female by exome sequencing in the scope of pre-IVF carrier screening. A putative single-exon deletion triggered MLPA. In addition, a fragment containing the exon of interest plus the two neighboring exons was analyzed by Nanopore long-read sequencing.

Results: Exome sequencing suggested a heterozygous deletion of exon 3 of the *IDS* gene, suggestive of carriership for the X-chromosome Hunter syndrome. Subsequent MLPA was consistent with this interpretation. Since the MLPA probe is indicated to be sensitive to DNA quality issues based on high GC content, we additionally performed long-read sequencing. There was no evidence for the suspected deletion, but we detected several heterozygous intronic variants. All of these represent pseudogene reference sequence, arguing for a copy-neutral pseudogene-gene conversion. One of the variants (rs470986) is known to cause misalignment of gene-derived reads to the pseudogene, explaining the initial exome sequencing observation. Another variant (rs1734484) overlaps with the ligation site of the critical MLPA probe, explaining the apparent MLPA confirmation.

Conclusion: A disease-association of the conversion is currently investigated by RNA sequencing. Our case highlights that for genes with a pseudogene, short-read sequencing + MLPA may be insufficient regarding CNVs. Instead, a multi-omics approach should be implemented.

P17 Bioinformatics, Machine Learning and Statistical Methods

P17.001.B Streamlining selection of variants for functional studies to reclassify variants of unknown significance

Emma MacKenzie[1,2], *Evan Reid*[3], *Joo Wook Ahn*[2,1], *Matthew Garner*[1,2]

[1]*Cambridge Genomics Laboratory, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,* [2]*NHS East Genomics, Cambridge, United Kingdom,* [3]*Cambridge Institute for Medical Research, The University of Cambridge, Cambridge, United Kingdom.*

Background: 75% of rare disease cases in the 100,000 Genomes Project remain unsolved. Functional studies allow reclassification of VUS; however, application to all VUSs is prohibited by cost and throughput limitations. Identifying variants that are most likely to benefit from functional studies will allow targeted follow-up testing.

Material and Methods: We utilise Exomiser scores, in-silico pathogenicity prediction tools and panelApp information to prioritise variants in specific genes from the unsolved 100,000 Genomes cohort.

These variants will be passed to research teams for functional analysis. Any findings which may result in a new diagnosis will be returned via the Genomics England Diagnostic Discovery pathway.

Results: For initial tool assessment, unclassified variants were compared to the outputs of previous SGE functional studies to assess variants from BAP1 (Waters et al, 2024) and DDX3X (Radford et al 2023). 4 out of 6 (66 %) returned BAP1 variants were classified as "depleting", and 2 out of 9 (22%) DDX3X variants were classified as "enriching". Tool application to the unsolved 100,000 Genomes cohort returned 1082 variants across 42 genes. Of these, 18 variants are within genes which are PanelApp green for the referral panel. Functional analysis is currently on going.

Conclusion: Our method prioritises variants that are likely to provide functionally actionable results, which can provide evidence of pathogenicity to VUS, in the long-term increasing the diagnostic yield of sequencing.This research was made possible through access to data and findings in the National Genomic Research Library via the Genomics England Research Environment.

P17.002.C Next-generation phenotyping advancing ACMG variant classification and newborn screening, demonstrated through Alagille syndrome

JingMei Li[1], *Sophia Kaptain*[1], *Hannah Klinkhammer*[1], *Hannah Weilland*[1], *Merle ten Hagen*[1], *Himanshu Goel*[2,3], *Rana Bitar*[4,5], *Miray Karakoyun*[6], *Kee Seang Chew*[7], *Choy Chen Kam*[7], *Christopher Chun Yu Mak*[8], *Brian Hon Yin Chung*[8,9], *Ho-Ming Luk*[10], *Sok Kun Tae*[7], *Meow-Keong Thong*[7], *Peter M. Krawitz*[1], *Tzung-Chien Hsieh*[11]

[1]*Institute for Genomic Statistics and Bioinformatics, University Hospital of Bonn, Bonn, Germany,* [2]*Hunter Genetics, Waratah, NSW, Australia,* [3]*School of Medicine and Public Health, University of Newcastle, Callaghan NSW, Australia,* [4]*Pediatric Gastroenterology Department, Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates,* [5]*Khalifa University, Abu Dhabi, United Arab Emirates,* [6]*Ege University, Faculty of Medicine, Department of Pediatric Gastroenterology Hepatology and Nutrition, Izmir, Turkey,* [7]*Department of Paediatrics, Faculty of Medicine, University Malaya, Kuala Lumpur, Malaysia,* [8]*Department of Paediatrics and Adolescent Medicine, The University of Hong Kong, Hong Kong, China,* [9]*Hong Kong Genome Institute, Hong Kong, China,* [10]*Department of Clinical Genetics, Hong Kong Children's Hospital, Hong Kong, China,* [11]*University Hospital Bonn, Bonn, Germany.*

Background: While next-generation phenotyping (NGP) is widely recognized for its diagnostic potential, its application to ACMG variant classification and newborn screening remains underexplored. Alagille syndrome (ALGS), an early-onset multisystem disorder with available medical therapies to prevent severe complications, serves as a compelling model to explore these applications. We demonstrated how NGP facilitates the reclassification of variants of uncertain significance (VUS) and enables newborn screening, particularly in diverse and underserved populations.

Material and Methods: Our model was trained on 121 ALGS patients from diverse ancestries, sourced from the GestaltMatcher Database, and validated against healthy controls. For newborn screening, ALGS cases were compared to healthy infants (age <1 year) from the UTKFace dataset. We encoded each image into 512 dimensional feature vectors and trained a Support Vector Machine (SVM) to classify between ALGS and healthy controls. Thresholds for ACMG PP4 criteria (supporting, moderate, strong) were established using a Bayesian framework.

Results: We established robust thresholds for PP4 criteria to facilitate VUS reclassification, enabling more confident variant interpretation. Our analysis highlighted performance differences across age groups and ancestries, underscoring the importance of diverse training data. In a simulated newborn screening scenario, our SVM model achieved a Positive Predictive Value (PPV) of 90%.

Conclusion: NGP expands beyond diagnostics to address gaps in ACMG variant classification and newborn screening, as demonstrated by its application to ALGS. This approach facilitates early intervention, reduces reliance on genetic expertise, and improves outcomes in underserved populations, highlighting its potential to advance global precision medicine.

P17.003.D Investigating variant pathogenicity prediction by examining the performance of in-silico predictive tools using clinical data

Roisin Sullivan, *Andreia Rogerio, Jamie Ellingford, Susan Walker, Dalia Kasperaviciute, Francisco Azuaje, Augusto Rendon*

Genomics England, London, United Kingdom.

Whole genome sequencing (WGS) data for patients with rare disorders are being interpreted clinically by NHS laboratory scientists through the 100,000 Genomes Project and NHS Genomic Medicine Service (GMS). The resulting variant classifications can be applied to evaluate and improve in-silico tool prediction. Here we present an interpretable and quantitative framework that identifies overlapping thresholds for error minimisation (FPR and FNR) and precision maximisation (PPV and NPV) for 10 in-silico algorithms applied to a cohort of missense variants (88.3% pathogenic / 11.7% benign) clinically interpreted as part of the 100,000 Genomes Project or GMS. We introduced a threshold of 0.75 for minimum precision and 0.3 for maximum error, resulting in BayesDel and MetaRNN presenting with overlapping thresholds, with the others unable to satisfy all four metrics. BayesDel's decision-thresholds range from 0.369 to 0.379 (FPR < 0.1, FNR < 0.2, PPV, NPV>0.75) and MetaRNN's from 0.291 to 0.317 (FPR < 0.1, FNR < 0.3, PPV, NPV>0.75). PR-AUC comparisons (ranking BayesDel first with a score of 80.6, followed by ClinPred (75.6) and AlphaMissense (71)) fail to reflect the observed high FNR and low NPV of ClinPred and AlphaMissense, highlighting the benefit of this framework. When investigating the impact of protein structure and organisation we noted that BayesDel outperformed in alpha helix domains (FPR, FNR < 0.3, PPV, NPV>0.7), and ClinPred in beta sheet domains (FPR, FNR < 0.25, PPV, NPV>0.68). Overall, this framework enables users to base their decision threshold selection on their desired key metric, allowing for trade-off analyses across metrics and models at both the patient-level and specific subsets of domain-associated variants.

P17.004.A Phenome-wide health associations of multi-allelic copy number variants in UK Biobank

Micaela Eisenberg[1], *Richard Packer*[2], *Nick Shrine*[2], *German Demidov*[3], *Edward J. Hollox*[1], *Katherine Fawcett*[2,4]

[1]*Department of Genetics, Genomics, and Cancer Sciences, University of Leicester, Leicester, United Kingdom,* [2]*Department of Population Health Sciences, University of Leicester, Leicester, United Kingdom,* [3]*Institute of Medical Genetics and Applied Genomics, University of Tuebingen, Tuebingen, Germany,* [4]*EMBL-EBI, Hinxton, United Kingdom.*

Background: The contribution of multi-allelic CNVs (mCNVs) to disease risk has not been widely studied, as they are difficult to characterise at large-scale genome-wide, and are often not strongly associated with flanking SNVs, limiting imputation approaches. Improved understanding of the role of mCNVs in disease risk could lead to novel insights into the pathobiology of disease.

Material and Methods: We used ClinCNV to robustly type 69 mCNVs from UK Biobank whole exome sequences in discovery (n = 152,853) and replication sets (n = 269,317). Discovery and replication PheWAS of these variants used DeepPheWAS, which interrogates clinically-curated composite phenotypes by integrating self-report, primary and secondary health care data. Separate PheWASs were conducted for unrelated individuals of African, European and South Asian ancestries. The false discovery rate (FDR) threshold for significant discovery associations was 0.01 for European ancestries and 0.05 for the smaller African (n = 1,943) and South Asian (n = 3,085) ancestries. Associations replicated when the direction of effect was consistent in discovery and replication sets and the replication p-value for association was less than 0.05.

Results: 174 mCNV-phenotype associations were detected from 26 mCNVs, of which 114 associations replicated. Four of eight potentially novel mCNV-phenotype signals were independent of neighbouring associated SNPs, including *SULT1A1/SULT1A2* with eGFR in Europeans (meta-analysed $p = 1.05 \times 10^{-9}$, beta = 0.016 [0.011; 0.021]), and *GOLPH3* with bundle branch block in South Asians (meta-analysed $p = 3.35 \times 10^{-6}$, OR = 2.25 [1.16, 4.37]).

Conclusion: We show that accurate typing and large sample sizes can reveal genetic associations of mCNVs, and our work provides several novel likely causative variants contributing to clinically-important traits.

P17.006.C Imputation and phasing methods impact polygenic scoring with low-coverage sequencing data across 27 diseases and traits

Sannimari Suhonen[1], *Sanni Ruotsalainen*[1], *Simone Rubinacci*[1], *Elisabeth Widén*[1], *Samuli Ripatti*[1,2,3], *Nina Mars*[1,2]

[1]*Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland,* [2]*Broad Institute of MIT and Harvard, Cambridge, MA, USA,* [3]*Department of Public Health, University of Helsinki, Helsinki, Finland.*

Background: Low-coverage whole-genome sequencing (lcWGS) is increasingly used in research to produce genome-wide genotypes. LcWGS offers a cost-effective alternative for array genotyping for polygenic risk scores (PRS) and is less prone to variant ascertainment bias. However, its performance for PRS calculation remains understudied. Here we compare imputation and phasing methods for lcWGS and the impact of coverage on PRS precision.

Material and Methods: We assessed the utility of imputed lcWGS data in PRS estimation, using 30x WGS data for 24 Finnish individuals with six downsampled low coverages (0.1x-2x) and a population-specific imputation panel. We compared three imputation and phasing approaches (Beagle4, Beagle5 and GLIMPSE2) across 27 disease and trait PRSs covering a great number of non-communicable diseases and their risk factors.

Results: Imputation and PRS calculation concordance compared to high-coverage WGS increased with lcWGS coverage in all approaches. LcWGS imputation with GLIMPSE2 outperformed the other two approaches, both in imputation and PRS concordance ($p < 1\times$;10-21 and $p < 1e\text{-}8$), with 0.5x reaching imputation and PRS concordance of $r2 > 0.90$. WithGLIMPSE2, PRS risk category reclassification was also minimal (all ≤10%) starting from 0.5x. Differences in PRS concordance between disease and trait PRSs were detected, with PRSs containing single high-impact variants showing poorer concordance.

Conclusion: Processing lcWGS data with dedicated imputation and phasing methods, such as GLIMPSE2, is important for optimal PRS calculation. With such approaches, coverage as low as 0.5x can achieve PRS performance comparable to genotyping arrays, making lcWGS a feasible option for PRS studies.

P17.007.D Detection of short tandem repeat expansions from exome sequencing data in patients with neurological conditions

Gaber Bergant, *Borut Peterlin*

University Medical Center Ljubljana, Clinical Institute of Genomic Medicine, Ljubljana, Slovenia.

Background: Diagnosing neuromuscular and neurodegenerative disorders presents a significant global healthcare challenge due to their genetic heterogeneity and the presence of elusive genetic variant types such as short tandem repeat (STR) expansions. These factors often contribute the elongation of an already complex diagnostic process of genetic diagnostics.

Material and Methods: We evaluated 714 patients referred for genetic diagnostics to our institution between 2013 and 2025, who presented with neuromuscular or neurodegenerative disorders and had negative exome or genome sequencing results. Based on symptoms compatible with tandem repeat disorders, 76 were selected for bioinformatic STR profiling using Expansion Hunter.

Results: In selected patients we identified 17 clinically relevant STR expansions. Pathogenic expansions were found in HTT (six patients), ATXN8OS (four patients), AR and DMPK (two patients each), and CNBP, FMR1, and FXN (one patient each).

Conclusion: Employing STR profiling we achieved a diagnostic yield of 22.4% in the selected cohort of patients and 2.4% in the overall group of patients with neuromuscular and neurodegenerative disorders. Bioinformatic characterization of STRs from exome and genome sequencing data proved to be a reliable method, with all variants confirmed by gold standard triplet repeat-primed PCR.

P17.008.A Proteome wide prediction of mode of inheritance and molecular mechanism underlying genetic diseases using structural interactomic

Ali Saadat, *Jacques Fellay*

EPFL school of life sciences, Lausanne, Switzerland.

Background: Genetic diseases are classified by their modes of inheritance (MOI) and molecular mechanisms. Autosomal dominant (AD) disorders arise from loss-of-function, gain-of-function, or dominant-negative variants, while autosomal recessive (AR) diseases are linked to loss-of-function variants. This study introduces a graph-of-graphs approach leveraging protein-protein interaction (PPI) networks and high-resolution protein structures to predict MOI and classify functional effects of AD proteins. Using graph neural networks (GNNs) integrated with structural interactomics, the method enables proteome-wide predictions, enhancing understanding of genetic disease mechanisms.

Material and Methods: Data on MOI and molecular mechanisms were collected for 4,737 proteins, categorized as AR (53%), AD (30%), and both (ADAR, 17%), with functional effect data for 1,276 AD proteins. A comprehensive PPI network with 17,248 nodes and 375,494 edges was constructed using STRINGdb, BioGRID, and other resources, enriched with protein structure data from AlphaFold and annotated with 78 protein features and 73 residue features.

Results: Models were developed using several GNN architectures, including graph attention, convolution, and isomorphism network (GAT, GCN, and GIN, respectively) and evaluated via precision, recall, and F1 scores. The GAT model outperformed previous state-of-the-art models for MOI prediction ($F1 = 0.74$), and the GCN was good at functional effect classification ($F1 = 0.61$). Applying the models to the human proteome, 16,184 autosomal proteins were classified, revealing pathway enrichments linked to cancer for AD and mitochondrial or neurodevelopmental roles for AR proteins.

Conclusion: This framework bridges network-level and structural insights, offering interpretable tools for genetic research. Future work will incorporate tissue-specific data.

P17.009.B PGS-Optimizer: A federated and modular framework for enhancing polygenic risk Score computation in diverse populations

Leman Binokay[1,2], *Tutku Yaraş*[1,2], *Hamit Mervan Çelik*[3,4], *Tolga Ayav*[3,4], *Yavuz Oktay*[1,5,6], *Tuğkan Tuğlular*[3,4], *Gökhan Karakülah*[1,2,6]

[1]*İzmir Biomedicine and Genome Center, 35340, İnciraltı, İzmir, Turkey,* [2]*İzmir International Biomedicine and Genome Institute, Dokuz Eylül University, 35340, İnciraltı, İzmir, Turkey,* [3]*Department of Computer Engineering, Faculty of Engineering, Izmir Institute of Technology, 35430, Urla, İzmir, Turkey,* [4]*Research Ecosystems Araştırma Geliştirme Yazılım Sanayi ve Ticaret A.Ş., 35430, Urla, İzmir, Turkey,* [5]*Department of Medical Biology and Genetics, Faculty of Medicine, Dokuz Eylül University, 35340, İnciraltı, İzmir, Turkey,* [6]*Solaris Genomics Arge ve Sağlık Teknolojileri A.Ş., 35340, İnciraltı, İzmir, Turkey.*

Background: Polygenic scores (PGS) are widely applied in genetic risk prediction, yet their accuracy is constrained by the dominance of genome-wide association studies (GWAS) in European populations. This limitation reduces the clinical utility of PGS in diverse

populations. Additionally, developing new PGS models is a complex task that requires significant effort, including data integration, algorithm selection, and rigorous evaluation. PGS-Optimizer is introduced to address these challenges through a federated and modular computational framework.

Material and Methods: PGS-Optimizer integrates cutting-edge PGS algorithms—PRS-CSx, PRScise2, Ldpred2, Lassosum2, and PLINK—within a federated learning infrastructure that facilitates secure, cross-institutional collaborations while preserving data privacy. The platform includes preprocessing modules for genotype quality control and imputation, ensuring consistency across datasets. Performance evaluation was conducted using synthetic datasets generated via HAPNEST, representing six distinct populations with varying sample sizes to assess the robustness and scalability of the framework.

Results: The platform demonstrated significant improvements in PGS accuracy and reproducibility across diverse population datasets. The federated learning approach provided secure model development across multiple institutions, while the modular architecture enabled efficient workflow customization.

Conclusion: PGS-Optimizer offers a scalable, reproducible, and privacy-preserving solution for advancing PGS research across diverse populations. Our tool is a continuously evolving platform, with regular updates planned to enhance functionality and expand population coverage. Future directions include the integration of machine learning-based risk models, expanded compatibility with emerging genomic datasets, and improved reporting capabilities.

P17.010.C A novel computational framework for differential and QTL transcript usage in single-cell data

Rubén Chazarra-Gil, *Iris Mestres-Pascual, Marta Melé*

Barcelona Supercomputing Center, Barcelona, Spain.

Background: Alternative transcript usage is a key regulator of gene expression, shaped by mechanisms such as alternative splicing and polyadenylation. Human individuals differ in their transcript usage across tissues and traits. Such differences are partially controlled by genetics and ultimately contribute to phenotypic variation. However, most studies have focused on bulk tissue level, masking cell type-specific regulation of transcript usage. The advent of large single-cell RNA-seq cohorts provides an opportunity to resolve these differences at single-cell resolution. However, two major challenges remain: transcript quantification in end-biased scRNA-seq data, and the lack of single-cell differential transcript usage methods suited for complex experimental designs.

Material and Methods: To address these limitations, we developed a novel computational framework for differential and QTL transcript usage analysis in single-cell data. Our approach tackles the coverage bias of scRNA-seq data by performing equivalence class quantification and models transcript usage differences between individuals using a non-parametric multivariate test.

Results: We applied our framework to a scRNA-seq dataset of immune blood cells from 80 European and 80 African individuals in baseline and under viral infection: influenza and covid. Both infections induced widespread transcript remodeling across cell types, particularly in monocytes, and affected immune response upregulated genes. Population differences in transcript usage were enriched for genetic variants associated with splicing regulation and were independent of gene expression changes.

Conclusion: Overall, we introduce a computational strategy to study transcript usage variation across multiple phenotypes in single-cell data, expanding the understanding of splicing and polyadenylation diversity across individuals in response to viral infection.

P17.011.D aiDIVA: Classification and prioritisation of causal variants in rare disease patients using Large Language Models

Dominic Boceck[1], Lucia Laugwitz[2], Marc Sturm[1], Tobias Haack[1], ***Stephan Ossowski***[1]

[1]Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tübingen, Germany, [2]Department of Neuropediatrics, Developmental Neurology and Social Pediatrics, University of Tübingen, Tübingen, Germany.

Background: Genome sequencing is a widely used diagnostic tool for detection of genetic disease variants. However, variant interpretation and identification of causal variants in patients with rare diseases (RD) is challenging and time-consuming and requires trained experts. Hence, there is a need for AI-driven clinical decision support systems that assist clinical experts in identifying causal variants or, in case of large-scale re-analysis of unsolved cases, automate the process.

Material and Methods: We introduce aiDIVA, a tool featuring multiple machine learning models trained on genomic and phenotypic data, to identify the causal variant of an RD patient. First, aiDIVA uses features based on genomic and clinical annotations to generate a pathogenicity score for each variant using 1) a random forest AI, and b) an evidence-based model. aiDIVA combines these models with clinical metadata (e.g., phenotype as HPO terms) to rank the most likely causal variants. Second, aiDIVA uses a similarity approach comparing disease phenotypes associated with a certain gene to the clinical information of the patient. Third, aiDIVA uses large language models (ChatGPT, LLaMA) to rank the top-10 candidates. Finally, a meta-AI model combines all scores to generate the final ranking.

Results: In a benchmark analysis with more than 3000 diagnostically solved RD patients of the University Clinics Tübingen, aiDIVA reported the causal variant in 97% among the top three candidates. Furthermore, aiDIVA provides interpretable explanations for each candidate.

Conclusion: aiDIVA has the potential to speed-up diagnostics by automatically indicating the causal gene in 97% of the solvable RD cases.

P17.012.A The Ensembl Variant Effect Predictor (VEP) and human pangenome assemblies: as featured on the new Ensembl beta website

Jamie Allen, *Olanrewaju Jaden Austine Orimoloye, Andrey G. Azov, Jyothish Bhai, Mehrnaz Charkhchi, Kamalkumar Dodiya, S. Nakib Hossain, Diana Lemos, Likhitha Surapaneni, Andres Veidenberg, Andrea Winterbottom, Jon Keatley, Leanne Haggerty, Sarah E. Hunt, Mallory A. Freeberg, Fergal J. Martin, Andrew D. Yates*

EMBL-EBI, Hinxton, United Kingdom.

Background: The Human Pangenome Reference Consortium (HPRC) aims to create a genome reference which better represents human genetic diversity by combining high quality haplotype assemblies from hundreds of individuals of different ancestries. Ensembl is a member of the HPRC and to further this ambition, the new Ensembl beta website (www.beta.ensembl.org) provides enhanced support for multiple, more diverse human genome assemblies. In addition to human GRCh37 and GRCh38, Ensembl beta supports the T2T-CHM13 assembly alongside 94 human haplotype assemblies produced by the HPRC, variant views and the capability to run a core version of Ensembl VEP is enabled for all these assemblies.

Material and Methods: Individual gene annotations were constructed using a scalable and accurate approach, centred on the use of local alignments of genes and gene clusters between the GRCh38 reference and target genomes. We lifted over variants from dbSNP156 to display on the new assemblies.

Results: Gene and variant views for the human pangenome assemblies are available on the new website as summary tracks on the Genome Browser and in greater detail in our Entity Viewer. Ensembl VEP enables the annotation and prioritisation of genomic variants on the pangenome assemblies.

Conclusion: Ensembl now enables more detailed visualisation and annotation of variants discovered against new, more diverse human haplotype assemblies, supporting the global effort in human genomics. These efforts enable identification of population-specific genetic variants that affect disease risk, treatment efficacy, and drug responses, which are crucial for realising the benefits of precision medicine.

P17.013.B Re-identifying Genomes by Linking Polygenic Scores to Phenotypic Traits

Théo Cavinato, *Robin Hofmeister, Anna-Sapfo Malaspinas, Zoltan Kutalik*

University of Lausanne, Lausanne, Switzerland.

Background: Access to an individual's genome can reveal sensitive information, such as their predisposition to certain diseases. To enable scientific research while protecting participants' privacy, researchers anonymize genomes by removing identifying information (e.g., names or zip codes). However, studies suggest that it may still be possible to re-identify a genome, even if fully anonymized, by inferring genetically predicted phenotypes and comparing them to the traits of known potential genome owners.

Material and Methods: Here, leveraging recent advances in GWAS, we investigate the feasibility of such re-identification. We introduce an approach that compares multiple traits of a target individual with the Polygenic Scores (PGSs) derived from a query genome to infer the probability that the genome belongs to the individual. Briefly, our approach learns the underlying residual distributions in a training dataset and uses a likelihood-ratio test (LRT) to decide whether a PGS profile and a set of traits belong to the same individual. We benchmarked our approach by extensive simulations of re-identification attempts using genomes and phenotypes from the UK Biobank.

Results: Re-identification accuracy increased with the number of traits used. Using 40 traits, for more than half of tested individuals, our LRT would guess the correct match with an error rate of 0.17%. Finally, we assessed how our approach could be leveraged to infer other unmeasured traits of the target individual and compared it to phenotype-based inference strategies.

Conclusion: We show that advances in phenotype inference raise privacy concerns, highlighting the need for careful handling of genomic data.

P17.014.C Clinical Evaluation of an AI System for Streamlined Variant Interpretation in Genetic Testing

*Jiri Ruzicka[1], **Jean-Marie Ravel**[2], Jerome Audoux[1], Alexandre Boulat[1], Julien Thevenon[3], Kevin Yauy[4], Laure Raymond[5], Marine Dancer[5], Yannis Lombardi[6], Nicolas Philippe[1], Michael GB Blum[7], Nicolas Duforet[1], Laurent Mesnard[8]*

[1]SeqOne, Montpellier, France, [2]Universite de Lorraine, CHRU de Nancy, Vandoeuvre-les-Nancy, France, [3]CHU GRENOBLE ALPES, GRENOBLE CEDEX 9, France, [4]CHU Montpellier, Montpellier, France, [5]Eurofins Biomnis, Lyon, France, [6]APHP.SORBONNE UNIVERSITE, Paris, France, [7]IAB, Université Grenoble Alpes, Grenoble, France, [8]APHP.-SORBONNE UNIVERSITE, PARIS, France.

Background: The growing use of whole exome/genome sequencing for diagnosing hereditary diseases has increased the interpretive workload for clinical laboratories. Efficient methods are needed to identify pathogenic variants and maximize diagnostic yield without overwhelming resources.

Material and Methods: We developed DiagAI, an AI-powered system trained on 2.5 million ClinVar variants to predict ACMG pathogenicity classes. DiagAI ranks variants, proposes diagnostic shortlists, and identifies probands likely to receive molecular diagnoses. It integrates molecular features, inheritance patterns, and phenotypic data when available. We retrospectively analyzed 966 exomes from a nephrology cohort, including 196 with causal variants and 770 undiagnosed cases.

Results: DiagAI identified 94.9% of causal variants in diagnostic exomes with HPO terms, compared to 90.8% without, with median shortlist sizes of 12 and 9 variants, respectively. It achieved a sensitivity of 57.1% and a specificity of 92.6% in tagging exomes likely to contain a diagnostic variant. With HPO terms, 74% of top-ranked (top 1) variants were diagnostic, versus 37% without, and DiagAI outperformed Exomiser and AIMARRVEL in this setting.

Conclusion: DiagAI generates accurate shortlists of variants that streamline the variant interpretation process. It provides a scalable solution for managing growing diagnostic test volumes without compromising quality.

P17.015.D PRC2-related epigenetic age acceleration in acute myeloid leukemia with *DNMT3A* and *IDH2* mutations

Yong Lei[1], *Zhengyi Yan*[1], *Shen Gu*[2]

[1]*The Chinese University of Hong Kong (shenzhen), Shenzhen, China,* [2]*The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Background: Age-associated DNA methylation at specific CpG sites has been developed as a biomarker that estimates the epigenetic age (EA) across human tissues. EA acceleration (EAA) is widely observed in patient cohorts, including those with hematological malignancies. Current causation analysis and biological interpretation of disease-dependent EAA remain less characterized.

Material and Methods: By harnessing causality-enriched epigenetic clocks, we determined the causal EAA for all statistically analyzable mutated genes in acute myeloid leukemia (AML) patients from TCGA. We identified two mutated DNA methylation (DNAm) associated genes (DNMT3A and IDH2) that were correlated with different damaging and protective DNAm changes during AML pathogenesis, respectively. To study the potential molecular mechanism driving EAA in AML, we profiled the DNAm status at polycomb repressive complex 2 targets (PRC2m), where has been reported to display a preferential hypomethylation manner in the DNMT3A mutated individual with clonal hematopoiesis.

Results: PRC2m from AML patients with mutated DNMT3A and IDH2 displayed distinct methylation alterations compared to other AML patients, suggesting their potential role in dysregulating the PRC2 binding landscape in the genome and the deposition of histone marks. Subsequent calculations exhibited that PRC2m was correlated with EA rather than chronological age in AML patients.

Conclusion: These findings indicate the first evidence for the biological implications of the gain or loss of methylation at PRC2 targets in mediating causal EAA in diseases. This study sheds light on the intricate connection and potential causality between genome-wide methylation alteration at PRC2 targets and the pathogenesis of AML with specific mutations.

P17.016.A Genome-wide canonical correlation analysis reveals maximally heritable disease patterns

Jianhan Wu, *Shihong Mao, Elias Larrazabal, Feiner James, Matteo Di Scipio, Alice Man, Ricky Lali, Michael Chong, Guillaume Paré*

McMaster University, Hamilton, ON, Canada.

Background: Methods for deconstructing biobank-scale phenotype structures have relied on modelling high-dimensional phenotype data without utilizing genetic information. Here, we introduce genome-wide canonical correlation analysis (GCA), a genetically informed method for dissecting patterns from biobank observations.

Material and Methods: GCA jointly models phenotype and genetic data and outputs the most heritable phenotype patterns along with their unique genetic risk scores in the forms of phenotype and genetic latent variables. We modelled 128 heritable phecodes across 16 disease categories with 638,587 common genetic variants in a discovery set of 274,770 unrelated UK Biobank participants of White British ancestry. Latent variables and coefficients obtained from discovery set were projected in validation set (n = 68,693) for evaluation of heritability, phenotype and genetic associations.

Results: GCA retrieved 54 heritable disease patterns ($h^2 > 0$, $p < 4 \times 10^{-4}$), among which, 17 exhibited multimorbid profiles in the validation set. Disease patterns were phenotypically and genetically heterogeneous. Decoding multimorbid profiles led to biologically relevant findings. The first and most heritable disease pattern was genetically associated with altered lifespan and healthspan while the third most heritable disease pattern described opposing risks between cancer and autoimmunity. Allelic coefficients obtained from GCA also support molecular interpretation. Diverse hallmarks of aging, including telomere length, were genetically associated with the first disease pattern whiles established and novel tumor immunotherapeutic targets, including PD-1 and PTPN2, were prioritized by the third disease pattern.

Conclusion: These findings validate GCA as a genetically informed method for dissecting biologically significant patterns from biobank-scale data.

P17.017.B A heritability-optimized method for functional prioritization of rare coding variants in complex traits

Keona Pang[1,2], *Nazia Pathan*[1,3,4], *Ann Le*[1,2], *Alice Man*[1,2,5], *Josef Graf*[6], *Daria Grafodatskaya*[4,7], *Michael Chong*[1,4,8], *Guillaume Paré*[1,8,4]

[1]*Population Health Research Institute, David Braley Cardiac, Vascular and Stroke Research Institute, Hamilton, ON, Canada,* [2]*Department of Medical Sciences, McMaster University, Hamilton, ON, Canada,* [3]*Faculty of Science, Chemistry & Chemical Biology, McMaster University, Hamilton, ON, Canada,* [4]*Department of Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada,* [5]*Michael G. DeGroote School of Medicine, McMaster University, Hamilton, ON, Canada,* [6]*Department of Computing and Software, Faculty of Engineering, McMaster University, Hamilton, ON, Canada,* [7]*Hamilton Regional Laboratory Medicine Program, Hamilton Health Sciences, Hamilton, ON, Canada,* [8]*Thrombosis and Atherosclerosis Research Institute, David Braley Cardiac, Vascular and Stroke Research Institute, Hamilton, ON, Canada.*

Background: Population sequencing studies are uncovering millions of uncharacterized rare (MAF < 1%) coding variants (RV). Predicting which RVs contribute to complex disease heritability remains an ongoing challenge.

Material and Methods: We propose RovHer (Rare variant heritability-optimized scores), a machine learning approach that integrates 45 variant-level and 30 gene-level features. RovHer employs exome-wide association statistics to generate unbiased, disease-agnostic scores that reflects the probability of functional impact for each RV. Additionally, we use a novel heritability-based benchmarking approach to assess how well the RVs prioritized by these scores explain the observed variability in the trait.

Results: Analysing 21 complex traits in up to 357,086 Caucasians in the UK Biobank, the top 1% (m = 13,410) of RVs prioritized by RovHer explained an average of 16.1% of RV heritability, representing a 10-fold increase over the 7 alternative methods tested (average 1.5%; range 1.2%–2.3%). We evaluate RovHer for clinical utility, particularly in identifying carriers of missense ultra-rare variants (MAF < 0.01%) at highest risk in 20 monogenic disease-gene pairings. Notably, the top 5% of carriers (n = 143) prioritized by RovHer had significantly elevated LDL-cholesterol levels of 6.8 mmol/L (P = 1.1e-150) and 3.8 higher odds of coronary artery disease (P = 4.0e-9), numerically exceeding the 6.6 mmol/L and 3.3-fold risk (n = 23) associated with loss-of-function variants respectively.

Conclusion: RovHer leverages RV association statistics to produce unbiased scores that consistently captures the smallest proportion of likely functional variants that maximally enriches for exome-wide heritability. Our tool exemplifies the potential of prioritized missense RVs in refining population-level risk assessments.

P17.018.C Boost statistical power to detect variants in small case cohorts leveraging gnomAD genome datasets

Jonas Frank, *Matthias Schlesner*

Biomedical Informatics, Data Mining and Data Analytics, Faculty of Applied Computer Science and Medical Faculty, University of Augsburg, Augsburg, Germany.

Background: Detecting genetic variants associated with diseases in small cohorts (e.g. < 1000 samples because of a disease's rarity) is challenging due to limited statistical power using GWAS. Expanding the control group size is a promising approach to overcome this limitation. Utilizing aggregated variant data from gnomAD genome datasets offers a scalable solution to enhance statistical power, even with constrained case cohort sizes.

Material and Methods: This workflow integrates allele count and number data from gnomAD, allowing the selection of control datasets by ethnicity to match the case cohort optimally. Analyses can be performed at gene level or within specified genomic regions. Raw vcf files are intersected, annotated and filtered using customizable thresholds for metrics like CADD or SpliceAI and allele frequency. Allele counts are summed and divided by the average allele number. A Fisher's exact test compares case and reference cohorts, with p-values adjusted via the Benjamini-Hochberg method.

Results: The workflow substantially increases statistical power in small case cohorts, enabling the identification of significant associations with disease-causing genes. Preliminary analyses suggest it is feasible to identify unrecognized, significantly correlated genes in rare disease cohorts of individuals screened free of known disease-causing mutations, with cohort sizes as small as 200 subjects.

Conclusion: This approach leverages gnomAD datasets to bolster statistical power in studies with small case cohorts. It enables the detection of genes or regions with increased variant burden, addressing the lack of individual-level data. The workflow provides a robust, adaptable pipeline for genetic association studies.

Background: With the latest advancements in throughput and quality, long-read sequencing (LRS) has the potential to replace existing short-read technologies as the gold standard for human genome analysis, in clinical diagnostics as well as in research. However, one major hurdle for clinical implementation is a lack of comprehensive bioinformatics pipelines that take the analysis all the way from raw data analysis to ranking and prioritisation of variants.

Material and Methods: Here we introduce Nallo, a Nextflow pipeline designed for analysis of data from both from PacBio and ONT. Nallo is easy to set up and runs on all common compute environments. Although developed for rare disease analysis, Nallo can also be used for population sequencing and other applications. The code and infrastructure adhere to the nf-core framework, which facilitates collaborative development across teams and borders[1].

Results: Nallo has been used to analyse over 100 research cases, and is currently being adopted by Swedish hospitals for the analysis of LRS data from patients affected by rare diseases. Nallo reports variants (SNVs, SVs, CNVs, TRs), which are then annotated, ranked and filtered. It also includes tools for genome assembly, methylation analysis and phasing. Nallo is openly available: https://github.com/genomic-medicine-sweden/nallo

Conclusion: Nallo provides a common analysis workflow that supports LRS research projects and translates into clinical practice. At present it is mainly used within Sweden, but we invite everyone to join the open source development and create a comprehensive LRS pipeline for the future together.

P17.020.A HIRUscan: a framework for prioritising germline variants through medical reports and genomic data

Kristina Ibañez[1], *Ander Martinez*[1], *Laura Martinez*[1], *Nooshin Bayat*[2], *Raul Valin*[1], *Serban Georgescu*[1]

[1]*Fujitsu Research of Europe, Madrid, Spain,* [2]*Fujitsu Research Of Europe Limited Sucursal En Espana, Madrid, Spain.*

Background: Genomic testing for rare diseases often remains slow, complex, and resource intensive. Over the past decade, advances in human genetics have significantly improved our ability to associate genetic variants to rare diseases. However, despite these powerful technologies, most rare disease patients still fail to receive a definitive diagnosis. Consequently, unsolved cases accumulate over time across hospitals and diagnostic

laboratories, creating a significant bottleneck in rare disease diagnosis.

Material and Methods: : HIRUscan is an advanced platform designed for variant interpretation and prioritisation in diagnostic and research genetic testing. Our deep learning AI models can handle texts in English and Spanish to extract phenotypic abnormalities from medical reports. These phenotypes are encoded hierarchically, according to the Human Phenotype Ontology (HPO) terms. By combining phenotype data with genomic information, HIRUscan classifies and prioritises genomic variants using an in-house pathogenicity prediction algorithm, in conjunction with advanced ACMG/ClinGen variant classification to assess variant significance. The platform generates a ranked list of candidate variants potentially linked to the patient's clinical features, facilitating streamlined and precise identification of disease-associated variants.

Results: Preliminary results indicate that HIRUscan achieves a positive predictive value of 93% (CI 91%–94.8%) across more than 1,200 well-phenotyped and clinically characterised families.

Conclusion: HIRUscan is a software solution for fast and accurate automated variant interpretation. It presents a unique opportunity to reanalyse unresolved rare disease cases by integrating comprehensive genomic data with detailed medical reports and significantly improve diagnostic outcomes.

P17.021.B Explainable AI for pathogenicity prediction of genetic variants in inherited heart disease

Nooshin Bayat[1], *Raul Valin*[1], *Julia González-Rincón*[2], *Laura Martinez Gomez*[1], *Kristina Ibanez*[1], *Shuya Abe*[3], *Masaru Fuji*[3], *Serban Georgescu*[4]

[1]*Fujitsu Research Of Europe Limited Sucursal En Espana, Madrid, Spain,* [2]*Fujitsu Technology Solutions S.A., Madrid, Spain,* [3]*Fujitsu Laboratory, Fujitsu Ltd, Kawasaki, Japan,* [4]*Fujitsu Research of Europe Ltd, Slough, United Kingdom.*

Background: Heart disease is a leading global cause of death. Inherited heart conditions, are familial heart disorders affecting about 1 in 250 people worldwide and can impact individuals of all ages [1]. AI algorithms have shown promise in predicting the pathogenicity of genetic variants, yet traditional models often lack explainability, limiting clinician trust. Explainable AI (XAI) improves transparency, supporting better clinical decision-making. This study evaluates an XAI algorithm for predicting pathogenicity in variants linked to inherited heart disease to improve classification accuracy and build trust in AI for enhanced diagnostic and personalized care outcomes.

Material and Methods: The Random Forest (RF) model [2] was tested to predict pathogenicity of variants located in 368 genes relevant to inherited heart diseases. The model was trained on ClinVar [3] data released in November 2023 and evaluated using three datasets from ClinVar released a year later (November 2024), ensuring it was tested on unseen data: (A) 354 novel variants (177 pathogenic, 177 benign), (B) 694 conflicting variants (350 pathogenic, 344 benign), and (C) 66 reclassified VUS (28 pathogenic, 38 benign).

Results: The RF model demonstrated high accuracy: 99.44% for novel variants, 99% for conflicting variants, and 95% for reclassified VUS. The ability of the model to provide clear explanations for these predictions was a key strength, improving trust in its outcomes.

Conclusion: The RF model showed strong performance and transparent predictions, supporting clinical decision-making. Further validation and refinement of explainability are needed to enhance clinical utility and ensure reliable real-world application.

P17.022.C Performing validity checks to support data integration for federated gnomAD releases

Kristen Laricchia[1,2], *Katherine Chao*[1,2], *Qin He*[1,2], *Daniel Marten*[1,2], *Michael Wilson*[1,2], *Julia Goodrich*[1,2], *gnomAD Consortium*[3], *Heidi Rehm*[1,2]

[1]*The Broad Institute of MIT and Harvard, Cambridge, MA, USA,* [2]*Massachusetts General Hospital, Boston, MA, USA,* [3]

Background: The Genome Aggregation Database (gnomAD) provides a reference dataset of genomic data that aids users in interpreting genetic variation. To further increase the size and diversity of this dataset, future releases will utilize a novel federated approach by incorporating aggregate frequencies from various groups otherwise restricted from sharing individual-level data, particularly sources for underrepresented groups with stricter data access policies. Ensuring the consistency and completeness of data from various sources will be essential to mitigate potential issues and delays during data integration and the production of a federated gnomAD release.

Material and Methods: We have produced a pipeline to perform validity checks on federated data. This pipeline minimizes complications at the initial stages of data integration by flagging irregularities, which includes identifying annotations with a high percent missingness, ensuring metrics align with expected patterns for chrX and chrY variants, and verifying that subset metrics aggregate to expected totals.

Results: This pipeline was tested using the gnomAD dataset and integrates previous assessments designed to prevent discrepancies in releases. The validity check pipeline is flexible in accommodating varied annotation names and formats. It outputs a report summarizing potential issues with data integrity to be resolved before proceeding with the quality control pipeline on variant data.

Conclusion: Producing a federated dataset presents new challenges requiring innovative methods. Incorporating validity checks early in the production process will help to accelerate data harmonization as we work toward producing a federated gnomAD release with high-quality allele frequency information from diverse sources of genetic data.

P17.024.A OrthoClust: a method for improved gene clustering using single cell CRISPR screening data

T. Demirtas, *M. Billmann;*

Institute of Human Genetics, University of Bonn & University Hospital Bonn, Bonn, Germany

Background: Understanding complex biological systems demands the integration of multi-dimensional omics information. Single-cell-resolved CRISPR screens have become a promising tool for systematically mapping gene function in a cell. In such an experiment, many genes are perturbed in a pool of cultured cells, always one specific cell contains one gene perturbation, and the perturbation barcode can be linked to that cell's transcriptome. While this technology has high potential, better computational tools are needed to optimize functional data extraction.

Material and Methods: In this study, we propose a new computational method that integrates the two orthogonal dimensions recorded in a typical single-cell perturbation experiment, enabling more precise characterization of functional annotation. Using the first genome-scale single-cell gene perturbation dataset published by Replogle and colleagues [1], we created two types of networks: an expression profile network, derived from gene expression vectors, and a perturbation profile network, derived from gene perturbation vectors. We then combined these networks into a single integrated network, leveraging their complementary transcriptional and functional signals.

Results: The integrated network, validated against CORUM, GO:BP, and PATHWAY annotations, showed superior precision-recall metrics and better identification of biologically significant complexes [2]. Using a Precision-Recall AUC threshold of 0.3, we found that 2 complexes surpassed it in the expression profile network, 24 in the perturbation profile network, and 38 in the integrated network, demonstrating a performance gain.

Conclusion: Our findings highlight the advantages of integrating transcriptional and perturbation profile data in single-cell CRISPR screens to improve functional insight extraction.

P17.025.B Genomic analysis of early-onset Parkinson's disease using long-read sequencing and optical genome mapping

André Fienemann[1], *Theresa Lüth*[1], *Susen Schaake*[1], *Carolin Gabbert*[1], *Marius Möller*[2], *Hauke Busch*[2], *Kristian K. Ullrich*[3], *Norbert Brüggemann*[1], *Katja Lohmann*[1], *Lara M. Lange*[1,4], *Sally A. Cowley*[5], *Philip Seibler*[1], *Jonas A. Gustafson*[6], *Danny E. Miller*[6], *Alexander Zimprich*[7], *Elisabeth Stögmann*[7], *Theresa König*[7], *Christine Klein*[1], *Joanne Trinh*[1]

[1]*Institute of Neurogenetics, University of Lübeck, Lübeck, Germany,* [2]*Institute of Experimental Dermatology, University of Lübeck, Lübeck, Germany,* [3]*Division Scientific IT Group, Max Planck Institute for Evolutionary Biology, Plön, Germany,* [4]*Laboratory of Neurogenetics, National Institute on Aging, National Institutes of Health, Bethesda, MD, USA,* [5]*James and Lillian Martin Centre for Stem Cell Research, Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom,* [6]*Division of Genetic Medicine, Department of Pediatrics, University of Washington, Seattle, WA, USA,* [7]*Department of Neurology, Medical University Wien, Wien, Austria.*

Background: While patients with Early-onset Parkinson's disease (EOPD, disease onset <50 years) often have a family history of PD, the occurrence of PD in many patients remains sporadic. The present study presents a new pipeline for structural variant (SV) detection to elucidate the contribution of pathogenic SVs in the disease etiology of EOPD by leveraging both Oxford Nanopore long-read sequencing (ONT) and Bionano optical genome mapping (OGM).

Material and Methods: ONT was performed for a discovery cohort of $N = 50$ unsolved EOPD patients. For a subset of $N = 14$, OGM was additionally conducted. A subsequent analysis pipeline based on AnnotSV, SVAFotate, ANNOVAR, and needLR was employed to detect, annotate, and filter for rare (population allele frequency ≤ 1%) pathogenic SVs and single nucleotide variants (SNVs) in known movement disorder genes or newly evaluated candidate genes. Variants (>500 bp) identified by ONT and OGM were compared using a range of ±8 kb based on the mean 95% CI of the start/end position of all OGM calls.

Results: Heterozygous deletions in *DNMT1* (123 kb), *DLG2* (398 kb), *CHMP1A* (167 bp), and *ZNF718* (46 kb) were detected. Heterozygous nonsynonymous SNVs were detected in *ITPR1*, *CHCHD2*, *PDE10A*, and *PSMF1*. About 58.6% of OGM deletions and 49% of insertions overlapped with ONT.

Conclusion: The established pipeline identified potential pathogenic variants affecting the disease etiology of EOPD. While both methods can detect large SVs, the presented comparison illustrates different aptitudes regarding insertion detection and highlights their complementary applicability. Novel variants in *PDE10A*, *PSMF1*, *DLG2*, *CHMP1A*, and *ZNF718* warrant replication in other PD cohorts.

P17.026.C Evaluation of the efficacy of neural networks and regression analysis in predicting osteoporosis using clinical and genetic data

Bulat Ildusovich Yalaev, *Rita Khusainova*

Endocrinology Research Centre, Moscow, Russian Federation.

Background: High hopes are placed on advanced developments in neural network training that aim to predict osteoporosis at an early stage, including the use of large amounts of genetic data. We conducted a comparative evaluation of neural network and regression analysis techniques to develop predictive risk models for osteoporosis, based on clinical factors and DNA markers of osteoporosis.

Material and Methods: The models were trained using genotype data from 152 DNA polymorphic variants and clinical parameters of 701 women and 501 men from Russia. The input parameters included anthropometric measurements, data on gender, bone mineral density (BMD) (Hologic), as well as genotyping results for candidate gene loci and replication results from a genome-wide association study (with the selection of the significant markers). Verification and testing were carried out in the Google Colab environment on the TensorFlow open source platform, as well as on the CatBoost. The Keras API was used as a high-level application programming interface for TensorFlow.

Results: The highest efficiency in neural network learning was achieved by the low BMD prediction model (AUC = 0.81), which included variants of the OPG gene (rs2073618, rs2073617, rs7844539, rs3102735, rs3134069) and variants of microRNA binding sites (rs1031820, rs6854081, rs2910164, rs10793442, rs1054204, rs11540149). The clinical and genetic model for predicting fractures in men had the highest level of prognostic

significance and included low BMD and the rs1712 variant (AUC = 0.905).

Conclusion: For the first time, high efficiency of neural network learning technology has been demonstrated for predicting osteoporosis based on risky single-nucleotide variants.

P17.027.D Panthera: A Transformer-Based Tool for Identifying Splicing Defects and Resolving Rare Undiagnosed Genetic Diseases

*Tommaso Tabaglio[1], Wei Yuen Cher[1], Jin Rong Ow[1], Keng Boon Dave Wee[1], **Ernesto Guccione**[2]*

*[1]A*STAR, Singapore, Singapore, [2]Icahn School of Medicine at Mount Sinai, New York, NY, USA.*

Background: Splicing defects contribute to genetic diseases, but their detection remains challenging due to complex multi-variant interactions, often unique to population-specific backgrounds. Many pathogenic splice variants remain undiagnosed, highlighting the need for advanced computational tools in clinical genetics.

Materials and Methods: We developed **Panthera**, an algorithmic toolset leveraging a **stacked transformer encoder model** trained on CHM13 and JG3.0.0 reference genomes. Panthera predicts splicing defects across **64 distinct pangenomic backgrounds** spanning five human superpopulations, enabling detection of complex **splice haplotypes** often missed by conventional analyses.

Results: Panthera accurately identified **known pathogenic splice haplotypes** in **CFTR** and **FAS** and uncovered **three novel splice-altering variants** in **PCCB** and **MLH1**, functionally validated using minigene assays. It was instrumental to diagnose novel deep-intronic causative mutations in the Citrin gene in a Japanese pool of patients. Its ability to detect splicing disruptions from both de novo mutations and ancestral genetic backgrounds demonstrates its potential for resolving undiagnosed genetic disorders.

Conclusion: Panthera is a **clinically applicable, population-aware tool** designed to improve genetic diagnosis by identifying splicing defects that might otherwise go unnoticed. We invite **clinicians, geneticists, and researchers** to collaborate and apply Panthera in clinical cases to help diagnose **previously unexplained genetic diseases**. Our lab welcomes partnerships to further explore novel disease-associated splicing variants and improve patient outcomes.

P17.028.A A fast, sensitive, and versatile tool for annotation and differential feature detection at single cell level

***H. Su**, X. Chen, W. Yang;*

The University of Hong Kong, Hong Kong SAR, China

Background: RNA diversity and functionality intricately underpin the historical, present, and future states of cells and tissues. RNA sequencing serves as a transformative tool, enabling the comprehensive quantification of mRNA species and providing profound insights into underlying molecular processes. Advances in single-cell technologies, such as scRNA-seq and scATAC-seq, have revolutionized the study of transcriptional heterogeneity and chromatin accessibility, providing cell-type-specific resolution in complex tissues. However, challenges such as data sparsity and subjective annotation processes hinder the accuracy of differential feature detection and cell-type annotation.

Material and Methods: To address these limitations, we present OTMODE, a Python-based framework leveraging optimal transport theory to improve differential feature identification and annotation accuracy in single-cell multi-omics data.

Results: In our benchmarking analyses, OTMODE consistently outperformed other state-of-the-art methodologies, such as DESeq2[1], MAST[2], and SnapATAC2[3] and demonstrated robust performance across diverse simulated datasets, including scRNA-seq and scATAC-seq data. Furthermore, OTMODE exhibited excellent control of false-positive rates in simulated datasets devoid of differentially expressed features, underscoring its precision. Additionally, OTMODE integrates seamlessly with Scanpy and demonstrates superior performance in computational efficiency and annotation reliability across simulated and real datasets, offering a robust and user-friendly solution for single-cell analysis.

Conclusion: Our study demonstrates that OTMODE effectively addresses these challenges by overcoming data sparsity and cellular heterogeneity while providing a universal framework capable of handling various types of omics data. We believe that the proposed framework has the potential to advance the exploration of complex and nuanced alterations in biological mechanisms across diverse omics contexts.

P17.029.B Integrating Multi-Omics and Machine Learning through Polygenic Risk Scores in Middle Eastern Populations for Cardiometabolic Traits

***Abdullah Shaar**[1], Mohamed Elshrif[1], Ehsan Ullah[1], Georges Nemer[2], Mohammed Bashir[3], Mohamad Saad[1]*

[1]Qatar Computing Research Institute, Hamad Bin Khalifa University, Doha, Qatar, [2]College of Health and Life Sciences, Hamad Bin Khalifa University, Doha, Qatar, [3]Hamad Medical Corporation, Doha, Qatar.

Background: Cardiometabolic traits like Type 2 Diabetes (T2D) and lipids share complex interrelated pathophysiology. Polygenic risk scores (PRSs) have been developed mainly in European cohorts, often focusing on single traits and lacking multi-omics integration. Here, we evaluated the use of machine learning (ML) to integrate multi-omics data through PRS, and explored the importance of ensemble learning to develop multi-trait PRS in the Middle East.

Material and Methods: Qatar Precision Health Institute dataset was used (13,994 whole genome sequence individuals, 2,906 with metabolomics and 2,845 with proteomics data). We studied 22 cardiometabolic traits (e.g., T2D, Hypertension, LDL-C, etc.). Local PRSs were developed, and 1,072 existing PRSs were evaluated. PRSs were combined linearly (ensemblePRS) or using ML models: support vector machines (SVM), random forests (RF), and xgboost.

Results: 948 of 1,072 PRS were associated with at least one trait ($P < 4.66 \times 10^{-5}$). For example, PGS000020 was the best for T2D (OR = 1.75, CI [1.54–1.99]; AUC = 0.60, CI 95% [0.58–0.63]; $P = 5.14 \times 10^{-18}$) and PGS003871 was the best for LDL-C ($R^2 = 0.12$, CI 95% [0.10–0.14]; $P = 2.91 \times 10^{-137}$). Local PRS slightly improved performance for 9 of 22 traits. EnsemblePRSs outperformed single PRSs (AUC = 0.62 vs. 0.60 for T2D). Xgboost surpassed RF and SVM (AUC = 0.64, 0.60, 0.61 for T2D, respectively). Multi-trait PRSs had an advantage over trait-specific PRSs, especially for lipids. Combining ensemblePRSs and xgboost predictions showed the best performance. Finally, adding omic scores showed marginal improvement for hypertension only.

Conclusion: Public PRSs transfer well to Middle Easterns for many cardiometabolic traits. Multi-trait and trait-specific PRSs combined with ML tools had the best performance.

P17.030.C AI-Driven Automation of Genetic Variant Interpretation: Enhancing Clinical Reporting with Large Language Models

Jean-Marie Ravel, Jiri Ruzicka, Nicolas Philippe, Dimitri Larue, Nicolas Duforet, Jérôme Audoux

SeqOne Genomics, Montpellier, France.

Background: Interpreting genetic variants and writing structured reports is a time-consuming task that requires synthesizing diverse sources of evidence. Large Language Models (LLMs) are well suited for this challenge, as they can process vast amounts of textual data, extract key insights, and generate structured interpretations efficiently.

Methods: We developed a Python-based computational pipeline integrating Retrieval-Augmented Generation (RAG) and few-shot prompting techniques to enhance the quality of AI-generated interpretations. The system employs multiple specialized AI agents: (1) a literature review agent that retrieves and prioritizes relevant publications via LitVar, with additional fine-tuning based on ClinVar pathogenic variant-associated literature; (2) a clinical feature extraction agent that synthesizes phenotype descriptions from OMIM in regards of patient's HPO terms; and (3) a classification agent that structures the final output based on ACMG/AMP variant interpretation guidelines.

Results: The AI-generated commentaries provide structured and clinically relevant interpretations of genetic variants. Each report consists of three key sections: (1) a description of the variant, including molecular characteristics and inheritance patterns; (2) a synthesis of associated clinical features based on OMIM and related databases; and (3) a proposed classification, integrating genotype-phenotype correlations and literature-based evidence.

Conclusion: By leveraging LLM-powered AI agents and computational algorithms, our approach streamlines the process of variant interpretation and report generation. This enables clinicians to focus on complex cases while benefiting from AI-assisted summaries that ensure consistency and scientific rigor. Moreover, by incorporating curated input data and expert annotations, we enhance the original content generated by human experts, ultimately optimizing time in clinical practice.

P17.031.D Transformer-Driven multi-modal integration of phenotypic, facial, and genomic data for optimized rare disease variant prioritization

Meghna Bhasin[1], *Tzung-Chien Hsieh*[2], *Alexej Knaus*[1], *Peter Krawitz*[3]

[1]*Institute for Genomic Statistics and Bioinformatics, Bonn, Germany,* [2]*University Hospital Bonn, Bonn, Germany,* [3]*IGSB, Bonn, Germany.*

Background: Variant prioritisation is a critical step in genomic analysis, crucial for identifying disease-associated genetic variations. Improving the variant prioritization accuracy requires the integration of phenotypic, facial, and genomic data. Existing tools often struggle to effectively combine these diverse data types. This study introduces a transformer-based framework that integrates Human Phenotype Ontology (HPO) terms, facial image embeddings, and genomic variant annotations to enhance variant prioritization.

Material and Methods: The framework processes phenotypic data encoded as HPO terms, facial images converted into embeddings, and genomic variants annotated with scores such as CADD and allele frequencies. These modalities are preprocessed and embedded in a shared latent space. A multi-modal transformer model dynamically weighs their contributions using attention mechanisms, prioritizing variants based on the combined input.

Results: Performance was evaluated using whole-exome sequencing data from 186 patients with rare disorders. The framework achieved improved diagnostic accuracy, outperforming existing tools such as PEDIA and Exomiser. Integration of facial phenotypes improved accuracy in syndromes with facial dysmorphism, while dynamic attention mechanisms enhanced the model's ability to prioritize causative variants in phenotypically diverse cases.

Conclusion: This study demonstrates the potential of transformer architectures to integrate phenotypic, facial, and genomic data for rare disease diagnostics. The framework surpasses current state-of-the-art tools, providing a scalable and accurate method for variant prioritization. Future extensions will explore how the model can adapt to patient-specific features, such as age and ethnicity, to improve prioritization accuracy in diverse populations.

P17.032.A Assessing nextflow transcriptomic pipelines for identifying candidate genes associated with neurodevelopmental disorders

Carlos A. Enriquez Sandoval[1], *Giulia De Riso, Postdoctoral fellow*[2], *Maria Cerminara*[3], *Slavica Trajkova*[4], *Chiara Fiorentino*[2], *Alessandra Bianchi*[3], *Marco Fontana*[5], *Iris Chen*[3], *Federico Zara*[5], *Silvia Boeri*[3], *Elisa De Grandis*[3], *Alfredo Brusco*[4], *Aldamaria Puliti*[5], *Michele Pinelli*[2], ***Emidio Capriotti***[1]

[1]*University of Bologna, Bologna, Italy,* [2]*University of Naples Federico II, Naples, Italy,* [3]*IRCCS Istituto Giannina Gaslini, Genoa, Italy,* [4]*University of Torino, Torino, Italy,* [5]*University of Genoa, Genoa, Italy.*

Background: Intellectual disorders (ID) and autism spectrum disorders (ASD) are heterogeneous neurodevelopmental (NDD) conditions with a strong genetic component. RNA-seq analysis is a powerful tool for the identification of aberrant or outlier gene expression and alternative splicing as functional evidence to support rare disease study and diagnosis. Here, we evaluated the effectiveness of Nextflow pipelines in identifying candidate differentially expressed genes in individuals with ID and/or ASD.

Materials and Methods: RNA sequencing (RNA-seq) data from 11 patients with ID and/or ASD and 7 family controls were analyzed using the nf-core *rnaseq* pipeline for quality control and expression quantification. Differential gene expression analysis was performed using the nf-core *differentialabundance* pipeline. Identified DEGs were further investigated through GeneTrek and DisGeNET to assess their relevance to NDD.

Results: The combination of *rnaseq* and *differentialabundance* pipelines allowed the identification of 6 over-expressed and 4 under-expressed protein-coding genes in the patient cohort. According to GeneTrek, among the over-expressed genes, PTK7 was associated with neurodevelopmental disorders with high confidence, while 2 other genes were considered potential candidates for further investigation. For the under-expressed genes, 3 out of 4 are also listed as possible candidates for neurodevelopmental disorders.

Conclusion: Despite the limited sample size, our findings highlight the effectiveness of Nextflow-based pipelines for RNA-seq analysis in identifying candidate genes associated with ID and/or ASD. Notably, PTK7 has been previously linked to neurodevelopmental disorders, while the other differentially expressed genes emerged as possible candidates for further investigation.

P17.033.B Latent-Variable Models for Integrating Rare and Common Variants in Disease Risk Prediction

Federico Billeci, *Silvia Bonàs Guarch, Jonathan Frazer, Mafalda Dias*

Center of Genomic Regulation, Barcelona, Spain.

Background: Current genetic models for disease prediction lack a unified framework to integrate both rare and common variants, as these are typically studied independently. This dichotomous approach likely contributes to diagnostic gaps in rare diseases and limits the identification of high-risk individuals for common traits.

Material and Methods: We propose a generative, latent-variable modelling framework to predict the joint impact of common and coding rare variants enabling the discovery of new disease subclasses. Rare variants are collapsed at the gene level using popEVE pathogenicity scores as weights, improving performance while reducing genotype dimensionality. This allows for the inclusion of a large number of rare variants while retaining single-variant information. Phenotype prediction is achieved through a Variational AutoEncoder (VAE) -like architecture that creates a latent representation of the genetic variants. Each individual's genotype is converted to a representation that disentangles common and rare variant contributions and maps their relationship to phenotypic severity.

Results: Using UK Biobank imputed genotypes and exome sequencing data (N ~ 400,000), we applied our framework to highly heterogeneous diseases with unclear diagnostic criteria and frequent comorbidities, including Type 2 Diabetes (T2D), Coronary Artery Disease and Hypertension. Our model significantly improved the identification of high-risk individuals for T2D and related complications compared to existing methods.

Conclusion: We developed a family of models that quantify the contributions of rare and common variants to individual disease risk. Our approach expands the number of patients who can receive a clearer genetic diagnosis, leading to more actionable therapeutic strategies.

P17.034.C Estimating the genetic basis of quantitative traits across populations

Ekaterina Maksimova, *Gasper Tkacik, Ilse Krätschmer, Matthew R. Robinson*

Institute of Science and Technology Austria, Klosterneuburg, Austria.

Background: Genome-wide association studies are being disproportionately skewed towards analyses in the European population, which induces health disparities for underrepresented groups and hinders understanding of underlying genetic mechanisms. However, these issues are not resolved by simply increasing the diversity of participants, while applying conventional methodology that does not account for differences in allele frequencies, linkage disequilibrium (LD) patterns, and environmental exposures across populations.

Material and Methods: We propose a multivariate Bayesian approach designed to work on summary statistics and individual-level data, which models effect sizes jointly both across genome and across populations and explicitly utilizes population-specific allele frequencies and LD. We compared the discovery and genomic prediction performance of this approach and other state-of-the-art methods on simulated data and height data from the UK Biobank.

Results: The proposed joint modelling of effect sizes allows for precise estimation of the covariance of effect sizes and testing for shared and population-specific effects. In simulation analyses, we demonstrate how such multivariate modelling leads to improved fine-mapping and cross-group polygenic prediction accuracy. On the real data, the proposed summary statistics model outperforms other existing multi-ancestry methods in prediction accuracy and reaches heritability estimates comparable to the results of the best individual-level models (e.g. 0.67 for height for European ancestry).

Conclusion: We provide empirical evidence that discovery and genomic prediction are greatly enhanced by analyzing effect sizes across genome and populations jointly. Therefore, multivariate analysis incorporating multi-ancestry data should be commonplace, improving our ability to infer shared and population-specific genetic architecture patterns of human complex traits.

P17.035.D The shared and differential genetic risk factors of neurodegeneration

Tomas De Sousa Gomes, *Emrah Kaçar, Ciara O'Donoghue, Russell L. McLaughlin, Ross P. Byrne*

Trinity College Dublin, Dublin, Ireland.

Background: Neurodegenerative diseases comprise many complex pathologies that result in neuronal loss. Heterogeneous in nature, they often exhibit overlapping symptomatologies, protein aggregates, and comorbid psychiatric disorders, resulting in diagnostic difficulties for even experienced neurologists. Recent literature suggests overlapping genetic risk for these diseases, which could be core to the biology of neurodegeneration.

Material and Methods: This research aims to identify the shared genetic risk factors that contribute to nine neurodegenerative traits, namely Alzheimer's Disease, Amyotrophic Lateral Sclerosis, Creutzfeldt-Jakob Disease, Frontotemporal Dementia, Lewy-body Dementia, Multiple Sclerosis, Neuromyelitis Optica, Parkinson's Disease, and Vascular Dementia. We analysed summary statistics from their largest genome-wide association studies (GWAS) using LD-score regression (LDSC) and genomic structural equation modeling (GenomicSEM) to examine genetic correlations between traits and model their complex interrelatedness. To uncover shared SNPs between neurodegenerative disorders, we used multi-trait analysis of GWAS (MTAG) and conjunctional false discovery rate (conjFDR) analysis as complementary methods. Gene ontology analysis was run on positionally mapped genes from significant loci using FUMA.

Results: We identified genetic correlations and a shared latent genetic factor between several neurodegenerative traits. MTAG analyses revealed 129 novel risk loci significantly associated with our nine neurodegenerative traits, 25 of which were reinforced by conjFDR as shared between two or more neurodegenerative traits. These loci were enriched for differential expression in dopaminergic neurons and several gene ontologies relevant to neurodegeneration (e.g. microglial cell activation, neuron death regulation).

Conclusion: Multi-trait analysis of neurodegenerative traits reveals shared genetic risk loci and improves our biological understanding of core neurodegenerative mechanisms.

P17.036.A Characterising the genetic architecture of thousands of human traits

Ole Hansen[1], *Jakob Grove*[2], *Bjarni Vilhjálmsson*[1]

[1]*Aarhus University, Risskov, Denmark,* [2]*Aarhus UniversityDepartment of Biomedicine, Aarhus C, Denmark.*

Background: Understanding the genetic architecture of health outcomes is important for improving disease risk prediction models and advancing personalised medicine. This includes estimating heritability, polygenicity, importance of selection, as well as evaluating the prediction accuracy of polygenic scores (PGS). In this study we present an efficient and parallelized pipeline that uses LDpred2-auto to efficiently infer the genetic architecture of human traits. We apply this to thousands of traits, creating a comprehensive map of genetic architecture for human diseases and phenotypes.

Material and Methods: GWAS summary statistics were obtained from the GWAS Catalog and filtered based on numerous criteria, including effective sample size (N < 50000) and having at least one genome-wide significant association. After applying LDpred2-auto with the HapMap3+ variants, we further filtered the results based on convergence. The pipeline supports high-performance computing and is publicly available on Github (https://github.com/olex2148/PGS-pipeline).

Results: We downloaded 64592 GWAS summary statistics, after filtering we applied LDpred2-auto to 2030 outcomes. LDpred2-auto converged without issues for 1908 outcomes, where we inferred PGS prediction accuracy R2), polygenicity p, SNP heritability SNP-h2, and selection coefficient α. We grouped these model parameters by trait categories based on ontology terms. When possible we also estimated observed out-of-sample prediction accuracy in the Lundbeck Foundation Initiative for Integrative Psychiatric Research (iPSYCH) cohort.

Conclusion: Our scalable LDpred2-auto pipeline can efficiently infer key parameters for thousands of heritable diseases and phenotypes. Our results provide a comprehensive map of genetic architecture in human health outcomes and provide important insights into disease aetiology and how to develop robust PGSs.

P17.037.B Next-generation phenotyping facilitates the identification of structural brain malformations in rare disorders through computational brain MRI analysis

Tzung-Chien Hsieh[1], *Bharatendu Chandra*[2,3], *Hannah Weiland*[1], *Merle ten Hagen*[1], *JingMei Li*[1], *Shriya Jaddu*[4,5], *Chi-Chia Chang*[6], *Sun-Yuan Hsieh*[6], *Hsin-Hung Chou*[7], *Gholson J. Lyon*[8], *William Dobyns*[9], *Wei-Liang Chen*[4,5]

[1]*Institute for Genomic Statistics and Bioinformatics, University Hospital of Bonn, Bonn, Germany,* [2]*University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA, USA,* [3]*Division of Medical Genetics and Genomics, Stead Family Department of Pediatrics, University of Iowa Hospitals and Clinics, Iowa City, IA, USA,* [4]*Department of Pediatric Neurology, Children's National Hospital, Washington, WA, USA,* [5]*Department of Genetics, George Washington University, Washington, WA, USA,* [6]*Department of Computer Science and Information Engineering, National Cheng Kung University, Tainan, Taiwan,* [7]*Department of Computer Science and Information Engineering, National Chi Nan University, Nantou, Taiwan,* [8]*Department of Human Genetics, New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY, USA,* [9]*University of Minnesota, Pediatric Genetics & Metabolsim, Minneapolis, MN, USA.*

Background: Many rare disorders present with structural brain malformations, posing challenges for neurologists in identifying the "brain gestalt" associated with these conditions. Next-generation phenotyping (NGP), which has successfully recognized facial gestalt of syndromes by training thousands of patient photos, can similarly be applied to brain MRI data. By learning patterns from brain MRIs, NGP can detect structural abnormalities such as lissencephaly. This study introduced a deep learning-based NGP approach to identify brain malformations, providing clinicians with diagnostic support for rare disorders.

Material and Methods: We curated 663 brain MRIs spanning 56 disorders in the GestaltMatcher Database. Using transfer learning with ResNet-50, pre-trained on the fastMRI dataset (6,970 MRIs) for age prediction, we encoded MRIs into feature vectors, creating the "Clinical Brain Phenotype Space (CBPS),"

where proximity reflects phenotypic similarity. Additionally, 1,279 pediatric MRIs from public datasets were encoded as healthy controls. Feature-space distances were used to estimate the probability of associated disorders.

Results: Evaluating Mowat-Wilson syndrome, lissencephaly, tubulinopathy, *RNU4-2*, and Ogden syndrome, CBPS distinguished conditions from controls with an accuracy of 90% via leave-one-out cross-validation. t-SNE visualization showed distinct clusters for these conditions, confirming CBPS's potential for phenotypic clustering and disease prediction.

Conclusion: This study demonstrated the application of NGP to structural brain malformations in rare disorders. While our initial analysis focused on five specific conditions, the results highlight the feasibility of extending this approach to a broader spectrum of genetic disorders.

P17.039.D A data-driven study to describe the functional landscape of pathogenic genomic variants in a cohort of 11,000 patients with rare diseases

Graciela Uría-Regojo[1], *Yolanda Benítez*[1,2], *Lidia Fernández-Caballero*[1,3], *Cristina Rodilla*[1,3], *Lucía LópezLópez*[1], *Almudena Avila-Fernandez*[1,3], *María José Trujillo-Tiebas*[1,3], *Berta Almoguera*[1,3], *Ana Osorio*[1,3], *Marta Corton*[1,3], *Carmen Ayuso*[1,3], *Pablo Minguez*[1,2,3]

[1]*Department of Genetics & Genomics, Instituto de Investigación Sanitaria-Fundación Jiménez Díaz University Hospital, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, 28040, Spain,* [2]*Bioinformatics Unit, Instituto de Investigación Sanitaria-Fundación Jiménez Díaz University Hospital, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, 28040, Spain,* [3]*Center for Biomedical Network Research on Rare Diseases (CIBERER), Instituto de Salud Carlos III, Madrid, 28029, Spain.*

Background: Rare diseases (RD) are life-limiting conditions with a low prevalence and a large phenotypic and genotypic heterogeneity. Diagnostic rates remain critically low (~50%) and need to be improved. This work employed a data-driven approach to extract global and specific genotype-phenotype associations in RDs.

Material and Methods: Genomic variants from a cohort of >11,000 patients with >125 RDs were studied using a common bioinformatics framework. Using case-control comparisons, we ranked the most frequent pathogenic variants (MFPVs) across ~30 groups of related diseases (GRDs). For each GRD, Gene Set Enrichment Analysis (GSEA) was performed on 1) the ranked MFPVs and on 2) the ranked genes based on their MFPVs' burden to extract associated functions (Interpro, Gene Ontology, Reactome, KEGG) and phenotypes (HPO). The GRDs were then analyzed collectively within a similarity network.

Results: We present ranked predicted pathogenic variants associated with each GRD, identifying 980 protein domains enriched in MFPVs across 37 GRDs. For each GRD we ranked genes based on their MFPVs' burden and provide a comprehensive overview of the biological processes, potentially affected pathways, and the resulting phenotypes. Additionally, we conducted a global analysis of shared and GRD-specific functions and phenotypes and we discussed a network of GRDs linked by their functional and phenotypic similarities. Finally, we wrapped these results into a prioritization strategy applied in the reanalysis of non-solved cases.

Conclusion: We report a global survey of variants, genes, functions and phenotypes associated to >125 RDs using a hypothesis-free strategy that feeds guided reanalysis of RD non-solved cases.

P17.040.A Generative Machine Learning approach to generate genotypes and phenotypes for privacy-preserving sharing of polygenic risk prediction data

Andrea Lampis[1,2], *Michela Massi*[1], *Nicola Pirastu*[1], *Andrea Mario Vergani*[1,2], *Matteo Matteucci*[2], *Francesca Ieva*[2,1], *Emanuele Di Angelantonio*[1,3]

[1]*Human Technopole, Milan, Italy,* [2]*Politecnico di Milano, Milan, Italy,* [3]*University of Cambridge, Cambridge, United Kingdom.*

Background/Objectives: Polygenic Risk Scores (PRSs) rely on GWAS summary statistics, which exclude non-linear SNP-SNP interactions. Machine Learning (ML) can model these effects and improve PRS performance, but requires large raw datasets, often inaccessible and difficult to combine due to privacy concerns. We propose a generativeAI method to create synthetic data, enabling privacy-preserving sharing and integration of raw data.

Methods: We trained a Latent Diffusion Model conditioned on a binary outcome in a simulated scenario: a disease with 20% prevalence determined by 2048 real SNPs. Generated data quality was assessed by comparing SNP correlation structure and concordance of GWAS betas between synthetic and real data, while verifying that no synthetic samples replicated real genotypes to assess privacy. Finally, predictive performance was tested by training ML models and canonical PRSs on generated or real datasets using Cross-Validation. We conducted the same experiments on real phenotypes, including Coronary Artery Disease (CAD) and Breast Cancer (BC) cases and controls from UK biobank.

Results: In simulated and real case scenarios, betas computed from synthetic and real data showed strong correlation (>0.75) while preserving SNP correlation structure and privacy. Cross-Validation showed that ML models trained on synthetic data performed comparably to canonical PRSs on real data.

Conclusions: We have shown that it is possible to generate realistic synthetic genotypic and phenotypic data that retain the information content of the training set while preserving participants' privacy. This enables the integration of restricted-access data for training powerful ML risk models, overcoming the limitations of current sumstats based PRSs.

P17.041.B Deep Learning Based Integration of MRI Radiomics and Multi-Omics for Medulloblastoma Subtyping and Prognosis prediction

Z. Wang, ***X. Nie****;*

CUHK, hongkong, China

Abstract

Background: Radiogenomics, which integrates imaging features with multi-omics data, provides a novel approach for understanding tumor heterogeneity and improving clinical decision-making. In medulloblastoma, a highly heterogeneous brain tumor, the correlation between MRI-based radiomic features and molecular characteristics remains underexplored. This study aims to develop imaging-driven biomarkers and predictive models for tumor subtype classification, prognosis assessment, and metastasis prediction using deep-learning approaches.

Materials and Methods: Multi-omics data, including methylation profiling, whole-genome sequencing (WGS), RNA sequencing (RNA-seq), single-cell ATAC-seq (snATAC), and spatial transcriptomics, were collected from multiple cohorts (Tiantan Cohort, EGA Cohort, ShijiTan Cohort). A structured workflow was designed, incorporating MRI-based methylation prediction, radiomic feature extraction from high-interest regions, deep-learning-based image-molecular association analysis, and validation of imaging biomarkers in patient stratification and prognostic modeling.

Results: MRI-based radiogenomic biomarkers successfully distinguished medulloblastoma subtypes, demonstrating strong correlations with molecular classifications. The integration of imaging and methylation data improved prognosis prediction, providing a non-invasive method for outcome assessment. Additionally, MRI features were significantly associated with metastasis-related molecular changes. Deep-learning models outperformed traditional approaches in imaging-molecular correlation analysis, enhancing the accuracy and reliability of tumor classification and risk prediction.

Conclusion: This study establishes a deep-learning-driven radiogenomic framework for medulloblastoma, offering a non-invasive strategy for tumor subtype classification, prognosis evaluation, and metastasis prediction. The findings highlight the potential of integrating MRI imaging with multi-omics data to advance precision oncology and facilitate personalized treatment strategies.

P17.042.C A Bayesian FPCA framework for modelling high-dimensional biomarker trajectories

*Salima Jaoua[1], Daniel Temko[2], **Hélène Ruffieux**[2]*

[1]University of Zurich, Zurich, Switzerland, [2]MRC Biostatistics Unit, University of Cambridge, Cambridge, Switzerland.

Background: The increasing availability of longitudinal measurements on large panels of gene products is set to improve our understanding of the molecular processes underlying disease risk and progression. While functional data analysis is an active area of research, methods for modelling complex multivariate functional dependencies remain limited.

Material and Methods: Motivated by a COVID-19 study conducted in Cambridge, we propose a Bayesian approach for representing high-dimensional biomarker curves, combining latent factor modelling and functional principal component analysis (FPCA). This approach captures correlations across biomarkers and time by positing that subsets of biomarkers contribute to a small number of FPCA expansions (e.g., representing latent disease processes) through biomarker-specific loadings. Subject variability is modelled using a small number of functional principal components, each characterised by a smoothly varying temporal function. We develop a variational inference algorithm, with analytical updates, that couples efficiency and principled parameter uncertainty quantification, and we propose strategies to learn the number of factors and FPCA components involved in each factor's expansion.

Results: Extensive numerical experiments illustrate the ability of the approach to (i) accurately estimate biomarker-specific loadings, FPCA latent functions and subject-specific component scores, and (ii) scale to high-dimensional datasets, e.g., with panels of 20,000 genes measured longitudinally for a few hundred subjects.

Conclusion: In the COVID-19 study, our framework helped disentangle disease heterogeneity and clarified which biomarkers coordinate over time, highlighting key biological pathways. More broadly, our approach also enables prediction of biomarker trajectories at the subject level, towards personalised treatments in a variety of disease contexts.

P17.043.D Analysis strategy for whole genome data in a national genome project in korea

***Jong Hwan Kim**, Jongbum Jeon, Soobok Joe, Haeun Seol, Jahyun Yun, Dongyoon Lee, Sol A Jeon, Jisu Kim, Yeyoung Yoon, Dayeon Kang, Keeok Haam, Ji Min Ahn, Jin Ok Yang, Haeyoung Jeong*

Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of.

Background: Efficient analysis of large-scale whole genome sequencing (WGS) data is crucial for advancing population genetics and identifying disease associations. Comprehensive strategies for WGS data can uncover environmental factors contributing to disease susceptibility, enabling tailored preventive measures and therapeutic interventions. Accumulating genomic data drives precision medicine, medical technology progress, and improved public health outcomes.

Material and Methods: We developed efficient strategies for germline and somatic variant calls, joint genotype analyses, and WGS-based gender and familial relationship analyses, tailored to user environments. Optimal CPU and memory configurations for GATK-based pipelines were explored, and a structured data storage system was established to ensure efficient data access and management.

Results: The strategies provided consistent analysis capacity regardless of scale, optimizing resource allocation. Enhanced CPU and memory configurations improved pipeline efficiency, while structured storage simplified data management. These results strengthened the scalability and reliability of WGS analyses under resource constraints.

Conclusion: This study optimizes the WGS analysis framework by significantly reducing processing times for germline, somatic, and joint genotyping. Furthermore, detailed specifications of required computational resources were provided, enabling users to easily implement and adapt the framework. These advancements prioritize user accessibility and efficiency, ensuring a streamlined approach to large-scale WGS data analysis.

P17.045.B Developing machine learning models for predicting cytochrome P450 ligand potency

***B. B. Sitabule**, S. S. Hazelhurst, H. H. Othman;*

University of the Witwatersrand, Johannesburg, South Africa

Background: Cytochrome P450 (CYP P450) enzymes are involved in over 90% of known metabolic reactions. To understand the

interaction between CYP P450 enzymes and their ligands, a variety of experiments have been performed including in silico methods such as machine learning (ML) predictions. ML models can predict the potential interactions of enzymes with ligands of interest.

Material and Methods: In this study, we developed ML models based on several algorithms including the Support Vector Machine, Extreme Gradient Boosting (XGBoost), Random Forest, Neural-network and K-Nearest Neighbor. The models serve to predict the potency of ligands with respect to CYP P450 enzyme sequences. To develop the models, over 30 000 enzyme assay data was acquired from BindingDB. From the data, CYP P450 enzyme sequences were encoded using AAindex indices and the ligands were encoded using molecular descriptors, which were generated using RDkit and Mordred. In addition, the IC50 values of the enzyme assays were also encoded.

Results: Dimensionality reduction was performed on the enzyme and ligand features prior to training the models. The performance of the models was assessed using accuracy scores and the Area Under the Curve (AUC) of the Receiver of Operating Characteristic curves. The best performing algorithm was XGBoost with an accuracy of 0.8 and an AUC score of 0.9.

Conclusion: This indicates that machine learning can be used to predict the potency of ligands with respect to enzymes of interest. Such models can be potentially employed for drug discovery, protein engineering and pharmacogenetics.

P17.046.C Mapping the mitochondrial RNA modification landscape using Nanopore sequencing

Lioba Lehmann[1], *Lukas Walz*[2], *Kristina Friedland*[2], *Susanne Gerber*[1]

[1]*University Medical Center Mainz, Mainz, Germany,* [2]*Institute of Pharmaceutical and Biomedical Sciences, Mainz, Germany.*

Background: N1-methyladenosine (m1A) modification in mitochondrial RNA (mtRNA) has emerged as a potential regulatory factor in neurodegenerative diseases, particularly Alzheimer's disease. Despite its potential significance, the distribution and dynamics of m1A modifications in disease states remain poorly understood, hindering accurate diagnostics and understanding of the disease. Thus, there is a strong need for novel analyses using Nanopore sequencing.

Material and Methods: We employed Nanopore sequencing to analyze mtRNA from Alzheimer's disease patients and age-matched controls. This technology enables direct detection of RNA modifications through characteristic current signal perturbations as native RNA molecules traverse the nanopore. A novel neural network-based detection tool was developed and trained on synthetic oligonucleotides containing known m1A sites. The analysis pipeline integrates multiple bioinformatic tools and custom visualization methods for comprehensive modification mapping.

Results: We profiled the RNA modification landscape of mtRNA from healthy human blood samples, establishing baseline modification patterns. Initial analyses demonstrate successful detection and mapping of m1A modifications across mitochondrial transcripts with high confidence. Systematic benchmarking of our neural network approach against existing tools shows improved detection accuracy. Comparative analysis revealed distinct m1A distribution patterns between patient and control groups.

Conclusion: While multiple RNA modifications exist in mtRNA, current detection tools show considerable variability in their results. Despite these challenges, Nanopore sequencing proves to be a valuable tool for direct RNA modification detection. We establish a robust framework for analyzing mitochondrial RNA modifications in neurodegenerative diseases, aiming to identify novel biomarkers for early disease detection and monitoring.

P17.047.D Resources for structural variant interpretation: Human Genome Structural Variation Consortium data and the Ensembl Variant Effect Predictor

Olanrewaju J. Austine-Orimoloye[1], *S Nakib Hossain*[1], *Diana Lemos*[1], *Likhitha Surapaneni*[1], *Jamie Allen*[1], *Sarah E. Hunt*[1], *Mallory A. Freeberg*[1], *Human Genome Structural Variation Consortium*[2]

[1]*EMBL-EBI, Hinxton, United Kingdom,* [2]

Background: The accurate identification and annotation of structural variants (SVs) is essential for genomic research and clinical variant interpretation. The Human Genome Structural Variation Consortium (HGSVC) exists to create accurate catalogues of precisely defined SVs and reusable methods for SV characterisation, interpretation and visualisation.

Material and Methods: To facilitate discovery, we have integrated HGSVC data into the International Genome Sample Resource (IGSR), a FAIR resource for genomic data sharing. To accelerate SV interpretation, we have extended the Ensembl Variant Effect Predictor (Ensembl VEP) functionalities.

Results: The IGSR data portal enables the discovery and download of HGSVC datasets, filtering by data type, sample or technology. The latest release includes a catalogue of precisely defined SVs from the haplotype-resolved assemblies of 65 individuals of diverse ancestry. These near-complete assemblies provide a more detailed insight into human genome variation. Ensembl VEP annotates SVs with the genes they overlap and predicts likely impact. Further information on gene function, reported phenotype association and measures of tolerance to loss of function variation, hyposensitivity and triplosensitivity are reported to aid interpretation.

Conclusion: These resources demonstrate advances in SV resolution and annotation which can help advance understanding of disease association and mechanism which could accelerate disease diagnosis.

P17.048.A Validation of identity-by-descent tools applied to whole-exome sequencing data

Maria Fahlström[1], *Camilla Novy*[1,2], *Geir Braathen*[1], *Øystein Holla*[1], *Magnus D. Vigeland*[3], *Trygve Holmøy*[2,4], *Helle Høyer*[1,2]

[1]*Department of Medical Genetics, Telemark Hospital Trust, Skien, Norway,* [2]*Faculty of Medicine, Institute of Clinical Medicine, University of Oslo, Oslo, Norway,* [3]*Department of Forensic Medicine, Oslo University Hospital, Oslo, Norway,* [4]*Department of Neurology, Akershus University Hospital, Lørenskog, Norway.*

Background: In many studies, it is important to know the degree of relatedness between participants. Most current tools for relatedness detection are primarily designed for SNP array or whole-genome sequencing data. This poses a challenge for labs relying on whole-exome sequencing (WES), as it remains unclear how these tools perform with WES data. We investigated the use

of WES data to uncover close and distant relationships by validating four identity-by-descent (IBD) tools: TRIBES, GRAPE, XIBD and DRUID.

Material and Methods: We included 30 individuals from a Norwegian family with a known tenth-generation pedigree and 30 presumed unrelated individuals from a Norwegian ALS cohort. All participants had provided a written informed consent. All samples underwent WES and were processed with an inhouse nextflow pipeline to produce a quality-filtered jointvcf. Using this vcf as input, we applied each IBD tool to estimate all 1770 pairwise relationships between the 60 individuals.

Results: Up to 5th degree, two of the tools exhibited strong precision and recall: TRIBES and GRAPE both matched exactly for degree 1 and 2, a majority of exact matches for degree 3 and within one degree for 4th and 5th degree. DRUID differed in that it produced very few exact matches, but matched within one to two degrees. For 6th degree relationships, TRIBES was the only tool exhibiting a majority of exact matches. Updated results and XIBD results will be presented at the meeting.

Conclusion: Whole-exome sequencing data for detection of relatedness up to 6th degree is feasible utilizing IBD tools.

P17.049.B KRAS-Driven Immune System Modulation in Pancreatic Cancer: Insights from Exosome-Mediated KRAS Inhibition

Havva O. Eyupoglu[1,2], *Erol Eyupoglu*[1], *Klaus Brusgaard*[3,4], *Sukru Tuzmen*[2,5], *Can Erzik*[1], *Nedime Serakinci*[6], *Mustafa Akkiprik*[1]

[1]*Department of Medical Biology and Genetics, Institute of Health Sciences, Marmara University, Istanbul, Turkey,* [2]*Faculty of Dentistry, Eastern Mediterranean University, Famagusta via Mersin 10, Turkey,* [3]*Odense University Hospital, Odense, Denmark,* [4]*Department of Clinical Genetics, Lillebaelt Hospital, Vejle, Denmark,* [5]*GenBiomics R&D, TechnoPark, Eastern Mediterranean University, Famagusta via Mersin 10, Turkey,* [6]*Faculty of Arts and Sciences, Cyprus International University, Nicosia via Mersin 10, Turkey.*

Background: *KRAS* mutations drive pancreatic ductal adenocarcinoma(PDAC) progression, yet their downstream effectors in immune evasion remain poorly characterized. While *KRAS*-driven immunomodulation has been studied, involvement of *TRIB1* and *RCAN1* in this process has not been reported. We investigated these genes as potential mediators of *KRAS*-dependent immunosuppression.

Material and Methods: We analyzed the GSE97594 dataset, where PANC-1 cells(*KRAS*G12D mutant) were treated with *KRAS*-targeting siRNA-loaded exosomes(iExosomes). Additionally, expression levels of *TRIB1* and *RCAN1* were compared between *KRAS*-mutant PANC-1 and *KRAS*-wildtype BxPC3. Differentially expressed genes were validated using Enrichr, TCGA-PAAD for clinical correlation, and Kaplan-Meier survival analysis. Immune infiltration analysis performed using TIMER and MCP-COUNTER.

Results: TRIB1 and RCAN1 were overexpressed in KRAS-mutant PANC-1 and upregulated in TCGA-PAAD tumor samples compared to *KRAS*-wildtype BxPC3. iExosomes-mediated *KRAS* inhibition significantly downregulated *TRIB1* and *RCAN1*. Pathway enrichment linked *TRIB1* to immune system-related signaling(NF-κB,IL-2/STAT5,TGF-β pathways) and *KRAS* signaling.*TRIB1* strongly correlated with *KRAS* expression, while *RCAN1* showed a weak association. High *TRIB1* and *RCAN1* expression predicted worse overall survival.*TRIB1* negatively correlated with CD8+ T cells and CD8+ effector memory cells. *RCAN1* positively correlated with CD8+ T cell infiltration.

Conclusion: Our findings for the first time reveals *TRIB1* and *RCAN1* as *KRAS*-driven immunomodulators in PDAC. Exosome-mediated *KRAS* inhibition downregulates *TRIB1*, suggesting its potential as a therapeutic target. *TRIB1's* strong prognostic value supports its role in clinical risk stratification and immunotherapy response prediction. Immune infiltration analysis suggests that *RCAN1* is associated with CD8+ T cell infiltration, while *TRIB1* may contribute to T cell dysfunction, reinforcing their roles in *KRAS*-mediated immunomodulation.

P17.050.C From sequencer to analysis: Establishment of an open-source, fully automated, scalable, database-integrated next-generation sequencing pre-processing framework

Rebecca Prause[1], *Anja Kögler*[1], *Tim Hutschenreiter*[2], *Thomas Groß*[1], *Alexander Krüger*[1], *Oliver Kutz*[2]

[1]*Core Unit for Molecular Tumor Diagnostics (CMTD), National Center for Tumor Diseases Dresden (NCT), NCT/UCC, Dresden, Germany,* [2]*Institute for Clinical Genetics, University Hospital Carl Gustav Carus at TUD Dresden University of Technology, Dresden, Germany.*

Background: From novel short-read sequencing technologies to the rapidly evolving field of long-read sequencing, the bioinformatic processing of genetic data has never been more diverse and demanding. Solutions that cater to the individual sequencers often lead to a series of independent scripts and pipelines, over time resulting in an IT infrastructure that is error-prone and associated with high maintenance costs. To conquer this challenge, there is a need for an automated, scalable, and adaptive bioinformatics framework, enabling a reliable and quick execution of routine operations across different sequencers.

Material and Methods: We developed a Python framework that currently encompasses ten intertwined but independently usable main modules. One of which continuously monitors the user-configured sequencers to identify new sequencing runs and to automatically start their processing. Furthermore, the framework closely interacts with the LIMS (GEPADO XPro) via API to automatically extract the metadata from samples and return processed sample information such as quality control parameters on a run and sample level.

Results: Our bioinformatics pre-processing pipeline unites automated sample sheet creation, data management, demultiplexing, and quality control of raw and processed data. The communication with the LIMS database enables the real-time monitoring of the sequencing run during processing and the modularized composition of the framework allows for the future implementation of new features, such as individualized downstream sample processing.

Conclusion: We developed an open-source, fully automated, scalable, database-integrated next-generation sequencing pre-processing pipeline, which automatically identifies completed sequencing runs on various sequencing devices and prepares them for further downstream processing.

P17.051.D Prediction of genes associated with Autism Spectrum Disorder using sequence and graph embedding

methods

João Pedro da Silva Inácio[1,2], Joana Vilela[1,2], Ana Rita Marques[1,2], João Pedro Xavier Santos[1,2], Célia Rasga[1,2], Astrid Moura Vicente[1,2], ***Hugo Filipe de Mesquita Costa Martiniano***[1,2]

[1]*Instituto Nacional de Saúde Doutor Ricardo jorge, Lisboa, Portugal,* [2]*BioISI–Biosystems and Integrative Sciences Institute, Faculty of Sciences, University of Lisbon, Lisboa, Portugal.*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder, characterized by a strong genetic component, heterogeneous phenotypic presentation and complex genetic architecture. Identification of ASD risk genes and biological pathways is key to understanding this disorder. Despite the large number of genes associated with ASD, its genetic etiology is still not fully understood. To address this challenge, we present a machine-learning approach for ASD risk gene prediction.

Material and Methods: We used gene representations based on graph and sequence embeddings, from protein-protein interaction (PPI) networks and from gene DNA and protein sequences, respectively, with supervised Machine Learning (ML) classifiers. Graph embeddings were produced with the Grape Python library and the STRING PPI database, protein embeddings were obtained with the ProtT5 model and gene embeddings with DNABERT-2. The list of ASD associated genes used to train the classification models was derived from the SFARI database

Results: We developed a Machine Learning-based approach to identify and rank ASD associated genes. Using a 5-fold nested stratified cross-validation, our method achieved an AUC of 0.90, F1 of 0.82, and MCC of 0.77. Our approach compares favorably with state-of-the-art approaches in identifying genes targeted by loss-of-function (LOF) mutations in the MSSNG and Simons Simplex Collection cohorts. Analysis of the network spanned by the top decile genes identified four communities, significantly enriched for biological pathways associated with ASD, including Chromatin Organization and Synaptic Signaling.

Conclusion: This study improves existing ASD risk gene predictions and brings us a step closer to better understanding this complex genetic disorder.

Lorena Melo de Jesus[1], *Lucas Bleicher*[2], *Monique Freire dos Reis*[1]

[1]*UFAM, Manaus, Brazil,* [2]*UFMG, Belo Horizonte, Brazil.*

Background: The ABAT gene encodes aminotransferases involved in reversible transamination reactions, including class III aminotransferases such as GABA transaminase (GABA-T). Mutations in ABAT (16p13.2), though rare, are linked to neonatal encephalopathy and psychomotor delay due to GABA-T deficiency. This study investigates structural correlations between ABAT mutations and clinical manifestations.

Material and Methods: Public databases like UniProt were used to obtain ABAT sequences classified as benign or pathogenic. PFstats identified conserved or co-evolving positions, and structural analyses were performed using PyMOL and Modeller to assess mutation effects on protein interactions, physicochemical properties, and structural location.

Results: Eighteen variants were selected (5 benign, 12 pathogenic, 1 VUS). The R19C variant, located in the signal peptide region, was excluded, resulting in 17 models based on the wild-type 1OHV structure. Six variants showed hydrophobic exposure discrepancies: Q56L (benign) had an unfavorable substitution, while R92Q, L487P, L211F, R220K, and L478P exhibited conservative substitutions. The V479F (VUS) mutation also displayed a conservative surface substitution. Interaction analysis revealed that G465D and G465S had increased interactions with R435, whereas six variants (R92Q, Y426, G478S, H484Q, L487P, and L487Q*) showed reduced molecular interactions, affecting different residues.

Conclusion: These findings suggest that specific ABAT mutations impact protein stability and interactions, potentially influencing their pathogenicity. Variants with altered hydrophobic exposure or molecular interactions may disrupt structural integrity. Further studies are needed to correlate these structural changes with clinical phenotypes.

P17.053.B Integration of common and ultra-rare variant burden to identify molecular subnetworks linked to membrane electrophysiology in genetic generalized epilepsy

Maryam Erfanian Omidvar[1], *Emadeldin Hassanin*[2], *Dheeraj Reddy Bobbili*[2], *Patrick May*[2], *Holger Lerche*[1]

[1]*Department of Neurology and Epileptology, Hertie Institute for Clinical Brain Research, University of Tübingen, Tübingen, Germany,* [2]*Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Esch-sur-Alzette, Luxembourg.*

Background: Common and ultra-rare variants are contributing risk factors for different epilepsy subtypes, particularly genetic generalized epilepsy (GGE). However, the extent to which these variants underlie the molecular mechanisms related to GGE pathogenesis has not been well understood. This study aims to identify gene networks and biological processes with potential association with GGE, along with candidate driver genes.

Material and Methods: We have integrated GGE-associated common variants from the ILAE Consortium's latest genome-wide association study with ultra-rare variants from whole-exome sequencing of 5,499 individuals by Epi25 Collaborative. The Burden of common and ultra-rare variants was integrated within a molecular interaction network using the NetColoc framework, which relies on a dual network propagation approach.

Results: Our work confirmed that common and ultra-rare variant burden associated with GGE was enriched in gene subnetworks representing epilepsy-related biological processes, including membrane electrophysiology, cell trafficking, and chromatin organization. Additionally, The GGE-associated variants, both common and ultra-rare, were enriched in subnetworks of genes with higher expression in inhibitory neurons compared to excitatory cells. Ultimately, we highlighted putative GGE-related genes, such as *USP8* and *SULT1A2*. These genes have not reached a genome-wide significance level for association with GGE, nor have they been reported as monogenic epilepsy-related genes. However, they show strong colocalization in subnetworks built under the influence of both common and ultra-rare variants.

Conclusion: This work has identified potential candidate genes and underscored the importance of biological processes, notably membrane electrophysiology, in GGE pathogenesis. Our findings can pinpoint new targets for therapeutic intervention and mechanistic studies.

P17.054.C Alignment to T2T-CHM13 reference genome solves reference mapping bias and improves read mapping at clinically relevant variants

Ilaria Cherchi, *Francesco Orlando, Orsetta Quaini, Marta Paoli, Yari Ciani, Francesca Demichelis*

University of Trento, Trento, Italy.

Background: The Telomere-to-Telomere (T2T) CHM13 reference genome demonstrates large-scale differences with previous human genome assemblies. We investigated whether the T2T assembly improves allelic variation analysis and signal detection from regulatory regions with respect to hg38.

Material and Methods: DNA sequencing human and cell line data from multiple designs (whole-genome, whole-exome, and targeted sequencing) at varying coverages (30x-1000x) were aligned to T2T-CHM13v2.0 and hg38 assemblies. Pileups at high minor allele frequency dbSNP sites were used to call heterozygous genotypes (variant allele fraction (VAF) between 0.2 and 0.8) on a sample basis to quantify the inflation of reference allele counts, the so-called reference mapping bias (RMB). UCSC repository ClinVar, CpG islands, and ENCODE TFBS tracks for hg38 and T2T reference genomes were analyzed through pairwise sequence alignment.

Results: Heterozygous SNP VAF distribution from T2T aligned data showed a significantly reduced RMB compared to hg38 data. We detected mismatches in the genomic sequence in the proximity (±150 bp) of SNPs with discordant VAFs across the two assemblies, suggesting that T2T resolves genomic inaccuracies in bases proximal to SNPs. Genomic differences within ChIP-seq peaks and CpG islands showed negligible impact on TFBS enrichment analyses and methylation calling. Focusing on ClinVar annotated sites, T2T improved read coverage and mapping quality metrics at clinically relevant variants compared to hg38, including pathogenic variants in *BRCA1* exon 17.

Conclusion: The alignment to T2T assembly solves RMB and improves read mapping at disease-associated genomic sites, possibly facilitating the detection of variants for precision medicine testing.

P17.055.D Interpretable neural network polygenic risk scores for common diseases

Julius Upmeier zu Belzen[1], *Lucas Arnoldt*[1], *Leonard Eckhoff*[1], *Sedra Abou Ghaloun*[1], *Leonhard Kohleick*[1], *Khuê Nguyen*[1], *Benjamin Wild*[1], *Roland Eils*[1,2]

[1]*Berlin Institute of Health - Charité Universitätsmedizin Berlin, Berlin, Germany,* [2]*University Hospital Heidelberg, Heidelberg, Germany.*

Background: Genetic contributions to complex human phenotypes like risks for common diseases are typically modelled by polygenic risk scores. While they perform well within cohorts, they assume independent variant effects and are thus not suited to model non-linear phenomena like epistasis or group-specific effects that depend on integration of covariates like sex or genetic principal components.

Materials and Methods: We present sparse neural networks utilizing prior knowledge from the Gene Ontology that integrate genotypes and covariates to predict disease risks. Our models are trained on UK-Biobank data and evaluated on the All-of-Us Cohort, together with polygenic risk score baselines that we derived based on UK-Biobank summary statistics and published scores from the PGS Catalog, using the same covariates as in our models.

Results: Our models match or outperform baselines for most of the phenotypes investigated, despite being trained on only a single cohort, the UK-Biobank. For diabetes type 2 specifically, we observe a ROC AUC of 0.605 of our model versus 0.581 for PGS000014 from the PGS Catalog. Furthermore, the proposed models are inherently interpretable since each neuron is mapped to a specific Gene Ontology term, and we observe that terms more important for the models also have higher relevance for the predicted phenotypes.

Conclusion: Using neural networks, we do not assume independence of variant effects, and can better integrate covariates, which leads to improved polygenic risk prediction across cohorts. While our approach introduces challenges like the requirement for access to individual-level data it enables modelling nonlinear effects at scale.

P17.056.A Seasonal human proteome: a population-based cohort study from South Asia

Albert Navarro-Gallinad[1], *Linda Repetto*[1], *Solène Cadiou*[1], *Giulia Pontali*[1], *Andrea Corbetta*[1], *Laura Bondi*[1], *Gianmauro Cuccuru*[1], *Alessia Mapelli*[1], *Xiyun Jiang*[2], *Michela Carlotta Massi*[1], *Claudia Giambartolomei*[1], *Emanuele Di Angelantonio*[1,2,3], *Adam S. Butterworth*[2,3], *Luisa Zuccolo*[1,4]

[1]*Human Technopole, Milan, Italy,* [2]*British Heart Foundation Cardiovascular Epidemiology Unit at University of Cambridge, Cambridge, United Kingdom,* [3]*Victor Phillip Dahdaleh Heart and Lung Research Institute at University of Cambridge, Cambridge, United Kingdom,* [4]*MRC Integrative Epidemiology Unit at the University of Bristol, Bristol, United Kingdom.*

Background: Chronic diseases account for 55–82% of deaths in South Asia, increasingly exacerbated by climate change. Proteins provide a dynamic and objective measure of how individuals' health responds to environmental changes. This study aims to identify seasonal plasma protein patterns and underlying environmental impacts on chronic disease.

Material and Methods: We analysed cross-sectional data from a South Asian cohort (N = 10,000), including plasma proteomic 7kSomaScanAssay. Individuals were grouped by blood-sampling date (2016–2019) to generate a seasonal profile dataset of 52 weekly values, balanced for sex, age, BMI and smoking. Protein weekly means and confidence intervals were estimated through bootstrap resampling (N = 1,000), and seasonality modelled by functional data analysis. We probed the role of seasonal proteins on disease through genetically-informed causal inference methods such as colocalization and Mendelian Randomization.

Results: We identified 24% (1535/6368) of the proteome as seasonal using the autocorrelation function. The seasonal proteome grouped into three data-driven clusters peaking before (N = 519), during (N = 557), and after (N = 459) the monsoon season. Seasonal proteins were more likely involved in active secretion and tissue damage, and less in cell leakage compared to non-seasonal proteins, suggesting a broad impact on biological processes. Preliminary results suggest some seasonal proteins causally contribute to cardiovascular and respiratory diseases, while others reflect disease consequences.

Conclusion: This study identified environmental signals in plasma proteins linked to chronic disease, marking the first step

toward targeting modifiable factors for public health interventions in a climate-affected country.

P17.057.B Multiple Instance Learning applied to population scale single-cell transcriptomics

Giuditta Clerici[1,2], *Jan Engelmann*[3], *Cardinal Project Working Group*[4], *Fabian J. Theis*[3], *Paolo Casale*[3], *Nicole Soranzo*[1,5,6], *Craig Glastonbury*[1]

[1]*Human Technopole, Milan, Italy,* [2]*Politecnico of Milano, Milan, Italy,* [3]*Helmholtz Center, Munich, Germany,* [45]*Wellcome Sanger Institute, Hinxton, United Kingdom,* [6]*University of Cambridge, Cambridge, United Kingdom.*

The extension of the human lifespan increases the burden of chronic and inflammatory diseases, but the molecular processes behind their heterogeneity are often unknown. Leveraging Electronic Health Records, genotype data, and single-cell RNA-seq, we aim to identify disease-associated cell states, uncover disease heterogeneity, and highlight shared cell states or gene programs across distinct diseases. This approach may guide target prioritization and drug repositioning.

We employ an attention-based multiple instance learning (MIL) framework, MixMIL, on single-cell transcriptomics to identify predictive cell states involved in diseases. First, we benchmark MixMIL using various dimensions of scVI space on a simulated dataset to determine optimal input configurations. The best-performing setup is then applied to the UK-Biobank Cardinal cohort (N = 5000 single-cell RNA-seq PBMC donors).

MixMIL achieves a good performance with 30 scVI latent factors as input, yielding an accuracy of 75%, area under the precision-recall curve of 0.91, and f1-score of 0.73 on the synthetic dataset for the prediction of the simulated class. In the Cardinal cohort, we will apply the same framework to predict 90 disease outcomes, then select the top attended cells and cluster individuals based on cell type proportions among these important cells. Individuals with varying proportions of key cells could exhibit distinct comorbidities, genetic risks (e.g., polygenic risk scores), or environmental exposures.

Our findings underscore MixMIL's utility in pinpointing disease-relevant cell states. In the future, we will benchmark other MIL methods, e.g. MultiMIL. Further analyses are essential to advance our understanding of disease mechanisms and therapeutic opportunities.

P17.059.D Sawfish: Integrating copy number segmentation with structural variant haplotype modeling to improve large-variant calling accuracy

Christopher T. Saunders, *James M. Holt, Juniper A. Lake, Jonathan R. Belyeu, Zev Kronenberg, William J. Rowell, Michael A. Eberle*

PacBio, Menlo Park, CA, USA.

Background: Sawfish is a structural variant (SV) caller for mapped high-quality long reads. It leverages SV haplotype assembly and haplotype representation in all downstream sample merging and genotyping steps to improve accuracy. Further improvements to sawfish are attainable by fully integrating depth-based segmentation with the existing SV haplotype model to enrich modeling of large and complex events.

Results: Sawfish has the highest accuracy on the GIAB draft T2T-HG002-Q100 SV benchmark[1] compared to pbsv[2] and Sniffles2[3]. For HiFi WGS 10x depth input, sawfish's F1-score is 0.940 compared to 0.871 and 0.920 for pbsv and Sniffles2, respectively. This accuracy rank persists at all tested depths up to 32x, across all SV size categories, and for SVs comprising the GIAB CMRG benchmark[4].

Sawfish also substantially improves on joint-genotyping accuracy. Genotype concordance was assessed against the known inheritance pattern for seven HiFi WGS samples comprising the 2nd and 3rd generations of CEPH-1463[5]. Here, sawfish calls 28,627 concordant and 3,987 discordant SV alleles (87.8% concordance), greatly improving on both concordant allele count and concordance rate of the next most concordant method, pbsv, with 23,629 concordant and 6,770 discordant alleles (77.7% concordance).

Fully integrating depth-based segmentation within sawfish shows that accuracy is improved by: 1) recharacterizing large breakend-based deletions and duplications which lack corresponding depth signatures, 2) filtering small depth-based calls lacking corresponding breakend signatures, and 3) allowing breakends to guide depth segmentation. This integration additionally allows all depth and breakend-based evidence to be harmonized into a consistent view of all large variants in the sample.

Hans, Roskilde, Denmark,* [3]*Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen,*

Copenhagen, Denmark, [4]Department of Mathematical Sciences, Faculty of Science, University of Copenhagen, Copenhagen, Denmark, [5]deCODE genetics/Amgen Inc., Reykjavik, Iceland, [6]Department of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark, [7]Department of Clinical Medicine, Faculty of Health, Aarhus University, Aarhus, Denmark, [8]Department of Clinical Immunology, Zealand University Hospital, Køge, Denmark, [9]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [10]Department of Neuroscience, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.

Background: Genomic cohort studies are key for novel discoveries, yet often biased by selection, as exemplified by the Danish Blood Donor Study (DBDS)—a nationwide genomic cohort comprising 140,000 individuals who are disproportionately younger, more likely to be female, more socioeconomically advantaged, and healthier than the general Danish population. Addressing selection bias to account for these systematic differences in genetic research therefore emerges as a pivotal challenge.

Material and Methods: Utilizing comprehensive national registry data, we employed a logistic lasso regression model to estimate inverse probability (IP) weights for all DBDS participants, thereby adjusting for selection bias. This allowed us to conduct IP-weighted GWA studies to evaluate how weighting affects SNP-level effects, genetic correlations, heritability estimates, and Mendelian randomization (MR) estimates.

Results: Selection bias in the DBDS cohort was substantially reduced through IP weighting, creating a pseudo-population closely resembling the general Danish population and reducing bias by nearly 90%. Weighted GWA studies revealed shifts in SNP-level effects, with some associations attenuated or amplified compared to unweighted analyses, while genetic correlation and heritability estimates shifted across multiple traits. Additionally, weighted analyses led to differences in MR-derived causal effect estimates, further underscoring the impact of selection bias on genetic evidence.

Conclusion: Applying IP weighting to the DBDS cohort effectively reduces selection bias, making it more representative of the general Danish population. Our findings highlight the necessity of addressing selection bias in genetic research to improve the accuracy and validity of genetic analyses.

P17.062.C Unveiling the Contribution of Rare Variants to Breast Cancer Risk using A Bayesian Hierarchical Model

Giulia Brunelli[1,2], Barbara Iadarola[1], Carla Debernardi[3], Danilo Tatoni[1,2], Elena Pasquinelli[2], Alessandra Renieri[2], Simone Furini[4], ***Romina D'Aurizio***[1]

[1]Institute of Informatics and Telematics (IIT), National Research Council (CNR), Pisa, Italy, [2]Department of Medical Biotechnologies Medical Genetics, University of Siena, Siena, Italy, [3]Department of Medical Sciences, University of Turin, Turin, Italy, [4]Department of Electrical, Electronic and Information Engineering "Guglielmo Marconi", University of Bologna, Bologna, Italy.

Background: Breast cancer (BC) is a complex genetic disease. The association at the variant-level of rare variants (RVs, MAF < 0.01) with BC risk in population studies poses challenges due to low statistical power and multiple testing burdens. Thus, current approaches focus on aggregated RVs in high-penetrance genes and known pathways. To investigate the single variant association to BC risk, and improve the interpretability and clinical utility, we propose an alternative approach: the Bayesian Hierarchical Generalized Linear Model (BhGLM).

Material and Methods: We trained and tested the BhGLM using the UK Biobank (UKBB) cohort (15868 BC cases, 165067 controls). We evaluated the identified RVs quality using ACMG and ClinVar annotations, and we built a RVscore embedding the cumulative impact of RVs in BC risk stratification.

Results: The BhGLM approach demonstrated high specificity levels (average FPR ≤ 0.001) in simulation settings. When evaluated on a short list of genes, BhGLM mostly selected pathogenic RVs with higher OR. When extended to the ClinicalExome (5369 genes), we identified a total of 550 LoF RVs in 494 genes. Notably, high levels of the RVScore were associated with an incremented risk of BC compared to PRS alone.

Conclusion: The Bayesan-based approach, not only introduces a novel methodological framework in the context of BC studies, but also enables the quantification of the collective impact of RVs on BC risk while preserving the capacity to interpret the contribution of individual variants.

Table 1. OR for RVScore across PRS classes

PRS class	Covariates	OR (95%CI)	P-Value	N Samples
Low PRS <33%	No Mut	0.54 (0.52–0.56)	< 0.001	11.429
	High RVScore	0.63 (0.58–0.68)	< 0.001	947
Medium PRS 33–66%	No Mut	1 (0.97–1.03)	1	11.422
	High RVScore	1.17 (1.08–1.26)	< 0.001	977
High PRS >66%	No Mut	2.06 (2–2.12)	< 0.001	11.435
	High RVScore	2.4 (2.22–2.59)	< 0.001	966

P17.063.D Large-scale case-control likelihood ratios to refine variant classification in breast cancer risk genes

Damianos Michaelides[1], *Maria Zanti[1], Joe Dennis[2], Douglas F. Easton[2], Amanda Spurdle[3], Kyriaki Michailidou[1]*

[1]Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [2]Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care of the University of Cambridge, Cambridge, United Kingdom, [3]QIMR Berghofer Medical Research Institute, Brisbane, Australia.

Background: While some variants in susceptibility genes are associated with a substantially increased risk of breast cancer, the impact of a large proportion of variants on risk is still unclear. Such variants, known as variants of uncertain significance, pose

challenges in clinical decision-making, and novel methodologies and data are needed to enhance classification rates.

Material and Methods: A case-control likelihood ratio approach was applied to obtain evidence for classification of rare variants in *CHEK2*, *ATM*, *TP53* and *PALB2*. Sequencing data from over 60K breast cancer cases and over 250K controls from the BRIDGES study of the Breast Cancer Association Consortium and the UK Biobank were used. Likelihood ratios for over 3K variants were computed and results were aligned following ACMG/AMP evidence thresholds. Sensitivity analyses using series of different age-specific penetrance estimates and different number of minimum carriers for each variant were carried out.

Results: Case-control likelihood ratio results showed consistency for variants classified in ClinVar. Using the criterion of variants reaching at least moderate evidence towards or against pathogenicity, the sensitivities and specificities were 66.7% and 100% (*CHEK2*), 88.9% and 81.4% (*ATM*), 79.2% and 94.6% (*PALB2*), and 83.3% and 97.2% (*TP53*). Across the four genes, likelihood ratio evidence in favour, or against, pathogenicity was obtained for an additional 334 rare variants currently annotated as variants of uncertain significance in ClinVar.

Conclusions: The case-control likelihood ratio approach applied to a large-scale sequencing dataset can improve variant classification in breast cancer risk genes.

P17.064.A A Hitchhiker guide to Structural Variant (SVs) Calling: a comprehensive benchmark through short-reads (srWGS) and long-reads (lrWGS) sequencing technologies

Giuseppe Giovanni Nardone[1], *Valentina Andrioletti*[2], *Aurora Santin*[3,1], *Anna Morgan*[3], *Beatrice Spedicati*[1,3], *Maria Pina Concas*[3], *Ivan Limongelli*[2], *Giorgia Girotto*[1]

[1]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy,* [2]*enGenome S.R.L, Pavia, Italy,* [3]*Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy.*

Background: With the advent of new sequencing technologies, SVs identification from Whole Genome Sequencing has become a central topic. However, variability in SVs calling performances persists due to the diversity of available tools and lack of standardized practices. Considering that, we performed a comprehensive benchmark to establish the best performing methodologies for different sequencing technologies.

Material and Methods: Deletions of the HG002 reference sample were evaluated. Benchmark was performed also on low complexity regions (LCR), comparing hg38 to a multi-genome. Several SVs calling tools in combination with different alignment software were evaluated for different sequencing technologies:

Software	Software type	Sequencing technology	Reference
DRAGENv4.2	SVs calling	srWGS	PMID: 39455800
DRAGENv4.0	SVs calling	srWGS	PMID: 39455800
Manta	SVs calling	srWGS	PMID: 26647377
MATCHCLIP	SVs calling	srWGS	PMID: 23967014
DELLY	SVs calling	srWGS	PMID: 22962449
Lumpy	SVs calling	srWGS	PMID: 24970577
SoftSV	SVs calling	srWGS	PMID: 25998133
inGAP	SVs calling	srWGS	PMID: 21715388
Wham	SVs calling	srWGS	PMID: 26625158

dysgu	SVs calling	lrWGS	PMID: 35100420
duet	SVs calling	lrWGS	PMID: 36344913
sniffles	SVs calling	lrWGS	PMID: 38168980
pbsv	SVs calling	lrWGS	https://github.com/PacificBiosciences/pbsv
SVIM	SVs calling	lrWGS	PMID: 30668829
minimap2	Alignment	srWGS, lrWGS	PMID: 29750242
winnowmap	Alignment	lrWGS	PMID: 32657365
ngmlr	Alignment	lrWGS	PMID: 29713083
lra	Alignment	lrWGS	PMID: 34153026
bwa-mem2	Alignment	srWGS	PMID: 19451168
dragmap	Alignment	srWGS	https://github.com/Illumina/DRAGMAP
bowtie2	Alignment	srWGS	PMID: 22388286
DRAGEN pipeline alignment	Alignment	srWGS	PMID: 39455800

Performances were evaluated calculating F1 score (F1), precision (P) and recall (R).

Results: For srWGS, DRAGEN yielded the best results (F1: 83% P: 90%, R: 77%). In LCR, the multi-genome outperformed hg38 (F1: 78%, P: 96%, R: 66%). Manta with minimap2 alignment showed comparable performance to DRAGEN (F1: 81%, P: 93%, R: 71%). For Nanopore lrWGS, duet was optimal at low coverages (5X - F1: 75%,P: 88%, R: 65%;10X - F1: 85%, P: 88%, R: 82%), while dysgu excelled at high coverages (20X - F1: 88%,P: 90%, R: 87%; 30X - F1: 89%, P: 90%, R: 89%). For PacBio, sniffles2 achieved the best results (F1: 90%, P: 89%, R:91%).

Conclusion: Our study showed for the first time that the choice of alignment software can drastically impact SVs calling from

srWGS. Moreover, we showed that SVs calling performances for lrWGS highly depend on the technology and the coverage level.

Background: Oligonucleotide genotyping arrays have genotyped millions of biobank participants worldwide. These genotyping arrays potentially offer a low-cost alternative to expensive, time-consuming single-gene assays for personalized pharmacogenetic (PGx) advice. *CYP2D6* metabolizes 25% of all drugs, but accurately genotyping this gene using oligonucleotide arrays is challenging due to a combination of single nucleotide polymorphisms, whole-gene copy number variants (CNVs) and hybrid alleles. To address this, we developed Asterix, a PGx passport pipeline with a custom *CYP2D6* CNV calling algorithm, enabling the generation of a comprehensive PGx profile for 12 genes using the Illumina Global Screening Array.

Material and Methods: *CYP2D6* variants and CNV status are modeled jointly per variant, allowing for differentiating hybrid alleles from whole-gene CNVs. For development and validation, we reanalyzed existing genetic data from the Lifelines biobank and separate validation datasets. We validated variant calling, phasing, imputation, and PGx passport accuracy using pedigree data, public reference data, and gold-standard PGx assays.

Results: We successfully validated our PGx passport pipeline. PCR-based profiling of *CYP2D6* CNV status confirmed the CNV calls from Asterix, eliminating the need for separate PCR-based detection. This opens up opportunities to return PGx profiles to millions of biobank participants that have already been genotyped worldwide. We did return 1,227 PGx passports to biobank participants via a layperson-friendly app.

Conclusion: We developed and validated a low-cost, clinical-grade PGx passport pipeline that can return comprehensive PGx profiles to biobank participants at minimal cost, ensuring effective and safe drug therapy based on their unique genetic makeup.

P17.067.D SCALT: automatic identification of cell types from single-cell RNA sequencing data

Daniele Traversa, *Alessia Canevotti, Matteo Chiara*

University of Milan, Milan, Italy.

Background: Single cell RNA sequencing (scRNAseq) marks a methodological breakthrough for the study of the organization and function of cells and cell types. Dimensionality reduction and unsupervised clustering represent the de facto standard methods for the analysis of scRNA-seq data. These techniques however require extensive manual curation/interpretation and results are not always reproducible. Here, we present SCALT, an innovative method which introduces a paradigm-shift for the annotation of cell identities from scRNAseq data.

Material and Methods: SCALT is implemented as a collection of R and Python scripts and is available at https://github.com/danitrave/SCALT. The method was tested on a reference standard benchmark and validated by using extensive collection of expert annotated cell identities from the DISCO and HPA repositories.

Results: SCALT is a novel information-theoretic based method for the identification/classification of cell types from scRNAseq data. Key features include: automatic identification of cell type marker genes, identification and stratification of similar cell types, confidence intervals for the annotation of alternative cell type identities. Applied to two reference benchmark datasets SCALT outperformed other state of the art methods, and correctly classified with the expert curated/assigned identity 95.3% of the 5 M distinct cell in the DISCO and HPA databases. The tool can currently annotate 293 distinct operationally defined cell type identities. Custom types can also be defined.

Conclusion: SCALT introduces an innovative approach for single cell RNA sequencing data analysis, and offers a reproducible and human interpretable framework for the delineation of cell types and their annotation.

P17.068.A Accurate detection of clinical Copy Number Variants in exomes with X chromosome reader-based Machine Learning

Elia Giuseppe Ceroni[1,2], *Paola Dimartino*[3,4], *Tania Giangregorio*[3], *Roberto Semeraro*[5], *Lisa-Marie Niestroj*[6], *Rita Selvatici*[7], *Pamela Magini*[3], *Dennis Lal*[8], *Alberto Magi*[9], *Marco Seri*[3], *Romina D'Aurizio*[1], ***Tommaso Pippucci***[3]

[1]*Institute of Informatics and Telematics (IIT), National Research Council (CNR), Pisa, Italy,* [2]*Department of Information Engineering and Mathematics, University of Siena, Siena, Italy,* [3]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [4]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [5]*Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy,* [6]*Faculty of Medicine and Cologne University Hospital, Cologne Center for Genomics, University of Cologne, Cologne, Germany,* [7]*Medical Genetics Unit, Department of*

Medical Sciences, University of Ferrara, Ferrara, Italy, [8]Faculty of Medicine and Cologne University Hospital, Cologne Center for Genomics, University of Cologne, Cologne, Italy, [9]Department of Information Engineering, University of Florence, Florence, Italy.

Background: Exome sequencing (ES) is now unanimously considered the first-tier diagnostic test for most genetic conditions. Although a plethora of ES-based CNV callers has been developed, each shows good performance in only a limited range of calling conditions or CNV classes and sizes. More flexibility is therefore needed for broad and robust clinical use.

Material and Methods: miXer is a light-weight machine learning tool that leverages the natural occurrence of one and two copies of the non pseudoautosomal X-chromosome in male and female exomes to discriminate genomic deletions and duplications. miXer was trained on real X-chromosome reads obtained by 6 widely used kits to capture most of the technical variability inherent to ES.

Results: Introducing a rigorous exon-level performance evaluation, we benchmarked miXer against state-of-the-art callers (ExomeDepth, DECoN, GATK-gCNV, CNVkit, EXCAVATOR2) on a comprehensive range of dbVar CNV examples synthetically embedded into the NA12878 exome, on a large ES dataset previously profiled with high-density SNP-arrays and on ES data of MLPA-validated intragenic DMD deletions. miXer globally outperformed the other callers on the synthetic benchmark, achieved higher accuracy on SNP-arrays than GATK-gCNV at the same working conditions (recall = 63%, specificity = 1) and showed sensitivity down to 2-exons for MLPA-validated events.

Conclusion: Importantly, miXer can generalize with unseen settings, requires a limited control-pool (10) and can be used either as a pre-trained model or after ad-hoc re-training on a small number (50) of samples, thus offering a reliable, resource-efficient, and highly accurate tool for clinical genomics and research applications. miXer is freely distributed as Docker package (http://github.com/ctglab/miXer).

P17.069.B Illuminating cellular mechanisms of Mendelian and complex diseases using interpretable machine-learning

*Chanan Argov, **Or Lazarescu**, Ariel Shneyour, Esti Yeger-Lotem*

Ben-Gurion University of the Negev, Be'er Sheva, Israel.

Background: The cellular basis of many Mendelian diseases, including the causal aberration, affected cell type, and aberration mode-of-action, remains unclear, hampering disease understanding and treatment.

Material and Methods: Here, we present an extensive machine learning (ML) framework, denoted DisCell, to address each of these challenges. DisCell harnesses single-cell transcriptomic, interatomic, and functional gene features of ~22,000 protein-coding genes across 172 fetal cell types from 15 main human organs.

Results: When applied to predict aberrant genes underlying inherited retinal disorder (IRD) and autism spectrum disorder (ASD) as case studies, DisCell achieved median auROC of 0.9 and auPRC of 0.6 (expected 0.1). In a larger set of 467 diseases and 31 cell types, DisCell improved considerably the prediction of affected cell types, relative to a recently-published method that utilized preferential gene expression (F1 score of 0.33 vs 0.19). Notably, the interpretation of the resulting DisCell models provided insight into disease processes.

Conclusion: Altogether, we show that interpretable ML methods combined with rich single-cell omics data can advance the genetic and cellular understanding of monogenic and complex diseases. The DisCell framework is available online for usage by non-programmers via a web interface at https://netbio.bgu.ac.il/discell/.

P17.070.C CADD-SV v2.0 effectively scores structural variant deleteriousness from coordinate and sequence-derived annotations

***Orazio Catona**[1], Martin Kircher[1,2]*

[1]Institute of Human Genetics, University Medical Center Schleswig-Holstein, University of Lübeck, Lübeck, Germany, [2]Berlin Institute of Health (BIH) at Charité-Universitätsmedizin Berlin, Berlin, Germany.

Background: Structural variants (SVs) are large genomic alterations, with potentially significant impacts on disease. While the interpretation of individual SV effects remains challenging, CADD-SV is a comprehensive tool designed to annotate and score the deleteriousness of SVs based on diverse genomic annotations.

Methods: We present an updated machine learning model that uses an expanded training set (labels and features) and overcomes the need of separate models to score SV effects. Thereby, it supports a broad spectrum of SV types, including deletions, insertions, duplications, and inversions. Our new model combines the rich coordinate-based annotations with sequence-derived annotations extracted using SegmentNT, a DNA language model (DLM) predicting DNA elements at single-nucleotide resolution. For example, SegmentNT predicts genes, exons, introns, splice sites, promoters, enhancers, and untranslated regions from only sequence. Utilizing this state-of-the-art DLM, CADD-SV v2.0 leverages the sequence of the altered genomic regions. With the reference sequence surrounding the SV as well as its new sequence as input, it provides sequence-specific annotations and information about potentially altered molecular effects.

Results: Extensive validation of our new model demonstrated substantial improvements over CADD-SV v1.1 and other SV scoring tools in prioritizing functionally relevant SVs. CADD-SV v2.0 achieves higher accuracy and recall across SV types and enables the scoring of inversions in addition to enhanced insertion and duplication evaluation.

Conclusion: CADD-SV v2.0 provides an improved framework for annotating and prioritizing SVs, offering greater accuracy in interpreting their functional impact and aiding in understanding their roles in disease.

P17.071.D More detail on epigenetic characteristics of enhancers and promoters

***Yufei Zhang**, Annkatrin Bressin, Elisabeth Altendorfer, Andreas Mayer, Martin Vingron*

Max Planck Institute for Molecular Genetics, Berlin, Germany.

Identification of regulatory elements is crucial for understanding gene regulatory networks. With the development of RNA-seq techniques, promoters can be easily detected based on experimentally determined transcription start sites (TSSs). Whereas,

identification of enhancers remains challenging and largely depends on chromatin profiles including chromatin accessibility and histone modifications.

In this study, we identify 10,672 putative enhancers using nascent RNA-seq profiles in the human K562 cell line. While the majority of identified enhancers exhibit classical enhancer features, a subset of enhancers located near TSSs have distinct chromatin patterns: These proximal enhancers share similar high levels of ATAC-seq as well as H3K27ac ChIP-seq with classical enhancers, but their H3K4me3 levels exceed the H3K4me1 levels, resembling promoter profiles more closely than classical enhancers.

To further explore proximal enhancers, we examine the epigenetic characteristics of identified enhancers. Because there are many CpG islands around TSSs, proximal enhancers generally have higher CpG content than distal enhancers. We find that H3K4me3 levels positively correlate and H3K4me1 levels negatively correlate with CpG content. This relationship applies to all identified enhancers and accounts for the atypical chromatin patterns observed at proximal enhancers. Interestingly, this trend is not observed at promoters, where H3K4me3 consistently dominates over H3K4me1 regardless of CpG content.

In conclusion, proximal enhancers complicate enhancer identification based on chromatin profiles, as their distinct features can reduce predictive accuracy. Future efforts will focus on developing improved strategies to accurately identify both classical and proximal enhancers.

P17.072.A Bayes PoPS: A Novel Bayesian Approach for Improved Polygenic Gene Prioritization in Complex Trait Genetics

Palle Duun Rohde[1], *Peter Sørensen*[2]

[1]*Genomic Medicine, Department of Health Science and Technology, Aalborg University, Aalborg, Denmark,* [2]*Center for Quantitative Genetics and Genomics, Aarhus University, Aarhus, Denmark.*

Background: Polygenic prioritization scoring (PoPS) integrates genome-wide association study (GWAS) summary statistics to identify genes associated with complex traits and diseases. It combines polygenic signals, linkage disequilibrium, and functional annotations, to assign a prioritization score to each gene. We demonstrate superior performance of a novel extension, namely Bayes PoPS.

Material and Methods: Bayes PoPS incorporates BayesR prior, eliminating the initial feature selection in PoPS. We simulated quantitative phenotypes using genotypic data from 335,000 UK Biobank participants across eight different genomic scenarios (Table), with ten independent replicates for each scenario. To assess various gene-set characteristics, we generated sets containing 20 to 100 genes, with five or twenty designated as causal (n_c). We calculated VEGAS gene-level association statistics, and derived PoPS and Bayes PoPS scores by utilising the gene-sets. The performance of each gene prioritization method was evaluated by area under the receiver operating characteristic curve (AUC).

Results: Across all simulations, Bayes PoPS consistently outperformed PoPS ($P < 2.2{\cdot}10^{-16}$). In scenarios with a higher proportion of genome-wide causal SNPs and few causal genes within gene-sets ($n_c = 5$), VEGAS outperformed both PoPS and Bayes PoPS. The power of Bayes PoPS to correctly prioritize genes significantly improved with a higher fraction of causal genes within gene-sets ($n_c = 20$).

Conclusion: Bayes PoPS demonstrated improved power to prioritize genes and robustly distinguish causal genes from polygenic background. This enhances gene discovery and interpretation in complex trait genetics, offer insights for downstream functional analyses and personalized medicine applications.

P17.073.B VarChat: leveraging generative AI to enhance genomic literature retrieval and summarization

Federica De Paoli[1], *Silvia Berardelli*[1,2], *Alessia Tudisco*[2], *Andrei Stefan Blindu*[1,2], *Ettore Rizzo*[1], *Ivan Limongelli*[1], *Susanna Zucca*[1]

[1]*enGenome srl, Pavia, Italy,* [2]*University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy.*

Background: The growing volume of genomic literature presents significant challenges for the efficient retrieval and synthesis of variant-specific information, which is essential for clinical and research applications. To address these challenges, we introduce VarChat, an innovative generative AI-based platform that leverages Large Language Models (LLMs) to optimize the retrieval and summarization of up-to-date literature, directly referencing genomic variants of interest.

Materials and Methods: VarChat integrates multiple literature databases within a hybrid Retrieval-Augmented Generation framework, combining sparse and dense retrieval approaches. It synthesizes fragmented findings into concise, scientifically accurate summaries while providing access to high-confidence references. Additionally, the platform features a guided chat interface, enabling users to explore specific functional and clinical implications of genomic variants. A LLM-based Named Entity Recognition (NER) module has been developed to enhance literature retrieval and expand coverage to include new variant types, such as CNVs and pharmacogenomic alleles.

Results: VarChat is freely accessible at varchat.engenome.com, natively integrated in eVai (evai.engenome.com), and recently into the UCSC Genome Browser. Preliminary results on a ClinVar-based

benchmark demonstrated that the LLM-Based NER module used for literature retrieval achieved a sensitivity of 72% in identifying variants with standard nomenclature, increasing to 91% when accounting for correct identification under non-standard nomenclature (e.g., unofficial gene symbols). Missed variants were located in supplementary materials, not currently preprocessed by the module.

Conclusions: By combining advanced literature preprocessing with hybrid retrieval techniques, VarChat accelerates the interpretation of genomic variants, providing critical support to the genomic community in advancing clinical decision-making.

P17.074.C Single cell transcriptome analysis and inference by machine learning on prostate cancer fusion biopsy specimens identifies cancer-associated cells with diagnostic gene expression signatures

Fernando Marín-Benesiu[1,2], *Verónica Arenas-Rodríguez*[1], *Sergio Cuenca-López*[3], *Álvaro Zorrilla-Carriquí*[1,2], *Beatriz Álvarez-González*[1,4], *Luis Javier Martínez-González*[1,2], *Maria Jesus Alvarez Cubero*[1,2]

[1]*Pfizer - Universidad de Granada - Junta de Andalucía Centre for Genomics and Oncological Research (GENYO), Granada, Spain,* [2]*Department of Biochemistry and Molecular Biology III and Immunology, University of Granada, Granada, Spain,* [3]*LORGEN G.P, PT, Ciencias de la Salud - Business Innovation Centre (BIC), Armilla, Spain,* [4]*Legal Medicine and Toxicology Department, University of Granada, Granada, Spain.*

Background: Prostate cancer (PC) is the second most common malignancy worldwide and the leading cancer in men. The PC tumour microenvironment conditions precise patient stratification and treatment efficacy. Single-cell RNA sequencing (scRNA-seq) enables detailed characterization of this complexity, while transperineal fusion-guided biopsy enhances diagnostic precision due to its higher specificity. However, studies using scRNA-seq from fusion-guided biopsy samples at diagnosis are limited.

Material and Methods: We analyzed the tumor microenvironment of 31 fusion-guided biopsies from 24 newly diagnosed PC patients, categorized into high (19 samples) and low (21 samples) tumorigenicity groups. scRNA-seq was performed to identify cancer cells enriched with PC-associated signatures. Differential abundance analyses using k-Nearest Neighbourhood clustering and pseudobulk gene expression data were used to develop machine learning models, including Elastic Net, validated via Leave-One-Out Cross Validation (LOOCV) and Bootstrap.

Results: scRNA-seq analysis revealed PC cell subpopulation such as PC cells and cancer-associated fibroblasts (CAFs). Differential abundance analysis identified high tumorgenicity-enriched cells (SpatialFDR < 0.01) characterized by overexpression of a subset of 52 genes such as *PCA3*, *SCHLAP1*, *CRISP3*, and *ERG*. Elastic Net models with LOOCV from the pseudobulk expression of these 52 genes showed robust performance (Accuracy, F1-score, G-mean, and AUC: 0.61–0.71). SHAP analysis identified *PCA3*, *TNFSF10*, *CPNE4*, and the novel *ENSG00000289332* as key discriminators of high vs. low tumorigenicity.

Conclusion: This study highlights the novel use of scRNA-seq in fusion-guided biopsy samples for PC diagnosis, with identification of PC and CAF cells and potential for new biomarker discovery, including the novel long non-coding RNA *ENSG00000289332*.

P17.075.D Weight loss maintenance metabolome and microbiome predictors

Tingyu Guo[1], *Zhanna Balkhiyarova,*[1], *Mari Näätänen*[2], *Carlos Gómez-Gallego*[2], *Anna Kårlund*[2,3], *Leila Karhunen*[2], *Marjukka Kolehmainen*[2], *Marika Kaakinen*[4,5], *Inga Prokopenko*[1], *Ayse Demirkan*[1]

[1]*University of Surrey, Guildford, United Kingdom,* [2]*University of Eastern Finland, Kuopio, Finland,* [3]*University of Turku, Turku, Finland,* [4]*Imperial College London, London, United Kingdom,* [5]*University of Helsinki, Helsinki, Finland.*

Background: Obesity poses many health-related and societal problems—successful weight loss maintenance (WL & WLM) remains challenging. The Finnish ELIPA food intervention study for WLM targeted this challenge while measuring gut microbiome and metabolome changes. We evaluated these omics factors contribution to WLM.

Material and Methods: ELIPA lasted 33 weeks, with sampling made at baseline before weight loss (stage1-week0), after WL/pre (stage2-week9), during (stage3-week21) and after weight maintenance (stage4-week33). Absolute weight change was modelled using random forest regression with 5-fold cross-validation. Metabolomic feature velocities (the rate of changes in abundance over WL, stages 1–2) were selected from 90 features via LASSO regression, while gut microbiome velocities (derived from enterotype clusters) were selected using linear regression before testing their relationships with weight change. Tested models were: two in full cohort (n = 82) with age/sex+/− metabolomics; two in microbiome subset (n = 32) with metabolomics+/-enterotype dynamics.

Results: In full cohort, glycine betaine velocity (variable importance, VI = 100%) was the strongest predictor of weight change. The microbiome enterotype velocity Cluster2 including *Faecalibacterium prausnitzii* contributed significantly (VI = 74%) when added to WLM model. In microbiome subset, stearamide (VI = 60.1%) and glycosidic compound MW488.3363 (VI = 100%) were important predictors combined with enterotype Cluster2 velocity (VI = 54%). The highest predictive accuracy was achieved for model including microbiome subset.

Conclusion: Dynamic changes in glycine betaine and stearamide metabolites are important for WLM with microbiome data enhancing model performance. These results highlight opportunity for personalized WLM strategies through targeted metabolite and microbial adaptation. Further validation in larger studies is needed to advance these biomarkers into clinical interventions.

P17.076.A Antiepileptic drugs effects on embryonic development: a transcriptome meta-analysis of in vitro studies and assessment of exposed newborns

Thayne W. Kowalski[1,2], *João V P Foletto*[1,2], *Lavinia Schuler-Faccini*[1,2], *Maria T V Sanseverino*[1,2], *Fernanda S L Vianna*[1,2]

[1]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil,* [2]*Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.*

Background: Antiepileptic drugs might present a risk for embryonic development, potentially causing craniofacial anomalies, congenital heart defects (CHD), and neural tube defects (NTD). However, the knowledge of antiepileptic-induced molecular disturbances in the embryo is scarce. Hence, this study aimed to evaluate genes differentially expressed (DEG) in human embryonic cells (hEC) and organoids exposed to antiepileptics, to compare these results to the DEG of newborns exposed to antiepileptics prenatally.

Material and Methods: Datasets of hEC or organoids exposed to antiepileptics were obtained in the GEO repository. Transcriptomes selected were processed in R language, evaluating DEG. A transcriptome meta-analysis was performed using the Fisher-P method. Physical examination of five newborns prenatally exposed to antiepileptics was performed and saliva samples were collected for RNA-seq performance.

Results: hEC transcriptome meta-analysis comprised 17 datasets of valproic acid (VPA) and six datasets of carbamazepine exposure; 317 DEG were identified. A second meta-analysis, of four organoids exposed to VPA, presented 411 DEG. Fifty-three DEG were common between both analyses: the homeobox *DLX4*, involved in craniofacial development; *TBX18*, a cardiovascular development transcription factor; and *NPFFR2*, a neurodevelopment gene. The RNA-seqs of five newborns, two exposed to VPA and three to carbamazepine (first trimester), are under evaluation. Two newborns present CHD, one exposed to VPA and another to carbamazepine; a third newborn, also exposed to carbamazepine, presents NTD.

Conclusion: Transcriptome meta-analysis based on in vitro assays can provide insights into genes potentially implicated in antiepileptics-induced embryopathies. This preliminary result will be confirmed by accessing the transcriptome of prenatally-exposed newborns.

P17.077.B A deep learning based web application for chromosomal abnormality detection using microscopic images

Mohadese Zare[1], *Firoozeh Modabber*[2], *Sanaz Movahed*[3], *Nasrin Ghasemi*[4]

[1]*Azerbaijan Shahid Madani university, Yazd, Iran, Islamic Republic of,* [2]*Azerbaijan Shahid Madani university, Shiraz, Iran, Islamic Republic of,* [3]*Azerbaijan Shahid Madani university, Tabriz, Iran, Islamic Republic of,* [4]*Yazd Reproductive sciences Institute, Yazd, Iran, Islamic Republic of.*

Background: Chromosomal abnormality, a major genetic disorder causing infertility and abortion, can be detected using traditional, time-consuming karyotype analysis methods, but advancements in image processing and deep learning offer potential automation.

Material and Methods: This study used microscopic chromosome images from the Gel Cell Laboratory to train a deep learning model. The initial model had suboptimal performance due to class imbalance. To address this, data balancing techniques were applied, and a refined dataset of 2,832 images was selected for training and optimization. Data augmentation techniques were applied to enhance the dataset. A Convolutional Neural Network (CNN) architecture and pretrained models were used, and performance was assessed using key metrics like accuracy, precision, recall, and F1-score. Ultimately, we designed a web application for evaluating model's performance on unseen local data.

Results: The CNN-based model demonstrated exceptional accuracy in identifying chromosomal anomalies, with 87% accuracy on the validation dataset and 85.03% accuracy on the test. It achieved precision of 83% and recall of 82%, demonstrating a balance between identifying positive cases and minimizing false predictions. Data augmentation improved performance, particularly in handling low-quality images. The model has been tested on local data through designed web application and achieved satisfying result.

Conclusion: The study demonstrates that deep learning, specifically CNNs, can effectively detect chromosomal abnormalities from microscopic images, providing a reliable tool for genetic laboratories for rapid and precise disease diagnosis, with future advancements exploring transfer learning.

P17.078.C Comprehensive in silico functional analyses of *HR* Gene pathogenic variants against Alopecia areata

Karthik Bonthala[1,2], *Chathyushya KB*[2], *Munikumar Manne*[2,3]

[1]*Imperial College London, London, United Kingdom,* [2]*Manna Biotech, Hyderabad, India,* [3]*ICMR- National Institute of Nutrition, Jamai-Osmania (Post), Hyderabad, India.*

Background: Alopecia areata is an autoimmune disorder characterized by abnormal hair loss, affecting approximately 2% of the global population. Research has linked the *HR* gene, which encodes the HR Lysine Demethylase and Nuclear Receptor Corepressor, located on chromosome 8. This study investigates the role of pathogenic variants in *HR* Gene through in silico methods to analyse their potential role in the pathogenesis of Alopecia areata.

Materials & Methods: A comprehensive analysis of these 297 single nucleotide polymorphisms (SNPs) in the *HR* Gene was performed, Identifying 30 variants as deleterious. Among these, four key SNPs, especially R1097H, R1099L, G1114R, and V1136D, exhibited the most substantial structural and functional effects on the protein, as determined by conserved and domain region analyses. The 3D structural predictions of the HR protein were generated using AlphaFold, and the results were further validated with I-TASSER. Molecular docking studies were then conducted to evaluate interactions with gene specific small molecules.

Results: N-oxalylglycine exhibited the lowest binding energy of −5.2 kcal/mol and formed strong interactions within 4Å of the following residues: Ala980, Leu981, Pro983, Leu984, Asp1012, Leu1013, Val1014, Ser1015, Leu1046, Gly1047, Ser1048, Gln1049, Arg1114, C1153, and Pro1157. Notably, N-oxalylglycine interacted with the significant SNP residue G1114R, highlighting its potential as a therapeutic candidate.

Conclusion: This study highlights the potential pathogenic role of specific *HR* gene variants in alopecia areata and identifies N-oxalylglycine as a promising molecule for further investigation. These findings contribute to the understanding of the molecular basis of Alopecia and opens approaches for targeted therapeutics.

P17.079.D Ancestry-specific database for cross-tissue Gene Expression Models: AGEMdb

Inti A. Pagnuco, *Francisco Herrerias Azcue, Stephen Eyre, Magnus Rattray, Andrew P. Morris*

The University of Manchester, Manchester, United Kingdom.

Background: Transcriptome-wide association studies (TWAS) link genetically regulated gene expression to traits or diseases. TWAS uses eQTL to predict gene expression and tests the association between the predicted expression and a trait. TWAS success relies on the accuracy of gene expression imputation models, which are trained using both genotype and gene expression data from the same samples. However, available resources, like the Genotype Tissue Expression (GTEx) Project, mainly focus on individuals of European ancestry, limiting prediction accuracy for other ancestry groups. To address this, we introduce the 'AGEMdb' (Ancestry-specific Gene Expression Models database), which includes gene expression models across 49 tissues for both European ancestry and African-American individuals in GTEx.

Material and Methods: Genotype and gene expression data were obtained from GTEx. After genotype quality-control, data from 689 European ancestry individuals and 111 African-American individual were retained. Gene expression was adjusted for confounding factors, and cross-tissue UTMOST models were trained separately for each ancestry group. These models were then used as input to the database.

Results: 'AGEMdb' is a web-based database hosting pre-trained gene expression imputation models in GTEx. Users can browse, search, and download models with flexible filtering by tissue type and gene. These models enable gene-trait association analysis in TWAS (UTMOST and similar tools) by predicting tissue-specific gene expression from genomic data. The inclusion of African-American models reduces European ancestry bias in human genetic/omic resources, enhancing inclusivity.

Conclusion: The 'AGEMdb' database is a valuable resource for ancestry-specific TWAS analysis, enhancing multi-tissue gene expression prediction accuracy across diverse populations.

Background: The study of pediatric rare diseases associated with intellectual disability, such as syndromic neurodevelopmental disorders (sNDD) and inborn errors of metabolism (IEM), faces significant challenges due to the limited number of cases available. This limitation prevents the generation of large patient cohorts necessary for the accomplishment of statistically robust studies and generation of new knowledge for better diagnosis and prognosis.

Material and Methods: Currently, within the European BETTER Consortium, we have selected 309 patients with sNDD, encompassing chromatinopathies and RASopathies. From these patients, we have obtained genomic data through next-generation sequencing (NGS), combined with phenotypic traits (HPOs) and functional biological data from early or late-diagnosed patients. These data shall be integrated in accordance with the FAIR principles into a federated platform, PADME (https://padme-analytics.de), which is capable of securely running distributed analyses at multiple European institutions and combining their data.

Results: A first prototype model of a federated analysis has been developed to work with a preliminary subset of data, being able to work with anonymized and interoperable datasets. This model of federated learning seeks to improve the specificity of the results obtained within each cohort, enabling work with multiple institutions that have real-world data, while ensuring GDPR compliance and increasing the robustness of the analyses.

Conclusion: This innovative approach, that integrates real-world and federated data, aims to delineate the causes of intellectual disability, and enhance the diagnosis and genotype-to-phenotype prediction of sNDD and IEM through the identification of novel genetic biomarkers, genetic modifiers, and/or disrupted signaling pathways.

P17.081.B GenDaB - a web database for human genes

Franziska Fritz, *Robin Steinhaus, Janina Schönberger, Maja Noack, Oliver Küchler, Dominik Seelow*

Berlin Institute of Health - Charité, Berlin, Germany.

Background: To assess a gene's involvement in a specific disease, researchers often have to comb through different websites to retrieve all information they need. Navigating through multiple

data sources and extracting only the required information is very labor-intensive and time consuming. We aim to streamline this process by providing a comprehensive and customizable one-stop-shop database for human genes.

Material and Methods: We have developed GenDaB, a user-friendly web-based database for human genes which allows researchers to retrieve the specific information they are interested in. It integrates data from various fields, including phenotypic data associated with a gene, protein function, gene and protein expression data, and protein-protein interactions. Users can query GenDaB with a list of genes or genomic regions. They can also filter genes for their specific properties, such as expression in a target tissue or known correlation with clinical signs.

GenDaB includes an API for easy integration in other applications or pipelines.

Results: GenDaB offers a user-friendly and comprehensive resource for researchers investigating human genes and their involvement in known diseases. The extensive search, filter and display options allow users to customize their queries based on their individual needs and retrieve only the information relevant to their research interest.

Conclusion: The GenDaB database is freely accessible at https://www.genecascade.org/gendab. It provides researchers with a powerful tool to gain comprehensive insights into human genes and their potential roles in diseases.

P17.082.C FinemappInG And pleiotRopy sOlver (FIGARO) pipeline for disentangling pleiotropy of large datasets

Arianna Landini[1], *Sodbo Sharapov, PHD*[1], *Alessandro Raveane*[1], *Matiss Ozols*[2], *Stephen Watt*[2], *Cardinal Project Working group*[3], *Marc Jan Bonder*[4], *Oliver Stegle*[5,2,6], *Nicole Soranzo*[1,2,7], *Nicola Pirastu*[1]

[1]*Human Technopole, Milan, Italy,* [2]*Wellcome Sanger Institute, Cambridge, United Kingdom,* [34]*Department of Genetics, University of Groningen, Groningen, Netherlands,* [5]*Division of Computational Genomics and Systems Genetics, German Cancer Research Center, Heidelberg, Germany,* [6]*European Molecular Biology Laboratory, Genome Biology Unit, Heidelberg, Germany,* [7]*University of Cambridge, Victor Phillip Dahdaleh Heart & Lung Research Institute, Cambridge, United Kingdom.*

Background: One of the main goals of genetic epidemiology is to identify variants influencing complex traits and understand how they exert their effects through biological layers. This helps reconstruct the causal relationships between traits. Given the abundance of genetic association studies available today, new tools are needed to efficiently process and summarise these relationships.

Material and Methods: We developed a statistical framework for untangling any type of genetic association summary statistics which performs: GWAS summary statistics harmonisation, identification of associated genomic regions through an ad hoc positional algorithm, fine-mapping of identified loci with SuSiE, pairwise colocalisation analysis, identification of coregulated association signals and joint fine-mapping by leveraging the results of multiple, colocalising traits to increase its precision. The framework relies on a combination of Nextflow pipeline and efficient storage of minimal data in AnnData objects to reduce computational and storage burden.

Results: We applied our approach to 10,641 eGenes over 28 cell types, resulting in 47,480 cis-eQTL tests carried out within the Cardinal study. After fine-mapping, the 79,416 credible sets (CS) obtained were stored in an AnnData object, reducing the disk storage by ~788 times. Colocalization was performed on pairs of CS sharing at least one SNP, resulting in 273,404 pairwise colocalization tests. CS were then grouped in 18,910 cis-regulated modules where the underlying causal SNP was shared across all.

Conclusion: Our pipeline provides a scalable, flexible, and memory-efficient solution for fine-mapping and colocalisation analysis of large-scale association data, helping uncover biologically relevant co-regulation mechanisms across diverse phenotypes.

P17.083.D Multiomic profiling of antibiotic response: Ampicillin, Aztreonam, Gentamicin and Cefepime's effect on multidrug-resistant *E. coli* strains

Kübra Teksen[1], *Melis Sardan Ekiz*[2], *Selinay Ozel*[2], *Ceylan Polat*[2], *Gulsah Merve Kılınc*[2], *Ergin Murat Altuner*[1], *İdil Yet*[2]

[1]*Kastamonu University, Kastamonu, Turkey,* [2]*Hacettepe University, Ankara, Turkey.*

Background: The misuse of antimicrobials has led to the rapid spread of antimicrobial resistance (AMR) in microorganisms, presenting a significant global health threat to effective infection treatments. Understanding how microorganisms respond to antibiotics is essential for developing new therapeutic strategies and advancing drug discovery.

Material and Methods: We investigated the proteomic, metabolomic and genomic profiles of three *Escherichia coli* (*E. coli*) strains with varying antibiotic resistance profiles, in comparison to a reference *E. coli* K12 strain. The focus was on strains exhibiting multidrug resistance to ampicillin, aztreonam, gentamicin, and cefepime, highlighting the role of active efflux pumps in antibiotic resistance mechanisms. We used UPLC and timsTOF-MS/MS to analyze metabolomic and proteomic profiles.

Results: Through integrated proteomic and metabolomic analyses, 450 proteins and 350 metabolites associated with resistance in the selected strains were identified. These findings indicate potential biomarkers that contribute to the bacterial survival under antibiotic stress. Notably, we observed differential protein expression linked to key metabolic shifts that facilitate resistance. These include changes in pathways related to cell wall biosynthesis, energy production, and stress response, which are critical for maintaining bacterial viability in the presence of antibiotics. Additional genome sequencing determined whether the changes in proteins originated from antibiotic treatment or from mutations in the genomes of the three *E. coli* strains.

Conclusion: Our findings underscore the potential of multi-omics approaches in advancing the understanding of antibiotic resistance and highlight the proteins and metabolites that may serve as targets for the development of novel antibiotics or resistance-modifying agents.

P17.084.A Transcript level quantification and splice junction detection in single-cell short-read expression data

Edoardo Giacopuzzi[1], *Alessandro Raveane*[1], *Davide Bolognini*[1], *Matiss Ozols*[2], *Stephen Watt*[2], *Azahara Fuentes-Trillo*[1], *Serena Scala*[3,4], *Luca Seffin*[5], *CARDINAL project Working group*[6], *Cecilia Dominguez Conde*[1], *Nicole Soranzo*[1], *Manuel Tardaguila*[1]

[1]Human Technopole, Milan, Italy, [2]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [3]IRCCS San Raffaele Scientific Institute, Milan, Italy, [4]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milan, Italy, [5]Vita-Salute San Raffaele University, Milan, Italy, [6]

Background: The analysis of splice junctions (SJ) and transcript expression at the single cell level informs understanding of cell-type specific patterns of gene regulation, giving new insights into cell biology, human traits, and disease mechanisms where alternative splicing is modified despite overall stable gene expression. However, transcript quantification and SJ detection are poorly explored in 10X Genomics scRNA-seq data.

Material and Methods: We compared computational methods for quantifying isoforms from 10X Genomics scRNA data, namely STARSolo, salmon-alevin, and kallisto-bustools. Using publicly available data and in-house generated data from 10X 3' and 5' libraries and relying on long-read single-cell data as ground truth, we compared the performance in quantifying isoform expression, transcript ranking, and transcript ratios within genes. We performed SJ analysis using LeafCutter (as described in Tian et al., Nature Genetics, 2024) and transcript quantification using the best-performing method on pseudo-bulk data in a cohort of ~5000 Europeanindividuals from the UK Biobank (CARDINAL project).

Results: Results show that scRNA data can be used to compare SJ usage and transcript quantification at the pseudo bulk cell-type level, and we propose a strategy to select genes for reliable transcript quantification. Preliminary data on the CARDINAL dataset demonstrate how our workflow can generate isoform and SJ quantification suitable for investigating the association with phenotype and genotypes.

Conclusion: We present an effective strategy for analyzing transcript-level expression in scRNA-seq datasets generated using 10X technology, and we show how this data can be used to gain new insights into cell-type specific transcript usage.

P17.085.B Comparative bioinformatics analysis of the transcriptome in High-Grade Serous Ovarian Cancer (HGSOC)

Beatrice Melli[1,2], *Vincenza Ylenia Cusenza*[2], *Valentina Vaccari*[3], *Sandra Martinelli*[2], *Eleonora Zanetti*[4], *Andrea Palicelli*[4], *Vincenzo Dario Mandato*[1], *Lorenzo Aguzzoli*[1], *Davide Nicoli*[2], *Roberta Zuntini*[3]

[1]Unit of Obstetrics and Gynecologic Oncology, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [2]Molecular Pathology, Azienda USL-IRCCS of Reggio Emilia, Reggio Emilia, Italy, [3]Medical Genetics Unit, Azienda USL IRCCS Reggio Emilia, Reggio Emilia, Italy, [4]Pathology Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy.

Background: High-grade serous ovarian cancer (HGSOC) accounts for 80% of ovarian cancer deaths. The heterogeneity of HGSOC leads to therapeutic resistance and poor outcomes. Exploration of differentially expressed genes (DEGs), performing pathway enrichment analysis (PEA), and analyzing protein-protein interaction (PPI) network through transcriptome analysis could identify new molecular mechanisms involved in this tumor and improve the knowledge about the heterogeneity of HGSOC.

Material and Methods: Preliminary Transcriptomic analyses of 8 samples of HGSOC were performed on RStudio (v4.3.2.) using the Bioconductor packages "EDASeq" for quality control; "edgeR", "DeSeq2", "limma" for DEGs analysis; "ReactomePA", "clusterProfiler" for PEA and "STRINGdb" for PPI analysis.

Results: The integration of results from bioinformatics analyses performed using the "edgeR", "DeSeq2" and "limma" packages showed 9,674 upregulated and 7,536 downregulated common DEGs on 20,812 genes. Validation of DEGs was conducted through real-time PCR, focusing on the top 50 commonly selected genes based on absolute logFC and p-value. These preliminary findings confirm the upregulation of the *PAX8* gene and highlight the involvement of the PI3K-Akt signaling pathway, as supported by the literature. The next step involves the comparative integration of additional bioinformatics tools to explore PEA and PPI network analyses, including the difference in results between analysis.

Conclusion: Comparing different Bioinformatics tools for the analysis of transcriptome could help to understand the molecular alteration involved in the pathogenicity and have a confirmation of obtained results. Furthermore, in-depth analysis can help to highlight different results to find hidden mechanisms involved in the prognosis of the tumor.

P17.086.C Automated extraction of HPO ids from clinical notes using Large Language Models

Alexandre Boulat[1], *Jean-Marie Ravel*[2], *Yannis Lombardi*[3], *Jiri Ruzicka*[1], *Nicolas Philippe*[1], *Jerome Audoux*[1], *Michael GB Blum*[4], *Nicolas Duforet*[1], *Laurent Mesnard*[5]

[1]SeqOne, Montpellier, France, [2]Universite de Lorraine, CHRU de Nancy, Vandoeuvre-les-Nancy, France, [3]APHP.SORBONNE UNIVERSITE, Paris, France, [4]IAB, Université Grenoble Alpes, Grenoble, France, [5]APHP.SORBONNE UNIVERSITE, PARIS, France.

Background: Given the vast number of variants that need to be interpreted in Whole Exome or Whole Genome analyses, prioritizing them based on the observed phenotype is essential. The use of standardized phenotypic ontology terms (HPO codes) plays a crucial role in identifying diagnostic variants. However, the upstream collection of HPO terms remains complex, limiting their practical use in clinical settings.

Material and Methods: Automatic extraction of HPO ids from raw clinical notes relies on an agentic Artificial Intelligence called PhenX. PhenX uses a Large Language Model to identify patient symptoms, then performs suggessive tasks to match them with Terms from the Human Phenotype Ontology and their IDs. The agent takes also cares of patient anonymization and prevents hallucinations.

Results: We assessed the quantity and quality of HPO IDs extracted by the Agentic AI in a cohort of nephrology patients. Each patient had clinician-validated HPO terms derived from consultation notes. For patients with a confirmed diagnosis, we analyzed the impact of extracted phenotypes on diagnostic gene rankings using PhenoGenius, a gene-phenotype matching tool. We evaluated three extraction protocols: fully expert-curated, semi-automated, and fully automated."

Conclusion: We present and evaluate PhenX, and Agentic AI for automatic phenotype extraction. While the rankings of diagnostic gene remain lower with expert curated Phenotypes, the agentic AI offers an efficient alternative to the time consumming task of extacting phenotypes from clinical notes.

P17.087.D Mapping Complex HGVS Variant Descriptions Across Genetic References

Mihai Lefter, *Jonathan K. Vis, Mark A. Santcroos, Xiaoyun Liu, Jeroen F. J. Laros*

Leiden University Medical Center, Leiden, Netherlands.

Background: The Human Genome Variation Society (HGVS) provides a set of recommendations for the accurate and unambiguous description of genetic variants. While existing methods attempt to normalize HGVS variant descriptions by independently manipulating them into a canonical form, they are generally effective only for small variants. Advancements in genomic technologies have led to more frequent recording of complex variant combinations and facilitated the development of improved and competing reference genomes (GRCh38 and T2T-CHM13). These developments drive the need for advanced solutions capable of also accurately mapping variants across references.

Material and Methods: We introduce methods for generating standardized HGVS descriptions for complex variants and mapping them between (related) reference sequences. A deterministic algorithm extracts canonical variants by comparing a reference sequence to an observed sequence. We apply this extraction process for variants of each molecular type (DNA, RNA and protein) which results in independent variant descriptions in each domain. By extracting the observed sequence against another reference, the original HGVS description is mapped while incorporating reference differences rather than merely lifting over variants. An additional extraction step identifies variants introduced by reference sequence differences, allowing them to be subsequently filtered out.

Results: Our method enables the seamless transfer of variant descriptions between different genome builds and molecular domains, while accounting for sequence differences. Furthermore, the method supports inter-species variant conversions, expanding its applicability across diverse genomic contexts.

Conclusion: These methods are integrated into the Mutalyzer 3 tool suite, available as a web application (https://mutalyzer.nl/) and a Python package (https://github.com/mutalyzer/mutalyzer).

P17.088.A Incorporation of clinical and molecular variant properties improves classification and calibration of in silico pathogenicity prediction tools

Ofer Isakov[1,2,3], *Reut Fluss*[1], *Dina Marek-Yagel*[1], *Shay Ben-Shachar*[1,3,4]

[1]*Clalit Research Institute, Ramat Gan, Israel,* [2]*Raphael Recanati Genetic Institute, Rabin Medical Center-Beilinson Hospital, Petach Tikva, Israel,* [3]*The Ivan and Francesca Berkowitz Family Living Laboratory Collaboration, at Harvard Medical School and Clalit Research Institute, Boston, MA, USA,* [4]*Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.*

Background: In silico pathogenicity prediction tools are essential for determining the potential pathogenicity of genetic variants and their performance can vary depending on molecular and clinical contexts. In this study we evaluated the performance variability of commonly used tools under different conditions and recalibrated score thresholds to better reflect evidence of pathogenicity.

Materials and Methods: ClinVar variants were analyzed using 25 tools. Tools were evaluated based on discriminatory performance on several variant subsets. For each subset, Bayesian methods were employed to recalibrate score thresholds corresponding to the levels of evidence defined by the American College of Medical Genetics (ACMG).

Results: The performance of tools varied significantly across different subsets. Tools exhibited reduced accuracy for variants with higher allele frequencies and lower discriminatory performance for variants located in regions with high conservation. Variants affecting autosomal recessive (AR) and X-linked (XL) genes were more accurately classified compared to those affecting autosomal dominant (AD) genes by most tools. Using simulated variant subsets the recalibrated thresholds consistently showed higher odds of correctly estimating pathogenicity (OR = 3.78 [1.74, 8.58]; $p < 0.001$). Compared to the genome-wide thresholds, the recalibrated method produced significantly higher scores for known pathogenic/likely-pathogenic (P/LP) variants and lower scores for benign/likely-benign (B/LB). This improved discriminatory performance was particularly notable in variants found in low-conservation regions and AR genes.

Conclusion: in silico pathogenicity prediction tools exhibit context-dependent performance variability. Score threshold recalibration extends the range of evidence and improves overall pathogenicity probability estimation and classification.

P17.090.C Enabling clinical translation of high-throughput functional assay data with MaveDB

Alan F. Rubin[1,2], *Jeremy Stone*[3], *Benjamin J. Capodanno*[3], *Estelle Y. Da*[1], *Sally B. Grindstaff*[3], *Nick Moore*[1], *Lea M. Starita*[3,4], *Douglas M. Fowler*[4,3]

[1]*Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,* [2]*University of Melbourne, Melbourne, Australia,* [3]*Brotman Baty Institute, Seattle, WA, USA,* [4]*University of Washington, Seattle, WA, USA.*

Background: A central problem in precision medicine is understanding the effects of individual DNA variants. Measuring their activity in the lab provides valuable evidence for clinical interpretation but can be both time- and resource-intensive. Multiplexed assays of variant effect (MAVEs) are a family of experimental techniques that allow researchers to measure many thousands of variants in a gene or other functional element in parallel, generating a large volume of high-quality functional evidence. Our goal is to increase the availability and discoverability of MAVE data for researchers and clinicians alike.

Material and Methods: We developed MaveDB, an open-source community-oriented database for MAVEs and other types of functional assays including those based on low- or medium-throughput approaches. MaveDB implements a user-friendly model for uploading and searching datasets, as well as a clinician-focused interface that provides detailed information and visualisations for individual variants. We are also driving the

creation and adoption of international standards for functional assay data.

Results: MaveDB has been embraced by the MAVE community as the database of record and already contains 2000 datasets comprising over 7 million individual variant-effect measurements. This includes MAVE data for several genes on the ACMG secondary findings list such as *BRCA1*, *CALM1/2/3*, *KCNQ1*, *MSH2*, *PTEN*, *SCN5A* and *TP53*. Availability of data standards has enabled integration of MaveDB data by diverse partner resources.

Conclusion: As more functional data continues to be generated, increasing availability and promoting standardisation will help get this important evidence into the hands of clinicians quickly to improve patient outcomes.

P17.091.D A DNA methylation-based diagnostic algorithm for rheumatoid arthritis

Astanand Jugessur[1], *Espen Riskedal*[2], *Silje Watterdal Syversen*[3], *Catherine Lund Hadley*[2], *Jennifer Ruth Harris*[1], *Maria Dahl Mjaavatten*[3], *Joe Sexton*[2], *Janis Neumann*[2], *Gina Hetland Brinkmann*[3], *Guro Løvik Goll*[3], *Grethe-Elisabeth Stenvik*[3], *Håkon Bøås*[1], *Arne Søraas*[2], *Karl Trygve Kalleberg*[2], *siri Lillegraven*[3], *Espen Andre Haavardsholm*[3]

[1]*Norwegian Institute of Public Health, Oslo, Norway,* [2]*Age Labs AS, Oslo, Norway,* [3]*Diakonhjemmet Hospital, Oslo, Norway.*

Background: Rheumatoid arthritis (RA), particularly seronegative disease, is difficult to diagnose early, which can delay treatment initiation. This study aims to develop a binary DNA methylation (DNAm)-based algorithm to diagnose RA.

Material and Methods: Three datasets (discovery, training, holdout) were constructed from DNAm profiles from 1,366 persons (treatment-naïve RA, other inflammatory/autoimmune diseases, healthy individuals). DNAm features that differentiate RA from other inflammatory/autoimmune diseases and healthy individuals were identified using the discovery set. Our classification algorithm was developed using machine learning techniques in the training set. Its diagnostic performance, with and without serological status, was evaluated in the holdout set containing RA cases (15 seropositive, 6 seronegative) and controls (14 other arthritides,11 healthy individuals).

Results: Our algorithm included 391 DNAm features (CpGs). Combined with serological status, it classified RA from controls in the holdout set with the following performance: sensitivity 0.90 [95% CI: 0.70–0.99], specificity 0.88 [95% CI: 0.69–0.97], and AUC 0.96 [95% CI: 0.91–1.00]. Its performance in classifying patients with seronegative RA versus those with other arthritides was: sensitivity 0.83 [95% CI: 0.36–1.00], specificity 0.79 [95% CI: 0.49–0.95], and AUC 0.81 [95% CI: 0.61–1.00].

Conclusion: The present DNAm-based classification algorithm may be clinically useful for the early diagnosis of RA, especially in seronegative patients.

P17.092.A A compendium of uniformly processed human single-cell gene expression quantitative trait loci

Peep Kolberg[1], *Kristiina Kuningas*[1], *Karatug O. Bircan*[2], *Abayomi Mosaku*[2], *Helen Parkinson*[2], *Laura W. Harris*[2], *Kaur Alasoo*[1]

[1]*University of Tartu, Tartu, Estonia,* [2]*EMBL-EBI, Cambridge, United Kingdom.*

Background: Molecular mechanisms underlying human complex traits and diseases remain poorly understood. While large-scale gene expression quantitative trait locus (eQTL) studies from bulk tissues have had some success in interpreting genetic associations with complex traits, bulk analysis can hide important cell-type-specific regulatory effects. Although single-cell eQTL studies are now starting to emerge, different labs use a heterogeneous set of approaches for data processing and cell type annotation, complicating the integration and comparison of results from these studies.

Material and Methods: Building on the success of the eQTL Catalogue (https://www.ebi.ac.uk/eqtl/), we have compiled a set of open source workflows for uniformly processing single-cell eQTL datasets. First, we use the nf-core/scrnaseq workflow to re-quantify gene expression from scRNA-seq data. We also developed Nextflow workflows for single-cell quality control, demultiplexing, and doublet detection using tools from the Demuxafy package. We also automatically annotate cell types with the CellTypist software package. Finally, we use the existing eQTL Catalogue bulk workflow to perform genotype imputation, association testing, and statistical fine-mapping.

Results: We have finished processing data from the first six single-cell eQTL studies and have made these results publicly available on the eQTL Catalogue FTP server and our interactive browser (https://elixir.ut.ee/eqtl/). We are currently working on the uniform processing of the next five datasets from various tissues. We have also publicly released all of our workflows.

Conclusion: We believe that the single-cell eQTL Catalogue will become a valuable novel resource for GWAS interpretation and drug target prioritisation.

P17.094.C SnakeSplice: A seamless workflow for splice variant discovery and visualization in RNA-Seq data

Oliver Küchler[1,2], *Felix Boschann*[1,2,3], *Johannes Kopp*[1,4,5], *Björn Fischer-Zirnsak*[1,4], *Dominik Seelow*[1,2]

[1]*Institute of Medical Genetics and Human Genetics, Charité, Berlin, Germany,* [2]*Exploratory Diagnostic Sciences, Berlin Institute of Health at Charité, Berlin, Germany,* [3]*BIH Biomedical Innovation Academy, BIH Charité Clinician Scientist Program, Berlin Institute of Health (BIH) at Charité, Berlin, Germany,* [4]*Max Planck Institute for Molecular Genetics, Berlin, Germany,* [5]*Institute of Chemistry and Biochemistry, Department of Biology, Chemistry and Pharmacy, Freie Universität Berlin, Berlin, Germany.*

Background: Correct splicing is essential for protein expression. Thus, defects in this process are associated with numerous

diseases. RNA sequencing (RNA-Seq) can be used to detect variants, and to study mRNA expression and isoform abundance. Yet, bridging the gap between complex data analysis and intuitive result presentation remains challenging.

Material and Methods: SnakeSplice is a comprehensive RNA-Seq analysis pipeline with five modules: (1) quality control, preprocessing, alignment, (2) gene fusion detection, (3) transcript quantification, differential expression, gene set enrichment analysis, (4) splicing pattern assessment and (5) variant detection. Additionally, SnakeSplice introduces PJD-tool, a novel method for identifying hitherto unknown "private" splice junctions. To evaluate its performance, we analyzed three positive control datasets (5/3/1 cases, 20 controls) with known splicing defects in BUD13, SUPT7L, and MRPL42, respectively, as well as 71 additional transcriptomic samples for exploratory analysis.

Results: SnakeSplice efficiently processes large-scale datasets by leveraging parallel computing and High-Performance Computing (HPC) resources. To enhance usability, SnakeSplice generates interactive HTML reports, making results easily accessible to broader research and clinical teams. The PJD-tool significantly improves the identification of novel splice sites, contributing to a deeper understanding of alternative splicing. In our validation, SnakeSplice correctly prioritized the known pathogenic splicing defects, ranking BUD13 and MRPL42 as top candidates and SUPT7L among the top 10 genes for further investigation.

Conclusion: SnakeSplice is an open-source, scalable workflow optimized for parallel computing environments. It provides an end-to-end solution for gene expression and splicing analysis, including detection of novel splice sites and generation of interactive HTML reports.

P17.095.D AION: an AI-driven dual-model variant interpretation framework for diagnostics and discovery

Andrea Bertana, Lourdes Rosano, Max Schelker, ***Rocio Acuna-Hidalgo***

Nostos Genomics GmbH, Berlin, Germany.

Background: As a regulatory-compliant variant interpretation platform, AION undergoes routine evaluation guided by clinical performance metrics. Balancing sensitivity and specificity is particularly challenging in genetic diagnostics, as capturing the long tail of pathogenic variants can increase false positives. Therefore, clinical performance must be tailored to the application: high specificity for diagnostics and high sensitivity for research.

Methods: To address these distinct needs, we have developed a dual-model variant prioritization framework in AION: a high-stringency approach, which prioritizes specificity for screening and diagnostics, and a low-stringency approach, which prioritizes sensitivity for research. We evaluated AION v3.14.0.0 across three datasets: 1) a synthetic dataset with disease-causing variants ($n = 1089$), 2) real-world clinical cases with diverse genetic conditions ($n = 125$) and 3) a negative control dataset where healthy controls were annotated with Mendelian disease phenotypes ($n = 100$). Sensitivity, ranking and specificity were assessed to measure clinical performance.

Results: The low-stringency model showed higher sensitivity (synthetic: 94.4% vs 89%; clinical: 85.2% vs 74.6%), but prioritized more candidate diagnoses (synthetic: 11.1 vs 1.12; clinical: 18.2 vs 2.2). Conversely, the high-stringency model accurately identified 41% of the negative dataset as having no pathogenic variants, requiring on average a review of only 1.17 results per case, underscoring its utility in diagnostics.

Conclusions: AION's dual-model framework provides a flexible, robust balance of sensitivity and specificity, leading to practical benefits like faster case review, improved detection of negative cases and higher case resolution rates. This ultimately enables more confident conclusions in variant interpretation, enhancing both diagnostic accuracy and speed and research efficiency.

P17.097.B A Framework to Maximise Genetic Diversity in Genome-Wide Association Study Meta-Analyses

Chuan Fu Yap*, Andrew P. Morris*

University of Manchester, Manchester, United Kingdom.

There have been recent efforts by the human genetics research community to increase the genetic diversity of participants contributing to genome-wide association studies (GWAS). The standard approach is to first assign participants to an "ancestry group" and then aggregate results across ancestry-specific GWAS through multi-ancestry meta-analysis. However, participants are typically assigned "continental" labels that may not reflect personal views of ethnicity/race or fully represent genetic diversity. Furthermore, some admixed participants are excluded because they cannot be assigned to a single ancestry group. Here, we present a novel pipeline for multi-ancestry meta-analysis that employs a continuous and multi-dimensional representation of ancestry by first projecting all participants onto genetic principal components (PCs) derived from the Human Genetic Diversity Project. Association analyses are then conducted for all participants in a mixed model with adjustment for PCs as covariates. Testing for interaction with PCs enables assessment of ancestry-correlated heterogeneity. We applied the new pipeline to meta-analysis of GWAS of type 2 diabetes in up to 55,090 cases and 503,503 controls of diverse ancestry. Despite increasing the genetic diversity of participants included in the meta-analysis, we demonstrate that association summary statistics were not more inflated for the new pipeline than the standard approach (genomic control lambda 1.159 for both). The new pipeline identifies 170 loci at genome-wide significance ($P < 5 \times 10^{-8}$), compared with 159 for the standard approach. The new pipeline increases sample size, and the diversity of participants included in multi-ancestry GWAS meta-analysis, offering enhanced power for discovery of loci that are relevant across global populations.

P17.099.D HLA-DRBindPred: An Explainable Machine Learning Identifier for HLA-DR4 Binding peptides

Zainab Jan*, Puthen Veettil Jithesh*

Hamad Bin Khalifa University, Doha, Qatar.

Background: HLA-DRB1*04:01 is associated with several autoimmune diseases such as multiple sclerosis, rheumatoid arthritis, diabetes, as well as with COVID-19. The identification of peptides binding to this allele is crucial for the development of immunotherapies and vaccines. Existing methods for predicting HLA-DRB1*04:01 binders have low accuracy, reducing their

reliability in identifying binders for immunological research and clinical applications.

Methods: In this study, we propose HLA-DR4BindPred, a novel machine learning-based predictor for identifying HLA-DRB1*04:01 binding peptides using 100,0000 peptide sequences. It utilizes a range of feature encoding schemes, including composite protein sequence representation (CPSR), extended pseudo amino acid composition (ExPseAAC), and dipeptide deviation from expected mean (DDE) to capture essential information from peptide sequences. Finally, random forest-based machine learning model was developed to identify HLA-DR4 binding peptides. Novel peptide motifs were also identified using MEME Suite.

Results: HLA-DR4BindPred model attained superior performance on all two benchmark datasets, namely, main, and alternate over tenfold cross validation. It outperformed the existing models and improved the prediction by 13.37%, 12.27%, 11.58%, 8.55%, and 6.5% in accuracy, specificity, sensitivity, MCC, and AUC, respectively, when compared to HLADR4Pred2.0 and NetMHCIIpan4.0. It also achieved a remarkable accuracy of 98.4% and AUC of 99.5%, setting a new benchmark in HLA-DRB1*04:01 binder prediction. For the explainability of the proposed model, SHAP method was employed to analyze the feature importance and its contribution to HLA-DRB1*04:01 binder prediction.

Conclusion: We believe that HLA-DR4BindPred will significantly accelerate the identification of novel HLA-DRB1*04:01 binders, enhancing immunotherapy, vaccine design, and therapeutic strategies for diseases associated with HLA-DRB1*04:01.

P17.100.A Unlocking genetic mysteries: AI-driven insights for variant interpretation

Susanna Zucca[1], *Federica De Paoli*[2], *Silvia Berardelli*[3,1], *Ettore Rizzo*[1], *Ivan Limongelli*[1]

[1]*enGenome, Pavia, Italy,* [2]*ENGENOME SRL, PAVIA, Italy,* [3]*University of Pavia, Pavia, Italy.*

Background: Identifying causative variants remains a significant challenge in genomics and is critical for improving the diagnostic yield of rare diseases. To address this, we have developed a suite of tools leveraging Artificial Intelligence (AI) to analyze genetic data and identify disease-causing variants. Through extensive benchmarking and collaborative efforts, our tools prioritize transparency and trust in AI predictions.

Material and Methods: We developed the *Suggested Diagnosis* AI system, which integrates pathogenicity, phenotypic data (as HPO terms), and familial inheritance patterns to prioritize causative variants within a Mendelian framework. This model incorporates a layer of Explainable AI (XAI) to elucidate the rationale behind its prediction results.In addition, moving beyond monogenic analysis, we designed an AI-driven layer to detect digenic and oligogenic variants. This module incorporates evidence of gene-gene interactions to improve the identification of complex genetic contributions to disease.

Results: The *Suggested Diagnosis* system (PMID:38520562, PMID:37577678) was benchmarked on six cohorts of WES and WGS data, successfully prioritizing causative variants in 85.7% of WES cases (top 20) and 100% of WGS cases (top 15). The digenic analysis module achieved a sensitivity of 73% (median rank 3) on 11 solved samples, improving to 81% on a larger manually curated dataset.

Conclusion: By enhancing precision and efficiency in genomic analysis, our solution accelerates diagnosis and improves diagnostic yield. It prioritizes monogenic, digenic, and oligogenic candidates through a hypothesis-driven approach. These modules are natively integrated into the eVai software (evai.engenome.com), an advanced solution for variant interpretation.

P17.101.B GeM Finder: Identification of Genotype-Dependent Mismapping as a frequent source of spurious variant calls

Emanuele Bonetti, *Yinxiu Zhan, Gianmaria Frigè, Luca Mazzarella*

European Institute of Oncology IRCCS, Milan, Italy.

Background: Homologous genomic regions have long posed challenges for variant calling. The probability of homology-driven misalignment is generally computed on reference genomes. Here, we provide evidence for Genotype-Dependent Mismapping (GDM) as a possible source of spurious variant calls. We show that in GDM-prone regions, the presence of specific polymorphic haplotypes "switches" the degree of homology to the point that reads cannot be unambiguously mapped. Thus, mappability changes on an individual basis and may lead to spurious calls. We develop a tool, GeM Finder, that provides a consistent methodology to identify GDM-prone regions and assess impact.

Material and Methods: GeM Finder combines BLAT-based homology detection with dbSNP-referenced haplotype analysis to quantify mismapping probabilities. GeM Finder was applied to The Cancer Genome Atlas (TCGA) and GENIE datasets, to identify genes with elevated likelihood of genotype-dependent mismapping.

Results: Cancer-associated genes such as KTM2C, NOTCH2, STAT5A, and STAT5B showed up to 15% mismapping in highly homologous regions. For KMT2C, one of the most affected genes, GeM Finder identified 455 haplotypes in BAGE2 (KMT2C paralog) capable of inducing ≥25% mismapping, showing that specific alleles act as mapping switches. Mismapping was strongly allele-dependent, affecting variant calling reliability. In GDM-positive cases, confirmation of the variant call by long-range PCR or long-read sequencing is required.

Conclusion: This study introduces GDM as a common source of spurious variant calls, and GeM Finder as a novel framework for addressing homology-related errors. By systematically identifying GDM, GeM Finder enhances the accuracy of genomic analyses, paving the way for improved clinical applications.

P17.102.C Population-scale identification of cell state-dependent genetic regulation

Jan P. Engelmann[1], *Fabiola Curion*[1], *Cardinal Project Working group*[2], *Nicole Soranzo*[3], *Fabian J. Theis*[1], *Francesco Paolo Casale*[1]

[1]*Helmholtz Munich, Munich, Germany,* [23]*Human Technopole, Milan, Italy.*

Background: Genome-wide association studies have uncovered numerous genetic variants associated with disease, but their

regulatory mechanisms remain poorly understood. While bulk RNA-sequencing has provided insights at the tissue level, single-cell data enable a more detailed view of genetic effects across different cell states. However, existing single-cell eQTL approaches either focus on manually annotated predefined cell types, or fail to scale to the population-scale cohorts. As a result, our understanding of cell state-dependence of regulatory effects remains limited.

Methods: We present G-MixMIL, an extension of our method, MixMIL [1], designed for scalable cell state-dependent eQTL mapping. G-MixMIL tests for cell state-dependent associations between a single gene's expression and genotype across individuals. By learning which cell states exhibit the strongest genetic regulation, the model identifies specific groups of cells without requiring detailed manual annotation. For calibrated statistical testing, we developed an approximate likelihood ratio test for our model.

Results: In the OneK1K sub-lymphoid compartment, G-MixMIL identified 538 eQTL effects exhibiting significant heterogeneity. Furthermore, we identified dynamic eQTL effects in B cells without relying on predefined differentiation trajectories. We will extend this approach to 4,978 UK Biobank (UKBB) individuals as part of the Cardinal Consortium, validating G-MixMIL's ability to discover sub-cell states from a population-scale dataset.

Conclusion: Our findings highlight the cell state-specific nature of genetic regulation and underscore the utility of G-MixMIL in discovering previously uncharacterized cell states. Ongoing work includes assessing overlaps with disease-associated variants and applying G-MixMIL to primary brain tissue, to understand the molecular mechanism of disease.

P17.103.D Unravelling HR-positive, HER2-negative Breast Cancer and its Tumor Microenvironment Heterogeneity Using Spatial Transcriptomics

Bengisu Karakose[1], *Matteo Serra*[1], *Nicolaas Van Renne*[1], *Fréderic Lifrange*[2], *David Venet*[1], *Delphine Vincent*[1], *Ghizlane Rouas*[1], *Mattia Rediti*[3], *Ligia Craciun*[4], *Denis Larsimont*[5], *Miikka Vikkula*[6], *François Duhoux*[7], *Françoise Rothe*[1], *Christos Sotiriou*[1]

[1]*Breast Cancer Translational Research Dept., Institute Jules Bordet, Brussels, Belgium, Brussels, Belgium,* [2]*CHU de Liège - Sart Tilman Site, Liège, Belgium, Liege, Belgium,* [3]*Metabolic reprogramming in solid tumors Lab, IFOM-IEO Campus, Milan, Italy, Milan, Italy,* [4]*Pathological Department, Institute Jules Bordet, Brussels, Belgium, Brussels, Belgium,* [5]*Pathology, Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Institut Jules Bordet, Brussels, Belgium, Brussels, Belgium,* [6]*de Duve Institute, University of Louvain, Human Molecular Genetics, Woluwe-Saint-Lambert, Belgium,* [7]*Medical Oncology department, Cliniques Universitaires Saint-Luc (UCLouvain Saint-Luc), Woluwe-Saint-Lambert, Belgium, Woluwe-Saint-Lambert, Belgium.*

Background: HR-positive, HER2-negative (HR+/HER2-) breast cancer exhibits significant molecular and cellular heterogeneity, influencing prognosis and treatment response. We applied spatial transcriptomics (ST) to dissect tumor microenvironment (TME) heterogeneity and its impact on clinical outcomes.

Methods: Spatial transcriptomics (Visium 10X) was performed on 86 HR+/HER2- of no-special-type of frozen tumor samples, and relative H&E slides were morphologically annotated. Single-cell deconvolution of ST spots was performed to increase the resolution of Visium data. Tumor and TME compartments were identified using morphological annotation, and differences in the abundance of deconvoluted cell types between two intrinsic molecular subtypes, LumA and LumB, were investigated. Weighted Gene Co-expression Network Analysis identified functional gene modules associated with relapse-free survival, validated using the METABRIC dataset.

Results: As expected, LumB tumors exhibithed worse relapse-free survival compared to LumA tumors ($p = 0.012$). Distinct spatial patterns emerged between LumA and LumB subtypes. LumA tumors were more enriched for CXCL12+ endothelial cells, naive B cells, and multiple CAF subtypes across both tumor and TME zones compared to LumB tumors, whereas LumB tumors exhibited higher infiltration of exhausted T cells (LAG3+), CXCL10+ macrophages, and lipid-associated macrophages (FABP5+) within TME regions compared to LumA tumors. Gene modules related to proliferation, metabolism, and innate immunity correlated with poorer disease outcomes. Specific immune populations derived from single-cell deconvolution mapped to different histological compartments, revealing distinct immune landscapes across tumor and TME zones.

Conclusion: These findings enhance the understanding of the TME in HR+/HER2- breast cancer, highlighting its critical role in tumor progression. Further validation is needed.

P17.104.A ILIAD: the ERN-ITHACA registry of rare diseases with intellectual disability and anomalies of development

Klea Vyshka[1], *Gerieke Been*[2], *Morris Swertz*[2], *Fernanda De Andrade*[2], *Joeri Van Der Velde*[2], *Molgenis Group, UMCG*[3], *Alain Verloes*[1], *ERN ITHACA Consortium*[3]

[1]*Robert Debré Hospital, Paris, France,* [2]*University Medical Center Groningen, Groningen, Netherlands,* [3]

Background: ERN ITHACA is the European reference network for rare malformative conditions, intellectual disabilities and neurodevelopmental disorders. ERN ITHACA has developed a "meta-registry" called ILIAD, connecting 71 HCPs, databases, and biobanks across the EU for patients with dysmorphic/multiple congenital anomalies syndromes and/or intellectual disability. Through the ERN ITHACA's expert and patient participation network, ILIAD is able to provide an infrastructure for diagnosis,

highly specialised multidisciplinary healthcare, evidence-based management, and collection of patient data.

Material and Methods: The registry is built on MOLGENIS open-source software, providing flexible data structures, user friendly data import and querying, and FAIR interfaces for programmatic data exchange. ILIAD consists of 2 components: a central, web-based registry and a network of linked satellite/client registries forming the ERN ITHACA registry federation. To date, two client installations have been successful and at least six more are ongoing. Data is modelled adhering to international interoperability standards from JRC and EJP-RD.

Results: In addition to the core registry, ILIAD includes subregistries of patients with biologically proven monogenic or genomic (chromosomal) diagnoses, under the supervision of ERN-based teams. ILIAD has adopted a data access policy, for requesting access to the data and the governance of the registry is in place to ensure compliance with applicable legal and regulatory requirements on the use of Personal Data.

Conclusion: We are well equipped to share ERN ITHACA patient data, yielding high-quality epidemiological insights and expert consensus statements, informing policy decisions that impact rare disease patients in general and care for ERN ITHACA patients in particular.

P17.105.B The nf-core/variantbenchmarking Pipeline within the GHGA Framework

Kübra Narci

German Cancer Research Center, Heidelberg, Germany.

Background: The German Human Genome-Phenome Archive (GHGA) provides a secure, scalable infrastructure for processing and benchmarking human omics data. As part of this effort, the nf-core/variantbenchmarking pipeline (https://github.com/nf-core/variantbenchmarking) was developed to benchmark small variants, indels, and structural variants in germline and somatic datasets, enabling reproducible and standardized analysis.

Material and Methods: Built with Nextflow, the pipeline ensures scalability and reproducibility across diverse environments, including local systems, HPCs, and cloud platforms. Users can benchmark using truth datasets (e.g., Genome in a Bottle, SEQC2) or custom VCF files. The pipeline supports normalization steps such as deduplication, variant splitting, filtration, and alignment correction, as well as benchmarking tools like hap.py, rtgtools, and truvari. It computes precision, recall, and F1 scores, offering detailed performance metrics.

Results: The pipeline facilitates accurate benchmarking and harmonization of variant-calling workflows, generating actionable performance insights like precision, recall, and F1 scores. By integrating with GHGA's secure infrastructure, it supports the preprocessing and benchmarking of human omics data while ensuring FAIR compliance. It is in nf-core github and It adheres to nf-core community guidelines, ensuring high-quality, reviewed code, modularity, and extensibility.

Conclusion: The nf-core/variantbenchmarking pipeline is specifically designed to accommodate varied research requirements, offering a modular approach that allows researchers to apply benchmarking methods most suitable for their analyses. GHGA's architecture is built on cloud computing infrastructures and includes an ethico-legal framework to ensure data protection compliance. GHGA enables researchers to conduct reproducible, rigorous, and secure research by standardizing bioinformatics workflows and governing reusability through harmonized metadata schemas.

P17.106.C SVX: Population-scale merging of structural variants with tandem repeat-aware refinement

***Tom O. Mokveld**, Juniper A. Lake, William J. Rowell, Egor Dolzhenko, Michael A. Eberle*

Pacific Biosciences, Menlo Park, CA, USA.

Background: Studies of structural variants (SVs) in large population cohorts remain challenging due to high data volumes and imprecise breakpoints in low sequence complexity regions like tandem repeats (TRs), which are estimated to account for 70% of all SVs [1]. Variability among SV discovery pipelines exacerbate these difficulties, often leading to distorted merging outcomes that undermine downstream analyses.

Material and Methods: To address this issue, we developed SVX, a fast, memory-efficient SV aggregation method written in Rust. SVX utilizes proximity-based SV graphs to link SVs whose breakpoints lie within specified distance or similarity thresholds, then merging clusters while preserving accurate breakpoints. Recognizing the confounding influence of repeat-driven artifacts, SVX integrates curated TR catalogs and specialized logic for refining variant boundaries in TR regions.

Results: Benchmarking on long-read datasets demonstrates that SVX scales effectively to thousands of samples and improves resolution within TRs and other regions. SVX achieves a balance between over-merging and under-merging, preserving allelic diversity and allowing for more accurate allele frequency estimations.

Conclusion: By combining a proximity-based graph framework with TR-aware logic, SVX provides a scalable solution for multi-sample SV merging, enabling the generation of population-scale SV callsets.

P17.107.D Evaluating regulatory variant effect prediction models with fine mapped chromatin QTLs

***Kristiina Kuningas**, Dzvenymyra-Marta Yarish, Kaur Alasoo*

University of Tartu, Tartu, Estonia.

Background: GWAS studies have identified numerous genetic variants associated with complex traits, yet interpreting their functional roles within regulatory DNA remains challenging. Chromatin quantitative trait loci (cQTLs) offer valuable insights into these regulatory mechanisms, but are limited in their sample size and cell type coverage. As an alternative, machine learning models such as Enformer and ChromBPNet can predict the effects of genetic variants on chromatin accessibility in a wide range of cell types. However, systematic evaluation of these predictions has been lacking.

Material and Methods: We created a validation dataset of genetically fine mapped causal cQTLs with empirically measured chromatin effects. Firstly, we uniformly processed 2,206 raw ATAC-seq and ChIP-seq samples from 30 datasets across 10 cQTL studies, covering eight distinct cell types. Using available genotype data from the same samples, we then fine mapped 10,119 likely causal cQTL variants (posterior inclusion probability > 0.5, variant located within accessible region).

Results: We evaluated the concordance between the predicted and measured chromatin QTL variant effects with two predictive models, ChromBPNet and Enformer. The average Spearman correlation was approximately 0.7 when evaluating both models on cQTLs from matched cell types. Interestingly, the correlation decreased to 0.4–0.5 for mismatched cell types, demonstrating that the models are able to capture cell-type-specific regulatory effects.

Conclusion: We believe our validation dataset can guide the development of more accurate variant effect prediction models, which can help us decode the regulatory DNA and contribute to a deeper understanding of the biological pathways between genetic variants and molecular traits.

P17.108.A QUANTITATIVE OMNIGENIC MODEL DISCOVERS INTERPRETABLE GENOME-WIDE ASSOCIATIONS

Natalia Ruzickova, *Michal Hledik, Gasper Tkacik*

Institute of Science and Technology Austria, Klosterneuburg, Austria.

As their statistical power grows, genome-wide association studies (GWAS) have identified an increasing number of loci underlying quantitative traits of interest. These loci are scattered throughout the genome and are individually responsible only for small fractions of the total heritable trait variance. The recently proposed omnigenic model provides a conceptual framework to explain these observations by postulating that numerous distant loci contribute to each complex trait via effect propagation through intracellular regulatory networks. We formalize this conceptual framework by proposing the "quantitative omnigenic model" (QOM), a statistical model that combines prior knowledge of the regulatory network topology with genomic data. By applying our model to gene expression traits in yeast, we demonstrate that QOM achieves similar gene expression prediction performance to traditional GWAS with hundreds of times less parameters, while simultaneously extracting candidate causal and quantitative chains of effect propagation through the regulatory network for every individual gene. We estimate the fraction of heritable trait variance in cis- and in trans-, break the latter down by effect propagation order, assess the trans- variance not attributable to transcriptional regulation, and show that QOM correctly accounts for the low-dimensional structure of gene expression covariance. We furthermore demonstrate the relevance of QOM for systems biology, by employing it as a statistical test for the quality of regulatory network reconstructions, and linking it to the propagation of nontranscriptional (including environmental) effects. Such methodology could be deployed also for individual pathways or regulatory modules, at the scale currently more tractable for mammalian organisms, including humans.

P17.109.B Sumstat Computational Data Hub, a high-performance storage and query infrastructure for Cross-Dataset Exploration of Genomics Summary Statistics

Bruno Ariano, *Claudia Giambartolomei, Nicola Pirastu, Emanuele Diangelantonio, Francesca Ieva, Nicole Soranzo, Gianmauro Cuccuru*

Human Technopole, Milan, Italy.

Background: Efficient storage and rapid querying of genomics summary statistics, such as genome-wide association studies (GWAS) and quantitative trait loci (QTL) data, are critical for investigate genes and variants linked to diseases. To address these challenges, we developed the Sumstat Computational Data Hub, leveraging TileDB, a high-performance multi-dimensional array database, to store and query terabytes of harmonized genomics association studies.

Material and Methods: By integrating TileDB column-storage engine with Python and Dask, this system offers a high-performance framework for parallelized harmonization, data exploration and genomic data processing.

This is paired with a NoSQL MongoDB to manage a metadata database. Furthermore, the system can accommodate any Python-based function that can be executed and used with Dask for parallel processing.

Results: The system was benchmarked on a 1.5 terabyte TileDB dataset storing pQTL data. Our tests showed that a single pQTL study could be extracted in approximately 7 seconds while loading the same data in txt.gz format using python and pandas took 46 seconds.

Conclusion: The **Sumstat Computational Data Hub** represents a significant advancement in genomics data management by offering an easy-to-use, scalable, and high-performance solution tailored to modern genomics workflows. Its ability to harmonize and query data across multiple genomic association datasets supports integrative analyses and accelerates discoveries in large-scale and comparative genomics studies.

P17.110.C Application of deep learning techniques to predict diabetes: insights from the Pima Indians diabetes database

Maryam Khaleghian

University of Tehran Kish International Campus, Kish, Iran, Islamic Republic of.

Background: The increasing availability of health datasets has enabled the application of machine learning (ML) and deep learning (DL) in genomics and precision medicine. However, challenges persist in optimizing these techniques for diagnostic and preventive healthcare. This study explores DL algorithms for analyzing complex health data, using the Pima Indians Diabetes Database as a model to extract meaningful insights.

Material and Methods: The Pima Indians Diabetes Database from Kaggle, containing patient demographics and clinical metrics, was utilized to identify key risk factors, predict outcomes, and analyze feature importance. Data preprocessing included

handling class imbalances, normalization, and outlier detection to improve model performance. Supervised ML algorithms, such as Gradient Boosting, were used for diabetes risk prediction, while DL models like convolutional neural networks (CNNs) and recurrent neural networks (RNNs) facilitated feature extraction and classification. Comparative evaluations of model accuracy, sensitivity, and specificity were conducted, and an ensemble model combining ML and DL techniques was developed to enhance predictive performance.

Results: The CNN model achieved 94.7% accuracy, while the RNN model reached 92.5%. The analysis of the feature importance identified glucose levels, BMI, and age as critical diabetes predictors. The ensemble model, integrating CNN and Gradient Boosting, improved sensitivity and minimized false positives. Visualization methods, including heatmaps and t-SNE, highlighted high-risk patient clusters, supporting targeted interventions.

Conclusion: This study demonstrates the effectiveness of ML and DL in predictive healthcare, enhancing disease understanding and aiding precision medicine. The findings highlight computational tools' transformative potential in improving patient outcomes and addressing complex health challenges.

P17.111.D SAVViDB: A web-based visualisation tool for enhancing splice-altering variant prediction and interpretation

Steven Monger[1], Tabitha Day[1], Paul Young[1], Yunkai Gao[1], Igor Vorechovsky[2], ***Eleni Giannoulatou***[1]

[1]Victor Chang Cardiac Research Institute, Darlinghurst NSW, Australia, [2]Faculty of Medicine, University of Southampton, Southampton, United Kingdom.

Background: Splice-altering variants (SAVs), genetic variants which disrupt pre-mRNA splicing, are a major source of pathogenic variants. Most go undetected, due largely to limitations of computational prediction methods.

Methods: We developed SAVViDB, a web application for visualising and understanding all major information related to predicting and interpreting SAVs. SAVViDB's unique visual representations enable insights into complex, multi-dimensional datasets and uncover between-dataset relationships through interactive highlighting. It supports both "exploratory" workflows (querying random regions with a single click) and "targeted" workflows (in-depth investigation of candidate pathogenic SAVs). Using SAVViDB we evaluated leading SAV predictors, identified limitations and proposed solutions.

Results: SAVViDB provided insights into the limitations of previously developed SAV predictors, and other opportunities to improve SAV discovery and interpretation. We found three pervasive issues with the leading SAV prediction tool, SpliceAI. Firstly, SpliceAI's distance constraint causes a mid-exonic "blind spot". Secondly, SpliceAI erroneously "masks" predicted losses of annotated splice sites. Thirdly, for many annotated splice sites, due to reference score errors, SpliceAI is incapable of detecting losses. The ensemble method AbSplice inherits these issues, and additionally, showed 70% lower sensitivity in detecting deep intronic SAVs, compared to its predecessor SpliceAI. For all of these issues, we identified their causes, quantified their impact, and developed solutions, which we provide as a new dataset "SpliceAI Patch".

Conclusion: SAVViDB is a novel visualisation tool for enhancing SAV prediction and interpretation, suitable for researchers, clinicians and developers. SAVViDB is freely available at https://savvidb.victorchang.edu.au/.

P17.112.A MitSorter: a standalone resource for methylation-based discrimination of mitochondrial DNA ONT reads

Sharon Natasha Cox[1], *Angelo Sante N. Varvara*[1], *Graziano Pesole*[1,2,3]

[1]University of Bari "Aldo Moro", Bari, Italy, [2]Institute of Biomembranes, Bioenergetics and Molecular Biotechnologies, National Research Council (CNR), Bari, Italy, [3]Consorzio Interuniversitario Biotecnologie, Trieste, Italy.

Background: The discrimination between mitochondrial DNA (mtDNA) and nuclear mitochondrial DNA segments (NUMTs) is crucial for variant calling, as NUMTs can confound the analysis of mtDNA mutations. As Oxford Nanopore Technologies(ONT) enables direct methylation detection, offering the opportunity to classify these sequences based on the lack of CpG methylation in human mtDNA, we developed MitSorter, a bioinformatic tool that distinguishes mtDNA from NUMTs.

Material and Methods: MitSorter processes ONT reads by integrating high-accuracy basecalling with Dorado and methylation-aware models to generate modification-aware BAM (modBAM) files. The tool assesses 5mCpG methylation at the read level, partitioning the dataset into two BAM files: unmethylated mtDNA reads and highly methylated NUMT reads. The tool was validated using the GIAB human ONT dataset.

Results: Mitochondrial-aligned reads showed a bimodal distribution. Considering all reads across three tested samples (N = 99,897), the majority (69%,N = 68,947) exhibited low CpG methylation levels (<5%), consistent with true mtDNA. A secondary peak at higher methylation levels (>60%) was observed, likely corresponding to NUMTs. The unsorted modBAM exhibited a mean 5mC fraction of 0.37 ± 0.13. MitSorter generated an unmethylated modBAM with a mean 5mC fraction of 0.0022 ± 0.0003, while the methylated modBAM had a 5mC fraction of 0.63 ± 0.28. Similar results were found for normal pancreatic tissue and for 12 private samples tested.

Conclusion: MitSorter is a reliable and efficient tool for distinguishing mtDNA from NUMTs using raw ONT data. This tool has the potential to revolutionize mtDNA variant analysis and facilitate the identification of novel NUMTs, as mtDNA-to-nuclear transfer is now considered an ongoing event, particularly in cancers.

P17.113.B UPDgraph: a bioinformatic tool to detect uniparental disomies (UPDs) using trio exome or genome sequencing data

Frédéric G. Masclaux*, Baptiste Micheli, Géraldine Van Winckel, Marc Abramowicz, Stefania Gimelli, Michel Guipponi, Sebastian Suchet, Omar Zgheib, Philippe Khau Van Kien, Rosalinda Giannini*

Hôpitaux Universitaires de Genève, Genève, Switzerland.

Background: Uniparental disomies of imprinted chromosomes can present with variable features both prenatally and postnatally, guiding the decision to perform whole exome or genome sequencing (WES, WGS) analysis prior to targeted methylation studies. We report three cases of trio WES illustrating the interest of a complementary bioinformatics pipeline for UPD detection.

Material and Methods: We analyzed two prenatal cases initially evaluated with cytogenetics and trio WES, yielding negative results with cumulative data indicating a likely UPD of chromosome 14: Kagami-Ogata and Temple syndromes. A third case exhibited progressive features of Silver-Russell syndrome, associated with maternal UPD of chromosome 7. We developed a tool, named UPDgraph, designed for the visual detection of UPD. UPDgraph needs a trio VCF file and a pedigree file as inputs and generates an ideogram as an image output. It is a simple python-based tool using minimal libraries (Matplotlib) and dependencies (Bedtools).

Results: Using UPDgraph on WES data, we efficiently identified all three UPD cases, later confirmed by MS-MLPA. UPDgraph's color-coded output enables quick visualization of UPD and differentiation between iso- and heterodisomy across affected chromosomal regions. UPDgraph displays variant origins in a compact and visually intuitive way.

Conclusion: Screening for UPD during trio-exome analysis is straightforward, enhancing the genetic evaluation of abnormal fetuses and syndromic patients. By incorporating this UPD detection tool into clinical practice, the diagnostic yield of trio WES and trio WGS cases can be significantly improved.

P17.114.C Pancreatic Islet Transcriptomics Identify MMP2 as a Biomarker Candidate in T3cD-Linked Pancreatic Cancer

Erol Eyupoglu[1], *Havva Ozgen Eyupoglu*[1], *Klaus Brusgaard*[2,3], *Mustafa Akkiprik*[1], *Nedime Serakinci*[4], *Can Erzik*[1]

[1]*Department of Medical Biology and Genetics, Institute of Health Sciences, Marmara University, Istanbul, Turkey,* [2]*Odense University Hospital, Odense, Denmark,* [3]*Department of Clinical Genetics, Lillebaelt Hospital, Vejle, Denmark,* [4]*Faculty of Art and Sciences, Cyprus International University, Nicosia via Mersin 10, Turkey.*

Background: Pancreatic cancer(PC) is a highly aggressive, late-diagnosed malignancy. New-onset diabetes (T3cD) is recognized as an early sign of PC, yet the underlying molecular mechanisms remain unclear. Limited transcriptomic studies focus on peripheral blood, whereas pancreatic tissue alterations remain underexplored. GSE76895, the only dataset with pancreatic islet transcriptomics from T3cD patients, provides a unique opportunity to study molecular changes but lacks distinction between malignant, benign, and pancreatitis cases, limiting cancer-specific findings. We applied bioinformatics-driven patient classification to refine the dataset and identify key transcriptomic changes in T3cD-associated PC.

Material and Methods: We analyzed GSE76895 (32 non-diabetic(ND) and 20 T3cD patients) using PCA, K-means clustering, and silhouette analysis to classify malignant pancreatic cases. DEG analysis (GEO2R,p-adj < 0.05, log2FC > 1) and pathway enrichment (Enrichr) were performed. Survival (KM-Plotter) and expression analysis (GEPIA2) validated the key genes.

Results: 18 malignant ND and 16 malignant T3cD cases revealed 1,503 DEGs. Pathway enrichment analysis confirmed key pancreatic cancer and diabetes-associated processes, distinguishing T3cD-PC from non-diabetic cases and supporting the intersection of diabetes-driven pancreatic changes, metabolic dysfunction, and malignancy. MMP2 emerged as a potential player in disease progression, showing involvement in pathways linked to cellular remodeling, metabolic alterations, and tumor microenvironment changes. MMP2 upregulation was validated in TCGA-PAAD and correlated with poor survival ($HR = 1.96$, $p = 0.011$).

Conclusion: This the first pancreatic islet-focused classification of T3cD-PC patients, linking cellular remodeling, metabolic dysfunction, and tumor progression. This study demonstrates MMP2 as a potential biomarker for early pancreatic cancer detection in high-risk diabetic patients.

P17.115.D BaCoN (Balanced Correlation Network) improves prediction of gene buffering

T. Rohde[1], *T. Y. Demirtas*[1], *A. H. Shaw*[1], *M. Billmann*[2];

[1]*Institute of Human Genetics, University of Bonn, School of Medicine and University Hospital Bonn, Bonn, Germany,* [2]*Institute of Human Genetics, University of Bonn & University Hospital Bonn, Bonn, Germany*

Buffering between genes, where one gene can compensate for the loss of another gene, is fundamental for robust cellular functions. Understanding gene buffering can help unmask previously unidentified gene-phenotype associations and guide the development of combinatorial or genotype-specific therapeutic strategies.

While experimentally testing all possible gene pairs using perturbation techniques such as CRISPR-Cas9 is infeasible, gene buffering can be predicted genome-wide under the assumption that a gene's buffering capacity depends on its expression level and the absence of this buffering capacity primes a severe fitness phenotype of the buffered gene.

We developed BaCoN (Balanced Correlation Network), a post-hoc unsupervised correction method that amplifies specific signals in expression-vs-fitness effect correlation-based networks and quantified 147 million potential buffering relationships across 1019 Cancer Dependency Map (DepMap) cell lines.

BaCoN outperformed state-of-the-art methods including multiple linear regression, based on our newly compiled metrics for gene buffering predictions. Adding BaCoN to batch corrected or Cholesky whitened data further boosts predictive performance. We characterized a high-confidence list of 744 buffering predictions, many of which could not be predicted by any other method. While buffering paralogs mostly reside on different chromosomes, which can be understood as a plausible architecture to facilitate genomic robustness, non-paralog buffering gene pairs were more equally distributed across the genome. BaCoN performance increases with more CRISPR screens and library genes considered, making it a valuable tool for gene buffering predictions from the constantly growing DepMap.

P17.116.A RepoGen: a scalable Python-based framework for genomic-driven target prioritisation and drug repurposing

Ivan Andrushevich Petukhov, *Gerome Breen, Jonathan Coleman*

King's College London, London, United Kingdom.

Background: Drug discovery is an expensive and time-consuming process, with >90% of drug candidates failing in clinical trials. Interestingly, therapeutic compounds with genetic evidence of disease association are more likely to succeed. Genome-wide

association studies (GWAS) have transformed our understanding of the genetic architecture of complex disorders and have shown promise in identifying prioritised targets within disorder-associated regions, opening the doors for enhanced genomic-driven drug discovery and repurposing through bioinformatics tools.

Material and Methods: Our framework combines several analytical approaches, including gene-drug enrichment analyses, endophenotype Mendelian randomisation to identify causal proteins, and negative correlation testing to probe established and investigational drug candidates. Unlike standalone tools, this platform also evaluates drug properties such as ADMET (absorption, distribution, metabolism, excretion, and toxicity) to rank repurposing candidates in a pathway-specific context. The tool is written in Python, built on a Snakemake framework, and packaged in a Singularity image for ease of use.

Results: To bridge the gap between genomic insights and translational drug discovery, we developed a scalable, Python-based platform that integrates multiple bioinformatics methodologies for target prioritization and drug repurposing. It offers several advantages over existing tools, including modularity, scalability for large-scale genomic and pharmacological datasets, compatibility with machine learning frameworks, and seamless integration of additional methodologies and datasets, including information on rare and structural variants.

Conclusion: RepoGen is a versatile and user-friendly framework that streamlines the identification of genetically supported drug targets and repurposing opportunities, offering researchers a robust resource to harness genomic data for precision medicine.

Background: COVID-19 has made a tremendous impact worldwide, stressing the healthcare system. Frontline workers had to manage in a short time many patients with no tools to prioritise those at high risk. The unpredictable course of the disease has shown the importance of individual genetics in determining clinical phenotypes. In this context, we aim to employ an AI-based approach that includes also specific genetic variants to help unravel the architecture of such complex diseases.

Material and Methods: We refined the best predictive model for COVID-19 mortality integrating 18 genetic and 12 clinical features, by a retrospective multicentric study. We trained three machine learning models (GBM, XGB, RF) on a dataset of 532 COVID-19 hospitalised Italian patients, recruited before vaccine availability.

Results: All the models reached great values for accuracy, AUROC, f1, f2 and PR-AUC metrics. Although GBM's PR-AUC optimization resulted in a better performance (0.473 ± 0.21), we chose to deeply analyse GBM's f1 optimization that provides fewer false negatives ($N_{f1} = 27$ versus $N_{PR\text{-}AUC} = 46$), being our main goal to answer. We delved into the feature importance to understand which features contribute to the model's decision: concerning the top 10, more than 50% was attributable to age, and the remainder was almost equally divided between genetic and clinical features. *HLA-DRA*rs3135363, *IL6*rs1800795, *ACE2*rs2285666, *CRP*rs2808635 globally accounted for 20%, demonstrating genetic data didn't confound, but implemented the model.

Conclusion: Integrating genetic and clinical data in intelligent systems is crucial for identifying high-risk cases, enhancing the management of hospitalised patients and preventing severe progression, increasingly enabling P4-medicine.

P17.119.D Prioritization of non-coding variation using improved DNA foundation models OR why is my model so bad at rare variants?

M. Celik[1], *S. Nair*[2], *G. Eraslan*[2], ***D. Garfield***[2];

[1]*University of California Irvine, Irvine, CA,* [2]*Genentech, South San Francisco, CA*

Background: Foundation models that predict chromatin accessibility or gene expression directly from DNA-sequence are highly performant, and attributions ascribed by these models identify relevant sequence features such as enhancers and TF binding sites. Absent fine-tunning, however, these models perform poorly on genetic variation, and even with fine-tunning fail to generalize. We focused here on a core question: Do models improve when they focus on rare variants that are more likely to disrupt fundamental features of regulatory sequence?

Material and Methods: We created a model (**Forzoi**) based on an optimized Borzoi architecture using Flash Attention and rotary embeddings that allows for a 10x-64x speed up in the evaluation of genetic variants. We used this model for zero-shot predictions of functional genetic variation across a range of allele frequencies using allele-specific open chromatin data and compared these results to models fine-tuned on the same data using a contrastive loss function.

Results: Despite having large effect sizes and more frequently contributing to allelic imbalance, rare variants were not detected zero-shot with greater performance than common variants. But while false negative rates were high, the effect sizes and directionality of predicted variants was correct with little evidence for "sign-switching" as observed in other models. Fine-tunning substantially improves performance and generalizes well to unseen genomic regions.

Conclusion: Fine-tunning on genetic data enriched for high effect, rare variants improves model performance and is generalizable. The resulting model can be (and has been) used for

predicting and interpreting medically relevant non-coding variation. Things are not hopeless.

P17.120.A 10 years of the Open Targets Platform: bringing the genetics of monogenic and complex traits together to identify and prioritise targets for drug discovery

Ellen McDonagh[1,2,3]

[1]*Open Targets, Wellcome Genome Campus, Hinxton, United Kingdom,* [2]*European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Wellcome Genome Campus, Hinxton, United Kingdom,* [3]*Wellcome Sanger Institute, Wellcome Genome Campus, Hinxton, United Kingdom.*

Background: The Open Targets Platform (https://platform.opentargets.org/) was established 10 years ago to provide an open resource to the research and industry community for systematic gene-disease association evidence to prioritise targets for drug discovery1. It now unifies the genetics of monogenic and complex traits, with additional layers of data and analysis to refine therapeutic hypotheses.

Material and Methods: >20 resources are integrated to support target-disease associations. Genetic evidence includes; predicted causal genes underlying complex traits through our Locus2Gene pipeline harnessing GWAS and functional genomics data2, gene burden analysis utilising rare variation from whole exome/genome analysis, rare disease clinical annotations. A gene-disease prioritisation tool ranks the associations based upon an evidence scoring framework for each data source, adjustable by users, and targets can be further prioritised based on clinical precedence, tractability and safety.

Results: The Platform associations page brings evidence from rare and common disease and genetics sources into one view to help unify underlying biological mechanisms. New variant pages display evidence from complex genetic analysis providing GWAS/molecular QTL credible sets alongside clinical and pharmacogenetic associations, and direction of effect annotation. This provides the ability to build evidence for the mechanism of a genetic variant across rare and common traits potentially connected, and can provide stronger evidence for the causal role of a gene in a given disease.

Conclusion: The Open Targets Platform provides a comprehensive resource for gene-disease association evidence to help prioritise targets for the development of safe and effective treatments for common and rare diseases1.

C.O.I. Disclosure:

E. McDonagh: None.

P17.121.B Molecular Dynamics Insights into SLC35A2: Unraveling Dimerization Interfaces and Pathogenic Mutations in MOGHE and CDG

Kristina Karandasheva[1], *Katja Kobow*[2]

[1]*Universitätsklinikum Erlangen, Neuropathologie, Erlangen, Germany,* [2]*Universitatsklinikum Erlangen, Neuropathologie, Erlangen, Germany.*

Background: SLC35A2 is a UDP-galactose transporter that plays a critical role in cellular glycosylation, yet its structural and functional mechanisms remain poorly understood due to the lack of experimental models. Mutations in SLC35A2 are associated with congenital disorders of glycosylation (CDG) and mild malformations of cortical development with oligodendroglial hyperplasia in epilepsy (MOGHE).

Material and Methods: We employed in-silico approaches to investigate the structural dynamics of SLC35A2. An AlphaFold-generated model of SLC35A2 was subjected to molecular dynamics (MD) experiments using NAMD QwikMD for equilibration and all-atom simulation. We also performed coarse-grained MD in membrane environments with Martini/Gromacs to explore the SLC35A2 homodimerization mechanism and its heterodimerization with SLC35A3. In silico mutagenesis was performed on SLC35A2 mutations identified in a MOGHE cohort and CDG patients to assess their impact on protein structure and function.

Results: We developed a reliable in-silico model of SLC35A2 and shed light on its conformational transitions during UDP-galactose transportation. We identified homo- and heterodimerization interfaces and revealed how specific mutations disrupt transporter stability and interactions.

Conclusion: Our computational investigation clarifies how SLC35A2's dynamic architecture and dimerization interfaces foster efficient UDP-galactose transport. More importantly, it highlights how specific pathogenic mutations can compromise this mechanism, offering a molecular rationale for glycosylation-related disorders such as MOGHE and CDG. By pinpointing regions critical for stability and function, these insights provide a valuable framework for targeted experimental validation and pave the way for therapeutic strategies aimed at rectifying glycosylation defects.

Background: Comprehensively characterizing genotype-phenotype correlations (GPCs) in Mendelian disease would create new opportunities for improving clinical management and understanding disease biology. However, heterogeneous approaches to data sharing and analyses have hindered progress in the field.

Material and Methods: We developed Genotype Phenotype Evaluation of Statistical Association (GPSEA), a framework for comprehensive characterization of GPCs. GPSEA ingests case-level data about individuals formatted as Global Alliance for Genomics and Health (GA4GH) phenopackets and visualizes the most salient aspects of the individuals. The visualizations guide assignment of each individual into one of (typically two) genotype classes based on disease diagnoses, sex, or genomic variants. Then, correlations with four main phenotype kinds can be tested: categorical, continuous, severity scores, and survival. We developed an independent filtering strategy to boost statistical power in testing of the categorical phenotypes encoded into Human Phenotype Ontology terms. GPSEA enables analysis of continuous phenotypes, such as metabolite levels as well as of the common clinical severity scores. Finally, the genotypes can be tested for correlations with disease or clinical manifestation onsets, or mortality.

Results: We applied GPSEA to 83 cohorts with 6059 previously published individuals with case-level phenotypes and genomic variants in one of 78 genes and 120 Mendelian diseases and identified 229 significant GPCs, with 43 cohorts having at least one statistically significant GPC. We provide GPSEA as a Python package for use in interactive computing environments.

Conclusion: These results highlight the power of standardized representations of clinical data for scalable discovery of GPCs in Mendelian disease.

P17.123.D Phenotype extraction from clinical descriptions using Large Language Models

Silvia Berardelli[1,2,3], *Federica De Paoli*[2], *Andrea Gazzo*[4], *Galadriel Brière*[3], *Benjamin Loire*[3], *Ivan Limongelli*[2], *Ettore Rizzo*[2], *Paolo Magni*[1], *Anaïs Baudot*[3], *Susanna Zucca*[2]

[1]University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy, [2]enGenome srl, Pavia, Italy, [3]Aix Marseille Univ, INSERM, MMG, Marseille, France, [4]Memorial Sloan Kettering Cancer Center, Department of Pathology and Laboratory Medicine, New York, NY, USA.

Background: Standardized phenotypic descriptions are crucial for accurate patient diagnosis in healthcare. Clinicians often find it challenging to manually identify these descriptions from scientific literature or patient records. Large Language Models (LLMs) show promise in automating the extraction of textual descriptions and mapping them into Human Phenotype Ontology (HPO) terms.

Material and Methods: We present an approach for phenotype extraction that leverages LLMs. The approach comprises Concept Recognition (CR), to identify candidate concepts in unformatted content and Entity Linking (EL), to map the descriptions to HPO terms. The approach combines GPT-4 for CR and PhenoBERT [PMID:35471885] for EL, addressing limitations of previous tools. To further improve EL, we introduced a method based on Knowledge Graphs (KG) embeddings. This extension allows overcoming the need of resources for fine-tuning and retraining models with every HPO update. An expert curated the ground truth of phenotypes, for evaluating our tool performances on a benchmark dataset of 76 scientific papers describing 488 patients with digenic and oligogenic variants from OLIDA [PMID:35411390].

Results: On average, four phenotypes were extracted per patient with an execution time of 1–2 minutes. Our approach achieved an exact match with ground truth in 92% of cases. Missing phenotypes account for 5%, while unnecessary phenotypes represent 3%. Work is ongoing to assess the performance of KG embeddings.

Conclusion: LLMs enable a reduction in manual curation and a faster standardization in phenotype extraction. Applied to the genomic context, they have the potential to speed up the diagnostic process.

P17.124.A Quality management strategy for population-scale genomic data of the national genome project in Korea

Jongbum Jeon, *Jong Hwan Kim, Soobok Joe, Keeok Haam, Sol A Jeon, Jahyun Yun, Jinseon Yoo, Haeun Seol, Yeyoung Yoon, Dongyoon Lee, Jisu Kim, Dayeon Kang, Boram Kang, Ji Min Ahn, Jin Ok Yang, Haeyoung Jeong*

Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of.

Background: A new wave of precision medicine has become an inevitable consequence of the drastic improvement in related technologies, including high-throughput sequencing, data analysis, and data sharing. Here, we introduce a population-scale whole genome sequencing (WGS) quality management system as part of the national genome project in Korea, which aims to collect high-quality genomic data for predicting and diagnosing diseases in vulnerable populations.

Material and Methods: To maintain data quality, we have embedded quality checkpoint steps and assessment pipelines in the WGS framework to ensure consistent and reliable identification of germline and somatic variants. We addressed the inspection process, which includes double SNP genotyping tests throughout the entire sequencing process. In a one-step analysis pipeline, we are harnessing 11 different tools for quality assurance.

Results: We established a comprehensive quality management framework, spanning from sample quality control to analysis-related quality control for large-scale WGS processing. This process scrutinizes various categories, including sequencing depth, sample swaps, cross-contamination, sample purity, and discrepancies between biomedical and WGS data. We also reported the statistics and representative cases of quality control for 15,000 participants in the pilot project.

Conclusion: This framework is suggested as a foundational method for executing large-scale population genomics research during phase I of the project, with plans to expand to a quarter million genomic datasets. The strategy has the potential to serve as a key element in harmonizing and integrating with other genomic research initiatives.

P17.125.B Comparative Examples of Using Computational Structural Tools to Interpret *MUTYH* Gene Missense Variants

Ravza Nur Yildirim[1], *Mehdi Kosaca*[2], *Irem Yilmazbilek*[1], *Ezgi Karaca Erek*[1,2], *Merve Keskinkilic*[3], *Ilhan Oztop*[3], *Ayfer Ulgenalp*[3], *Okay Ahmet Caglayan*[1,3]

[1]*Izmir Biomedicine and Genome Center, Izmir, Turkey,* [2]*Izmir International Biomedicine and Genome Institute, Izmir, Turkey,* [3]*Dokuz Eylul University Research and Application Hospital, Izmir, Turkey.*

Background: Mutations in the *MUTYH* gene cause DNA damage, contributing to carcinogenesis. *Insilico* analyses, leveraging various algorithms, are valuable for predicting the impact of missense variants due to time and resources efficiency.

Material and Methods: AlphaFold-generated human_MutY structure (PDB-ID:Q9UIF7) was aligned with Musmusculus_MutY-dsDNA complex (PDB-ID:7EF8). After removing the mouse structure, dsDNA and human_MutY were refined using HADDOCK, and the best-scoring model was selected. The thermodynamic effects of missense variants were assessed using PremPS, mCSM, and DynaMut2, and compared with predictions from AlphaMissense and EVE. Nineteen known pathogenic/benign variants and five variants of uncertain significance (VUS) in *MUTYH* were analyzed.

Results: Fourteen of 16 pathogenic variants were destabilizing according to at least two tools. Two pathogenic variants were destabilizing only in PremPS: Y176C as pathogenic by both AlphaMissense and EVE, R106W as pathogenic only by EVE. Three benign variants were predicted as benign by AlphaMissense and EVE, and two showing stabilizing effects. M198V, a benign variant, exhibited destabilizing effects in all tools. All VUS' were predicted as benign by AlphaMissense. EVE predicted for two VUS' as pathogenic.

Conclusion: Our analysis suggests mCSM frequently predict destabilizing effects, while PremPS and EVE demonstrate greater consistency in predicting pathogenic variants. A263G was re-evaluated based on ACMG criteria, suggesting potential pathogenicity. This study highlights the utility of computational tools in predicting the effects of *MUTYH* missense variants in a Turkish patient cohort suspected of hereditary cancer syndrome. Furthermore, it underscores the importance of caution when interpreting missense variants using *insilico* tools.

P17.126.C Optimizing insert size ditribution in whole exome sequencing for improved variant detection

Luca Bertoli[1], *Matteo Orlandi*[1], *Filippo Lucchini*[1], *Chiara Degli Esposti*[2], *Massimo Delledonne*[1,2]

[1]*University of Verona, Verona, Italy,* [2]*Genartis srl, Verona, Italy.*

Next-generation sequencing plays a crucial role in clinical genetics, particularly in the diagnosing of rare disorders. Whole Exome Sequencing (WES) is widely used due to its cost-effectiveness compared to targeted panels or whole-genome sequencing. Optimizing library preparation to obtain longer insert sizes has been shown to enhance mappability in challenging genomic regions, such as pseudogenes, thereby increasing variant detection.

In this study, we analyzed multiple NA12878 WES replicates by segmenting them into insert size intervals ranging from 1 to 1000 bases. Our findings confirm that longer fragments improve mappability in difficult regions and reduce false-negative variant calls.

Additionally, they contribute more effectively to mapped coverage by reducing the number of overlapping bases between mate reads, which are typically counted once when computing the mapped coverage. However, as insert size increases, a growing proportion of reads partially or fully map outside the regions of interest (ROIs), leading to reduced target coverage for the same amount of sequenced data.

While genotypability and variant calling improve with increasing fragment length, surpassing a certain threshold leads to an accumulation of near- and off-target bases, ultimately reducing the benefits for coverage depth. These findings highlight the importance of fine-tuning insert size distribution to enhance variant detection while minimizing the sequencing costs of WES experiments.

P17.127.D VARista: a free web platform for streamlined whole-genome variant analysis across T2T, hg38, and hg19

Noam Hadar[1], ***Matan Meir Jean***[2], *Tomer Poleg*[2], *Vadim A. Dolgin*[2], *Ohad Birk*[3]

[1]*Ben Gurion University of the Negev, Beer Sheva, Israel,* [2]*Ben-Gurion university of the Negev, beer sheva, Israel,* [3]*Soroka Medical Center, Beer Sheva, Israel.*

Background: Efficient analysis of genomic variants is crucial for advancing our understanding of genetic disorders. Existing tools, however, often pose challenges such as high complexity, delayed integration with cutting-edge resources, and significant costs. To address these issues, we developed VARista, a freely available web-based platform designed to simplify variant analysis workflow, with an emphasis on aiding research into rare monogenic diseases.

Material and Methods: VARista offers simplified analysis of VCF files from hg19, hg38, and notably, the latest T2T assembly. The platform integrates essential features for variant analysis, including comprehensive gene summaries and links to invaluable resources. It provides access to detailed tissue and cell-specific expression data, enhancing research precision. Additionally, VARista includes tools for PCR design and incorporates analyses from SpliceAI and AlphaMissense, enriching the platform with deep biological insights. Importantly, it integrates minor-allele-frequency data from the latest versions of gnomAD4 and ALFA, collectively spanning over 1,000,000 samples, thus offering a broad genomic context for variant evaluation, all aimed at enhancing the user's focus on biological insights.

Results: VARista efficiently narrows down and prioritizes variants, offering users essential biological context. This facilitates quicker, more informed decision-making in identifying disease-associated genetic variants. https://VARista.link

Conclusion: VARista emerges as a key resource for the genomic research community, combining ease of use with a robust set of features for variant analysis. By bridging the gap between complex genomic data and actionable insights, VARista empowers researchers to make better-informed decisions and accelerate breakthroughs in the understanding and treatment of genetic diseases.

P17.128.A Latent variable analysis of kidney function genome-wide association studies enhances detection of functional variants

David Bruce Emmert Jr[1], *Ryosuke Fujii*[2], *Dariush Ghasemi-Semeskandeh*[1], *Cristian Pattaro*[1]

[1]*Eurac Research, Bolzano, Italy,* [2]*Department of Preventive Medical Sciences, Fujita Health University School of Medical Sciences, Toyoake, Japan.*

Background: Chronic kidney disease affects >10% population worldwide and ranks among the top causes of death. Due to disease complexity and lack of specific biomarkers, genome-wide structural equation modeling (GenomicSEM) has emerged as a potential method for identifying molecular targets of unobservable traits that reflect a series of observed biomarkers. We applied GenomicSEM to European-ancestry GWAS summary statistics released by the CKDGen Consortium and by UK Biobank, identifying a single latent kidney function factor in which we observed enhanced detection of missense variants, compared to the underlying GWAS traits.

Material and Methods: Using approximately 6 million variants from GWAS summary statistics for eGFRcrea and eGFRcys, BUN, and UA, we employed the "commonfactorGWAS" function from GenomicSEM v0.05c to estimate the GWAS of the corresponding latent kidney function trait. Genome-wide significant signals from all the traits were identified and tested for independence using GCTA-COJO for multi-SNP-based joint and conditional analysis. Independent signals were annotated using VEP.

Results: Based on Fisher's exact test, we observed a significant increase in the proportion of missense variants among of the generated credible sets in the latent kidney function trait compared to standard traits such as eGFRcrea (P-value = 0.0004998) eGFRcys (P-value = 0.0009995).

Conclusion: Application of genome-wide SEM analysis to kidney function traits enhances the detection of functional variants for further molecular target prioritization.

P17.129.B From genomic structure to risk prediction: Developing a CNV-based polygenic risk score for epilepsy

Lisa-Marie Niestroj[1,2], *Elaheh Vojgani*[1,2], *Costin Leu*[3,4,5], *Patrick May*[6], *Dennis Lal*[3,4,5], *Epi25 Consortium*[7], *Michael Nothnagel*[1,2]

[1]*Cologne Center for Genomics, University of Cologne, Cologne, Germany,* [2]*University of Cologne, Faculty of Medicine, Cologne, Germany,* [3]*Department of Neurology, McGovern Medical School at UTHealth, Houston, TX, USA,* [4]*Center for Neurogenetics, UTHealth Houston, Houston, TX, USA,* [5]*Epilepsy Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, USA,* [6]*Luxembourg Centre for Systems Biomedicine, Esch-sur-Alzette, Luxembourg,* [7]

Background: Polygenic risk scores (PRS) based on single nucleotide polymorphisms (SNPs) have been widely developed for predicting complex genetic disorders but often overlook structural variants, such as copy-number variants (CNVs). CNVs, particularly deletions and duplications, are known contributors to epilepsy risk, yet their role in PRS remains unexplored. We present the development of a CNV-based PRS for epilepsy using the Epi25 cohort, one of the largest epilepsy cohorts to date.

Material and Methods: Our study includes 23,049 epilepsy cases from the Epi25 consortium and 8,029 controls. Samples were genotyped using the Illumina Global Screening Array and underwent stringent CNV quality control. CNVs were categorized as deletions or duplications. The cohort was split into Preparation (~75%, N = 23,289), Training (~13%, N = 4,096), and Test (~12%, N = 3,753) datasets. Using the Training dataset, we will derive a CNV-based PRS incorporating CNV frequency, size, genomic location, and overlap with epilepsy-relevant genes. The PRS will be validated in the Test dataset.

Results: Preliminary analyses confirm high CNV call quality, with balanced CNV representation in cases and controls. CNV burden is significantly enriched in epilepsy subtypes, particularly for rare deletions in hotspot regions and duplications spanning epilepsy-associated genes. Our dataset is well-suited for developing a CNV-based PRS, with early findings suggesting its potential to enhance risk prediction beyond SNP-based approaches.

Conclusion: This study pioneers a CNV-based PRS for epilepsy, complementing SNP-based models and highlighting the unique contribution of CNVs. Our findings underscore CNV-based PRS as a promising tool for predicting epilepsy risk and understanding its genetic architecture.

P17.130.C ANTARES (AdvaNced Technologies for genomics in rARe pEdiatric disorderS): automated AI-driven pipeline for clinical and genetic database creation

Matteo Bellini[1], *Andrea Bombarda*[2], *Lucrezia Goisis*[1], *Chiara Mongodi*[1], *Martina Saletta*[2], *Paolo Cazzaniga*[2], *Domenico Fabio Savo*[2], *Maria Iascone*[1]

[1]*Laboratory of Medical Genetics, ASST Papa Giovanni XXIII, Bergamo, Italy,* [2]*University of Bergamo, Bergamo, Italy.*

Background: Creating structured and high-quality clinical databases is crucial for advancing medical research and improving patient care. However, manually entering information from clinical reports into such databases is both time-consuming and error-prone. Leveraging artificial intelligence (AI) and natural language

processing techniques, including the extraction of Human Phenotype Ontology (HPO) terms, offers an innovative solution for automatically generating databases from clinical reports. Furthermore, this solution allows for the automatic association of the extracted clinical data with the genetic data contained in the vcf files resulting from the genome analysis.

Material and Methods: To address these challenges, we developed an automated pipeline that utilizes AI to populate a clinical and genetic database. Starting with a clinical report written in Italian, the pipeline translates it into English, extracts the HPO terms, and converts this information into JSON files. Lastly, from the identified cases, only variants of interest are extracted from vcf files and annotated.

Results: The automated approach significantly reduced the time and cost associated with the database population, improving the accuracy of the stored information. The pipeline ensures consistency and adaptability for future structural changes. The resulting database also allows the reanalysis of inconclusive cases after discovering new genes and enables the identification of cases with phenotypes suitable for specific studies.

Conclusion: This method suggests the potential of an AI-driven database population in genetic research. It offers a scalable, efficient, and reliable alternative to manual curation. By improving data accessibility and enabling advanced analysis, this approach might support ongoing advancements in genomics.

P17.131.D A bioinformatics approach to evaluating familial relationships through genetic similarity at selected SNP sites

Giovanni Cerchia, *Susanna Zucca, Ivan Limongelli, Ettore Rizzo*

enGenome srl, Pavia, Italy.

Background: Establishing family relatedness is a critical aspect of genetic studies, enabling verification of biological parenthood and the presence of consanguinity between parents. Reliable tools and methodologies are essential to ensure accurate results, particularly in clinical and research contexts.

Material and Methods: We implemented a bioinformatic procedure using bcftools and Somalier (PMID 32664994), a novel tool for relatedness assessment based on a curated set of Single Nucleotide Polymorphisms (SNPs). Individual VCFs of family members are merged into a single dataset, setting missing variants to homozygous reference calls, and then split back by sample. Somalier is subsequently applied to compute relatedness between family members, with ad hoc established thresholds on different relatedness metrics based on the number of shared homozygous and heterozygous sites. The procedure was validated using an internal dataset comprising different genomic data types, including WGS, WES, and clinical WES of familial cases. This validation focused on identifying parent-proband relationships and detecting consanguinity up to third-degree relatives between parents.

Results: On a dataset of 151 sample pairs, with the established cut-off values, we achieved high performance for parental verification with 100% specificity and 99.2% sensitivity. For consanguinity detection, specificity reached 97.9%, while sensitivity was lower at 47.1% on 64 pairs.

Conclusion: Parental verification is accurate, making the procedure suitable for clinical applications. Consanguinity checks require further optimization to improve sensitivity. Future efforts will focus on refining the methodology and expand this validation.

P17.132.A miR-RF: a machine learning (ML) algorithm for the prioritisation of clinically relevant SNVs in miRNAs

Alessia Canevotti[1], *Daniele Traversa*[2], *Graziano Pesole*[3], *Matteo Chiara*[2]

[1]*Università degli Studi di Milano, Università degli Studi di Bari Aldo Moro, Milano, Italy,* [2]*Università degli Studi di Milano, Milano, Italy,* [3]*Università degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: MicroRNAs (miRNAs) are short non-coding RNAs that downregulate gene expression either through translational repression or by inducing the degradation of their target mRNAs. Accurate annotation of miRNA genes is critical for studying their molecular functions and implications in human disorders. Currently, miRBase and mirGene are the core resources for the annotation of miRNAs. However, mirBase reports 1917 miRNAs genes for Homo sapiens, while mirGene only 508. We developed miR-RF, a computational method for the annotation of miRNAs, to: 1) assess the functional activity of miRNAs in mirBase and MirGene; 2) study the effect of single nucleotide variants (SNVs) on miRNAs, in the healthy population and disease.

Material and Methods: miR-RF was developed in Python (v3.9) and R (v4.1.2). The Caret package was used to provide ML-algorithms. miRNAs sequences were retrieved from MirGene (v3) and mirBase (v22). To evaluate the impact of SNVs miRNAs were mutated in-silico.

Results: miR-RF outperformed other computational methods for the annotation of miRNAs: 93% of MiRGene entries (471) and 63% of mirBase entries (1178) were classified as "bona-fide" miRNAs. SNVs predicted to deactivate miRNAs were under-represented (p-value 6.7e-10) in the general population, indicating negative selection. Applied to somatic SNVs in cancer, miR-RF identified several potential disruptive mutations in known oncosuppressor miRNAs. All these miRNAs were downregulated, compatible with negative selection in cancer. Similar patterns of "inactivation" and downregulation were also observed for miR-1182 and miR-664b, not previously linked with tumors.

Conclusion: miR-RF accurately annotates miRNAs and facilitates the identification of clinically-relevant mutations and miRNAs.

P17.133.B A global expression profile of bladder cancer in early stage: a meta-analysis reveals new promising therapeutic targets

Z. Piryaei[1], *R. Dalirfardouei*[2], ***F. Piryaei***[3,4];

[1]*Department of Bioinformatics, Comprehensive University of the Islamic Revolution, Tehran, Iran, Islamic Republic of,* [2]*Department of Medical Biotechnology, School of Advanced Medical Sciences and Technologies, Hamadan University of Medical Sciences, Hamadan, Iran, Islamic Republic of,* [3]*Research Center for Molecular Medicine, Institute of Cancer, Avicenna Health Research Institute, Hamadan*

University of Medical Sciences, Hamadan, Iran, Islamic Republic of, [4]Department of Medical Genetics, School of Medicine, Hamadan University of Medical Sciences, Hamadan, Iran, Islamic Republic of

Background: Bladder cancer (BC) is the fourth most common type of cancer in men. Several types of BC are classified by the type of cancerous cell in the tissue. Ta, papillary tumor without invading the bladder wall, can be considered for targeted therapy rather than resection since the recurrence is common. In this study, a meta-analysis was performed to find the differentially expressed genes impaired in Ta BC.

Material and Methods: Studies related to Ta were found in NCBI-GEO (GSE120736, GSE128959, GSE13507, GSE146870, GSE32548, GSE32894). Ta and adjacent samples (as controls) were selected from each study, and their expression profiles were pooled after excluding the poor-quality samples. Using the ARSyNseq (ASCA Removal of Systematic Noise for sequencing data) method implemented in the NOISeq package, batch effects were removed. The Limma package was utilized to identify meta-differentially expressed genes (Meta-DEGs). Finally, using the Enrichr database, Meta-DEGs were enriched.

Results: 1947 and 2133 Meta-DEGs were down-regulated (top: NDUFS6, VDAC2, TRUB2, SLC17A5, FDXR) and 2133 up-regulated (top: XPNPEP3, AKR1D1, LILRB1, AIRE, TACSTD2), respectively. GO terms enriched by down-regulated genes indicate that immune system-related pathways are suppressed in Ta. Significantly, GO terms enriched by up-regulated genes indicate a dramatic increase in cell proliferation, differentiation, progression of cancer, and migration.

Conclusion: Our findings suggest to develop novel methods to monitor early tumors and recurrence, and to achieve personalized therapies. Clinical trials are performed to explore the effectiveness of inhibitors of immune system components, and the key Meta-DEGs detected in this study can be promising targets.

P17.134.C When AI and whole-genome sequencing collide: shaping the future of healthcare in the era of precision medicine

Petar Brlek[1], *Luka Bulic*[1], *Mateo Sokač*[2], *Leo Mršić*[2], *Dragan Primorac*[1]

[1]*St. Catherine Specialty Hospital, Zagreb, Croatia,* [2]*Algebra University, Zagreb, Croatia.*

Background: Personalized medicine relies on genetic testing as a cornerstone for improving diagnostics, treatment selection, and disease prevention. Integrating whole genome sequencing (WGS) with machine learning offers unprecedented opportunities to refine clinical decision-making, optimize therapeutic strategies, and enhance patient outcomes. By analyzing vast genomic datasets, it becomes possible to tailor interventions with greater precision, ultimately transforming modern healthcare.

Material and Methods: Machine learning algorithms were applied to develop classification models based on nutrigenetic analysis, enabling personalized dietary recommendations aimed at preventing prevalent multifactorial diseases. Furthermore, pharmacogenomic profiling was conducted using the UMAP and HDBSCAN algorithm, providing comprehensive insights into Croatian population-specific drug response variations. A statistical model for molecular tumor classification was also developed using over 20,000 samples, facilitating the molecular diagnosis and targeted treatment of secondary neoplasms of unknown primary origin.

Results: Preliminary validation of nutrigenetic, pharmacogenetic, and oncogenetic machine learning models indicates that integrating WGS with machine learning significantly enhances predictive accuracy, improving preventive, diagnostic, and therapeutic protocols. Ongoing clinical validation across diverse patient cohorts aims to confirm the robustness and real-world applicability of these models.

Conclusion: These findings underscore the necessity of integrating nutrigenetics for the prevention of multifactorial diseases, pharmacogenetics for individualized treatment, and oncogenetic machine learning models for precise diagnosis and targeted therapy of malignancies. As precision medicine continues to evolve, the seamless incorporation of genomic data and artificial intelligence will drive innovation, leading to more effective treatments and improved healthcare efficiency.

P17.136.A Comparison of the probability of mtDNA deletions in regions flanked by different combinations of direct and inverted repeats

V. Shamanskiy, *K. Popadin;*

Immanuel Kant Baltic Federal University, Kaliningrad, Russian Federation

Background: Accumulation of large-scale somatic mitochondrial deletions is associated with both healthy aging and age-related mitochondrial encephalomyopathies. Deletions are often flanked by direct nucleotide repeats and several hypotheses were raised to explain the deletion formation with the participation of the direct repeats. Here, we hypothesized that beside the direct repeats inverted repeats may play an important role structuring mtDNA.

Material and Methods: Using a collection of human mtDNA deletions and global and local mtDNA properties (distribution of direct and inverted repeats) we revise the risks of somatic mtDNA deletion.

Results: Comparison of the probability of mtDNA deletions in regions flanked by different combinations of direct and inverted repeats uncovering that, in addition to direct repeats, which are known to affect deletions, there is a strong impact of the secondary structure of single-stranded mtDNA during replication. The secondary structure while replication is shaped by inverted repeats which can form stems and shorten the effective distance between two direct repeats, thereby increasing the possibility of deletions.

Conclusion: Our results support a recent discovery that mtDNA deletions can originate through replication slippage. An understanding of the mechanisms of deletion formation allows to predict the genetic risks of mtDNA deletions for different human haplogroups - first examples being D4a and D5a haplogroups characterized by increased longevity.

P17.138.C Evaluation of Twist CNV Backbone Spike-in Panels at different probe densities and samples coverage for large pathological CNV detection

Ivan Limongelli[1], *Valentina Andrioletti*[1], *Tina Han*[2], *Alessandro Davassi*[2], *Susanna Zucca*[1]

[1]*enGenome srl, Pavia, Italy,* [2]*Twist Bioscience, South San Francisco, CA, USA.*

Background: Copy Number Variants can cause severe clinical outcomes. Array-based tests have been the gold standard for CNV detection. However, with the increasing use of Next Generation Sequencing (NGS), detecting large CNVs through Whole Exome Sequencing analysis is becoming more appealing. This study aimed to validate an optimized method for detecting large CNVs using Twist WES panels paired with newly designed CNV Backbone Spike-in Panels.

Material and Methods: Twist CNV Backbone Spike-in Panel was added to the Twist Exome 2.0 plus Comprehensive Exome Spike-in Panel and tested on 43 Coriell samples with array-confirmed CNVs. Three different probe densities were tested: 25 kb, 50 kb, and 100 kb. The 43 test samples and 12 additional reference samples were sequenced on Illumina NovaSeq 6000. To simulate different sequencing coverages, the original reads (at mean depth of 160X) were in silico sub-sampled at various read depths, i.e. 55X and 80X. CNVs were called using the enGenome eVai Secondary Workflow, which uses a read-depth approach. To benchmark our results, 52 array-confirmed large CNVs were evaluated for each probe design.

Results: An average of 345 PASS CNV variants per sample was identified, with the highest number of variants (358) called using the 25 kb design. The sensitivity was 98.08% for all probe designs, with only one variant missed, for all tested coverages. The FPR was <1% for all three designs.

Conclusion: These results demonstrate that these new panels can effectively identify large CNVs with a sensitivity comparable to array-based methods while maintaining the SNV/INDEL detection capabilities of NGS methods.

P17.139.D Creation of a population-specific genetic variation repository software system for sensitive data that incorporates Indigenous data sovereignty principles

Wyeth W. Wasserman[1], *Brad Winter*[1], *Benjamin Halliday*[2], *David Markie*[2], *Brittany Hewitson*[1], *Sam Hawarden*[2], *Phillip Wilcox*[2], *Stephen Robertson*[3]

[1]*University of British Columbia, Vancouver, BC, Canada,* [2]*University of Otago, Dunedin, New Zealand,* [3]*Otago University, Dunedin, New Zealand.*

Background: Genome sequencing technologies have transformed the diagnosis of rare genetic disorders to allow low-cost determination of genetic variation in patients and family members. Key to the identification of causal variants is the exclusion of common variants that are unlikely to be causal for extremely rare conditions. While global shared resources, such as the gnomAD database, provide valuable insights into common genetic variation, population-specific variants are inconsistently covered. To remedy this, national and population-specific data collections have been created that report the frequency of observed DNA sequence variants in the target population. To meet the commitment to maintaining data sovereignty recognized in the United Nations Declaration on the Rights of Indigenous Peoples, some projects must maintain restricted access to variation data.

Material and Methods: The software, available in a public repository, is developed for use with standard databases and uses Python, Django, and React JS for the web application.

Results: To enable two such projects in Canada and Aotearoa (New Zealand), a set of software modules has been developed that can empower projects with similar data sovereignty commitments, such as the CARE principles, to access and adapt for their use. The modules support needs that arise when engaging with sensitive data, such as auditability of access, appropriate limitations on use, and the ability to integrate existing authentication tools into the application. The web application also includes clinician-focused features including a robust variant search, links to external resources, and transcript effect predictors.

Conclusion: Access provided via a GitHub repository.

P17.140.A Varaico collects genetic variants from full-text literature (www.varaico.com)

Johannes Birgmeier, *Maximilian Haeussler*

University of California, Santa Cruz, Santa Cruz, CA, USA.

Background: Building on the previously published Avada (Automatic Variants Database), we created a computational pipeline called Varaico to collect genetic variants from the literature fully automatically.

Material and Methods: Varaico downloads PubMed titles and abstracts and uses a machine learning classifier to find papers potentially containing genetic variants. It then downloads the full text of relevant papers directly from publishers or PubMed Central if available. In the full text, gene mentions are detected by matching words against a list of gene names. Variant mentions in HGVS notation are detected using regular expressions. Detected gene and variant mentions are linked by checking given reference sequences in the variant description against RefSeq transcripts of the gene. Matching gene-variant pairs are mapped to genomic coordinates using alignments of RefSeq transcripts to a genome assembly.

Results: In a first run up to 2024-12-16, Varaico processed 37,991,294 PubMed titles and abstracts, of which 1,400,457 were classified as potentially containing genetic variants. It downloaded 748,738 full text papers. A median of 8 gene mentions and 4 variant descriptions per paper were discovered in the full text of 331,709 papers with at least one gene and variant mention. Gene and variant mentions were combined and mapped to 3,271,528 distinct genomic coordinates, with a mean of 1.8 citing papers per variant.

Conclusion: Varaico successfully finds genetic variants in the primary literature that may aid in diagnosing patients with genetic diseases. Varaico variants are available at the UCSC genome browser track https://hgwdev-jbirgmei.gi.ucsc.edu/cgi-bin/hgTracks?hgS_otherUserSessionName=varaico-hg19 as well as at www.varaico.com.

P17.141.B Predicting the clinical impact of copy number variations using a machine learning approach

Michaela Gažiová[1,2], *Jaroslav Budiš*[1,3,4], *Tomáš Sládeček*[1,3,2], *Marcel Kucharík*[1,3], *Zuzana Pös*[1,2,5], *Ondrej Pös*[1,3,2], *Zuzana Hanzlíková*[1,2,5],

Jakub Styk[1,3], Monika Kubáňová[1,6], Diana Rusňáková[1,3], Juraj Gazdarica[1,3,4], Jozef Sitarčík[1,3,4], Werner Krampl[1,3], Ján Radvánszky[1,2,5], Tomáš Szemes[1,3,2]

[1]Geneton Ltd., Bratislava, Slovakia, [2]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, [3]Comenius University Science Park, Bratislava, Slovakia, [4]Slovak Center of Scientific and Technical Information, Bratislava, Slovakia, [5]Institute of Clinical and Translational Research, Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia, [6]Faculty of Medicine, Comenius University, Bratislava, Slovakia.

Background: Copy number variations' (CNVs) presence may cause problems in the function of the organism in case of disturbing of the pathways. Several bioinformatic methods for evaluating clinical significance have been developed to differentiate CNVs between benign and pathogenic. Those tools are typically based on ACMG guidelines (classification tools). However, prediction tools based on machine/deep learning approaches are still a new field which is recently developing. Therefore the determination of CNV's clinical impact is remaining challenging.

Material and Methods: We collected information and accessions of genes, regulatory elements, dosage-sensitive regions, and other CNVs from publicly available databases. Based on them the annotations for analysing CNV were created. With the help of machine learning methods and annotations for CNV created in the previous step, we developed the prediction models, which were trained on CNV records from ClinVar respectively for loss and gains.

Results: According to the created CNV annotations, we selected the annotations that best fit and have shown the best ability to predict the pathogenicity of CNV in the model. We compared the prediction power of the model with the publicly available tools for evaluating CNV.

Conclusion: Automated bioinformatic tools for CNV annotation and prediction of clinical significance have a great potential to facilitate the evaluation process by eliminating lengthy manual annotation, providing predictions, and aiding interpretation for faster and more precise diagnostics.

P17.143.D Signaling Molecules-Mediated Genetic Landscape of Obesity: A Systems Biology Approach

***Austeja Letukiene**, Valentina Gineviciene*

Vilnius university, Vilnius, Lithuania.

Background: Predisposition to obesity is polygenic, resulting from genetic-environment interactions. Genome-wide association studies (GWAS) have revealed numerous obesity-related loci, but existing data focuses on isolated molecular pathways. Further research is required to elucidate causal genes, their roles, and mechanistic pathways. This study aims to investigate obesity's molecular pathophysiology using computational bioinformatic tools and algorithms to integrate causal genes and variants with multi-system data, identifying key mechanisms and causes of obesity for clinical translation.

Material and Methods: We conducted integrative analyses with advanced bioinformatics tools. SNP annotation and pathogenicity were assessed using SIFT and PolyPhen-2, with signaling pathways mapping via KEGG. Genetic, functional, and pathway data were integrated to reveal interactions and clinical correlations using network analysis algorithms STRING and Cytoscape. Our computational approach focused on genetic variants affecting a broad spectrum of molecular phenotypes, validated using Benjamini-Hochberg correction.

Results: Initial analysis identified 9,863 obesity-associated SNPs with significant in silico evidence and 444,811 SNPs linked to complex signaling pathways and 25 key organokines. Signaling pathways alterations were observed in hormonal regulation (insulin resistance via apelin, adiponectin; hypertension via resistin; appetite control via leptin) and inflammation (IL-6, TNF-alpha).

Conclusion: Our network-based, multi-system integrative approach leverages GWAS data to uncover synergistic genetic interactions. Using bioinformatics-driven algorithms, we enable broader target SNP selection and assistance for pre-study planning, optimizing research design processes and cost while supporting broader hypotheses by leveraging insights from smaller-scale GWAS studies. This scalable systems biology approach enables an exploration of overlapping pathways and supports broader polygenic diseases (obesity) pathogenesis studies.

P17.144.A cellink: A Scalable Framework for Integrating Genetic and Single-Cell Data

*Jan Paul Engelmann[1,2], Eva Holtkamp[1,2], **Lucas Arnoldt**[1,2], Lorenzo Consoli[1,2], Antonio Nappi[1,2], Christopher Lance[1,2], Julien Gagneur[1,2], Francesco Paolo Casale[1,2], Fabian J. Theis[1,2]*

[1]Helmholtz Munich, Munich, Germany, [2]Technical University of Munich, Munich, Germany.

Background: Integrating genetic data with single-cell omics is crucial for deciphering cellular heterogeneity, which is a key step toward advancing personalized medicine. While AnnData, a class for handling annotated data matrices, has become the standard data analysis structure used by various tools in single-cell research, there is a need for an extended framework that efficiently handles genetic data and scales to biobank-level datasets.

Material and Methods: *cellink* facilitates analysis by prioritizing the donor as the central unit and seamlessly integrating cell-level and donor-level data through its novel DonorData structure. Genetic data is efficiently loaded via *dask*, ensuring scalability for large datasets while extending AnnData with specialized genetic annotations. Crucially, genetic data and single-cell modalities remain synchronized, preserving their pairing even through filtering operations such as selecting cell types or patient-level treatments.

Results: *cellink* is a toolkit designed for streamlined analysis, offering a comprehensive set of tools for variant preprocessing, annotation, and selection, alongside specialized downstream analyses tailored for single-cell genomics. With our package, users

can easily perform genetic analysis of single-cell expression, including eQTL mapping, colocalization with disease loci and rare variant association studies. Additionally, *cellink* supports interoperability with standard genetic analysis workflows through data exports and includes dataloaders for deep learning, enabling AI-driven insights.

Conclusion: *cellink* bridges the gap between single-cell omics and individual-level genetic data by extending the widely used AnnData framework. It enables user-friendly and efficient analysis, enhances interoperability with genetic workflows, and integrates genetics with single-cell genomics to advance personalized medicine.

P17.146.C Assessing targeted viral detection between different metagenomic tools

Magdalena Mroczek[1,2], *Marek Nowicki*[2,3], *Dhananjay Mukhedkar*[4,5], *Ville Nikolai Pimenoff*[4,6], *Laila Sara Arroyo Mühr*[4]

[1]*University of Basel, Basel, Switzerland,* [2]*Interdisciplinary Centre for Mathematical and Computational Modelling, University of Warsaw, Warsaw, Poland,* [3]*Faculty of Mathematics and Computer Science, Nicolaus Copernicus University in Toruń, Torun, Poland,* [4]*Department of Clinical Science, Intervention and Technology, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden,* [5]*Hopsworks AB, Stockholm, Sweden,* [6]*Unit of Population Health and Borealis Biobank, University of Oulu, Oulu, Finland.*

Background: Human papillomaviruses (HPVs) are among the most diverse viral families that infect humans. Because of the large number of closely related HPV genotypes with similar sequences and the abundance of non-viral DNA in human-derived biological samples, it can be challenging to correctly detect HPV genotypes using existing bioinformatical tools in high-throughput sequencing data. PCR-based diagnostic detection remains a gold standard for detecting HPV infection. Recently, however, we created a k-mer-based Tversky indexing method (HPV-KITE) as a targeted metagenomic tool for HPV detection. In this study we assess the accuracy of six different metagenomic tools to detect HPV infection from shallow sequenced metagenome data.

Material and Methods: Using RNA and DNA metagenome data we assessed the performance of HPV-KITE (k-mer-based Tversky indexing, which is under development), Kraken2, Diamond, Viromescan, VirusFinder, HPVDetector and VirusSeq. Computational analyses were performed using Puhti and Mahti supercomputers of the CSC-Finland.

Results: Parameters such as processing time, scalability, accuracy, and system requirements have been assessed. K-mer-based methods are generally faster, but alignment methods show typically higher accuracies. However, the difference in the precision of the detection depends largely on the sequencing data type and quality as well as the complexities of the targeted infections.

Conclusion: Metagenomics tools are promising methods for systematic infection network estimation if strain-level infection resolution is sustained. Benchmarking, however, is needed to assess the best metagenomic tools for the best purposes and data types.

Background/Objectives: The 16p11.2 region is frequently emphasized in CNV studies for the neurodevelopmental disorders. Clinical results of CNVs in this region has not been clearly established. We aimed to create specific symptom clusters of CNVs in this region by using advanced bioinformatics and statistical methods.

Material and Methods: For this study, we scanned microarray analysis results oft he 7568 cases who applied to the outpatient clinic of Medical Genetics between 2015 and 2022. We used k-Means clustering algorithm, C4.5 decision tree classifier, Random Tree classifier, Random Forest classifier, Logistic regression and Support Vector Machines algorithms as machine learning methods. Detailed symptom screening and scales were used in our study for the diagnosis of Autism Spectrum Disorder (ASD), which is closely associated with this region. Social communication, restricted and repetitive behaviors, sensory symptoms, aggression and regression were evaluated using 25 symptoms.

Results: We determined 147 cases (1.94%) carrying a 16p11.2 CNV. Body mass index and agression levels was found to be statistically significantly higher in patients with pathogenic CNVs. The ASD symptom-based study concluded that the accuracy rate of 76.60% with 25 Autism symptoms increased to 80.85% when the classification process was performed for five symptoms. Especially agression and repetitive behaviors differed between common and pathogenic CNVs.

Conclusion: We argued that there is a widespread effect in the diagnosis of ASD along the 16p11.2 region including both common CNVs and pathogenic CNVs.

Grants: This study was supported by TÜBİTAK, 1002 Research Project Number 321S239.

P17.148.A mapPat: tracking pathogens evolution in space and time

Erika Ferrandi[1], *Graziano Pesole*[2], *Matteo Chiara*[1]

[1]*Università degli Studi di Milano, Milan, Italy,* [2]*Università degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: The COVID-19 pandemic highlighted the importance of genomic surveillance for monitoring pathogens evolution, mitigating the spread of infectious disorders and informing decision making by public health authorities. Since the need for the summarisation and interpretation of large bodies of data, computational methods are critical for the implementation of effective genomic surveillance strategies.

Material and Methods: Developed in R (v4.4.1) under Shiny (v1.9.1), mapPat uses publicly available metadata and sequences from GISAID or NextStrain to summarise key features of variants, lineages and mutations at different times and geographic levels.

Results: mapPat is an R Shiny application for the interactive visualisation of pathogens genomic data in space and time. It collects data in tabular format by processing publicly available metadata and associated sequences. Users interact with mapPat by setting filters through a dedicated control panel; once a selection is applied, tabs are populated with informative plots and the selected data can be visualised and inspected. mapPat allows the dynamic monitoring of the evolution of variants, lineages and mutations in the genome of a pathogen at glance, through informative geographic maps and elegant data visuals. The tool was tested by retrospective analysis of SARS-CoV-2 circulation in Italy.

Conclusion: mapPat may support fighting future pandemics providing a fine grained map of pathogens evolution and circulation, and thus represents a useful method for the genomic surveillance of pathogens. mapPat is available at GitHub (https://github.com/F3rika/mapPat.git) together with a dedicated Zenodo Repository (https://doi.org/10.5281/zenodo.14163899) of precomputed datasets.

P17.149.B Evaluation of SNV and CNV calling on the clinically relevant high-homology gene PMS2

Valentina Andrioletti[1], *Mayra Sauer*[2], *Thomas Risch*[2], *Anna Benet-Pages*[2,3], *Barbara Klink*[2], *Elke Holinski-Feder*[2,4], *Ettore Rizzo*[1], *Ivan Limongelli*[1], *Susanna Zucca*[1]

[1]*enGenome srl, Pavia, Italy,* [2]*MGZ Munchen, Munich, Germany,* [3]*Institute of Neurogenomics, Helmholtz Zentrum München, German Research Centre for Environmental Health, Munich, Germany,* [4]*Department of Medicine IV, Klinikum der Universität, Ludwig-Maximilians University, Munich, Germany.*

Background: Variant calling is challenging in high-homology regions when using short-read sequencing due to ambiguous alignment. This impacts the analysis of clinically relevant genes like PMS2, a well-known tumor suppressor gene involved in mismatch repair, sharing high homology with PMS2CL. Having the promise of long-read sequencing to improve the accuracy of variant calling in these regions, we compared single nucleotide variant (SNV) and copy number variation (CNV) calling performances with state-of-the-art short and long-reads applications.

Material and Methods: The enGenome-eVai-Secondary-Workflow was applied to analyze samples sequenced by the MGZ Laboratory using target enrichment with both short-read (Illumina; exome-TWIST) and long-read (PacBio; custom hereditary tumor gene panel-TWIST) platforms. 20 PMS2-positive samples were selected. The short-read workflow was optimized by masking the pseudogene region, while the long-read analysis leveraging on the PacBio "Paraphase" module to accurately resolve haplotypes and call variants is ongoing.

Results: A benchmark analysis evaluated both the sensitivity and false positive rate of the two sequencing approaches (short-read and long-read). Preliminary data on short-reads showed a Sensitivity of 100%. Regarding the long-read data, we expect to equal these metrics for both SNV and CNVs, with improved specificity.

Conclusion: Calling SNVs and CNVs in high-homology regions is possible with an optimized short-read workflow, but differentiating between *PMS2* and *PMS2CL* calls still presents a limit. PacBio long-read sequencing promises to overcome the alignment issues inherent in high-homology regions. This study highlights the potential of both sequencing technologies in calling variants within challenging genomic regions, while emphasizing the importance of workflow optimization.

P17.150.C UCSC Genome Browser Track Decorators

Gerardo Perez, *Galt P. Barber, Jonathan Casper, Hiram Clawson, Mark Diekhans, Clay Fischer, Jairo Navarro Gonzalez, Angie S. Hinrichs, Christopher M. Lee, Luis R. Nassar, Brian J. Raney, Matthew L. Speir, Marijke J. Van Baren, David Haussler, W. James Kent, Maximilian Haeussler*

UC Santa Cruz Genomics Institute, Santa Cruz, CA, USA.

The UCSC Genome Browser is a widely utilized web-based tool for visualization and analysis of genomic data, encompassing over 5000 assemblies from diverse organisms. Genome annotations, referred to as "features," are typically represented as colored rectangles ("exons") connected by thin lines ("introns"). This visualization tool lacked the flexibility to highlight specific feature components within a single track, often necessitating additional tracks. To address this limitation, we introduced track decorators, a feature that allows you to convey additional information on features by overlaying colored shapes and symbols on them. Track decorators support two visualization styles: "block" and "glyph." The "block" style can overlay exon and intron regions with distinct colors and labels, such as mapping protein domain boundaries onto transcripts within a single track. The "glyph" style can display symbols, such as triangles, to indicate genomic insertion sites. These decorators can be applied to BED 12+, bigBed, PSL, and bigGenePred format tracks. Ongoing advancements include the

development of Hub Space, which will provide users with dedicated storage for uploading annotation files and attaching them as track hubs. Additionally, we continue to make progress on the Liftover on the Fly feature, which enables the automatic lifting of annotations to unannotated genomes without the need for manual track lifting.

P17.151.D Integrating Artificial Intelligence into Cancer Genomics: Opportunities and Challenges for North Cyprus

Fezel Nizam, *Pembe Savaş, Havva Çobanoğulları*

Eastern Mediterranean University, Famagusta, North Cyprus, Mersin 10 Turkey, Turkey.

Background: Artificial Intelligence (AI) is transforming cancer genomics by enabling personalized oncology treatments, improving early detection, and enhancing precision medicine. AI-driven approaches facilitate mutation detection, risk prediction, and therapy optimization, offering significant potential for cancer care. However, North Cyprus faces challenges such as limited genomic infrastructure, data privacy concerns, and the need for AI capacity building. This review explores AI applications in cancer genomics within the North Cypriot context, highlighting its role in tumor profiling, treatment stratification, and cost-effective cancer care.

Material and Methods: This study examines machine learning models for tumor-specific mutation analysis, AI-driven diagnostics for early detection, and predictive models for treatment response. The establishment of local cancer genomic databases and the use of federated learning systems ensure patient privacy while enabling regional collaboration. Challenges such as resource limitations, regulatory barriers, and ethical considerations are assessed, alongside best practices from global AI applications.

Results: AI-driven models improve cancer diagnosis accuracy and treatment decision-making. AI-based genomic profiling enhances personalized therapy selection, particularly for breast and colorectal cancers. A local cancer genomic database is crucial for population-specific treatment strategies. However, insufficient genomic data, limited computational resources, and regulatory hurdles remain challenges.

Conclusion: AI-driven cancer genomics has the potential to revolutionize oncology care in North Cyprus. Addressing data accessibility, infrastructure, and policy barriers is essential for sustainable implementation. This study outlines a roadmap for AI-driven cancer genomics, emphasizing strategic investments, collaborative frameworks, and policy development to enhance cancer care outcomes.

P17.152.A Reproducibility of Genomic Variant Detection by NGS in Rare Disease Diagnostic Setting

Emre Özzeybek, *Mehmet Baysan, Ugur Özbek*

Rare and Undiagnosed Diseases Platform (RUDiP), Izmir Biomedicine and Genome Center, Izmir, Turkey.

Background: NGS technologies have revolutionized clinical genetics by allowing rapid and comprehensive analysis of genetic data. Currently, in Türkiye, genetic clinics use whole-genome sequencing (WES) as their first-tier diagnostic test for its cost-effectiveness. As a broader test, whole-genome sequencing (WGS) is expected to replace WES in practice as costs diminish. Considering the rapid adoption of sequencing technologies in disease diagnosis, the reproducibility of variant detection is crucial.

Materials and Methods: Per RareBoost Project goals, we aim to diagnose rare and undiagnosed patients and further rare disease research and innovation. To clarify undiagnosed rare disease patients with WES-negative results, we reanalyzed these patients' previous raw data. We used the same genomic pipeline for all re/analyses: BWA for alignment, DeepVariant for SNP/indel annotation and Manta for structural variant annotation. 10 of these patients showed no causative variants and we performed WGS analysis for further investigation. The WES analyses were performed with 100X, WGS with 30X depth. We used the number of variants called as the medium for comparison.

Results: We observed a limited overlap between WES and WGS analyses on exon regions. The limited documentation for the old sequencing data and the differences between WES enrichment kits and the selection of different reference genomes are potentially the major reasons behind these differences.

Conclusion: Our results demonstrate the importance of detailed record-keeping for sequencing analyses to establish reproducibility for NGS-based diagnosis in rare diseases. These comparisons would also help understand the gain from using WGS rather than WES.

P17.153.B Approximating Linkage Disequilibrium Matrices from Summary Statistics for Fine-Mapping Applications

Giulia Elizabeth de Sanctis, *Claudia Giambartolomei, Nicola Pirastu, Sodbo Sharapov, PHD, Francesca Ieva*

Human Technopole, Milan, Italy.

Background: Accurate fine-mapping relies on linkage disequilibrium (LD) matrices, but their large size and privacy concerns limit data sharing, posing challenges for collaborative studies. We propose a method to approximate LD matrices directly from summary statistics, enabling their use in fine-mapping applications. Our approach is evaluated using UK Biobank data from 30,000 individuals.

Material and Methods: We simulated various scenarios to assess the number of individuals and phenotypes required for accurate LD approximation, ensuring robustness across different genomic regions. Fine-mapping performance was evaluated by comparing the number of true positives identified using our approximated LD matrices in SuSiE against results obtained with an insample reference LD panel.

Conclusion: Preliminary findings indicate that our method reliably approximates LD matrices allowing for precise downstream applications. We aim to develop an R package to facilitate their use for fine-mapping applications. This approach could be particularly advantageous in meta-analyses, where selecting an appropriate LD reference panel is often challenging.

P17.154.C GenePath - A novel data-driven framework for reverse phenotyping

Alexander Mordhorst[1], *Peter N. Robinson*[2], *Dominik Seelow*[2], *Denise Horn*[1]

[1]*Institut für Medizinische Genetik und Humangenetik | Charité – Universitätsmedizin Berlin, Berlin, Germany,* [2]*Berlin Institute of Health at Charité, Berlin, Germany.*

Background: The advent of diagnostic genomics poses new challenges in respect to variant prioritization. These challenges are mainly addressed via the use of scores relying either on the prediction of variant pathogenicity or phenotypic information. The patient phenotype on the other hand is in a clinical genomics setting usually only evaluated once before genomic data has been obtained and might be incompletely captured either in relation to its full extent or in relation to the minimum amount of information necessary to in- and exclude gene variants and therefore solve the case. The process of suggesting further measures of phenotypisation, based upon genetic data - a process called reverse phenotyping - is at the moment fully based on human expert knowledge and lacks structured and data-driven frameworks, a gap we aim to address.

Material and Methods: Python, HPO, MaxO

Results: We created a model based on the HPO and MaxO ontologies which instantiates a knowledge-graph using genomic data and a-priori captured phenotypic information as inputs. This graph then can be exploited to estimate case-complexity and suggest a diagnostic route based on the information gain attached to each possible diagnostic measure.

Conclusion: Graph-based models can be used to suggest further phenotyping measures to explore an a-priori captured and maybe incomplete patient phenotype based on genomic data.

P18 Large scale genomics (GWAS) and other -omics association studies

P18.001.D Multi-omics resources and long-term conditions in the Extended Cohort for E-health, Environment and DNA (EXCEED)

Chiara Batini[1,2], *Brandon Lim*[1], *Alexander T. Williams*[1], *Gerald Sze*[1,2], *Kayesha Coley*[1], *Nick Shrine*[1], *David J. Shepherd*[1], *Edward J. Hollox*[3], *Louise V. Wain*[1,2], *Martin D. Tobin*[1,2], *Catherine John*[1,2]

[1]*Department of Population Health Sciences, University of Leicester, Leicester, United Kingdom,* [2]*University Hospitals of Leicester NHS Trust, Leicester, United Kingdom,* [3]*Department of Genetics and Genome Biology, University of Leicester, Leicester, United Kingdom.*

Background: The Extended Cohort for E-health, Environment and DNA (EXCEED) is a longitudinal health study aimed at understanding the environmental and biological causes of long-term health conditions. It includes ~11,000 participants aged 18 and above from the Midlands (UK), who completed baseline lifestyle questionnaires, agreed to linkage of their electronic health records, and provided biological samples for genomics, proteomics, metabolomics and glycomics.

Material and Methods: Genetic data were obtained using the UK Biobank Axiom array and through imputation to the TOPMed reference panel. Ancestry groups were defined using k-means clustering on principal components and 1000 Genome Project Phase 3 (1KGP) populations as reference. Liquid chromatography and mass spectrometry were used to measure 319 proteins, 7750 metabolites and 39 glycoproteins levels. We performed association testing between genetic variants and protein levels using regenie in 1KG-EUR-like individuals, and defined cis-pQTL as the sentinel variant within 1 Mb of the cognate gene transcription start site.

Results: After standard quality control procedures, we obtained genomic data for 8499 individuals, proteomic for 1979, metabolomic for 1524 and glycomic for 900. The largest overlap was between genomic and proteomic data, including 1551 individuals, while full overlap between all omics data was available for 541 participants. We detected cis-pQTLs for 114 proteins; 59 of these proteins were not represented in UK Biobank proteomic data.

Conclusion: Here we present a comprehensive description of the omics variation observed in EXCEED, and we will discuss its impact on multiple long-term conditions.

P18.002.A Mapping the protein-genetic landscape: SomaLogic versus Scanning SWATH

Michele Filosi[1], *Eva König*[2], *Solène Cadiou*[3], *Johannes Rainer*[1], *Alessia Mapelli*[3], *Giulia Pontali*[3], *Dariush Ghasemi-Semeskandeh*[3], *Michela C. Massi*[3], *Gianmauro Cuccuru*[3], *Francisco Domingues*[1], *Cristian Pattaro*[1], *Peter P. Pramstaller*[1], *Emanuele Di Angelantonio*[3], *Markus Ralser*[4], *Christian Fuchsberger*[1]

[1]*Eurac Research, Bozen, Italy,* [2]*Eurac Research, Bolzano, Italy,* [3]*Fondazione Human Technopole, Milan, Italy,* [4]*Charité - Universitätsmedizin, Berlin, Germany.*

Background: Plasma protein levels provide insight into the physiological state of individuals. Various technologies are now available for high-throughput screening of protein profiles, and numerous studies have explored the effect of genetic variants on protein expression (pQTL). However, a systematic comparison of pQTL findings across different technologies are still limited. While somalogic uses aptamer binding techology, Scanning SWATH uses mass-spectrometry, thus they provide distinct information at the protein level, which may relate to distinct underlying biological mechanisms.

Material and Methods: We measured 103 blood protein profiles in 2388 participants to the Cooperative Health Research in South Tyrol (CHRIS) study using both Somalogic and Scanning SWATH technology. Protein profiles were normalized using indirect inverse-normal transformation, removing the effects of age, sex, the top 10 genetic principal components, and use of hormonal contraceptives. Genome-wide association studies were conducted using the Regenie pipeline. Results were clumped and fine-mapped to identify independent loci, and the association results were compared at the locus-protein level.

Results: We identified 117 and 76 loci for the Somalogic and Scanning SWATH platforms respectively, 30 are common between the two platforms. After fine-mapping we found 64 loci unique to Somalogic and 31 loci unique to the Scanning SWATH dataset.

Conclusion: Despite the distinct methodologies, a significant number of genetic associations were consistently identified across both technologies. Each platform also revealed unique genetic associations that were not detected by the other. These technology-specific associations suggest that different platforms can uncover distinct biological mechanisms and pathways, which may be linked to various disease phenotypes.

P18.003.B 10K newborn genome screening project in Qingdao, China: clinical findings and precision health insights

Mingyan Fang

BGI Research, Shenzhen, China.

Background: The 10K Newborn Genome Screening Project in Qingdao, China, aims to explore whole genome sequencing (WGS) as a tool for precision health and newborn screening. In this study, we expand on our previous pilot involving 321 newborns by reporting on the full cohort of 10,000 unselected newborns.

Material and Methods: We performed WGS at 65X depth on 9,992 newborns to analyze 245 inheritable and metabolic diseases. WGS validation was conducted on 17 mass spectrometry-positive cases, confirming 3 and identifying 43 additional positive cases. We also analyzed genomic data from 7,140 consented newborns, identifying variants, including high-confidence protein-truncating variants (PTVs), copy number variations (CNVs), and pathogenic variants. Additionally, we performed microbiome analysis, pharmacogenomic profiling of 257 genes, and genome-wide association studies (GWAS) on 42 metabolic markers.

Results: In total, 2.7% (274/9992) of newborns were screen-positive, with 40.7% carrying at least one disease mutation. Newborns carried 0–10 pathogenic variants, with most carrying 3–6. We identified 1,281 unique rare variants across 328 genes. Microbiome analysis revealed cytomegalovirus in half of the newborns, with rates varying by delivery route and birth season. Pharmacogenomic analysis identified 593,206 variants, with 45.37% novel in East Asians. GWAS identified 4,145 significant SNPs and 1,326 novel associations, including six novel missense variants linked to metabolism.

Conclusion: This comprehensive study represents the largest newborn WGS screening effort to date, providing critical insights into genetic diseases, precision health, and pharmacogenomics. Our findings underscore the potential of WGS to advance newborn screening and inform early interventions in precision medicine.

P18.004.C Protein Quantitative Trait Loci meta-analysis of 7,000 protein levels measured in UK INTERVAL and Italian CHRIS studies provides new insights into the genetic architecture of the human plasma proteome (Award Candidate)

Solène Cadiou[1], *Alessia Mapelli*[1], *Giulia Pontali*[1], *Eva König*[2], *Michele Filosi*[2], *Dariush Ghasemi-Semeskandeh*[1], *Brian R. Ferolito*[3], *Michela C. Massi*[1], *Gianmauro Cuccuru*[1], *Xiyun Jiang*[4], *Johannes Rainer*[2], *Peter Pramstaller*[2], *Cristian Pattaro*[2], *Alexandre Pereira*[3], *Emanuele Di Angelantonio*[1,4], *Claudia Giambartolomei*[1,3], *Christian Fuchsberger*[2], *Adam S. Butterworth*[4]

[1]*Fondazione Human Technopole, Milano, Italy,* [2]*Institute for Biomedicine, Eurac Research, Bolzano, Italy,* [3]*Veterans Affairs Healthcare System, Boston, MA, USA,* [4]*University of Cambridge, Cambridge, United Kingdom.*

Background: Circulating plasma proteins are critical disease markers and drug targets, yet the genetic factors influencing their inter-individual variation are not fully understood. Here we provide an updated characterization of the genetic architecture of the human plasma proteome, leveraging the 7k aptamer-based protein platform at scale for the first time.

Methods: Plasma protein levels from 7143 proteins were measured using the SomaLogic 7k assay in two European cohorts: the UK-based INTERVAL[1] study (9251 samples) and the Italian CHRIS[2] cohort (4194 samples). Genome-wide protein quantitative trait locus (pQTL) analyses were conducted independently in each study, followed by meta-analysis. We identified regional associations, performed conditional analysis to select independent signals, and tested them for colocalization across proteins. Mendelian Randomization (MR) and colocalization with 2011 traits were conducted using an external dataset comprising meta-analyses of European ancestry samples from the Million Veteran Program, UK Biobank, and FinnGen biobanks. We additionally tested our *cis*-pQTLs for colocalization with expressionQTL in various tissues.

Results: We identified 7870 significant pQTL (1784 cis and 6086 trans), including 3171 novel associations. Newly assessed proteins were less detectable and less likely to show *cis* associations compared to proteins assessed previously. 7994 significant MR associations were found, with 729 possible new opportunities of drug retargeting. 5472 *cis*-pQTLs showed at least one significant colocalization with cis-eQTLs.

Conclusion: Our study, the first of its scale across European populations, provides new actionable insights in the genetic architecture of the human proteome and gives perspective on the benefits of expanding proteomic assays for genomic research.

P18.005.D GWAS of 59,102 glaucoma cases reveals 230 independent loci and highlights pathways involved in glaucoma

Xinyuan Zhang[1], *Neelroop Parikshak*[1], *Rujin Wang*[1], *Olle Melander*[2], *GHS-RGC DiscovEHR Collaboration*[3], *MAYO-RGC Project Generation*[3], *Penn Medicine Biobank*[3], *Colorado Center for Personalized Medicine – RGC collaboration*[3], *UCLA-RGC ATLAS Collaboration*[3], *FinnGen*[3], *UK Biobank*[3], *Giovanni Coppola*[1], *Eric Jorgenson*[1]

[1]*Regeneron Genetics Center, Tarrytown, NY, USA,* [2]*Department of Clinical Science Malmo, Lund University, Malmo, Sweden,* [3]

Glaucoma is a leading cause of irreversible blindness worldwide. Elevated intraocular pressure (IOP) is the major modifiable risk factor. Current treatments can reduce IOP but no treatments to date restore retinal ganglion cell function. Human genetic studies have the potential to identify new therapeutic targets that could address this need. In this study, we performed the largest GWAS for glaucoma to date, which consists of 59,102 cases and 1,190,670 controls. We identified 230 independent common variant loci - nearly doubling the number of loci discovered by the largest previous study (Gharahkhani, P. *et al*. 2021). Out of these independent loci, 138 our loci are novel, and 81 overlap with loci previously associated with GWAS of IOP. For example, previous studies have shown that rare LoF variation in *ANGPTL7* reduces IOP. Our increased sample size and inclusion of FinnGen enabled identification of a common variant rs147660927 [p.Arg220Cys, MAF EUR = 0.01%, MAF FIN = 4.1%] in *ANGPTL7*, which is associated with 31% lower disease risk. To further

understand the contribution of diverse molecular pathways, we used Multi-marker Analysis of GenoMic Annotation (MAGMA) analysis to search for significantly enriched pathways. Our analysis highlighted the following pathways: circulatory system development and cardiovascular system pathways ($P = 7.3 \times 10^{-9}$), molecules associated with elastic fibers ($P = 8.2 \times 10^{-8}$) and enzyme linked receptor protein signaling pathway ($P = 6.7 \times 10^{-7}$). Our study expands the spectrum of variation linking glaucoma to IOP, supports known roles of inflammation and extracellular matrix biology, and suggests new protein signaling pathways that might play a role in glaucoma.

P18.006.A Rare variant association study reveals small open reading frames (smORFs) as novel regulators of cardiometabolic diseases (Award Candidate)

Hyung Chul Kim[1,2], *Ruebena Dawes*[1,2], *Yuyang Chen*[1,2], *Jing Yu*[3], *Angie Bookout*[4], *Alexander Drong*[4], *Caroline Wright*[5], *Joanna Howson*[3], *Nicola Whiffin*[1,2]

[1]*Big Data Institute, University of Oxford, Oxford, United Kingdom,* [2]*Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [3]*Novo Nordisk Research Centre, Oxford, United Kingdom,* [4]*Bio Innovation Hub, Novo Nordisk, Cambridge, MA, USA,* [5]*University of Exeter, Exeter, United Kingdom.*

Background: Small open reading frames (smORFs) are small translated regions of ≤150 codons. They are often poorly annotated and their mechanisms remain largely unexplored. Recent ribosome profiling (ribo-seq) experiments have identified tens of thousands of novel smORFs. Here, we generated a set of high-confidence smORFs using 11 ribo-seq datasets and investigated their association with cardiometabolic traits (e.g. HbA1c and blood lipid profile).

Material and Methods: We aggregated 10 publicly available and 1 in-house ribo-seq datasets across 17 tissues and cell lines to define a set of high-confidence smORFs, defined as those found in ≥2 datasets. We then performed a rare variant association study for cardiometabolic traits from UK Biobank within these smORF regions, using custom annotations to identify smORF-disrupting variants.

Results: We identified 13,048 high-confidence smORFs. We then filtered to rare variants (MAF < 0.001) which impact the smORFs, such as start loss, stop loss and frameshift, and selected 5,993 smORFs with aggregate rare variant count >20. Using smORF-based collapsing analysis on this smORF subset, we identified 106 smORFs that are linked to cardiometabolic traits. Of these smORFs, 69 (65.1%) were located in 5′ UTR, 25 (23.6%) were located on lncRNAs, and the rest were located in 3′ UTR or out-of-frame within the CDS regions.

Conclusion: We curated a set of high-confidence smORFs and demonstrated smORFs as novel regulatory regions associated with various cardiometabolic traits. This finding underscores the potential of these regulatory elements in risk stratification and drug target discovery.

Healthcare costs offer a summary measure of overall morbidity and its treatment. Quantifying the genetic contribution to these costs can inform public health policy and reveal genetic determinants of overall morbidity. We analysed healthcare costs, including inpatient, outpatient, and prescription costs, for 1.45 million individuals across seven healthcare systems with differing cost structures. Annual per-patient costs ranged widely, from €483 in the Estonian Biobank to €458,455 in the Mass General Brigham Biobank. A GWAS meta-analysis identified 53 and 183 significant loci for inpatient and prescription costs, respectively. Most effects were modest, the top inpatient locus, rs2814985 near ILRUN, was associated with a ~1% annual cost increase per allele. One-third of loci showed sex- or age-specific effects. For example, female carriers of rs62237617 near CHEK2 had 9% higher annual costs compared to 4% in males, potentially reflecting increased breast and ovarian cancer risk. Despite differences in healthcare systems, genetic correlations across inpatient studies were strong (median $rg = 0.88$), and 95% of loci showed minimal heterogeneity. PheWAS highlighted links to risk factors (e.g., BMI) and chronic diseases (e.g., asthma, depression). Using UK Biobank exome sequencing data, we found higher inpatient costs for individuals with putative loss-of-function (pLOF) variants in clinically relevant genes, including BRCA1/2, MSH2, and APC. For BRCA2 pLOF carriers, annual costs were ~1.8 times higher than non-carriers. Polygenic scores for healthcare cost also predicted costs, with the highest decile in FinnGen incurring 25% higher median costs than mid-percentiles. Genetic variation significantly influences healthcare expenditure globally, improving our understanding of morbidity.

P18.008.C Uncovering T1D's Hidden Variants: Insights from the Largest Whole ExomeSequencing Study in Europe

Khrystyna Shchubelka[1,2], *Walter Wolfsberger*[1], *Karolina Kuliś*[3], *Joanna Polańska*[3], *Taras K. Oleksyk*[1], *Ukraine T1D Exomes Consortium*[4]

[1]*Oakland University, Rochester, MI, USA,* [2]*Uzhhorod National University, Uzhhorod, Ukraine,* [3]*Silesian Institute of Technology, Gliwice, Poland,* [4]

Background: Type 1 Diabetes (T1D) genetic studies in Europe primarily focus on Western European populations, leaving Central and Eastern Europe underrepresented. Rare, endemic variants that may significantly influence T1D risk are often overlooked due to low frequency in broader analyses. This study represents the largest whole exome sequencing (WES) and genotyping effort for T1D in Europe, providing insights into previously unexplored genetic diversity, including MODY (Maturity-Onset Diabetes of the Young). Our objective is to emphasize the importance of diversity in genetic research.

Material and Methods: We established a collaborative network in Ukraine and neighboring countries, collecting approximately 11,000 samples. Of these, 2,667 T1D patients and 4,529 controls were sequenced using Twist exome capture with whole-genome genotyping. A genome-wide association study (GWAS) was performed, complemented by gene set enrichment analysis (GSEA) to identify novel T1D genetic factors based on effect size. MODY-related variants were also screened.

Results: Our analysis confirmed the highly significant roles of HLA loci (e.g., HLA-DQA1, HLA-G) in T1D ($p < 5 \times 10^{-50}$) and identified novel genetic variants unique to Eastern European populations. MODY-related variants led to the reclassification of several misdiagnosed T1D cases, highlighting the diagnostic value of genetic studies.

Conclusion: Despite challenging conditions due to the war, this study demonstrates the feasibility of large-scale genetic research in resource-limited settings. Our findings will be available as an open-access resource via the "Genomics of T1D in Ukraine" portal and ENA, supporting global research efforts and collaboration.

P18.009.D Advancing target discovery through systematic, scalable analysis of common human variation and traits

Yakov A. Tsepilov[1,2], *Daniel Suveges*[1,3], *Szymon Szyszkowski*[1,2], *Daniel Considine*[1,2], *Xiangyu Ge*[1,2], *Irene López Santiago*[1,3], *Tobi Alegbe*[1,3], *Vivien W. Ho*[1,3], *Kirill Tsukanov*[1,3], *Annalisa Buniello*[1,3], *Ellen M. McDonagh*[1,3], *David Ochoa*[1,3]

[1]*Open Targets, Cambridge, United Kingdom,* [2]*Wellcome Sanger Institute, Cambridge, United Kingdom,* [3]*European Bioinformatics Institute - EMBL-EBI, Cambridge, United Kingdom.*

Background: Open Targets (OT) is a collaborative partnership between academia and industry that uses human genetics and genomics to enhance drug target identification. We present a new post-GWAS pipeline optimized for scalable, reproducible statistical genetics and genomics analyses for drug target prioritisation, significantly expanding previous OT Genetics. This update processes all publicly available GWAS from the GWAS Catalog, FinnGen, eQTL Catalogue, and UKB-PPP, making it the most extensive human common variation analysis to date.

Material and Methods: The open-source OT Gentropy pipeline leverages PySpark for ETL and runs on Google Cloud Platform or locally. It ingests multi-omic datasets, integrates GWAS fine-mapping results, and includes modules for data harmonization, ancestry-specific fine-mapping (PICS, SuSiE), colocalization (eCAVIAR, COLOC), and drug target prioritisation (L2G score).

Results: Applied to 90K GWAS Catalog studies (15% non-European), 2.7K FinnGen R12 studies, 3K UKB-PPP studies, and eQTL datasets, our analysis generated 486K complex trait credible sets (3.5× previous OTG) and 1.8M molQTL credible sets. The enhanced L2G model achieved 0.97 AUC and 0.8 average precision, identifying >358K credible sets with L2G > 0.5, resulting in over 400K gene-disease associations. Prioritised targets show enrichment for known drug targets (phase IV OR = 2.9, p = 3.8e-13).

Conclusion: Gentropy is openly available (https://github.com/opentargets/gentropy), with results integrated into the Open Targets Platform (https://platform.opentargets.org/), expanding opportunities for genetics-driven drug discovery.

P18.010.A scDCF: A framework for detecting disease-associated cells in single-cell RNA-seq leveraging healthy panels and GWAS findings

Caicai Zhang, *Frank Qingyun Wang, Xiao Dang, Wanling Yang*

The University of Hong Kong, Hong Kong, Hong Kong.

Background: Understanding how genetic risk factors influence disease processes at the cellular level remains a key challenge in complex disease research. Identifying cellular contexts of genetic risk is critical for unraveling disease mechanisms. Advances in single-cell RNA sequencing (scRNA-seq) and genome-wide association studies (GWAS) offer powerful tools, but integrating these data types requires robust computational methods.

Material and Methods: We developed the single-cell Disease Cell Finder (scDCF), a computational framework integrating GWAS findings with scRNA-seq data to identify disease-associated cells. scDCF leverages a healthy reference panel, Monte Carlo simulations, and statistical validation to detect significant gene expression changes linked to disease-related genetic variants. This framework was applied to systemic lupus erythematosus (SLE), Sjogren's syndrome (SJS), and chronic kidney disease (CKD).

Results: scDCF identified key disease-associated cell types and subpopulations across datasets. In SLE, age-associated B cells, CD8+GZMH+ T cells, and Th1-like CD4+ T cells were enriched for interferon-stimulated genes and cytotoxic markers. In SJS, epithelial cells of serous and mucous acini exhibited heightened antigen presentation and stress responses, implicating epithelial-immune crosstalk in autoimmune activation. In CKD, proximal tubule epithelial cells displayed metabolic dysregulation and fibrosis-related gene expression, highlighting epithelial injury's role in disease progression.

Conclusion: scDCF effectively integrates GWAS-driven gene prioritization with single-cell transcriptomics to identify disease-associated cells and pathways. This approach provides insights into cellular mechanisms of complex diseases and offers a framework to study genetic risk in disease progression.

P18.011.B Combining machine learning and single-cell omics to reveal the mechanism of action of pleiotropic variants

Camilla Marinelli, *Daniela Fusco, Mathilde André, Lucia Troiani, Martina Noè, Fabrizio Pizzagalli, Davide Marnetto, Paolo Provero*

Università di Torino, Torino, Italy.

Background: Genome-wide association studies complemented by the analysis of genetic correlation, intermediate molecular phenotypes, and colocalization can provide valuable insight on the shared genetic determinants of complex traits. Epigenomic and transcriptomic data at the single-cell level can deepen our understanding of the molecular processes and the specific cells involved. We apply machine learning techniques to single-cell chromatin accessibility data to gain mechanistic insight into regulatory variants pleiotropically associated with body mass index (BMI) and magnetic resonance imaging (MRI)-derived brain morphology traits.

Material and Methods: Gapped k-mer support vector machines (gkmSVMs) trained on single-nucleus ATAC-seq data for 107 brain cell types were applied to credible sets of SNPs previously identified as affecting both BMI and MRI traits through gene expression (pleiotropic variants), thus identifying the cell types most likely to mediate their effects. Motif analysis and single-cell transcriptomics allowed prioritizing candidate transcription factors (TFs) involved in the mechanism through allele-dependent binding.

Results: Nine out of 128 pleiotropic variants were predicted to impact chromatin accessibility in brain cell types. For example, rs7187776, affecting BMI and caudate volume through TUFM expression, was predicted to impact chromatin accessibility specifically in microglia. Motif analysis revealed that the alternate allele creates a strong binding site for ETS TFs, while single-cell transcriptomics suggested FLI1 and ETV6 as specific candidates.

Conclusion: Combining genetic analysis and single-cell omics through machine learning provides insights into the regulatory roles of trait-associated SNPs, highlighting potential mechanisms by which pleiotropic genetic variation influences complex traits through intermediate molecular phenotypes.

P18.012.C Five-hundred and three loci influencing immunoglobulin levels in humans

Zain Ali[1], *Gudmar Thorleifsson*[2], *Aitzkoa Lopez de Lapuente Portilla*[1], *Antton Lamarca*[1], *Caterina Cafaro*[1], *Ludvig Ekdahl*[1], *Gisli Halldorsson*[2], *Erna V. Ivarsdottir*[2], *Unnur Thorsteinsdottir*[2,3], *Ingileif Jonsdottir*[1], *Thorunn Olafsdottir*[2,3], *Kari Stefansson*[2], *Björn Nilsson*[1,4]

[1]*Lund University, Lund, Sweden,* [2]*deCODE Genetics, Reykjavik, Iceland,* [3]*University of Iceland, Reykjavik, Iceland,* [4]*Broad Institute, Cambridge, MA, USA.*

Background: Immunoglobulins (Igs) are the effector molecules of the adaptive humoral immune system. In order to understand further the genes and pathways involved in Ig production we conducted a large-scale genome-wide association study on serum IgA, IgG, IgM and six composite Ig traits in 114,271 individuals in the UK, Iceland and Sweden. To our knowledge this is the largest population genetic analysis of serum Ig traits conducted to date.

Material and Methods: Serum Ig measurements are routinely measured in the clinic enabling genetic analysis of electronic health records. Composite Ig traits were constructed through linear transformations of primary Ig measurements and were designed to capture specific stages of B cell development such as class switching efficiency or total Ig production. High-confidence target genes were assigned using statistical fine-mapping and colocalization analysis.

Results: We uncover 503 independent associations that reach genome-wide significance for at least one trait, 450 of which are novel. We identified 309 high-confidence causal genes, many of which had no previously established role in Ig production. These have multiple different functions and specifically indicate that genetic variation in Ig levels is determined by normal B-cell development, antigen presentation, class-switch recombination, Ig synthesis and Ig homeostasis. Furthermore, 157 signals correspond to known disease loci. Particularly, we find an enrichment of rare risk variants for congenital immunodeficiencies and B-cell malignancies.

Conclusion: Our analysis provides a high-resolution view of the genes and pathways controlling humoral immunity, and a unique resource for B-cell research and clinical genetic analysis of B-cell disorders.

P18.013.D Shared genetic architecture of brain shape and IBD is specifically enriched for inflammatory response genes

Seppe Goovaerts, *Jay Devine, Nina Claessens, Meng Yuan, Toomas Kivisild, Isabelle Cleynen, Peter Claes*

KU Leuven, Leuven, Belgium.

Background: The gut-brain axis (GBA) is a bidirectional communication network linking the central and enteric nervous systems. Its dysregulation is implicated in inflammatory bowel disease (IBD) and psychiatric conditions. Understanding its genetic basis is crucial for uncovering disease mechanisms and potential therapies.

Material and Methods: We conducted a genome-wide association study (GWAS) on cortical brain shape in 48,564 UK Biobank participants. Using the conjunctional false discovery rate (FDR), we identified shared genetic signals with a previously published IBD GWAS on 25,042 cases and 34,915 controls. We modeled genetic effects on brain morphology, performed Gene Ontology overrepresentation analysis, and conducted PheWAS to explore biological relevance of the shared loci. Additionally, we

examined directional selection based on ancient European genomes.

Results: We identified 193 shared genomic loci (1% FDR), including immune-related genes (*IL23R, IL1R2, IL10/27, SLC22A4, CARD9*). These loci were enriched for immune processes relative to all brain loci, and explained brain shape variation in regions linked to major depressive disorder. PheWAS revealed pleiotropy with immunological, autoimmune, and psychiatric traits, including schizophrenia. Two independent top SNPs increased in allele frequency from <5% to >40% in the last 9000 years.

Conclusion: These findings support the immune system's role in the shared genetic basis of brain and gut function and suggest immune-related adaptive evolution influences brain morphology. The enrichment of shared loci for inflammatory response genes reinforces links between neuroinflammation and psychiatric conditions like depression and schizophrenia, offering a foundation for further research into GBA-related diseases.

P18.014.A Integration of multi-omics to identify regulators gene involved in multiple sclerosis disease activity

Elisabetta Mascia[1], *Beatrice Pignolet*[2,3], *Alice Chiodi*[4], *Antonino Giordano*[1,5], *Kaalindi Misra*[1], *Melissa Sorosina*[1], *Ferdinando Clarelli*[1], *Valentina Nale*[4], *Florence Bucciarelli*[2], *Massimo Filippi*[5,6,7], *Roland Liblau*[2], *Alexander Kel*[8], *Ettore Mosca*[4], *Federica Esposito*[1,6]

[1]*Laboratory of Human Genetics of Neurological Disorders, Institute of Experimental Neurology, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*Toulouse Institute for Infectious and Inflammatory Diseases (Infinity), University of Toulouse, CNRS, INSERM, Toulouse, France,* [3]*Neurosciences Department, Toulouse University Hospital, Toulouse, France,* [4]*Institute of Biomedical Technologies, National Research Council, Segrate, Italy,* [5]*Vita-Salute San Raffaele University, Milan, Italy,* [6]*Neurology and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy,* [7]*Neuroimaging Research Unit, Institute of Experimental Neurology, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy,* [8]*geneXplain GmbH (GXP), Wolfenbüttel, Germany.*

Background: Multiple sclerosis (MS) is a complex disorder characterized by high heterogeneity in terms of phenotypic expression, prognosis and treatment response. In the present study we aimed to identify molecular markers and signatures of disease activity through the integration of multi-layer information including clinical, molecular and environmental data.

Material and Methods: 1626 Italian and French MS patients were recruited and classified according to the NEDA status (No Evidence of Disease Activity). Whole genome genotype (Infinium OmniExpress-24 array) was performed in the entire cohort. In a subset of 261 untreated MS patients we assessed the transcriptomic (mRNA-Seq), miRNA (miRNA-Seq) and methylation (Illumina EPIC array) profiles. The gene-wise scores, derived from the association of the single-omic data with the NEDA status, were then used to develop an interactome, identifying key players (regulators); pathways associated with disease activity were evaluated applying a systems biology approach (mND).

To identify transcription factors and master regulators involved in disease activity, we applied the "Genome Enhancer" software (geneXplain) to transcriptomics and epigenomics data.

Results: a gene network of ~400 genes was identified; genes (i.e. IL2RA, VCAM1) and process (i.e. IFNγ response, TNFα signalling via NFkb) related to MS were significantly enriched. Among the transcription factors and master regulators associated with MS disease activity, the most promising molecular target is STAT5B. The validation of STAT5B as master regulator in MS disease activity is ongoing through CUT&RUN experiments.

Conclusion: STAT5B seems to be involved in the regulation of genes associated with disease activity in MS patients.

P18.015.B A transcriptome-wide association study of brain sulcal morphology in a developmental cohort

Irene Treccani[1], *Alessandro Amaolo*[2], *Camilla Marinelli, PhD Student*[2], *Mahan Shafie*[2], *Ilaria Boscolo Galazzo*[1], *Gloria Menegaz*[1], *Davide Marnetto*[2], *Fabrizio Pizzagalli*[2], *Paolo Provero*[2]

[1]*University of Verona, Verona, Italy,* [2]*University of Torino, Torino, Italy.*

Background: Sulcal morphology is crucial for neurodevelopment and neurodegeneration, but its genetic determinants have been investigated only in adult cohorts. Transcriptome-wide association studies (TWAS) identify trait-associated genes by imputing the genetic component of gene expression and testing it for association with measured traits. We performed a TWAS to identify genes associated with sulcal morphology in a cohort of pre-adolescents.

Material and Methods: We analyzed 4,396 European individuals from the Adolescent Brain Cognitive Development (ABCD) study. Four sulcal shape descriptors were analyzed (depth, length, width, and surface area) from 122 regions automatically segmented and labelled across the whole brain. Left and right sulci were analyzed separately and bilaterally averaged, resulting in 732 traits. TWAS was performed by associating the genetic component of gene expression in 13 brain tissues with such traits.

Results: TWAS identified 460 genes significantly associated with 561 sulcal morphology traits. Some of them, such as NSF, KANSL1, and LARS2, are located within large loci previously implicated in sulcal morphology by a GWAS of an adult cohort, thus providing independent validation and gene-level fine mapping of such associations. Newly found associations include SFTA2, previously associated by GWAS studies with autism spectrum disorder and schizophrenia, and TRIM47, associated with several other measures of brain morphology.

Conclusion: We identified genes involved in sulcal morphology measured during development, partially overlapping those identified in an independent study of an adult population and revealing new associations, thus enhancing our understanding of cortical folding genetics, with implications for neurodevelopmental and neuropsychiatric disorders.

P18.016.C Update on the genetics of dizygotic twinning

N. Martin;

Queensland Institute of Medical Research, BRISBANE, Australia

Background: The propensity to give birth to non-identical twins is a complex trait that runs in families. To elucidate factors regulating female fertility and infertility, we conducted a genome-wide association meta-analysis.

Material and Methods: The GWAMA included five independent studies of mothers of spontaneous dizygotic (DZ) twins (8,265 cases, and 264,567 controls) and of independent DZ twin offspring (26,252 cases, 417,433 controls).

Results: In addition to *FSHB* and *SMAD3* previously identified, we identified four new loci: *GNRH1, FSHR, ZFPM1* and *IPO8*. Of these, the first two loci have well-established roles in female reproduction whereas *ZFPM1* and *IPO8* have not previously been implicated. Significant genetic correlations were found with multiple aspects of female reproduction and body size, as well as evidence that there has been selection against DZ twinning during evolution. A DZT risk score of the 26 top SNPs from our meta-analysis in European-origin participants did a poor job of predicting twinning rate in 47 non-European populations ($r = 0.23$ between risk score and population prevalence), indicating that separate GWAS are needed in African and Asian populations to explore the causes of their respectively very high and very low DZ twinning rates. The same PGS, at the bottom end of the scale also predicted ovarian insufficiency as a cause of female infertility, suggesting a translational application of our work.

Conclusion: DZ twinning defines the top end of a continuous scale of female fertility which is strongly genetically influenced. Those at the bottom end are at markedly higher risk of anovulatory infertility.

N. Martin: None.

P18.017.D Discovery of core genes for autoimmune thyroid disease and polyautoimmunity via genome-wide aggregation of *trans*-effects using UK Biobank proteomics study

Andrii Iakovliev, *Athina Spiliopoulou, Helen Colhoun, Paul M. McKeigue, Professor of Genetic Epidemiology and Statistical*

University of Edinburgh, Edinburgh, United Kingdom.

Background: Autoimmune thyroid disease (AITD) is the most common autoimmune disorder, often coexisting with other autoimmune diseases—a phenomenon termed polyautoimmunity. The "omnigenic" sparse effector hypothesis postulates that the polygenic effects of common genetic variants on disease coalesce via *trans*-effects on a sparse set of core genes. This study aims to identify core genes for AITD and polyautoimmunity using genome-wide aggregated *trans*-effects (GATE) analysis inspired by this hypothesis.

Material and Methods: We used pQTL summary statistics from UKB-PPP and deCODE to compute GATE scores in a target dataset (24766/451447 cases/controls) from UK Biobank. We tested for association between AITD and GATE scores, one protein at a time, and identified core genes based on the strength of the association, the number of independent *trans*-loci contributing to each score, and retained core genes with uncorrelated scores.

Results: *PDCD1* (LogOR = 0.18, $P = 10^{-138}$) emerged as the strongest. Other putative core genes with standardised LogOR>0.01 include immune checkpoint receptors *TIGIT* ($P = 10^{-119}$), *LAG3* ($P = 10^{-13}$), *LGALS9* ($P = 10^{-34}$), *CD27* ($P = 10^{-26}$), *TNFRSF9* ($P = 10^{-28}$), *TNFRSF14* ($P = 10^{-33}$), *TNFRSF8* ($P = 10^{-45}$), *LAIR1* ($P = 10^{-44}$); genes in the interferon signalling pathway *IFNL1* ($P = 10^{-95}$), *DDX58* ($P = 10^{-49}$); encode chemokines *CXCL9* ($P = 10^{-50}$), *CXCL10* ($P = 10^{-78}$), *CXCL13* ($P = 10^{-45}$), and NK cells receptors *NCR1* ($P = 10^{-29}$), *KLRB1* ($P = 10^{-14}$).

Conclusion: These results combined with findings previously reported for type 1 diabetes and rheumatoid arthritis, establish a key role for immune checkpoints in AITD and polyautoimmunity, and the first map of polyautoimmunity using core genes. They also suggest that PD-1 agonists, now being developed for rheumatoid arthritis, may help to reduce risk of other autoimmune conditions.

P18.018.A Single-cell genomics data predicts the success of clinical trials and facilitates drug repurposing

Sodbo Sharapov[1], *Arianna Landini*[1], *Alessandro Raveane*[1], *Matiss Ozols*[2], *Stephen Watt*[2], *Cardinal Project Working group*[3], *Marc Jan Bonder*[4], *Oliver Stegle*[2,5,6], *Nicole Soranzo*[1,2,7]

[1]Human Technopole, Milan, Italy, [2]Wellcome Sanger Institute, Hinxton, United Kingdom, [34]Department of Genetics, Groningen, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [5]Division of Computational Genomics and Systems Genetics, German Cancer Research Center, Heidelberg, Germany, [6]European Molecular Biology Laboratory, Genome Biology Unit, Heidelberg, Germany, [7]University of Cambridge, Victor Phillip Dahdaleh Heart & Lung Research Institute, Cambridge, United Kingdom.

Background: Prioritizing drug targets is a critical bottleneck in pharmaceutical development. Single-cell (sc) transcriptomics can pinpoint causal genes for complex diseases by verifying if genetic variants responsible for gene expression differences are also causal to disease. We investigated whether this knowledge applied to drug target genes increases the chances of success in clinical trials and provide evidence for drug repurposing.

Material and Methods: We integrated historical clinical trial data, GWASs of 36 diseases and traits, and cis sc-eQTLs from PBMCs of ~ 5,000 UK Biobank donors across 28 cell types. First, we performed genome-wide colocalization analysis between 47,037 scRNA eQTLs and diseases. Each target-indication (T-I) pair was classified based on the presence or absence of colocalization of their eQTL with corresponding indication-related disease and compared with their success in reaching different phases of drug validation.

Results: Pairs of T-I with evidence of colocalization of target's eQTLs and disease were significantly more likely to progress through clinical trial phases compared to non-colocalizing targets: OR = 7.51 [5.21–10.50] to pass Preclinical Phase, OR = 2.75 [1.65–4.30] to pass Phase I, OR = 2.84 [1.22–5.64] to pass Phase II, and OR = 2.42 [0.66–6.26] to pass Phase III. Subgroup analyses revealed strong support from sc-eQTL for cardiovascular, gastrointestinal, and metabolic diseases. We identified multiple marketed drugs whose targets have eQTLs, colocalized with novel indications, supporting drug repurposing.

Conclusion: These findings underscore the importance of genetic colocalization in early-stage drug design. By prioritizing eQTL-supported targets, pharmaceutical pipelines can enhance clinical success rates and uncover drug repurposing opportunities.

P18.019.B HLA PheWAS studies in the China Kadoorie Biobank and UK Biobank

Ruth Nanjala[1], *Esther Ng*[1], *Sam Morris*[2], *Iona Y. Millwood*[2], *Guillaume Butler-Laporte*[3,4,5], *Kuang Lin*[2], *Ling Yang*[2], *Pang Yao*[2], *Alexander Mentzer*[3], *John A. Todd*[3], *Robin G. Walters*[2], *Yang Luo, PI*[1]

[1]Kennedy Institute of Rheumatology, Nufffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences,

University of Oxford, Oxford, United Kingdom, [2]Clinical Trial Service Unit and Epidemiological Studies Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom, [3]Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, [4]Lady Davis Institute, Jewish General Hospital, McGill University, Montréal, QC, Canada, [5]Division of Infectious Diseases, McGill University Health Centre, Montréal, QC, Canada.

Background: The Major Histocompatibility Complex (MHC) region harbours the highest number of significant associations in genome wide association studies. However, the full phenotypic impact of the MHC locus across a wide range of diseases remain unknown.

Material and Methods: We imputed Human Leukocyte antigen (HLA) alleles from genotype data within the China Kadoorie Biobank (CKB, N>100,000) and the UK Biobank (UKB, N>500,000) using a multi-ancestry HLA reference panel. We quantified HLA diversity in CKB using a customized R package [https://github.com/yang-luo-lab/HLADiversity]. Furthermore, we performed mixed logistic regression analysis correcting for age, sex and genetic relatedness across 200 phenotypes in both biobanks.

Results: We observed 316 unique HLA alleles at 2-field resolution in the CKB dataset. HLA allele frequencies among the ten CKB regions showed distinct north-south division. From the CKB and UKB PheWAS analysis, we observed previously reported significant HLA-disease associations across various phenotypes with consistent effects across two ancestral groups. However, there exist ancestry-specific associations. For example, DRB1*04:01 is the strongest risk allele associated with rheumatoid arthritis in UKB ($\beta = 0.410$), while DRB1*04:05 confers the strongest risk in CKB ($\beta = 0.578$). Additionally, meta-analysis identified potentially novel HLA associations, including HLA-DRB1*03:01 with thyrotoxicosis hyperthyroidism ($P = 1.21 \times 10^{-140}$, OR = 1.747) and HLA-A*02:01 with shingles ($P = 1.10 \times 10^{-26}$, OR = 0.866).

Conclusion: We present findings on the influence of HLA variants on multiple phenotypes across global biobanks. Our results underscore the significant role of HLA alleles in shaping a diverse range of disease phenotypes worldwide.

Background: Obesity is a global epidemic associated with adverse effects on health and quality of life. Improved understanding of its underlying pathophysiology is essential for developing counteractive measures. For this purpose, our aim was to search for sequence variants with large effects on body mass index (BMI).

Material and Methods: We performed a multi-ancestry meta-analysis of 13 genome-wide association studies on BMI that included data derived from 1,534,555 individuals of European ancestry, 339,657 of Asian ancestry, and 130,968 of African ancestry. We focused on sequence variants with an absolute effect greater than 1 kg/m^2.

Results: An intergenic 262,760 base pair deletion at the *MC4R* locus associated with 4.11 kg/m^2 higher BMI per allele ($P = 4.5 \times 10^{-9}$; 95% confidence interval [CI; 2.76, 5.46 kg/m^2]), likely through downregulation of *MC4R*. A rare *FRS3* missense variant, p.Glu115Lys, was only found in Finland and associated with 1.09 kg/m^2 lower BMI per allele ($P = 6.6 \times 10^{-12}$; 95% CI [−1.40, −0.78 kg/m^2]). Three other low-frequency missense variants in *FRS3* associated with BMI with smaller effects ($P < 2.6 \times 10^{-4}$) and were enriched in different ancestries. In a gene-based burden test of *FRS3* predicted loss-of-function variants, loss of FRS3 function associated with a 2.24 kg/m^2 increase in BMI ($P = 0.0062$; 95% CI [0.62, 3.85 kg/m^2]).

Conclusion: *FRS3* is a novel BMI-associated gene that encodes an adaptor protein known to act downstream of BDNF and TrkB, which, upon activation, decrease appetite and food intake through previously unknown signaling pathways. Our work provides a convincing downstream component of the BDNF-TrkB pathway, a potential target for obesity treatment.

Background: Protein expression (PEX) signatures underlying sex-specific biology remain understudied. By exploring the overlap and divergence in PEX within and between sexes, we aim to uncover mechanisms underlying sex-linked phenotypes, and their health implications.

Material and Methods: We included 51,292 individuals with 29,19 plasma proteins measured across five studies (UK Biobank, FinnGen, MESA, Biobank Japan, Japan COVID-19 Task Force). To understand proteome-wide sex-linked variability, we derived an XGBoost-based Proteomic Sex Index (PSI) comprising 31 proteins, using 9,128 individuals from UKB. High PSI indicates the proteome is shifted from the genetic sex-typical values.

Results: We observed sex-biased PEX in 80% ($p < 2e-05$) of proteins in UKB. Sex bias estimates correlated well across studies (Pearson's r: 0.72–0.80). Interestingly, 11% of proteins were differently associated with sex before versus after menopause in women.

PSI was associated with sex-differential phenotypes in meta-analyses: e.g., males with high PSI had lower testosterone (nmol/L, beta = −2.66, 95% confidence intervals:−0.32,−0.21) and were shorter (cm, beta = −0.43; 95% confidence intervals:−0.52,−0.34).

We identified five genome-wide significant loci in within-sex PSI GWASs in UKB. Two were shared (MMP3, CDH15), and the other loci with known pQTLs were XG in males and PZP in females. We calculated PSI polygenic score (PGS) within FinnGen and examined its correlations with 678 diseases. Higher PSI PGS in females is associated with a lower risk of female-biased diseases.

Conclusion: These findings reveal complex patterns of sex-biased proteomic variability, providing insights into sex-specific health risks.

P18.022.A The host genetic architecture of Epstein-Barr virus (EBV) abundance in blood

Axel Schmidt, *Sylvia Richter, T. Madhu Alawathurage, Friederike David, Sabrina K. Henne, Eva C. Beins, Kerstin U. Ludwig*

Institute of Human Genetics, University Hospital Bonn, Bonn, Germany.

Background: Epstein-Barr virus (EBV) is an endemic DNA virus, with about 95% of the adult population being infected. Primary infections are usually asymptomatic in childhood and present as infectious mononucleosis in later life. EBV persists latently within lymphocytes and is associated with a variety of disorders, such as autoimmune and tumour diseases (e.g. Multiple Sclerosis (MS)). However, little is known about the host's interaction with EBV. Here, we used genome sequence (GS) data of the UKBiobank to quantify EBV abundance and analyse the host genetics of EBV-control.

Material and Methods: EBV-reads were extracted from UKBiobank GS data and the presence of EBV-reads ("EBV-read-positivity") was characterized using clinical and serology information. Genome-wide common and rare-variant association studies were performed in 360,764 European individuals using Regenie with covariates (e.g. blood count traits, age, sex, sequencing yield). The distribution of polygenic risk scores (PRS) for EBV-read positivity was compared across different disease cohorts reflecting EBV-associated traits.

Results: 78,771 of 486,315 individuals carried >=1 EBV-read. EBV-reads were practically absent in seronegative individuals (specificity: 99.5%) and strongly overrepresented in individuals with reported HIV. GWAS identified robust associations across the MHC-region and 24 non-MHC loci, including loci harboring genes involved in antigen processing. RVAS identified TNFRSF13B, underlying common variable immune deficiency, as a significant gene outside of MHC. EBV-read-positivity-PRS was significantly associated with MS and driven by the MHC region.

Conclusion: We here provide novel insights into the genetic architecture of immune control in latent EBV infection and its relevance to EBV-associated disease.

P18.023.B Assortative mating exacerbates the impact of rare pathogenic CNVs

Caterina Cevallos, *Chiara Auwerx, Robin Hofmeister, Tabea Schoeler, Zoltan Kutalik, Alexandre Reymond*

University of Lausanne, Lausanne, Switzerland.

Background: CNVs are linked to a spectrum of outcomes, ranging from subtle to severe phenotypic changes. We explored the distribution and impact of an individual's polygenic scores (PGSs) in different CNV backgrounds.

Material and Methods: Leveraging CNVs and PGSs for 331,522 unrelated white British UK Biobank participants, we modeled 104 established CNV-trait associations involving 38 phenotypes. Linear regressions assessed the individual and joint contribution of CNVs and PGS to phenotypic variability. We tested whether healthy cohort bias results in CNV carriers exhibiting lower PGS to counteract the CNV effect.

Results: We demonstrate an additive PGS-CNV contribution for 74 (71%) CNV-trait pairs but do not identify any significant CNVxPGS interactions, e.g. a 22.7 mmol/mol increase in glycated hemoglobin between the bottom and top PGS quintiles of 16p11.2-BP4-5 deletion carriers ($p = 1.7e-4$) paralleling higher prevalence of type 2 diabetes (13% vs 46%; $p = 0.049$). Four CNV-trait pairs show a significantly higher PGS burden in CNV carriers *vs* copy-neutral individuals, with an additional 30 nominally significant pairs, indicating that CNV carriers systematically exhibit higher PGS load (34/34; $p = 1.1e-10$). Assortative mating (AM) is a likely explanation, evidenced by the strong association between the observed CNV-PGS correlations and their predicted values by the AM mechanism ($r = 0.55$, $p = 3.9e-4$), consolidated by 51% average CNV inheritance rate of 28 testable CNVs.

Conclusion: AM leads carriers of inherited rare CNVs to accumulate higher PGS burden, exacerbating CNV's effect. This interplay contributes to variable expressivity, enabling carrier stratification and identification of those at risk for severe clinical outcomes.

P18.024.C Genetic architecture and risk prediction of gestational diabetes mellitus in over 116,144 Chinese pregnancies

Yuqin Gu[1], *Hao Zheng*[1], *Piao Wang*[2], *Yanhong Liu*[1], *Xinxin Guo*[1], *Yuandan Wei*[1], *Zijing Yang*[1], *Shiyao Cheng*[1], *Yanchao Chen*[1], *Liang Hu*[2], *Xiaohang Chen*[2], *Quanfu Zhang*[3], *Guobo Chen*[4], *Fengxiang Wei*[2], *Jianxin Zhen*[3], *Siyang Liu*[1]

[1]*School of Public Health (Shenzhen), Shenzhen Campus of Sun Yat-sen University, Shenzhen, China,* [2]*The Genetics Laboratory, Longgang District Maternity & Child Healthcare Hospital of Shenzhen City (Longgang Maternity and Child Institute of Shantou University Medical College), Shenzhen, China,* [3]*Central Laboratory, Shenzhen Baoan Women's and Children's Hospital, Shenzhen, China,* [4]*Department of Genetic and Genomic Medicine, Center for Productive Medicine, Clinical Research Institute, Zhejiang Provincial People's*

Hospital, People's Hospital of Hangzhou Medical College, Shenzhen, China.

Background: Gestational diabetes mellitus (GDM), a heritable metabolic disorder and the most common pregnancy-related condition, remains understudied regarding its genetic architecture and its potential for early prediction using genetic data.

Material and Methods: In this study, we conducted genome-wide association studies(GWAS) on 116,144 Chinese pregnancies, leveraging their non-invasive prenatal test (NIPT) sequencing data and detailed prenatal records. Based on GWAS findings, we developed polygenic risk scores(PRS) and applied an XGBoost model to predict GDM, which utilized PRS, non-genetic factors, or a combination of both.

Results: We identified 14 novel loci for GDM and 115 for five glycemic traits, with allele frequencies of 0.01–0.5 and absolute effect sizes of 0.03–0.79. Approximately 50% of these loci were specific to GDM and gestational glycemic levels, distinct from type 2 diabetes and general glycemic levels in East Asians. A machine learning model integrating PRS and prenatal records predicted GDM before 20 weeks of gestation, achieving an AUC of 0.729 with accuracy of 0.835. Compared to the phenotypic model with AUC of 0.712 and accuracy of 0.835, the combined model showed significance improvement in predictive performance, as demonstrated by DeLong's test($P < 0.05$). Shapley values highlighted PRS as key contributors.

Conclusion: This study represents the largest GWAS to date on GDM and five glycemic traits in an East Asian cohort. Our findings provide the first comprehensive insights into the genetic architecture of GDM in East Asians and introduces a model that integrates PRS with early electronic health records to enhance the prediction and classification of GDM risk.

P18.025.D Rare variant imputation followed by exome-wide association analysis uncovers novel protein quantitative trait loci

Eva König[1], *Michele Filosi*[1], *Johannes Rainer*[1], *Cristian Pattaro*[1], *Peter P. Pramstaller*[1], *Solène Cadiou*[2], *Alessia Mapelli*[2,3], *Giulia Pontali*[2], *Dariush Ghasemi-Semeskandeh*[2], *Michela C. Massi*[2], *Gianmauro Cuccuru*[2], *Claudia Giambartolomei*[2], *Emanuele Di Angelantonio*[2], *Christian Fuchsberger*[1]

[1]*Institute for Biomedicine, Eurac Research, Bolzano, Italy,* [2]*Fondazione Human Technopole, Milano, Italy,* [3]*Politecnico di Milano, Milano, Italy.*

Background: Plasma protein levels provide insight into the physiological state of individuals, yet the genetic factors influencing protein expression are incompletely characterized. Previous efforts have concentrated on analyzing common variants[1] or investigated a limited number of proteins[2]. Rare exonic variants are enriched for impact on molecular function, yet rare variant studies are often under-powered.

Methods: Plasma protein levels of 7,281 proteins were measured in 4,194 individuals of the Cooperative Health Research in South Tyrol (CHRIS) study[3] using the SomaLogic 7K platform. Since whole-exome sequenced was only available for a subset ($n = 2,396$) of individuals, a custom reference panel was used to impute exonic variants into the whole cohort, achieving a mean accuracy of 0.91 in a validation sample. Exome-wide association analysis was performed using REGENIE. GCTA was used to identify independent signals with minor allele frequency <1%. Skat and skato tests were used to perform gene-based tests.

Results: We identified 937 and 319 independent protein quantitative trait loci (pQTLs) and gene-based associations, respectively. High and moderate impact variants were enriched in rare cis-pQTLs compared to common cis-pQTLs. Only 19% of pQTLs were novel compared to 46% of gene-level associations. For 23% of the gene-level associations, no single pQTL in the gene achieved significance. For 23 pQTLs, the variant was reported as (likely) pathogenic in ClinVar.

Conclusions: We confirm previously reported associations but also provide novel insights into rare associations with the blood proteome, highlighting the value of imputation enhanced rare variant association studies and gene-based tests.

P18.026.A Dissecting the genomic and epigenomic landscape of children's adipose tissue

Mauro Tutino[1], *Kathrin Landgraf*[2,3], *Georgia Katsoula*[1,4], *Peter Kreitmaier*[1,4], *Norbert Bittner*[1], *Konstantinos Hatzikotoulas*[1], *Antje Körner*[2,3,5], *Eleftheria Zeggini*[1,4]

[1]*Institute of Translational Genomics, Helmholtz Zentrum München – German Research Center for Environmental Health, Neuherberg, Germany,* [2]*University of Leipzig, Medical Faculty, University Hospital for Children and Adolescents, Center for Pediatric Research, Leipzig, Germany,* [3]*Helmholtz Institute for Metabolic, Obesity and Vascular Research (HI-MAG) of the Helmholtz Zentrum München at the University of Leipzig and University Hospital Leipzig, Leipzig, Germany,* [4]*Technical University of Munich, TUM School of Medicine and Health, Graduate School of Experimental Medicine, Munich, Germany,* [5]*University of Leipzig, Medical Faculty, LIFE–Leipzig Research Center for Civilization Diseases, Leipzig, Germany.*

Background: Understanding age- and tissue-specific molecular mechanisms is important for elucidating metabolic disease aetiopathology. While some studies have explored DNA methylation quantitative trait loci (mQTLs) and gene expression QTLs (eQTLs) in adult adipose tissue, their regulation in child adipose tissue has never been studied.

Material and Methods: We mapped *cis*-mQTL ($N = 288$), eQTL ($N = 349$) and transcript QTL (tQTL; $N = 349$) in primary child adipose tissue and compared the results to adult datasets to identify age-specific genetic regulation. Over-representation analysis was performed to test for enrichment of the childhood-specific eQTL-targeted genes (eGenes) in biological pathways. The molecular QTL maps were integrated with genome-wide association study (GWAS) summary statistics for adulthood and childhood obesity traits and adult metabolic traits through colocalization.

Results: Child adipose tissue showed unique characteristics compared to adult datasets, with 22.2% of the eGenes not identified in adult adipose tissue. For mQTLs, up to 45% of mCpGs were age-specific. Childhood-specific eGenes were enriched in aging, anatomical structure development, and morphogenesis pathways ($qval < 0.05$). Colocalization analysis revealed 1,449 GWAS signals colocalizing with mQTLs, 478 with eQTLs, and 480 with tQTLs, with 158 loci colocalizing across all three traits. Of 408 colocalizing eGenes, 216 (52.9%) were also reported in the Open Targets Genetics database.

Conclusion: These findings show that studying the genetic regulation of molecular traits in children can identify a large

number of signals currently missed by adult adipose tissue datasets. This contributes to a better understanding of early processes related to obesity and metabolic disease in children and adults.

P18.027.B A systematic approach to map downstream effects of proteins on the paired plasma and urine metabolome

Inga Steinbrenner[1], *Oleg Borisov*[1], *Zulema Rodriguez-Hernández*[1], *Anna Kottgen*[1,2], *Pascal Schlosser*[1,2]

[1]*Institute of Genetic Epidemiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany,* [2]*Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA.*

Background: Proteins mediate and catalyze many metabolic functions, including enzymatic reactions and transport processes in the kidney that operate at the interface of plasma and urine. Using readouts of the proteome and metabolome, we employed hypothesis-generating genetic causal inference methods to study their molecular relationships across biofluids.

Methods: We conducted proteome-wide association studies (PWAS, 1,303 cis-pQTL protein models) for the levels of 1,296 plasma and 1,399 urine metabolites, leveraging summary statistics from genome-wide association studies of metabolites (N = 5,023). Downstream analyses included statistical colocalization to address the risk of genetic confounding due to linkage disequilibrium and a phenome-wide PWAS to explore the (patho-)physiological effects of proteins significantly associated with metabolites across 4,360 phenotypes in the UK Biobank.

Results: We identified 282 putative causal effects of proteins evenly distributed on plasma and urine metabolite levels. Colocalization analyses supported 157 of the 282 findings (posterior probability of a shared causal variant >80%). For 36 of the 61 implicated unique proteins, we identified 326 putative causal effects on health outcomes ($p < 1.8e\text{-}7$). Levels of the kidney membrane enzyme DPEP1 and the urine dipeptide metabolite prolylglycine displayed the strongest association ($p = 3.6e\text{-}293$), consistent with its role as a dipeptidase. DPEP1 was associated with 13 metabolites and 21 health outcomes including higher hemoglobin concentration and reduced hypertension incidence. Using the Open Targets database, 17 metabolites and 19 proteins were among potential drug targets in clinical trials.

Conclusion: This in vivo causal inference screening of the proteome and metabolome highlights dozens of enzymes, their associated metabolites and clinical correlates.

P18.028.D Deep learning derived adipocyte size reveals adipocyte hypertrophy is under genetic control

Emil Jørsboe[1,2], *Phil Kubitz*[3], *Julius Honecker*[3], *Torben Hansen*[2], *Hans Hauner*[3], *Matthias Blüher*[4], *Philip D. Charles*[1], *Cecilia M. Lindgren*[1], *Christoffer Nellåker*[1], *Melina Claussnitzer*[5]

[1]*University of Oxford, Oxford, United Kingdom,* [2]*University of Copenhagen, Copenhagen, Denmark,* [3]*Technical University of Munich, Munich, Germany,* [4]*University of Leipzig, Leipzig, Germany,* [5]*Broad Institute, Cambridge, MA, USA.*

Background: Fat distribution and macro structure of adipose tissue are important factors in predicting obesity-associated diseases. To investigate the relationship between adipocyte hypertrophy, (using mean adipocyte size) and obesity-related traits, and the genetics of it, we performed the largest study of automatic adipocyte phenotyping using both histological and genetic data.

Material and Methods: Utilising visual deep learning based tools for doing semantic segmentation of subcutaneous and visceral adipose tissue histology samples (N = 2,667) in 5 independent cohorts. The pipeline was able to do rapid inference across 9,000 whole slide images, and segment over 27 million adipocytes.

Results: Estimates of mean adipocyte size were validated against Glastonbury et al. 2020 showing a high level of concordance. We show that adipocyte hypertrophy confers an adverse metabolic profile with increased levels of leptin, fasting plasma glucose, glycated hemoglobin and triglycerides. It confers decreased levels of adiponectin and HDL cholesterol. We performed the largest GWAS (NSubcutaneous = 2066, NVisceral = 1878) and subsequent meta-analysis of mean adipocyte size, we find one genome-wide significant locus (rs73184721) associated with increased 95%-quantile of adipocyte size in visceral adipose tissue. Analysing females only we find two genome-wide significant loci, one variant (rs140503338) is associated with increased mean adipocyte size in subcutaneous adipose tissue, the other variant (rs11656704) is associated with decreased 95%-quantile of adipocyte size in visceral adipose tissue.

Conclusion: We show that adipocyte hypertrophy is associated with an adverse metabolic profile. The presence of extremely large adipocytes is under genetic control.

P18.029.C Identification and analysis of pQTL-dense regions and their connection to protein functionality

Alessia Mapelli[1,2], *Solene Cadiou, PhD*[3], *Dariush Ghasemi-Semeskandeh*[2], *Michele Filosi*[4], *Michela C. Massi*[2], *Giulia Pontali*[2], *Eva König*[4], *Gianmauro Cuccuru*[2], *Johannes Rainer*[4], *Cristian Pattaro*[4], *Peter P. Pramstaller*[4], *Xiyun Jiang*[5], *Francesca Ieva*[1,2], *Christian Fuchsberger*[4], *Emanuele Di Angelantonio*[2,5], *Adam S. Butterworth*[5], *Claudia Giambartolomei*[2]

[1]*Politecnico di Milano, Milan, Italy,* [2]*Fondazione Human Technopole, Milan, Italy,* [3]*Fundazione Human Technopole, Milano, Italy,* [4]*Eurac Research, Bolzano, Italy,* [5]*University of Cambridge, Cambridge, United Kingdom.*

Background: Protein quantitative trait loci (pQTL) studies reveal numerous genetic variants regulating protein expression. These variants are unevenly distributed, forming hotspots in specific genomic regions, suggesting shared regulatory mechanisms for target proteins. Understanding the distribution of genetic variants is essential for deciphering genetic functions and regulatory pathways. This study aims to map genetic-variant hotspots and investigate signal clustering and functionality within these regions.

Material and Methods: We used the results of a genome-wide pQTL study of 7289 proteins, meta-analyzing data from the INTERVAL (9657 samples) and Cooperative Health Research in South Tyrol (CHRIS) study (4225 samples) cohorts. A custom pipeline was developed to characterize signal densities across chromosomes spatially. We performed a colocalization analysis on

the identified hotspots. The results for each region are represented in a network where protein pairs are connected if any of their significant genome-wide signals colocalize. Community detection network algorithms partitioned these hotspots into distinct protein modules, potentially associated with shared regulatory mechanisms. Enrichment analysis was used to characterise the community's functionality and differences.

Results: Our study identified 22 highly pleiotropic genomic hotspots accounting for 68% of trans signals alongside 16% of our cis signals. Many corresponded to known loci, such as ABO, while others were novel. Functional studies of less-characterized, highly dense loci provided insights into their biological roles.

Conclusion: We provide a framework for identifying genomic regions that influence the expression of multiple proteins, offering new insights into the different potential roles of hotspots in regulating protein expression.

P18.030.B Genome-wide association study of *Staphylococcus aureus* nasal carriage identifies genetic loci linked to cardiometabolic traits

Khoa Manh Dinh[1,2], *Lotte Aas Hindhede*[2], *Maiken Astrup Madsen*[2], *Joseph Dowsett*[1], *Maria Didriksen*[1], *Andrew Schork*[3,4], *Erik Sørensen*[1], *Ole Birger Pedersen*[5], *Ingileif Jonsdottír*[6], *Karí Stefansson*[6], *Lise Tornvig Erikstrup*[7], *Sisse Rye Ostrowski*[1,8], *Christian Erikstrup*[2]

[1]*Department of Clinical Immunology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark,* [2]*Department of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark,* [3]*Institute for Biological Psychiatry, Mental Health Center - Sct Hans, Copenhagen University Hospital, Copenhagen, Denmark,* [4]*Section for Geogenetics, GLOBE Institute, Faculty of Health and Medical Science, Copenhagen, Denmark,* [5]*Department of Clinical Immunology, Zealand University Hospital, Køge, Denmark,* [6]*deCODE genetics, Amgen Inc., Reykjavik, Iceland,* [7]*Department of Clinical Microbiology, Aarhus University Hospital, Aarhus, Denmark,* [8]*Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.*

Background: *Staphylococcus aureus* is a leading cause of bacterial infection-related deaths globally. Nasal carriage with *S. aureus*, found in 30–40% of the population, is typically asymptomatic but increases infection risk. The transition from harmless colonisation to invasive infection is poorly understood and likely influenced by host factors. This study aimed to identify new genetic variants associated with nasal carriage and infection risk.

Material and Methods: Genotype data from 135,000 individuals in the Danish Blood Donor Study (DBDS) were available. A subset was classified as *S. aureus* carriers or non-carriers based on a single swab ($n = 8{,}324$), while swabs on two occasions further differentiated carriers into persistent and intermittent carriers ($n = 3{,}024$).

Results: Combined-sex GWAS on nasal carriage using REGENIE identified the lead SNP rs78440534 (beta = 0.19, $P = 0.94 \times 10^{-8}$) within *IRF8* and the sex-specific GWAS revealed targets in *CCDC85A* (rs1522687, beta = 0.24, $P = 8.92 \times 10^{-8}$) in men and *HLA-DPA1* (rs3128952, beta = 0.31, $P = 4.67 \times 10^{-7}$) in women. A *KRAS* variant (rs11047908, beta = −0.64, $P = 8.12 \times 10^{-8}$) was associated with persistent carriage and a *DSCAM* variant was associated with intermittent carriage (rs1888497, beta = 0.64, $P = 3.25 \times 10^{-8}$). These variant have previously been linked to white blood cell components (rs78440534), body mass index (rs1522687), bone density (rs3128952) and to body fat and reproductive hormone concentrations (rs11047908 and rs1888497).

Conclusion: This largest GWAS on *S. aureus* nasal carriage revealed novel genetic determinants differing by sex and carriage phenotype. Our ongoing research will replicate findings, perform meta-analysis, and explore genetic factors influencing the transition from carriage to infection using the DBDS, Copenhagen Hospital Biobank (>323,000 participants), and other international cohorts.

P18.031.A Decoding syncope: genetic loci linked to sleep, psychiatric disorders, cardiovascular and autonomic dysregulation

Francesca Minnai[1,2,3], *Hele Haapaniemi*[3], *Reyhane Egthedarian*[3], *FinnGen*[4], *Million Veteran Program*[4], *Estonian BioBank Research Team*[4], *DeCODE Genetics Research Group*[4], *Richa Saxena*[5,6,7], *Lea Urpa*[3], *Martin Broberg*[3], *Satu Strausz*[3], *Erik Abner*[8], *Hanna Maria Ollila*[3,5,9]

[1]*Institute for Biomedical Technologies-National Research Council, Segrate, Milan, Italy,* [2]*Department of Medical Biotechnology and Translational Medicine (BioMeTra), Università degli Studi di Milano, Milan, Italy,* [3]*Institute for Molecular Medicine Finland, FIMM, HiLIFE, University of Helsinki, Helsinki, Finland,* [45]*Broad Institute of Harvard and MIT and Center of Genomic Medicine, Massachusetts General Hospital, Boston, MA, USA,* [6]*Centre for Genomic Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA,* [7]*Department of Anesthesia, Critical Care and Pain Medicine, Massachusetts General Hospital, Boston, MA, USA,* [8]*Estonian Genome Center, Institute of Genomics, University of Tartu, Tartu, Estonia,* [9]*Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA.*

Background: Syncope and collapse (i.e. fainting) is a transient loss of consciousness, usually caused by reduced cerebral perfusion due to vasodilatation. Syncope is common, more frequent in females with a lifetime prevalence of 35% but the understanding of its genetic background remain incomplete.

Material and Methods: We performed a new genome-wide association study (GWAS) meta-analysis for syncope and collapse across four European cohorts (FinnGen, VA Million Veteran Program, Estonian BioBank, DeCODE Genetics), encompassing a total of 1,545,493 participants.

Results: We identified 75 genomic risk loci ($P < 5.0 \times 10^{-8}$), of which 57 were not previously reported, mapping near 487 different genes. The strongest association was observed on chromosome 2, with the lead intergenic variant rs12465214 ($P = 3.45 \times 10^{-75}$) near *ZNF804A*, the risk gene for schizophrenia, previously reported as implicated in syncope risk. New associations were discovered: e.g., a locus was identified near *PAX8* (rs62158163, $P = 6.88 \times 10^{-10}$), a gene involved in circadian rhythm and sleep duration. Functional analyses reported that several loci mapped to genes involved in sleep regulation (e.g., insomnia, nightmares, long sleep), psychiatric traits (e.g., mood instability, smoking, neuroticism), and autonomic dysregulation. Genetic correlation results also showed a shared genetic background between syncope and these traits. Stratified linkage disequilibrium score regression (sLDSC) also suggested which

brain regions and cell types may be implicated in syncope through genetic regulation mechanisms, revealing a multifaceted pathway underlying the genetic architecture of syncope.

Conclusion: This study highlights the previously reported complex genetic architecture of syncope, and reveals novel promising associations with sleep, psychiatric, and autonomic-related traits for further investigation.

P18.032.C GWAS of in infant and early childhood height identifies 179 loci and reveals three cluster with different biology

Nicolas Fragoso-Bargas[1], *Adina E. Lupu*[1], *Jonas H. Sundfjord*[1], *Roya Karimi*[1], *Pål R. Njølstad*[1,2], *Marc Vaudel*[1,3,4], *Stefan Johansson*[1,5]

[1]*Mohn Center for Diabetes Precision Medicine, Department of Clinical Science, University of Bergen, Bergen, Norway,* [2]*Children and Youth Clinic, Haukeland University Hospital, Bergen, Norway,* [3]*Computational Biology Unit, Department of Informatics, University of Bergen, Bergen, Norway,* [4]*Department of Genetics and Bioinformatics, Health Data and Digitalization, Norwegian Institute of Public Healt, Oslo, Norway,* [5]*Department of Medical Genetics, Haukeland University Hospital, Bergen, Norway.*

Background: We have limited knowledge on height genetics in childhood and its potential relationships with health outcomes. We characterized the genetics of height from birth to 8 years of age.

Material and Methods: GWAS was performed on height at 12 time points in the Norwegian MoBa study, with sample sizes ranging from 72473 (birth) to 27813 (8 years). Significant SNP effect sizes across time were subjected to hierarchical clustering and compared with self-recalled height at age 10 and adulthood UKBB GWAS. GLAD4U Enrichment analysis and genetic correlations were performed.

Results: We identified 179 independent SNPs across all time points and obtained three clusters: Cluster 1; contains SNPs with their strongest effects during infancy, Cluster 2; includes SNPs with strong effects from 1 to 8 years of age and weaker in adulthood. Cluster 3; consists of SNPs with constant effects starting from 1 year old, which increase in adulthood. Enrichment based on Clusters 1 and 2 SNPs showed traits related to glucose homeostasis. We identified 19 signals not associated with adult height. All belonged to clusters 1 and 2. Some of these SNPs were nearby genes such as *UBE2E* (rs822762) and *SELL*(rs6663862), related to type 2 diabetes, and *AKR1C1*(rs2904799), related to progesterone metabolism. Length at birth was genetically correlated ($p < 0.05$) with fasting insulin ($rg = -0.18$) and HOMA-IR ($rg = -0.19$). Height at 7 years was correlated ($rg = 0.12$) with T2D and preeclampsia ($rg = 0.18$).

Conclusion: We show that childhood height has a time dependent dynamic genetic basis and close links to metabolic related traits.

P18.033.D The refinement of the priority index pipeline reveals known ALS biological pathways and suggests novel drug targets

Ali Amin Al Olama[1], *Rebecca Harrison*[1], *Yuki Kuniyoshi*[1], *Siddharth Sethi*[1], *Iha Hiroyuki*[2], *Ikeda Daisuke*[2], *Harpreet Saini*[1]

[1]*Astex Pharmaceuticals (UK), Cambridge, United Kingdom,* [2]*Otsuka Pharmaceutical, Tokushima, Japan.*

Background: Previously, we adapted the priority index pipeline (Pi) by Fang et al. (2019) to identify potential genes associated with Amyotrophic Lateral Sclerosis (ALS). Our recent work involved refining the pipeline by optimizing input data, integrating genes from pathway enrichment analysis, and adjusting internal parameters to enhance its capabilities.

Material and Methods: A GWAS summary statistic exclusively from European samples [van Rheenen et al., 2021] and top genes identified through an enrichment pathway analysis using Pascal [Lamparter et al., 2016] were utilised to choose input variants for the pipeline. The prioritisation of genes involved integrating various predictors, including gene proximity, chromatin interactions, eQTL associations, ontology connections, and network associations through Fisher's combined meta-analysis. The combined p-values were recalibrated to create a Pi rating scale, ranging from 0 to 5.

Results: Initially, 1,382 variants meeting FDR adjusted $P <= 0.05$ criteria were picked from an ALS GWAS that exclusively utilised European samples. Pascal analysis using the GWAS summary statistics unveiled 320 ALS-related genes. A 50k bp gene region identified 21,152 variants after eliminating duplicates from the initial selection which are associated with 756 genes through proximity, chromatin interactions in brain cells, and their impact on spinal cord and brain cortex expression. Using the combined information, Pi pipeline produced a ranked list of 5,694 ALS-linked genes.

Conclusion: The top identified genes show enrichment in ALS-related pathways, particularly in autophagy. Optimizing input data using both GWAS and pathway information improved the ranking of established ALS genes and provided potential novel targets.

P18.034.A Biological age acceleration is more prevalent in men than in women at time of spontaneous intracerebral hemorrhage and ischemic stroke

Cristina Gallego Fabrega[1], *Joan Jimenez-Baldo*[2], *Natalia Cullell*[3], *Jara Cárcel Márquez*[1], *Elena Muiño*[1], *Laia Llucià-Carol*[1], *Jesus M. Martín-Campos*[1], *Laia Mariné Llorente*[1], *Paula Villatoro González*[1], *Paula Boldo*[1], *Ana Aguilera Simón*[4], *Pol Camps Renom*[4], *Luís Prats Sánchez*[4], *Joan Martí Fabregas*[4], *Jaume Roquer*[2], *Jordi Jiménez Conde*[2], *Israel Fernández Cadenas*[1]

[1]*Stroke Pharmacogenomics and Genetics Group. Institut de Recerca Sant Pau (IR SANT PAU), Barcelona, Spain, Barcelona, Spain,* [2]*Department of Neurology, Neurovascular Research Group, IMIM-Hospital del Mar, Barcelona, Spain, Barcelona, Spain,* [3]*Fundació per a Docencia i Recerca, Mútua Terrassa; Terrassa (Barcelona), Spain, Barcelona, Spain,* [4]*Department of Neurology, Hospital de la Santa Creu i Sant Pau. Institut de Recerca Sant Pau (IR SANT PAU), Barcelona, Spain.*

Background: Spontaneous intracerebral hemorrhage (ICH) occurs later in life in women compared to men. Although previous studies have demonstrated epigenetic age acceleration (EAA) differences in ischemic stroke (IS) patients - a measure of an individual's biological aging -it remains unknown whether this sex dimorphism also applies to ICH patients

Methods: We joined two ICH cohorts ($N = 200$, 45% women: 76.8 ± 13 years; 55% men: 67.9 ± 14 years). DNAm levels were obtained from whole blood samples using Illumina's EPIC array.

We evaluated three age-predictor clocks (Horvath, Hannum and Zhang.BLUP) and one health-status clock (Levine) and their respective EAA metrics including extrinsic EAA (EEAA) and intrinsic EAA (IEAA) measures. We compared aging measures between women and men, then performed an ICH-location stratification and interaction analysis followed by specificity analyses evaluating sex differences in non-stroke samples (N = 350) a new IS cohort (N = 657) and a sex-stroke phenotype interaction study.

Results: Women at time of ICH present lower EAA values than men (Horvath-EAA, p-value $= 1 \times 10^{-04}$; Hannum-EAA, p-value $= 8.1 \times 10^{-06}$; Zhang.BLUP-EAA, p-value $= 4.4 \times 10^{-04}$) as well as lower extrinsic IEAA values (Horvath-IEAA, p-value $= 3.1 \times 10^{-03}$; Hannum-IEAA, p-value $= 6.5 \times 10^{-04}$). We observed a sex-ICH location interaction (Zhang.BLUP-EAA, p-value $= 6.8 \times 10^{-02}$) apparently driven by differences in deep-ICH patients. Likewise, a sex-stroke phenotype interaction was observed, were non-ICH females have lower acceleration values (Hannum-EAA: −10,37) than non-ICH men (Hannum-EAA: −8,01), but the differences are smaller than in ICH cases (ICH-women Hannum-EAA: −9,26, ICH-men Hannum-EAA: −2,6)

Conclusion: Women show lower epigenetic age acceleration than men after ICH, driven by deep-ICH, with weaker but similar patterns in IS patients and non-stroke controls.

P18.035.B Genome of Europe pilot studies: stepping-stones towards a pan-European reference database

Anthony F. Herzig[1], *Astrid Vicente*[2,3], *Hugo Martiniano*[2,3], *Emmanuelle Genin*[1,4], *Helen Ray-Jones*[5], *Jeroen van Rooij*[5], *André Uitterlinden*[5], *The Genome of Europe Consortium*[6]

[1]*Inserm, Univ Brest, EFS, UMR 1078, GGB, Brest, France,* [2]*Instituto Nacional de Saúde Doutor Ricardo Jorge, Av Padre Cruz, Lisbon, Portugal,* [3]*Biosystems and Integrative Sciences Institute (BioISI), Faculdade de Ciências da Universidade de Lisboa, Lisbon, Portugal,* [4]*CHRU Brest, Brest, France,* [5]*Laboratory for Population Genomics, Erasmus MC, Rotterdam, Netherlands,* [6]

Background: Within the 1 million genomes (1+MG) initiative, a digital Europe (DEP)-funded project called the Genome of Europe (GoE) will collect whole-genome sequencing data from >100,000 European citizens across 51 contributing partners from 29 countries. GoE aims to improve and disseminate understanding of the genetic dimension to public health in Europe, through interactions with the European Rare Disease Research Alliance (ERDERA), the European Genomic Data Infrastructure (GDI), and the upcoming Personalised Cancer Medicine (PCM) Joint Action.

Methods: The GoE analyses will operate in a federated environment established by the GDI project, which raises technological and methodological challenges. Here we provide progress updates on the six use cases of GoE, following the beginning of the project in October 2024.

Results: To inform aggregation of individual-level data, we have begun pilot studies to determine methodology for describing population structure in independent datasets, through techniques such as federated principal-component analyses. Functionalities for variant frequency look-up tools have been evaluated, including assessment of the potential impact of heterogeneity in sequencing technology and bioinformatic pipelines. We also assess possible approaches for federated imputation algorithms and perspectives for generating polygenic (risk) score distributions, calibrated for ancestry. GoE will place particular attention on clinically-relevant variant frequencies in actionable-disease and pharmacogenetic genes. Structural variation, potentially of high impact, will also be investigated in GoE via long-read sequencing for >5,000 individuals.

Conclusion: Progress has begun to leverage the prospective >100,000 whole genome-sequences of GoE for public health genomics; with an outlined roadmap for alignment with other key European initiatives.

P18.036.C GWAS meta-analysis identifies five novel susceptibility loci for endometrial cancer

Dhanya Ramachandran[1], *Xuemin Wang*[2], *Triin Laisk*[3], *Ying Zheng*[1], *Daffodil M. Canson*[2], *Pik Fang Kho*[2], *Bianca Naumann*[2], *Carly J. Chapman*[2], *Kristine Bousset*[1], *Anna V. Krause*[1], *Peter Schürmann*[1], *Britta Wieland*[1], *Patricia Hanel*[1], *Fabienne Hülse*[1], *Norman Häfner*[4], *Ingo B. Runnebaum*[4], *Natalia Dubrowinskaja*[1], *Nurzhan Turmanov*[1], *Tatyana Yugay*[5], *Zura Berkutnova Yessimsiitova*[6], *Endometrial Cancer Association Consortium*[7], *Epidemiology of Endometrial Cancer Consortium*[7], *Amanda B. Spurdle*[2], *Yosef Yarden*[8], *Estonian Biobank Research Team*[7], *Reedik Mägi*[3], *Peter Hillemanns*[1], *Dylan M. Glubb*[2], *Thilo Dörk*[1], *Tracy A. O'Mara*[2]

[1]*Hannover Medical School, Hannover, Germany,* [2]*QIMR Berghofer Medical Research Institute, Brisbane, Australia,* [3]*University of Tartu, Tartu, Estonia,* [4]*Friedrich Schiller University Jena, Jena, Germany,* [5]*Rahat Clinics, Amaty, Kazakhstan,* [6]*al-Farabi Kazakh National University, Almaty, Kazakhstan,* [78]*Weizmann Institute of Science, Rehovot, Israel.*

Background: Endometrial cancer is the most common gynaecological cancer in developed countries. In addition to environmental risk factors, genetic predisposition contributes towards endometrial cancer development but is still incompletely defined.

Methods: Building on genome-wide association studies (GWAS) by the Endometrial Cancer Association Consortium, we conducted a GWAS meta-analysis of 17,278 endometrial cancer cases and 289,180 controls, incorporating biobank samples from the UK, Finland, Estonia and Japan.

Results: GWAS analysis identified five novel risk loci (3p25.2, 3q25.2, 6q22.31, 12q21.2, and 17q24.2). Corresponding gene-based analyses supported findings for three of the novel loci, at *NAV3* (12q21.2), *PPARG* (3p25.2), and *BPTF* (17q24.2), as well as two additional candidate risk regions at *ATF7IP2* (16p13.2-p13.13) and *RPP21* (6p22.1). Validation genotyping in further independent case-control series replicated the most significant locus at 12q21.2, and functional genomic data suggested *NAV3* as a candidate causal gene. Silencing *NAV3* in endometrial cell lines accelerated cell division and wound healing capacity whereas NAV3 over-expression reduced cell survival and increased cell death, indicating that NAV3 acts as a tumour suppressor in endometrial cells.

Conclusion: Our large study extends the number of genomic risk loci identified for endometrial carcinoma by one-third and proposes a novel role of *NAV3* in the aetiology of this common cancer.

P18.037.D Mitochondrial heteroplasmy is associated with disease manifestation in *LRRK2*-related Parkinson's disease

Theresa Lüth[1], *Susen Schaake*[1], *Björn-Hergen Laabs*[2], *Sebastian Sendel*[3], *Inke R. König*[2], *Amke Caliebe*[3], *Anne Grünewald*[1,4], *Hansi Weissensteiner*[5], *Christine Klein*[1], *Bradford Casey*[6], *Joanne Trinh*[1]

[1]*Institute of Neurogenetics, University of Lübeck, Lübeck, Germany,* [2]*Institute of Medical Biometry and Statistics, University of Lübeck, Lübeck, Germany,* [3]*Institute of Medical Informatics and Statistics, Kiel University and University Hospital Schleswig-Holstein, Kiel, Germany,* [4]*Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Esch-sur-Alzette, Luxembourg,* [5]*Institute of Genetic Epidemiology, Medical University of Innsbruck, Innsbruck, Austria,* [6]*The Michael J. Fox Foundation for Parkinson's Research, New York, NY, USA.*

Background: Mitochondrial heteroplasmy has been implicated in predicting disease status in monogenic *PRKN/PINK*-related Parkinson's disease (PD). While mitochondrial dysfunction and mitochondrial DNA (mtDNA) abnormalities have also been reported in *LRRK2*-associated PD (*LRRK2*-PD), the relationship between heteroplasmy and PD risk among *LRRK2* variant carries has not been thoroughly explored yet.

Methods: We assessed *LRRK2* variant carriers from our in-house cohort, which was complemented by the analysis of N = 2669 individuals from the Parkinson's Progression Markers Initiative. In total, we include N = 461 *LRRK2* variant carriers (affected: N = 230, unaffected: N = 231, pathogenic *LRRK2* variants: p.Gly2019Ser and Arg1441Gly). Blood-derived DNA underwent long-range PCR of the complete mitochondrial genome, followed by deep Nanopore long-read sequencing. Heteroplasmy was identified using *Mutserve2* variant caller. The association with affection status was assessed with a multiple logistic regression model, adjusting for age. The correlation between age and heteroplasmic variant load was assessed using the Spearman correlation.

Results: A higher mitochondrial heteroplasmic variant load was associated with PD affection status in *LRRK2* variant carriers ($\beta = 0.32$, $p = 0.005$). Notably, heteroplasmy correlated with age in affected carriers (rho = 0.16, $p = 0.016$) but not in unaffected carriers. As a future perspective, heteroplasmy in *LRRK2*-PD can be investigated utilizing the genetic data available within the Global Parkinson's genetic program.

Conclusion: Our findings reveal an accumulation of mtDNA heteroplasmy in affected *LRRK2* variant carriers. These results suggest that mitochondrial heteroplasmy could serve as a blood-based biomarker for predicting *LRRK2*-PD risk.

P18.038.A Sex-specific effects of prenatal alcohol exposure on DNA methylation and gene expression in human placenta

Karita Rämö[1], *Pauliina Auvinen*[1], *Essi Wallén*[1], *Hanna Kahila*[2], *Nina Kaminen-Ahola*[1]

[1]*Environmental Epigenetics Laboratory, Department of Medical and Clinical Genetics, Medicum, University of Helsinki, Helsinki, Finland,* [2]*Department of Obstetrics and Gynecology, Helsinki University Hospital and University of Helsinki, Helsinki, Finland.*

Background/Objectives: Prenatal alcohol exposure (PAE) is one of the most common causes of birth defects and some of the PAE-associated phenotypes are known to be sex-specific. However, the molecular mechanisms causing these differences are still largely unknown. Here, for the first time, we study the sex-specific effects of PAE on genome-wide DNA methylation (DNAm) and gene expression in human placenta.

Methods: We studied placental samples from our epiFASD cohort of PAE (n = 87), smoking-exposed (n = 11), and control newborns (n = 77). Genome-wide DNAm analyses were performed with Infinium MethylationEPIC microarray (Illumina). Data was normalized with InterpolatedXY method, which normalizes both autosomal and sex chromosome probes without introducing artificial sex bias to the data, cell-type adjusted with CIBERSORT method, and analyzed with limma R package. Gene expression was studied with 3'mRNA sequencing and analyzed with DESeq2 R package. We also analyzed differentially methylated regions and conducted pathways analyses.

Results: PAE-associated DNAm changes were highly sex-specific, and many genes with DNAm changes are linked to PAE phenotypes and have developmentally important functions. Our results revealed male-specific hypomethylation in TACR3, our previously identified PAE candidate gene. Interestingly, we found more PAE-associated placental gene expression changes in males (201 genes with FDR < 0.05) compared to females (23 genes with FDR < 0.05).

Conclusion: We discovered clear and highly interesting sex-specific differences in DNA methylation and gene expression, which should be considered in future studies of PAE. Furthermore, these findings help to define the etiology of sex-specific phenotypes of PAE.

P18.040.C Unravelling the shared genetics and biological mechanisms of ADHD and obesity

Sufyan Suleman[1], *Trine Tollerup Nielsen*[1], *Asmat Ullah, Postdoc*[1,2], *Romane Julie Lunay*[1], *The GIANT Consortium*[3], *Psychiatric Genomics Consortium*[3], *Roelof A.J Smit*[4,2], *Ruth J.F Loos*[4,2], *Ditte Demontis*[1,2]

[1]*Department of Biomedicine, Aarhus University, Aarhus, Denmark,* [2]*The Novo Nordisk Foundation Center for Genomic Mechanisms of Disease, Broad Institute of MIT and Harvard, Cambridge, MA, USA,* [34]*The Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark.*

Background: Attention deficit hyperactivity disorder (ADHD) affects approximately 5% of children and 2.5% of adults, and is characterized by inattentiveness, impulsivity, and hyperactivity. Adults with ADHD have a 70% higher risk of developing obesity compared to individuals without ADHD, elevating cardiometabolic disease risk. This project aims to uncover the shared genetic architecture of ADHD and obesity through cross-disorder genome-wide analyses.

Material and Methods: We performed a large-scale cross-phenotype genome-wide association study (GWAS) of ADHD (38,691 individuals with ADHD and 186,843 controls) and body mass index (BMI) (N = 1.6M, serving as a proxy for obesity) in European population. Variants with concordant direction of effect on the two phenotypes were identified. The gene-based associations were calculated using MAGMA, and for genome-wide significant loci sets of credible variants were identified using

FINEMAP and linked to genes by integration with functional genomics data implemented in FLAMES. Subsequently, enrichment analyses were performed to identify affected tissues, brain developmental stages and cell types. Identified concordant variants will be used as basis for ADHD-BMI polygenic score (PGS) analyses in UK Biobank testing for phenome-wide association analyses.

Results: Preliminary findings revealed 206 genome-wide significant loci with a posterior probability of both phenotypes contributing greater than 0.9, involving 612 genes. The evaluation of the ADHD-BMI PRS in UK Biobank and inferred shared biological causes of ADHD and obesity concordant variants will be presented during the conference.

Conclusion: This study offers a foundation for understanding shared biological pathways of ADHD and obesity and informing future research and risk assessment strategies.

P18.041.D Genetics of disease susceptibility and age of diagnosis for psychiatric disorders are surprisingly independent

Genona Maseras[1], *Florian Privé*[1], *Emil M. Pedersen*[1], *Fenfen Ge*[1], *Clara Albiñana*[2], *Liselotte V. Petersen*[1,3], *Esben Agerbo*[1,3], *Katherine Musliner*[4], *Oleguer Plana-Ripoll*[1,5], *Bjarni J. Vilhjálmsson*[1,6,7]

[1]*National Centre for Register-based Research, Department of Public Health, Aarhus University, Aarhus, Denmark,* [2]*Oxford University, Oxford, United Kingdom,* [3]*Lundbeck Foundation Initiative for Integrative Psychiatric Research (iPSYCH), Aarhus University, Aarhus, Denmark,* [4]*Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,* [5]*Department of Clinical Epidemiology, Aarhus University and Aarhus University Hospital, Denmark, Aarhus, Denmark,* [6]*Bioinformatics Research Centre, Department of Molecular Biology and Genetics, Aarhus University, Aarhus, Denmark,* [7]*Novo Nordisk Foundation Center for Genomics Mechanisms of Diseases, the Broad Institute of MIT and Harvard, Cambridge, MA, USA.*

Background: Early onset of psychiatric disorders is linked to increased clinical severity and poorer outcomes. However, the strength of this association and the extent driven by genetics is poorly understood. Most genome-wide association studies (GWAS) have prioritized understanding disease susceptibility, ignoring age-at-diagnosis (AAD) information, or including it as a covariate despite evidence that it is heritable. This study examines the genetics of AAD and whether early diagnosis reflects higher genetic burden.

Material and Methods: Using iPSYCH data, we conducted GWAS for case-control status and AAD for ADHD, autism spectrum disorder (ASD), schizophrenia (SCZ), and major depressive disorder (MDD). LD Score Regression was used to estimate heritabilities for AAD and disease susceptibility, and their genetic correlations. We validated theoretical expectations by simulating AAD and case-control status under time-to-event models.

Results: We found that heritability of AAD is disorder-specific, with estimates of 0.15 (0.02) for ADHD, 0.11 (0.02) for ASD, and 0.03 (0.01) for MDD. We also identified two genome-wide significant variants for AAD of ADHD and one for AAD of SCZ. We estimated the genetic correlations between AAD and disease susceptibility, and found them to be surprisingly close to zero, in particular for ADHD, −0.014 (0.059), and ASD −0.139 (0.095).

Conclusion: AAD is a critical yet often overlooked trait in psychiatric genetics. Time-to-event GWAS approaches can improve understanding of genetic influences across the course of disease but require validation. Our findings suggest that genetic factors influencing disease onset may differ from those driving susceptibility, implying distinct genetic subtypes based on early versus late onset.

Buitelaar*[6,7,8], *C. F. Beckmann*[6,7,9], *T. Charman*[10], *EU–AIMS/AIMS-2-Trials LEAP group, D. G. Murphy*[11,12], *R. Delorme*[2], *E. Loth*[11,12], *T. Bourgeron*[1];

[1]*Human Genetics and Cognitive Functions, Institut Pasteur, UMR3571 CNRS, Université de Paris Cité, Paris, France,* [2]*Department of Child and Adolescent Psychiatry, Hôpital Robert Debré, APHP, Paris, France,* [3]*Department of Genetics, Hôpital Robert Debré, APHP, Paris, France,* [4]*Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom,* [5]*Department of Child and Adolescent Psychiatry, University Hospital, Goethe University, Frankfurt, Germany,* [6]*Donders Institute for Brain, Cognition, and Behavior, Radboud University Nijmegen, Nijmegen, Netherlands,* [7]*Department for Cognitive Neuroscience, Radboud University Medical Center, Nijmegen, Netherlands,* [8]*Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands,* [9]*Wellcome Centre for Integrative Neuroimaging, University of Oxford, Oxford, United Kingdom,* [10]*Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom,* [11]*Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom,* [12]*Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: We present a new resource for autism research combining quantitative phenotypic data, whole-genome sequencing (WGS), and brain structural and functional data (MRI, EEG). Participants include autistic individuals with or without intellectual developmental disability (IDD), relatives and typically developed (TD) individuals from the EUAIMS/AIMS2-Trials-LEAP and InovAND cohorts.

Material and Methods: Among 5,198 participants (39.23% females, mean age 18.56), 2,025 had a diagnosis of autism (>70% without IDD), 67 had a diagnosis of IDD, 1,803 are non-autistic relatives, and 1,303 are TD. WGS data is available for 2,720 individuals: 840 with autism, 37 with IDD, 1,118 non-autistic relatives, and 592 TD. For a subset of 346 individuals (172 autistic, 158 non-autistic) data across all modalities is available (WGS, MRI, EEG, clinical).

Results: Using IQ, the short sensory profile, and Vineland II data, autistic and non-autistic individuals were stratified into six clusters: Cluster 1 includes 75% of TD individuals, Cluster 2 and 3 includes autistic individuals with IDD. Cluster 2 is enriched in de novo variants falling in High Confidence NDD genes and in low polygenic scores for intelligence. Clusters 3, 4 and 5 contain individuals with high polygenic scores for autism. Cluster 3 shows an increased temporal cortex thickness. Interestingly, Cluster 6, including individuals with high intensity of sensory problems, does not show a specific genetic and brain profile.

Conclusion: This resource supports researchers integrating multiscale data to explore links between genetic variations, brain

anatomy/function, and autism's phenotypic diversity. A webpage will share project details and results obtained with this resource.

P18.043.B Central role of glycosylation processes in human genetic susceptibility to SARS-CoV-2 infections with Omicron variants

Frank Geller[1], *Xiaoping Wu*[1], *Vilma Lammi*[2], *Erik Abner*[3], *Jesse Valliere*[4], *Katerina Nastou*[1], *Ole Pedersen*[5], *Jacqueline Lane*[4], *Ria Lassaunière*[1], *Hanna Ollila*[6], *Sisse Ostrowski*[7], *Bjarke Feenstra*[1]

[1]*Statens Serum Institut, Copenhagen, Denmark,* [2]*University of Helsinki, University of Helsinki, Finland,* [3]*University of Tartu, Institute of Genomics, Tartu, Estonia,* [4]*Massachusetts General Hospital, Boston, MA, USA,* [5]*Zealand University Hospital, Køge, Denmark,* [6]*University of Helsinki, Helsinki, Finland,* [7]*Copenhagen University Hospital, Copenhagen, Denmark.*

Background: The genetics of SARS-CoV-2 infection has been investigated by the Host Genetics Initiative in about 220,000 cases diagnosed before the predominance of the Omicron variant in late 2021. We performed a genome-wide association study of SARS-CoV-2 infection with Omicron variants including more than 150,000 cases and more than 550,000 controls with no known SARS-CoV-2 infection from four cohorts.

Material and Methods: Cases of SARS-CoV-2 infection with Omicron and controls were identified from electronic health records in Denmark, Finland, Estonia and the US.

Results: We identified 13 genome-wide significant loci, of which only five were previously described as associated with SARS-CoV-2 infection. The strongest signal was a SNP intronic of *ST6GAL1*, a gene affecting immune development and function, and connected to three other associated loci (harboring *MUC1*, *MUC5AC* and *MUC16*) through O-glycan biosynthesis. We also found further evidence for an involvement of blood group systems in SARS-CoV-2 infection, as we observed association 1) for a different lead SNP at the *ABO* locus indicating a protective effect of blood group B against Omicron infection, 2) for the *FUT2* SNP tagging secretor status also reported for SARS-CoV-2 infection with earlier variants, and 3) for the strongest protein quantitative trait locus for *FUT3* (Lewis gene).

Conclusion: Our study shows that the human genetic architecture of SARS-CoV-2 infection is under constant development. The results provide robust evidence for individual genetic variation related to glycosylation translating into susceptibility to SARS-CoV-2 infections with Omicron variants.

P18.044.C Investigating the use of Lysosomal PRS to estimate Parkinson's Disease risk

Paola Dimartino[1], *Amabel Tenghe*[2], *Ashwin AK Sreelatha*[2], *Luis G. González Ricardo*[2], *Enza Maria Valente*[1,3], *Manu Sharma*[2], *COURAGE-PD Consortium*[4]

[1]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [2]*Centre for Genetic Epidemiology, Institute for Clinical Epidemiology and Applied Biometry, University of Tübingen, Tübingen, Germany,* [3]*IRCCS Mondino Foundation, Pavia, Italy,* [4]

Background: Parkinson's disease (PD) is a complex disorder resulting from the interplay of environmental and genetic factors. As only 5–10% of cases can be explained by monogenic forms, a polygenic additive effect has been proposed to explain the missing heritability. Considering that several PD genes are involved in the dysregulation of lysosomal clearance (i.e., LRRK2, VPS35 and GBA1), promoting pathological alpha-synuclein aggregation, we constructed a lysosomal pathway PRS to establish its contribution on PD risk.

Material and Methods: Using the latest European PD-GWAS summary statistics, we extracted all SNPs encompassing a manually curated list of lysosomal pathway genes. Lysosomal-PRS were created for the European COURAGE-PD cohorts not included in the base dataset exploiting PRSice and PRSet, using our largest cohort for model's training. A meta-analysis of all cohorts was performed using metafor.

Results: We selected a total of 980 lysosomal genes after querying KEGG, Gene Ontology and GSEA databases and extracted 367.626 SNPs from the PD-GWAS summary statistics. After performing individual-cohort QC following our established pipeline, we carried out the analysis on 23 European sites (average N = 649). Our training set comprised 2739 individuals (PD = 51%). PRSice C+T was used to select the best model fitting the training set, obtaining 58 significant SNPs (model p-val: 3.16E-20). Using this model, we obtained 4% improvement in correctly classifying patients with PD (PRS model: AUC = 0.68; null model: AUC = 0.64).

Conclusion: Our study highlighted lysosomal-PRS showed better predictive power for PD.

P18.045.D Whole-genome sequence analysis of 450'000 individuals across diverse populations identifies new rare and low-frequency colorectal cancer risk variants

Aurélie Kamoun[1], *Liza Darrous*[1], *Simon Leyss*[1], *Gareth Hawkes*[2], *Robin Beaumont*[2], *Harry Wright*[2], *Michael Weedon*[2], *Lauric Ferrat*[1], *Timothy Frayling*[1]

[1]*University of Geneva, Geneva, Switzerland,* [2]*University of Exeter, Exeter, United Kingdom.*

Background: Genome-wide association studies have primarily identified common variants with small effects. To uncover rarer variants with larger effects on colorectal cancer (CRC) risk, where excess adiposity has a strong causal role, we meta-analysed 70 million variants, in 450'000 individuals with whole-genome sequencing (WGS) data from All of Us (AOU) and UK Biobank (UKB).

Material and Methods: We performed extensive QC at the sample, variant, and genotype levels. We selected cases using either a strict (N = 11'402) or a broad (N = 37'110) definition, the latter including benign tumours, and kept as controls all participants with no history of cancer (N = 409'937). The selection was based on available ICD9/10 and SNOMED codes for AOU, and ICD9/10, READ2 and CTV3 codes for UKB. We validated our phenotype definitions using polygenic risk scores. Pan-ancestry analyses in AOU were conducted using REGENIE, adjusting for 16 population PCs. Additional analyses were run in UKB and AOU individuals with ≥80% predicted European ancestry, adjusting for 20 population PCs.

Results: From the broad case definition, we identified 27 variants at Bonferroni significance ($p < 7e\text{-}10$) with a MAF below 0.05 spanning 5 distance independent loci, including 24 novel risk variants for CRC, most of them in or near genes involved in the disease onset or progression (*ASXL1*, *EIF3H*, *TP53*, *CHRDL2*, *ARHGAP11A-SCG5*). The rarest variant (MAF = 0.0003) was identified in both pan-ancestry and European only analyses and reached an odd-ratio of 3.

Conclusion: Our findings highlight the potential of population-based WGS to identify rarer germline variations for colorectal cancer risk.

P18.046.A Cross-ancestry meta-GWAS identified novel loci and causal pathways for carotid intima media-thickness in over 157,261 participants

Devendra Meena[1], *Jingxian Huang*[1], *Jian Huang*[2], *Ioanna Tzoulaki*[1], *Abbas Dehghan*[1], *The Cohorts for Heart and Aging Research in Genomic Epidemiology (CHARGE)*[3], *The University College London Edinburgh Bristol (UCLEB)*[3], *The UK Biobank*[3]

[1]*Department of Epidemiology and Biostatistics, Imperial college London, London, United Kingdom,* [2]*Institute for Human Development and Potential, Agency for Science, Technology and Research (A*STAR), Connexis, Singapore,* [3]

Background: Atherosclerotic cardiovascular disease (CVD) remains the leading cause of morbidity and mortality, impacting over 523 million people worldwide. Carotid atherosclerosis, measured by carotid intima-media thickness (cIMT), is a strong predictor of future CVD events, including stroke. Genome-wide association studies (GWAS) have identified over 42 loci associated with cIMT, however, individuals from non-European populations remain underrepresented.

Material and Methods: We performed a large-scale cross-ancestry meta-GWAS of cIMT, encompassing up to 157,261 participants from five population groups of diverse ancestries: European, East Asian, African, admixed Latin Americans (Brazilian, and Hispanic). The meta-GWAS was performed using a fixed-effects inverse-variance-weighted model and meta-regression of multi-ethnic genetic association (MR-MEGA).

Results: Our analysis identified 61 loci, of which 33 are novel. Cross-ancestry fine-mapping identified 12 loci with less than five variants in 95% credible sets, highlighting potential causal variants. Mendelian randomisation suggested a potential causal association between cIMT and large artery stroke, but not for small-vessel stroke. Post-GWAS analyses, including transcriptome-wide association studies, further supported the GWAS findings by offering insights into the pathways underlying the identified loci. Finally, by integrating multi-omics data from publicly available datasets, we prioritized up to 20 plausible causal candidate genes and pathways involved in atherosclerosis, prioritizing genes and pathways for in vitro and in vivo validation. These findings may inform improved risk prediction and novel therapeutic strategies for atherosclerotic cardiovascular disease.

Conclusion: Our study is the first cross-ancestry GWAS for cIMT, paving the way for future efforts to identify cIMT loci in non-European populations.

P18.047.B Functional dissection of 15q15.1 GWAS risk variants implicates *CHST14* in endometrial cancer development

Dylan Glubb[1], *Bianca Naumann*[1], *Hollie Rowland*[1], *Carly Chapman*[1], *Jason Gertz*[2], *Tracy O'Mara*[1]

[1]*QIMR Berghofer, Brisbane, Australia,* [2]*University of Utah, Salt Lake City, UT, USA.*

Background: The largest published endometrial cancer GWAS identified a credible set of 47 risk variants located in non-coding regions at the 15q15.1 locus. Previously observed enrichment of endometrial cancer GWAS variation in enhancer/promoter chromatin loops suggests these variants exert their effects through related gene regulation.

Material and Methods: 15q15.1 risk variants were mapped to putative enhancers, and target promoters identified using H3K27Ac HiChIP chromatin looping analysis in Ishikawa endometrial cancer cells. CRISPR interference validated enhancer activity and target gene regulation. Reporter gene assays tested the effect of risk variants on promoter activity. Colony formation, growth in low attachment and sulfated glycosaminoglycan assays were performed in Ishikawa and SPEC2 endometrial cancer cells following gene knockdown using siRNA or LNA GapmeRs.

Results: We identified eight risk variants in five putative enhancers at 15q15.1. Enhancer/promoter looping data implicated 13 target genes with robust expression in endometrial cancer cells. CRISPR interference validated enhancer activity and identified four target genes, including CHST14 and PAK6. Risk alleles in an enhancer targeting CHST14 and PAK6 increased promoter activity by ~2-fold. Knockdown of CHST14, encoding the enzyme responsible for sulfating the glycosaminoglycan dermatan, impaired cancer cell phenotypes and reduced sulfated glycosaminoglycan levels in two cell lines.

Conclusion: These findings identify CHST14 as a novel endometrial cancer susceptibility gene that may mediate its effects through increased production of sulfated glycosaminoglycan, a key constituent of the extracellular matrix.

P18.048.C The common and rare facets of germline polygenicity converge through intercellular crosstalk in the tumor microenvironment of nasopharyngeal carcinoma

Xiaomeng Bai[1,2,3], *Yang Liu*[1], *Jin-Xin Bei*[1,4,5], ***Yanni Zeng***[1,2,3]

[1]*State Key Lab of Oncology in South China, Guangdong Key Lab of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Dept. of Experimental Research, SYSUCC - Zhongshan School of Medicine, SYSU, Guangzhou, China,* [2]*Faculty of Forensic Medicine, Guangdong Province Translational Forensic Medicine Engineering Technology Research Center, Guangzhou, China,* [3]*Guangdong Province Key Laboratory of Brain Function and Disease, Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, China,* [4]*Department of Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore,* [5]*Sun Yat-sen University Institute of Advanced Studies Hong Kong, Science Park, Hong Kong SAR, China.*

Background: Germline genetic variations contribute to risk of nasopharyngeal carcinoma (NPC). Tumor microenvironment (TME) plays a crucial role in tumorigenesis. However, whether NPC-risk-associated genes express span multiple types within TME and

whether cell types enriched for genetic associations interact with each other are largely unknown.

Material and Methods: We integrate the genetic association data concerning both common or rare variants for NPC (N = 9645) and transcriptomic data of NPC tumors tissues (single-cell RNA **sequencing**: N = 31, bulk RNA **sequencing**: N = 180, spatial transcriptome: N = 7), conducting single cell level genetic association and cell-cell interaction analysis to uncover the contribution of NPC genetic susceptibility to the intercellular communication within the TME.

Results: We find that common and rare genetic association in NPC are enriched in antigen-presenting cells and tumor epithelial/stromal cells, respectively. Notably, such cell types of strong genetic association also exhibit enhanced interactions and closer spatial proximity than the cell types depleted for genetic associations. In particular, strong crosstalk is detected between the cell type with the strongest common genetic association (Langerhans dendritic cells) and the cell type with the strongest rare genetic association (an epithelial cell subtype marked by HILPDA). Clinically, joint consideration of the tumor infiltration levels of the two genetically-associated and inter-connected subtypes substantially improves the prediction for NPC prognosis.

Conclusion: We bring together genetic associations of both common and rare variants with multi-OMIC data of tumors, uncovering significant crosstalk between genetic-association-enriched cell types within the NPC TME. Understanding the genetically-influenced TME interactions substantially improves the prediction of clinical prognosis.

P18.049.D Extracting longitudinal traits to uncover the genetic architecture of adolescent facial growth

Nina Claessens[1], *Seppe Goovaerts*[1], *Jay Devine*[1], *Damian JJ Farnell*[2], *Mary L. Marazita*[3], *John R. Shaffer*[3], *Mark D. Shriver*[4], *Noah Herrick*[3], *Susan Walsh*[5], *Seth M. Weinberg*[3], *Peter Claes*[1]

[1]*KU Leuven, Leuven, Belgium,* [2]*Cardiff University, Cardiff, United Kingdom,* [3]*University of Pittsburgh, Pittsburgh, PA, USA,* [4]*Pennsylvania State University, Pennsylvania, PA, USA,* [5]*Indiana University, Indianapolis, IN, USA.*

Background: During adolescence, complex changes in hard and soft tissues impact facial appearance. While cross-sectional datasets are typically used to model average facial growth, they cannot track individual growth trajectories, leaving the genetics of postnatal facial growth largely unexplored. This is crucial for orthodontics and craniofacial surgery, where variation in timing and growth rate can impact outcomes.

Material and methods: We extracted dense 3D facial landmarks from magnetic resonance images in the longitudinal ABCD study (N = 916) at ages 10, 12, and 14. To focus on growth rather than shape, we subtracted each individual's average face from their image at each timepoint. We then used functional principal component analysis to extract the principal trajectories of facial growth. Scores on these trajectories were used in a multivariate genome-wide association study. To boost genomic discovery, we leveraged pleiotropy with bone density and height at puberty onset using a conditional false discovery rate.

Results: The principal trajectories described both global and local changes and distinguished spatial (width versus lengthwise) and temporal (early versus late) growth differences. We identified two independent genomic loci (P < 5e-8) and 30 additional loci (5% FDR) by leveraging auxiliary traits. This includes one near *HMGA2*, a known growth-related gene, and another near *TTC5*, mutations in which cause global developmental delay and dysmorphic facial features.

Conclusion: We demonstrate how facial growth can be modeled from longitudinal imaging data and used to uncover genetic factors for facial growth. This work lays the foundation for future morphometric and genetic studies on individual facial growth.

P18.050.A rHDL Uncovers Tissue-Specific Pleiotropy Landscape in Plasma and Serum Proteomes

Ranran Zhai

Fudan University, Guangzhou, China.

Background: Pleiotropy, where a single genetic variant influences multiple traits, is key to understanding complex diseases. Yet, scalable methods to quantify pleiotropy across proteomic datasets remain limited.

Material and Methods: We introduce rHDL (reversed high-definition likelihood), a maximum likelihood framework that estimates SNP-level pleiotropy by modeling the joint distribution of genome-association summary statistics across thousands of proteins. We applied rHDL to harmonize summary statistics of 1,350 proteins from two large-scale studies: plasma proteins (N = 35,559) and serum proteins (N = 5,368). Both were measured using SomaScan.

Results: rHDL identified 154 and 114 independent pleiotropic SNPs ($P < 5e-8$) for the plasma and serum proteomes. Among them, only 11 SNPs were overlapped, some of which were established pleiotropic loci, such as *CFH* and *ABO*. While the pleiotropic loci of the plasma proteome were enriched for complement cascade, the serum pleiotropic loci were enriched for coagulation pathways, e.g., the *VTN* locus exhibited the strongest pleiotropy in serum ($P < 1e-300$, 140 associated proteins). These differences suggest tissue-specific genetic influences on protein expression and pleiotropy, even when the same proteomic technology was used.

Conclusion: rHDL offers a robust method for evaluating pleiotropy across proteomes. The method's scalability supports future applications to multi-omics data, prioritizing SNPs for functional interrogation. Our findings highlight the importance of considering tissue context in genetic studies and provide new insights into the genetic architecture of complex diseases.

P18.051.B The impact of genetics on different measures of metabolomic aging and common disease

Luke Jostins-Dean[1], *Mattia Cordioli*[2], *Sini Kerminen*[2], *Kirsten Schut*[2], *Peter Würtz*[2], *Antti Kangas*[2], *Jeffrey Barrett*[2]

[1]*Nightingale Health, Oxford, United Kingdom,* [2]*Nightingale Health, Helsinki, Finland.*

Background: We performed metabolomic profiling in a large biobank, and derived three metabolomic aging measures. We investigated their genetic determinants and interactions with genetic disease susceptibility.

Material and Methods: We measured 251 metabolomic parameters in UK Biobank blood samples using 1H-NMR and calculated three aging measures:

1. **Mortality Metabolomic Risk Age** indicates an individual's 10-year mortality risk. E.g. a risk age of 70 indicates the same predicted mortality as the average 70-year-old.
2. **Incident Disease Metabolomic Risk Age** reflects 10-year risk of 10 diseases with the largest loss of disability-adjusted life years.
3. **Metabolomic Clock Age** predicts chronological age from metabolomic parameters.

Models were trained on 245,009 and tested on 220,378 European ancestry individuals. GWAS was performed for 9.9M imputed variants using linear regression, adjusted for age, sex, and principal components. Interactions with polygenic risk scores (PGS) were assessed using Cox regression.

Results: Mortality and disease risk ages were highly correlated ($r = 0.906$) and moderately with clock age (r~0.45). Key metabolites for all scores included glycoprotein acetylation (an inflammation marker) and PUFA/MUFA ratio. Omega-3 was clock specific; LDL was disease/mortality specific.

241 loci were associated with metabolomic aging. 122 were shared across scores, including at *FADS2*, *HP* (haploglobin) and *APOE*. 76 were unique to mortality/disease, 9 to clock age. Mortality/disease ages showed negative interactions with diabetes and myocardial infarction PGS, indicating a weaker role for genetic risk in individuals with advanced metabolomic age.

Conclusion: Metabolomic profiling reveals shared and unique genetic drivers of healthy aging and modifies genetic disease risk.

Background: Studying endophenotypes of gut (dys)motility may represent an effective strategy to identify its genetic determinants and characterize molecular pathways relevant to irritable bowel syndrome (IBS) and other gastrointestinal disorders.

Material and Methods: We performed a multi-ancestry genome-wide association study (GWAS) meta-analysis of stool frequency (number of bowel movements per week) in 268,606 individuals of European (EUR) and East Asian (EAS) ancestry from six population-based cohorts. Heritability and genetic correlations with other traits were estimated, followed by Mendelian Randomization to identify causal relationships across these. Association signals were functionally annotated and fine mapped, to prioritize candidate genes/variants and corresponding causative mechanisms.

Results: EAS and EUR populations showed similar SNP heritability (5.6% and 7.0%, respectively) and genetic architecture ($r_g = 0.88$). Genetic correlations with gastrointestinal and psychiatric disorders were confirmed (r_g range 0.18–0.47), and novel correlations with multiple cardiovascular traits (r_g range 0.12–0.14) were detected and highlighted by computational analysis of drug signatures. Altogether, 21 independent GWAS signals were detected, 18 across ethnicities and 3 EUR-specific. Three loci were fine mapped to a single causative variant (PIP range 0.74–0.93), involving genes relevant to glia (*ZFHX4-AS1*), neuronal function (*XPR1*) and development (*SLC35F3*). Strong candidates in other loci include genes functionally linked to bile acid synthesis (*KLB*), cholinergic transmission (*COLQ*), and metabolic disorders (*FTO* and *CDKAL1*).

Conclusion: Multi-ancestry GWAS meta-analyses of stool frequency resulted in the discovery of candidate genes and molecular pathways relevant to the physiology of gut motility across ethnicities. Several of these offer actionable targets towards therapeutic exploitation in IBS and other dysmotility syndromes.

P18.054.A Impact of cell type-specific genetic variations in aortic distensibility

M. Chopra[1,2], *N. Hynes*[3,4], *C. Seoighe*[1,2];

[1]School of Mathematical and Statistical Sciences, University of Galway, Galway, Ireland, [2]SFI Centre for Research Training in Genomics Data Science, University of Galway, Galway, Ireland, [3]CORRIB-CURAM-Vascular Group, University of Galway, Galway, Ireland, [4]Western Vascular Institute, Galway Clinic, Galway, Ireland

Background: Aortic distensibility is the ability of arteries to expand with pulse pressure induced by the cardiac cycle, and it often diminishes with age. Previous GWA studies have identified SNPs linked to distensibility. Despite the established genetic associations, the mechanisms driving changes in distensibility remain unclear. This study aims to illuminate factors influencing distensibility using existing gene expression data, focusing on age-related changes in aortic cellular composition, alongside associated genetic variations and cell type-specific gene expression (CT-GE).

Methods: We applied a deep-learning model to segment 62,497 CMRI images from UKBB and calculated aortic distensibility. GWA was conducted on 56,765 participants using BOLT-LMM. We utilized CIBERSORTx to perform GE deconvolution on 432 GTEx participants with aortic GE data, analyzing changes in cell composition and CT-GE associated with age and GWA hits.

Results: Distensibility was calculated for 56,765 subjects. None of the 33 independent SNPs across 12 loci from the GWA showed an association with inferred cellular proportions, following multiple test correction. Pericytes and Fibroblast-I proportions declined with age, whereas VSMC-II tended to increase. CT-GE analysis revealed associations of GWA SNPs with *SRR* gene expression in VSMC-I, VSMC-II, and Fibroblast-I cells and with expression of *CDH13* in VSMC-II.

Conclusion: This study contributes to understanding of variation in aortic distensibility associated with age and genotype. Examining variation in aortic distensibility through the lens of gene expression in the relevant tissue suggested that variation in the expression of *SRR* in VSMC-II and Fibroblast-I, and *CDH13* in VSMC-II could contribute to the observed genetic associations.

P18.055.B Novel rare variants underlying adiposity-related traits: A whole-genome sequence analysis of 745,000 individuals across diverse populations

Liza Darrous[1], *Lauric Aurélien Ferrat*[1], *Gareth Hawkes*[2], *Harry Wright*[2], *Robin Beaumont*[2], *Michael Weedon*[2], *Aurélie Kamoun*[1], *Timothy Frayling*[1]

[1]*University of Geneva, Geneva, Switzerland,* [2]*University of Exeter, Exeter, United Kingdom.*

Genome-wide association studies (GWAS) have largely uncovered common variants with modest effects on complex traits. To identify rarer variants with larger effects on adiposity-related traits (Body Mass Index, Waist-Hip Ratio adjusted for BMI, and Triglycerides), we examined 111 million variants observed in at least 20 of 745,000 individuals with whole-genome sequencing (WGS) data from the UK Biobank and All of Us studies, over 80% of which were rare ($0.001 > MAF > 0.0001$) or very rare ($MAF < 0.0001$).

In each study, we performed pan-ancestry analyses using an additive model in REGENIE, adjusting for 40 PCs in UK Biobank and 16 PCs in All of Us, and repeated analyses in individuals with ≥80% predicted European ancestry using 20 ancestry-specific PCs.

For BMI and WHRadjBMI, we discovered 2 and 3 independent rare or very rare variants respectively, at a conservative Bonferroni-corrected P-value (< 4.47–6.28e-10), after conditioning on variants from the largest published GWAS. For Triglycerides, we identified 7 such variants, of which 3 were located >500 kb from known variants.

Variants identified included those present in as few as 1 in 9,000 people. Examples included known and novel variants in or near INHBE and PLIN1 (WHRadjBMI), ASPSCR1 (BMI), and LIPE (Triglycerides), with effect sizes ranging from 0.13 to 0.78 standard deviations and consistent across pan-ancestry and European-only analyses.

Our findings highlight the role of rare variants in metabolic traits and demonstrate the growing potential of WGS in identifying rare, highly penetrant alleles, advancing our understanding of adiposity and lipid metabolism.

P18.057.D Novel insights into handling of trace elements in urine via large-scale genetic screening

Oleg Borisov[1], *Marie Sadler*[2,3,4], *Jean-Pierre Ghobril*[2], *Yong Li*[1], *Zulema Rodriguez-Hernandez*[1], *Maïwenn Perrais*[5,6], *Aurélien Thomas*[5,6], *Murielle Bochud*[2,3], *Zoltán Kutalik*[2,3,4], *Anna Köttgen*[1]

[1]*Institute of Genetic Epidemiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany,* [2]*University Center for General Medicine and Public Health (UNISANTE), Lausanne, Switzerland,* [3]*University of Lausanne, Lausanne, Switzerland,* [4]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [5]*Unit of Forensic Toxicology and Chemistry, University Centre of Legal Medicine Lausanne-Geneva, Geneva University Hospital and University of Geneva, Geneva, Switzerland,* [6]*Faculty Unit of Toxicology, University Centre of Legal Medicine Lausanne-Geneva, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland.*

Background: Trace elements (TEs) are vital for maintaining essential physiological functions but can also exhibit toxic effects. Previous genome-wide association studies (GWASs) have concentrated on genetic determinants of blood TE levels. Studies of the genetic architecture of urinary TE concentrations can provide complementary insights into TE regulation and metabolism, given the importance of the kidney in regulating TE levels.

Material and Methods: We measured 22 TEs by mass spectrometry (ICP-MS) from urine samples of up to 10142 individuals from three cohorts: GCKD ($N = 4870$), CoLaus ($N = 4541$), and SKIPOGH ($N = 731$). We performed a GWAS of every TE in each cohort ($N = 9.6$ million variants) and meta-analyzed the results using an inverse variance weighted method. We then employed genetic colocalization analysis and integrated published blood TE GWAS results to assess whether TE metabolism is driven by the same or distinct loci in urine and blood.

Results: Our meta-analysis identified four genome-wide significant loci ($p < 5e\text{-}8$) associated with urinary cadmium, selenium ($N = 2$), and chromium. Genetic variants associated with urinary cadmium at the XKR9/LACTB2 locus colocalized with blood cadmium levels ($PP.H4 = 0.68$), LACTB2 expression in blood ($PP.H4 = 0.7$, eQTLGen) and plasma LACT2B levels ($PP.H4 = 0.69$, UKB-PPP). We also discovered a novel association between urinary selenium and the INMT locus (encoding indolethylamine N-methyltransferase involved in selenium metabolism), not previously implicated in blood TE studies.

Conclusion: This first GWAS of 22 urinary TEs revealed shared and distinct genetic determinants of TE handling between blood and urine, highlighting the value of studying multiple biological biofluids to understand TE regulation in the human body.

P18.058.A The genomic structure of normal and maladaptive personality in the Genetics Links to Anxiety and Depression sample using improved linkage disequilibrium score regression

Johan Zvrskovec[1,2], *Rujia Wang*[1,2], *Jonathan R I Coleman*[1,2], *Thalia Eley*[1], *Raquel Iniesta*[1], *Gerome Breen*[1,2]

[1]*King's College London, London, United Kingdom,* [2]*UK National Institute for Health and Care Research (NIHR), London, United Kingdom.*

Background: Personality traits are dimensional phenotypic constructs correlating with most other behavioural traits. Typically, genetic correlations mirror phenotypic. The commensurability of personality across normal and maladaptive personality, frameworks employing different number of factors, and the genetic underpinnings of these, has been less investigated in larger samples.

Material and Methods: Subjects from the Genetic Links to Anxiety and Depression study and the United Kingdom National Institute of Health and Social Care Research BioResource were assessed for normal and extreme personality measurements using the HEXACO (N = 14,190) normal personality scale, the EPQ Neuroticism scale (N = 20,139), and the Personality PID-5 brief form (N = 20,144). Heritabilities and genetic correlations were obtained using an improved version of LD score regression (LDSR) and GCTA-GREML.

Results: The six HEXACO dimensions, 5 PID-5 factors, and EPQ Neuroticism had significant GCTA GREML heritabilities between 8–15%. Notable LDSR genetic correlations (rg) were seen for Honesty-Humility with Neuroticism [rg = −0.59 (0.3), p = 0.017] and Negative Affect [rg = −0.57 (0.26), p = 0.038]. Additionally, a strong genetic relationship between PTSD and extreme personality was seen. Personality dimensions where phenotypic and genetic correlations were consistent included Extraversion and Detachment, where for some other traits such as Openness and Psychoticism, genetic correlations did not reflect phenotypic.

Conclusion: Our findings highlight specific consistent and inconsistent relationships across phenotypic and genetic measurements for normal and maladaptive personality dimensions and psychiatric disorders, as well as the utility of a personality framework with six dimensions.

P18.059.B Whole exome analysis identifies genetic variants contributing to serological antibody responses against pathogens

Zhengyang Zhu, *Michael Inouye*

University of Cambridge, Cambridge, United Kingdom.

Background: Genetic factors influence immune responses to infections, but the underlying mechanisms remain poorly understood. This study investigates the genetic determinants of serological antibody responses and their broader phenotypic associations.

Material and Methods: Whole exome sequencing data from 7,192 individuals in the UK Biobank was analysed to identify genetic variants contributing to variability in antibody responses against common pathogens. Association testing, fine-mapping, and gene burden analyses were employed to uncover causal loci influencing immune responses. A phenome-wide association study (PheWAS) was then conducted to examine the broader phenotypic effects of these genetic risk alleles.

Results: The study identified 31 exonic variants significantly associated with antibody responses, including loci within the major histocompatibility complex (MHC) region. Fine-mapping refined these associations to 30 putative causal variants. The PheWAS revealed 304 significant associations between 25 genetic variants and 98 clinical traits, with colocalization analyses identifying 36 instances of shared genetic effects across different phenotypes. These findings suggest that infection-related genetic variants also influence susceptibility to non-communicable diseases, revealing pleiotropic effects.

Conclusion: These results highlight the complex interplay between genetics and immune responses, demonstrating the utility of exome sequencing in identifying functionally relevant genetic variants. The study advances our understanding of host-pathogen interactions and lays the foundation for future personalized strategies in infectious disease prevention and treatment.

Instituto de Investigación Sanitaria de Canarias, Las Palmas de Gran Canaria, Spain, [18]Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada.

Background. Acute respiratory distress syndrome (ARDS) is a severe inflammatory lung disorder, mainly caused by sepsis, with a hospital mortality rate of around 40%. ARDS pathogenesis involves complex genetic and environmental interactions. This study aimed to identify novel genetic variants associated with post-sepsis ARDS to better understand its underlying biological mechanisms.

Materials and Methods: We conducted genome-wide association studies (GWAS) in three independent cohorts from Spain, Germany and United Kingdom. We meta-analysed the results to generate the largest meta-GWAS of sepsis-associated ARDS to date comprising 716 sepsis-associated ARDS cases and 4,399 sepsis controls. Variant associations were declared statistically significant if they had a meta-analysis $p < 5 \times 10\text{-}8$. Bayesian fine-mapping and in-silico functional assessments were performed, along with rare variant collapsing analyses using whole exome sequencing (WES) data from a patient subset (260 cases and 537 controls). Validation of results was sought in data from 430 sepsis-associated ARDS cases and 1,398 controls with sepsis from two other independent studies.

Results: We identified a novel genome-wide significant association with post-sepsis ARDS ($p = 3.43 \times 10\text{-}8$) intergenic to *ANKRD31* and *HMGCR* and previously linked to lipid and cholesterol metabolism. While it did not reach nominal significance in the two additional validation cohorts, it had consistent direction of effects across all 5 studies. Gene-based rare exonic variant analysis results would also suggest the role of this locus on ARDS.

Conclusion: A common variant between *ANKRD31* and *HMGCR* is associated with post-sepsis ARDS risk, implicating lipid metabolism in ARDS pathophysiology. Validation in independent studies is needed.

P18.061.D Shared genetics across fibrotic traits

Johan Bundgaard[1,2], *Søren Rand*[1], *Ole B. Vesterager Pedersen*[3,4], *Erik Sørensen*[5], *Christian Erikstrup*[6], *Henning Bundgaard*[1,7], *Hildur M. Ægisdóttir*[8], *Ástrós Th. Skúladóttir*[9], *Anna Helgadóttir*[8], *Kari Stefansson*[8,10], *Sisse Rye Ostrowski*[11,4], *Jonas Ghouse*[6,12,1]

[1]Department of Cardiology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [2]Department of Clinical Biochemistry, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [3]Department of Clinical Immunology, Zealand University Hospital, Køge, Denmark, [4]Department of Clinical Medicine, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark, [5]Department of Clinical Immunology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark, [6]Department of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark, [7]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark, [8]deCODE genetics/Amgen, Inc., Reykjavik, Iceland, [9]deCODE genetics/Amgen, Inc., Reykjavik, Iceland, [10]Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland, [11]Department of Clinical Immunology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, [12]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark.

Background: Shared pathophysiologic features of fibrotic traits, irrespective of location-of-onset, have been suggested across various fibrotic traits. However, the degree and specificity of shared genetic underpinnings across fibrotic traits remain poorly understood.

Methods: We investigated the genetic architecture of 13 fibrotic traits, including both organ (e.g., cirrhosis, idiopathic pulmonary fibrosis, and myocardial fibrosis) and non-organ fibrotic traits (e.g., Dupuytren's contracture, trigger finger and Peyronie's disease). We conducted genome-wide meta-analyses for eight fibrotic traits and queried publicly available data for an additional five fibrotic traits. Global genetic correlations were assessed using Linkage Disequilibrium Score Regression, and locus-specific genetic overlap was evaluated through pairwise colocalization analyses.

Results: Across all 13 fibrotic traits, we identified 342 genome-wide significant variants, of which 108 were novel. The most significant risk variant was for Dupuytren's contracture in *WNT7B* (known rs28971325, MAF = 23%, $\beta = 0.85$, $P = 6.8 \times 10^{-1384}$). The strongest global genetic correlation was observed between carpal tunnel syndrome and trigger finger ($r_g = 0.59$, $P = 4.0 \times 10^{-78}$). Notably, four risk variants reached genome-wide significance across three or more fibrotic traits, including rs28971325 (posterior probability $4 = 0.99$), which was associated with Dupuytren's contracture, Peyronie's disease, and plantar fibromatosis, and rs11205303 near MTMR11/OTUD7B, which was implicated in carpal tunnel syndrome, Dupuytren's contracture, and Peyronie's disease.

Conclusion: Our findings demonstrate a shared genetic architecture across multiple fibrotic traits, revealing key overlapping biological pathways while also identifying distinct genetic signals for specific fibrotic conditions.

P18.062.A Glycemic vs. Erythrocytic Genetic Influences on HbA1c: Insights from an East Asian Cohort

Seogyun Jeong, *Sanghun Lee, Younggwang Kim, Myeongseog Woo*

Dankook University, youngin, Korea, Republic of.

Background: Glycated hemoglobin (HbA1c) is vital for diagnosing type 2 diabetes (T2D) and monitoring long-term glycemic control. Although previous genome-wide association studies (GWAS) have uncovered single nucleotide polymorphisms (SNPs) associated with HbA1c, the distinction between glycemic- and erythrocyte-driven genetic influences remains underexplored, particularly in East Asian populations.

Material and Methods: We retrieved 45 top-ranking SNPs associated with HbA1c from the Korean Genome and Epidemiology Study (KNIH PheWeb GWAS, N = 51,385). To characterize their mechanistic pathways, we performed linear regressions in a Korean cohort (N = 2,116), adjusting for principal components 1–10, sex, and age. Associations between these SNPs and three phenotypic domains—HbA1c levels, glycemic traits (e.g., fasting glucose), and erythrocytic traits (e.g., hemoglobin, hematocrit)—were tested. Variants were classified as "glycemic" or "erythrocytic" if they significantly overlapped ($P < 0.05$) with relevant traits in addition to HbA1c. SNPs with trait-specific (but not HbA1c) associations were categorized as candidate variants.

Results: Among 16 HbA1c-associated SNPs ($P < 0.05$), nine (e.g., rs1799884, rs340515) showed glycemic-related associations, while two (rs59616136, rs2305196) were linked to erythrocytic measures. We also discovered 11 glycemic and six erythrocytic candidate SNPs that did not coincide with HbA1c signals. Notably, certain erythrocytic variants may alter red blood cell dynamics, leading to HbA1c values that do not accurately represent glycemic status in some individuals.

Conclusion: By delineating glycemic- versus erythrocytic-based genetic influences, these findings highlight the need for genotype-informed interpretation of HbA1c, potentially refining T2D diagnosis and personalized diabetes care.

P18.063.B Genetic and Prognostic Insights from Deep Learning Segmentation of Carotid Lumen Diameter

Dennis Bontempi[1,2], *Sofia Ortin Vela*[1,2], *Bianca Mazini*[3], *Leah Böttger*[1,2], *Olga Trofimova*[1,2], *Sven Bergmann*[1,2,4]

[1]*University of Lausanne, Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [3]*Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland,* [4]*University of Cape Town, Cape Town, South Africa.*

Background: Carotid ultrasound is a non-invasive imaging modality widely used in clinical practice to assess vascular anatomy and function. A key application is measuring carotid Intima-Media Thickness (cIMT), an important marker of atherosclerotic burden in the common carotid arteries (CCAs). Emerging research indicates that increased cIMT may lead to a compensatory enlargement of the lumen diameter (cLD) in CCAs. However, the genetic determinants of cLD, its association with other cardiovascular traits, and its prognostic value remain unexplored.

Material and Methods: To investigate these questions, we trained a Deep Learning model to automatically segment the carotid artery from ultrasound images, enabling the extraction of cLD measurements in CCAs. We applied genome-wide association studies (GWAS) to examine the genetic basis of cLD and its relationship with cIMT using a cohort of 18 804 individuals from the UK Biobank. Furthermore, we investigated cLD's prognostic power by running a survival analysis to assess its association with cardiovascular events.

Results: We found that cLD and cIMT exhibit distinct heritability estimates, indicating different genetic and environmental influences. Additionally, we investigated the predictive power of cLD and cIMT and demonstrated that these image-derived phenotypes provide complementary prognostic information independent of demographics and cardiovascular risk factors.

Conclusion: The study highlights the distinct genetic architecture and prognostic significance of cLD and cIMT, suggesting their potential for improving cardiovascular risk stratification in clinical practice.

P18.064.C Genomic associations and mediation of serum 18-Oxocortisol levels at the KCNJ5 locus

Luisa Foco[1], *Stephanie Baron*[2], *Simon Travers*[2], *Eva König*[1], *Peter P. Pramstaller*[1], *Maria-Christina Zennaro*[3], *Cristian Pattaro*[1]

[1]*Institute for Biomedicine, Eurac Research, Bolzano, Italy,* [2]*Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Service de Physiologie, Paris, France, Paris, France,* [3]*Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Service de Génétique, Paris, France., Paris, France.*

Background: Steroid hormones generated by the adrenal cortex form an extensive and tightly regulated causal cascade. In general population studies, genomic investigations are challenged by low steroid concentration causing data censoring and asymmetry, and by joint regulatory mechanisms which may prevent assignment of identified loci to specific steroids. To establish a modelling framework facing these issues, we piloted an association study between 18-Oxocortisol, a hallmark of KCNJ5-related aldosterone-producing adenomas, and the KCNJ5 locus itself.

Material and Methods: We quantified 5 mineralocorticoids, 7 glucocorticoids and 1 androgen, representing the zona glomerulosa, fasciculata and reticularis in 3204 individuals from the Cooperative Health Research in South Tyrol (CHRIS) study through serum LC-MS/MS. We fit a Tobit regression on 18-Oxocortisol controlling for age, sex, age-sex interaction, sex hormone intake, corticosteroid drugs and anti-hypertensive drugs. Inverse-normally transformed residuals were tested for association with 15,027 HRC-imputed variants in KCNJ5±1 Mb ($\alpha = 7.4 \times 10^{-5}$). Sensitivity analysis was performed by additionally adjusting for: each steroid in turn; all glucocorticoids; all steroids.

Results: 18-Oxocortisol was associated with two independent variants. Top association at rs949101 ($p = 1.5 \times 10^{-7}$) was attenuated by all-steroid adjustment ($p = 3.9 \times 10^{-6}$) but not by all-glucocorticoid adjustment ($p = 4.8 \times 10^{-8}$). Adjustment for single steroids identified a ~30% association attenuation and loss of significance when adjusting for the mineralocorticoid 11-Deoxycorticosterone ($p = 1.75 \times 10^{-4}$).

Conclusion: While results might suggest interplay between mineralo- and glucocorticoid metabolism, the apparent mediation likely reflects progesterone metabolism, which regulates the balance between 11-Deoxycorticosterone and the whole glucocorticoid chain levels. Caution is recommended when blindly applying mediation models to unknown pathways.

P18.065.D Unraveling shared biological mechanisms of depression and Body Mass Index

Asmat Ullah[1,2], *Trine T. Nielsen*[3], *roelof A.J. Smit*[4], *Sufyan Suleman*[3], *The GIANT Consortium*[5], *The MDD Working Group of the Psychiatric GenomicsConsortium*[5], *Ruth J.F. Loos*[4], *Ditte Demontis*[3,2]

[1]*Aarhus University, Aarhus, Denmark,* [2]*The Novo Nordisk Foundation Center for Genomic Mechanisms of Disease, Broad Institute of MIT and Harvard, Cambridge, MA, USA,* [3]*Department of Biomedicine, Aarhus University, Aarhus, Denmark,* [4]*Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen University, Copenhagen, Denmark,* [5]

Background: Major Depressive disorder (MDD) and increased body mass index (BMI) are complex, highly polygenic, and interlinked phenotypes with a genetic correlation of 0.17. This study aims to elucidate the shared genetics and biological mechanisms of depression and increased BMI.

Methods and Results: We assessed whether BMI and psychiatric disorders share an underlying latent genetic factor using GenomicSEM. BMI, MDD, attention-deficit/hyperactivity disorder, and autism demonstrated positive loadings on the shared latent factor. Bivariate mixture modelling implemented in MiXeR revealed 9300 shared variants between BMI and MDD, 57% with concordant directions of effect. The to-date largest cross-disorder GWAS of MDD and BMI was performed, revealing 907 genome-wide significant loci with concordant directions of effect and a high posterior probability (> 0.9) of a contribution to the signal from both phenotypes. MAGMA property analysis identified a significant association of BMI-MDD risk genes with genes highly expressed in brain tissues. For concordant genome-wide significant loci sets of credible variants were integrated with functional genomics data in FLAMES to identify risk genes. This identified 582 potential shared risk genes, and analyses in Syngo, revealed an enrichment of these genes in postsynaptic regions. Risk genes were linked to cell types by estimating the single cell disease relevance score using single-cell RNA-seq data from brain derived cell types, which revealed that BMI-MDD genes are enriched in brain regions including cerebellar hemisphere, cerebellum etc.

Conclusion: There is substantial genetic overlap between MDD and BMI with shared cellular mechanisms in brain cells involved in each condition also individually.

P18.066.A Rare variant effects on cell type-specific gene expression in immune cells from 4978 UK Biobank participants

Eva Holtkamp[1,2], *Marcel Mück*[3], *Magnus Wahlberg*[3], *Brian Clarke*[3], *Julien Gagneur*[1,2], *Nicole Soranzo*[4,5], *Oliver Stegle*[3,6]

[1]*Technical University of Munich, Munich, Germany,* [2]*Helmholtz Center, Munich, Germany,* [3]*German Cancer Research Center (DKFZ), Heidelberg, Germany,* [4]*Human Technopole, Milan, Italy,* [5]*Wellcome Sanger Institut, Hinxton, United Kingdom,* [6]*European Molecular Biology Laboratory (EMBL), Heidelberg, Germany.*

Background: Recent population-based single-cell eQTL studies have elucidated how common genetic variation influences expression across immune cell types. Still, the effect of rare variants on gene expression and their link to clinical traits remains poorly understood due to the lack of suitable datasets. Here, we leverage recently generated scRNA-seq profiles of PBMCs from 4978 UK Biobank (UKB) participants—the largest dataset to date integrating single-cell expression across 28 cell types with matched whole-genome-sequencing (WGS) and comprehensive medical records—to map the impact of rare variants on gene expression across immune cell types.

Material and Methods: For 4978 UKB participants with available RNA-seq, we processed matched WGS data to extract rare variants covering the full pre-mature transcript, including UTRs not covered by WES. We adapt our DeepRVAT1 framework to aggregate rare variant effects into transcript-level impairment scores, integrating diverse functional annotations such as missense, loss of function, splicing, RNA-protein binding, and chromatin effects.

Results: We will investigate cell type-specific associations between gene expression and immune-related clinical phenotypes, focusing on genes previously implicated in these phenotypes through rare variant association studies. Second, we use transcript-level impairment scores to i) study how rare variants affect transcript abundance in *cis*, and ii) to find cell-type specific regulatory interactions in *trans* by linking increased impairment to altered target gene expression.

Conclusion: Leveraging matched scRNA-seq and WGS data at an unprecedented scale, this study will elucidate the impact of rare variants on transcript stability and gene regulatory interactions across human immune cell types.

P18.067.B Increased burden of rare variants in GWAS associated genes in familial multiple sclerosis

Aleksander Turk[1], *Aleš Maver*[1], *Peter Juvan*[1], *Jelena Drulović*[2], *Šarlota Mesaroš*[2], *Ivana Novaković*[3], *Nada S. Čizmarević*[4], *Smiljana Ristić*[5], *Ivana S. Matić*[4], *Borut Peterlin*[1]

[1]*Clinical Institute of Genomic Medicine, Ljubljana, Slovenia,* [2]*Clinic of Neurology, Belgrade, Serbia,* [3]*Institute of Human Geneitcs, Belgrade, Serbia,* [4]*Department of Medical Biology and Genetics, Rijeka, Croatia,* [5]*nadasc@medri.uniri.hr, Rijeka, Croatia.*

Background: Multiple sclerosis (MS) is an immune-mediated neurodegenerative disease affecting the central nervous system with many known genetic risk factors. Although genome-wide association studies (GWAS) have identified common genetic variants with small effects associated with MS, the role of rare variants with large effects in MS aetiology remains underexplored. We hypothesized that rare variants in MS-associated genes from GWAS studies (GWAS-associated genes) are more likely to contribute to familial MS (FMS) risk than to sporadic MS (SMS). Therefore, we aimed to assess the burden of rare, predicted pathogenic (RPP) variants in GWAS-associated genes in FMS and SMS patients compared to controls.

Material and Methods: Using a generalized linear model, rare genetic variants in 111 GWAS-associated genes were assessed in the whole-exome sequences of 87 FMS, 89 SMS and 3866 control cases.

Results: We demonstrate that RPP variants were significantly overrepresented in the FMS cohort whereas their frequency was not increased in the SMS cohort compared to controls (p-values 5.27×10^{-74} and 1.00, respectively). Six genes (*ALPK2, ANKRD55, INTS8, IQCB1, JADE2*, and *MALT1*) significantly contributed to the burden of RPP in the FMS group.

Conclusion: We conclude that rare variants in genes identified by GWAS might contribute to the genetic predisposition of familial MS patients.

P18.068.C Analysis of *TMEM109* rare genetic variation underlying cardiovascular diseases and traits among 500000 individuals in the UK Biobank

Xueyu Guo, *Silvia Paracchini, Samantha Pitt*

School of Medicine, University of St Andrews, St Andrews, Fife, United Kingdom.

Background: Calcium ion (Ca^{2+}) leakage from the sarcoplasmic reticulum is a known contributor to heart failure in cardiac muscle. Our recent study identified Mitsugumin 23 (MG23) as an intracellular Ca^{2+}-conducting ion channel that facilitates this leakage in cardiac cells[1]. Our functional data demonstrated that knocking out of MG23 in a pressure-overload mouse model protects against left ventricular hypertrophy and cardiac dysfunction, linking it to cardiovascular disease (CVD) progression[2]. This current study utilizes UK Biobank[3] data to investigate the impact of rare variants in *TMEM109*, which encodes MG23, on CVD related phenotypes, and to pinpoint candidate variants for further functional verification.

Material and Methods: We analyzed whole-exome sequencing and phenotypic data from nearly 500,000 UK Biobank participants. Rare damaging *TMEM109* variants (minor allele frequency < 5%) were assessed for associations with 25 curated CVD phenotypes[4], including binary traits (hypertension, heart failure) and continuous traits (systolic and diastolic blood pressure).

Results: Our analysis identified a statistically significant gene-based association with decreased diastolic blood pressure (DBP) ($p < 2E-03$), driven by a missense variant ($p < 5E-03$), after multiple-testing adjustments. The *TMEM109* heterozygous profile revealed two deleterious missense variants carried by two individuals with CVD and these variants are linked to multiple CVD phenotypes, as supported by our analysis and data from Genebass, a public association study database[5].

Conclusion: Rare missense variants in *TMEM109* are significantly associated with decreased DBP, suggesting their protective role in CVD progression. Together with our experimental observations, we suggest that MG23 is involved in regulation of cardiovascular function.

P18.069.D Metabolic pathways associated with alternative lengthening of telomeres and their therapeutic potential

Anilú Margarita Saucedo-Sariñana[1], *Isaac Armendáriz-Castillo*[2,3,4], *Jennyfer García-Cárdenas*[2], *Pamela Espinoza*[4], *Katherine Hidalgo-Fernández*[2], *Lizbeth Peña-Zúñiga*[2], *Ronie Martínez*[2], *Juan Moromenacho*[2], *Jhonatan Cruz-Varela*[5], *María Esperanza Cerdán*[3], *Andrés Herrera-Yela*[6], *Andrés López-Cortés*[7], *Santiago Guerrero*[2]

[1]*Universidad Autónoma de Guadalajara, Zapopan, Mexico,* [2]*Universidad Internacional de Ecuador, Quito, Ecuador,* [3]*Universidade da Coruña, Galicia, Spain,* [4]*Instituto Nacional de Investigación en Salud Pública, Quito, Ecuador,* [5]*Universidad Yachay Tech, Urcuqui, Ecuador,* [6]*Universidad Internacional SEK, Quito, Ecuador,* [7]*Universidad de Las Américas, Quito, Ecuador.*

Background: Telomeres are nucleoprotein complexes that protect the ends of eukaryotic chromosomes from degradation, recombination, and end to end fusion. In cancer, most tumors activate various telomere maintenance mechanisms that enable them to elongate their telomeres and achieve cellular immortality. Alternative Lengthening of Telomeres (ALT) is a telomerase-independent mechanism employed by several aggressive cancers to maintain telomere length, contributing to their malignancy and resistance to conventional therapies.

Material and Methods: ALT-related metabolites were identified by analyzing interactions between 120 ALT-associated proteins and 106 Pan-Cancer oncogenes. Data were obtained from the Human Metabolome Database and interactions were extracted using the xml2 package in RStudio. Enrichment analysis was performed on the Small Molecule Pathway Database (SMPDB), KEGG PATHWAY, and MetaboAnalyst 5.0 to identify metabolic and drug pathways. A joint pathway analysis integrated ALT-related genes and metabolites. Finally, Cytoscape v3.9.1 was used to construct a high-confidence protein-metabolite interaction network.

Results: 39 ALT-related proteins were found to interact with 42 different metabolites in our analysis. Additional networking analysis revealed a complex interaction between metabolites and ALT-related proteins, suggesting that Pan-Cancer oncogenes may have an impact on these pathways. Three metabolic pathways have been primarily related with the ALT mechanism: purine metabolism, cysteine and methionine metabolism, and nicotinate and nicotinamide metabolism. We prioritized FDA-approved drugs (azathioprine, thioguanine, and mercaptopurine) that could target ALT-positive tumors through purine metabolism.

Conclusion: This work provides a wide perspective of the metabolomic pathways associated with ALT and reveals potential therapeutic targets that require further experimental validation.

P18.070.A A Comparative Study of the Human Skin Microbiome in Korean and American Populations Using Public Metagenomic Data

Young Gwang Kim, *Seo Gyun Jeong, Sang Hun Lee, Myeong Seog Woo*

Dankook University, Yongin, Korea, Republic of.

Background: Ethnicity significantly influences the human skin microbiome, affecting immune responses and skin health. While environmental and lifestyle factors contribute to microbiome variation, genetic background also plays a key role. This study aims to analyze the skin microbiome differences between Korean and American populations using publicly available metagenomic data.

Material and Methods: We utilized publicly available metagenomic datasets from SRAdb, selecting studies on Korean and American populations. Metadata was retrieved using EDirect, and raw data was processed through SRA Toolkit for FASTQ conversion. QIIME2 (2023.09) was employed for quality control, denoising, taxonomic classification (Silva 138). Alpha diversity metrics were compared using the Wilcoxon test. Beta diversity was assessed using PERMANOVA to evaluate microbial community differences and determine statistical significance. Taxonomic composition at the phylum and genus levels was analyzed to identify ethnicity-associated microbial patterns.

Results: Korean samples exhibited significantly higher alpha diversity than American samples (Chao1, OTU, Faith PD, $p = 2.00e-16$; Shannon, $p = 9.10e-04$; Simpson, $p = 1.60e-02$). Beta diversity analysis (PERMANOVA, $p = 5.00e-02$) showed distinct clustering. At the phylum level, Koreans had lower *Actinobacteriota* ($p = 4.20e-05$) and *Firmicutes* ($p = 4.39e-30$) but higher *Proteobacteria* ($p = 2.51e-04$). At the genus level, *Cutibacterium* was more abundant in Koreans ($p = 2.24e-04$), while *Corynebacterium* ($p = 9.07e-36$), *Staphylococcus* ($p = 5.79e-08$), and *Streptococcus* ($p = 9.26e-20$) were lower.

Conclusion: These findings highlight the impact of ethnicity on skin microbiome composition and emphasize the need for diverse representation in microbiome research to improve dermatological and precision medicine applications.

P18.071.B Novel genetic variant regulating anti-spike IgG response to Covid-19 BNT162b2 vaccination

Alessandro Testori[1], *Antonella Mulas*[2], *Mara Marongiu*[2], *Monia Lobina*[2], *Mariagrazia Piras*[2], *SerGenCov Group*[3], *Alessandra Testa*[4], *Marcella Devoto*[5], *Anna Maristella Steri*[1], *Edoardo Fiorillo*[2]

[1]*IRGB - CNR, Monserrato (Cagliari), Italy,* [2]*IRGB - CNR, Lanusei (Nuoro), Italy,* [34]*IFC CNR, Reggio Calabria, Italy,* [5]*Department of Translational and Precision Medicine, Università Sapienza, Italy.*

Background: The heterogeneity of the immune response to COVID-19 vaccine is partially explained by host genetic factors. Studies have demonstrated that inter-individual differences in the HLA region may influence the production of antibodies following vaccination. Their level is the result of humoral and cellular immunity regulating the response to infection and protecting against severe outcomes.

Material and Methods: To elucidate the mechanisms underlying antibody response to Pfizer-BioNTech vaccine, we conducted a GWAS testing more than 8 million variants on anti-spike immunoglobulin G levels in an Italian cohort of 1,968 fully vaccinated subjects. Association was adjusted for sex, age, BMI, smoking habit, and time elapsed between vaccine administration and blood draw. Flow cytometry data[1] were used to perform colocalization analysis.

Results: We identified a novel signal in the *CMTM8* gene and confirmed major signals at the HLA locus near the *HLA-B* gene, at the significance threshold of 5×10^{-8}. The novel variant affects Anti-S IgG levels after vaccination and is an eQTL for the *CMTM8* gene in blood and in immune cells ($CD4^+$ T cells, $CD8^+$ T cells, macrophages, and monocytes). Colocalization at the *CMTM8* locus suggests a shared genetic mechanism between antibody production and the expression of the CD66b marker in myeloid-derived suppressor cells.

Conclusion: These findings confirm the role of genetic regulation in modulating response to Pfizer-BioNTech vaccine. Genetic studies in diverse cohorts are important to define the involvement of genetic loci, including those outside the HLA region, in controlling antibody production following vaccination.

P18.072.C Rett syndrome clinical variability: integrating MECP2 variant type, PRS and rare SNV/SV in additional genes

Heyran Huseynli[1,2], *Kristina Zguro*[1,2], *Giulia Brunelli*[2], *Simone Pesaresi*[2], *Elena Pasquinelli*[1,2], *Caterina Lo Rizzo*[1,2,3], *Roberto Canitano*[4], *Sabrina Buoni*[4], *Simone Furini*[5], *Romina D'aurizio*[6], *Susanna Croci*[1,2], *Margherita Baldassarri*[1,2,3], *Chiara Fallerini*[1,2], *Alessandra Renieri*[1,2,3]

[1]*Medical Genetics, University of Siena, Siena, Italy,* [2]*Med Biotech Hub and Competence Centre, Department of Medical Biotechnologies, University of Siena, Siena, Italy,* [3]*Genetica Medica, Azienda Ospedaliera Universitaria Senese, Siena, Italy,* [4]*Neuropsychiatric Unit, Azienda Ospedaliera Senese, Siena, Italy,* [5]*Department of Electrical, Electronic and Information Engineering "Guglielmo Marconi", University of Bologna, Bologna, Italy,* [6]*CTGLab, Institute of Informatics and Telematics (IIT), National Research Council (CNR), Via Moruzzi 1, 56124, Pisa, Italy.*

Background: Rett syndrome (RTT) is a neurodevelopmental disorder and a leading genetic cause of intellectual disability in females. While mutations in MECP2 are the primary cause, the huge clinical variability suggests additional genetic factors may contribute.

Material and Methods: A cohort of 245 RTT patients with known MECP2 mutations and balanced X inactivation in blood. Clinical severity assessed using the Clinical Severity Score (CSS). Polygenic Risk Scores (PRS) analyses performed for intelligence and epilepsy. Whole Exome Sequencing (WES) by NovaSeq6000 used to identify rare pathogenic variants other than MECP2. Long read- sequencing by Oxford Nanopore ongoing for adding clinical variability derived from structural variants.

Results: PRS analyses showed no significant contributions to epilepsy or cognitive severity alone. However, when integrated with MECP2 mutation type significant association with IQ < 40 become evident: early truncating versus missense (p. 0.0334) and early versus late truncating MECP2 variants (p.0.0063). Rare pathogenic/likely pathogenic variants were identified in 26% of patients, implicating genes associated with neurodegeneration, epilepsy, and scoliosis and work is ongoing for statistical integration.

Conclusion: The integration of PRS, MECP2 type of variants and rare SNV/SV in additional genes may contribute to new insights into RTT's genetic complexity and variability, advancing our understanding of the disorder.

P18.073.D Trans-Ancestry Genome-Wide Association Study Meta-Analysis Identifies CTNNA2 as a Novel Risk Locus for Recurrent Miscarriage

Yevheniya Sharhorodska[1,2,3], *Chiara Scapoli*[3], *Oleg-Roman Gnateyko*[1], *Danuta Zastavna*[1], *Halyna Makukh*[4], *Inga Prokopenko*[2]

[1]*Institute of Hereditary Pathology of National Academy of Medical Sciences of Ukraine, Lviv, Ukraine,* [2]*University of Surrey, Guildford, United Kingdom,* [3]*University of Ferrara, Ferrara, Italy,* [4]*Scientific Medical Genetic Center "LeoGENE", Lviv, Ukraine.*

Background: Recurrent Pregnancy Loss (RPL) affects ~5% of reproductive-age women and is defined as the loss of two or more pregnancies before 24 weeks of gestation. Approximately 50% of RPL cases remain idiopathic. The genetics of RPL remains poorly understood, given difficulties with RPL phenotype definition. We investigated genetic susceptibility of RPL using a trans-ancestry genome-wide association study (GWAS) meta-analysis.

Material and Methods: We conducted ancestry-specific GWAS of self-reported recurrent miscarriage in 15,337/136,258 individuals among cases with 2+miscarriages and controls with no miscarriages of European (discovery), African, White, South/North Asian, East Asian descent using BOLT-LMM on the UK Biobank (UKBB). We also used TOPMed-imputed LUCAR (Lviv Ukrainian Cohort for Advancing Reproductive Health) GWAS from Western Ukraine. LUCAR includes 350 women with clinically confirmed idiopathic RPL and 454 control women with at least one healthy child. The GWAS of six datasets (31,024 cases/272,974controls) were combined using trans-ancestry meta-regression within MR-MEGA software tool.

Results: We identified a genome-wide significant association at rs4852592-G (OR(95%CI) = 1.0018(0.976–1.029), *P-value* $= 3.52 \times 10^{-8}$) located near *CTNNA2* gene. The association signal is primarily driven by the largest European-ancestry subset of UKBB. However, we validated ($P < 0.05$) this association at

rs4852592 in the East Asian UKBB (*P-value* = 0.0042) and LUCAR (*P-value* = 0.031) studies.

Conclusion: Our study reveals novel RPL risk locus near CTNNA2 gene, which acts as a link between the cadherin adhesion receptors and the cytoskeleton in regulating cell-cell adhesion, foetal neurodevelopment. It is elevated in the endometrium during implantation, potentially increasing RPL risk, and is nominally associated with gestational age, making it putative biological target.

C.O.I. Disclosure:

P18.074.A Whole-Genome sequence analysis of 600,000 individuals across diverse populations identifies rare alleles with large effects on type 2 diabetes

Lauric Aurélien Ferrat[1], *Liza Darrous*[1], *Aurélie Kamoun*[1], *Harry Wright*[2], *Gareth Hawkes*[2], *Robin Beaumont*[2], *Michael Weedon*[2], *Timothy Frayling*[1]

[1]*University of Geneva, Geneva, Switzerland,* [2]*University of Exeter, Exeter, United Kingdom.*

Background: Genome-wide association studies of common phenotypes have primarily identified common variants with small effects.

Material and Methods: To uncover rarer variants with larger effects on type 2 diabetes, we analyzed 84 million variants, observed in at least 20 of 599,676 individuals with whole-genome sequencing data from the All of Us and UK Biobank studies. In each study, we used two definitions of type 2 diabetes, strict (n cases = 44,331), and broad (n cases = 73,598). The selection was based on available ICD9/10, SNOMED codes and Hba1c reading for AOU, and ICD9/10, READ2 and CTV3 codes for UKB, and self-reports for both. We performed pan-ancestry analyses using an additive model in REGENIE, adjusting for sex, age, age square, 40 PCs in UK Biobank and 16 PCs in All of Us.

Results: From the broad case definition, we identified 26 variants at Bonferroni significance ($p < 5.95 \times 10\text{-}10$) with a MAF below 0.05 spanning 8 distance independent loci. A variant at position chr20:44413714 had the smallest MAF and was present in less than 1 in 900 people. The odd ratios of the 26 variants ranged from 1.4 to 4.5. Thirteen variants were new and were all within 100 kb from known variants, and all in or near genes involved in the disease onset or progression (HNF-4, LINC02932, TCF7L2, TCF7L3).

Conclusion: Further studies are needed to assess independence of the variants from known signals, but our findings demonstrate the potential for detecting rare penetrant alleles both novel and previously known.

P18.075.B Genome-wide meta-analysis conducted in three large biobanks expands the genetic landscape of lumbar disc herniations

Ville Salo[1], *Juhani Maatta*[1], *Eeva Sliz*[1], *FinnGen*[2], *Ene Reimann*[3], *Reedik Mägi*[3], *Estonian Biobank research team*[2], *Kadri Reis*[3], *Abdelrahman G. Elhanas*[3], *Anu Reigo*[3], *Priit Palta*[3], *Esko Tonu*[3], *Jaro Karppinen*[1], *Johannes Kettunen*[1]

[1]*University of Oulu, Oulu, Finland,* [23]*University of Tartu, Tartu, Estonia.*

Background: Given that lumbar disc herniation (LDH) is a prevalent spinal condition that causes significant individual suffering and societal costs[1], the genetic basis of LDH has received relatively little research. Our aim was to increase understanding of the genetic factors influencing LDH.

Material and Methods: We performed a genome-wide association analysis (GWAS) of LDH (ICD-10:M51) in the FinnGen project and in Estonian and UK biobanks, followed by a genome-wide meta-analysis to combine the results. The meta-analysis comprised a total of 80 724 cases, and 748 975 controls. Sensitivity analyses were also conducted with more strict case definitions, by limiting LDH cases to the ones with radiculopathy (M51.1) and to those who have undergone surgery.

Results: In the meta-analysis, we identified 41 novel and replicated 23 known loci located more than 1 MB apart, each containing at least one variant associated with LDH at the genome level[2,3]. In sensitivity analysis, we also identified five novel loci associated with LDH-related surgical operations and replicated three previously associated loci.

Conclusion: The previously unreported LDH risk loci that we identified expand the understanding of the hereditary causes of LDH. While changes in disc-related structures and inflammation-related factors play a major role in the etiology of LDH, our results from multiple downstream analyses suggest that nervous system-related mechanisms may also be implicated. Overall, our research contributes to a deeper understanding of the genetic factors behind LDH, potentially paving the way for the development of new therapeutics and prevention methods for symptomatic LDH in the future.

P18.076.C Characterization of `eoPRED` a placental DNA methylation predictor of early-onset preeclampsia and maternal vascular malperfusion

Hannah J. Illing[1,2], *Linda M. Ernst*[3], *Alexa A. Freedman*[3,4], *Ella O. Beraldo*[1,2], *Lauren Keenan-Devlin*[3], *Ann E. Borders*[3,4], *Gregory E. Miller*[4], *Wendy P. Robinson*[1,2]

[1]*BC Children's Hospital Research Institute, Vancouver, BC, Canada,* [2]*University of British Columbia, Vancouver, BC, Canada,* [3]*Endeavor Health, Chicago, IL, USA,* [4]*Northwestern University, Evanston, IL, USA.*

Background: Abnormal placental pathology, particularly maternal vascular malperfusion (MVM), is associated with preeclampsia, fetal growth restriction, and adverse heart and brain development. The eoPRED tool is a DNAme-based method that estimates the similarity of a placental methylome to one of early-onset preeclampsia (EOPE, diagnosis<34 weeks). However, eoPRED has only been validated in several small datasets lacking pathology information. We hypothesized that eoPRED could quantitively assess placental pathology, therefore it could help identify factors contributing to placental dysfunction.

Material and Methods: We utilized Illumina EPICv1 DNAme data from placentas from the Stress Pregnancy and Health dataset (n = 493) with detailed pathology information (29% MVM), to assess associations between eoPRED score, pathology, and birth outcomes.

Results: The eoPRED score was higher in placentas from pregnancies affected by EOPE (n = 7) than LOPE (n = 42) p = 0.03) and no preeclampsia controls (n = 402, p < 0.01). In controls, eoPRED was negatively associated with gestational age (R = −0.18, p < 0.001), birth weight (R = −0.11, p = 0.03), and

placental efficiency ($R = -0.11$, $p = 0.03$). Furthermore, eoPRED correlated with the grade of MVM ($R = 0.34$, $p < 0.01$), but not other pathology findings. We identified 108 CpGs that were differentially methylated (FDR < 0.01, $|\Delta\beta|>0.05$) in association with high-grade MVM, including 8 CpGs in *TTTY14* on the Y chromosome.

Conclusion: eoPRED is correlated with EOPE, but also MVM pathology. Furthermore, eoPRED is associated with adverse pregnancy outcomes even in the absence of preeclampsia. This tool has utility for quantifying the pathophysiology of EOPE and other conditions associated with placental dysfunction and can be useful to assess in placental datasets where pathology information is unavailable.

Background: Prediabetes and type 2 diabetes (T2D) are characterized by insufficient insulin secretion and poor sensitivity, leading to complications and increased mortality. Genetic predisposition is known to play a role in these metabolic disorders. Not all individuals with prediabetes develop T2D, highlighting the importance of understanding the molecular mechanisms involved in this progression.

Material: To investigate these differences, we utilized genomics and plasma proteomics data from 450 individuals enrolled in the prediabetes lifestyle intervention study.

Results: Through differential protein expression analysis, we identified 225 out of 2523 proteins to be differentially expressed in 318 individuals with prediabetes compared to 88 individuals with T2D. Using a mixture model framework, we identified 65 shared protein quantitative trait loci (pQTL) effects suggesting overlapping genetic regulation of proteins. Further, we identified four differential pQTLs i.e., genetic variants with significant effect in only one condition, near genes coding for proteins SELE, ACP5, SCLY, and GYS1, showing significant positive effects on protein levels in prediabetes but not in T2D. These proteins were also found to be differentially expressed in prediabetes compared to T2D. Notably, knockout studies of SCLY in mice link it to glucose and lipid homeostasis, implicating pathways associated with fatty liver disease and glucose intolerance. Additionally, we identified 20 shared pQTLs with opposite effects between prediabetes and T2D, underscoring differences in genetic regulation between the two states.

Conclusion: Our study provides new insights into the molecular mechanisms underlying progression from prediabetes to T2D and a better understanding of the role of their genetic regulation.

Background: Cardiac conduction disorders (CDs) represent interrupted impulse conduction at the SA-node (sick sinus syndrome, SSS), AV-node/His-bundle (atrioventricular block, AVB), or ventricular branches (left/right bundle branch block, LBBB/RBBB). With a lifetime prevalence of ~20%, they frequently require pacemaker implantation and may signify more widespread myocardial fibrosis. There is limited knowledge on the pathophysiology of CD subphenotypes.

Methods: We meta-analyzed genome-wide association studies (GWASs) of SSS (21,055 cases), AVB (80,052 cases), LBBB (42,181 cases) and RBBB (34,305 cases) across seven datasets of European ancestry. Shared associations with other cardiac phenotypes were explored.

Results: We identified 163 associations (94 novel associations at 84 loci) across the four GWASs including AVB missense variants in the energy metabolism genes GFM1 and GMPR and the myopathy-linked MLIP and SUN1 genes. Variants at RNF207, BAG3, NKX2-5 and CCDC141 preferentially associated with high-degree AVB. Rare missense variants in A2ML1 and ion channel gene TRPM4 associated with LBBB and RBBB, respectively. RBBB variants were enriched in regulatory regions of GATA4/ESRRG pathways, known to be involved in cardiac hypertrophic response. We did not observe causal linear relationships of cardiomyopathies with CDs but there were multiple shared associations, including a previously unreported CD variant association with hypertrophic cardiomyopathy at CCDC141.

Conclusion: There is limited overlap between genetic backgrounds of different types of CDs. CDs have complex allele-specific relationships with cardiac remodeling phenotypes and GATA4/ESRRG-mediated hypertrophic response likely plays a role. The findings may aid in future therapeutic developments and individual risk assessment, e.g. for CD severity and cardiomyopathy.

P18.081.D Large-scale proteomics of CSF and plasma identifies biomarkers and provides insights into Parkinson's disease pathogenesis

Astros Thorarensen Skuladottir[1,2], *David Bäckström*[3], *Arni F. Gunnarsson*[1], *Florian Zink*[1], *Miles Trupp*[3], *Anders Öhman*[4], *Monica Holmberg*[5], *Lars Forsgren*[3], *Hreinn Stefansson*[1], *Kari Stefansson*[1]

Background: Parkinson's disease (PD) is a progressive neurodegenerative disorder with a long preclinical phase, where neuronal degeneration begins before motor symptoms appear. Its complexity has hindered biomarker discovery and therapy development. High-throughput proteomics enables fluid biomarker research, with cerebrospinal fluid (CSF) offering central nervous system (CNS)-specific insights. However, standardized CSF collection remains a challenge. DDC has emerged as a potential diagnostic biomarker, though drug effects remain uncertain. Additionally, integrating genomics with proteomics facilitates the identification of key players in PD pathogenesis.

Material and Methods: We measured protein levels in CSF from PD patients and neurologically healthy controls, as well as in plasma from population-based cohorts. Our analyses included a CSF pQTL analysis, meta-analyses of CSF and plasma proteomics comparing early-phase PD patients to controls, and longitudinal protein correlation analyses, using CSF and plasma samples collected over eight years to assess associations between protein levels, PD progression scores, and disease duration.

Results: We present evidence supporting HIP1R as a causal PD gene, likely contributing to pathogenesis by disrupted synaptic vesicle turnover revealed by decreased CSF protein levels. Furthermore, we confirm DDC as a potential diagnostic biomarker in CSF, with elevated levels in CSF, but not plasma, of drug-naïve patients. Finally, we identify integrins, including ITGAV, ITGAM, ITGA11, and ITGB2, as promising plasma biomarkers for neurodegeneration detection and progression.

Conclusion: Our large-scale approach reveals clinically relevant protein signatures, underscoring distinct PD diseases mechanisms in the CNS versus systemic compartments.

P18.082.A Longitudinal analysis of genetic and environmental interplay in human metabolic profiles and the implication for metabolic health

Alberto Zenere[1], *Jing Wang*[1], *Xingyue Wang*[1], *Göran Bergström*[2], *Fredrik Edfors*[3], *Mathias Uhlén*[3], *Wen Zhong*[1]

[1]*Linköping University, Linköping, Sweden,* [2]*Gothenburg University, Gothenburg, Sweden,* [3]*Royal Institute of Technology, Stockholm, Sweden.*

Background: Metabolites' levels are regulated by a complex interplay of genetic predispositions and environmental exposures. Understanding how genetics and environmental factors shape metabolic profiles is crucial for advancing metabolic health.

Material and Methods: Longitudinal data of 527 metabolites, measured during a 2-year wellness study involving 101 healthy participants, were integrated with paired whole-genome sequencing, proteomics, extensive clinical phenotyping and lifestyle questionnaires. GWAS and multivariate analyses were performed to evaluate the regulation of the human metabolome. Prediction models based on central nodes in the protein-metabolite network were trained to predict multiple metabolic diseases.

Results: Our findings highlighted a considerable role of genetics in regulating the human metabolome, identifying 22 plasma metabolites as genetically predetermined. Environmental factors such as seasonal variation, weight management, smoking, and stress also significantly influenced metabolite levels. We developed an integrative metabolite-protein network comprising 5,649 significant protein-metabolite pairs and identified 87 causal metabolite-protein associations under genetic regulation, validated in an independent cohort. Key proteins representing individual metabolic profiles were identified and validated in the UK Biobank, showing great potential for predicting metabolic diseases and metabolic risk assessment.

Conclusion: In this study, we provided a comprehensive annotation of the genetic, clinical, proteomic and environmental factors that regulate the levels of 527 metabolites in plasma. We showed that each individual possesses a unique and stable protein-metabolic profile, determined primarily by genetics, sex and body composition, emphasizing metabolic individuality. Moreover, our results demonstrated the importance of plasma

proteins in capturing individualized metabolic variabilities and monitoring metabolic health.

Background: People living with HIV (PLWH) exhibit premature aging and a higher prevalence of age-related conditions such as cardiovascular and chronic kidney disease, despite effective antiretroviral therapy (ART). The underlying biological mechanisms contributing to this phenomenon remain poorly understood. Metabolomics, the analysis of small molecules in biological samples, offers a powerful tool for investigating the molecular mechanisms of health perturbations. Previous studies indicate that ART only partially addresses the metabolic disturbances caused by HIV and might contribute to additional metabolic dysregulation. We here integrate metabolomic and genomic profiling to explore the biological underpinning of age-related comorbidities in PLWH.

Material and Methods: Using a genome-wide association study framework and untargeted metabolome measurements, we searched for assocations between human genetic variants and the plasma concentrations of 1930 metabolites among 1244 individuals from the Swiss HIV Cohort Study.

Results: We identified 27 significantly associated metabolites across 12 genetic loci, including metabolic enzyme genes such as NAT8 and FUT2. Expression quantitative trait loci analysis confirmed plausible biological connections between genetic variants and metabolites. Of the 27 associations with metabolites, 8 had been reported in previous studies. We identified genetic links to plant-derived metabolites, uncovering novel genetic regulation of exogenous compound metabolism in humans. Finally, Mendelian Randomization was applied to investigate the causal relationship between these metabolites and age-related diseases.

Conclusion: We conducted a genome-wide search for associations with plasma metabolites in PLWH, revealing some genetic-metabolic links that were not detected in the general population and could be linked to age-related comorbidities in PLWH.

P18.084.C Understanding the genetic basis for sleep and psychiatric disorders

Reyhane Eghtedarian[1], *Pau Pauigdevall*[2], *Samuel Jones*[1], *Helena Kilpinen*[2,3], *Hanna Ollila*[4,5,6]

[1]*Institute for molecular medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland,* [2]*Helsinki Institute of Life Science (HiLIFE), University of Helsinki, Helsinki, Finland,* [3]*Faculty of Biological and Environmental Sciences, University of Helsinki, Helsinki, Finland,* [4]*Institute for molecular medicine Finland (FIMM), HiLife, University of Helsinki, Helsinki, Finland,* [5]*Department of Anesthesia, Critical Care and Pain Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA,* [6]*Center for Genomic Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.*

Background: Sleep is vital for mental and physical health, but modern lifestyles often lead to poor sleep. Sleep and psychiatric disorders have a bidirectional relationship; sleep problems can worsen mental health, and psychiatric conditions can disrupt sleep. While it is known that both sleep and psychiatric disorders have a strong genetic basis, the overlap of their genetic risk factors remains unknown.

Material and Methods: In this study, we leveraged genome-wide association study (GWAS) data of over 50 sleep and psychiatric phenotypes and performed genetic correlation analysis to understand the shared genetic basis underlying these conditions. Further, we explored the enrichment of SNP-based heritability of these disorders in various tissues by stratified linkage disequilibrium score regression (LDSC) analysis using publicly available gene expression and chromatin data from a wide range of human, mouse, and rat tissues.

Results: We found significant negative correlations between sleep duration and post-traumatic stress disorder ($R = -0.227$, $p = 4.12e\text{-}4$), and between chronotype and autism spectrum disorder ($R = -0.172$, $p = 2.41e\text{-}7$). Additionally, we observed positive genetic correlations between nightmares and mood instability ($R = 0.6$, $p = 4.73e\text{-}6$), and between insomnia and depression ($R = 0.457$, $p = 6.72e\text{-}91$). LDSC analysis showed the enriched heritability of most sleep and psychiatric disorders in tissues of the central nervous system, particularly brain regions including the prefrontal cortex, angular and anterior gyrus ($p < 0.05$).

Conclusion: Overall, our findings highlight the shared genetic basis of sleep and psychiatric disorders, and highlight tissues of the central nervous system as most relevant for understanding disease heritability.

P18.085.D Postnatal depression GWAS in the Genetic Links to Anxiety and Depression (GLAD) Study and UK Biobank

Jared Gichohi Maina[1,2], *Rujia Wang*[1,2], *Saakshi Kakar*[1,2], *Sang-Hyuck Lee*[1,2], *Gursharan Kalsi*[1,2], *Thalia Eley*[1,2], *Gerome Breen*[1,2]

[1]*Social, Genetic, and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom,* [2]*National Institute for Health and Care Research Maudsley Biomedical Research Centre, South London and Maudsley NHS Trust, London, United Kingdom.*

Background: Postnatal depression (PND) is a common subtype of major depression disorder (MDD) that is often under-researched in psychiatric genetics. In this study we present results of a genome-wide association study (GWAS) of PND.

Material and Methods: We defined PND in the Genetics Links to Anxiety and Depression (GLAD) Study and the UK Biobank using a combination of self-report and diagnostic algorithms. The combined sample size in the two cohorts included 6,413 cases and 18,122 controls ($N = 24{,}535$). We performed a GWAS in REGENIE

and estimated SNP heritability using the LDSC tool. Functional mapping and annotation were done using FUMA.

Results: Our GWAS results identified 1 genome-wide significant signal on chromosome 13, rs12224658, near the *OR4C4/OR4A5* genes. This signal has not been reported in current large scale GWAS of PND or MDD. The observed SNP heritability estimate was 5.8%. Ongoing work focuses on refining the definition of PND in GLAD and UK Biobank to increase sample sizes, followed by meta-analysis with the latest large-scale study of PND. Genetic correlation with other traits will be estimated in the combined dataset.

Conclusion: We performed a GWAS of PND in the UK utilising data from the largest study of depression in the world and UK Biobank and identified one genome-wide significant signal. Results from our work will build on existing research and improve our understanding of the distinct genetic aetiology of PND compared to MDD.

Background: Lung graft survival remains insufficient, with only 50.6% survival at 5 years post-transplantation. Chronic lung allograft dysfunction (CLAD) is the primary barrier to long-term survival. Understanding the molecular mechanisms underlying CLAD is critical for improving outcomes. We performed the first genome-wide association study (GWAS) investigating donor and recipient's genetic factors associated with CLAD.

Material and Methods: CLAD is defined by a ≥20% decline in forced expiratory volume from baseline (3 months post-transplant without infection or other causes). We genotyped 392 European donor-recipient pairs from the multicentric COLT cohort (Cohort in Lung Transplantation) using the Affymetrix Axiom PRMA microarray. We tested 7 million SNPs for association with CLAD using multivariate logistic regression models corrected for age, sex, initial disease and genetic ancestry. The GWAS was performed at three levels: donors-only, recipients-only, and donor-recipient mismatches.

Results: No significant associations were found in donor genotypes or donor-recipient mismatches. However, 13 recipients SNPs were significantly associated with CLAD ($P < 5 \times 10^{-8}$). Our top signals (34% in CLAD vs 66% in non CLAD recipients, $P = 2.18 \times 10^{-9}$, $OR = 0.39$) encompassed the *PLXDC2* gene, previously associated with the risk for bronchopulmonary dysplasia. Importantly, we demonstrated with scRNAseq data from lung explants ($n = 4$) that *PLXDC2* was mostly expressed in monocytes and strongly down regulated in CLAD vs healthy controls ($P = 2.22 \times 10^{-16}$).

Conclusion: This first GWAS in lung transplantation displaying a biologically relevant candidate gene from the recipient's genome, suggesting its role in CLAD pathogenesis. Our study calls for larger genomic initiatives in lung transplantation to increase the power of signal discovery.

P18.088.C Transcriptome-wide association study and network analysis reveal tissue-specificity of genetic determinants of multiple sclerosis severity

Ettore Mosca[1], *Ada Sula*[1], *Elisabetta Mascia*[2], *Alice Chiodi*[1], *Melissa Sorosina*[2], *Antonino Giordano*[2,3,4], *Massimo Filippi*[3,4,5], ***Ferdinando Clarelli***[2], *Federica Esposito*[2,3]

[1]*Institute of Biomedical Technologies, National Research Council (CNR), Milan, Italy,* [2]*IRCCS San Raffaele Scientific Institute, Division of Neuroscience, Institute of Experimental Neurology, Laboratory of Human Genetics of Neurological Disorders, Milan, Italy,* [3]*IRCCS Ospedale San Raffaele, Neurology Unit and MS Center, Milan, Italy,* [4]*Università Vita-Salute San Raffaele, Milan, Italy,* [5]*IRCCS Ospedale San Raffaele, Division of Neuroscience, Institute of Experimental Neurology, Neuroimaging of CNS white matter Unit, Milan, Italy.*

Background: Multiple sclerosis (MS) is a major cause of neurological impairment in young adults. While effective therapies are available for the relapsing-remitting form, progression of MS has very limited treatment options. To improve understanding of the biological substrates of MS severity, we integrated genome-wide association studies (GWAS) of disease severity with gene expression data, performing tissue-specific transcriptome-wide association studies (TWAS), followed by a thorough investigation of involved network modules.

Material and Methods: We meta-analysed statistics from two GWAS on MS severity: the multi-centric study performed by the International Multiple Sclerosis Genetics Consortium ($N = 12,584$) and a study involving an Italian cohort ($N = 1,286$). To perform TWAS, we used gene-expression predictive models in 12 brain regions from GTEx v8, using FUSION tool to test association of genetically predicted expression with severity endpoint. The TWAS statistics were projected onto corresponding tissue-specific interactomes from HumanBase. Using "dmfind" network analysis

tool, we scored modules based on the presence of connected genes with significant TWAS statistics and tissue-specificity.

Results: Overall, TWAS was based on meta-analysed statistics for 7,891,356 imputed variants. We found genes whose genetically controlled expression was significantly associated ($p < 0.05$) with MS severity in each tissue (50–220 genes). Network analysis revealed a set of "high scoring" gene modules (10–80 genes), characterized by high tissue specificity and high TWAS statistics. Interestingly, spinal cord emerged as a tissue with top-scoring modules.

Conclusion: Our analysis provided evidence of tissue-selective manifestation of MS severity genetic determinants. Further work is required to validate and interpret the molecular mechanisms underlying such tissue-specificity.

P18.089.D Bulk and single-cell transcriptomic insights into treatment-induced changes in tuberculosis patients from Tanzania

Simon Tang[1,2], *Laura Zaragoza-Infante*[3,4], *Jerry Hella*[5], *Klaus Reither*[3,4], *Damien Portevin*[3,4], *Sebastien Gagneux*[3,4], *Jacques Fellay*[1,2,6]

[1]*École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [3]*Swiss Tropical and Public Health Institute, Allschwil, Switzerland,* [4]*University of Basel, Basel, Switzerland,* [5]*Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of,* [6]*Biomedical Data Science Center, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland.*

Background: Transcriptomic analysis has allowed researchers to investigate how an individual's gene expression is modulated by *Mycobacterium tuberculosis* infection and antimycobacterial drugs [1-2]. However, most studies have only used bulk RNAseq, which cannot ascertain how cell-type composition and cell-type specific responses impact global expression patterns. Thus, we sought to characterise these potential influences using pre- and post-treatment clinical samples from Tanzanian patients.

Material and Methods: Blood samples were collected between 2019–2021 from 24 patients immediately before and six months after treatment. scRNAseq was performed by following BD Rhapsody's mRNA Whole Transcriptome Analysis (WTA) Library Preparation Protocol. Bulk RNAseq was performed by following the Illumina Stranded mRNA Prep Protocol. Bioinformatic analysis was performed in R.

Results: Our bulk transcriptomic analysis confirmed previously published gene signatures, notably the downregulation of immunoglobulin-associated genes after treatment (e.g. IGHA1-2, IGLV2-8). Through our scRNAseq analysis, we showed that shifts in both cell-type composition and cell-type-specific expression changes impacted the bulk expression patterns. The proportion of B cells and CD4+ memory T cells increased following treatment ($p = 0.048$). Furthermore, natural killer cells and monocytes exhibited differential gene expression profiles distinct from the bulk expression pattern.

Conclusion: These findings highlight the value of scRNAseq in recontextualising gene expression patterns observed in bulk RNAseq, facilitating a greater understanding into the complex biology of tuberculosis. Further analysis into applying deconvolutional pipelines on publicly available bulk RNAseq datasets will help assess the generalisability of our results.

P18.090.A Genetic Drivers of Alzheimer's Disease Pathology: A GWAS and QTL analysis in a novel European neuropathological cohort

Celeste Laureyssen[1,2], *Fahri Küçükali*[1,2], *Jasper Van Dongen*[1,3], *Klara Gawor*[4], *Alicja Ronisz*[5], *Markus Otto*[6], *Christine A.F. Von Arnim*[7], *Philip Vandamme*[8,9], *Rik Vandenberghe*[9,10], *Dietmar R. Thal*[4,11], *Kristel Sleegers*[1,2]

[1]*Complex Genetics of Alzheimer's Disease group, VIB Center for Molecular Neurology, Antwerp, Belgium,* [2]*Department of Biomedical Sciences, University of Antwerp, Antwerp, Belgium,* [3] *Department of Biomedical Sciences, University of Antwerp, Antwerp, Belgium,* [4]*KU Leuven, Laboratory of Neuropathology, Department of Imaging and Pathology, and Leuven Brain Institute, Leuven, Belgium,* [5]*KU Leuven, Laboratory of Neuropathology, Department of Imaging and Pathology, and Leuven Brain Institute, Antwerp, Belgium,* [6]*Martin-Luther-University Halle-Wittenberg, Department of Neurology, Halle, Germany,* [7]*University Medical Center Göttingen, Department of Geriatrics, Göttingen, Germany,* [8]*KU Leuven, Laboratory of Neurobiology, Leuven, Belgium,* [9]*UZ Leuven, Department of Neurology, Leuven, Belgium,* [10]*KU Leuven, Laboratory of Cognitive Neurology, Department of Neurosciences, Leuven Brain Institute, Leuven, Belgium,* [11]*University Hospital Leuven, Department of Pathology, Leuven, Belgium.*

Background: Alzheimer's disease (AD) is a heterogeneous disorder with a substantial genetic component. Traditional genome-wide association studies (GWAS) rely on clinical diagnoses of large cohorts, which are compromised by phenotypic heterogeneity. We conducted GWAS in a novel European neuropathological cohort ($n = 414$) with detailed neuropathological characterization to identify genetic associations with specific AD-related lesions.

Material and Methods: AVITI low-coverage whole-genome sequencing was performed at 1x coverage. SNPs and indels were imputed using GLIMPSE2, referencing the 1000 Genomes Project panel. Association testing was conducted in PLINK2. Variants reaching genome-wide significance ($p < 5 \times 10^{-8}$) and notable subthreshold loci were evaluated for potential roles as quantitative trait loci (QTLs).

Results: We identified genome-wide significant and suggestive loci contributing to the heterogeneity of AD risk. In addition to APOE, we discovered an intronic variant in GYPE and a variant upstream of ADAMTS16, both showed nominal associations with ABC score, reflecting AD pathology. Both were significantly linked to Braak staging (Tau neuropathological score), suggesting a potential role in tau-related lesions. Significant associations with co-morbidities were found, like granulovacuolar degeneration (necroptotic cell death), with an intronic variant in XAF1, and an intronic variant in NRF1 associated with Hirano body scores (actin aggregates).

Conclusion: Despite sample size constraints, we identified genome-wide significant associations with AD-related lesions by controlling for phenotypic heterogeneity. Results from QTL analyses highlight the molecular relevance of several loci and suggest potential novel risk genes. Moving forward, we will prioritize replication and meta-analysis in independent cohorts, functional validation and targeted resequencing.

P18.091.B Gut microbiome composition and function reflect socioeconomic deprivation

Yu Lin[1], *Nathan Cheetham*[1], *Alessia Visconti*[1], *Mario Falchi*[1], *Ana Valdes*[2], *Cristina Menni*[1,3]

[1]*Department of Twin Research & Genetic Epidemiology, King's College London, London, United Kingdom,* [2]*Academic Rheumatology Clinical Sciences Building, Nottingham City Hospital, University of Nottingham, Nottingham, United Kingdom,* [3]*Università Degli Studi di Milano, Milan, Italy.*

Background: Socioeconomic status (SES) correlates with adverse health outcomes, but underlying biological mechanisms remain unclear. We examined the influence of area-level deprivation, measured by the Townsend Deprivation Index, on gut microbiome composition and function (using shotgun metagenomics). We also explored how the gut microbiome mediates the effects of deprivation on metabolic and mental health outcomes.

Material and Methods: In 1,390 female individuals from TwinsUK, we investigated changes in microbial diversity, composition and function across deprivation levels using linear mixed models as implemented in Maaslin2 adjusting for age, BMI, family and multiple testing (FDR < 0.2). XGboost models assessed whether selected bacteria could distinguish between the most and least deprived groups. Mediation analysis examined the role of microbes in linking social deprivation to metabolic and mental health outcomes.

Results: Individuals with higher Townsend deprivation exhibited reduced alpha diversity (Jonckheere-Terpstra $P < 0.001$) and distinct shifts in microbial composition were observed across deprivation levels (PERMANOVA $P = 0.001$). Twenty microbial species were linked to deprivation and moderately distinguished deprived groups (AUC = 0.73). Altered energy metabolism pathways were identified in deprived individuals. Townsend deprivation was linked with higher levels of glucose, overweight and anxiety. Two social deprivation linked microbial species were consistently associated with these clinical outcomes, with *Intestinimonas_massiliensis* and *Ruminococcaceae_unclassified_SGB15236* mediating the relationship between deprivation, overweight and glucose levels. *Intestinimonas_massiliensis* also mediates the association between deprivation and anxiety.

Conclusion: Socioeconomic deprivation reshapes microbiome composition. Our data highlights the mediating effect of the gut microbiome on mental and metabolic health disparities.

P18.092.C Mapping genetic blueprints of human plasma blood proteins: A GWAS study in KORA

Markéta Fuchs[1], *Jonathan Adam*[1], *Birgit Linkohr*[1], *DigiMed Bayern Consortium*[2], *Annette Peters*[1], *Karsten Suhre*[3], *Christian Gieger*[1]

[1]*Helmholtz Zentrum Munich, Munich, Germany,* [23]*Weill Cornell Medicine Qatar, Doha, Qatar.*

Background: Genome-wide association studies (GWAS) analyzed thousands of genetic variants to uncover statistical associations with diseases and traits. Integrating genomics with protein levels in human blood samples provides new understanding of key loci. Protein Quantitative Trait Loci (pQTLs) offer substantial effect sizes and complement other analyses, as protein levels are often directly implicated in disease processes. We integrated proteomic profiling across three timepoints in KORA (Cooperative Health Research in the Region of Augsburg, Germany) to investigate temporal trends between genetic variation and protein expression.

Methods: We explored a novel plasma proteomics longitudinal dataset acquired through mass spectrometry assay. We utilized samples measured in baseline KORA S4 = 3652, 7-years follow-up F4 = 2854, 14-years follow-up FF4 = 2005 participants. The SNP-protein associations (842 relative protein concentrations, post-QC) were tested using Matrix-eQTL by modeling the effect of genotype as additive linear model. Age, sex and BMI were included as covariates.

Results: We identified 4,133 significant genetic associations linked to 537 proteins. An interactive online platform with supplementary material is being developed for easy result access. We validated our findings by cross-referencing these associations with MS-based peptide data. Subsequently, we examined association between age and proteins while accounting for other covariates (SNP, time, sex, BMI) using a linear mixed model. 1,472 SNPs were identified as associated with age after Bonferroni correction. Ongoing analysis examines the SNP-age associations for novelty by cross-referencing with existing literature.

Conclusion: Our goal is to prioritize novel associations for deeper investigation, including their potential functional implications and mechanisms.

P18.093.D Leveraging same-cell single-nucleus multiomics across PBMCs from 271 donors to understand how genetic variation affects gene regulation

Roy Oelen[1], *Maryna Korshevniuk*[1], *Martijn J. van der Werff*[1], *Dan Kaptijn*[1], *Jelmer Niewold*[1], *Corinna Losert*[2], *sc-eQTLGen Consortium*[3], *Matthias Heinig*[2], *Harm-Jan Westra*[1], *Marc J. Bonder*[1], *Lude H. Franke*[1], *Monique G. van der Wijst*[1]

[1]*UMCG, Groningen, Netherlands,* [2]*Helmholtz Munich, Munich, Germany,* [3]

Background: Many, mostly non-coding, genetic variants have been linked to disease. Through single-cell eQTL analysis we have

linked such variants to (celltype-specific) gene expression changes. However, nominating both causal and relevant variants in a locus remains difficult.

Material and Methods: To better understand the upstream regulatory mechanisms through which genetic variants act, allowing better prioritization of likely causal variant disrupting regulation, we performed single-nucleus multiome (RNA + ATAC) experiments across 318 blood samples from 271 individuals.

Results: 5,365 genes showed an eQTL effect (15% of top effects are in open chromatin, and 69% are co-localizing with a caQTL in the matching context) across the six major blood cell types. For these co-localizing QTL effects, 92% were concordant across modalities. We then identified cis-regulatory elements where chromatin levels of genomic regions correlated with expression levels of specific genes, and found examples where this correlation was modulated by genetic variation and stimulation status. For example, the correlation between peak Chr1:89,556,742-89,557,773 and gene *LRRC8B* was modulated by a SNP located in the peak. Interestingly, this genotypic effect became weaker after pathogen stimulation, indicating that openness is the rate-limiting factor for *LRRC8B* transcription in the steady state, as opposed to the abundance of upstream regulators in the stimulated setting.

Conclusion: By taking advantage of same-cell open chromatin and expression information, we were able to better nominate and understand likely relevant variants and provide a first hint that the rate-limiting regulatory step of these variants may be context-dependent.

P18.094.A Uncovering genetic variations in the KIV-2 variable number tandem repeat of the *LPA* gene: implications for lipoprotein(a) concentration and cardiovascular risk

Silvia Di Maio[1], *Peter Zöscher*[1], *Hansi Weissensteiner*[1], *Lukas Forer*[1], *Johanna F. Schachtl-Riess*[1], *Stephan Amstler*[1], *Gertraud Streiter*[1], *Cathrin Pfurtscheller*[1], *Anna Köttgen*[2], *Kai-Uwe Eckardt*[3,4], *Florian Kronenberg*[1], *Stefan Coassin*[1], *Sebastian Schönherr*[1]

[1]*Institute of Genetic Epidemiology, Medical University of Innsbruck, Innsbruck, Austria,* [2]*Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg, Germany,* [3]*Department of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany,* [4]*Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany.*

Background: Variable Number Tandem Repeats (VNTRs) are repetitive DNA sequences in the human genome. Over 100 VNTRs are located in protein-coding, medically relevant genes, like the KIV-2 VNTR in the *LPA* gene. *LPA* almost monogenically controls the concentration of the strong cardiovascular risk factor lipoprotein(a). Due to its structure, the KIV-2 VNTR analysis is often limited to resource-intensive approaches. Thus, VNTRs cannot be resolved in available biobank-scale sequencing data and are largely missed in GWAS.

Material and Methods: We previously published an in-silico workflow to detect intra-repeat variation at scale in exome data. Here, we applied this method for the first time to 4,867 whole-exome sequencing samples from the German Chronic Kidney Disease study and implemented a novel VNTR-wide association testing approach. Significant signals were further investigated with quantile regression on median Lp(a) concentrations and Cox regression on cardiovascular risk in 186,607 UK Biobank samples.

Results: We replicated all major findings from our previously established PCR-based approaches. Furthermore, we identified four novel significant associations with increasing or decreasing Lp(a) concentrations (Table 1), and even one new significant association with decreased CVD risk in UK Biobank (position 515A>G). Most importantly, the KIV-2 SNPs reduced the missing heritability of the Lp(a) variance, improving state-of-the-art polygenic risk scores ($r^2 = 44\%$) by about 7%.

Conclusion: Our framework unlocks variant calling and characterization in the KIV-2 VNTR from sequencing data at scale and can be used as a blueprint for other VNTRs and traits.

Novel associations between KIV-2 variants and Lp(a) concentration

Position within KIV-2 reference	Number of Carriers	Quantile regression beta [95% C.I.] mg/dL	p-value
672C>T	158	+11.88 [5.79;17.97]	3.39e-04
4968G>A	2,803	+3.52 [1.82;5.22]	1.98e-04
584C>T	179	−3.23 [−5.16;−1.3]	3.55e-06

P18.095.B Multi-trait meta-analyses and gene prioritization based on co-morbidity categories provide novel insights into the genetic architecture of hypothyroidism

Hermina Jakupović[1], *Chloé V. Pittman*[1], *Sofie Bliddal*[2,3], *Ulla Feldt-Rasmussen*[2,4], *Tuğçe Karaderi*[1]

[1]*Center for Health Data Science, Section for Health Data Science and Artificial Intelligence, Department of Public Health, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [2]*Department of Nephrology and Endocrinology, Rigshospitalet, Copenhagen, Denmark,* [3]*Department of Gynaecology and Obstetrics, Hvidovre Hospital, Copenhagen, Denmark,* [4]*Institute of Clinical Medicine, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark.*

Background: Hypothyroidism is a common endocrine condition with extensive heterogeneity in symptoms, co-morbidities, and treatment effects. We studied the genetic underpinnings of

hypothyroidism in the context of its co-morbidities for an improved understanding of the disease biology and mechanisms.

Material and Methods: By leveraging publicly available genome-wide association study (GWAS) summary statistics, we aimed to (1) identify new genetic associations for hypothyroidism, and (2) explore the genetic overlap across 26 genetically correlated conditions, by performing seven co-morbidity-category-based multi-trait GWAS meta-analyses (MTAG), boosting statistical power by joint analysis of multiple traits. Based on the new associations identified, gene prioritization was carried out to detect and characterize the potentially functional genes using two parallel SNP-to-Gene methods; (1) Otargen, based on Open Targets Genetics, and (2) combined-S2G-Framework (cS2G).

Results: One-hundred-fourteen new variants in 92 loci for hypothyroidism ($p < 5 \times 10^{-8}$) lead to 1,134 genes prioritized. Twenty-six of 1,134 genes were prioritized as 'top-scoring' across the methods, including 16 nearest protein-coding genes such as *GLIS3, NRG1, KCTD5*, and *SLC25A37*, that had significant thyroid expression patterns. Among the genes of interest, *GLIS3* variants were previously associated with multiple co-morbidities of hypothyroidism, including rheumatoid arthritis, type 1 diabetes, depression, as well as thyroid-related traits, blood cholesterol, and sex hormone levels. *GLIS3* loss-of-function mutations lead to hyperglycemia, hyperinsulinemia, and congenital hypothyroidism.

Conclusion: MTAG revealed new genetic associations for hypothyroidism based on publicly available data, providing novel insights into its genetic architecture and advancing the understanding of the shared genetics and common biological processes between hypothyroidism and its co-morbidities.

P18.096.C Identification of novel variants influencing the expression of drug-targetable genes involved with Multiple Sclerosis (MS) through a combination of insilico and invitro techniques

Endri Visha[1], *Nicola Pomella*[1], *Ferdinando Clarelli*[2], *Lucia Corrado*[1], *Alaa Habeeb*[1], *Elisa Gorla*[1], *Fjorilda Caushi*[1], *Beatrice Piola*[1], *Diego Cotella*[1], *Laura Follia*[1], *Gianluca Baldanzi*[1], *Martina Tosi*[1], *Domizia Vecchio*[3], *Massimo Filippi*[4], *Maurizio Leone*[5], *Filippo Martinelli Boneschi*[6], *Federica Esposito*[7], *Nadia Barizzone*[1], *Sandra D'Alfonso*[8]

[1]*Università Del Piemonte Orientale, Novara, Italy,* [2]*IRCCS San Raffaele Scientific Institute, Laboratory of Human Genetics of Neurological Disorders, Institute of Experimental Neurology, Division of Neuroscience, Milano, Italy,* [3]*University Hospital "Maggiore Della Carità", Department Of Neurology, Novara, Italy,* [4]*San Raffaele Scientific Institute, Neurology and Neurorehabilitation Unit, Neurophysiology Service, Neuroimaging Research Unit, Division of Neuroscience, Vita-Salute San Raffaele University, Milano, Italy,* [5]*Scientific Direction, Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Foggia, Italy,* [6]*ASST Santi Paolo Carlo, Department Of Health Sciences, Neurology Unit And Multiple Sclerosis Center, Milan, Italy,* [7]*IRCCS Ospedale San Raffaele, Laboratory of Human Genetics of Neurological Disorders, Institute of Experimental Neurology, Division of Neuroscience, Neurology and Neurorehabilitation Unit, Milano, Italy,* [8]*Università del Piemonte Orientale, NOVARA, Italy.*

Background: Multiple Sclerosis (MS) is a complex autoimmune disorder. Starting from 200 MS risk loci from Genome-Wide Association Studies, we focus on 5 regions showing replication in an Italian cohort. To overcome fine mapping limitations due to Linkage Disequilibrium we utilized Massively Parallel Reporter Assays (MPRA) to discover associated causative variants.

Material and Methods: We applied MPRA on regions encompassing SNPs in high LD (r2>0.77). We used mpralm for significance filter and to obtain the logFC of each SNP. We then used MotifBreakR and MEME suite to find Transcription Factors (TF) that bind to MS risk alleles. Open Target Genetics allowed the prediction of target genes and identification of drugs.

Results: We identified variants altering the expression of 4 different genes out of the 5 tested through preferential binding of TF. MEF2B binding on Rs1883832 and AHR binding to RS6974022 on the CD40 region targeting the CD40 gene with Iscalimab as a drug, TCF4, and E2F4 binding on 3 variants in the PRDX5 region with VEGF-B as a target gene, VEGF154 and CONBERCEPT as drugs. Lastly, TGIF2 and PROX1 binding on 2 variants in the IFNGR2 region with the IFNGR2 gene as a target, and INTERFERON GAMMA-1B as a drug, and TBX3 binding on 1 variant in the TEC region targeting the TEC gene with Capivarsetib as a drug. As a follow-up, the FREP assay will prove the binding of these TF to the sequences.

Conclusion: The combination of in silico and in vitro tools is able to identify variants primarily associated with complex diseases.

P18.098.A Clinical implications of a structural variant in the iron transport gene SLC11A2: Insights from two large Danish cohorts

Nanna Brøns[1], *Andreas Stribolt Rigas*[1], *Kathrine Agergård Kaspersen*[2], *Joseph Dowsett*[1], *Ole Birger Pedersen*[3,4], *Christian Erikstrup*[2], *Thomas Folkmann Hansen*[5], *Erik Sørensen*[1], *Andreas Glenthøj*[6], *Sisse Rye Ostrowski*[1,4]

[1]*Department of Clinical Immunology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark,* [2]*Department of Clinical Immunology, Århus University Hospital, Århus, Denmark,* [3]*Department of Clinical Immunology, Zealand University Hospital, Køge, Denmark,* [4]*Department of Clinical Medicine, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark,* [5]*Danish Headache Center, Department of Neurology, Copenhagen University Hospital - Glostrup, Copenhagen, Denmark,* [6]*Department of Haematology, Copenhagen University Hosital - Rigshospitalet, Copenhagen, Denmark.*

Background: *SLC11A2* encodes divalent metal transporter-1, essential for iron absorption. A rare 3.55 kb deletion in the 3′-untranslated region of *SLC11A2* was linked to iron deficiency anemia in homozygote Icelandic carriers. Heterozygotes also showed reduced expression of iron response element positive *SLC11A2* transcripts. This study examines the impact of this structural variant on phenotypes in two large Danish cohorts.

Material and Methods: We analyzed 119,987 participants from the Danish Blood Donor Study (DBDS) and 378,977 from the Copenhagen Hospital Biobank (CHB). Genotyping was performed using the Illumina Global Screening Array. Carrier status was identified via GraphTyper2. Biomarker data, prescription use, and diagnoses were obtained from Danish health registries and DBDS data. Associations between carrier status and outcomes were evaluated using Cox, logistic, and linear regression models. Random effects models were used for repeated biomarker measurements.

Results: The minor allele frequency was 0.0072 across cohorts. No homozygotes were identified in DBDS and fewer than five in CHB. Heterozygote carriers had lower ferritin levels (DBDS: 8–9% lower; CHB: 7–9% lower). In DBDS women, heterozygote carriage was associated with higher risks of iron deficiency (HR 1.34, 95%CI 1.13–1.61), low hemoglobin (HR 1.36, 95%CI 1.21–1.53), and oral iron treatment (OR 1.82, 95%CI 1.21–2.61). Male carriers had 22% lower hepcidin levels (DBDS) and increased iron deficiency risk (CHB: HR 1.21, 95%CI 1.02–1.43) but normal hemoglobin levels. No associations were found with cardiovascular disease or diabetes.

Conclusion: This study highlights the significant impact of the *SLC11A2* structural variant on iron status in healthy and patient populations.

P18.099.B Colocalization of a COPD lung function GWAS and a single-cell lung eQTL study

Rahel B. Eberle[1,2], *Heena Rijhwani*[1], *Courtney Tern*[1], *Aabida Saferali*[1], *John Ziniti*[1], *Mark D. Robinson*[3], *Michael H. Cho*[1]

[1]*Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA,* [2]*University of Zurich, Master Program in Biostatistics, Zürich, Switzerland,* [3]*Department of Molecular Life Sciences, University of Zurich, Zürich, Switzerland.*

Background: Genetic association studies of chronic obstructive pulmonary disease (COPD) and its diagnostic, spirometry FEV1/FVC ratio, have identified hundreds of associations and their effector genes through bulk expression quantitative trait loci (eQTL) studies, such as the *DSP* (desmoplakin) gene, but the responsible cell types remain unknown. We sought to identify effector genes and cell types using single-cell lung eQTL data.

Material and Methods: We colocalized genome-wide significant variants from a lung function FEV1/FVC GWAS in > 580,000 multi-ancestry participants (Shrine 2023) with single-cell lung eQTL from 114 donors (Natri 2024). We included overlapping variants between GWAS and eQTL datasets with 100 kb flanks of the lead lung function variants using a prior probability of shared effect of 1e-5 (coloc R package). We tested across 38 cell types and considered colocalization at a posterior probability (PPH4) of 0.7.

Results: Testing 142 regions, we identified 12 loci with PPH4 > 0.7 in any cell type. Noteworthily, we found a PPH4 of 0.99 at the *DSP* locus (lead variant, rs2076295, in contrast to the variant previously reported to colocalize at this locus), in type 2 alveolar cells, and a PPH4 of 0.89 in alveolar type 1 cells.

Conclusion: In an eQTL colocalization analysis, we identified 12 COPD-related lung function loci that colocalized in single-cell eQTL studies, including *DSP*. rs2076295 likely plays a cell type-specific role in COPD susceptibility. Future work will include examination of the relationship of single-cell and bulk eQTL.

P18.100.C GWAS and functional genomics reveal candidate susceptibility genes for endometrial cancer

Tracy A. O'Mara, *Bianca Naumann, Matthew Barker, Serena Gallozzi, Dylan M. Glubb*

QIMR Berghofer, Brisbane, Australia.

Background: Endometrial cancer is one of the most common malignancies worldwide, with ~420,300 new cases diagnosed in 2022. Only four drugs have received FDA approval for endometrial cancer in the last four decades. Genetic studies of disease offer a promising approach to identify new effective drug targets. Indeed, it has been observed that there is a four-fold increase in the proportion of drug targets that are supported by relevant genetic evidence between pre-clinical development and regulatory drug approval. Thus, we propose that susceptibility genes at endometrial cancer GWAS risk loci will provide novel therapeutic targets underlying disease causality.

Material and Methods: Through GWAS we have identified 21 genetic loci associated with endometrial cancer risk, resolved to 497 fine-mapped candidate causal risk variants. We performed various functional genomic assays to map regulatory features in endometrial models (ATAC-seq, H3K27Ac-HiChIP, H3K27Ac-CuT&TAG). These and publicly available datasets were integrated using six complementary approaches to prioritise functional endometrial cancer risk variants and their potential regulatory targets.

Results: Using LD score regression, we demonstrated significant enrichment of endometrial cancer heritability within regulatory elements mapped in endometrial models. We prioritised 73 candidate effector genes of endometrial cancer GWAS-risk variation, including three genes identified by all six approaches (*PPARG*, *BPTF* and *LINC02523*). Additionally, five endometrial cancer driver genes were found.

Conclusion: Regulatory elements in endometrial models likely mediate the effects of risk variation, revealing candidate effector genes. We prioritised *BPTF*, a promising therapeutic target implicated in several cancers, including endometrial cancer.

P18.101.D A genetic atlas of human protein complexes in 1000 adults from the Orkney Isles

Ting Li[1], *Jiantao Chen*[2], *Ao Lan*[2], *James Wilson*[3], *Xia Shen*[1,4]

[1]*Fudan University, Shanghai, China,* [2]*Sun Yat-sen University, Guangzhou, China,* [3]*University of Edinburgh, Edinburgh,* [4]*Karolinska Institutet, Stockholm, Sweden.*

Protein complexes are fundamental for biological processes and molecular interaction**s**, yet their roles in human health remain largely unexplored. Quantifying protein complexes at a population scale is of great challenge.In this study, we developed and integrated advanced experimental assays with AI-assisted computational methods to achieve **high-throughput scoring of over 3,000 human protein complexes** in more than 1,000 individuals from the isolated Orkney Islands.We provide a **comprehensive genetic atlas** of human protein complexes, identifying **2,846 protein complex QTL (pcQTL)** that regulate protein complex interactions, including **1,106 cis- and 1,740 trans-associations**. These findings offered **unprecedented insights into protein**

interactions beyond the resolution of standard bulk proteomics.-Through causal inference, we linked protein complexes to diseases such as **mesothelioma, heart disease, and hypothyroidism**, revealing protein complexes as potential biomarkers and therapeutic targets. This study established a novel approach in proteomics, paving the way for precision medicine and targeted interventions that leverage the network of protein interactions in human health and disease.

P18.102.A 131 genetic loci highlight immunological pathways and tissues in asthma and nasal polyposis

Elmo Saarentaus[1,2], *Kasper Fischer-Rasmussen*[3], *Eeva Sliz*[4], *Argyro Argyro Bizaki-Vallaskangas*[5], *FinnGen*[6], *Tarja Laitinen*[1], *Sanna Toppila-Salmi*[7,1], *Hannu Kankaanranta*[8,5,9], *Johannes Kettunen*[4], *Klaus Bønnelykke*[3], *Aarno Palotie*[1,10,11], *Antti Mäkitie*[1,2]

[1]*University of Helsinki, Helsinki, Finland,* [2]*Helsinki University Central Hospital HUS, Helsinki, Finland,* [3]*University of Copenhagen, Copenhagen, Denmark,* [4]*University of Oulu, Oulu, Finland,* [5]*University of Tampere, Tampere, Finland,* [67]*University of Eastern Finland, Kuopio, Finland,* [8]*University of Gothenburg, Gothenburg, Sweden,* [9]*Seinäjoki Central Hospital, Seinäjoki, Finland,* [10]*Broad Institute of MIT and Harvard, Cambridge, MA, USA,* [11]*Massachusetts General Hospital, Boston, MA, USA.*

Background: Coexistence of asthma and chronic rhinosinusitis with nasal polyposis (CRSwNP) associate with allergic phenotypes, disease severity and failure of first-line treatment for both asthma and CRSwNP. Recent studies have highlighted shared genetic components for these diseases.

Material and Methods: To better understand this shared component, we performed genome-wide meta-analyses of asthma (n = 71,481), CRSwNP (n = 9626) and chronic rhinosinusitis without nasal polyposis (CRSsNP, n = 15,448) in FinnGen and UKB (685,602 controls).

Results: We detected 131 genomic associations, including 29 novel loci for asthma, 33 novel loci for CRSwNP, and one for CRSsNP. A shared impact to asthma and CRSwNP was observed at 62 loci. A cross-trait meta-analysis using all disorders further implicated 17 loci associating with asthma or asthma and CRSwNP. These loci largely cluster into three groups, with a shared risk being most frequent. We also find 12 nonsynonymous associating variants, including a novel *TP63* missense variant linked with CRSwNP (OR = 1.519 [1.331–1.734]). Gene set analyses confirmed enrichment of type 2 inflammation genes, and linked *FOXP3* signaling to CRSwNP.

Conclusion: Our results highlight new shared and separate genetic pathways for CRSwNP and asthma. These provide several avenues of further investigation in functional and epidemiological follow-up, and evidence for immunological and non-immunological mechanisms behind both diseases.

P18.104.C Cross-species transcriptome meta-analysis of anterior cruciate ligament rupture

Livia Beccacece[1], *Stefano Pallotti*[1], *Yiyun Li*[2], *Jie Huang*[3], *Valerio Napolioni*[1]

[1]*University of Camerino, Camerino, Italy,* [2]*The Chinese University of Hong Kong, Shenzhen, China,* [3]*Southern University of Science and Technology, Shenzhen, China.*

Background: The Anterior Cruciate Ligament (ACL) plays a critical role in maintaining the musculoskeletal stability of the knee. Its injury has been linked to an increased risk of developing osteoarthritis. This study aims to identify cross-species responses to ACL rupture providing insights on its molecular basis.

Material and Methods: We analyzed five publicly available transcriptomic datasets from *Homo sapiens*, *Mus musculus*, *Canis lupus familiaris*, and *Oryctolagus cuniculus*. Differential gene expression analysis was performed for each dataset, producing a genome-wide transcriptional signature of fold-change significance for individual genes. Stouffer's method was used to integrate the results, identifying genes significantly deregulated across all species. Additionally, gene-set enrichment analysis revealed pathways that were consistently upregulated or downregulated.

Results: A positive correlation in expression was observed between human and the other three species ($r^2 = 0.177–0.305$, $p \leq 2.7 \times 10^{-113}$), identifying 210 genes as the most consistently up- and down-regulated in response to ACL rupture ($p\text{-adjusted} \leq 1.27 \times 10^{-23}$). These genes are primarily involved in cellular mitosis, collagen pathways, and cartilage development. Furthermore, 60 pathways were found to be significantly up- or down-regulated across all species ($p\text{-adjusted} \leq 4.57 \times 10^{-4}$). Among these, the upregulation of inhibition of bone mineralization ($p\text{-adjusted} \leq 2.99 \times 10^{-6}$) aligns with previous findings on reduction of subchondral bone mineral density following ACL rupture.

Conclusion: This study highlights that distinct species exhibit common molecular responses to ACL rupture, underscoring the value of mice, dogs, and rabbits as potential translational model organisms for ACL rupture research. Furthermore, the identified genes and pathways highlight the molecular mechanisms underlying ACL rupture.

P18.105.D Multi-stage genome-wide association studies showed new insights to subarachnoid hemorrhage in the multi-ethnic populations

E. Hong[1], *H. Jo*[2], *E. Hong*[3], *H. Jo*[2];

[1]*Institute of New Frontier Research, Hallym University College of Medicine, Chuncheon, Gangwon-do, Korea, Republic of,* [2]*Kangwon National University, Chuncheon, Gangwon-do, Korea, Republic of,* [3]*Chuncheon, Gangwon-do, Korea, Republic of*

Background: Subarachnoid hemorrhage (SAH) due to intracranial aneurysm (IA) rupture is a life-threatening condition with high mortality (up to 50%) and morbidity in the survivors (up to 30%). Previous genome-wide association studies (GWASs) have still limitations to explain a genetic heritability of SAH. Here, we performed a two-stage GWAS and meta-analysis to identify genetic susceptibilities to SAH in the large-scale populations.

Material and Methods: Two-stage Korean GWAS involved 151/175 SAH and 99/175 non-ruptured patients at discovery (2015–2019 years)/validation (2020–2023 years) stage, respectively, sharing 6,429,498 markers after a high-captured genotype-imputation process after pruning imputation score < 0.5. Independent GWASs collected 31/1539 SAH and 11/447 non-ruptured patients in Asian-/European-ancestry populations, respectively, from UK Biobank genotype-imputation data, sharing 93,095,623

markers. Genome-wide meta-analyses were performed by weighting each GWAS by the inverse variance approach.

Results: Nine variants within a serine/threonine-protein kinase 3 (*STK3*:8q22.2) gene showed a genome-wide significant association with SAH formation and complete linkage disequilibrium (LD) at the combined stage (OR = 0.46, $p = 4.51 \times 10^{-8}$), dramatically replicated at discovery and validation stages ($p = 0.0456$ and 2.76×10^{-7}, respectively). Twenty-seven of gene regions showed a suggestive association with SAH formation ($p < 1 \times 10^{-5}$), including two large LD structures such as *SLC2A13-LRRK2* (12q12) and *CCL15-CCL14* (17q12). None of any loci improved an association in either Asian- or European-ancestry GWAS meta-analyses including Korean GWAS results.

Conclusion: Our study shows novel insight modifiers in *STK3* susceptibility to SAH in the large-scale samples. Our findings will be warranted to validate in an independent population, thereby understanding genomic aspect to the pathology and etiology of SAH.

P18.106.A Shared Genetic Variants Linking ALS, Sporadic FTD, and Cognitive Traits

Emrah Kacar, *Tomas Gomes, Ciara O'Donoghue, Russell McLaughlin, Ross Byrne*

Complex Trait Genetics Lab, Smurfit Institute of Genetics, Trinity College Dublin, Dublin, Ireland.

Background: Cognitive impairment, including deficits in executive function, verbal fluency, and social cognition, affects ~50% of ALS patients with ~15% meeting criteria for frontotemporal dementia (FTD). The genetic basis of cognitive decline in ALS remains poorly understood. This study investigates shared genetic factors underlying ALS, sporadic FTD (sFTD), and cognitive traits to uncover biological mechanisms.

Material and Methods: Multi-trait GWAS analysis (MTAG) was conducted using European ancestry data for ALS (n = 138,086), sFTD (n = 19,993), and cognitive traits, including cognitive performance (n = 257,828), executive function (n = 78,547-11,263), fluid intelligence (n = 171,304), and memory (n = 331,679). Shared loci were validated using conjunctional FDR (conjFDR), and local genetic correlations between ALS and sFTD were assessed via LAVA.

Results: ALS showed significant negative genetic correlations with cognitive traits, including cognitive performance (CP) ($r = -0.19$, $p = 4.85 \times 10^{-6}$) and fluid intelligence ($r = -0.20$, $p = 2.74 \times 10^{-6}$). MTAG for ALS boosted by CP identified novel associations in NEGR1, CLCN3, MEF2C, EXOC4, TSNARE1, and EFL1/SAXO2. ConjFDR validated findings for MEF2C, EXOC4, and EFL1/SAXO2, and revealed MYO19 as a new locus. Gene set annotation implicated Mecp2-mediated gene activation. LAVA detected two significant local genetic correlations between ALS and sFTD, involving ERGIC1 (chromosome 5) and SLC9A8/SPATA2 (chromosome 20).

Conclusion: This study highlights shared genetic architecture between ALS, sFTD, and cognitive traits, with 7 novel risk genes identified. While local genetic correlations confirmed prior findings, limitations in sFTD GWAS design and sample size restricted discovery of additional loci.

P18.107.B Genetic mapping of lifespan and mitochondrial stress response in *C. elegans*

Xiaoxu Li

École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland.

Background: The mitochondrial unfolded protein response (UPRmt) is one of the mito-nuclear regulatory circuits that can restore mitochondrial function upon a variety of stress conditions, improving metabolic health and extending lifespan. However, the complex gene interactions that influence this pathway and its relationship to aging and healthspan remain to be elucidated.

Material and Methods: Doxycycline (Dox) was applied to trigger mitochondrial stress in a worm genetic reference population with 85 *C. elegans* recombinant inbred advanced intercross lines (RIAILs). In this study, we assessed molecular profiles—transcriptome, proteome, metabolome, and lipidome—and life-history traits, including lifespan, development, growth dynamics, and reproduction.

Results: Here, we found that Dox-induced lifespan extension exhibited large variations within 85 strains. Using multi-omics integration, aging molecular signature was also uncovered, which can be partially reversed by Dox. To indicate the mechanisms underlying Dox-induced lifespan extension, we applied quantitative trait locus analyses and found one UPRmt modulator, *fipp-1/FIP1L1*, which was validated in *C.elegans* and humans. In human UK biobank, *FIP1L1* was also associated with metabolic homeostasis.

Conclusion: Overall, our findings demonstrate a novel UPRmt modulator across species and provide insights into potential translational research.

P18.108.C Decoding diversity in disease: a novel approach to scoring genes in polygenic and rare diseases for diagnostic insights

Aleksandra Suwalska[1], *Karolina Kulis*[1], *Walter Wolfsberger*[2], *Khrystyna Shchubelka*[2], *Ana Topf*[3], *Marie Vandroux*[4], *Sara Pini*[5], *Marco Savarese*[6], *Jocelyn Laporte*[4], *Volker Straub*[3], *Filippo M. Santorelli*[7], *Rossella Tupler*[5], *Taras Oleksyk*[2], *Joanna Polanska*[1]

[1]*Department of Data Science and Engineering, Silesian University of Technology, Gliwice, Poland,* [2]*Department of Biological Sciences, Oakland University, Rochester, MI, USA,* [3]*John Walton Muscular Dystrophy Research Centre, Translational and Clinical Research Institute, Newcastle Hospitals NHS Foundation Trust, Newcastle University, Newcastle Upon Tyne, United Kingdom,* [4]*Department of Translational Medicine and Neurogenetics, Institut de Génétique et de Biologie Moléculaire et Cellulaire, Illkirch-Graffenstaden, France,* [5]*Department of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy,* [6]*Folkhalsan Research Center, University of Helsinki, Helsinki, Finland,* [7]*Department of Molecular Medicine, IRCCS Fondazione Stella Maris, Pisa, Italy.*

Background: The diagnosis of numerous polygenic or rare conditions remains a significant challenge due to their complex and understudied aetiology. There is an urgent requirement to develop sophisticated computational tools that will facilitate understanding of the underlying molecular mechanisms.

Material and Methods: A gene scoring system was developed to quantitatively assess the impact of genomic variants, enabling the assessment of their contribution to diseases with unclear aetiology. The effectiveness of the gene scoring system was then tested on WES datasets from polygenic (type 1 diabetes T1DM, 2667 patients and 4529 controls, an ethnically homogenous

Ukrainian cohort) and rare diseases (neuromuscular diseases NMD, 884 patients and 70 controls from the British population), with scores compared using the Mann-Whitney U test and effect size calculated as rank biserial correlation coefficient. Gene set enrichment analysis (GSEA) was then performed, with genes being ranked based on the effect size.

Results: Genes with at least a small effect size were identified as associated with the studied diseases. For T1DM, the top genes included HLA-DRB5, HLA-DRB1, HLA-DQA1, HLA-DQB1, and LTA. The significantly highlighted pathways were strongly linked to immune response and T1DM development. In NMDs, the top enriched pathways include the extracellular matrix organisation, Notch signalling, and intracellular signalling by second messengers.

Conclusion: The proposed gene scoring effectively identifies critical genomic variations and associated pathways in both polygenic and rare diseases. The approach provides valuable insights into the molecular mechanisms, highlighting its potential to support accurate diagnosis and further research into disease pathogenesis.

Background: Inclusion Body Myositis (IBM) is a subtype of the heterogeneous idiopathic inflammatory myopathies (IIM) autoimmune disorders. IBM has a complex aetiology with a combination of inflammatory and degenerative aspects. This study was performed to be the first large scale genome-wide association study of patients with IBM.

Material and Methods: We analysed 1036 Caucasian IBM patient samples collected via the International Centre for Genomic Medicine in Neuromuscular Diseases framework and matched with 4240 samples from the Wellcome Trust Case Control Consortium (WTCCC) and the National Blood Survey cohort. Following quality control and imputation, single variant association testing was conducted using the Scalable and Accurate Implementation of Generalized Mixed Model (SAIGE). Further downstream analysis tests such as gene-set enrichment, pathway-analysis, co-localisation, and functional prediction were also performed.

Results: As with previous IIM GWAS studies the HLA locus DRB1 region was the most associated. A further four novel loci non-HLA loci passed genome-wide significance: AHRR, CD200, RMI2, and ORMDL3, as well as previous IIM associated loci PTPN22 and SH2B3/ATXN2. Further analysis found significant association with the genes SCHIP1, GSDMB and PDCD6. Functional annotation also found enrichment of the lead SNPs within regulatory elements in muscle and immune cell types.

Conclusion: We found strong associations and novel loci in IBM in muscular and immune cell types for both autoimmune and neurodegenerative pathways.

P18.110.A Data-processing pipeline to find and evaluate possible associations of tandem repeat alleles with ulcerative colitis

Ingrid Lojova[1,2,3], *Andrej Balaz*[1,4], *Marcel Kucharik*[1,2,4], *Jaroslav Minarik*[1,3], *Svatopluk Puterka*[5], *Juraj Gazdarica*[2,4,6], *Andrea Zatkova*[1], *Tatiana Sedlackova*[2,4], *Tomas Szemes*[2,3,4], *Jaroslav Budis*[2,4], *Jan Radvanszky*[1,2,3]

[1]*Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*Comenius University Science Park, Bratislava, Slovakia,* [3]*Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [4]*Geneton Ltd., Bratislava, Slovakia,* [5]*Institute of Informatics, Faculty of Informatics and Information Technologies of Slovak University of Technology, Bratislava, Slovakia,* [6]*Slovak Center of Scientific and Technical Information, Bratislava, Slovakia.*

Background: Complex diseases are influenced by several factors, including tens/hundreds of different genomic elements. Although conventional GWAS (genome-wide association studies) already identified SNVs (single nucleotide variants) linked to many diseases, tandem repeats (TRs) seem to contribute to disease susceptibility significantly. Fine mapping of TRs near already associated SNVs, therefore, offers a possibility to study genomic determination. We characterized TR motif variability in genomic loci associated with ulcerative colitis (UC).

Material and Methods: Our pipeline was developed and validated using a whole-genome sequencing dataset of 17 UC patients and 109 controls. It integrates in-house applications, including PolyRisk to define relevant SNVs, a python script to identify TR motifs within ±25 kbp of each SNV, Dante for TR genotyping, visualization and statistical comparisons.

Results: Based on specific filtering of GWAS-reported associations and polygenic score calculations, we selected 135 SNVs potentially relevant to UC in our patients. Within their ±25 kbp regions, we found 2015 TR motifs and characterized their nucleotide-scale variability and distribution patterns.

Conclusion: We have created a pipeline to find associations of TR alleles with UC. We found that TRs near UC-associated SNVs are variable, even with certain distribution differences between the studied groups. These loci may influence disease susceptibility, but further validation with larger cohorts and automated analyses is needed. Expanding this approach to additional complex diseases may enhance understanding of their genetic architecture.

P18.111.B The light within: architecture, health, circadian rhythms, and the power of omic science

*Nouha Bouayed Abdelmoula[1], Balkiss Abdelmoula[1], **Ellyssa Abdelmoula**[2]*

[1]Medical University of Sfax, Sfax, Tunisia, [2]Ecole Nationale d'Architecture et d'Urbanisme de Tunis, Tunis, Tunisia.

Background: In the context of anthropization of today, it is well-established that architectural design significantly affects the health and well-being of people living in cities.

Material and Methods: A comprehensive literature review was conducted by analyzing recent studies through academic databases to identify research exploring the relationship between architectural design, light exposure, and health outcomes, with a particular focus on circadian rhythm disruption.

Results: Our search revealed that Light is a powerful external signal for the circadian system. Its detection involves three types of photoreceptors in the retina particularly the specific type of ganglion cell (ipRGCs) that expresses a photosensitive pigment called melanopsin (Opn4), making them intrinsically photosensitive. IpRGCs are not involved in image perception but in the detection of ambient light influencing the circadian rhythm. Epidemiological studies have linked circadian disruption to an increased susceptibility to many diseases such as cancers. Studies exploring the connection between architecture, light, and circadian biology are rare. A recent study used a genome-wide gene-by-environment approach to examine how light affects genes linked to chronotype and circadian rhythms. It identified a light sensitivity locus in the ARL14EP gene, showing a genetic correlation between light sensitivity, a later chronotype, and an increased risk of PTSD and insomnia.

Conclusion: It appears that architectural design can affect the circadian biology of individuals by influencing their exposure to light, but further and more innovative research, such as using circadian transcriptional profiles and genome-wide gene-by-environment interaction studies, is needed.

P18.112.C Exploring the role of maternal epigenetic drift in spontaneous preterm birth

***Davide Sacco**[1,2], Luciano Calzari[3], Anna Maria Di Blasio[4], Giulia Zangheri[5], Fulvio Ferrara[6], Lucy Costantino[2], Michele Vignali[5], Davide Gentilini[1,3]*

[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, [2]Medical Genetics Laboratory, Centro Diagnostico Italiano, Milano, Italy, [3]Bioinformatics and Statistical Genomics Unit, Istituto Auxologico Italiano IRCCS, Cusano Milanino, Milano, Italy, [4]Molecular Biology Laboratory, Istituto Auxologico Italiano IRCCS, Cusano Milanino, Pavia, Italy, [5]Department of Biomedical Science for the Health, University of Milan, Macedonio Melloni Hospital, Milano, Italy, [6]Integrated Laboratory Medicine Services, Centro Diagnostico Italiano, 20147, Milano, Italy.

Background: Recent studies suggest maternal DNA methylation may influence preterm birth. However, epigenetic drift, defined as the accumulation of sporadic aberrations in the methylome, termed stochastic epigenetic mutations (SEMs), remains under-explored in maternal blood and its correlation with offspring.

Material and Methods: This study analyzed 35 mother-child pairs (PTB n = 18, Fullterm n = 17) using the Illumina Methylation 450k Array from maternal and cord blood. SEMs are extreme DNA methylation outlier values. Once identified, we used a logistic model to evaluate the global epigenetic drift between PTB and full-term groups, and SKAT test for gene-level drift.

Results: Maternal hypomethylated SEMs were significantly associated with PTB (FDR = 0.02, OR = 1.042, 95% CI: 1.017–1.084), indicating a 4.2% higher likelihood of PTB per unit increase in SEMs burden. SKAT identified 367 maternal PTB-associated genes, enriched in the focal adhesion pathway. In offspring, hypomethylated epigenetic drift was also higher in PTB infants, with SKAT identifying 45 genes, including KRT1 and TESK1, shared with maternal results.

Conclusion: Hypomethylated drift may contribute to PTB onset through gene alterations in the focal adhesion pathway, and disrupting this pathway can be associated with preterm labor. The shared drift in offspring could suggest a potential inheritance mechanism, predisposing preterm infants to long-term health risks. For instance, KRT1, a gene associated with keratinocyte-related diseases in newborns, shows evidence of maternal drift, suggesting that this shared drift could increase susceptibility to these conditions in preterm infants. Further studies with larger sample sizes are necessary to validate these findings.

Genome-wide association studies (GWASs) based on common single nucleotide polymorphisms (SNPs) have identified several loci associated with the risk of monoclonal gammopathy of unknown significance (MGUS), a precursor condition for multiple myeloma (MM). We hypothesized that analyzing haplotypes might be more useful than analyzing individual SNPs, as it could identify functional chromosomal units that collectively contribute to MGUS risk. To test this hypothesis, we used data from our previous GWAS on 992 MGUS cases and 2910 controls from three European populations. We identified 23 haplotypes that were associated with the risk of MGUS at the genome-wide significance level ($p < 5 \times 10-8$) and showed consistent results among all three populations. In 10 genomic regions, strong promoter, enhancer and regulatory element-related histone marks and their connections to target genes as well as genome segmentation data supported the importance of these regions in MGUS susceptibility. Several associated haplotypes affected pathways important for MM cell survival such as ubiquitin-proteasome system (RNF186, OTUD3), PI3K/AKT/mTOR (HINT3), innate immunity (SEC14L1, ZBP1), cell death regulation (BID) and NOTCH signaling (RBPJ). These pathways are currently important therapeutic targets for MM, which may highlight the advantage of the haplotype approach homing to functional units.

Background: Genome-wide association studies (GWAS) and single cell RNA-seq provide essential data for genetic cell-type mapping. Integrating these data enables understanding genetic variation at the cell-type level. However, no standards exist for evaluating methods that infer how genetic variation influences traits using cell-type-resolved transcriptomes.
