P01 Cancer Genetics

P01.001.A Human synonymous codon variation is constrained within multivalent coding regions (Award Candidate)

Rhys Dore[1], *Jernej Ule*[1,2]

[1]*King's College London, London, United Kingdom,* [2]*The Francis Crick Institute, London, United Kingdom.*

Background: Cellular homeostasis hinges on precise protein dosage control, particularly for proteins harbouring disordered low complexity domains (LCDs). We recently reported a new regulatory mechanism termed 'interstasis', facilitating mutual dosage regulation of LCD-containing proteins. Interstasis leverages multivalent CDS regions encoding LCDs, which stems from the repetitive amino acid arrangement, similarity of codons for biophysically akin amino acids, and conserved synonymous codon biases. Specific RNA-binding proteins bind to multivalent RNA regions and orchestrate the interstasis through feedback regulation of mRNAs encoding LCD-containing proteins.

Materials and methods: Exploring the impact of RNA multivalency on human genetic variation in coding regions, we analysed common polymorphisms from dbSNP. Additionally, we similarly explored somatic variation in cancer using data from Cosmic.

Results: For germline human variation, we found that the more multivalent a CDS region is, the greater the relative synonymous constraint - i.e. the less variation is tolerated in synonymous relative to non-synonymous variation. In cases such as arginine that contains 6 possible codons, human synonymous variation tends to maintain high RNA multivalency by mimicking the codons of other nearby amino acids.For somatic variation in cancer, multivalent regions exhibited increased relative synonymous variation in Cosmic as compared to dbSNP, and we identified transcripts with particularly high rates of multivalence-disrupting synonymous variants as candidates for further study.

Conclusion: Our findings underscore the importance of synonymous constraint patterns linked to RNA multivalency in LCDs. This opens new opportunities for future investigations to explore the contribution of these constraints for the interstasis-mediated dosage control of LCD-containing proteins.

P01.002.B A germline and somatic mutation sorting (GeMSort) algorithm for extracting presumed germline pathogenic variants in liquid genomic profiling: insights from C-CAT database

Satoyo Oda[1], *Manami Matsukawa*[1], *Chikako Tomozawa*[1], *Noriko Tanabe*[2], *Tomoko Watanabe*[1], *Takafumi Koyama*[1], *Teruhiko Yoshida*[1], *Makoto Hirata*[1]

[1]*National Cancer Center Hospital, Tokyo, Japan,* [2]*Saitama Medical Center, Saitama, Japan.*

Background: Liquid biopsy comprehensive genomic profiling (CGP) testing is performed on circulating tumor DNA to identify somatic variants with the aim of determining therapeutic strategies. Pathogenic variants of germline origin in genes

associated with hereditary tumor syndromes can be simultaneously detected using this test. Nonetheless, it is often challenging to differentiate whether the variants are of somatic or germline origin. The differentiation criteria were primarily based on the allele frequencies of the variants (VAF). However, more evidence is needed to establish clear criteria, and it is often difficult to differentiate the origin of variants based on VAF alone.

Material and methods: In this study, using the national database of the Center for Cancer Genomics and Advanced Therapeutics (C-CAT), which accumulates real-world data on CGP testing in Japan, we analyzed 169,370 variants detected in 11,399 patients registered with FoundationOne Liquid CDx testing.

Results: By extracting the predominantly presumed somatic and germline variants, we established a criterion for VAF that could achieve high specificity and sensitivity. Further investigation into the detection status of other variants led to the development of an algorithm for differentiating somatic/germline variants of genes associated with hereditary tumor syndromes. Based on this algorithm, 726 variants were extracted as presumed germline pathogenic variants among the genes with high germline conversion rates in 710 patients.

Conclusion: This algorithm should help to discriminate with high accuracy whether the variants detected in liquid CGP tests are of somatic/germline origin, although further analyses are required to confirm the validity of this algorithm.

P01.003.C STAG2 as a new player in medulloblastoma: in vitro and in vivo models

Antonella Lettieri, *Silvia Castiglioni, Simona Totaro, Silvia Rasetti, Elisabetta Di Fede, Chiara Parodi, Paolo Grazioli, Elisa A. Colombo, Esi Taci, Thomas Vaccari, Cristina CG Gervasini, Valentina Massa*

Università degli Studi di Milano, Milano, Italy.

Background: Medulloblastoma (MB) is a cerebellar embryonic tumor, probably due to neural progenitor impaired differentiation. However, the underlying genetics and predisposing factors are still unclear. The cohesin complex role in cerebellum development, gene expression regulation, and DNA signaling repair suggest this structure as a possible oncogenic candidate. Among cohesins, STAG2 is the most frequently affected in cancers, and its loss of function is believed to promote tumorigenesis by altering DNA architecture.

Material and methods: We studied the impact of *STAG2* silencing on cell functioning and DNA damage in 2D and cell spheroid models. Then, we exploited 3D cerebellum organoids to study the effect of *STAG2* deficiency on its development. Last, the in vivo fly model obtained by *SA1* silencing, the ortholog of *STAG2*, was characterized to assess tumor-related phenotypic features by investigating neural precursors differentiation and flies' viability.

Results: In vitro, we highlighted that: (1) *STAG2*-deficient cells present increased DNA damage and (2) *STAG2*-silenced cerebellum organoids exhibit a deregulated expression of genes related to cerebellar development. In vivo, we showed a defective differentiation of neuroblasts during larvae development and mass formation within adult fly brains with a lowered life expectancy consistent with the malignant phenotype.

Conclusion: These models not only aim at unveiling the contribution of STAG2 in promoting MB tumorigenesis but will also represent a basis for testing possible targeted therapies, such as PARP inhibitors, recently implemented in trials for tumors carrying cohesin variants and shown to be more effective in cases with altered DNA signaling repair.

P01.004.D Identification of methylation-based Wilms tumour signatures to recognise children with underlying genetic predisposition

Franziska Oberhammer[1], *Sophie E. van Peer*[1], *Freerk van Dijk*[1], *Ronald R. de Krijger*[1,2], *Marry M. van den Heuvel-Eibrink*[1], *Marjolijn C. Jongmans*[1,3], *Lennart A. Kester*[1], *Roland P. Kuiper*[1,3]

[1]*Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands,* [2]*Department of Pathology, University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Department of Genetics, University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Recognising cancer predisposition in paediatric oncology is crucial, as it may impact diagnosis, treatment, and surveillance. Approximately 10% of childhood cancers have an underlying predisposition, reaching up to 30% in Wilms tumours (WT). Identifying predispositions remains challenging due to the large number of (epi)genetic factors, phenotypic variability, and potential mosaicism. Tumours sharing a genetic predisposition often exhibit common somatic signatures, including DNA methylation patterns. We hypothesise that these somatic molecular patterns can identify specific types of underlying predisposition, independent of phenotypic presentation.

Material and methods: We performed unsupervised hierarchical clustering of DNA methylation data in a cohort of 139 WT patients with known predispositions. For 121 patients, matching RNA-seq data were available, and for 105 patients, whole genome sequencing data were included to correlate molecular patterns with genetic aberrations.

Results: Five distinct methylation subgroups were identified. One subgroup included all samples with pathogenic germline *WT1* variants (7/7, 100%) and most samples with somatic *WT1* aberrations (9/11, 81%), along with additional pathogenic *CTNNB1* variants. Patients diagnosed with Beckwith-Wiedemann spectrum were predominantly distributed across two other subgroups. These findings suggest that specific WT subtypes are associated with distinct molecular and genetic features, which can aid in preselecting cases for genetic referral.

Conclusion: Our findings provide proof-of-principle for a tumour-first approach using methylation data to identify WT predispositions. Future efforts will focus on developing a classifier based on these insights for integration into routine diagnostics, enabling efficient identification of patients with a predisposition for WT development.

P01.005.A Comparative analysis of *BRCA* pathogenic variant testing: first nation-wide population screening program versus genetic counseling

Rachel Michaelson-Cohen[1], *Ephrat Levy-Lahad*[2], *Ariela Tomer*[2], *Shunit Armon*[1], *Naama Srebnik*[1], *Sari Lieberman*[3]

[1]*Shaare Zedek Medical Center, faculty of Medicine, Hebrew University, Jerusalem, Israel,* [2]*Shaare Zedek Medical Center,*

Jerusalem, Israel, [3]Shaare Zedek Medical Center, faculty of Medicine, Hebrew University, JERUSALEM, Israel.

Background: Israel recently initiated the first nation-wide population screening (PS) program for *BRCA* pathogenic variants (PVs), which is expected to reduce morbidity and mortality. However, implementation presents unique challenges. We aimed to compare characteristics, risk-reducing actions and psychosocial outcomes of PS vs. carriers identified following onco-genetic counselling (GC).

Materials and methods: All healthy *BRCA1/2* PV carriers identified 2021–2024 attending the high-risk surveillance-clinic in Shaare-Zedek Medical-Center; data collected from medical records and psychosocial and knowledge-assessment questionnaires.

Results: Women were referred to PS by gynecologists (41.7%), breast-surgeons (17.7%) or family-practitioners (6.2%). PS group included 202 women; GC group 150. Table compares characteristics, risk-reducing measures, and psychosocial outcomes. Mean age (37.6yrs ± 11) and college-level education (82.8%) were comparable between groups. PS carriers were less likely to have cancer family history, (30.4% vs. 72.7% $p < 0.001$), and more likely to have a *BRCA2* (vs. *BRCA1*) PV than GC (62.9% vs. 48.7%, $p = 0.01$). Risk-reducing-salpingo-oophorectomy (RRSO) rates at the recommended age were similar between groups, in PS carriers: *BRCA1* ≥ 40yrs: 79.2%, *BRCA2* ≥ 45yrs: 81.4%. Both groups reported high general satisfaction, but PS reported slightly lower satisfaction with pretest information, delivery of results, and health decision. Groups had similar perceived control (PPC), distress (IES) anxiety (STAI), and knowledge scores. In multivariate-analysis, there were no significant differences in psychosocial outcomes.

Conclusion: This first nation-wide *BRCA*-PS resulted in actionable measures with high uptake of RRSO and demonstrates favorable psychosocial outcomes. The data provides support for PS, but refinement and long-term evaluation are necessary.

	Population screening $n = 202$ *n* (%) or (mean ± SD)	**Genetic counseling $n = 150$ *n* (%) or (mean ± SD)**	**Total $n = 352$ n (%) or (mean ± SD)**	***p*-value**

P01.006.B Optical genome mapping in hematological malignancies: is it time for conventional cytogenetic approaches to stand aside?

Chiara Mongodi, *Alessandra Crottini, Monica Pingue, Barbara Facchinetti, Lucrezia Goisis, Camilla Lucca, Daniela Marchetti, Paolo Fruscella, Pierfrancesca Comi, Sara Mingotti, Marco Palmieri, Matteo Bellini, Maria Iascone, Laura Pezzoli*

Laboratory of Medical Genetics, ASST Papa Giovanni XXIII, Bergamo, Italy.

Background: Chromosomal aberrations characterization in onco-hematology is performed by Conventional Cytogenetic Techniques (CCT), often sequentially required to complete the diagnostic workflow. Optical Genome Mapping (OGM) is an innovative technology that analyzes ultra-high molecular weight DNA to detect chromosomal aberrations with high resolution. Our study evaluates OGM application in hematological malignancies diagnostic routine.

Material and methods: We analyzed 18 samples from patients with hematological malignancies, including 10 chronic lymphocytic leukemia (CLL), seven acute myeloid leukemia (AML), and one chronic myeloid leukemia (CML).

Results: Using SaphyrTM, OGM analysis takes 4–6 working days for six samples. Twelve samples completed the study, while six samples failed during the process. OGM analysis confirmed the presence of all the abnormalities (aneuploidies, deletions and translocations) found using CCT. In addition, OGM made it possible to characterize abnormalities underrepresented in the sample (VAF 6%), to define the genetic origin of additional chromosomal material, and to detect complex abnormalities such as marker chromosomes and chromothripsis events.

Conclusion: Our data show complete concordance between OGM and CCT results. Since CCT includes karyotype and FISH panels for CLL, OGM is cost-effective regarding analysis time and operator dependency. However, for AML and CML at the onset, OGM may not be cost-effective because it is not compliant with guideline reporting requirements. OGM has the potential to improve the detection of chromosomal abnormalities, making it particularly suitable for the characterization of hematologic malignancies. Further standardization and automation of OGM protocols are essential to make them applicable to diagnostic routines.

P01.007.C Multi-locus inherited neoplasia allele syndrome (MINAS): prevalence and phenotype in the German Consortium of Hereditary Breast and Ovarian Cancer

Natalie Herold[1], *Bernd Auber*[2], *Susanne Morlot*[2,3], *Marion Kiechle*[4], *Jan Hauke*[1], *Bahriye Aktas*[5], *Kerstin Rhiem*[1], *Cornelia Meisel*[6], *Dorothee Speiser*[7], *Christoph Engel*[8], *Eric Hahnen*[1], *Rita Schmutzler*[1], *Monika M. Golas*[9,10]

Background: Next generation sequencing in families with hereditary breast and ovarian cancer (HBOC) has increased the detection of individuals with a MINAS. However, data on triple-heterozygous (TH) pathogenic variant (PV) carriers remain limited. Large registry studies are necessary to determine genotype-phenotype correlations, assess cancer risks, and develop personalized prevention recommendations for MINAS.

Materials and methods: We searched the database of the German Consortium (GC) of HBOC for individuals with a co-occurrence of two or more PVs in the GC-HBOC gene panel that comprises cancer predisposition genes for HBOC and candidate genes. We analyzed the genotypes and phenotypes of index patients and family members.

Results: In a cohort of over 26,000 PV carriers, we identified 409 individuals with two or more PVs. Among these, twelve individuals from seven families carried three PVs. All TH individuals carried PVs in at least one of the genes *BRCA1*, *BRCA2*, or *CHEK2*, in part combined with PVs in other genes, reflecting the prevalence of single heterozygotes in the database. Genotypes and phenotypes of TH individuals are shown in Table 1.

Conclusion: In summary, the database proved to be a valuable tool for genotype-phenotype correlation. Critical evaluation of counselees' pedigrees and consideration of multiple PVs is crucial, especially when cancer cases occur in both hereditary lines. Future studies, in which both index persons and their family members are examined using gene panels, may enable comprehensive identification of individuals with MINAS, leading to more personalized prevention methods.

Genotype and phenotype of TH individuals. BC breast cancer, OC ovarian cancer, incl. candidate genes

Family	Gene 1	Gene 2 including candidate gene *NBN*	Gene 3 including candidate gene *FANCM*	Sex	Index	Phenotype of TH individual (age in years)

Background: Diagnostic analysis of mRNA is essential, as altered splicing is a frequent cause of genetic diseases. High throughput splicing studies remain challenging to implement in routine diagnostics. To address this, we developed SEALigHTS (splice and expression analyses by ligation and high throughput sequencing), a rapid and cost-effective RT-MLPA-derived technique applicable on easily accessible samples for simultaneous panel RNA analysis of multiple patients, using probes designed at exon extremities.

Material and methods: After reverse transcription and probing on cDNA, neighbouring probes are ligated, sequenced by NGS and quantified using unique molecular identifiers. We designed a panel covering 42 genes (2,195 probes) implicated in breast and/or ovarian, colorectal cancer and polyposis predispositions. We studied 37 highly evocative patients and initiated the multicenter prospective project STRATEGIC, designed to include 1,000 consecutive patients suspected of a cancer predisposition. This protocol aims to evaluate the added value of systematically combining RNA and DNA analyses in routine practices.

Results: Following a training phase on 40 samples, SEALigHTS was validated in another laboratory on 56 samples carrying splicing variants previously characterized by RNAseq, achieving 96% sensitivity and 94% specificity. Preliminary results in highly evocative and the first 120 STRATEGIC patients underscore the significant contribution of RNA analysis with 7 new diagnoses total, including detection of deep intronic variants, reclassification of a duplication, identification of splicing variants poorly predicted by in silico tools.

Conclusion: These findings highlight the potential of SEALigHTS to enhance genetic diagnostics and improve our knowledge on variant typically overlooked at the RNA level.

P01.010.B Homologous recombination deficiency is uncommon in the cancers from children with heterozygous germline pathogenic *BRCA1*, *BRCA2* or *PALB2* variants

***Lianne C. Suurenbroek[1]**, Michelle M. Kleisman[1], Anne S. Blokland[1], Stavros Glentis[2], Agata Pastorczak[3], Ninad Oak[4], Kim E. Nichols[4], Kristian W. Pajtler[5], Steffen Hirsch[5,6], Robert J. Autry[5], Marjolijn C.J. Jongmans[1,7], Roland P. Kuiper[1]*

[1]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, [2]First Department of Pediatrics, National and Kapodistrian University of Athens, Athens, Greece, [3]Department of Genetic Predisposition to Cancer, Medical University of Łódź, Łódź, Poland, [4]Department of Oncology, St. Jude Children's Research Hospital, Memphis, TN, USA, [5]Hopp Children's Cancer Center (KiTZ), Heidelberg, Germany, [6]Institute of Human Genetics, University Hospital Heidelberg, Heidelberg, Germany, [7]Department of Genetics, University Medical Center Utrecht, Utrecht, Netherlands.

Background: In 5–15% of pediatric cancer cases, a germline pathogenic variant (gPV) in a cancer predisposing gene can be identified. For some genes, biallelic variants are known to cause pediatric cancer, whereas heterozygous variants are associated with adult cancer. Examples include *BRCA1*, *BRCA2* and *PALB2*, which play a role in homologous recombination (HR). Although previous studies have claimed enrichment of gPVs in *BRCA1* and *BRCA2* in pediatric cancer, it is unclear how often these variants cause tumour initiation.

Material and methods: We analysed indicators of causality, including somatic second hits and mutational footprints associated with HR deficiency (HRD), in whole genome sequencing (WGS) data of pediatric cancers with a heterozygous gPV in *BRCA1*, *BRCA2* or *PALB2* (n = 49), and in 7 cases of *BRCA2*-associated Fanconi anaemia (FA) as positive controls. Additionally, the CHORD classifier was applied, which integrates single base substitutions (SBSs), insertions/deletions (indels) and structural variants into a single HRD prediction. An unselected WGS control cohort of 653 pediatric tumours was included.

Results: In only one osteosarcoma case with a gPV in *BRCA2* did we identify a somatic second hit. SBS signature SBS3 was found in 32% of control cases and thus appeared unsuitable for HRD detection. Indel signature ID6 and CHORD confidently showed signs of HRD in this osteosarcoma and the FA cases, but not in the other samples.

Conclusion: HRD due to a somatic second hit was found in one osteosarcoma but appears to be rare in pediatric cancer patients with heterozygous gPVs in *BRCA1*, *BRCA2* or *PALB2*.

P01.011.C Cancer risks for *MSH6* pathogenic variant carriers

Anne-Sophie van der Werf – 't Lam[1], *James G. Dowty*[2], *Morrison Italia*[2], *Astrid C. Bakker*[1], *Fernande C.H.A. Koops*[1], *Fonnet Bleeker*[3], *Encarna Gomez Garcia*[4], *Liselotte P. van Hest*[5], *Hans J.P. Gille*[5], *Mirjam M. de Jong*[6], *Tom G.W. Letteboer*[7], *Floor A.M. Duijkers*[7], *Anja Wagner*[8], *Ellis L. Eikenboom*[8], *Christi J. van Asperen*[1], *Sanne W. ten Broeke*[6], *Aung K. Win*[2], *Mark A. Jenkins*[2], *Maartje Nielsen*[9]

[1]*Leiden Universiity Medical Center, Leiden, Netherlands,* [2]*The University of Melbourne, Melbourne, Australia,* [3]*Netherlands Cancer Institute, Amsterdam, Netherlands,* [4]*Maastricht University Medical Center, Maastricht, Netherlands,* [5]*Amsterdam UMC, location Vrije Universiteit Amsterdam and location University of Amsterdam, Amsterdam, Netherlands,* [6]*University Medical Center Groningen, Groningen, Netherlands,* [7]*University Medical Center Utrecht, Utrecht, Netherlands,* [8]*Erasmus MC Cancer Institute, University Medical Center Rotterdam, Rotterdam, Netherlands,* [9]*Leiden University Medical Center, Leiden, Netherlands.*

Background: Lynch syndrome (LS) is a hereditary cancer syndrome caused by (likely) pathogenic variants (LP/P) in DNA mismatch repair genes, including *MSH6*. It is associated with elevated lifetime risks for colorectal cancer (CRC), endometrial cancer (EC), and other malignancies. However, cancer risks specific to *MSH6*-associated LS, particularly for non-colorectal cancers, remain poorly defined. This study aims to provide refined cancer risk estimates for individuals with *MSH6* LP/P.

Material and methods: We conducted a retrospective cohort study of 360 families with 1118 known *MSH6* LP/P carriers identified in the Netherlands between 1995 and 2020. Pedigree data were collected from multiple clinical centers, and cancer diagnoses were confirmed through medical records. Age- and sex-specific hazard ratios (HRs) and cumulative risks (CRs) were estimated using segregation analysis, appropriately adjusted for ascertainment.

Results: CR by age 80 for *MSH6* LP/P carriers were 36% in males (95% CI:25–48%) and 21% in females (95% CI 13–32%) for CRC, and 23% in females (95% CI:15–43%) for EC. Elevated risks were observed for ovarian cancer (OC) (6.4%, 95% CI:3–14.8%; HR 5.58, p = 0.00037), urinary tract cancers (10.1% in males, 4.1% in females; HR 2.52, p = 0.012), and biliary tract cancers (4.9% in males, 4.2% in females; HR 2.76, p = 0.031). No increased risks were identified for prostate or breast cancer.

Conclusion: This study refines cancer risk estimates for MSH6 LP/P carriers, suggesting the need for delayed CRC screening in males and females and proactive discussions regarding prophylactic surgery for females to address elevated risks for EC and OC.

P01.012.D Identification of cancer somatic mutations in miRNA genes

Paulina Galka-Marciniak[1], *Martyna Urbanek-Trzeciak*[1], *Natalia Szostak*[1], *Adrian Tire*[1], *Paulina Nawrocka-Muszynska*[1], *Katarzyna Chojnacka*[1], *Daniel Kuznicki*[1], *Malwina Suszynska*[1], *Marzena A. Lewandowska*[2], *Laura Susok*[3], *Anna Philips*[1], *Michael Sand*[3], *Jolanta Jura*[4], *Katarzyna Klonowska*[1], *Magdalena Ratajska*[5], *Hanna Dams-Kozlowska*[6], *Piotr Kozlowski*[1]

[1]*Institute of Bioorganic Chemistry Polish Academy of Sciences, Poznan, Poland,* [2]*The Ludwik Rydygier Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland,* [3]*Ruhr-University Bochum, Bochum, Germany,* [4]*Jagiellonian University, Cracow, Poland,* [5]*Medical University of Gdansk, Gdansk, Poland,* [6]*Poznan University of Medical Sciences, Poznan, Poland.*

Background: miRNAs are noncoding RNAs that play an important role in cancer, acting as tumor suppressors or oncogenes. Although thousands of somatic mutations, including numerous cancer-driving mutations, have been identified in protein-coding sequences, very little is still known about cancer somatic mutations in miRNA genes. The delay in this area results mainly from the lack of appropriate tools and experimental approaches dedicated to the analysis of noncoding elements, including miRNA genes.

Material and methods: We developed Whole MIRnome Sequencing (WMS), a new Next Generation Sequencing (NGS)-based platform, dedicated to targeted sequencing of all miRNA genes and a panel of genes playing a role in miRNA biogenesis and functioning. We used OncodriveFML to analyze the pattern of somatic mutations and detect signals of positive selection to reveal candidate cancer drivers.

Results: Using WMS, we sequenced, with high coverage (>700x), ~280 cancer samples of different cancer types, including fresh frozen and degraded FFPE samples. We identified 1,272 cancer somatic mutations, whose reliability was confirmed by several alternative methods. Many of the mutations were located in functional regions of cancer-related miRNA genes such as *MIR1*, *MIR101*, *MIR139*, *MIR146B*, and *MIR34C*. We also identified several overmutated miRNAs and one potential miRNA driver gene, *MIR3928*, specifically mutated in basal cell carcinoma (BCC).

Conclusion: WMS is a cost-effective and sample-saving tool for identifying germline and somatic mutations in miRNA genes in different types of samples. Our proof-of-concept experiment demonstrated that WMS may provide data for identifying potential cancer drivers and characterizing miRNA genes of interest.

P01.013.A Subclass dependent biomarkers involved in uveal melanoma progression, cell plasticity and metastatic risk

Erwin Brosens, *Quincy C.C. van den Bosch, Jolanda Vaarwater, Frank Magielsen, Thierry P.P. van den Bosch, Rob M. Verdijk, Emine Kilic*

ErasmusMC, Rotterdam, Netherlands.

Background: Uveal Melanoma (UM) is an aggressive cancer originating from melanocytes in the uveal tract. Despite extensive research, the survival rate for metastatic UM has not significantly improved. To date, there are at least five subclasses, each with unique survival patterns and genomic profiles. We aimed to identify subclass-specific biomarkers, validate their oncogenic relevance, and evaluate candidates in their spatial context.

Material and methods: Biomarkers were identified in two independent in-house multi-omics datasets and validated in three additional validation cohorts. Cell proliferation, motility, and morphology were investigated after knock-out or overexpression in UM cell lines and dissemination and tumor volume in xenograft zebrafish experiments. We evaluated the spatial context of biomarker expression in high, intermediate, and low-risk whole tumor and tissue microarray slides.

Results: We identified and validated several potential oncogenic biomarkers, including six transcription factors (ELL2, KDM5B, REXO4, COL9A3, RBFOX2, and FOXD1) in high-risk UM and six transcripts (ABHD6, CSRNP1, BTG2, DHX16, and TAGLN) that differentiate between intermediate-high and intermediate-low risk. In-vitro and in-vivo experiments of biomarkers (FOXD1, RBFOX2, COL9A3) show effects on cell morphology, attachment, and proliferation in high-risk cells, increased levels of plasticity markers, reduced tumor volume and cell dissemination and a more aggressive behaviour in vitro and in vivo.

Conclusion: Metastatic risk is influenced by genetic and transcriptional drivers. Our in-vitro and in-vivo experiments underscore the oncogenic relevance of these drivers. We are currently correlating spatial differences and the microenvironment of cells expressing these drivers to better understand the impacted regulatory mechanisms.

P01.014.B TP53 p.R181H is associated with a distinct phenotype enabling personalized clinical handling (Award Candidate)

Alexander Sun Zhang[1], *Meis Omran*[1], *Cecilia Arthur*[1], *Helena Malmgren*[1], *Rita Barbosa-Matos*[2], *Susana Seixas*[2], *Carla Oliveira*[2], *Emma Tham*[1], *Svetlana Bajalica Lagercrantz*[1]

[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*University of Porto, Porto, Portugal.*

Background: Heritable *TP53* related cancer syndrome, also known as Li-Fraumeni Syndrome (LFS), is a severe cancer predisposition syndrome caused by germline variants in the *TP53* tumor suppressor gene. Due to the broad tumor spectrum, clinical management and cancer surveillance are challenging. Currently, all LFS patients undergo a standardized surveillance program, including whole-body magnetic resonance imaging (MRI), regardless of their specific *TP53* variant. The *TP53* variant p.R181H is particularly prevalent in the Swedish LFS cohort, and carriers may benefit from a more personalized approach to clinical management and surveillance.

Material and methods: We analyzed genomic and clinical data from the Swedish nationwide germline *TP53* database (SWEP53), including 189 individuals from 86 families. Our study assessed cancer incidence, tumor type and survival rates. Additionally, we performed haplotype analysis to investigate whether p.R181H is a founder variant.

Results: The p.R181H variant was present in 22% of all Swedish g*TP53* families (19 of 86) and is a potential Swedish founder. Compared to carriers of other *TP53* variants, individuals with p.R181H had lower cancer incidence ($p < 0.0001$) and longer survival ($p < 0.0001$). Adult female carriers primarily developed breast cancer, with the earliest onset occurring at 29 years old, and no cases of childhood cancers (<18 years) were observed in the cohort.

Conclusion: Carriers of germline *TP53* variant p.R181H could benefit from targeted surveillance with exclusively breast MRI and children should not be tested until adulthood.

P01.015.C Impact of optical genome mapping in acute leukemia diagnosis - insights following one-year of clinical deployment as a first-line diagnostic test

Julia NC Parlow[1], *Zeid Hamadeh*[1,2], *Eric McGinnis*[1,2], ***Tara Spence***[1,2]

[1]*Cytogenomics Laboratory, Department of Pathology and Laboratory Medicine, Vancouver General Hospital, Vancouver, BC, Canada,* [2]*Department of Pathology and Laboratory Medicine, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada.*

Background: With the clinical implementation of optical genome mapping (OGM) as a first-line diagnostic test for newly diagnosed acute leukemias in November 2023, our lab underwent a transformative shift in standard-of-care (SOC) testing. Here, we present our one-year experience with test deployment and prospectively evaluated clinical utility.

Materials and methods: One year following clinical implementation, 158 adults with acute leukemia were profiled by OGM, including 113 AML/high-grade myeloid neoplasms, 34 B-ALL, 7 T-ALL, and 4 mixed phenotype or undifferentiated acute leukemias. Performance metrics were monitored, including quality control (QC) success rate, analytic performance and added clinical yield against parallel karyotype and FISH testing.

Results: We demonstrate 80% (127/158) first-pass and 100% overall QC success rates. Of 248 variants detected by karyotype/FISH, 245 were concordantly detected by OGM (sensitivity 98.8%). In 158 cases, we reported over 483 variants (average ~3/case), including 269 tier-1A/B variants. A reportable finding by OGM was identified in 32% (25/77) cases identified as normal/failed by karyotype, including 40% (10/25) having a tier-1A variant. We

identified 24% (38/158) cases with added clinical yield, whereby a tier-1A/1B/2 finding was not identified by SOC, including 9.5% (15/158) cases with significantly altered classification/diagnoses primarily due to identification of clinically relevant rearrangements.

Conclusion: OGM has demonstrated striking clinical utility, uncovering diagnostically and prognostically significant alterations previously cryptic by low resolution analyses. With extensive planning, thorough training, engagement of clinical partners and conservative retention of parallel karyotype testing, implementation of this novel technology has been feasible and clinically impactful to our patient population.

P01.016.D Characterisation of copy number variants with a multigene NGS panel in hereditary cancer patients, reveals a distinctive *PALB2* contribution to the diagnostic yield

Elena Tenedini[1,2], *Lia Bonamici*[1], *Lucia Artuso*[2], *Marco Marino*[2], *Angela Toss*[1,3], *Elena Barbieri*[3], *Marta Venturelli*[1,3], *Isabella Marchi*[3], *Rossella Manfredini*[4], *Massimo Dominici*[1,3], *Laura Cortesi*[1,3], *Enrico Tagliafico*[5]

[1]*Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, Modena, Italy,* [2]*Diagnostic Hematology and Clinical Genomics Unit, Department of Laboratory Medicine and Pathology, Modena University Hospital, Modena, Italy,* [3]*Oncology Unit, Department of Oncology and Hematology, University Hospital of Modena, Modena, Italy,* [4]*Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy,* [5]*Department of Medical and Surgical Sciences, University of Modena and Reggio Emili, Modena, Italy.*

Background: The use of Next Generation Sequencing multi-gene panels has led to the identification of numerous genetic variants associated with breast, ovarian, and pancreatic cancer. Despite these advancements, many DNA alterations remain under characterized. Copy Number Variations (CNVs), defined as deletions and duplications of specific DNA regions, account for up to 10% of pathogenic variants and can occur in any gene tested in routine diagnostics. However, CNVs results in cancer-predisposing genes beyond *BRCA1* and *BRCA2*, such as *PALB2*, remain limited.

Material and methods: This study analyzed data from 2949 patients, primarily affected by breast or ovarian cancer, who underwent diagnostic testing with a 22-gene hereditary cancer panel between 2018 and 2023, with a focus on CNVs data.

Results: Aligned with comparison studies a total diagnostic yield of 14.8% was observed, with pathogenic variants in *BRCA1*, *BRCA2*, *CHEK2*, *ATM*, and *PALB2* accounting for over half of the positive findings. In contrast, CNVs were found in 1.4% of patients, displaying a peculiar distribution pattern. *PALB2* exhibited the highest frequency of pathogenic CNVs (66.7%) and these alterations represented 62.2% of all *PALB2* pathogenic variants. Notably, 24/28 *PALB2* CNV carriers shared an identical pathogenic exon 11 deletion. Further investigations revealed common breakpoints and origin among patients, suggesting that geography may have shaped genetic variability in the cohort.

Conclusion: These data provide insights into the relevance of CNVs detection, which can provide valuable information in variant-associated cancer risk assessment and reveal distinctive patterns of variant prevalence and distribution across different regions and ethnic groups.

E. Tenedini: None. **L. Bonamici:** None. **L. Artuso:** None. **M. Marino:** None. **A. Toss:** None. **E. Barbieri:** None. **M. Venturelli:** None. **I. Marchi:** None. **R. Manfredini:** None. **M. Dominici:** None. **L. Cortesi:** None. **E. Tagliafico:** None.

P01.017.A Impact of *TET2* mutations on clinicopathological features and therapy response in 889 sporadic colorectal cancers

Simone G. De Micco[1], *Michela Tulino*[1], *Federico Manai*[1], *Ivan Dorna*[2], *Rossella Tricarico*[1]

[1]*Department of Biology and Biotechnology "L. Spallanzani", University of Pavia, Pavia, Italy,* [2]*Anthilla srl, Caronno Pertusella, Italy.*

Background: TET2 is a DNA demethylase critical for maintaining epigenomic stability and a known tumor suppressor in hematologic malignancies. Colorectal cancer (CRC) is characterized by genomic and epigenomic instability, which drives tumorigenesis. Studies in mice have revealed that *TET2* loss promotes inflammation, a key driver of CRC development. Emerging evidence suggests that *TET2* plays a role in modulating responses to cancer therapies. However, its contribution to CRC pathogenesis and therapeutic outcomes remains poorly defined.

Material and methods: We analyzed 889 primary CRC samples from the AACR GENIE Biopharma Collaborative CRC 2.0 dataset, containing genomic and phenomic data. An in-house computational pipeline identified *TET2* mutations (SNVs and Indels) and evaluated associations with clinicopathological features, co-occurring mutations, pathways, and therapy outcomes. Statistical analyses included Fisher's exact tests (Benjamini-Hochberg correction) and log-rank tests. Pathway enrichment focused on co-occurring mutations.

Results: *TET2* mutations were identified in 6.4% of CRCs, predominantly as missense (81.9%). These mutations were significantly associated with stage II, grade II, right-sided tumors, and MSI-High status (all $p < 0.05$). Co-occurring mutations, such as *POLE* and *POLD1* (adj $p < 0.05$), are usually linked to increased mutational burden, while enrichment in DNA damage response and chromatin remodeling pathways suggests roles in modulating chemosensitivity. Patients with *TET2*-mutated tumors showed significantly improved overall survival compared to wild-type, both with FOLFOX treatment ($p < 0.05$) and without it ($p = 0.021$).

Conclusion: *TET2* mutations are associated with a CRC subset characterized by specific clinicopathological features and favorable survival outcomes. Validation on larger cohorts is ongoing.

P01.018.B Genetic landscape of prostate cancer in over 1000 patients - a germline and somatic approach

Aikaterini Oikonomaki, Andromachi Vagena, Stamatina Roussou, Olga Dimou, Eirini Tsiasioti, Stavroula Samara, Georgia Christopoulou, ***Pantelis Constantoulakis***

Genotypos M.S.A., Genetics and Genomics, Athens, Greece.

Background: Prostate cancer (PC) is the most common cancer among males. Somatic loss of function (LoF) variants in tumor-suppressor genes with high allele frequency in prostate tumours reflect, in several cases, a germline origin. Herein, we present the mutation spectra and the prevalence of disease-causing variants in PC patients.

Materials and methods: A total of 509 formalin-fixed paraffin embedded (FFPE) tissues and 500 peripheral blood samples from unselected prostate cancer patients were referred to our center for clinical genetic testing. Libraries were prepared according to the

manufacturer (AmoyDx® HANDLE HRR NGS Panel, Amoy Diagnostics Co.) and sequenced on a NextSeq500 system (Illumina). Bioinformatic analyses were performed using the AmoyDx ANDAS Data Analyzer.

Results: The prevalence of germline pathogenic/likely pathogenic variants was 11% (55/500). The most frequently mutated genes were *BRCA2* (4.8%) and *ATM* (2.2%), followed by *CHEK2* (0.8%), *BRIP1* (0.8%), *BARD1* (0.6%), *PALB2* and *RAD54L* (0.4% respectively). A total of 128/509 (25.2%) tumour samples harboured LoF variants. Consistently, the most commonly mutated genes were *BRCA2* (4.1%) and *ATM* (2.4%). Rare somatic variants were detected with 2.4% total frequency in other genes tested (*CHEK2, PALB2, RAD54L, RAD51C*). Interestingly, *PTEN* clinically significant somatic variants present high prevalence accounting for 2.2% of prostate tumours.

Conclusion: Overall, our data agree that the *BRCA2* gene is the key-player in PC followed by *ATM*. The detection of mutations in other genes such as *CHEK2, PALB2* and *PTEN* in significant rates, underlines the necessity to include gene panel testing in the clinical management of PC patients.

P01.019.C Functional role of miR-93-5p in prostate cancer: from target gene identification to biomarker evaluation

Patricia Porras-Quesada[1,2], *Lucía Chica-Redecillas*[1,2], *Álvaro Ruiz-San José*[1,2], *Pilar Sánchez*[1], *María Jesús Álvarez-Cubero*[1,2,3], *Luis Javier Martínez-González*[1,2]

[1]*Department of Biochemistry and Molecular Biology III and Immunology, Faculty of Medicine, University of Granada, Granada, Spain,* [2]*GENYO, Centre for Genomics and Oncological Research, Pfizer, University of Granada, Andalusian Regional Government, Granada, Spain,* [3]*Biosanitary Research Institute, ibs.GRANADA, Granada, Spain.*

Background: Despite being one of the most prevalent malignancies among men, prostate cancer (PC) still lacks reliable non-invasive biomarkers for accurate diagnosis and patient stratification. Current methods, including prostate-specific antigen (PSA) testing, present specificity and prognostic value limitations. MicroRNAs have emerged as promising alternatives due to their stability in bodily fluids and regulatory role in gene expression. Among them, miR-93-5p has been linked to several malignancies, but its potential as a biomarker and functional relevance in PC remains unclear. This study explores its role in PC, focusing on its diagnostic and prognostic value.

Material and methods: miR-93-5p expression was analyzed in PC patients and control individuals using The Cancer Genome Atlas (n = 550) dataset, and an independent cohort of prostate tissue (n = 254) and plasma samples (n = 254). Using an integrative approach combining cell transfection assays, RNA sequencing, Western-Blot analysis, and computational affinity prediction studies, we identified miR-93-5p direct targets, which were further validated through in silico and in vitro analyses using the same cohorts.

Results: miR-93-5p was significantly upregulated in PC and its combination with PSA improved diagnostic accuracy over PSA alone. Functional studies revealed its involvement in key cancer-related pathways, including MAPK, FoxO, and TGF-beta. Target gene analysis identified *TGFBR2* and *SEMA7A* as direct targets, both showing significant downregulation in PC and a strong inverse correlation with miR-93-5p.

Conclusion: These findings support miR-93-5p as a promising biomarker for PC diagnosis and patient stratification, while also opening new perspectives for therapeutic strategies by revealing its key role in PC tumorigenesis.

Ludmil*[11], *Hans Morreau*[3], *Tom van Wezel*[3], *Sergi Castellvi-Bel*[12], *Yael Goldberg*[13], ***Maartje Nielsen***[1], *MCM8-MCM9 study group*[1]

[1]*Clinical Genetics, Leiden, Netherlands,* [2]*Institute of Cancer and Genomic Sciences, University of Birmingham, Birmingham, United Kingdom,* [3]*Pathology, Leiden University Medical Center, Leiden, Netherlands,* [4]*Sequencing Analysis Support Core, Department of Biomedical Data Sciences, Leiden, Netherlands,* [5]*b Department of Cellular and Molecular Medicine, UC San Diego, San Diego, CA, USA,* [6]*Princess Maxima Center for Pediatric Oncology, Utrecht, utrecht, Netherlands,* [7]*Oncology Section and Molecular Biology Laboratory, Hospital of Gastroenterology, Buenos Aires, Argentina,* [8]*FRCB-IDIBAPS, Barcelona, Spain,* [9]*Institut d'Investigacio Biomedica de Bellvitge -IDIBELL, Hospitalet de Llobregat, Spain,* [10]*Hereditary Cancer Program, Catalan Institute of Oncology, Oncobell Program, Barcelona, Spain,* [11]*Department of Cellular and Molecular Medicine, UC San Diego, San Diego, CA, USA,* [12]*Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Genetic Predisposition to Colore, Barcelona, Spain,* [13]*RMC, Petah Tikva, Israel.*

Background: *MCM8* and *MCM9* are proposed cancer predisposition genes, linked to polyposis and early-onset cancer, in addition to hypogonadism. Given the uncertain range of phenotypic manifestations, this study aimed to delineate the molecular and clinical characteristics.

Material and methods: Collecting *MCM8/9* biallelics through case reports, ERN Genturis and analysing cancer risk with data from the 100K Genomes Project/UK biobank. Tumor analyses though WGS.

Results: We found significant enrichment of biallelic *MCM9* variants in individuals with colonic polyps (OR 6.51, 95%CI 1.24–34.11; $P = 0.03$), rectal polyps (OR 8.40, 95%CI 1.28–55.35; $P = 0.03$), and gastric cancer (OR 27.03, 95%CI 2.93–248.5; $P = 0.004$) in data from the 100K Genomes Project, compared to controls. No similar enrichment was found for *MCM8* or in the 200K UK Biobank. Likewise, in 26 *MCM8* and 28 *MCM9* variant carriers, we documented polyposis, gastric cancer, and early-onset colorectal cancer in *MCM9*, but not in *MCM8* carriers. Moreover, this case serie indicated that, beyond hypogonadism, biallelic *MCM8* and *MCM9* variants are associated with early-onset germ cell tumors (occurring <15 yr). Tumors from *MCM8*/*MCM9* variant carriers predominantly displayed clock-like mutational processes, with no evidence of DNA repair deficiency-associated signatures.

Conclusion: Collectively, our data indicates that biallelic *MCM9* variants are associated with polyposis, gastric cancer, and early-onset CRC, while both biallelic *MCM8* and *MCM9* variants are linked to hypogonadism and the early development of germ cell tumors. These findings underscore the importance of including *MCM8*/*MCM9* in diagnostic gene panels for certain clinical contexts and suggest that biallelic carriers may benefit from cancer surveillance.

P01.021.A Integrative pathway analysis and epitope-based immunotherapy for targeting cancer stem cells in pancreatic cancer

M. Darabi[1], *M. Zare*[2];

[1]*Islamic Azad University Shoushtar, Shoushtar, Iran, Islamic Republic of,* [2]*Yazd Reproductive Sciences Institute, Computer Science, Yazd, Iran, Islamic Republic of*

Background: Pancreatic cancer remains one of the deadliest malignancies due to late diagnosis, aggressive tumor biology, and therapy resistance. Cancer stem cells (CSCs) play a crucial role in tumor progression, metastasis, and immune evasion. Targeting CSCs through immunotherapy offers a promising strategy for improving patient outcomes.

Material and methods: We integrated bioinformatics and pathway analysis to identify key CSC markers (CD44, CD133, EPCAM) and their roles in pancreatic cancer. Epitope-based vaccine design was performed using immune-dominant peptides predicted for HLA-binding affinity. Identified epitopes were assessed for immunogenicity, safety, allergenicity, and population coverage. Pathway enrichment analysis was conducted to determine CSC-associated metabolic and signaling pathways.

Results: High-affinity HLA-A02:01 and HLA-A24:02-restricted epitopes were identified, demonstrating strong immunogenic potential. Pathway analysis revealed critical CSC survival mechanisms, including metabolic dysregulation and immune evasion pathways. Screening confirmed epitope safety and broad population applicability.

Conclusion: Our findings support the development of peptide-based vaccines targeting CSCs, providing a novel immunotherapeutic approach for pancreatic cancer. Future validation and clinical translation will be essential to enhancing treatment efficacy and overcoming therapy resistance.

P01.022.B Distinct genomic and transcriptomic profiles of clear cell renal cell carcinomas and kidney cysts revealed in a von Hippel-Lindau disease patient

Francesca Corea[1,2], *Isaline Rowe*[1], *Alessandro Larcher*[1], *Giovanni Battista Pipitone*[1], *Giulia Maria Scotti*[3], *Roberta Lucianò*[4], *Miriam Sant'Angelo*[1], *Nazario Tenace*[1], *Irene Franco*[1], *Claudio Doglioni*[1], *Maurilio Ponzoni*[1], *Francesco Montorsi*[1,2], *Umberto Capitanio*[1], *Paola Carrera*[1], *Andrea Salonia*[1,2]

[1]*IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*Vita-Salute San Raffaele University, Milan, Italy,* [3]*Human Technopole, Milan, Italy,* [4]*Azienda Sanitaria Provinciale 5 - Messina, Messina, Italy.*

Background: Patients with von Hippel-Lindau (VHL) disease develop multiple kidney cysts and clear cell renal cell carcinomas (ccRCCs) throughout their lifetime. While kidney cysts are typically considered precursors to ccRCCs, molecular evidence supporting this progression has been lacking.

Material and methods: To shed light on the molecular relationships and distinctions among these lesions, we analyzed a clinical case with multiple kidney cysts and tumors co-occurring at the time of resection. Comprehensive profiling was conducted using whole genome sequencing (WGS), RNA sequencing (RNA-seq), and pathological examinations on six ccRCCs and four cysts from the same VHL patient.

Results: Cysts and ccRCCs displayed distinct transcriptomic profiles: tumors exhibited increased glycolysis and hypoxia response, while cysts were enriched in extracellular matrix organization, inflammation, and markers of the nephron's distal portion. Deconvolution analysis revealed differing stromal and immune microenvironments, with cysts enriched in myofibroblast and plasma cell signatures, whereas tumors were associated with tumor-associated macrophages (TAMs) and tumor vasculature signatures. Genomic analysis showed that kidney cysts and ccRCCs were mostly clonally independent, with distinct somatic single-nucleotide variants' sets. While both lesions shared similar somatic mutational signatures, their somatic copy number landscapes diverged significantly. Notably, only tumors exhibited chromosome 3p loss, resulting in VHL loss of heterozygosity, without additional detectable driver mutations.

Conclusion: These findings reveal a molecular distinction between kidney cysts and ccRCCs, suggesting that these lesions can have distinct and independent origins, challenging the assumption of a linear cyst-to-tumor progression in VHL disease.

P01.023.C EX^{2}TRICAN study: uncovering genetic predisposition factors in extreme cancer phenotypes through germline exome sequencing

Benoit Mazel[1], *Anaïs Folletet*[2], *Amandine Beaudouin*[2], *Allan Lançon*[2], *Léa Patay*[1], *Amandine Baurand*[1], *Caroline Sawka*[1], *Manon Réda*[2], *Juliette Santenard*[1], *Anthony Comte*[2], *Vincent Goussot*[2], *Valentin Derangère*[2], *Laurence Faivre*[1], *Sophie Nambot*[1], ***Juliette Albuisson***[2]

[1]*CHU Dijon Bourgogne, Dijon, France,* [2]*Centre de Lutte Contre le Cancer Georges François Leclerc-UNICANCER, Dijon, France.*

Background: Hereditary cancer syndromes often remain unexplained despite up-to-date panel-based genetic testing. Our study investigates the utility of germline exome sequencing (ES) to unravel cancer genetic predisposition by identifying new cancer genes in patients with extreme cancer phenotypes. Unexplained familial aggregation or early-onset cancers (before age 40, or before age 30 for breast cancer) were studied.

Methods: Germline ES was performed for all cases, in solo, duo, trio or quatuor strategy, depending on the family history and relatives' availability. Variants were prioritized using a dedicated algorithm, and a merged list of 1563 cancer genes from 3 cancer databases. Pathogenicity was assessed using ACMG/CanVIG-UK guidelines.

Results: Since 2017, 189 individuals from 7 different centers were included (Table 1). 51% (50/97) of affected cases harbored at least one genetic germline variant of interest. Several variants were prioritized for further study based on predicted loss-of-function, de novo status, or recurrence within the same pathology group (Table 2).

Discussion: This study demonstrates the added value of germline ES in providing insights into hereditary cancer, particularly by identifying novel candidate genes or questioning

the spectrum of known predisposition genes. Ongoing studies aim to refine these insights and confirm some of our candidates' involvement. Our findings support the broader use of germline ES in suspected hereditary cancer predisposition.

Table 1. Study population by cancer type and affected status.

Cancer type	Index cases	Affected relatives	Relatives with ambiguous status	Unaffected relatives	TOTAL

Background: Serrated polyposis syndrome (SPS) is characterized by numerous and/or large serrated polyps and increased colorectal cancer risk. The underlying etiology is largely unknown(1). *DOT1L* (Disruptor of telomeric silencing 1-like), encodes for the only lysine methyltransferase that catalyzes the mono-, di- and trimethylation of histone H3 at lysine 79 (H3K79). This methylation is linked to active gene transcription and plays an important role in SPS (2). *DOT1L* has been proposed as a candidate gene for germline SPS predisposition (3). We aimed to provide functional evidence supporting *DOT1L* as a new hereditary gene for SPS.

Material and methods: Findings from a discovery cohort (39 patients, 16 SPS families), were replicated in 211 SPS patients. Two knock-in cellular models with the DOT1L rare, pathogenic genetic variants identified were generated with CRISPR-Cas9. We examined protein expression of di- and tri-H3K79 methylation, and target gene expression. An additional SPS cohort (184 patients) was checked for additional variants, where four potentially pathogenic variants were also identified in the additional SPS cohort.

Results: Two DOT1L variants (p.Asp1159His and p.Val1103Met) were functionally assessed by evaluating the global protein levels of H3K79me2 and me3, and expression of target genes. Cells showed an increase in global H3K79me2 coinciding with increased target gene expression of *MYC*, *CCND1* and *CDKN1A*, especially for p.Asp1159His.

Conclusion: Our findings suggest that *DOT1L* genetic variants can impact the global H3K79me2 pattern, therefore affecting the expression of target genes like *MYC*, *CCND1* and *CDKN1A*. This functional alteration might explain the mechanism underlying *DOT1L* SPS germline predisposition.

P01.025.A Molecular and clinical differences between constitutional and somatic *POLE* and *POLD1* exonuclease domain pathogenic variants in cancer

Julen Viana-Errasti[1,2,3], *Raúl Marín*[1,2,4], *Sandra García-Mulero*[2,5], *Tirso Pons*[6], *Mariona Terradas*[1,2,3], *Gabriel Capellá*[1,2,3], *Victor Moreno*[2,4,7], *Pilar Mur*[1,2,3], *Laura Valle*[1,2,3]

[1]*Hereditary Cancer Program, Catalan Institute of Oncology, IDIBELL, Hospitalet de Llobregat, Barcelona, Spain,* [2]*Program in Molecular Mechanisms and Experimental Therapy in Oncology (Oncobell), IDIBELL, Hospitalet de Llobregat, Barcelona, Spain,* [3]*Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Madrid, Spain,* [4]*Oncology Data Analytics Program (ODAP), Catalan Institute of Oncology, Hospitalet de Llobregat, Barcelona, Spain,* [5]*Department of Pathology and Experimental Therapy, Universidad de Barcelona Facultad de Medicina y Ciencias de La Salud, Hospitalet de Llobregat, Barcelona, Spain,* [6]*Department of Immunology and Oncology, National Center for Biotechnology (CNB-CSIC), Spanish National Research Council, Madrid, Spain,* [7]*Department of Clinical Sciences, Faculty of Medicine and Health Sciences, Universitat de Barcelona Institute of Complex Systems (UBICS), University of Barcelona, Hospitalet de Llobregat, Barcelona, Spain.*

Background: Germline and somatic pathogenic variants in the exonuclease domain (ED) of *POLE* and *POLD1* impair the proofreading activity of the polymerases ε and δ, leading to hypermutated tumors. Despite shared mutational features, molecular and clinical differences between *POLE* and *POLD1* mutations, and between somatic and germline variants, remain incompletely understood.

Materials and methods: We systematically compared the molecular and clinical features of somatic and germline *POLE* and *POLD1* ED pathogenic variants (n = 31). The analysis considered associated clinical phenotypes, mismatch repair (MMR) deficiency status, tumor mutational burden (TMB), and mutational signatures. The study included 360 proofreading-deficient tumors from TCGA and COSMIC and 70 families with polymerase proofreading-associated polyposis.

Results: Somatic variants predominantly occurred in endometrial cancers, while colorectal cancer was most common in hereditary cases. Cancer risks and tumor spectra differed between *POLE* and *POLD1* mutation carriers. Aggressive clinical phenotypes were linked to specific germline *POLE* mutations or co-occurrence of germline pathogenic variants in *POLD1* or *POLE* ED and an MMR gene. Tumor mutational signatures analysis confirmed unique hypermutator profiles for *POLE* and *POLD1* proofreading deficiencies. In combination with MMR deficiency, tumors accumulated more mutations and had different mutational spectra. *POLE* deficiency showed haploinsufficiency, while *POLD1* required a somatic second hit or co-occurrence with MMR deficiency to trigger carcinogenesis.

Conclusions: Differences between *POLE* and *POLD1*, and between somatic and germline mutations influence clinical presentations, mutagenic potential, and reliance on cooperating defects in tumorigenesis. These insights advance understanding of proofreading-deficient cancers, with implications for diagnostics, genetic counseling, and precision oncology.

P01.026.B New insights into variants in the *NF1* and *NF2* uORFs and their role in neurofibromatosis development

Alexandra Filatova, *Anna Kuzevanova, Roman Peshkov, Victoria Serzhanova, Mikhail Skoblov, Head of the Department*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Variants in uORFs cause hereditary diseases, primarily by creating an out-of-frame overlap with the downstream CDS, while other types of uORF variants remain unnoticed.

Material and methods: Variants altering *NF1*/*NF2* uORFs were identified using the uORF_annotator tool. Their impact on translation efficiency was experimentally assessed using a dual-luciferase assay and qPCR.

Results: Patients with neurofibromatosis, lacking variants in the coding sequences of the *NF1/NF2* genes, were analyzed for 5`UTR variants. Two novel variants in the *NF1* uORF were identified. We experimentally validated their effect on main CDS translation, along with several additional disease-associated *NF1/NF2* variants from HGMD and ClinVar. All tested variants altered uORF structure via frameshift or stop codon removal, causing an out-of-frame overlap with the main CDS, reducing protein translation, and contributing to disease. Next, we introduced additional SNVs that alter *NF1/NF2* uORFs structure without leading to overlap with the main CDS and measured their impact on protein translation efficiency. We found that variants altering the uORF length or the distance between its stop codon and the CDS start can significantly reduce the expression of the main CDS. In some cases, the level of this reduction is nearly identical to that caused by variants leading to out-of-frame overlaps. This suggests that such variants may also lead to the disease development, although they have not been previously described.

Conclusion: Using uORFs in the *NF1* and *NF2* genes as an example, we demonstrated that variants altering the uORF structure without affecting the main CDS can potentially cause inherited diseases.

P01.028.D Optimising risk factor information in multifactorial risk assessment, including polygenic score, to inform risk-based breast cancerscreening

Xin Yang[1], *Juliet A. Usher-Smith*[1], *Kristina M. Blackmore*[2], *Jennifer D. Brooks*[3], *Kathleen A. Bell*[4], *Tim Carver*[1], *Amy Chang*[4], *Jocelyne Chiquette*[5], *Douglas F. Easton*[1], *Andrea Eisen*[4], *Laurence Eloy*[6], *Samantha Fienberg*[4], *Yann Joly*[7], *Raymond H. Kim*[4], *Bartha Knoppers*[8], *Laurence Lambert-Côté*[5], *Hermann Nabi*[5], *Nora Pashayan*[1], *Tracy L. Stockley*[7], *Annie Turgeon*[5], *Meghan J. Walker*[4], *Michel Dorval*[5], *Anna M. Chiarelli*[9], *Antonis C. Antoniou*[1], *Jacques Simard*[5]

[1]*University of Cambridge, Cambridge, United Kingdom,* [2]*Ontario Health, Toronta, ON, Canada,* [3]*University of Toronto, Toronto, ON, Canada,* [4]*Ontario Health, Toronto, ON, Canada,* [5]*CHU de Québec-Université Laval Research Center, Quebec City, QC, Canada,* [6]*Ministère de la Santé et des Services sociaux, Quebec City, ON, Canada,* [7]*McGill University, Montreal, QC, Canada,* [8]*McGill University, Westmount, QC, Canada,* [9]*Ontario Health, Cambridge, ON, Canada.*

Background: Risk-based breast cancer (BC) screening tailors age range, screening modalities and intervals to target women most likely to benefit. This study aims to identify the most important risk predictors for risk stratification, and to optimise data requirements for BC risk assessment in screening programmes.

Material and methods: We estimated 10-year BC risks using BOADICEA v.6 (CanRisk) in 3,753 women aged 40–70 with no prior cancer history, from the PERSPECTIVE I&I cohort. The risk classification ability of combinations of risk factors were evaluated against a full multifactorial model that included: questionnaire-based risk factors (QRFs), polygenic score (PGS), mammographic density (MD), and pedigree-structured multi-cancer family history up to second-degree relatives (FH).

Results: Under the full model 16.7% of women were at "higher-than-average" ($1.5 \leq RR < 2.7$) and 5.2% at "high" risk ($RR \geq 2.7$). Excluding PGS resulted in the overall highest reclassification rate (18.6%), followed by QRF (12.8%), MD (12.0%), and FH (10.3%). Including only first- and second-degree relatives' BC status yielded a comparable risk classification to the complete FH data (reclassification rate = 0.5%). Younger women (40–49) had higher reclassification rates when MD (17%) or FH (17%) were excluded, compared to women aged 50–70 (9.2% and 11.3%). Adding PGS to information already collected in breast screening programs in Canada brought risk classification close to the full model.

Conclusion: PGS contributes substantially to classification and could enhance risk-based BC screening recommendations. Younger women's risk predictions are particularly sensitive to the omission of FH and MD, emphasising the need to prioritise these factors in this demographic.

Background: The ICCon Database is a comprehensive national repository of genetic testing, demographic, and cancer data for carriers (≥18 years) of a pathogenic/likely pathogenic variant (P/LPV) in a cancer-predisposition gene. Here we review current carrier-data and describe the most frequently observed cancer-predisposition P/LPVs in Australia.

Material and methods: The ICCon Database currently houses data for 30,000+ carriers identified through one of Australia's 18 public Familial Cancer Centres between 1990s-2023 (67 unique genes; 70% female).

Results: In each Australian State, 50–59% of submitted carries have a P/LPV in *BRCA1/2*; the combined mismatch repair-genes are present in 16–27%. The combined *SDH*-genes are present in 2–4%, notably higher in Tasmania (10%). Other single-genes prominent nationally are *APC* (3–8%); *CHEK2* (1–3%); *PALB2* (1–3%); *FLCN* (1–2%). Other unique genes are present at similar frequencies (1–3%) in individual states.

The Ashkenazi Jewish BRCA1/2, and the European CHEK2, founder variants occur at the highest frequency nationally. Summary of the most frequently observed P/LPVs:

	Gene	Sequence Variation	% P/LPVs in same gene	% All P/LPVs
1	BRCA1	c.68_69del: p.Glu23Valfs*17	7	1.7
2	CHEK2	c.1100del: p.Thr367Metfs*15	71	1.6
3 =	BRCA1	c.5266dup: p.Gln1756Profs*74	6	1.5
4 =	BRCA2	c.5946del: p.Ser1982Argfs*22	5	1.5
5	BRCA2	c.6275_6276del: p.Leu2092Profs*7	4	1.3

The rate at which new carriers are detected in Australia more than doubled in 13 years, between 2010 and 2023.

Reported cancer diagnoses at the time of presentation largely align with known cancer-gene risk associations, but with an important minority of unexpected diagnoses.

Conclusion: Variations in gene and P/LPV frequency across states appear to reflect historical demographic differences. The data provides a detailed landscape of the evolution of cancer-predisposition in the clinical-setting and will be useful for planning future services and facilitating new cancer research.

P01.030.B Germline pathogenic variants in ESMO-recommended genes found during molecular profiling of tumour tissues: results of the first 2 years of the FPG500 study

Arianna Panfili, *Simona Duranti, Camilla Nero, Ilenia Marino, Iolanda Mozzetta, Tina Pasciuto, Luciano Giacò, Simone Rossi, Chiara Parrillo, Giulia Maneri, Alessia Perrucci, Francesco Fanfani, Anna Fagotti, Emanuela Lucci Cordisco, Maria Alessandra Calegari, Lisa Salvatore, Alessia Piermattei, Antonio Vitale, Claudio Ricciardi Tenore, Elisa De Paolis, Floriana Camarda, Martina Rinelli, Annamaria Pietrosante, Jessica Preziosi, Flavia Giacomini, Maria De Bonis, Ketty Peris, Roberto Iacovelli, Giovanni Schinzari, Cinzia Bagalà, Stefano Margaritora, Andrea Urbani, Emilio Bria, Luca Tagliaferri, Guido Rindi, Rocco Trisolini, Angelo Minucci, Sergio Alfieri, Giampaolo Tortora, Giovanni Scambia, Maurizio Genuardi*

Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy.

Background: Comprehensive cancer genome profiling (CGP) is recommended for identifying actionable somatic mutations in select cancer patients, with somatic variants potentially linked to hereditary cancer syndromes (HCS).

Materials and methods: "FPG500" is a prospective trial enrolling cancer patients for somatic molecular assessment based on national guidelines. This analysis reports the prevalence of germline pathogenic variants (PVs) among patients enrolled from January 2022 to December 2023, profiled using TruSight Oncology 500 solution.

Results: Of 2696 cases with a CGP report, one fifth of cases with 623 suspected germline PVs were referred for genetic counseling, with a compliance to genetic counseling of 80%. 356 patients underwent germline testing and 75% harbored at least one PV, accounting for 10% of the entire cohort, with 68% of tested variants confirmed to be of germline origin. Interestingly, 24% of germline variants were found in an off-tumor context, while 17% of confirmed on-tumor germline PVs were in moderate-risk genes. Additional 19 PVs were identified using alternative panels due to either a suspicion raised by the results of other somatic tests or in patients referred to the genetics clinic based on clinical criteria.

Conclusions: This study confirms that approximately 10% of an unselected cancer population who underwent CGP is associated with an HCS. The somatic multigene panel allowed also the identification of a high percentage of germline variants as secondary findings or in mild- and low-penetrance genes. Integrating CGP with genetic counseling offers a comprehensive approach, aiding personalized treatment and broader familial risk assessment and preventive care.

P01.031.C Solid tumors in Noonan syndrome, Costello syndrome, and related RASopathies: insights from a large monocentric cohort, updated genotype-phenotype analysis, and comprehensive literature review

Germana Viscogliosi[1], Valentina Trevisan[2], Denise Pires Marafon[1], Chiara Ritarossi[3], Roberta Pastorino[1], Roberta Onesimo[2], Elisabetta Flex[3], Maurizio Genuardi[1], Marco Tartaglia[4], Giuseppe Zampino[1], Simone Martinelli[3], ***Chiara Leoni***[5]

[1]*Università Cattolica del Sacro Cuore, Roma, Italy,* [2]*Fondazione Policlinico Gemelli, Roma, Italy,* [3]*Istituto Superiore di Sanità, Roma, Italy,* [4]*Ospedale Pediatrico Bambino Gesù, Roma, Italy,* [5]*Fondazione Policlinico Gemelli, rome, Italy.*

Background. The RAS-MAPK signaling cascade mediates cell response to various growth factors, cytokines and hormones, modulating cell proliferation, differentiation, and survival, which are key events implicated in tumorigenesis. RASopathies are a group of neurodevelopmental disorders with overlapping clinical presentations caused by enhanced signaling through the RAS-MAPK cascade(1). Among RASopathies, Noonan syndrome (NS), Costello syndrome (CS), and CBL-associated syndrome share an increased cancer risk, while data concerning other RASopathies remain anecdotal(2,3).

Methods: We assessed the prevalence and type of solid tumors in RASopathies by a retrospective analysis on a large monocentric cohort of affected individuals. We compared these findings with currently available public data collected through systematic literature review.

Results: This study presents the largest single-center cohort of individuals with RASopathies and solid tumors reported to date. It documents the occurrence of solid neoplasms in 10.8% of individuals with NS, 47.8% with CS, and 7.3% with cardio-facio-cutaneous syndrome (CFCS). Several CS patients experienced multiple tumors, while CFCS patients relapsing neoplasia. Our data confirms an earlier onset of solid tumors in RASopathies, especially in CS compared to the general population. Notably, *PTPN11*- and *SOS1*-positive NS patients exhibit a distinct spectrum of rare tumors, different from those observed in CS. Finally, we identify a subset of high-risk candidate variants in RASopathy genes that predispose to solid tumors.

Conclusion: The collected data provide further insights into RASopathies as cancer predisposition syndromes and emphasize the need for tailored surveillance and evidence-based clinical guidelines specific to each RASopathy subtype.

P01.032.D Investigating the genetic predisposition of rare hereditary cancer syndromes via the Hellenic Precision Medicine Network

Paraskevi Apostolou[1], *Vasiliki Dellatola[1], Effrosyni Mendrinou[1], Irene Stefanaki[2], Elena Fountzila[3], Drakoulis Yannoukakos[1], Irene Konstantopoulou[1], Florentia Fostira[1]*

[1]*Human Molecular Genetics Laboratory, INRaSTES, National Center for Scientific Research "Demokritos", Athens, Greece,* [2]*1st Department of Dermatology and Venereology, Medical School, National and Kapodistrian University of Athens, "A. Sygros" Hospital for Skin and Venereal Diseases, Athens, Greece,* [3]*Department of Medical Oncology, St. Lukes's Hospital, Thessaloniki, Greece.*

Background: Greece lacks organized genetic centers, certified counselors and geneticists. Genetic testing for hereditary cancer is generally not reimbursed by national healthcare insurance policies, except in selected cases. As a result, patients and their families bear the financial burden. To address this gap, a state-funded program, Hellenic Network of Precision Medicine (HNPM), has been established to both investigate cancer biomarkers and hereditary cancer susceptibility. HNPM leverages the expertise of research and academic laboratories to seamlessly integrate diagnostic and research needs.

Material and methods: Through the dedicated HNPM portal, from September 2024 to January 2025, 192 patients (mean age at diagnosis 49.5 years; range 19–80 years) with malignant/pre-malignant diagnoses fulfilling international testing criteria were referred to the Human Molecular Genetics Laboratory, which serves as a reference laboratory in hereditary cancer in the last 30 years. Analysis was performed via massively parallel sequencing and MLPA.

Results: Overall, 20.8% (40/192) of patients carried germline pathogenic variants (PVs) distributed in six cancer susceptibility genes known to be associated with rare or ultra-rare cancer syndromes. The reported rate of variants of unknown significance (VUS) was 1%. A large fraction, i.e. 60%, of the families already proceeded to cascade testing for the familial PV.

Conclusion: This initial approach emphasizes the importance of an organized infrastructure, which includes laboratories with extensive expertise in the field. By offering *pro bono* genetic testing for hereditary cancer predisposition, a number of rare hereditary cancer cases are promptly identified whilst paving the way for personalized treatments and cancer prevention.

P01.033.A Precision medicine in pediatric cancer patients: INT-per-Kids trial experience

Piergiorgio Modena[1], *Luca Bergamaschi*[2], *Loris De Cecco*[3], *Matilde Oriani*[3], *Marzia Giagnacovo*[1], *Maura Massimino*[4], *Michela Casanova*[4], *Patrizia Gasparini*[5]

[1]*Genetics Unit, ASST Lariana General Hospital, Como, Italy,* [2]*Pediatric Oncology, Fondazione Istituto Nazionale Tumori, Milano, Italy,* [3]*Integrated Biology Platform, Fondazione Istituto Nazionale dei Tumori, Milano, Italy,* [4]*Pediatric Oncology Unit, Fondazione Istituto Nazionale dei Tumori, Milano, Italy,* [5]*Epigenomics and Biomarkers of Solid Tumors, Fondazione Istituto Nazionale dei Tumori, Milano, Italy.*

Background: Refractory/relapsing patients merit molecular tumor re-evaluation to inform about salvage targeted treatments. Precision medicine recently expanded this option to WES+RNA-seq tumor analyses. We present our initial experience, based on the first 41 pediatric patients enrolled in INT-per-Kids trial, focused to refractory/relapsing solid tumors.

Material and methods: Forty-one metastatic/relapsing tumor and matched normal samples were analyzed with KAPA DNA-HyperExome and KAPA RNA-HyperPrep next-generation-sequencing. Either formalin-fixed paraffin-embedded (FFPE) or frozen tumor tissue was used. Data were analyzed with Mercury bioinformatic platform (Integragen) and actionable alterations were verified by independent techniques. Therapeutic implications were discussed in multidisciplinary Molecular Tumor Board sessions. Ethical committee approval and informed consents were obtained.

Results: Technical success rate was 93% for DNA-analyses and 82% for RNA-analyses. Samples from FFPE provided significant inferior quality parameters. Pathology supervision revealed crucial for appropriate sample management. In 36/41 patients relevant, previously hidden information was revealed, including individual cases of high copy number amplification events, homozygous deletion events, rare fusion genes undetected at diagnosis stage, unsuspected very high tumor mutational burden. Target-based therapy was undertaken in 2 patients carrying actionable, "ready-to-use" alterations and additional 3/36 patients were enrolled in Phase 1 /2 trials based on investigational targets and drugs. No relevant/challenging incidental findings were reported.

Conclusion: We set up the laboratory steps for advanced molecular analyses in refractory/relapsing solid tumor pediatric patients. Results disclosed a number of impactful information and we anticipate that running these -omics approaches in earlier stages of disease in the frame of clinical trials will benefit patients' management.

P01.034.B Identification of germline predisposition to colorectal cancer in a Spanish cohort of adolescent and young adult patients: DNA-RNA analysis results

Laia Bonjoch[1], *Gemma Llargués-Sistac*[1], *María Daca*[2], *Teresa Ocaña*[2], *María Teresa Rodrigo*[2], *Sandra López-Prades*[2], *Miriam Cuatrecasas*[2], *Guerau Fernandez*[3], *Anna Esteve-Codina*[4], *Raul Tonda*[4], *Genís Parra*[4], *Lorena Moreno*[2], *Èlia Grau*[2], *Bárbara Rivera*[5], *Alba Ortega*[2], *Jenifer Muñoz*[6], *Aina Aguayo*[1], *Xavier Dominguez-Rovira*[1], *Coral Arnau-Collell*[2], *Antoni Castells*[2], *Francesc Balaguer*[2], *Leticia Moreira*[2], ***Sergi Castellvi-Bel***[1]

[1]*Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomediques August Pi i Sunyer (FRCB-IDIBAPS), Barcelona, Spain,* [2]*Hospital Clínic Barcelona, Barcelona, Spain,* [3]*Hospital Sant Joan de Déu, Barcelona, Spain,* [4]*CNAG, Barcelona, Spain,* [5]*IDIBELL, Hospitalet de Llobregat, Spain,* [6]*Fundació de Recerca Clínic Barcelona-Institut d'Investigacions Biomediques August Pi i Sunyer (FRCB-IDIBAPS), CIBEREHD, Barcelona, Spain.*

Background/objectives: Colorectal cancer (CRC) incidence has declined but early-onset cases are increasing globally (1). Our study focused on adolescents and young adults with CRC (AYACRC). The proportion of cases due to hereditary cancer is around 16–20% (2). We aimed to identify germline alterations predisposing to CRC.

Methods: Forty-three AYACRC patients (age range 19–45) formed the cohort, which included 27 women (62.8%). Only three patients presented mismatch-repair deficient (MMRd) tumors. Germline blood whole-genome sequencing (WGS) and RNA sequencing were performed and integrated. We scrutinized for rare (<1%), pathogenic variants, focusing on 1,657 genes reportedly involved in germline predisposition to cancer (3), or from CRC signaling pathways. When focusing on DNA-only results, we carefully inspected known hereditary cancer genes, especially those for CRC and breast cancer.

Results: Aberrant expression analysis did not detect any plausible hereditary cancer alteration. One splicing variation was linked with a *MSH2* variant (c.212-478T>G). Through DNA-only approach, we detected a variant in a CRC/breast cancer family (*ATM*, p.Ser917PhefsTer3), a controversial *MLH1* variant in a concordant MMRd case (p.K618A), *PMS1* alterations in 2 patients, suggestive variants in juvenile polyposis genes, and a pathogenic variant (p.Met1?) in *ARHGEF28*, a familial thyroid cancer candidate (4) in a CRC/thyroid cancer family.

Conclusion: Our approach for DNA-RNA analysis yield is limited. Germline predisposition could not be the main CRC susceptibility force for our AYA-CRC patients. Also, hereditary cancer pleiotropy could exist in some cases. This study is part of a multiomic effort and somatic, metabolomic or microbiome characterization may shed additional light.

Background: Rare Tumour Risk Syndromes (RTRS) are a subset of rare diseases, each defined as affecting fewer than 5:10.000 individuals. However, collectively, RTRS represent a significant clinical, social, and financial burden, requiring specialized diagnosis, continuous surveillance, and lifelong management. Herein, we aim at evaluating the prevalence of RTRS carriers receiving care in European Reference Centres.

Material and methods: Clinical data from eight RTRS (Hereditary Diffuse Gastric Cancer-HDGC, Gastrointestinal Stromal Tumour Syndrome-GIST, Birt-Hogg-Dubbé Syndrome- BHD, Hereditary Leiomyomatosis and Renal Cell Carcinomas- HLRCC, Li-Fraumeni Syndrome-LFS, PTEN Hamartoma Tumour Syndrome-PHTS, Familial Malignant Melanoma-FMM, and Peutz-Jeghers Syndrome-PJS) were collected from 2000 to 2024 across nine European Reference Centers in seven countries. Carrier families, variant carriers, and non-carriers were enrolled.

Results: A total of 1.108 RTRS families were identified (28% LFS, 26% PHTS, 16% PJS, 9% HDGC, 8% BHD, 6% HLRCC, 6% FMM, and 1% GIST). A total of 1.967 RTRS carriers were/are being offered multidisciplinary care to treat or prevent advanced disease, while 2.026 non-carriers were discharged, reducing unnecessary follow-ups and mental distress, and alleviating the burden on healthcare systems. Based on the total population of 16.6 million served by the nine centers, the prevalence of these RTRS carriers was calculated as 1.18:10,000.

Conclusion: LFS, PHTS, and PJS are the most prevalent RTRS in speacialized centers, collectively comprising 70% of families and carriers. While RTRS remain rare even when combined, their collective burden underscores the importance of European collaboration, specialized care, and tailored healthcare strategies to improve diagnosis, management, and policy decisions.

P01.037.A ATM and hereditary cancer syndromes: a five-year retrospective analysis of oncogenetic testing in a french center

Iulian BAN, ***Lamisse MANSOUR-HENDILI****, Ana Maria NAVARRO, Karen BAUDRY, Tatiana KOGUT-KUBIAK, Carole CORSINI, Pascal Pujol, Jérôme Solassol*

CHU MONTPELLIER, Montpellier, France.

Background: The tumor-suppressor gene *ATM*, encoding a serine/threonine kinase essential for DNA double-strand break repair, has emerged as a significant cancer susceptibility gene. Multiple case-control studies and large-scale genomic analyses have shown that heterozygous carriers of pathogenic (P) and likely pathogenic (LP) *ATM* variants are at increased cancer risk, particularly for breast and pancreatic malignancies. Recent data from the UK Biobank have further quantified these risks with robust statistical evidence. Despite accumulating molecular and epidemiological data, *ATM* is not currently included in French national guidelines for germline cancer predisposition testing.

Material and methods: We retrospectively analyzed (SeqONE™) negative NGS (Agilent™) data from 2500 individuals with hereditary breast-ovarian, digestive, or pancreatic cancer syndromes, referred for oncogenetic testing between 2019 and 2024 at the Laboratory of Solid Tumor Biology, CHU Montpellier. Data were re-screened with a specific focus on the *ATM* gene (not routinely included in standard genetic screening panels in France).

Results: Thirty-five patients (1.4%) carried heterozygous P or LP *ATM* variants, all loss-of-function. These variants were primarily associated with hereditary breast-ovarian cancer syndrome, characterized by a specific histological pattern, and to a lesser extent with digestive and pancreatic cancers. Compared with the European non-Finnish population in the gnomAD v3 non-cancer database (0.3%), the calculated relative risk (RR) was 3.9 across all cancer subtypes.

Conclusion: Given the relative frequency of *ATM* variants in our cohort and the elevated RR, the *ATM* gene should be incorporated into routine oncogenetic testing in France to enable an identification and a better management of at-risk individuals.

P01.038.B Whole genome sequencing enhances the diagnostic yield in central nervous system tumours - technical advantages and limitations

Rebecca Ellmers*[1], Zita Reisz[2], Kelly Eggleton[1], Ross Laxton[1], Priyal Hirani[1], Chirag Limbachia[1], Leena Bhaw[1], Smitha Nevis[1], Philip Davidson[3], Alexander Smith[3], Seemu Ali[3], Clodagh McGuire[3], Safa Al-Sarraj[2], Istvan Bodi[2], Nikhil Agarwal[2], Andrew King[2], Keyoumars Ashkan[4], Barnaby Clark[1]*

[1]Molecular Neuropathology, King's College Hospital, Synnovis, London, United Kingdom, [2]Clinical Neuropathology, King's College Hospital NHS Foundation Trust, London, United Kingdom, [3]Bioinformatics, King's College Hospital, Synnovis, London, United Kingdom, [4]Neurosurgery Department, King's College Hospital NHS Foundation Trust, London, United Kingdom.

Background: Accurate diagnosis and prognostic stratification of central nervous system tumours remains a challenge due to their molecular complexity. We aimed to evaluate the added diagnostic

value of whole genome sequencing (WGS) compared to standard-of-care (SOC) molecular tests.

Material and methods: Fresh brain tumour samples from 255 patients (102 paediatric/TYA, 153 adult) were analysed by a multimodal NGS panel (covering 305 DNA and 76 RNA targets) and DNA methylation array (DKFZ). Comparative analysis with WGS data included detection of small nucleotide (SNVs) and structural variants (SVs), loss of heterozygosity and germline findings.

Results: WGS confirmed 96.7% of the known pathogenic SNVs and found an additional 90 novel variants. Germline variants were detected in 26 cases (identification rate of 10%). Additional findings to SOC included: four cases of high tumour mutational burden (TMB), chromoanagenesis events (33 cases), and genome-wide ploidy gains (40 cases). WGS did not tier 17 variants previously identified via SOC testing, including 14 SNVs and 3 SVs. Regular drop outs included TERT promoter variants which occur in a low complexity, high homopolymer region of the genome.

Conclusion: WGS offers a single-test molecular approach with improved diagnostic utility over the standard-of-care tests, currently with increased turnaround time. Challenges occur in regions of low complexity which can be compounded by poor mapping, low coverage, and high TMB. Further work must be undertaken to improve bioinformatic filtering, including white-listing, in order to ensure all relevant variants are tiered for analysis and prevent the need for manual interrogation of raw data.

Background: BRIP1 plays a critical role in maintaining genome integrity through the Homologous Recombination pathway. Monoallelic germline pathogenic/likely pathogenic variants (gPV/gLPV) have been associated with an increased risk of cancers, notably breast/ovarian cancers. However, the comprehensive spectrum of cancers remains poorly characterized and carriers-specific recommendations lack precision.

Material and methods: We retrospectively analyzed *BRIP1* in patients tested for predisposition to breast/ovarian, prostate, digestive, pancreatic cancers and sarcomas at Institut Curie and Cochin Hospital (Paris-France). The analysis focused on identifying gPV/gLPV in *BRIP1*. Rare missense variants of uncertain significance (gnomAD frequency <0.01%) with a CADD score ≥20 (VUS^+) were also collected. Statistical enrichment analysis was performed using Fisher's exact test (v4.1.0 gnomAD cohort as a control population). Clinical and tumor data were collected.

Results: Between 2018 and 2021, 19,100 panels from 17,977 patients were analyzed, including 13,722 HBOC, 732 prostate, 3507 digestive, 998 pancreas and 141 sarcomas panels. A total of 201 variants was identified (1%) including 56 gPV/gLPV (0.3%) and 145 VUS^+ (0.8%). We identified 47 (0.3%), 1 (0.1%), 1 (0.1%), 5 (0.1%) and 2 (1.4%) gPV/gLPV in each group, respectively. The enrichment analysis suggested a significant association between gPV/gLPV and breast/ovarian cancers and sarcomas with odds ratio of 1.7 (IC[1.3–2.3]; $p = 0.001$) and 7 (IC[1.7–28.5]; $p = 0.003$), respectively.

Conclusion: Our results align with previous studies and suggest an expansion of the *BRIP1* tumor spectrum. Further analyses on paired tumor samples (biallelic inactivation and Homologous Recombination Deficiency) are planned to provide deeper insights into causality with potential therapeutic implications.

Background: The detection of circulating tumor DNA (ctDNA) through liquid biopsy has primarily focused on plasma from the blood of cancer patients. However, this method requires trained personnel, specific equipment, and several millilitres of blood for plasma collection and storage. We explored the possibility of detecting ctDNA directly in archived blood samples from cancer patients.

Material and methods: We retrospectively analysed matched whole blood ($n = 10$), and plasma ($n = 10$) collected more than ten years ago from melanoma patients. DNA was extracted from 9 tumours and sequenced at 30X whole exome sequencing to derive patient-specific mutations. We extracted DNA from blood and performed paired-end, shallow WGS. We analyzed the data for somatic copy number aberrations (SCNAs) tumour fraction estimation, and single nucleotide variants (SNVs).

Results: In archived blood, detected SCNAs reflected the profile observed in plasma and tumour from the same patients. Using the bioinformatic pipeline ichorCNA, tumour fraction ranged from 5% to 40% in blood. We identify distinct fragmentation profiles in

whole blood with nucleosome fragmentation patterns similar to plasma cfDNA. Analysis of SNVs by Integration of Variant Reads pipeline, detected ctDNA in nine out of the 10 patients with mutant allele fractions ranging from 1%–30%.

Conclusion: ctDNA can be detected directly from thawed whole blood and suggests the potential for ctDNA analysis in existing archived blood collections. Compared to conventional protocols based on plasma cfDNA, the proposed process is novel, simple and requires minimal blood volume, allowing existing biobanks to maximise discovery research across various types of cancer.

Background: Solving the structure of mRNA transcripts represents a significant challenge for both research and molecular diagnostic purposes. Current approaches lack a unified bioinformatic framework for accurate isoform annotation. To address it, we developed SOSTAR (iSofOrmS annoTAtoR), a versatile pipeline for assembly, quantification and annotation of RNA isoforms. This tool was validated using both short and long read sequencing data. Furthermore, the tool was extended to encompass the analysis of artificial constructions derived from multi-exonic minigene splicing assays.

Material and methods: From alignment and assembly achieved by minimap2 and StringTie tools respectively, SOSTAR enables comprehensive annotation which assigns an human-readable nomenclature to the isoforms. SOSTAR was validated on 40 samples including those with complex genetic alterations such as the insertion of an SVA element, genomic deletion and duplication, sequenced by both Illumina and Oxford Nanopore Technologies platforms. Twenty artificial constructions from 9 genes were considered to evaluate SOSTAR.

Results: The structure of transcripts was annotated with a resolution of one base relative to a reference transcript. All major alternative splicing events reported in the literature were identified and complex splicing events such as pseudoexons were accurately annotated. The application of SOSTAR pipeline allowed the comprehensive annotation of isoforms obtained from multi-exonic minigenes sequenced in a single experiment.

Conclusion: SOSTAR is a powerful tool for elucidating transcript structures from both short and long read sequencing data. It opens up new possibilities for the analysis of multi-functional splicing assays. To validate its diagnosis value, a cohort of 110 patients is under analysis.

Background: In contrast to female breast cancer, male breast cancer (MBC) is a rare and still poorly understood malignancy but its incidence is increasing. Risk factors for MBC described to date include both environmental and genetic aetiologies, but the primary risk factor currently identified is the presence of a germline pathogenic variant or likely pathogenic variant in the *BRCA2, BRCA1* and/or *PALB2* genes.

Material and methods: To identify novel potential MBC-specific predisposition genes, we performed a large germline whole-exome sequencing (WES) study in 122 MBC patients without evidence of genetic predisposition due to *BRCA2, BRCA1* and/or *PALB2* genes, with and without family history of cancer. We then compared the frequency of occurrence of germline variants between the MBC cohort and a non-cancer male control population from GnomAD database. Only variants that were significantly more frequent in the MBC cohort (adjusted p-value < 0.05) were selected and then automatically classified to retain only pathogenic and likely pathogenic variants that could be associated with the risk of developing MBC.

Results: This work led us to identify, in the MBC population, germline variants in DNA repair pathways but also in other cellular functions, suggesting that these pathways may be involved in MBC risk.

Conclusion: To our knowledge, this work is the first one performing a whole exome study in a large MBC population. Considering the role of genetics and environment, an additional analysis is under current to identify a multifactorial profile of MBC risk by combining patient's genetic and environmental data.

Background: Von Hippel-Lindau disease (VHL) is a rare genetic disease characterized by predisposition to hemangioblastomas of the central nervous system (CNS-HB) and retina (R-HB), clear cell renal cell carcinomas (ccRCC), pheochromocytomas (PCC) and pancreatic neuroendocrine tumours (PNET). VHL is caused by germline heterozygous pathogenic variants (PV) in the *VHL* tumor-suppressor gene. Here, we report the exploration of two typical VHL families without any identified *VHL* PV (*VHL*wt).

Material: Family A: proband presented R-HB at 29yo, multiple CNS-HB at 34yo and bilateral ccRCC at 37yo. At 57yo, his mother developed bilateral ccRCC, bilateral R-Hb and PCC. Family B: 38yo female patient with bilateral ccRCC and probable PNET at 42yo.

Results: No *VHL* variant was found in both families. In family A, a germline *ELOC* p.(Glu92Gly) variant was identified in both affected patients. In patient B, the p.(Tyr79Cys) *ELOC* PV was found in germline DNA. In all analyzed tumor tissues (n = 7), the *ELOC* variant was associated with LOH.

Conclusion: *ELOC* gene encodes the elongin C protein, which binds to pVHL. *ELOC* PVs have been already described as somatic driver mutations in sporadic ccRCCs but litterature reports only one case of patient with germline p.(Tyr79Cys) *ELOC* variant (Andreou *et al*., 2022). Here we report another case with clinical diagnostic for VHL carrying the same germline VP and also a family presenting a new *ELOC* variant segregating with the disease. Therefore, we propose *ELOC* as a novel VHL predisposition gene, emphasizing the need for European collaboration to refine the clinical spectrum of ELOC-associated VHL disease.

Background: DICER1 tumor predisposition syndrome (DTPS) is a rare pleiotropic hereditary condition affecting children and young adults. Identification of *DICER1* carriers is key for prevention and actionability in families. However, DTPS diagnosis is hindered by its incomplete penetrance and broad phenotypic spectrum. We aimed to characterize *DICER1* variants in large cancer predisposition cohorts to determine their prevalence in the actual clinical setting and elucidate the clinical extent of the disease.

Methods: We analyzed *DICER1* sequencing data from 92 children and 6108 adults with a suspected cancer predisposition syndrome. Clinical and *DICER1* somatic data from selected carriers and public datasets were studied. Functional analyses were conducted on a variant of unknown significance.

Results: The prevalence of germline *DICER1* PVs was 1:30 in children and 1:3054 in adults (Table 1). No adult referral phenotype was a known DTPS-associated tumor, although 3/5 carriers also developed thyroid alterations. We provide functional evidence supporting the pathogenicity of a novel in-frame deletion. A 56-year-old woman with an ovarian carcinoma and a toxic diffuse thyroid hyperplasia was found to have a postzygotic hotspot missense.

Conclusion: The prevalence of *DICER1* PVs in cancer predisposition populations was 5–6 times that reported in the general population. Pediatric-onset DTPS is well characterized, whereas adult carriers mainly present with thyroid abnormalities in the absence of DICER1-related family history, thus requiring accurate criteria for its identification when in constellation with other tumor types. Postzygotic hotspot missenses may exist without the expected severe phenotype.

P01.045.A Impact of updated variant classification criteria on *BRCA1* and *BRCA2* gene variants: a retrospective analysis

Diogo Fernandes da Rocha[1], *Sónia Sousa*[2], *Pedro Louro*[1,3], *Sérgio Castedo*[2,4]

[1]*Serviço de Genética Humana, Hospital Universitário de São João, Unidade Local de Saúde de São João, Porto, Portugal,* [2]*Instituto de Patologia e Imunologia Molecular da Universidade do Porto (Ipatimup), Porto, Portugal,* [3]*Faculdade de Ciências da Saúde, Universidade da Beira Interior, Covilhã, Portugal,* [4]*i3S – Instituto de Investigação e Inovação em Saúde, Porto, Portugal.*

Background: The ClinGen/ENIGMA (Evidence-based Network for the Interpretation of Germline Mutant Alleles) *BRCA1* and *BRCA2* Expert Panel (VCEP) recently updated the 2015 ACMG/AMP variant interpretation guidelines, refining criteria for pathogenicity and benignity and introducing new classification combinations (PMID: 39142283).

Material and methods: To assess the impact of these revised guidelines, the clinical lab Instituto de Patologia e Imunologia Molecular da Universidade do Porto (Ipatimup Diagnostics) performed a reclassification of all previously identified *BRCA1* and *BRCA2* germline variants. Variants were categorized by type and reassessed based on a comprehensive review of evidence, including population databases, literature, in silico prediction models, and laboratory-developed tools.

Results: A total of 154 *BRCA1* and 322 *BRCA2* variants were reviewed. While molecular diagnoses remained largely unchanged, there was a notable reduction in VUS and an increase in LB/B classifications. This shift was largely due to the activation of the 'BP1_Strong' criteria, which allowed the reclassification of certain synonymous and missense variants as LB, provided they do not affect critical functional domains or splicing. Reclassified variants with clinical implications prompted updated reports for clinicians.

Conclusion: Implementing the new ClinGen ENIGMA VCEP criteria for *BRCA1* and *BRCA2* has reduced inconclusive results in genetic testing by almost 70%. This advancement enhances diagnostic accuracy and supports more reliable patient management, ultimately improving the quality of care.

P01.046.B DNA long-read sequencing, an interest for genetics predispositions to breast and ovarian cancer

Crystal Renaud[1,2,3], *Antoine Chouteau*[1], *Camille Aucouturier*[1,2,3], *Raphael Leman*[1,2], *Alexandre Atkinson*[1], *Thibaut Lavole*[1], *Agathe Sorreda-Ricou*[1,2], *Flavie Boulouard*[1,2], *Dominique Vaur*[1,2], *Nicolas Goardon*[1,2], *Sophie Krieger*[1,2,3], *Laurent Castéra*[1,2]

[1]*Laboratory of Biology and Cancer Genetics, Centre Francois Baclesse, FHU G4 Genomics, Caen, France,* [2]*Inserm U1245, Université de Rouen, Rouen, France,* [3]*UNICAEN, Université de Caen Normandie, Caen, France.*

Background: Current molecular diagnostic methods for Hereditary Breast and Ovarian Cancer (HBOC) are based on short-read sequencing (SRS) of exons and flanking regions. These approaches can fail to detect complex events. Emergence of long-read sequencing (LRS) enables identification of these events, no matter how complex. We propose here a complete LRS method: from DNA extraction to final bioinformatic analysis.

Material and methods: We selected 200 families whose phenotype was in favour of HBOC syndrome and SRS results were negative. After extraction of high molecular weight DNA, sequencing was performed on the PromethION P2 solo using adaptive sampling technology on a panel of 161 genes. After demultiplexing and basecalling with Dorado, the pipeline performs alignment with minimap2, single nucleotide variants calling by Clair3 and annotation with SnpEff, VEP and GreenVaran. Structural variants were called by Sniffles and annotated by AnnotSV and GreenVaran. Copy number variants were investigated using CNVkit.

Results: Two hundred patients were sequenced. The average coverage for our panel genes was 50 reads. Adaptive sampling gave an average coverage of 5 reads for the other regions, allowing for shallow sequencing. All positive controls were detected by the pipeline. Although the analyses are being processed, we already fully characterized 3 insertions of Alu elements, 2 duplications.

Conclusion: In conclusion, LRS makes allows the characterisation of complex events. Our approach facilitates the analysis of a large number of patients by LRS. The analysis of the 200 patients could explain part of the missing hereditary through the discovery of new variants.

P01.047.C Comprehensive systematic literature review of *BRCA1* and *BRCA2* variants uncovers the significance of ENIGMA guidelines on clinically actionable variants

Melida Mahinic[1], *Denis Trivanovic*[1], *Rhea Kerawala*[2], *Betty Mattias*[2], *Jeffrey Bissonnette*[2], *Anna McGill*[2], *Almina Gajic*[1], *Annika Grewal*[2],

Arijana Cehic[1], Armina Heric[1], Azra Cickusic[1], Diane Nefcy[2], Elizabeth Wiley[2], Elma Lakota[1], Haris Kajtazovic[1], Haris Lokvancic[1], Ilma Cehic[1], Indira Valjevac[1], Jane Beckwell[2], Jessica Bugarin[2], Kathryn Curry[2], Lejla Maglic[1], Lejla Mujkic[1], Mahir Coric[1], Maida Ljubijankic[1], Majda Basic[1], Mirnesa Cviko Nalbantic[1], Natalie Syverud[1], Osman Hamzagic[1], Paty Romero[2], Selma Cajo[1], Selma Fatic[1], Selma Selimovic[1], Selma Tabakovic[1], Zach Young[2], Amina Kozaric[1], Mark J. Kiel[2]

[1]Genomenon, Sarajevo, Bosnia and Herzegovina, [2]Genomenon, Ann Arbor, MI, USA.

Background: *BRCA1* and *BRCA2* mutations significantly increase the risk of developing breast, ovarian, and other cancers. Rigorous classification is crucial for diagnosis and patient management.

Material and methods: Mastermind Genomic Search Engine (Genomenon) was used to collect BRCA1/2 variants from the literature, followed by a semi-automated curation with manual expert review according to the ACMG/AMP criteria. The classification of variants, including the application of PM5(S), was completed according to the ClinGen ENIGMA *BRCA1* and *BRCA2* Expert Panel Specifications to the ACMG/AMP Variant Interpretation Guidelines for BRCA1 Version 1.1.0. The PM5(S) was applied for variants with premature termination codon (PTC) in an exon with an existing pathogenic PTC variant.

Results: Systematic literature review of 16,223 articles revealed 25,046 *BRCA1* and 11,799 *BRCA2* variants, respectively. The curation of *BRCA1* resulted in 8146 Pathogenic/Likely Pathogenic, 13,979 VUS, and 2,908 Benign/Likely Benign variants. The curation of *BRCA2* resulted in 4153 Pathogenic/Likely Pathogenic, 7050 VUS, and 592 Benign/Likely Benign variants. PM5(S) was applied to 1,242 *BRCA1* variants and 19 *BRCA2* variants which led to the upgrade of 1,077 BRCA1/2 variants. Out of those, 500 variants were upgraded from VUS to pathogenic and 577 BRCA1/2 variants were upgraded from LP to P. Furthermore, 225 BRCA1/2 that were upgraded from VUS to pathogenic did not have patient data.

Conclusion: The application of the PM5(S) criterion led to the clinically significant upgrade of BRCA1/2 variants. This recalibration of variant classifications, driven by the nuanced interpretation of PM5(S), resulted in significant shifts in the overall assessment framework.

P01.048.D Consequences of *BCL2* promoter/5'UTR mutations in lymphoid malignancies

Daniel Kuznicki, *Malwina Suszynska, Paulina Galka-Marciniak, Wladyslaw Wegorek, Tugce Kocamanoglu, Piotr Kozłowski*

Institute of Bioorganic Chemistry, Polish Academy of Sciences, Poznań, Poland.

Background: B-cell non-Hodgkin lymphomas (BNHL) and chronic lymphocytic leukemia (CLL) frequently exhibit dysregulation of the anti-apoptotic *BCL2* gene family. This study investigates the association between mutations in the *BCL2* promoter and 5'UTR regions and the gene expression levels, alongside their broader impact on molecular pathways in tumor-derived samples.

Material and methods: Somatic variants from WGS and transcriptomic data from RNA-seq were obtained from the PCAWG (106 BNHL and 73 CLL samples) and the Hartwig repository (25 BNHL samples). Differential expression analysis was conducted using limma, and pathway-level effects were examined through Gene Set Enrichment Analysis (GSEA).

Results: 40% of BNHL and 16% of CLL samples were mutated in the *BCL2* promoter/5'UTR regions. The mutated samples exhibited a ~5-fold and ~1.2-fold higher expression of *BCL2* in BNHL and CLL respectively, though the causal relationship remains uncertain. Notably, basal *BCL2* expression in CLL was approximately 10 times higher than in BNHL. Differential expression analysis revealed 955 upregulated and 990 downregulated genes in mutated samples. GSEA highlighted significant downregulation of the cell cycle and DNA replication genes, with concurrent upregulation of cell adhesion molecules pathway. Dysregulated genes included *IGF2BP1*, *TERT*, and *SOX11*. Modest downregulation of *APOBEC3A* and *AIDCA* was also observed.

Conclusion: *BCL2* 5'UTR/promoter mutations are associated with increased expression levels and alterations in key oncogenic and immune-related genes/pathways. Although a direct causal link cannot be confirmed, these findings highlight the potential significance of these mutations in BNHL and CLL pathogenesis. Further studies are essential to clarify their mechanistic role and therapeutic/diagnostic potential.

All variations were found somatic excepted the MSH3 c.2814del that was found germline (G).

[1]*Département de Biologie et de Pathologie des Tumeurs, Centre de Lutte Contre le Cancer Georges François Leclerc, Dijon, France,* [2]*Unité d'Oncogénétique, Centre de Lutte Contre le Cancer Georges François Leclerc, Dijon, France,* [3]*Centre de Génétique, FHU-TRANSLAD, Centre Hospitalier Universitaire Dijon-Bourgogne, Dijon, France,* [4]*INSERM UMR 1231 GAD, Génétique des Anomalies du Développement, Université Bourgogne Franche-Comté, Dijon, France,* [5]*Département d'Oncologie Médicale, Centre de Lutte Contre le Cancer Georges François Leclerc, Dijon, France,* [6]*Plateforme de Transfert en Biologie Cancérologique, Centre de Lutte Contre le Cancer Georges François Leclerc, Dijon, France,* [7]*INSERM UMR 1231 GIMI, Genomic and Immunotherapy Medical Institute, Université Bourgogne Franche-Comté, Dijon, France.*

Background: Tumor Exome Sequencing (TES) is a powerful tool to identify strong molecular drivers and key genomic biomarkers in most cancer types, like GIS, TMB or mutational signatures. In the context of EX[2]TRICAN study, based on Germline Exome Sequencing (GES) in extreme cancer phenotypes, we evaluated the contribution of TES in the elucidation of molecular, possibly alternative causes of these phenotypes.

Material and methods: TES+GES was performed in 26 tumors among 97 cases from EX[2]TRICAN study. SNV, CNV variants and various genomic signatures were obtained (Table).

Results: 26 tumors from 15 tumor types were sequenced. 3 groups were identified: sporadic tumors with necessary and sufficient somatic drivers (n = 10, 38%, Table), tumors with somatic drivers that do not confirm sporadicity (n = 6, 23%), tumors without any somatic driver (n = 10, 38%). Surprisingly, we could identify sporadic colorectal cancer caused by POLE or POLD1 somatic mutations in 2 young patients aged 31 and 35.

Conclusion: TES is a powerful tool to identify causes of extreme cancer phenotypes where genetic predisposition is suspected: in 37% of cases, the presence of causal somatic drivers provides arguments for the diagnosis of sporadic cancer. TES showed its utility in confirming the causality of a candidate variant (either germline or somatic), when associated with specific signatures like TMB, SBS, GIS. This approach also provides useful information for family screening and follow-up decisions. These findings encourage us to integrate TES in the diagnosis strategy of extreme cancer phenotypes.

P01.050.B Re-evaluation of *ATM* variants reported as variants of uncertain significance in breast cancer patients: impact of updated ClinGen guidelines

Merve Berfin Aktan Karaca, *Mehmet Kocabey, Tufan Cankaya, Ayfer Ulgenalp, Ahmet Okay Caglayan*

Dokuz Eylul University Faculty of Medicine Department of Medical Genetics, Izmir, Turkey.

Background: The *ATM* gene plays a critical role in DNA damage response, and its germline variants have been associated with hereditary breast, pancreatic, prostate and gastric cancers. Because of reduced penetrance and limited knowledge of functional effects, pathogenicity assessment is complicated, which in turn results in variants of uncertain significance (VUS). The 2024 ClinGen Hereditary Breast-Ovarian and Pancreatic Variant Curation Expert Panel (HBOP-VCEP) guidelines provided gene-specific modifications to the interpretation framework, aiming to better delineate classification of *ATM* variants.

Material and methods: In this study, a total of 465 patients who were referred to our center and underwent next-generation sequencing panel for breast cancer between 2020 and 2024 were retrospectively examined. All *ATM* variants that are reported as VUS were included 47 unique VUS was detected in 67 patients. Reanalysis of these variants were performed in accordance with updated ClinGen HBOP-VCEP specifications.

Results: Nineteen out of 47 variants (40.4%) were reclassified: 16 as likely benign, 2 as benign, and 1 as likely pathogenic. The refined classification was primarily driven by the incorporation of updated population frequency thresholds, updated in silico score thresholds, and updated segregation data evidence strengths in the new criteria. One variant was reclassified, not because of guideline specifications, but because of recent emergence of functional evidence.

Conclusion: This study highlights the impact of periodic re-evaluation of VUS in clinically significant genes like ATM. The implementation of updated, gene-specific guidelines enhances the accuracy of interpretation, reduces the uncertainty in genetic counseling, and improves clinical decision-making for breast cancer patients.

P01.051.C Genotype and phenotype in carriers of pathogenic variants in *RAD51C* and *RAD51D* genes

Eliana Zacchi[1], ***Sonia Filoni***[1], *Giovanni Innella*[1,2], *Sara Miccoli*[1], *Lea Godino*[1], *Giulia Lanzoni*[1], *Simona Ferrari*[1], *Daniela Turchetti*[1,2]

[1]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [2]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy.*

Background: Beyond *BRCA1/2*, other genes were recently implicated in Hereditary Breast/Ovarian Cancer, including *RAD51C* and *RAD51D*, for which evidence on cancer risks needs to be collected.

Material and methods: The records of families carrying variants in *RAD51C/D*, either diagnosed by our Laboratory or referred to our Cancer Genetics Clinic after testing, were reviewed.

Results: *RAD51C/D* variants were identified in 24 individuals from 11 families (table 1).

Gene	Variant	N. of families	N. of carriers (patients/ asymptomatic relatives)
RAD51C	c.1026+5_1026+7delGTA	2	5 (4/1)
RAD51C	c.905-2_905-1del	3	5 (4/1)
RAD51C	c.904+5G>T	2	3 (2/1)
RAD51D	c.694C > T (p.Arg232Ter)	2	6 (2/4)
RAD51D	c.803G > A (p.Trp268Ter)	1	3 (3/0)
RAD51D	c.817C > T (p.Arg273Ter)	1	2 (1/1)

Seven carriers (29,2%) developed Ovarian Cancer (OC), 7 (29,2%) Breast Cancer (BC), one (4,2%) both, one had colon cancer (4,2%), while 8 (33,3%), were asymptomatic relatives (6 women, 2 men, aged 34–73). Four cancer patients (16,7%) developed additional malignancies: cholangiocarcinoma, melanoma, rectal

adenocarcinoma, and leukemia. OC was diagnosed at an average age of 57 years (range 50–76) and had high histologic grade in all cases: 6 serous type, one endometrioid, one undifferentiated. After a mean time from diagnosis of 140 months (range: 13–259), 6 patients were alive, 2 deceased (mean time from diagnosis to death: 133 month). BC was diagnosed at an average age of 55 years (range 34–68). Triple-negative histology was observed in 5 cases (62.5%); two patients (29%) developed metachronous contralateral triple-negative carcinomas. After a mean time from diagnosis of 56 months (range: 2–211), all patients were alive.

Conclusions: Data observed suggest favorable prognosis for *RAD51C/D*-associated OC, prevalence of triple-negative histology for BC and tendency to develop multiple primary cancers. If confirmed, these features will inform tailored carrier management.

P01.052.D Exploring cfDNA copy number profiles to monitor tumor dynamics in pancreatic adenocarcinoma

Nele Vandenbussche[1,2], *Luìs Abreu de Carvalho*[3], *Greet Wieme*[1], *Bram Parton*[1,2], *Béatrice Lintermans*[1,2], *Suzane Ribeiro*[4], *Anne Hoorens*[5], *Karen Geboes*[4], *Frederik Berrevoet*[3], *Kathleen Claes*[6,1]

[1]*Department of Biomolecular Medicine, Ghent University, Ghent, Belgium,* [2]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [3]*Department of General and Hepatico-Pancreatico-Biliary Surgery and Liver Transplantation, Ghent University Hospital, Ghent, Belgium,* [4]*Department of Gastroenterology, Ghent University Hospital, Ghent, Belgium,* [5]*Department of Pathology, Ghent University Hospital, Ghent, Belgium,* [6]*Center for Medical Genetics, Ghent University Hospital, Gent, Belgium.*

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a leading cause of cancer-related mortality due to its aggressive nature and late-stage diagnosis. Circulating tumor DNA (ctDNA) offers a minimally invasive approach to monitor tumor dynamics. We investigated cfDNA profiles across PDAC stages and treatment timelines, utilizing shallow whole genome sequencing (sWGS).

Material and methods: We collected 121 cfDNA samples from 59 PDAC patients. The cfDNA samples were analyzed with sWGS, using WISECONDOR for copy number profile abnormality (CPA) scores and ichorCNA for tumor fractions (TF). We evaluated whether these markers could distinguish PDAC stages and monitor disease progression, comparing their utility to CA19-9 levels and imaging.

Results: Patients with resectable tumors had significantly lower CPA scores (0.65 ± 0.35) and TF ($3.6 \pm 1.9\%$) than metastatic patients (CPA: 3.47 ± 1.7, TF: $15.1 \pm 8.0\%$). Borderline resectable, locally advanced and early metastatic cases had CPA (0.61 ± 0.21) and TF ($3.3 \pm 1.1\%$) values similar to resectable cases, indicating that CPA and TF are primarily increased in metastatic PDAC. CPA and TF were significantly correlated, though preliminary data suggests CPA may be more robust. No significant correlation was found between cfDNA concentration and CPA or TF. Both markers showed no clear correlation with CA19-9 but, in some patients, aligned better with disease state than CA19-9.

Conclusions: sWGS of cfDNA provides a cost-effective tool that may complement CA19-9 and imaging, particularly in metastasized PDAC. Ongoing analyses include investigating whether alterations of specific genomic regions are associated with prognosis.

P01.053.A Molecular implications of transposable element activity in non-muscle invasive bladder cancer progression

Burcu Akman[1,2], *Leman Binokay*[1,3], *Mustafa Gürses*[4,5], *Muhammet Memon*[3], *Kutsal Yörükoglu*[6], *Ugur Mungan*[4], *Gökhan Karakülah*[1,3], *Serap Erkek-Ozhan*[1,2]

[1]*Basic and Translational Research Program, İzmir Biomedicine and Genome Center, Izmir, Turkey,* [2]*Rare and Undiagnosed Disease Platform, Izmir Biomedicine and Genome Center, Izmir, Turkey,* [3]*İzmir International Biomedicine and Genome Institute, Dokuz Eylül University, Izmir, Turkey,* [4]*Department of Urology, Faculty of Medicine, Dokuz Eylül University, Izmir, Turkey,* [5]*Department of Urology, Mus State Hospital, Mus, Turkey,* [6]*Department of Pathology, Faculty of Medicine, Dokuz Eylül University, Izmir, Turkey.*

Background: Non-muscle invasive bladder cancer (NMIBC) exhibits great molecular heterogeneity. Understanding the genetic and epigenetic alterations underlying NMIBC subtypes is crucial for prognosis and therapeutic advancements. Recent studies have suggested a role for transposable elements (TEs) in oncogenic processes, but their impact on NMIBC remains largely unexplored.

Material and methods: Tumor samples from 18 NMIBC patients were analyzed using whole-exome sequencing (WES) to identify key mutations, revealing frequent alterations in *KMT2C, KDM6A, EP300, FGFR3*, and *KMT2D*. Molecular subtypes using the consensusNMIBC classifier were determined via RNA sequencing (RNA-seq). Differential gene expression analysis was conducted between Class 1 ($n = 9$), associated with favorable prognosis, and Class 2a ($n = 8$), characterized by poor prognosis. TE activity was assessed using the SQuIRE tool, and transcription factor (TF) motif enrichment analysis was performed using Homer.

Results: TE activity was significantly elevated in Class 2a tumors, particularly in LTR, DNA, LINE, and SINE elements. Locus-specific TE activation analysis identified 247 genes associated with TE expression, predominantly linked to cell cycle regulation. Spearman correlation analysis for expression levels of TE and genes within the same topologically associating domains (TADs) identified 428 genes. Homer motif analysis revealed significant enrichment of PAX6 binding sites on genomic sequences of TEs, and PAX6 expression was notably upregulated in Class 2a tumors, validated in an independent dataset.

Conclusion: These findings suggest a potential role of TE activation in driving oncogenic transcriptional programs in aggressive NMIBC subtypes. The association between TE activity and PAX6 upregulation highlights a novel regulatory mechanism in NMIBC progression.

P01.055.C Effect of BAP1 inactivation on uveal melanoma class-specific epigenome formation in an isogenic BAP1 knockout model

Michael Zeschnigk[1], *Laura Steenpas*[2], *Nicole Barwinski*[1], *Ulrich Pfeffer*[3], *Christopher Schroeder*[1], *Yasaman Arjmand Abbassi*[1]

[1]*University Hospital Essen, Institute of Human Genetics, Essen, Germany,* [2]*Leibniz-Institute DSMZ-German Collection of Microorganisms and Cell Cultures GmbH, Braunschweig, Germany,* [3]*Ospedale Policlinico San Martino, c/o CBA - torre 1–21, Genua, Italy.*

Background: Uveal melanoma (UM) is the most common primary ocular malignancy in adults. The two main classes of UM associated with metastatic progression can be distinguished by molecular features, including chromosome 3 status or DNA methylation patterns. The poor prognosis monosomy 3 UM class is characterised by inactivating mutations of the TSG BAP1, which encodes an enzyme that deubiquitinates histone H2A at lysine 119. To test the impact of BAP1 on the formation of the UM class-specific DNA methylation pattern, we generated an isogenic *BAP1* knockout (KO) cell culture model.

Material and methods: The UM 92-1 cell line was subjected to CRISPR-Cas9-mediated genome editing targeting the *BAP1* gene. Whole genome methylation analysis was performed by EM (enzymatic modification) sequencing with a median coverage of 15-fold.

Results: We generated 4 different *BAP1* KO cell lines with. Western blotting confirmed the absence of BAP1 and increased H2A mono-ubiquitination in all *BAP1* KO clones. Principal component analysis of genome-wide methylation data comparing *BAP1* WT and *BAP1* KO cells grouped samples according to their *BAP1* genotype and showed a consistent *BAP1*-dependent methylation pattern. There was no obvious difference in the methylation pattern between early and late passages after genome editing, suggesting that methylation changes are stably transferred over many passages.

Conclusion: *BAP1* inactivation in UM cell line with disomy 3 results in a stable change of the genome wide methylation pattern. However, to achieve the full M3 epi-phenotype additional factors are needed.

P01.056.D Unraveling the role of ROS1 in breast cCancer: functional impact of the c.6005+2T > G variant

Arianna Orsini[1], *Chiara Diquigiovanni*[1], *Bianca De Nicolo*[2,1], *Erica Cataldi Stagetti*[1], *Nicola Rizzardi*[3], *Sabrina Valente*[1,2], *Livia Gozzellino*[1], *Annalisa Astolfi*[1,2], *Christian Bergamini*[3], *Elena Bonora*[1,2]

[1]*Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy,* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [3]*Department of Pharmacology and Biotechnology (FABIT), University of Bologna, Bologna, Italy.*

Background: We recently discovered novel damaging variants in hereditary breast cancer cases in ROS1, a receptor tyrosine kinase with unknown ligands and functions, including the heterozygous variant c.6005+2T > G. This variant disrupts a donor splice site, resulting in the use of a cryptic splice site with partial intron retention and insertion of a premature stop codon in ROS1.

Material and methods: We utilized skin-derived fibroblasts from two first-degree cousins with early-onset BC carrying the c.6005+2T > G variant and control cells to evaluate tumor-related properties, perform RNA sequencing (RNAseq) analysis, and study mitochondrial alterations.

Results: Western blot analysis in mutant fibroblasts vs. controls indicated that the c.6005+2T > G variant was translated into a shorter protein due to the use of a premature stop codon. Compared to controls, mutant fibroblasts showed an altered ROS1 localization at the plasma membrane via immunofluorescence labeling, coupled to an increased migration rate via wound healing assay. RNAseq identified 2186 differentially expressed genes with a P-value < 10-3 between mutant and control fibroblasts, with significant dysregulation of genes related to migration and extracellular matrix organization, confirmed by real-time quantitative PCR. Furthermore, RNAseq analysis showed a significant dysregulation of mitochondrial genes, such as the mitochondrial iron-sulphur clusters, downregulated in mutant fibroblasts. Tetramethylrhodamine staining showed a mitochondrial hyperfusion in mutant fibroblasts, supporting mitochondrial alterations. Electron microscopy analyses are currently ongoing to define in further detail the subcellular organization of ROS1-mutant cells.

Conclusion: The findings suggest that mutant ROS1 enhances migration capacity and modifies mitochondrial functions, supporting a role of ROS1 in BC development.

Background: LS is highly underdiagnosed worldwide. The ItaLynch study aims to evaluate an oncologist-led diagnostic pathway for LS integrating germline genetic testing (GGT) into oncology.

Material and methods: ItaLynch is a prospective Italian study on Mismatch deficient CRC patients. It started in 2021 and is ongoing in 23 centers. The diagnostic pathway is based on four key steps: Universal Screening (dMMR testing by immunohistochemistry- IHC); Reflex Testing in MLH1-deficient (dMLH1) patients ($BRAF^{V600E}$ and, if wild-type, MLH1 promoter-methylation); Lynch Alert (LA, positive or negative) added to all dMMR CRC pathology reports, based on patients' likelihood of LS; Oncologist-Led Mainstream GGT for patients with a positive LA. Carriers of a germline pathogenic variant (PV), and those with VUS or clinical red flags and non-informative test results, are referred to genetic counseling (GC).

Results: As of Dec. 19/2024, 1146 dMMR CRC patients have been enrolled. Among the 937 patients eligible, 714 (76%) were dMLH1, and 223 (24%) displayed loss of non-MLH1 protein (68%). At the time of writing, out of 321 LA-positive patients (34%), 217 have undergone oncologist-led GGT (68%): 97 carried an LS-associated PV (45%), 14 a VUS (6%). Post-test GC was attended by 70/97 PV-carriers (72%) and 12/14 patients with VUS (86%).

Conclusion: The LA flagging system that identifies dMMR CRC patients with a high likelihood of LS, together with oncologist-led GGT, obtained a high diagnostic yield in our large cohort of dMMR CRCs. Further analyses are ongoing to evaluate the performance of and explore barriers and facilitators in the ItaLynch pathway

P01.058.B Decoding the puzzle of human somatic mtDNA mutagenesis: bridging species life-history traits and organ-specific cellular properties

*B. Efimenko[1], A. G. Mikhailova[1], E. Tretiakov[2], **K. Popadin**[1];*

[1]Immanuel Kant Baltic Federal University, Kaliningrad, Russian Federation, [2]Department of Molecular Neurosciences, Center for Brain Research, Medical University of Vienna, Vienna, Austria

Background: Mitochondrial DNA (mtDNA) mutagenesis in human cancers is still enigmatic: external mutagens like UV light or tobacco smoke, known to impact nuclear DNA, don't seem to affect mtDNA. This discrepancy suggests a dominant, mitochondria-specific internal mutagen. To understand this, we analyzed mtDNA mutational spectra across a wide range of vertebrates, uncovering that some mutations (A > G on the heavy chain) are linked to internal, age-related chemical damage, likely oxidative (https://doi.org/10.1093/nar/gkac779). Others (C > T on the heavy chain) stem from internal replication processes (https://doi.org/10.1101/2023.12.08.570826). Leveraging our insights, we hypothesized that in somatic mtDNA mutagenesis, slow-dividing cells would exhibit more damage-related mutations, while fast-dividing cells would show a predominance of replication-associated mutations, i.e. we posited a variable damage-to-replication ratio (A > G/C > T) across tissues with different replication rates.

Material and methods: To test this, we reanalyzed the two most comprehensive human mtDNA datasets: the TCGA, with 7611 mutations across 37 cancer types and 21 tissues, and the GTEx, with 2762 mutations in 25 healthy tissues.

Results: In both datasets, a higher damage-to-replication ratio was found in organs with slow-dividing cells (neurons, ovary, heart, skeletal muscles) and a lower ratio in those with rapid cell division (colon, intestine, stomach, vagina). Furthermore, a decrease in this ratio in late-stage somatic mutations across all cancer types (TCGA data) aligns with the anticipated increase in cell turnover during carcinogenesis.

Conclusion: Our research shows that mtDNA mutations can reveal cell traits, unveiling their potential importance in biomedical applications.

P01.060.D The role of CREBBP in refining stratification of pediatric patients with B-cell acute lymphoblastic leukemia

Elizabeta Krstevska Bozhinovikj[1], *Nadica Matevska-Geshkovska[1], Marija Staninova Stojovska[1], Svetlana Kocheva[2], Aleksandra Jovanovska[2], Aleksandar Dimovski[1,3]*

[1]Center for Biomolecular Pharmaceutical Analyses, Faculty of Pharmacy, University Ss. Cyril and Methodius in Skopje, Skopje, North Macedonia, The Republic of, [2]University Clinic for Children's diseases, Faculty of Medicine, University Ss. Cyril and Methodius in Skopje, Skopje, North Macedonia, The Republic of, [3]Research Center for Genetic Engineering and Biotechnology, Macedonian Academy of Sciences and Arts, Skopje, North Macedonia, The Republic of.

Background: Around half of the relapses in pediatric B-cell acute lymphoblastic leukemia (B-ALL) occur in patients initially classified as standard-risk. There is a growing need for refining the stratification in this group of patients.

Material and methods: A total of 55 pediatric patients with B-ALL were included in this study. All patients were treated according to the ALL-IC-BFM 2002 protocol and five of them experienced disease relapse in a median follow-up of 48 months. Numerical/structural chromosomal abnormalities and copy number alterations in disease-related genes were analyzed using RT-PCR and MLPA methods. Whole exome sequencing was performed for all patients with relapse (samples obtained both at diagnosis and at relapse) and for five additional patients in remission.

Results: Alterations in the CREBBP gene were identified in 4/5 (80%) of the patients with relapse, two of whom exhibited high-hyperdiploidy and standard-risk features. The mutations were persistent in both diagnostic and relapse clones in one patient (c.3836+1G > A), acquired at relapse in two patients (p.R1446H; p.H1487Y), or involved a change in the same amino acid in one patient (R1446H at diagnosis; R1446C at relapse). None of the examined patients in remission featured alterations in this gene. The remaining patient with relapse had TP53 and EBF1 deletions, which were rare or absent in our cohort.

Conclusion: Screening for alterations in CREBBP gene at diagnosis and/or during chemotherapy could contribute to the identification of a significant number of patients with predefined or acquired chemoresistant clones, which may improve risk stratification in pediatric B-ALL.

P01.061.A Cancer diagnoses in patients with neurofibromatosis type 1 - a registry-based study

Ana Blatnik, *Ksenija Strojnik, Barbara Stojanov, Iva Opalič, Aleksander Novaković, Aljoša Andlovic, Romi Cencelj Arnež, Mateja Krajc*

Institute of Oncology Ljubljana, Ljubljana, Slovenia.

Background: Neurofibromatosis type 1 (NF1) is a multisystem disorder caused by pathogenic variants (PV) in the *NF1* gene and characterised by distinctive cutaneous, ocular, neurological, cardiovascular, and musculoskeletal features as well as an increased cancer risk. Our analysis aimed to estimate the prevalence of non-neurofibroma neoplasms in a group of adult NF1 patients referred for tumour surveillance.

Material and methods: This study included all NF1 patients referred to the Department of Clinical Cancer Genetics, Institute of Oncology Ljubljana, between 2019 and 2024. Their medical records were reviewed, and the diagnoses of cancer/neoplasia were verified using data from the Slovenian Cancer Registry.

Results: We identified 73 patients (median age 42, range 18–75) with a clinical diagnosis of NF1 which was confirmed using genetic testing in 95.9% of all cases. The PV were presumed to be de novo in 52% of our patients. Most patients were female (71.2%) and had no diagnosis of cancer (57.5%). Of the 42.4% who developed a non-neurofibroma neoplasm, 30.1% had one diagnosis and 12.3% had multiple. Sarcomas were the most common neoplasm, seen in 15%. Of these, 8.2% had GIST, 4.1% MPNST, and 2.7% other sarcomas. Breast cancer was diagnosed in 11% of NF1 patients, all of them female. Gliomas were reported in 8.2% and pheochromocytomas in 5.5%. Interestingly, 2 patients (2.7%) were diagnosed with polycythaemia vera.

Conclusion: The prevalence of neoplasia in our NF1 patients was high but comparable to other studies, with an excess of cancers known to be associated with the disorder.

P01.062.B Spatial transcriptomics reveal differentially expressed genes in pancreatic neuroendocrine tumors

Raitis Peculis[1], *Helvijs Niedra*[1], *Rihards Saksis*[1], *Ilona Mandrika*[1], *Sofija Vilisova*[2], *Jurijs Nazarovs*[2], *Austra Breikša*[2], *Aija Geriņa*[2], *Julie Earl*[3], *Ignacio Ruz-Caracuel*[4], *Marta Gabriela Rosas*[4], *Aldis Puķītis*[2], *Natalja Senterjakova*[2], *Vita Rovīte*[1]

[1]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [2]*Pauls Stradins Clinical University Hospital, Riga, Latvia,* [3]*Ramón y Cajal Health Research Institute, Ramón y Cajal University Hospital, Madrid, Spain,* [4]*Department of Pathology, Ramón y Cajal University Hospital, Madrid, Spain.*

Background: Pancreatic neuroendocrine tumors (PanNETs) arise from α and β cells of islets of Langerhans. These neoplasms make up about 7% of all neuroendocrine tumors and less than 2% of all pancreatic neoplasms. Because PanNETs are uncommon, studies thoroughly examining their overall transcriptomic landscape are scarce.

Material and methods: We employed GeoMx digital spatial profiling (DSP) in this study to characterise expression in eight PanNETs. Gene expression from 45 regions of interest from tumor and and 18 from normal islet tissue were used for DSP. These specific tissue compartments were identified using morphology markers.

Results: Total of 360 unique differentially expressed genes (DEG) (FDR < 0.05 and Log2FC > 0.5) were detected when comparing different PanNET grades with normal islet tissues. Majority of these were downregulated in tumor tissue. Twenty-six of all DEG were overlapping across all three tumor grades and five genes (RBP4, SPINK1, PLA2G1B, EGR1, and CD99) were consistently downregulated with relatively high Log2FC below −1.27. EGR1 and CD99 are of particular interest in PanNETs. EGR1 is known to activate p53/TP53 and TGFB1 expression, potentially preventing tumor formation. Our data show inverse correlation of EGR1 and higher tumor grade. Meanwhile, CD99 has been linked to markers of poorer PanNET prognosis, including local invasion, lymph node metastasis, and lymphatic or blood vessel invasion.

Conclusion: Using spatial transcriptomics, we have identified multiple DEG between PanNET and normal islet cells of which at least two are likely to be tumor development related and are consistently downregulated across all tumor grades.

P01.063.C Demonstration of a splice site effect of the missense p.(Glu224Ala) variant in TP53 in a Li-Fraumeni family

Ferruccio Romano[1], *Serena Cappato*[1], *Patrizia De Marco*[1], *Ludovica Menta*[2], *Francesca Faravelli*[1], *Paola Monti*[3], *Irena Velkova*[3], *Elisa Marcaccini*[3], *Paola Menichini*[3], *Viviana Gismondi*[3], *Gabriella Cirmena*[3], *Daniela Rivera*[3], *Deborah Schönegger*[4], *Pierre Hainaut*[4], *Renata Bocciardi*[1], *Valeria Capra*[1]

[1]*IRCCS Giannina Gaslini, Genova, Italy,* [2]*DINOGMI, Genova, Italy,* [3]*IRCCS Ospedale San Martino, Genova, Italy,* [4]*Grenoble Alpes University, Grenoble, France.*

Background: Carriers of pathogenic *TP53* germline variants have a higher risk of developing rhabdomyosarcoma. Here we report the case of a two-years-old child, deceased for a retroperitoneal rhabdomyosarcoma, carrying the maternally inherited c.671A>C p.(Glu224Ala) germline variant in the *TP53* gene, considered of uncertain significance (VUS). Functional assays were performed to verify the hypothesis of a possible role of the variant.

Material and methods: The variant was identified by whole exome sequencing analysis on the family trio. In vitro experiments on yeast, along with in silico analyses- minigene assay and cDNA analysis from maternally derived cells- were applied.

Results: Assays in yeast and mammalian cells demonstrated that the c.671A>C p.(Glu224Ala) missense variant has a wild-type functional profile. The variant affects the last codon of the exon 6 at junction with the intron, and SpliceAI predicted the alteration of the acceptor splicing with significant delta value effect. A minigene approach demonstrated the skipping of exon 6, with a frameshift in the coding sequence and the generation of a premature stop codon, that may likely target the variant transcript to the nonsense mediated mRNA decay. The loss of heterozygosity in *TP53* mRNA in maternally derived cells supported this hypothesis.

Conclusions: We demonstrated that the c.671A > C substitution alters P53 function by impairing the splicing rather than by altering the protein structure through the aminoacidic change. We collected functional data suitable to support the re-classification of a VUS into likely pathogenic and provided a conclusive molecular diagnosis useful for the proper family management.

P01.064.D Longitudinal measurement of mutated *EGFR* ctDNA in plasma of advanced NSCLC patients on first-line tyrosine kinase inhibitors - a potential for early detection of drug resistance and therapy effectiveness monitoring

Adam Szpechcinski[1], *Maciej Bryl*[2], *Emil Wojda*[3], *Krystyna Maszkowska-Kopij*[4], *Pawel Sliwinski*[5], *Mateusz Polaczek*[3], *Joanna Chorostowska-Wynimko*[1]

[1]*Institute of Tuberculosis and Lung Diseases, Department of Genetics and Clinical Immunology, Warsaw, Poland,* [2]*E.J. Zeyland Wielkopolska Center of Pulmonology and Thoracic Surgery, Department of Clinical Oncology with Daily Chemotherapy Unit, Poznan, Poland,* [3]*Institute of Tuberculosis and Lung Diseases, III Clinics of Lung Diseases and Oncology, Warsaw, Poland,* [4]*Institute of Tuberculosis and Lung Diseases, Outpatient Clinic, Warsaw, Poland,* [5]*Institute of Tuberculosis and Lung Diseases, II Clinics of Lung Diseases, Warsaw, Poland.*

Background: Non-invasive access to circulating tumor DNA (ctDNA) in plasma of non-small cell lung cancer (NSCLC) patients enables the dynamic monitoring of mutated *EGFR* gene (*mtEGFR*) levels during treatment with EGFR tyrosine kinase inhibitors (TKIs) instead of retrospective evaluation of re-biopsied tumor tissue. We evaluated the clinical value of longitudinal measurement of *mtEGFR* levels for the real-time treatment monitoring and early detection of drug resistance in advanced NSCLC patients receiving first-line EGFR-TKIs.

Material and methods: Peripheral blood was prospectively collected from 52 advanced NSCLC patients at the time of diagnosis (baseline) and then every month during the EGFR-TKI treatment until clinical progression. The *mtEGFR* was analyzed semiquantitively using cobas EGFR Mutation Test v2 (Roche, Germany) and verified using ddPCR.

Results: The median (min-max) progression-free survival (PFS) was 10.3 (1.8–35.6) months. Significant differences in PFS were found between patients who demonstrated complete clearance of baseline *mtEGFR* level in plasma within 1–2 month of treatment and patients whose *mtEGFR* levels were similar or higher than baseline [12 (4.5–35.6) vs. 8.35 (1.8–17.5) months, $p = 0.0099$], and patients with undetectable *mtEGFR* in plasma at diagnosis and during treatment [9.8 (1.8–30) months, $p = 0.04620$]. A drug-resistance variant, p.T790M, was detected in plasma of 13/52 (25%) patients before or upon clinical progression. Cobas test demonstrated high concordance with ddPCR ($R = 0.76$, $p < 0.0001$).

Conclusion: The dynamic changes of plasma *mtEGFR* levels in NSCLC patients reflect well their responses to EGFR-TKIs. The longitudinal monitoring of plasma *mtEGFR* levels allows to observe disease progression on EGFR-TKIs much earlier than conventional imaging techniques.

P01.065.A *MUTYH*-associated polyposis: genotype-phenotype correlations in a single-centre cohort of 170 patients

Claudia Monaco[1], *Davide Ferrari*[1], *Emanuele Mini*[2], *Valeria Pensotti*[3], *Giovanna De Vecchi*[3], *Sara Volorio*[3], *Frederique Mariette*[3], *Paolo Mariani*[3], *Clorinda Brignola*[1], *Stefano Signoroni*[1], *Daniela Zaffaroni*[1], *Marco Vitellaro*[1], *Maria Teresa Ricci*[1]

[1]*Unit of Hereditary Digestive Tract Tumours, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [2]*General Surgery Residency Programme, Università degli Studi di Milano, Milan, Italy,* [3]*Cancer Genetics Test Laboratory, Cogentech s.r.l. Società Benefit a Socio Unico, Milan, Italy.*

Background: Biallelic germline pathogenic variants (PVs) in MUTYH are responsible of MUTYH-Associated Polyposis (MAP), an autosomal recessive disorder associated with polyposis and increased risk of colorectal cancer (CRC).

Material and methods: Retrospective review of clinical and genotype data of patients with confirmed genetic diagnosis of MAP included in the Hereditary Colorectal Cancer Registry of Fondazione IRCCS Istituto Nazionale dei Tumori (Milan). Clinical information considered were: age at polyposis diagnosis, number of polyps, occurrence and age at CRC diagnosis, occurrence of multifocal and/or metachronous CRC, upper gastrointestinal (UGI) adenomas and extracolonic tumors.

Results: 170 MAP patients, belonging to 131 families, were included in the study. Eighteen different *MUTYH* pathogenic/likely pathogenic variants were identified. The most frequent were p.(Tyr179Cys), p.(Gly396Asp) and p.(Glu480del) (NM_001128425.2), with allele frequencies of 33%, 23% and 12%, respectively. Patients homozygotes for p.(Gly396Asp) or compound heterozygotes for p.(Gly396Asp) and a second PV ($n = 56$) showed a significantly later age at diagnosis compared to patients carrying other *MUTYH* PVs ($n = 114$) both for polyposis (51.7 vs 43.6 years) and CRC (54.6 vs 44.8 years). Furthermore, patients carrying at least one p.(Gly396Asp) variant also had a lower incidence of UGI adenomas (2.4% vs 23.3%).

Conclusion: The present study provides further evidences of genotype-phenotype correlations in MAP. The variant p.(Gly396Asp) is associated with lower UGI adenoma risk and a later polyposis and CRC onset, in accordance with previous reports and functional assays. Given the rarity of MAP, multicenter studies are necessary to explore the possibility of personalizing surveillance programs according to genotype.

P01.066.B Comparative analysis of circular RNA and messenger RNA profiles in microsatellite stable and unstable colorectal cancers

Sabine Vautier[1], *Corentin Levacher*[2], *Stéphanie Baert-Desurmont*[1], *France Blanchard*[3], *Edwige Kasper*[1], *Louison Leblond*[3], *Florent Marguet*[3], *Philippe Ruminy*[4], *Claude Houdayer*[1]

[1]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, FHU-G4 Génomique and CHU Rouen, Department of Genetics, ROUEN, France,* [2]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, ROUEN, France,* [3]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, CHU Rouen, Department of Pathology, ROUEN, France,* [4]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, Centre Henri Becquerel, ROUEN, France.*

Background: Circular RNAs (circRNAs), emerging regulators of genetic information, share the spliceosome biogenesis pathway with messenger RNAs (mRNAs) and influence their expression. Evidence increasingly supports their role in colorectal cancer (CRC) tumorigenesis. This study explores circRNAs in two distinct

pathways of colorectal tumorigenesis: microsatellite instability (MSI) and microsatellite stability (MSS).

Material and methods: Circular (circ) and linear (lin) exon-exon junctions were quantified using exon-specific probes targeting 48 involved in CRC predisposition and tumorigenesis process. RNA was extracted from colorectal FFPE samples (stage 1 to 4 adenocarcinoma and adenomas). MSS-IHC tumors (MSS-TT; n = 21) and adjacent normal tissue (MSS-NT; n = 16) were selected from patients with a severe personal or familial cancer history without a known genetic cause. MSI-IHC tumors (MSI-TT; n = 13) and normal adjacent tissue (MSI-NT; n = 14) were also analyzed.

Results: Principal component analysis distinguished NT from TT samples based on circular and linear junction sums. CircRNA abundance was higher in samples with elevated muscle content (Kruskal-Wallis test p-value = 0.034). Linear regression, adjusted for muscle content, showed significantly reduced global circRNA levels in tumors compared to healthy tissues (MSI and MSS combined, p-value = 0.00268). In the MSS group, significant differences were observed between MSS-NT and MSS-TT for circ/lin ratios, and for linear and circular junction counts for specific genes. MSI analysis revealed distinct gene profiles, with significant differences only in linear junction counts.

Conclusion: Our study suggests differences in circRNA profiles between MSI and MSS tissues. This potential pathway-specific regulation might be linked to splicing mechanism alterations involving circRNA synthesis.

P01.067.C Pre-test group genetic counselling for patients seeking cancer susceptibility predictive testing - an innovative service delivery initiative

V. Tripathi[1], *S. Monks*[2], *A. Butler*[1], *D. Meikle*[1], *H. Osman*[1], *E. Carden*[1], *A. Shaw*[1], *A. Kulkarni*[1], *L. Izzat*[1], *S. Talukdar*[1], *C. Parmar*[1];

[1]*Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom,* [2]*University Hospitals Bristol NHS Trust, London, United Kingdom*

Background: Point of care testing and personalised medicine have begun to change management for patients in the cancer pathway while generating familial risk information for their at-risk relatives. Constraints in NHS funding, workforce availability and digital infrastructures have led to family members waiting for prolonged periods to access clinical genetic services thereby delaying predictive testing. Group genetic counselling for patients at risk of high-risk cancer susceptibility familial pathogenic variants was piloted at the Guy's regional genetics service to expand capacity and reduce waiting times.

Methods: Suitable patients were given information describing the model with consent forms for participation. The group genetic counselling ran for an hour with a focus on information provision to facilitate decision making. Each individual patient was then seen separately by a clinician for a twenty-minute genetic counselling consultation. We ran this both virtually and in person for families with hereditary breast ovarian cancer and Lynch syndrome.

Results: We delivered 17 group sessions of 180 patients with 96 % accepting the offer. Likert scales were used to capture patient experience and feedback before and after the clinic. A 20% increase in capacity was enabled within the service. Patients and staff reported a positive experience with this model.

Conclusion: Group genetic counselling has the potential to transform care for patients without compromising quality of care. Patients reported utility in the shorter individual sessions which allowed personalised decision making. This novel model of care can be adopted across health services to enable shorter waiting times.

Background: Despite therapeutic advancements, metastatic colorectal cancer (mCRC) remains a leading cause of death, with a 5-year survival rate of 14%. Treatment for *RAS* wild-type mCRC patients includes chemotherapy and an anti-epidermal growth factor receptor (anti-EGFR) agent as first-line therapy, followed by second-line treatment with chemotherapy plus an anti-vascular endothelial growth factor (anti-VEGF) agent. However, patients eventually progress with limited therapeutic options for successive lines. The A-REPEAT study (NCT03311750) evaluated the efficacy of anti-EGFR re-challenge as third-line therapy.

Materials and methods: Twenty-three *RAS* wild-type mCRC patients were recruited upon progression to second-line treatment. The primary objective was to evaluate the response rate (RR) to third-line treatment with panitumumab plus chemotherapy. Blood was serially obtained at diagnosis and every 2 months and subjected to the NeoThetis Colorectal cancer liquid biopsy assay (Medicover Genetics) while tissue samples were tested using a custom Ampliseq assay, to identify factors predictive of response to anti-EGFR re-challenge.

Results: The objective RR was 13% while disease control rate was 52%. NGS genotyping of tissue and liquid biopsies revealed *TP53*, *APC*, *KRAS* and *NRAS* as the most frequently altered genes. About half of the patients tested via liquid biopsy had *RAS* mutations prior to anti-EGFR re-challenge. Patient response or control of disease did not correlate with the plasma *RAS* status, possibly due to the small cohort size.

Conclusion: Liquid biopsies have the potential to guide anti-EGFR re-challenge in mCRC patients. Larger cohorts are required to determine the role of *RAS* and other biomarkers in response to anti-EGFR re-challenge.

Background: Synonymous variants (sSNVs), despite not altering protein sequences, can influence gene regulation, including splicing. Unlike missense variants (mSNVs), the role of sSNVs in cancer predisposition remains poorly understood. This study investigates the functional impact of sSNVs in neuroblastoma, a pediatric cancer arising from aberrant neural crest development.

Material and methods: Whole-exome sequencing was conducted on 724 neuroblastoma cases and 2858 healthy controls. Rare variants (minor allele frequency [MAF] < 1%) were analyzed in 138 cancer predisposition genes (CPGs) using pathogenicity prediction tools, including synVEP, REVEL, PhyloP, FastCons, GERP, and SpliceAI.

Results: Considering all variants, we found similar rates of rare sSNVs and mSNVs in cases (16.9% and 27.3%, respectively) and in controls (18.7% and 32.6%, respectively). Moreover, 38.2% of rare sSNVs were predicted to be pathogenic by synVEP (scores ≥ 0.75), compared to 4.3% of rare mSNVs by REVEL (scores ≥ 0.75). Rare sSNVs were identified in 102 (74%) of the 138 CPGs in patients. Rare sSNVs in CPGs demonstrated significantly higher conservation compared to non-CPGs (PhyloP, $p = 0.02$; FastCons, $p = 0.009$; GERP, $p = 0.03$). Additionally, 21% of these variants recurred in at least two patients, a pattern also observed for mSNVs. Splicing analysis predicted disruptions in key genes, including SMARCA4, PALB2, FANCA and ATM (SpliceAI > 0.5), already found mutated by mSNVs in neuroblastoma patients.

Conclusion: Our findings suggest that sSNVs share pathogenic features with mSNVs, suggesting their functional impact. This highlights the importance of integrating sSNVs into cancer predisposition analyses.

P01.070.B Integrating somatic mutation testing in Estonia: widening treatment options for ovarian cancer

Mikk Tooming[1,2], *Kadri Rekker*[2], *Kadri Toome*[2], *Olga Fjodorova*[2], *Piret Laidre*[2], *Tõnu Jõgi*[3], *Kristiina Ojamaa*[3], *Eva-Maria Niine-Roolaht*[4], *Piret Kaarde*[4], *Jüri Piirsoo*[5,6], *Katrin Õunap*[1,2], *Tiina Kahre*[1,2]

[1]*Department of Genetics and Personalized Medicine, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia,* [2]*Genetics and Personalized Medicine Clinic, Tartu University Hospital, Tartu, Estonia,* [3]*Haematology and Oncology Clinic, Tartu University Hospital, Tartu, Estonia,* [4]*Surgery Clinic, North Estonian Medical Center, Tallinn, Estonia,* [5]*Centre of Oncology, East-Tallinn Central Hospital, Tallinn, Estonia,* [6]*Department of Oncogynecology, West-Tallinn Central Hospital, Tallinn, Estonia.*

Background: In Estonia, ~140 cases of ovarian cancer (OC) are diagnosed each year. Somatic testing was incorporated into the routine care of OC patients in 2020. This study aimed to investigate the landscape of actionable variants (AV) in the tumor tissues of Estonian OC patients to identify patients who can benefit from targeted therapy.

Material and methods: The study included 346 OC tumors referred from tertiary hospitals to the Genetics and Personalized Medicine Clinic at Tartu University Hospital between 2020 and 2024 for comprehensive tumor profiling. Tumor samples were analyzed using the Illumina TruSight Oncology 500 somatic mutation gene panel (523 genes). Homologous recombination deficiency (HRD) testing was implemented in 2023.

Results: The uptake of somatic testing increased from 39 samples in 2020 to 115 samples in 2024. AV were determined according to OncoKB level 1/2 in solid tumors. In our study, 28.9% (91/346) had actionable single nucleotide variants. The primary AV were found in *BRCA1* 14.2% (49/346) and *BRCA2* 5.2% (18/346). Additionally, eight samples (2.3%) had actionable amplifications, seven in *ERBB2* and one in *MET* gene. Furthermore, four samples had actionable fusions, two in *FGFR2* gene. A high tumor mutation burden was observed in 4% (14/346), and microsatellite instability was found in 2.9% (10/346). HRD was identified in 36.2% (55/152) of samples.

Conclusion: The diagnostic efficacy of OncoKB level 1/2 actionable gene alterations in OC samples in Estonia was 29.8% (103/346). These patients can potentially be offered targeted therapy or included in clinical trials.

P01.071.C Phenotypic spectrum in 170 patients with *MUTYH*-associated polyposis: results from a hereditary colorectal cancer registry

Maria Teresa Ricci[1], *Claudia Monaco*[1], *Emanuele Mini*[2], *Emanuele Rausa*[1], *Sara Lauricella*[1], *Daniela Zaffaroni*[1], *Clorinda Brignola*[1], *Stefano Signoroni*[1], *Antonio Zaccara*[1], *Marco Vitellaro*[1], *Davide Ferrari*[1]

[1]*Unit of Hereditary Digestive Tract Tumours, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [2]*General Surgery Residency Programme, Università degli Studi di Milano, Milan, Italy.*

Background: *MUTYH*-associated Polyposis (MAP) predisposes to adenomas and colorectal cancer (CRC). However, the phenotypic manifestations are variable and controversial.

Material and methods: Retrospective review of clinical information of patients with genetically confirmed MAP included in the Hereditary Colorectal Cancer Registry at the Fondazione IRCCS Istituto Nazionale dei Tumori, Milan.

Results: Overall, 170 MAP patients, belonging to 131 families, were identified: the mean age at polyposis diagnosis was 46.5 years (range 21–75), and the majority (110/170; 64.7%) presented symptomatically. Total polyp count was provided for 101 patients

(59.4%), and 31.7% (32/101) reported more than 100 polyps. Sixty-seven individuals (39.4%) had hyperplastic and/or serrated lesions in addition to adenomas. More than half of the patients (101/170; 59.4%) developed CRC; of these, thirty-five (34.6%) had multifocal tumors and thirteen metachronous tumors (12.9%). The mean age at first CRC diagnosis was 48.1 years (range 21–75) and most patients (94/170; 55.3%) presented both polyps and CRC at diagnosis. Overall, 148 patients (87%) underwent at least one surgical treatment and in 66.2% (98/148) of these cases a total colectomy was performed. Among the 127 patients (74.7%) who underwent upper gastrointestinal tract (UGI) endoscopy, twenty-one (16.5%) presented duodenal adenomas. Extra-colonic malignancies were diagnosed in forty-one patients (24.1%), with endometrium (Standardized Incidence Ratio: 7.2), thyroid (SIR: 9.9), lower urinary tract (SIR: 6.4) and skin tumors (SIR: 6.9) having a higher incidence than the general population.

Conclusion: A comprehensive characterization of the phenotypic variability in MAP patients is essential to improve diagnosis and management.

Background/objectives: Mesothelioma is a rare and aggressive disease with poor prognosis. Molecularly guided therapy is currently not part of standard care. We characterized a cohort of patients with advanced mesotheliomas clinically and molecularly using a broad multiomics approach.

Methods: 51 mesothelioma cases, including 21 peritoneal, 28 pleural, one synchronous and one pericardial mesothelioma, from the prospective observational German multicenter precision oncology program DKFZ/NCT/DKTK MASTER were included. Retrospective data analysis of 44 cases included parallel tumor and control genome or exome sequencing and transcriptome analysis. A molecular tumor board (MTB) assessed clinical actionability of somatic and germline alterations.

Results: 37/44 (84%) samples undergoing retrospective analysis demonstrated positivity in at least one biomarker indicating deficiency of homologous recombination (HR). Germline variant evaluation across 141 cancer predisposition genes (CPGs) revealed 13 pathogenic germline variants (PGVs) in 13/51 (25%) patients, ten thereof in genes associated with HR and eight in autosomal dominant CPGs. PGVs in *BAP1* occurred thrice. Loss of heterozygosity was observed in four tumors with PGVs in autosomal dominant CPGs (*ATM*, *BAP1*, *BRCA2*, *NF1*). PGVs impacted therapy recommendations (TR) in two patients, targeting impaired DNA damage response. Among 46/51 (90%) patients with TR, tyrosine kinase inhibition was recommended most frequently. TR were applied in six cases; three patients received immune checkpoint inhibitors.

Conclusion: Comprehensive molecular analysis provides insight into therapeutic potential. Based on the PGV yield and the potential clinical impact on patients and their relatives, parallel germline testing and molecular tumor characterization should be considered for all mesothelioma patients. **Grants:** DKFZ-HIPO-H021

P01.073.A Uncovering novel structural variants in pediatric low grade gliomas

Miriam Bornhorst[1], *Nicole Del Risco*[2], *Suraj Rangnath*[3], *D'Andre Spencer*[4], *Natalie Bizon*[1], *Alyssa Hohman*[1], *Shejuan An*[1], *Mahdi Muhamad*[1], *Hayk Barseghyan*[4]

[1]*Ann & Robert Lurie Children's Hospital of Chicago, Chicago, IL, USA,* [2]*George Washington University, Washington, DC, USA,* [3]*University of Michigan, Ann Arbor, MI, USA,* [4]*Children's National Hospital, Washington, DC, USA.*

Background: Despite the high success rate of treatment in pediatric patients with low grade gliomas (LGGs), some children have LGGs that behave more aggressively, leading to multiple recurrences, metastasis, and/or death. The reason for this discrepancy is not fully understood but may be due to the underlying differences in genomic composition. Short-read sequencing presents gaps in structural variant (SV) identification due to its underlying methodology, which creates a gap in our understanding of variants that influence tumor behavior and treatment response.

Material and methods: Here, we used optical genome mapping (OGM) to detect SV in a cohort of aggressive (postmortem, metastatic, or recurrent following standard of care therapy) and non-aggressive (surgery alone) LGG samples.

Results: The initial analysis focused on identification of known clinically significant fusions, such as the KIAA1549::BRAF fusion. OGM successfully identified these fusions in LGG samples with varying levels of variant allele fraction (VAF), supporting that LGG patients have different degrees of cell compositions carrying SVs. Further stratification of samples based on aggressive vs non-aggressive tumor behavior showed that aggressive tumors on average contain more SVs, including large chromosomal aberrations, than their non-aggressive counterparts.

Conclusion: This preliminary data demonstrates that the application of OGM in metastatic, refractory, and recurrent pediatric LGGs to define SV patterns could elucidate novel mechanisms involved in tumor behavior.

P01.075.C Development of a risk score based on clinical-pathological features to predict the presence of germline*BRCA1/2*pathogenic variants in ovarian cancer patients

Giovanni Innella[1,2], *Giulia Erini*[1], *Antonio De Leo*[1,2], *Lea Godino*[2], *Luca Caramanna*[1], *Simona Ferrari*[2], *Sara Miccoli*[2], *Anna M. Perrone*[1,2], *Claudio Zamagni*[2], *Pierandrea De Iaco*[1,2], *Daniela Turchetti*[1,2], *Paola Rucci*[1]

[1]*ALMA MATER STUDIORUM - UNIVERSITA' DI BOLOGNA, Bologna, Italy,* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: As the identification of germline *BRCA1/2* pathogenic variants is crucial to inform ovarian cancer (OC) treatment, here we aimed to develop a model to predict *BRCA1/2* status in OC patients.

Material and methods: The association between clinical-pathological features and *BRCA1/2* status was analyzed in a series of 1009 OC patients, using Fisher's exact test. Logistic regression models and a Decision Tree Classification algorithm were then used to develop a risk score.

Results: Compared to non-carriers, *BRCA1/2* carriers (216; 21.4%) presented significantly ($p < 0.05$) more frequently with serous histotype non-low-grade (92.3% vs. 71.6%), family OC history (31.6% vs. 5.7%), family breast cancer (BC) history (53.7% vs. 31.6%), previous BC (20.9% vs. 8.5%), advanced stage (78.8% vs. 69.5%) and younger age (56.9 vs. 60.8 years). Multivariable logistic regression confirmed histotype, family history of BC/OC, previous BC and age as independently and significantly associated with *BRCA1/2* status. ORs derived after calibration according to Decision Tree Classification algorithm results were used to assign weights from 1 to 3 to each feature (serous histotype, non-low-grade = 3, low-grade serous histotype/high-grade endometrioid histotype/family OC history = 2, age at diagnosis<50 years/family and personal BC history = 1) and to develop a score ranging from 0 to 10, associated with increasing risk of *BRCA1/2* variants (from 0.6% for score 0 to 88% for score ≥ 7). The AUC of the score was 0.78 (95% CI 0.74–0.82) and the optimal cut-off was ≥4 points (sensitivity 81%, specificity 62.3%).

Conclusion: The proposed risk score may support clinicians in the assessment of OC patients.

P01.076.D Distinct de novo *NF1* variants in gametes of affected parents and multiple complex events underline the high mutation rate in Type I Neurofibromatosis

Enrico Ambrosini[1], *Davide Martorana*[1], *Fiorenza Soli*[2], *Antonietta Taiani*[3], *Ilenia Rita Cannizzaro*[3], *Sabrina Busciglio*[3], *Elisa Gravagno*[1], *Sofia Cesarini*[3], *Patrizia Caggiati*[1], *Vera Uliana*[1], *Valeria Barili*[3], *Antonio Percesepe*[1,3]

[1]Medical Genetics Unit, University Hospital of Parma, Parma, Italy, [2]Medical Genetics Service, Clinical Pathology Lab, APSS Trento, Trento, Italy, [3]University of Parma, Parma, Italy.

Background: The NF1 gene shows one of the highest mutation rates, estimated to be on the order of 10^{-4} per generation, with 50% of NF1 patients harboring de novo variants. Due to this high frequency of new mutational events, mostly on the paternal allele, co-occurrence of two or more different *NF1* pathogenic variants has been reported in at least 11 independent families.

Material and methods: We employed next-generation sequencing (NGS), multiplex ligation-dependent probe amplification (MLPA) and long-read sequencing to investigate four families exhibiting peculiar mutational events related to the *NF1* high mutation rate.

Results: In two unrelated families, the proband displayed a de novo NF1 variant, while their respective affected father carried a different pathogenic variant. In both cases, the mothers showed no signs and tested negative. Long-read approach revealed that the de novo event took place on the paternal allele. Another NF1 patient, with a severe pseudoarthrosis of the tibia, showed three alternative nucleotides (G > T/C) at position 2376 of *NF1*, with variant fractions of 41%, 37% and 22%, respectively. Sanger sequencing confirmed the triple peak, suggesting the occurrence of two independent mutational events in a mosaic state. Finally, in a fourth patient we identified a deletion encompassing *NF1* and other 5′-contiguous genes, alongside a duplication at the adjacent 3′-end (involving *UTP6*, *SUZ12* and *LRRC37B*), suggesting a complex rearrangement.

Conclusion: The *NF1* high mutation rate should be considered in the diagnostic process and may complicate genetic counselling, altering recurrence risk and potentially explaining localized clinical manifestations or negative NGS results.

P01.078.B Germline genomic testing in pediatric oncology - insights from a single-center experience

Britannia Morgan Fleming[1], *Yam Amir*[1], *Hagit Baris Feldman*[1,2], *Daphna Marom*[1,2], *Uri Hamiel*[1,2]

[1]Genetics Institute and Genomic Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel.

Background: Up to 8–12% of childhood cancers are attributed to germline mutations in cancer-predisposing genes (CPGs). Israel's unique population - characterized by founder mutations and a high consanguinity rate - may influence the prevalence of germline CPG variants in pediatric cancer. However, data on Israeli pediatric patients remain scarce. This study evaluates the diagnostic yield of germline genomic testing in pediatric oncology patients at a newly established genetics clinic.

Material and methods: We retrospectively analyzed pediatric oncology patients (≤25 years) referred to the Genetics Institute at Tel Aviv Sourasky Medical Center (September 2019-December 2024). Genetic testing (panel/whole-exome sequencing) was recommended following clinical evaluation on an individualized basis. We determined the overall diagnostic yield, then stratified results by demographics, tumor type, and syndromic features.

Results: Among 147 referred patients (93 male, 54 female; ages 3 months-24 years, mean 8 years), 92 (63%) underwent genomic testing. Pathogenic/likely pathogenic variants were identified in 18/92 (20%) across multiple CPGs. Among mutation-positive patients, 56% (10/18) had additional systemic findings, compared to 18% (13/74) of mutation-negative patients ($p = 0.0019$). The highest CPG detection rates were in soft tissue sarcomas (3/7, 43%), Wilms tumor (1/3, 33%), neuroblastoma (2/7, 29%), leukemia (3/14, 21%), and CNS tumors (5/25, 20%).

Conclusion: Our findings suggest a higher-than-expected diagnostic yield of germline genomic testing in Israeli pediatric oncology patients, potentially influenced by population-specific factors. The association between pathogenic variants and syndromic features underscores the importance of comprehensive clinical evaluation. These results support tailored genetic counseling and expanded genomic testing in pediatric oncology.

P01.079.C Molecular profiling of VHL mutations in sporadic ccRCC patients from India

Srilagna Chatterjee, *Madhusudan Das*

University of Calcutta, Kolkata, India.

Background: Clear cell renal cell carcinoma (ccRCC) is the most common subtype of renal cancer, with von Hippel-Lindau (VHL) gene alterations playing a key role in its pathogenesis. While global studies have extensively reported on VHL mutations, there is limited data from Indian subcontinent. This study aimed to characterize VHL gene variants in sporadic ccRCC patients from this region and explore their clinical significance.

Material and methods: Blood and tumour tissue samples were collected from 210 sporadic ccRCC patients and genomic DNA was sequenced using Sanger sequencing. Variants were annotated using in-silico tools and classified based on ACMG guidelines. Protein-protein docking and flexibility analysis were employed to study the interaction between wild-type and mutated VHL models with HIF1A and Elongin C. Statistical analysis was conducted to correlate VHL risk variants with clinical parameters and patient outcomes.

Results: Thirty VHL variants were identified across 171 patients, including seven novel missense mutations, 23 previously reported SNVs, and three novel non-coding variants. In silico analysis showed that mutations negatively impacted pVHL stability and weakened VHL-HIF and VHL-Elongin C interactions. The intronic variant rs61758376 G > C and 3′UTR variant rs1642742 A > G were found to be significantly associated with an increased risk of ccRCC ($OR = 1.676$, $p = 0.0074$; $OR = 1.735$, $p = 0.0171$, respectively). rs1642742 GG genotype was also significantly associated with larger tumour size ($p < 0.05$), advanced tumour stage (pT4) and reduced overall survival (Kaplan Meir log-rank $p = 0.029$).

Conclusion: This study provides novel genetic data from an understudied population and links VHL variants with ccRCC risk and clinical outcomes.

P01.080.D Genetic characterisation of CSC-associated mutations in prostate cancer: biomarkers on chromosome 17q24-25

Sergio Cuenca-López[1], *Verónica Arenas-Rodríguez*[2], *Patricia María Porras-Quesada*[2,3], *Jose María González-Cabezuelo*[4], *Juan Miguel Guerrero-González*[2], *Francisco Fernández-Rosado*[1], *Carmen Entrala-Bernal*[1], *María Jesús Álvarez-Cubero*[3,2], *Luis Javier Martínez-González*[3,2]

[1]Lorgen G.P., Granada, Spain, [2]Pfizer - Universidad de Granada - Junta de Andalucía Centre for Genomics and Oncological Research (GENYO), Granada, Spain, [3]Department of Biochemistry and Molecular Biology III and Immunology, University of Granada., Granada, Spain, [4]Meridiem Seeds, Almería, Spain.

Background: Cancer stem cells (CSCs) are critical drivers of tumor heterogeneity, fueling disease progression and therapy resistance. Prostate cancer (PC), characterized by its variability in clinical outcomes, presents an urgent need for biomarkers linked to CSCs. Prior cytogenetic studies highlighted recurrent alterations in chromosome 17q24-25 within CSC-enriched cultures, suggesting a key role in PC.

Material and methods: To explore this genomic hotspot, we designed a targeted capture panel covering 11 subregions and performed next-generation sequencing (NGS) on CSC-enriched and non-enriched prostate cancer cell lines (PC3 and LNCaP), alongside patient-derived solid biopsies and controls. Subsequent bioinformatic analyses aimed to pinpoint mutations uniquely associated with these populations, distinguishing them from variants found in non-enriched cultures and common genetic backgrounds.

Results: Bioinformatic analysis first identified a unique set of CSC-associated variants present in CSC-enriched cell line cultures. These variants were then investigated in patient-derived prostate cancer biopsy samples, leading to the identification of a panel spanning 13 genes. Among these, four genes (*GRB2*, *PRKCA*, *RPTOR*, and *PRKAR1A*) are particularly notable due to their well-established roles in insulin and mTOR pathways. These genes play crucial roles in pathways closely associated with prostate cancer biology and interact functionally with one another, underscoring their potential as biomarkers.

Conclusion: This study lays the groundwork for identifying CSC-specific genetic patterns, with promising implications for the early diagnosis, classification, and prognosis of PC. Future work will focus on validating these markers and assessing their clinical utility, aiming to bridge the gap between CSC biology and personalized cancer management.

P01.082.B The c-Maf-inducing protein (CMIP) as a regulator of cancer progression

Doha Khair[1,2,3], *Hofit Gadot*[1,2], *Audrey Bettoun Bramy*[1,2], *Alina Kurolap*[1,2], *Hagit Baris Feldman*[1,2,3]

[1]The Genetics Institute and Genomics Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]The Translational Genetics and Genomics Research (TGGR) Laboratory, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel.

Background: The c-Maf-inducing protein (CMIP) is a relatively understudied adapter protein. Several studies showed that CMIP is involved in poor cancer prognosis in several cancer types, such as triple negative breast cancer, ovarian, lung and brain cancer. Nevertheless, the exact underlying mechanisms remain unclear. One study showed that *CMIP* knockdown or overexpression correspondingly affect the expression of *MDM2*, which has previously been identified as an oncogene since it is a known regulator of the tumor suppressor p53. We aim to elucidate the mechanism by which *CMIP* expression regulates cancer progression.

Material and methods: To investigate whether CMIP leads to cancer cell proliferation, we performed a colony formation assay on the MCF7 breast cancer cell line. We tested the effect of CMIP overexpression (using plasmid transfection) and downregulation (using siCMIP) on MDM2 and p53 downstream pathways. Additionally, we conducted RNA-seq analysis on MCF7 cells with either overexpressed or siCMIP to gain an unbiased overview of affected pathways.

Results: Colony formation assay revealed that CMIP down-regulation inhibits cancer cell proliferation. We further investigated whether the pathway involved was related to MDM2-p53. While CMIP overexpression led to an upregulation of MDM2, it did not influence p53-related genes under different cancer-promoting conditions. RNA-seq analysis revealed that siCMIP-treated cells exhibit a notable downregulation of interferon type I genes and a reduction in autophagy-related genes.

Conclusion: CMIP might regulate autophagy, which is known to promote cancer cell survival, through interferon signaling. Determining the role of CMIP in cancer development can unlock new candidate targets for treatment.

P01.083.C Exposing the DNA methylation-responsive compartment of the leukemic genome supports its potential as a novel therapeutic target in T-ALL

Maike Bensberg[1], *Aida Selimović-Pašić*[1], *Lisa Haglund*[2], *Júlia Goldmann*[1], ***Sandra Hellberg***[1], *Colm E. Nestor*[1]

[1]Department of Biomedical and Clinical Sciences, Linköping University, Linköping, Sweden, [2]Linköping University, Linköping, Sweden.

Background: T-cell acute lymphoblastic leukaemia (T-ALL) exhibits exceptionally high global levels of DNA methylation, with the silencing of the DNA demethylating enzyme TET2 implicated in T-ALL's hypermethylation phenotype. We propose that hypomethylating agents (HMA) could be particularly potent in T-ALL patients with this hypermethylation phenotype. Despite the use of HMAs in treating other hematological malignancies, the role of altered DNA methylation in T-cell cancer biology and its potential as a therapeutic target in T-ALL remain unresolved.

Material and methods: Here we used a novel, reversible DNMT1-specific inhibitor and conventional HMAs to assess the effects of global DNA methylation loss in leukemic cells, integrating toxicity studies, whole genome DNA methylation, and total RNA-sequencing.

Results: We demonstrate that extensive removal of DNA methylation, even in the absence of DNA damage, results in cell death, and that toxicity is negatively correlated with global levels of DNA methylation. Notably, whereas DNA demethylation caused limited transcriptional changes globally, key tumour suppressor genes, such as TET2 and PAX5, were upregulated in a methylation-dependent manner. Few endogenous retroviruses were reactivated after demethylation, and no profound dysregulation of immune-related genes was observed, challenging the contribution of 'viral mimicry' to the observed toxicity.

Conclusion: These findings provide fundamental insights into the role of DNA methylation in cancer, clearly demonstrating that the removal of DNA methylation alone is sufficient to induce cell death in cancer cells. Furthermore, the distinct upregulation of silenced tumour suppressor genes has important implications for

future therapeutic strategies targeting the unique DNA methylation phenotype in T-ALL.

Background: Serrated polyposis syndrome (SPS) is a clinical condition characterized by multiple and/or large serrated polyps associated with higher colorectal cancer risk (1). Tumor protein p53 binding protein 1 (TP53BP1) is involved in DNA damage response, cell cycle regulation and senescence (2). It was previously suggested as a candidate for SPS germline predisposition(3). The aim of our study was to evaluate *TP53BP1* as a hereditary gene for SPS by performing a functional characterization.

Material and methods: Initial sequencing was performed in SPS cohort of 16 families (39 patients) and validated in 211 SPS cases to find rare, potentially pathogenic genetic variants. We produced CRISPR/Cas9 knock-in cellular models for *TP53BP1* (HAP1 and HCT116 cells) for four genetic variants. We assessed the recruitment of proteins involved in DNA damage response by immufluorescence, overall DNA damage levels by ELISA, and changes in gene expression of senescence markers (*CDKN2A*, *CDKN1A* and *TP53*) by quantitative real-time PCR.

Results: Three rare, predicted pathogenic variants were identified within the *TP53BP1* gene in the discovery and validation cohorts. Four additional variants were found in two external SPS cohorts (4, S.Aretz pers. comm.) Functional characterization of variants revealed significant differences in all three markers of senescence in HAP1 cells carrying the identified genetic variants when compared with the wild-type sequence.

Conclusion: Cells carrying the detected *TP53BP1* variants showed an escape from senescence when compared to cells with wild-type or a neutral variant. Therefore, *TP53BP1* can be postulated as a new hereditary gene for SPS germline predisposition.

P01.085.A Diagnostic and prognostic molecular classification of pediatric Ependymoma in Italy

Marzia Giagnacovo[1], *Loris De Cecco*[2], *Matilde Oriani*[3], *Manila Antonelli*[4], *Elisabetta Schiavello*[5], *Veronica Biassoni*[6], *Maura Massimino*[6], *Piergiorgio Modena*[7]

[1]*Genetics Unit, ASST Lariana General Hospital, Como, Italy,* [2]*Integrated Biology Platform, Fondazione Istituto Nazionale dei Tumori, Milano, Milano, Italy,* [3]*Integrated Biology Platform, Fondazione Istituto Nazionale dei Tumori, Milano, Italy,* [4]*Department of Radiological, Oncological and Anatomo-Pathological Sciences, Sapienza University, Roma, Italy,* [5]*Pediatric Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy,* [6]*Pediatric Oncology Unit, Fondazione Istituto Nazionale dei Tumori, Milano, Italy,* [7]*SSD Genetica, ASST Lariana General Hospital, Como, Italy.*

Background: Ependymomas (EPD) are classified according to WHO-2021 by histopatological, molecular and anatomic site features. We provide data on the diagnostic and prognostic markers analyzed in the initial series of 80 Italian pediatric EPD patients enrolled in current SIOP-Ependymoma II clinical trial.

Material and methods: Molecular classification was based on FFPE primary tumor samples. Methylation profiling was performed using Infinium MethylationEPICv2.0 arrays. Fusion genes were analyzed by real time-PCR and sequencing. The TERT expression was analyzed by real time-PCR. Copy-number data were inferred from methylation profiling and CGH-Array.

Results: Methylation profiling was successful in 90% of cases. The CNV/CGH-Array analyses revealed relevant candidate prognostic alterations, including chromosome 1q gain, 6q loss and CDKN2A homozygous loss. In supratentorial EPD cases, the ZFTA-RELA fusion genes was identified in 18/31 cases and the YAP1-MAMLD1 fusion was identified in 2/31 cases. The TERT expression was significantly associated with the presence of RELA fusion. The presence of fusion genes was occasionally associated with chromoanagenesis events. In one fusion-negative supratentorial case, a EWSR1 rearrangement with a breakpoint in intron 7 was revealed.

Conclusion: Molecular diagnostic and prognostic analyses of Ependymoma according to WHO 2021 are feasible and straightforward. The ZFTA-RELA is the most frequent fusion gene and is associated with TERT overexpression. A sample was reclassified as a rare EWSR1-fused brain tumor. Upfront evaluation of prognostic markers will allow a prospective validation in the frame of ongoing SIOP-EPD II trial, in order to inform the molecular stratification strategies for future trials.

P01.086.B Assessment of the 2022 second revision of the International Staging System (R2-ISS) in patients with newly diagnosed multiple myeloma

S. Min;

Seegene Medical Foundation, Seoul, Korea, Republic of

Background: Multiple myeloma(MM) is a hematologic disease with heterogeneous outcomes. In 2022, the Second Revision of

the International Staging System(R2-ISS) was published by the European Myeloma Network(EMN). In this study, we applied R2-ISS to MM patients in Korea and compared R2-ISS to the R-ISS.

Material and methods: Total 489 patients(M:F = 272:217) with newly diagnosed MM between 2015 and 2023 were studied. Bone marrow examinations, chromosomal analysis, FISH, and laboratory tests were performed at the time of diagnosis. All patients were classified according to the R-ISS and R2-ISS. A landmark survival analysis was performed on the 2-year survival rate.

Results: According to the R-ISS, the patients were classified to 55(11.2%) in risk group I, 323(66.1%) in II, and 111(22.7%) in III. The patients were re-classified into 4 risk groups according to R2-ISS, group I: 33 patients(6.7%), II: 104 patients(21.3%), III: 253 patients(51.7%), and IV: 99 patients(20.2%). 23 patients(41.8%) in R-ISS group I were re-classified to R2-ISS group II, 220(68.1%) and 21 patients(6.5%) were re-classified to R2-ISS group III and IV. According to the landmark survival analysis, the 2-year survival rate of patients in R2-ISS group I: 89.5%, II: 83.9%, III: 68.4%, and IV: 46.3%. The differences among the R2-ISS groups were statistically significant($p < 0.05$).

Conclusion: We observed the patients were clearly divided into higher-risk(III, IV) and lower-risk groups(I, II). R2-ISS is an updated risk stratification system and is expected to be a useful tool for predicting patient prognosis and planning treatment.

P01.087.C Brain MRI surveillance of optic pathway glioma in pediatric neurofibromatosis Type 1: findings from a Cohort of 61 patients

Adam Bishara[1], *Shayna Zelcer*[1,2], *Inas Makar*[1,2], *Spencer VanMil*[1,2], *Majdina Isovic*[2], *Valerie Vegso*[2], *Tamara Vanhooren*[1,2], *Maria MacDonald*[1,2], *Igor Karp*[1], *Natalya Karp*[1,2]

[1]*Western University, London, ON, Canada,* [2]*London Health Siences Centre, London, ON, Canada.*

Background: Children with neurofibromatosis type 1 (NF1) rarely die from optic pathway gliomas (OPG) but may experience vision loss, proptosis, hydrocephalus, precocious puberty, and social or daily life difficulties. There is no standardized method for monitoring OPG in pediatric NF1 patients. Although annual ophthalmological examinations (OE) are recommended, brain MRI for pre-symptomatic OPG detection is optional. This study evaluates the effectiveness of MRI compared to OE in diagnosing OPG through an ambispective analysis of 61 children from 2013 to the present.

Materials and methods: We reviewed medical records retrospectively and prospectively. In the prospective phase, brain MRI was performed at diagnosis or at 18 months, followed by scans every two years until age eight and again at 18 years. All participants underwent annual OE. RESULTS Of the 61 patients, 21 (34%) had OPG. Six had OPG before their initial clinic visit, with the status of five unknown. Among the remaining 50 patients, 15 (30%) were diagnosed via MRI at a median age of 2 years. Three patients required chemotherapy due to complications; one with chiasmal OPG had normal OE results before MRI detected progression. Two patients reported vision difficulties, with abnormal OE preceding MRI confirmation. Chemotherapy began at ages 4, 5, and 7, but one patient did not regain vision post-treatment.

Conclusion: Our findings suggest that MRI is more effective than OE in detecting OPG. Early detection through MRI surveillance alongside OE is critical to preventing vision loss. Further studies are needed to determine the optimal frequency of MRI surveillance.

P01.088.D Investigating the tumor microenvironment through single-cell transcriptomics in pre- and post-chemotherapy neuroblastoma patients

Michele Minopoli[1], *Ferdinando Bonfiglio*[2], *Teresa Mairoino*[2], *Matilde Tirelli*[2], *Martina Morini*[3], *Katia Mazzocco*[3], *Valerio Gaetano Vellone*[3], *Achille Iolascon*[2], *Mario Capasso*[2]

[1]*University of Naples Federico II, Department of Chemical Engineering, Materials and Industrial Production / CEINGE Biotecnologie Avanzate s.c.ar.l, Naples, Italy,* [2]*CEINGE Biotecnologie Avanzate s.c.ar.l / University of Naples Federico II, Department of Molecular and Medical Biotechnologies, Naples, Italy,* [3]*IRCCS Giannina Gaslini Institute, Genoa, Italy.*

Background: Neuroblastoma (NB) is the most common extracranial solid tumor in children, with high-risk cases still showing poor outcomes despite improved therapeutic protocols. Tumor microenvironment plays a pivotal role in resistance to therapy, and specific cell types, e.g., cancer-associated fibroblasts (CAFs) might be involved in this process. Here we performed single-cell RNAseq (scRNAseq) on NB biopsies before and after treatment to investigate microenvironment changes at the single cell resolution.

Material and methods: Matched (pre/post chemotherapy) biopsies (n = 33) from 18 patients were processed with the Gexscope kit. Expression data was imported in R and analyzed with the Seurat pipeline. Non-tumor cells were selected according to multiple references and the absence of copy number variation. Specific cellular subtypes were identified based on the presence of specific markers from literature.

Results: A total of 23,457 non tumor cells were identified, mainly composed of immune (35%) and Schwann cells (23%). We found an increase of Schwann cells in post-chemo cells compared to pre-chemotherapy cells (35.8% vs 1.7%), also myeloid cells were increased after chemotherapy (22.4% vs 17.3%), while B- and T-cells were decreased. Focusing on the fibroblast subtypes, we found 1458 CAFs in pre-chemotherapy samples and 2332 CAFs in post-chemotherapy samples. Although this difference was not significant, we identified specific CAF subtypes, e.g., inflammatory CAFs, involved in tumor progression and immunosuppression.

Conclusion: scRNAseq is a powerful tool to investigate differences in tumor microenvironment at single-cell resolution. Further analysis on other cell subtypes (e.g., immune cells) are currently ongoing.

P01.089.A Multi-omic characterization of hereditary prostate cancer: *AXIN2* and *DICER1* mutations in tumor development

Lucía Chica-Redecillas[1,2], *Patricia María Porras-Quesada*[1,2], *Fernando Marin-Benesiu*[1,2], *Sergio Cuenca-Lopez*[3,1], *Elena Arance*[1,2], *Luis Javier Martinez-Gonzalez*[1,2], *Maria Jesus Alvarez-Cubero*[1,2,4]

[1]*Department of Biochemistry and Molecular Biology III, Faculty of Medicine, University of Granada, Granada, Spain,* [2]*Centre for Genomics and Oncological Research: Pfizer, University of Granada, Andalusian Regional Government (GENYO), Granada, Spain,* [3]*LORGEN G.P, Parque Tecnológico de la Salud - Business Innovation*

Centre (BIC), Granada, Spain, [4]IBS, Biosanitary Research Institute (ibs. GRANADA), University of Granada, Granada, Spain.

Background: Only 5%–10% of all prostate cancer (PC) cases are hereditary. Existing clinical guidelines, such as those from the National Comprehensive Cancer Network, are insufficient for diagnosing and stratifying these patients due to the heterogeneity and complexity of this cancer. Present study aims to identify genetic factors contributing to hereditary PC through a multi-omic approach.

Material and methods: A multi-omic analysis was conducted on a Spanish multi-case PC family, incorporating exome, transcriptome, and epigenomic profiling. Data integration encompassed microRNA-gene interactions and methylation-gene associations to provide a holistic molecular perspective.

Results: Analysis of 34 genes, selected based on clinical guidelines and literature, revealed 268 variants in 26 genes, predominantly intronic (91.4%) and unreported (84.3%). While no pathogenic mutations were identified in genes recommended by clinical guidelines, ten identical mutations were detected in *AXIN2*, *DICER1*, and *BARD1* across all PC cases studied. Due to the critical roles of *AXIN2* and *DICER1* in the Wnt signaling pathway, our focus led to the identification of a shared intronic mutation in the nonsense-mediated decay β-catenin isoform. Transcriptomic analysis revealed *ALDH1A1* overexpression, a well-established Wnt/β-catenin target gene, while epigenetic studies indicated differential DNA methylation and miRNA expression linked to key oncogenic pathways.

Conclusion: Our study underscores the role of intronic mutations in PC development and highlights the potential of incorporating *AXIN2* and *DICER1*, due to their important role in Wnt signaling pathway, in clinical gene panels for better risk assessment. Further research in additional families is crucial to confirm these findings and improve genetic screening methods.

P01.090.B Resolving discordant tumor and germline testing results in MMR-deficient Carcinomas: paired testing approach to distinguish Lynch and Lynch-like syndromes

Ece Çepni[1], *Merve Çelik*[2], *Orhun Çığ Taşkın*[3], *Meltem Batıbay*[4], *Emre Balık*[5], *Doğan Vatansever*[6], *Serpil Eraslan*[4], *Hülya Kayserili*[7,4]

[1]*Institute of Health Sciences, Koç University, Istanbul, Turkey,* [2]*Genetic Diseases Evaluation Center, Koc University Hospital, Istanbul, Turkey,* [3]*Department of Pathology, Koç University School of Medicine (KUSoM), Istanbul, Turkey,* [4]*Genetic Diseases Evaluation Center, Koç University Hospital, Istanbul, Turkey,* [5]*Department of General Surgery, Koç University School of Medicine (KUSoM), Istanbul, Turkey,* [6]*Department of Obstetrics and Gynecology, Koç University School of Medicine (KUSoM), Istanbul, Turkey,* [7]*Department of Medical Genetics, Koç University School of Medicine (KUSoM), Istanbul, Turkey.*

Introduction: Lynch syndrome(LS) is the most common hereditary cancer predisposition syndrome accounting for ~3% of all colorectal and endometrial carcinomas. First-line approach to differentiate between LS and sporadic cancer is immunohistochemical(IHC) staining to assess MMR protein expression in tumor tissue. Reflex genetic testing after an abnormal IHC result includes tumor *MLH1* methylation and/or BRAF V600E, then targeted germline testing. However, MMR IHC might be impaired without underlying MMR hypermethylation,BRAF alteration, or germline MMR pathogenic variant(PV). Differentiating "Lynch-like syndromes" is essential for patient management and cascade counseling.

Methods: We examined the results of paired tumor *MLH1* hypermethylation/BRAF mutation and comprehensive germline testing in a cohort of 51 individuals with Lynch-associated tumours showing abnormal MMR IHC ("mismatch repair deficient = MMRd").

Results: Among 51 MMRd patients, 68% (34/51) had MMR hypermethylation; including one with constitutional MLH1 hypermethylation. 44 patients [29/44 MMR hypermethylation, 15/44 normal MMR-methylation] were available for germline testing by NGS panel [Illumina TruSight Cancer/TruSight Hereditary Cancer Panel] and dijital MLPA analysis [MRC-Holland D001-B1/C1]. The overall rate of inconclusive results was 27% (12/44), including one patient with *MLH1* hypermethylation and germline *MSH6* PV, one with *MLH1* hypermethylation and germline *SMARCA4* PV, two with normal methylation and germline PV in non-MMR genes (*NBN, BARD1*). Notably, eight MMRd patients had negative tumor methylation/germline tests, indicating potential false negatives in IHC (8/44).

Conclusions: Our findings indicate that IHC-guided testing alone may miss germline mutations in other MMR and non-MMR genes, reinforcing that the ideal strategy for achieving a higher diagnostic yield for LS is paired tumor and germline testing.

P01.091.C Spectrum of germline and somatic variants in the *DICER1* gene in pediatric patients with DICER1-specific tumors

Maria Skvortsova, *Liudmila Yasko, Margarita Teleshova, Nataliya Andreeva, Anastasiya Salomatina, Nina Gegeliya, Alexander Druy, Denis Kachanov, Maria Kurnikova*

Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation.

Background: DICER1 syndrome is characterized by predisposition to a tumor growth during the lifetime and caused by germline pathogenic variants (PVs) in the *DICER1* gene. We present the results of germline and tumor tissue genetic testing in children with DICER1-associated malignant and benign tumors during a 6-year period in our Center (2019–2024).

Material and methods: The retrospective analysis of 29 probands aged 9 month-18 years old with a variety of solid tumors suspected of DICER1 syndrome were evaluated. The molecular genetic testing methods included a panel-based and whole genome NGS, MLPA and Sanger sequencing.

Results: Among 29 probands suspected of DICER1 syndrome, the germline PVs in the *DICER1* gene were confirmed in 19 probands. One proband had PV (c.5426G>T/p.G1809V) in one of the hotspot codons in the RNase IIIb domain, inherited from a mosaic father. The germline PVs were not found in 10/29 (34,4%) probands. The spectrum of the tumors in these 10 patients included pleuropulmonal blastoma (5 cases), cystic nephroma (2 cases), Sertoli-Leydig cell tumor (2 cases) and embryonal rhabdomyosarcoma (1 case). In 3/10 cases two *DICER1* variants in the tumor tissue were detected, but for none of them the germline status was confirmed.

Conclusion: About two-thirds of probands suspected of DICER1 syndrome had germline PVs in the *DICER1* gene. Further studies are needed in those 3 cases when two variants were found to determine if they are indeed originated from tumors only, or if those cases may reflect a somatic mosaicism.

P01.092.D Beckwith-Wiedemann Spectrum and acute lymphoblastic leukemia

*Maria Luca[1], Federico Rondot[1], Paola Quarello[2,3], Elena Barisone[3], Nicoletta Bertorello[3], Alessandro Mussa[2,4], Franca Fagioli[2,3], **Diana Carli**[1,5]*

[1]Department of Medical Sciences, University of Torino, Torino, Italy, [2]Department of Public Health and Pediatric Sciences, University of Torino, Torino, Italy, [3]Pediatric Onco-hematology Division, Regina Margherita Children's Hospital, Città Della Salute e Della Scienza, Torino, Italy, [4]Clinical Genetics Unit, Regina Margherita Children's Hospital, Città Della Salute e Della Scienza, Torino, Italy, [5]Immunogenetics and Transplant Biology Unit, University Hospital Città della Salute e della Scienza di Torino, Torino, Italy.

Background: Beckwith-Wiedemann Spectrum (BWSp) is a cancer predisposition syndrome primarily associated with embryonal tumors such as nephroblastoma and hepatoblastoma. Its correlation with hematological malignancies, particularly Acute Lymphoblastic Leukemia (ALL), is unclear. ALL is the most common pediatric cancer, with a cumulative risk of 0.05–0.07% before 18 years. Extremely limited data, based on single reports, suggest an ALL incidence of ~0.5% in BWSp patients with chromosome 11 paternal uniparental disomy (UPD(11)pat) and ~1.4% in those CDKN1C-mutated.

Material and methods: We report two new cases of ALL in BWSp patients and review the existing literature.

Results: The literature review identified six cases of ALL in BWSp patients (3 males), with a mean age at diagnosis of 8.2 years (range 2–21). Among them, two had CDKN1C variants, one UPD(11)pat, one IC2-Loss of Methylation (LoM) due to a 11p15 microdeletion, and two were untested. Two had T-ALL, three B-ALL, and one was unspecified. One B-ALL case was Philadelphia-positive. Additionally, we report a male with mosaic UPD(11)pat who developed B-ALL at 6 years and a female with IC2-LoM diagnosed with Philadelphia-positive B-ALL at 4.8 years.

Conclusion: T-ALL represents 10–15% of pediatric ALL but accounted for 2/7 (29%) of BWSp-ALL cases. Similarly, Philadelphia-positive B-ALL is rare in pediatric patients (3–5%) but accounted for 2/4 (50%) of BWSp-B-ALL cases, suggesting a possible overrepresentation in the BWSp context. The currently available data are too limited to draw definitive conclusions. Further studies are needed to determine ALL incidence, subtype distribution, treatment response, and toxicity in BWSp patients

P01.093.A Detection of germline mutations in patients with cutaneous melanomaby universal genetic testing*vs*guideline based testing and identification of novel potential relevant genes

*Denise Vurchio[1,2], Simona Mellone[1], Laura Cristina Gironi[3], Alba Bianco[1,2], Giulia Borgonovi[1,2], Giulia Paglino[1,2], Alessandro Ugonotti[1,2], Sara Ronzani[1], **Caterina Lonati**[1], Maurizio Sciancalepore[1], Alice Spano[1], Esposto Elia[3], Francesca Zottarelli[3,2], Edoardo Cammarata[3], Giulia Giorgione[3], Umberto Dianzani[1,2], Paola Savoia[3,2], Mara Giordano[1,2]*

[1]Laboratorio di Genetica, SCDU Biochimica Clinica, Azienda Ospedaliero Universitaria Maggiore della Carità, Novara, Italy, [2]Dipartimento di Scienze della Salute, Università del Piemonte Orientale, Novara, Italy, [3]SCDU Dermatologia, Azienda Ospedaliero Universitaria Maggiore della Carità, Novara, Italy.

Background: The most frequently implicated gene in familial melanoma is ***CDKN2A***, accounting for 20%–45% of cases, while other risk genes include ***MITF, CDK4, TERT, POT1*** **and** ***MC1R***. Current guidelines recommend screening for patients meeting specific criteria: family history of Cutaneous Melanoma (CM), multiple primary melanomas, a history of CM-associated cancers. However, these criteria may fail to detect clinically relevant mutations in some individuals, potentially impacting cancer prevention strategies. This study aimed to assess the utility of extending genetic testing to CM patients who do not meet standard eligibility criteria.

Material and methods: Between June 2019-May 2024, **790 patients** were recruited, with **244** fulfilling the established criteria **(group 1)** and **546**not meeting them (**group 2**). A **multigene panel** was used to analyze CM-associated genes along with genes associated to other cancer syndromes (e.g. **BRCA1-2, CHECK2, ATM**).

Results: The results showed that **31.9% of group 1 patients (N = 78)** carried **pathogenic/likely pathogenic (P/LP) variants**, compared to **6.4% (N = 35) in group 2**. Six patients carried **P/LP variants** in genes related to other cancer syndromes, whose correlation to CM requires further investigation. For five negative patients, that strongly met inclusion criteria, **exome equencing** was performed revealing **P/LP in four cases** in genes potentially associated with melanoma, namely ***FLG, CDH13, MAP2K2*****, and** ***PHF10***.

Conclusion: These findings suggest that expanding genetic testing criteria for CM patients can help identify individuals carrying significant mutations that would otherwise go undetected. Considering the benefits of early diagnosis and cancer prevention, the cost-effectiveness of universal genetic screening should be further explored.

P01.094.B Investigation of Lynch-related variants in breast cancer cases: is there an overlooked association?

***Etkin Özkan**, Mehmet Kocabey, Elçin Bora, Ayfer Ulgenalp, Ahmet Okay Caglayan*

Dokuz Eylul University, izmir, Turkey.

Background: Lynch syndrome is one of the most prevalent hereditary cancer syndromes. Its prevalence is approximately 1 in 279. While many studies have suggested a modest increase in breast cancer risk, the relationship between breast cancer and Lynch syndrome remains controversial. This study aims to enhance our understanding of the potential association between Lynch syndrome and breast cancer through an analysis of our own data.

Material and methods: Next-generation sequencing panel data, including hereditary cancer predisposition genes, of 861 patients diagnosed with breast cancer between 2018 and 2024 were collected retrospectively. Variants classified as pathogenic (P), likely pathogenic (LP), and variant of uncertain significance (VUS) in Lynch syndrome-associated genes were re-analyzed.

Results: Among the 861 patients, 84 P/LP and VUS variants were identified in 81 individuals. In the *MLH1* gene, 3 LP variants (0.35%) and 37 VUS (4.30%); in the *MSH2*, 1 LP variant (0.12%) and 14 VUS (1.63%); in the *MSH6*, 28 VUS (3.25%) and in *PMS2* gene, 1 VUS (0.12%) were detected. Overall, LP variants were observed in 0.46%, VUS were observed in 9.29% of the patients. Patients with detected likely pathogenic variants did not have colorectal or endometrial cancer history.

Conclusion: When compared to the population prevalence of Lynch syndrome, the frequency of LP/P variants identified in the breast cancer cohort was found to be similar. In cases where breast cancer is the only symptom, Lynch syndrome should be considered only after the exclusion of primary breast cancer associated gene mutations.

P01.095.C Metabolic dependencies in esophageal adenocarcinoma: exploring *TP53* mutation-driven phenotypes for targeted therapies

Erica Cataldi Stagetti[1], *Nicola Rizzardi*[2], *Arianna Orsini*[1], *Bianca De Nicolo*[1,3], *Chiara Diquigiovanni*[1], *Sandro Mattioli*[4], *Christian Bergamini*[2], *Elena Bonora*[1,3]

[1]*Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy,* [2]*Department of Pharmacy and Biotechnology, University of Bologna, Bologna, Italy,* [3]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [4]*Division of Thoracic Surgery, Maria Cecilia Hospital, Ravenna, Italy.*

Background: Esophageal adenocarcinoma (EAC) is an aggressive malignancy with a rising incidence and poor prognosis. High genomic heterogeneity in EAC hinder prevention, early diagnosis and targeted therapies development. *TP53* is the most frequently mutated gene, with missense mutations strongly linked to reduced cancer-specific survival. This study aims to identify novel molecular vulnerabilities by analyzing the metabolism of three in-vitro cell models representative of different stages of tumor progression and with distinct *TP53* mutations: OE33 and FLO-1 cells carry missense variants (p.Cys135Tyr and p.Cys277Phe, respectively), OE19 cells carry a frameshift variant (p.Asn310Lysfs*27).

Methods: Live cell imaging and recording, ATP/ADP and lactate quantification, real-time PCR were used on the different cell lines.

Results: OE33 cells predominantly use oxidative metabolism but display limited adaptability to environmental changes, maybe due to a higher differentiation state *vs*. the other cells. OE19 cells are mainly dependent on oxidative metabolism, showing adaptability to glucose and glutamine deprivation. They use galactose as alternative energy substrate due to increased *GALE* expression and their growth is impaired by electron transport chain inhibitors, i.e. Antimycin A ($P = 0.0133$). FLO-1 cells rely on glycolytic metabolism, with elevated glucose consumption and lactate production, marked *GAPDH* expression ($P < 0.0001$) and glutamine-dependent proliferation. Their growth is unaffected by acidic conditions (pH 6.8), as observed in tumor niches.

Conclusion: We identified unique metabolic phenotypes in three in vitro models of EAC, possibly driven by distinct TP53 mutations. Targeting these specific metabolic vulnerabilities can yield insights for personalized therapies, improving treatment outcomes for EAC patients.

P01.096.D Murine migration-stimulating factor ortholog: insights into FN1 splicing and cancer

Anita Capalbo[1], *giulia cardamone*[2], *letizia straniero*[3], *valeria rimoldi*[3], *nicole ziliotto*[4], *sonia valentino*[1], *marina sironi*[1], *roberto leone*[1], *andrea doni*[1], *barbara bottazzi*[1], *alberto mantovani*[1], *Rosanna Asselta*[3]

[1]*Humanitas Research Hospital, Rozzano, Milan, Italy,* [2]*Institute of Biochemistry I, Faculty of Medicine, Goethe University Frankfurt, frankfurt, Germany,* [3]*Humanitas University, Pieve Emanuele, Italy,* [4]*Department of Pharmacy, University of Pisa, Pisa, Italy.*

Background: Fibronectin 1 (FN1) is a key extracellular matrix (ECM) glycoprotein involved in cell adhesion, migration, and tissue remodelling. Among its isoforms, the Migration-Stimulating Factor (MSF) is a truncated oncofetal variant with potent motogenic properties, implicated in cancer progression and metastasis. Despite extensive research on human MSF, the lack of a murine ortholog has limited preclinical investigations. This study identifies and characterizes the murine MSF ortholog, elucidating its expression, regulatory mechanisms, and functional relevance in cancer biology.

Materials and methods: We identified murine MSF through alternative polyadenylation analysis in FN1. 3′ RACE and Sanger sequencing were used to reconstruct its transcripts, followed by qPCR to assess expression in murine tissues and pancreatic cancer cells (PANC02). Functional validation included gapmer-mediated silencing, proliferation assays, and RNA-seq. The secretion pathway is under investigation using the RUSH system.

Results: We identified two murine MSF isoforms with distinct 3′-UTRs, analogous to human MSF. Expression analysis showed MSF overexpression in PANC02 cells compared to non-tumorigenic controls. Silencing experiments led to a significant reduction in proliferation (−40%). Preliminary RNA-seq analysis suggests potential downregulation of ECM remodeling and growth factor signaling genes in MSF-silenced cells, indicating a possible role for MSF in modulating these pathways. Additionally, we identified circRNA involvement in MSF regulation, suggesting a post-transcriptional control mechanism.

Conclusion: Murine MSF is functionally analogous to human MSF, promoting tumorigenic processes through. Its regulation via alternative polyadenylation and circRNAs highlights its role in ECM dynamics. These findings provide a foundation for future investigations into MSF-targeted cancer therapies.

P01.097.A Identification of biological process involved in bladder cancer through multi-omics integration

Tze Yin Lim[1,2], *Alessandra Allione*[1], *Clara Viberti*[1], *Carla Debernardi*[1], *Cecilia Di Primio*[1], *Francesco Soria*[3], *Paolo Gontero*[3], *Carlotta Sacerdote*[4], *Simone Sanna-Cherchi*[2], *Giuseppe Matullo*[5]

[1]*Unit of Genomic, Dept. of Medical Sciences, University of Turin, Turin, Italy,* [2]*Division of Nephrology, Columbia University, New York, NY, USA,* [3]*Division of Urology, Molinette Hospital, Turin, Italy,* [4]*Piedmont Centre for Epidemiology and Cancer Prevention, Turin, Italy,* [5]*Dept. Medical Sciences, University of Turin, Torino, Italy.*

Background: Bladder cancer (BLCA) is the 9th most prevalent cancer, and its heterogeneity in clinical outcomes necessitates a deeper understanding of its underlying molecular mechanisms. This study leverages multiomics data of 120 individuals from the

Torino Bladder Cancer Study (TBCS) to explore molecular pathways involved in BLCA.

Methods: TBCS included histologically confirmed BLCA patients (enrolled 1994–2007) from Turin, with non-cancer controls that were matched for age, sex, ancestry, and smoking status. We analyzed peripheral blood data from 120 individuals (58 cases, 62 controls) who have been subjected to genome-wide genotyping, mRNA profiling, and DNA methylation profiling. Single-omics analyses were conducted using PLINK2 and the R packages minfi, ChAMP, and limma, and then integrated using Multi-omics factor analysis (MOFA). For the MOFA analysis, we selected 64 pruned SNPs from the GWAS, along with the residuals of 951 differentially methylated CpGs and 144 differentially expressed genes ($P < 0.05$), to serve as features in the model.

Results: MOFA identified 15 factors that accounted for the variability within the data, with gene expression and methylation CpGs explaining >40% of total variance. Factor 1 showed the strongest correlation with disease status, tumour grade and number of recurrences. Enrichment analysis showed that the top 30 features that carried the most weight were predominantly involved in the Interleukin-2 and Interleukin-12-mediated signaling pathways, suggesting their roles in disease pathogenesis.

Conclusions: This analysis provides a systematic framework to investigate BLCA pathobiology, potentially reflecting both tumor-derived and host immune responses through a multiomics analysis.

P01.098.B CD39 expression and STAT3 activation in Sézary Syndrome: insights into genetic regulation and potential therapeutic targets

Yuliya Yakymiv[1], *Sara Marchisio*[1], *Liyun Lin*[1], *Erika Ortolan*[1], *Rebecca Casu*[1], *Verdiana Pullano*[2], *Chiara Leso*[3], *Renata Ponti*[4], *Gabriele Roccuzzo*[4], *Alfredo Brusco*[2], *Ada Funaro*[1], *Pietro Quaglino*[4]

[1]*Laboratory of Immunogenetics, Department of Medical Sciences, University of Turin, Turin, Italy,* [2]*Department of Neuroscience "Rita Levi Montalcini", University of Turin, Turin, Italy,* [3]*Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy,* [4]*Dermatologic Clinic, Department of Medical Sciences, University of Turin, Turin, Italy.*

Background: Sézary Syndrome (SS) is an aggressive cutaneous T-cell lymphoma characterized by clonal CD4+ T-cell expansion, clinical heterogeneity, and unclear molecular and genetic mechanisms. We identified aberrant expression of CD39 and CD73 in SS CD4+T lymphocytes, leading to accumulation of immunosuppressive adenosine, which may drive phenotypic variability in SS patients.

Material and methods: A cohort of 20 SS patients was genotyped for the SNPs rs10748643 (A > G) and rs7096317 (G > A) in the ENTPD1/CD39 gene using Sanger sequencing, combined with multiparametric flow cytometry. PBMCs from SS patients and HUT-78 cell line were used for functional assays (Western blot, PrestoBlue, CFSE).

Results: CD39 expression is genetically regulated by rs10748643 and rs7096317, which are in perfect linkage disequilibrium ($r^2 = 1$). Homozygous individuals for rs10748643G and rs7096317A expressed the highest CD39 levels, particularly in CD4+ SS cells and Treg cells, but not in other cell subsets. CD4+ SS cells showed reduced proliferation upon stimulation through TCR or IL-2 and unmodified CD39 expression regardless of genotype. At the molecular level, both circulating CD4+ SS cells and HUT-78 cells exhibited high levels of phosphorylated STAT3, a key transcriptional factor in the JAK/STAT pathway, particularly in CD39+ SS cells, along with enhanced mTOR activation and MCL-1 upregulation. STAT3 inhibition with Stattic-V reduced phospho-STAT3 levels, decreasing cell survival and CD39 expression, suggesting a role for STAT3 in CD39 transcriptional regulation in SS.

Conclusion: The genetic regulation of CD39 and its interaction with STAT3 signaling provide novel insights into SS pathogenesis, supporting potential therapeutic strategies targeting CD39 and STAT3 in SS.

P01.099.C Pathogenic variants in cancer genes in the Slovenian population

Urška Kotnik, *Aleš Maver, Borut Peterlin, Luca Lovrecic*

Clinical Institute of Genomic Medicine, University Medical Centre Ljubljana, Ljubljana, Slovenia.

Background: Reporting secondary findings is recommended for genes associated with hereditary cancer[1]. The proportion of pathogenic variants in cancer-related genes in human populations varies significantly[4,3], therefore population-specific results are needed to help assess genomic risks and disease burden in the given population and aid in public health genomic development[4].

Methods: All rare loss of function variants and known pathogenic variants in ClinVar in the 27 dominant hereditary cancer-related genes of the ACMG Secondary Findings v3.2 list1 were collected from the genomic data of the 14,000 individuals in the Slovenian genome database. The variants were classified according to the ACMG criteria[5] and the population burden of (likely) pathogenic findings was estimated.

Results: The (likely) pathogenic variants were most frequently found in the *BRCA1* and *BRCA2* genes (0.34% and 0.32% respectively), followed by *PALB2* (0.14%), *PMS2* (15%), *MSH6* (0.08%) and *RET* (0.07%). The burden of pathogenic variants in *APC*, *MEN1*, *MLH1*, *MSH2*, *NF2*, *PTEN*, *RB1*, *SDHAF2*, *SDHB*, *SDHD*, *SMAD4*, *TMEM127*, *VHL* and *WT1* was between 0.03% and 0.01%. No pathogenic variants were found in *BMPR1A*, *MAX*, *SDHC*, *STK11*, *TSC1*, *TSC2*, and *TP53* in our unaffected population. The cumulative prevalence of pathogenic variants in hereditary cancer-related genes in the Slovenian non-cancer population was 1.27%.

Conclusion: The proportion of (likely) pathogenic variants in the Slovenian population in the medically actionable genes, associated with hereditary cancer, is 1.27%. The highest proportion is in genes, associated with hereditary breast and gynecologic cancer, as we reported previously[6].

P01.100.D Collecting multifactorial breast cancer risk information: evaluating the MyCanRisk tool

Cameron John Wilson, *Stephanie Archer, Francisca Stutzin Donoso, Juliet Usher-Smith, Antonis Antoniou, Doug Easton, Fiona Walter, Fiona Dorling, Lorenzo Ficorella, Marc Tischkowitz, Nichola Fennell, Timothy Carver*

University of Cambridge, Cambridge, United Kingdom.

Background: The MyCanRisk tool is a platform-independent application designed to support the collection of information required for multifactorial risk assessment using the CanRisk tool (www.canrisk.org). It enables patients to provide information about personal risk factors before a healthcare professional completes the risk assessment, streamlining the assessment process. This study evaluates MyCanRisk's efficacy, user-friendliness, and alignment with existing clinical methods.

Material and methods: A mixed-methods study was conducted with 51 women (aged ≥ 18) who had a family history of breast cancer but no personal cancer diagnosis. Participants completed the MyCanRisk tool and, two weeks later, underwent a structured interview modelled on best practices in clinical genetics. Risk factor information from both methods was compared and Cohen's Kappa (κ) was used to evaluate consistency in risk categorisation. Reflective interviews with a subset of participants (n = 15) provided qualitative insights into user experience and tool usability which were analysed thematically.

Results: The agreement between MyCanRisk and structured interviews for risk categorisation was substantial (κ = 0.81, 95% CI 0.65–0.97). The MyCanRisk tool was judged to be usable, with participants highlighting its clarity and flexibility. Some participants shared difficulty recalling details, mixed emotional impacts, and provided suggestions for enhanced guidance, consistent with existing challenges in collecting family history and conducting multifactorial risk assessment in clinical practice.

Conclusion: MyCanRisk is a user-friendly and effective tool for collecting risk factor information, and offers the opportunity to streamline breast cancer risk assessment using CanRisk. These findings support the further integration of MyCanRisk into clinical and research settings.

P01.101.A Genetic profiling for renal cell carcinoma risk assessment: multi-SNP analysis in a spanish cohort

Carmen M. Morales Álvarez, *Elena Arance Criado, Fernando Marín Benesiu, Juan M. Guerrero González, María J. Álvarez Cubero, Luis J. Martínez González*

Department of Biochemistry and Molecular Biology III and Immunology, Faculty of Medicine, University of Granada. GENYO. Centre for Genomics and Oncological Research: Pfizer / University of Granada / Andalusian Regional Government PTS Granada, Granada, Spain.

Background: Renal cell carcinoma (RCC) is a heterogeneous malignancy influenced by genetic and environmental factors. Genome-wide association studies (GWAS) have identified several RCC susceptibility SNPs within key genes, including *ITPR2, DPF3, EPAS1, PVT1*, and *MYC*, which are involved in calcium signaling, chromatin remodeling, hypoxia response, and oncogenesis. Despite their biological relevance, the functional impact of these genetic variations in sporadic RCC remains poorly characterized. This study aims to identify potential genetic biomarkers for early diagnosis in a Spanish cohort.

Material and methods: Buccal swabs from 259 healthy controls and 168 RCC patients were genotyped for key SNPs, and expression analysis was conducted on 30 formalin-fixed, paraffin-embedded renal tissue samples, including both tumor and adjacent healthy tissue. Statistical analyses were performed to evaluate the relationships between genotypes, gene expression, and RCC risk.

Results: The CC genotype of *ITPR2* rs10771279 was associated with a protective effect, with higher *ITPR2* expression observed in healthy tissue compared to RCC. The C risk allele of *DPF3* rs4903064 correlated with increased RCC risk and elevated *DPF3* expression, suggesting a role in hypoxia-inducible pathways. Similarly, *EPAS1* rs7579899 showed a significant association with RCC risk, consistent with its role in hypoxia-regulated pathways. Although *PVT1* rs35252396 did not reach statistical significance, *PVT1* gene expression was significantly upregulated in RCC tissue.

Conclusion: This study identifies key SNPs and genes, including *ITPR2, DPF3*, and *EPAS1*, as contributors to RCC susceptibility, with multi-SNP combinations showing strong predictive potential, underscoring the value of genetic profiling in RCC risk assessment.

P01.103.C KRAS p.G12C and PIK3CA p.Q546K as tumors biomarkers for reclassifying variants of uncertain significance in MUTYH

Giovana Tardin Torrezan[1], *Ana Beatriz D. Medeiros*[1], *José Claudio C. Rocha*[1], *Vanessa N. Kozak*[2], *Clarissa G. Picanço-Albuquerque*[3], *Dirce M. Carraro*[1]

[1]*A.C.Camargo Cancer Center, São Paulo, Brazil,* [2]*Hospital Erasto Gaertner, Curitiba, Brazil,* [3]*Instituto do Câncer do Ceará, Fortaleza, Brazil.*

Background: *MUTYH*-associated polyposis (MAP) is an underdiagnosed recessive syndrome that predisposes individuals to colorectal cancer (CRC). Biallelic MUTYH loss leads to a distinct somatic mutational signature, characterized by G > T transversions, frequently resulting in KRAS p.G12C and PIK3CA p.Q546K mutations in CRC and adenomas of MAP patients—mutations rarely observed in sporadic tumors. This study aims to assess the utility of detecting KRAS p.G12C and PIK3CA p.Q546K in adenomas and CRCs for classifying variants of uncertain significance (VUS) in MUTYH.

Material and methods: We analyzed the frequency of KRAS p.G12C and PIK3CA p.Q546K mutations in adenomas and CRC tissues from 16 MAP patients and 3 individuals harboring MUTYH VUS (NM_001128425.2: p.Trp113Arg, p.Pro301Arg, and p.Lys450Met, detected in homozygosity or compound heterozygosity with a pathogenic variant).

Results: Among 17 adenomas from MAP patients, 8 (47%) carried KRAS p.G12C, while none harbored PIK3CA p.Q546K. In 13 CRCs, these mutations were detected in 92% and 38% of cases, respectively. In suspected MAP cases, KRAS p.G12C and PIK3CA p.Q546K were identified in one adenoma and one CRC from the p.Trp113Arg carrier, while KRAS p.G12C was found in one CRC from the p.Pro301Arg carrier. These findings support their classification as likely pathogenic according to ACMG PP4_moderate or PP4_supporting criteria.

Conclusions: The high prevalence of KRAS p.G12C and PIK3CA p.Q546K in MAP-associated CRC and adenomas highlights their potential as biomarkers for classifying MUTYH VUS. This simple approach offers a valuable complementary strategy for variant interpretation, improving the accuracy of genetic diagnoses for individuals with suspected MAP.

P01.104.D Familial case of ultra rare constitutional mismatch repair deficiency - like syndrome

Maria Kurnikova, *Roman Moiseenko, Anna Kazakova, Ruslan Abasov, Anastasiya Salomatina, Olga Soldatkina, Maria Skvortsova, Medina Gurzhihanova, Denis Kachanov, Liudmila Yasko*

Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation.

Background: The proband was an 8-year-old female with nephroblastoma that manifested at the age of 20 months. The patient also had multiple café-au-lait (CAL) spots, as well as depigmented areas, and microcephaly. Her older sibling had two metachronous tumors: choroid plexus papilloma at the age of 2, and esthesioneuroblastoma at the age of 5 which led to a lethal outcome at the age of 7 years. He also had seizures, speech delay and multiple CAL spots. Both parents were clinically healthy. The diagnosis of constitutional mismatch repair deficiency (CMMRD) syndrome was suspected.

Material and methods: NGS-based sequencing with a target panel of cancer predisposition genes was carried out, with a special focus on *MLH1*, *MSH2*, *MSH6* and *PMS2* genes, but no pathogenic or likely pathogenic variants were detected. The next step was trio whole genome sequencing in both short- and long-read format.

Results: Two rare changes in the *MAD1L1* gene in trans were considered to be of particular interest - c.244C>T/p.Arg82Ter (exon 4) and c.1888C>T/p.Arg630Cys (exon 18). In 2022, the first and the only one to date case of autosomal recessive mosaic variegated aneuploidy (MVA) syndrome 7 with inflammation and tumor predisposition associated with the *MAD1L1* gene was described in a 36-year-old female with a dozen of malignant and benign neoplasms (1).

Conclusion: As far as we know, this case may be the second described case of MVA type 7 in the literature. Further studies are needed to prove the causativity of the variants for the patient's phenotype.

P01.105.A Long-term chromosomal aberrations in fibroblasts 20 years after total body irradiation

Sylvia Voreck[1], *Simone Olivieri*[1], *Stefanie Beck-Wödl*[1], *Cristiana Roggia*[1], *Kathrin Grundmann-Hauser*[1], *Christopher Schroeder*[1], *Elena Buena-Atienza*[1], *Leon Schütz*[1], *Marc Sturm*[1], *Matthis Synofzik*[2,3], *Anna Hofmann*[2,4], *Elgin Hoffmann*[5], *Tobias Haack*[1], *Olaf Riess*[1], *Ulrike Mau-Holzmann*[1]

[1]*Institute of Medical Genetics and Applied Genomics, Eberhard Karls University, Tuebingen, Germany,* [2]*Department of Neurodegeneration, Eberhard Karls University Tübingen, Tuebingen, Germany,* [3]*Hertie Institute for Clinical Brain Research and Centre of Neurology, Tuebingen, Germany,* [4]*Department of Neurology, Washington University School of Medicine, St. Louis, MO, USA,* [5]*Department of Radiation Oncology, Eberhard Karls University, Tuebingen, Germany.*

Background: Total body irradiation (TBI) and prophylactic whole brain radiation therapy (WBRT) can cause long-term radiation effects, such as chromosomal aberrations in skin fibroblasts and white matter changes potentially linked to cognitive decline.

Case study: A 45-year-old female was referred to our genetics clinic with cognitive deficits and cerebrospinal fluid biosignature suggestive of early-onset Alzheimer's. At 26, she was diagnosed with Pre-B-Cell Acute Lymphoblastic Leukemia (ALL) and treated with allogeneic stem cell transplantation requiring TBI-based conditioning with hyperfractionated radiotherapy (12 Gy) and WBRT (24 Gy). Family history included ALL (sister), breast cancer (mother) and lymphoma (maternal grandmother).

Methods: A skin biopsy was obtained and fibroblasts were cultured using standard protocols. Karyotyping was performed on G-banded metaphase chromosomes. Genome sequencing was performed on DNA from cultivated fibroblasts to evaluate possible predisposition to dementia and hematopoietic neoplasms.

Results: Aside from the heterozygous *APOE* ε4 risk allele and a heterozygous variant of unclear significance in *NOS3*, the genome analysis did not reveal any (likely) pathogenic variants. Interestingly, the chromosome analysis showed multiple aberrations in all mitoses of 2 cultures which included multiple reciprocal translocations and inversions together with numerical aberrations. These findings were verified in a second skin biopsy.

Conclusion: No causative variants for chromosomal breakage or hereditary cancer predisposition syndromes were found in the genome analysis (pending verification with LR-genome analysis). Our current findings suggest that the complex chromosomal aberrations possibly resulted from the ALL treatment 20 years ago. Further research regarding a possible causative connection with early-onset dementia is warranted.

P01.106.B Elucidating the role of human leukocyte antigens in antidrug antibody formation from a large Cohort study of early-phase non-standard cancer immunotherapy trials

Tony Kam-Thong[1], ***Petar Scepanovic***[1], *Virginia Schmid*[1], *David Lamparter*[1], *Min Sun*[1], *Marco Berrera*[1], *Linnea Franssen*[1], *Hans Peter Grimm*[1], *Guillemette Duchateau-Nguyen*[1], *Andreas Roller*[1], *Eric Wei*[2], *Victor Alejandro Iglesias*[2], *Rajat Mohindra*[3], *Dominik Heinzmann*[4], *Vaios Karanikas*[1], *Cameron Adams*[5], *Sarah Louise Mycroft*[6], *Benjamin Fairfax*[7], *Nicolas Staedler*[1]

[1]*Roche Pharmaceutical Research and Early Development (pRED), Basel, Switzerland,* [2]*Roche Product Development Clinical Operations, Basel, Switzerland,* [3]*Roche Product Development Safety and Risk Management, Basel, Switzerland,* [4]*Roche Product Development, Basel, Switzerland,* [5]*Roche Genentech Research and Early Development (gRED), San Francisco, CA, USA,* [6]*Roche Early Development Oncology Clinical Safety, Welwyn Garden City, United Kingdom,* [7]*Weatherall Institute for Molecular Medicine, Oxford, United Kingdom.*

Background: Checkpoint inhibitors (CPIs) have revolutionized cancer treatment, but the development of antidrug antibodies (ADA) can limit their efficacy and increase immune-related adverse events. Identifying biomarkers predictive of ADA formation is critical. Human leukocyte antigen (HLA) genes, known for their role in immune responses, have been linked to ADA formation in CPI therapy. However, the impact of HLA alleles on ADA development in non-CPI cancer immunotherapy (CIT) remains largely unexplored.

Methods: To investigate the association between HLA alleles and ADA formation, we analyzed a harmonized dataset from 23 early-phase clinical trials, encompassing 12 diverse molecules and various cancer indications, including 3'568 patients, both CPI-naïve and CPI-experienced. ADA status was determined using

standardized definitions based on therapeutic antibody-specific titers. We employed an HLA-wide approach to assess associations with persistent ADA formation.

Results: After Bonferroni correction, we found no statistically significant associations with low consistency in the ranking of HLA alleles. However, results for CPI as a standard-of-care combination therapy showed an odds ratio of 1.84 (CI 95% 1.02–3.21) for the DRB1*01:01 variant, consistent with previous findings in atezolizumab monotherapy trials.

Conclusions: This study represents a systematic investigation of the role of the HLA region in ADA formation in non-standard CITs. The low correlation among HLA allele rankings suggests that genetic predisposition to ADA formation is likely molecule-specific. However, these results may be influenced by low statistical power and other confounding factors. Future work will integrate T-cell epitope prediction models to further elucidate the immunogenicity cascade and differences observed across therapeutic antibodies.

P01.107.C Common and rare variants integration for Breast Cancer risk stratification to personalize risk-adapted preventive measures

Carla Debernardi[1], *Alessia Russo*[1], *Federica Ragno*[1], *Elisabetta Casalone*[2], *Max Tamlander*[3], *Nina Mars*[4], *Elisabeth Widen*[4], *Samuli Ripatti*[4], *Giuseppe Matullo*[5]

[1]*University of Turin, Torino, Italy,* [2]*University of Turin, Turin, Italy,* [3]*Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland,* [4]*University of Helsinki, Helsinki, Finland,* [5]*Dept. Medical Sciences, University of Turin, Torino, Italy.*

Background: Common low-risk variants are presently not used to guide clinical management of familial breast cancer (BC). Many studies suggest that the combined effects of BC-associated single nucleotide polymorphisms (SNPs) can improve BC risk stratification using polygenic risk scores (PRS). We explored the additive impact of PRS and the potential modulation of the effect of mutations in high/moderate risk susceptibility genes in BC patients.

Material and methods: We analysed the genetic profiles of 195 Italian BC patients using Illumina SNP array and Whole Exome Sequencing (WES) Firstly, we compared two different PRSs, PGS000335 (1,079,089 SNPs) and our new optimized PRS composed by 4606 SNPs. Then, we evaluated the modulation of BC risk by the PRS and the potential combined effects of rare variants using the Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm V.5 model (BOADICEA), calculating lifetime risks retrospectively both with and without individual PRS.

Results: The BC patients PRSs distributions were higher compared to controls. *BRCA1/2* variants had a major role in stratifying lifetime risk, while PRS improves risk estimation for patients with variants with an uncertain meaning and non-carriers. Using PRS could also improve the risk prediction for those patients carrying a mutation on gene with a moderate BC risk as *ATM*, *CHECK2*, *BARD1*, *BRIP1, RAD51C* and *RAD51D*.

Conclusion: PRSs may be helpful to personalize risk-adapted preventive measures for women with BC, even when they carry mutations in high/moderate risk genes.

P01.108.D Long noncoding RNA NEAT1 interacts with the miR-3648 axis in imatinib resistant chronic myeloid leukemia cell model

Zeynep MUTLU[1,2], *Cagla Kayabasi*[3], *Osman Doluca*[4]

[1]*Malatya Turgut Ozal University, Medicine Faculty, Department of Medical Biology, Malatya, Turkey,* [2]*Dokuz Eylül University, Medicine Faculty, Multidisciplinary Laboratory, Izmir, Turkey,* [3]*Balıkesir University, Medicine Faculty, Department of Medical Biology, Balıkesir, Turkey,* [4]*Izmir University of Economics Dept. of Biomedical Engineering, Izmir, Turkey.*

Background: Chronic myeloid leukemia (CML) is a hematopoietic malignancy caused by the formation of the Philadelphia chromosome (Ph, 9;22). This results in the expression of the BCR-ABL fusion protein, which possesses tyrosine kinase activity. The leukemogenic nature of BCR-ABL1 makes it a therapeutic target in CML treatment. Imatinib, the first clinically approved tyrosine kinase inhibitor (TKI), is an ATP-competitive inhibitor that specifically binds to the BCR-ABL oncoprotein, suppressing its kinase activity. However, resistance to BCR-ABL tyrosine kinase inhibitors has been observed over time. This resistance can also occur independently of BCR-ABL1 mutations. Therefore, this study aims to investigate the epigenetic regulation of the imatinib resistance mechanism in CML. Long non-coding RNAs (lncRNAs) are RNA molecules ranging from 200 bp to 100 kbp in length that play a role in epigenetic mechanisms and gene expression regulation. The long non-coding RNA NEAT1 is responsible for gene regulation and facilitates the formation of nuclear bodies called 'paraspeckles.'

Material and methods: In this study, RNA pull-down using biotinylated primers specific to NEAT1 and RNA sequencing were performed in the imatinib-resistant K562 cell line to investigate the presence of miRNAs retained in NEAT1/paraspeckles.

Results: miR-3648 was found to be associated with NEAT1 in imatinib-resistant K562 cells compared to imatinib-sensitive K562 cells.

Conclusion: We hypothesize that miR-3648, which is retained within paraspeckles in imatinib-resistant K562 cells, may contribute to the imatinib resistance mechanism by being unable to bind to its target genes, thereby affecting cell survival rates.

P01.109.A The role of *TET2* mutations and expression in high grade serous ovarian carcinoma: impact on molecular and clinico-pathological features

Federico Manai, *Michela Tulino, Simone G. De Micco, Rossella Tricarico*

Department of Biology and Biotechnology "L. Spallanzani", University of Pavia, Pavia, Italy.

Background: High Grade Serous Ovarian Carcinoma (HGSOC) is the deadliest gynecological cancer, with limited understanding of the role of epigenetic mechanisms in its pathogenesis. TET2, an enzyme involved in DNA demethylation, plays a critical role in maintaining epigenomic stability. Although *TET2* alterations have been linked to tumorigenesis and therapy response in other cancers, their role in HGSOC remains poorly understood, highlighting the need to investigate their molecular and clinical implications.

Material and methods: Genomic and transcriptomic analyses of *TP53*-mutated HGSOC samples were conducted using AACR GENIE (n = 3641) and TCGA GDC (n = 222) datasets. Genomic analysis examined *TET2* mutations and their associations with demographic and clinical parameters, while transcriptomic analysis evaluated correlations between *TET2* expression and therapy resistance pathways. Statistical methods included Spearman correlation, Chi-square tests, and Kaplan-Meier survival analysis.

Results: *TET2* mutations were identified in 6% of patients, predominantly among Black and Asian populations, with missense mutations being the most frequent. These mutations correlated with alterations in the therapy resistance pathway. Transcriptomic analysis revealed higher *TET2* expression in Black and Asian populations compared to White counterparts, correlating strongly with mRNA levels of therapy resistance genes and a trend toward worse overall survival.

Conclusion: These preliminary findings suggest that *TET2* mutations and expression may influence therapy response and survival in HGSOC. Further validation is required to confirm these observations and clarify the mechanisms underlying *TET2*'s role in therapy resistance. Understanding these processes could pave the way for developing TET2-based biomarkers and personalized therapeutic strategies, ultimately improving outcomes for patients with *TET2* alterations.

P01.110.B DMU-212 potently and selectively targets leukemia stem cells in vitro

Cagla Kayabasi[1], *Besra Ozmen Yelken*[2], *Tugce Balci Okcanoglu*[3], *Cumhur Gunduz*[4]

[1]*Balikesir University, Faculty of Medicine, Department of Medical Biology, Balikesir, Turkey,* [2]*Izmir Bakircay University, Faculty of Medicine, Department of Medical Biology, Izmir, Turkey,* [3]*Girne University, Faculty of Medicine, Department of Medical Biology, Kyrenia, Cyprus,* [4]*Ege University, Faculty of Medicine, Department of Medical Biology, Izmir, Turkey.*

Background: Leukemia stem cells (LSCs) drive relapse and chemoresistance through self-renewal, dormancy, and impaired differentiation. Resveratrol, a plant-derived polyphenol, has anti-leukemic potential, whereas its methylated analog, DMU-212, demonstrates enhanced efficacy, positioning it as a promising therapeutic candidate. This study investigated the anti-leukemic effects of DMU-212 on LSCs and its concomitant effects on hematopoietic stem cells (HSCs).

Materials and methods: The cytotoxic effects of resveratrol and DMU-212 on LSC (CD44+/CD133+/CD38-) and HSC (CD34+/CD38-) were assessed using CCK-8 assay. IC_{50}-induced apoptosis (AnnexinV/PI, DNA-fragmentation, active-caspase-3), anti-proliferation (CFSE), cell-cycle arrest (PI-staining) analyzed by flow-cytometry; cell survival (clonogenicity), gene expressions (qRT-PCR), genotoxicity (micronucleus), DNA damage (γH2AX) were evaluated.

Results: DMU-212 (IC_{50}:16.65 μM) exhibited higher cytotoxicity in LSCs than resveratrol (IC_{50}:95.43 μM). DMU-212 (16.65 μM) induced stronger late apoptosis, caspase-3 activation, and DNA fragmentation in LSCs relative to resveratrol (16.65 μM), accompanied by the regulation of apoptosis-related genes, including *BCL2L1, CASP3*, and *FASLG*. The survival fraction of DMU-212-treated LSCs reduced to 5.35% and the proliferation was significantly inhibited due to G_2/M arrest. The anti-proliferative effects were associated with the regulation of *CCNB1, CDC25A, TP53, ELK1, HRAS, JUN, KRAS, MAP2K2, JAK1, JAK2, SOCS3, STAT5B, AKT2, EIF4EBP, FOXO1, PDK1, PIK3CD*. DMU-212 also increased polyploidy, micronucleus formation, and γH2AX levels in LSCs. Both resveratrol and DMU-212 exhibited minimal adverse effects on HSCs.

Conclusion: DMU-212 selectively targets LSCs through apoptotic, anti-proliferative, and genotoxic mechanisms, while sparing healthy HSCs. These findings underscore its potential as a highly effective and low-toxicity therapeutic strategy for leukemia treatment.

Effects of resveratrol and DMU-212 on LSC and HSC (Fold change relative to control)

	Resveratrol (LSC)	DMU-212 (LSC)	Resveratrol (HSC)	DMU-212 (HSC)
Apoptosis	1.6	4.1	0.64	0.44
Caspase-3 Activation	2.8	4.2	0.39	1.25
DNA Fragmentation	3.2	8.6	0.2	1.25
Survival Fraction (%)	94.72	5.35	44.32	29
Proliferation Suppression	2	3.2	2.2	2.5
γH2AX	4.55	6.72	2.6	2.06

P01.111.C Synergistic effect of Venetoclax and hypomethylating agents is independent of methylation loss

Lisa Haglund, *Aida Selimović-Pašić, Maike Bensberg, Julia Goldmann, Sandra Hellberg, Colm E. Nestor*

Linköping University, Linköping, Sweden.

Background: The BCL-2 inhibitor Venetoclax in combination with the hypomethylating agents (HMAs), 5-azacytidine (AZA) and decitabine (DEC) is clinically approved for use in acute myeloid

leukemia (AML). However, the molecular mechanisms underlying their synergy, particularly the role of DNA demethylation, remain poorly understood due to the dual effects of traditional HMAs, inducing both DNA demethylation and extensive DNA damage.

Material and methods: To investigate the role of DNA methylation in driving Venetoclax synergy with HMAs, we compared a novel DNMT1-specific inhibitor, which induces DNA demethylation with minimal DNA damage, to AZA and DEC. Cytarabine (ARAC), a DNA-damaging cytidine analogue without demethylating activity, was included as a comparator. AML cell lines were treated with each agent alone and in combination with Venetoclax, and synergistic effects were evaluated based on cell viability. Additionally, global methylation was assessed through enzymatic methyl-sequencing.

Results: DNA demethylation alone did not induce synergy with venetoclax. In contrast, a strong synergistic effect was observed when Venetoclax was combined with AZA and DEC, both of which induce DNA damage in addition to demethylation. Interestingly, ARAC, despite lacking demethylating properties, also demonstrated significant synergy with Venetoclax.

Conclusion: Preliminary results show that the synergy observed between Venetoclax and the traditional HMAs is primarily driven by DNA damage, not methylation loss. Interestingly, DNA demethylation alone, achieved by using the novel DNMT1-inhibitor, appear to be antagonistic, questioning the relevance of targeting DNA methylation. These findings suggest that the therapeutic benefit in AML is linked to DNA damage rather than changes in DNA methylation.

P01.112.D Identification of a novel *PMS2* duplication in exons 1–12: implications in Lynch syndrome and hereditary cancer predisposition

Gabriella Shianiou[1], *Ioanna Andreou*[1], *Petroula Gerasimou*[1], *Andri Miltiadous*[1], *Andri Mitsidou*[1], *Katerina Nicolaou*[1], *Yiannos Kyprianou*[1], *Agathi Elpidoforou*[1], *Christina Ioannou*[1], *Christina Zartila*[1], *Andrea Christofi*[1], *Marina Johnson*[1], *Efi Georgiou*[1], *Chrysanthi Avgousti*[1], *Maria Kanezou*[1], *Jianxiang Chi*[1], *George Orphanos*[2], *Paul Costeas*[1]

[1]*Karaiskakio Foundation, Nicosia, Cyprus,* [2]*German Oncology Center, Limassol, Cyprus.*

Background: Lynch syndrome (LS) is an autosomal dominant cancer predisposition syndrome caused by pathogenic variants in DNA mismatch repair (MMR) genes, including *PMS2*. While mutations in *PMS2* are well-documented, structural variations, such as large duplications, remain underexplored. Here, we report a novel duplication of *PMS2* exons 1–12 in two unrelated patients, highlighting its potential pathogenicity in LS.

Materials and methods: Two unrelated female cancer patients were referred for hereditary cancer predisposition investigation. The first, an 86-year-old with pancreatic and breast cancers, and the second, a 30-year-old with metastatic lung cancer and a family history of cancer. Genetic testing included Next Generation Sequencing (NGS) using Agilent SureSelect panel to exclude potential pathogenic mutations, and digital multiplex ligation-dependent probe amplification (MLPA) to assess copy number variations (CNVs) in cancer-related genes.

Results: A previously unreported duplication of exons 1–12 in *PMS2* gene was identified by digital MLPA and confirmed with conventional *PMS2*-specific MLPA. Subsequent family studies on the first patient's two sons revealed that one carried the same duplication.

Conclusion: This study identifies a novel *PMS2* exon 1–12 duplication possibly associated with LS. To our knowledge, this specific variant is absent from current literature. Its presence in two unrelated cancer patients along with familial segregation in one case, suggests a possible pathogenic role and supports its relevance in hereditary cancer predisposition. This finding expands the mutational spectrum of *PMS2* and highlights the importance of considering structural variations in hereditary cancer investigations. Further functional studies are needed to confirm its clinical implications in cancer.

P01.113.A Genetic landscape of pediatric hematologic malignancies in Latvia: insights from whole-genome and RNA sequencing

Monta Briviba[1], *Agnese Viluma*[1], *Agnese Grzelahovska*[1], *Maija Rozenberga*[1], *Annija Alise Zodane*[1], *Santa Kursite*[2], *Anna Valaine*[2], *Jelena Sorokina*[2], *Dace Enkure*[2], *Janis Klovins*[1]

[1]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [2]*Children's Clinical University Hospital, Riga, Latvia.*

Background: Pediatric hematologic malignancies, such as B-cell acute lymphoblastic leukemia and acute myeloid leukemia, present distinct genetic profiles that are critical for risk stratification and treatment planning. This study aimed to explore the genetic landscape of these malignancies in a Latvian cohort using whole-genome sequencing and RNA sequencing.

Material and Methods: Whole-genome sequencing and RNA sequencing data were analyzed from 42 pediatric patients diagnosed with hematologic malignancies in Latvia between 2019 and 2022. Tumor and normal tissue samples were collected for genetic analysis, including structural variations and gene fusions.

Results: Somatic single nucleotide variants were identified in 130 target genes, with 28% of these genes exhibiting mutations in multiple patients. Frequently affected genes included *NRAS*, *MYC*, and *WT1*. Subtype-defining alterations such as hyperdiploidy and the *ETV6-RUNX1* fusion were observed among the most common findings in B-cell acute lymphoblastic leukemia. Chromosomal abnormalities were detected in 61% (25/41) of cases, with large chromosomal rearrangements (>30 kb) identified on chromosomes 7, 14, and X. Chromosome 21 was the most affected in terms of whole-chromosome copy number alterations. Notably, *ETV6-RUNX2* was discovered as a novel gene fusion in this cohort.

Conclusion: This study emphasizes the role of whole-genome sequencing in uncovering genetic complexities of pediatric hematologic malignancies, aiding in diagnosis and the development of targeted therapies.

P01.114.B Molecular characterization of pediatric ALL: identifying key pathways and potential biomarkers through transcriptome analysis

Klementina Črepinšek[1,2], *Urška Janžič*[2], *Barbara Slapnik*[1,2], *Robert Šket*[1,2], *Tine Tesovnik*[1,2], *Barbara Jenko Bizjan*[1,2], *Jernej Kovač*[1,2], *Blaž*

Vrhovšek[1,2], Marko Kavčič[1,2], Tomaž Prelog[1], Janez Jazbec[1,2], Maruša Debeljak[1,2]

[1]University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.

Background: Acute lymphoblastic leukaemia (ALL) represents 25% of pediatric malignancies, making it the most prevalent childhood cancer. This study aimed to characterize transcriptome profiles of B- and T-cell ALL to elucidate disease heterogeneity and identify potential novel biomarkers for personalized treatment approaches.

Material and methods: We performed RNA sequencing on pediatric bone marrow and peripheral blood samples from B-ALL and T-ALL patients. Comprehensive differential gene expression and pathway enrichment analyses were conducted to identify significant molecular signatures.

Results: Differential gene expression analysis revealed over 8,000 differentially expressed genes between B- and T-ALL. Immunoregulatory interactions between lymphoid and non-lymphoid cells emerged as potential contributors to T-ALL's poorer prognosis. In B-ALL, while pathway analysis revealed signatures distinguishing patients with and without relapse, the primary source of variability stemmed from distinct genetic subtypes. Further analysis indicated that increased oncogene expression and decreased tumor suppressor gene expression correlated with more aggressive disease in specific B-ALL subgroups and in T-ALL patients with poor outcome. Additionally, gene expression patterns showed poor correlation with immuno-phenotypes in T-ALL, consistent with existing literature.

Conclusion: This study provides valuable insights into ALL's molecular landscape, demonstrating distinct gene expression signatures between and within ALL subtypes. Our findings enhance understanding of biological mechanisms underlying ALL development and progression, particularly regarding the role of immunoregulatory pathways and the impact of dysregulated oncogene and tumor suppressor expression on disease severity. These insights emphasize the need for detailed molecular profiling to identify targeted therapeutic strategies and prognostic biomarkers, potentially advancing personalized medicine in pediatric ALL.

P01.115.C Beyond BRCA: risk assessment and genetic aetiology of ovarian cancer in African women

***Bianca Rossouw**[1], Amanda Krause[1], Bernard Uzabakiriho[2], Langanani Mbodi[3], Trudy Smith[4], William Edridge[5], Fiona Baine-Savanhu[1]*

[1]National Health Laboratory Service and the University of the Witwatersrand, Johannesburg, South Africa, [2]Rahima Moosa Mother and Child Hospital and the University of the Witwatersrand, Johannesburg, South Africa, [3]Charlotte Maxeke Johannesburg Academic Hospital and the University of the Witwatersrand, Johannesburg, South Africa, [4]Wits Donald Gordon Medical Centre and the University of the Witwatersrand, Johannesburg, South Africa, [5]Chris Hani Baragwanath Academic Hospital and the University of the Witwatersrand, Johannesburg, South Africa.

Background: Ovarian cancer, often termed the "silent killer," is hereditary in approximately 20% of cases. However, the genetic aetiology of ovarian cancer in African women remains poorly understood, with risk assessments based on studies in European populations and limited evidence of their applicability to African patients.

Material and methods: We conducted a scoping literature review of germline genetic testing in African women with ovarian cancer and evaluated the utility of risk assessment tools in 20 black African women diagnosed with ovarian cancer. These patients form part of a whole-exome sequencing project investigating ovarian cancer in African women.

Results: The review included 30 studies, predominantly involving African American and North African cohorts. Only four studies focused on ovarian cancer, while the rest involved breast cancer cohorts that included ovarian cancer cases. Across 110 African families with ovarian cancer, 75 disease-causing variants were identified, 92% of which were in *BRCA1* and *BRCA2*. Notably, 22 of the 30 studies exclusively tested for these genes, although variants in *BARD1*, *CHEK2*, *EP300*, *NTHL1*, *PALB2*, *PMS2*, and *TP53* were also reported.

Among the 20 patients recruited thus far risk assessment tools (Manchester, CanRisk, PREMM5) yielded low scores for 13 patients. The mean age of diagnosis was 48 years, and only six had a family history of cancer.

Conclusion: The findings highlight limited research on hereditary ovarian cancer in African women and the need for comprehensive approaches, such as exome sequencing, to refine genetic testing and risk assessment tools tailored to African women with ovarian cancer.

P01.116.D PTPRJ and PTPRC activation as targets to counteract oncogenic FLT3-ITD-mediated cell transformation in AML

***Boban Dobrevski**[1,2], Petra Geisseová[1], Jörg P. Müller[1]*

[1]Institute for Molecular Cell Biology, Center for Molecular Biomedicine, Friedrich Schiller University and Jena University Hospital, Jena, Germany, [2]Ss. Cyril and Methodius University in Skopje, Faculty of Medicine - Skopje, Institute for Immunobiology and Human Genetics, Skopje, North Macedonia, The Republic of.

Background: Nearly 30 % of Acute Myeloid Leukaemia (AML) patients carry activating mutations in the FMS-like tyrosine kinase 3 (FLT3). Most common are Internal Tandem Duplication (ITD) mutations in the juxtamembrane domain of this receptor tyrosine kinase, causing loss of auto-inhibition of the kinase resulting in constitutive FLT3 activity, retention of the immature receptor in the biogenesis route and aberrant activation of STAT5 signalling. Thus, FLT3-ITD proteins induce uncontrolled cell proliferation, block cell differentiation and drive cell transformation. Receptor Protein Tyrosine Phosphatases (RPTP) antagonize FLT3 activities. Here we address the effects of PTPRJ and PTPRC overexpression on FLT3 phosphorylation and FLT3 downstream signalling.

Material and methods: FLT3-WT/ITD and PTPRJ/PTPRC proteins were co-expressed using transient transfection in HEK293T cells. Cell lysates were processed with immune blotting and FLT3 phosphorylation as well as activation of downstream targets AKT, ERK1/2 and STAT5 were characterized.

Results: Overexpression of both RPTP dephosphorylated FLT3 wild type and consequently diminished phosphorylation of downstream signalling proteins AKT and ERK1/2. While PTPRC efficiently dephosphorylated FLT3-ITD resulting in increased maturation of the receptor and significant reduction of downstream signalling, PTPRJ hardly affected FLT3-ITD activity. This difference can be explained by FLT3-ITD-mediated ROS

production resulting in PTPRJ oxidation, which lead to diminished phosphatase activity.

Conclusion: Activation of RPTP, in particular PTPRC, is an attractive target to antagonise oncogenic FLT3-ITD signalling. In particular, abrogation of RPTP oligomerization, which subsequently increases their activity, is an attractive way to counteract FLT3-ITD-mediated cell transformation and therefore target AML.

P01.117.A FIRE: a decision tree algorithm for automating oncogenicity classification of cancer somatic variants using the ClinGen/CGC/VICC framework

Michela Tulino[1], *Simone G. De Micco*[1], *Andrei S. Blindu*[2,3], *Federica De Paoli*[3], *Ivan Dorna*[4], *Federico Manai*[1], *Rossella Tricarico*[1]

[1]*Department of Biology and Biotechnology "L. Spallanzani", University of Pavia, Pavia, Italy,* [2]*Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Pavia, Italy,* [3]*enGenome srl, Pavia, Italy,* [4]*Anthilla srl, Caronno Pertusella, Italy.*

Background: Accurate classification of somatic variants is critical for precision oncology. The ClinGen/CGC/VICC 5-tier framework provides structured guidelines to support clinical interpretation. However, no tool fully integrates this framework into an automated system. ClinVar annotates a subset of somatic variants, VIC employs a hybrid approach with FDA-approved evidence, and OncoKB prioritizes therapy-linked predictions over oncogenicity classification. The lack of a standardized system limits consistency in variant interpretation and clinical decision-making. To address this, we developed FIRE, a decision tree-based model to automate classification, enhance reproducibility, and minimize variability.

Material and methods: In this preliminary study, FIRE was tested on 253 benchmark variants (oncogenic and benign) from five cancer genes in ClinVar. The model applies weighted scoring to ClinGen/CGC/VICC evidence categories, integrating population data, computational predictions, and variant type. FIRE's performance was assessed using F1-score, sensitivity, and false positive rate (FPR). It was validated on 157 SNVs and Indels in *TET2* from colorectal (CRC) and ovarian cancer (OC) AACR GENIE datasets.

Results: FIRE correctly classified 70% of benchmark variants, achieving an F1-score of 0.92, sensitivity of 1, and FPR of 0.58. In CRC and OC datasets, FIRE classified 44% of previously unclassified *TET2* variants, identifying 30 oncogenic, 37 likely oncogenic, and 2 likely benign variants. The remaining 56% were Variants of Uncertain Significance.

Conclusion: These findings highlight FIRE's ability to classify somatic variants, particularly likely oncogenic or oncogenic. Future work will benchmark FIRE against existing tools, refine feature weighting, integrate additional ClinGen/CGC/VICC evidence, and expand classification to more cancer genes.

Background: Malignant melanoma is a rapidly progressing cancer responsible for 80% of skin cancer deaths, despite being only 4% of skin cancer cases. In contrast, basal cell carcinoma is the most common skin disorder worldwide. This study investigates the relationship between two genetic polymorphisms related to melanogenesis: rs1126809 in the *TYR* gene and rs2733832 in the *TYRP1* gene, and their association with melanoma and carcinoma.

Material and methods: Samples of blood, waxed tissue, or saliva were collected from 155 healthy controls, 127 melanoma patients, and 112 carcinoma patients. DNA was extracted, and the genes of interest were genotyped using TaqMan probes. The results were analyzed using a Pearson chi-square test. A meta-analysis was also conducted, incorporating published studies related to our single nucleotide polymorphisms (SNPs) and the diseases under investigation, which significantly increased the sample size.

Results: In our cohort, no significant differences were observed; however, there was a tendency to develop melanoma more frequently in individuals with the A risk allele for the rs1126809 (TYR) polymorphism, following a dominant model (p-value: 0.084). After performing the meta-analysis, we found a strong association between rs2733832 (TYRP1) and melanoma (p-value: 6.21*10^-6), as well as between rs1126809 (TYR) and melanoma (p-value: 2.72*10^-7), and a trend toward association with carcinoma (p-value: 0.056).

Conclusion: Identifying reliable biomarkers for melanoma is vital due to its high mortality rate. This study suggests that SNPs rs1126809 and rs2733832 may serve as decision-support biomarkers for managing patients at risk for melanoma.

P01.119.C Germline pathogenic variants in patients with a suspicion of hereditary paraganglioma-pheochromocytoma syndrome-a single centre experience

Fulvia Brugnoletti, *Aurélie Ayme, Amandine Cadènes, Jean-Louis Blouin, Jean-Christophe Tille, Claudio De Vito, Frédéric Triponez, Maria Mavromati, Sophie Leboulleux, Pierre Olivier Chappuis*

Geneva University Hospitals, Geneva, Switzerland.

Background: Around 40% of patients diagnosed with paraganglioma (PGL) and/or pheochromocytoma (PCC) carry germline pathogenic/likely pathogenic variants (PV/LPV) in one susceptibility genes, mainly in succinate dehydrogenase genes (SDHx). Individuals harboring germline SDHx PV/LPV tend to develop tumours at a younger age with multifocal and/or bilateral disease, high malignant incidence, and recurrence rate.

Material and methods: We reviewed all cases addressed to our Oncogenetic Unit for a suspicion of hereditary PGL/PCC syndrome from 2016 to 2024. Germline analysis was performed using the following gene panel: *FH, MAX, MEN1, NF1, RET, SDHA, SDHAF2, SDHB, SDHC, SDHD, TMEM127* and *VHL*.

Results: 28 patients underwent genetic testing for a suspicion of hereditary PGL/PCC syndrome. In 9/28 (32%) a germline PV/LPV was identified in the following genes: *SDHB* (5/9), *SDHA* (1/9), *SDHAF2* (1/

9), *SDHD* (1/9), and 1 *VHL* (1/9). Among these cases, 5 presented with single (n = 2) or multiple (n = 3) PGLs, 1 with PCC, while 2 had a diagnosis of early onset renal cancer. One patient was referred for a single cervical PGL identified during baseline assessment for a gastric GIST. Median age at diagnosis was 34 years (range, 12–53). Immunohistochemical data were available for 7/9 tumoral tissues: all of them showed a loss of SDH expression.

Conclusion: Around 30% of patients with a suspicion of PGL/PCC hereditary syndrome harbor germline PV/LPV in SDHx genes, with the highest proportion in *SDHB*. These results highlight the importance of germline evaluation for all patients with features of hereditary PGL/PPC syndrome.

P01.120.D Clinical and molecular spectrum of DDX41 variants in Korean patients with hematologic malignancies

Boram Kim

Samsung Medical Center, Seoul, Korea, Republic of.

Background: Hereditary hematologic malignancy is characterized by an increased risk for hematologic malignancies due to germline variants in cancer predisposition genes. Among them, germline *DDX41* variants are the most frequent especially in adults and found in 1.5% of myeloid neoplasms. In this study, we investigated the frequency and significance of *DDX41* variants in Korean patients.

Material and methods: We retrospectively reviewed 713 patients who were suspected as hematologic malignancies and underwent targeted sequencing of 50 genes in our institution from August 2020 to July 2023. Among them, we analyzed the clinical characteristics of patients with *DDX41* variants.

Results: Of 713 patients, 29 patients had germline and/or somatic *DDX41* variants and a total of 22 variants were identified. Fifteen variants were presumable germline variants, and 11 patients (1.5%) were diagnosed as hematologic neoplasms with germline *DDX41* variant presenting as 6 MDS (6/90, 6.7%), 4 AML (4/165, 2.4%), and 1 MPN (1/148, 0.7%). The median age of hematologic neoplasms with germline *DDX41* variant was 69 with male predominance (8:3). *DDX41* Y259C variant was the most common germline variant (63.6%) and the R525H variant was the most common somatic variant (24.1%).

Conclusion: Our study demonstrated the clinicopathological characteristics of *DDX41* variants in Korean patients with hematologic malignancies. Our findings highlight the importance of assessment of *DDX41* variants in hematologic malignancies.

P01.122.B Longitudinal DNA-methylation profiling of CLL patients with simple and complex karyotypes

Thorben Frederik Scholz[1,2], *Alicja Pacholewska*[1,2], *Christina Grimm*[1,2], *Elena Wasserburger*[1,2], *Marcel Kaluza*[1,3], *Nima Abedpour*[1,3], *Michael Hallek*[1,4], *Paula Cramer*[1,4], *Barbara Franziska Eichhorst*[1,4], *Michal Ruth Schweiger*[1,2,5]

[1]*University Hospital Cologne, Cologne, Germany,* [2]*Institut for Translational Epigenetics, Cologne, Germany,* [3]*Department of Translational Genomics, Cologne, Germany,* [4]*Department of Internal Medicine, Cologne, Germany,* [5]*West German Genome Center, Cologne, Germany.*

Background: Chronic lymphocytic leukemia (CLL) is characterized by theaccumulation of malignant B cells with clinically heterogeneous outcomes.Aberrant global DNA hypomethylation and promotor specific hypermethylation attumor suppressor genes are a common feature during tumor progression. DNAmethylation signatures also distinguish CLL into subtypes with distinctprognostic outcomes. CLL patients with complex karyotypes show an overall poorprognosis but the underlying mechanism remains unclear. The aim of this studyis to compare CLL patients with normal and complex karyotypes and to gaininsight into the role of DNA methylation in tumor progression mechanisms and touncover potential new treatment options.

Materials and methods: We analyzed DNA methylation profiles from 15 patients withTp53 WT and either normal or complex karyotypes at diagnosis and relapse. DNAmethylation profiles were obtained by targeted enriched bisulfite sequencingusing an 84 MB bait library targeting CpG islands and promoter regions.Methylation profiles were called using bismark 0.24.2 using the latest hs1genome as the reference.

Results: Initial data revealed differences in global DNA methylationprofiles between baseline CLL and relapse, with only few regionshypermethylated and most regions hypomethylated upon relapse. Comparison between a favorable andunfavorable karyotype will be presented upon the conference.

Conclusion: The methylation profiles between basic and relapsed CLLreveal only few differences, which might be attenuated by the complexity of thepatient's karyotype. Further studies will show the interconnection between DNAmethylation alterations and disease progression.

P01.123.C Genetic landscape of Lynch syndrome:insights from a Turkish cohort

Alper Baysal, *Zeki Sakalli, Haluk Akin, Asli Ece Solmaz*

Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey.

Background: Lynch syndrome (LS) is an autosomal dominant genetic condition associated with a significantly increased risk of colorectal, endometrial, and various other cancers. The syndrome arises due to mutations in DNA mismatch repair (MMR) genes, most commonly MLH1, MSH2, MSH6, EPCAM and PMS2. These mutations lead to microsatellite instability, which promotes tumor formation. Lynch syndrome accounts for approximately 3–5% of colorectal cancers, making it one of the most common hereditary cancer syndromes.

Material and methods: A total of 131 patients who were referred to the Department of Medical Genetics at Ege University Hospital between 2018 and 2024 and were found to have variants in Lynch syndrome-associated genes in a cancer panel were analyzed.

Results: Among the 131 patients analyzed, *MLH1* variants were detected in 49 patients, *MSH2* in 25, *MSH6* in 34, and *PMS2* in 26. *MLH1*, *MSH2*, and *PMS2* variants were most commonly found in colorectal cancer patients (20, 11, 7 cases, respectively), while *MSH6* variants were most frequent in breast cancer patients(16 cases). A total of 15 variants were classified as pathogenic, and 10 as likely pathogenic. Copy number variations (CNVs) were detected in 19 patients, including 10 deletions and 9 duplications.

Conclusion: These findings highlight the role of *MLH1, MSH2, MSH6*, and *PMS2* variants in cancer susceptibility and underscore

the importance of genetic analysis in identifying individuals at risk. Additionally, this study contributes to the literature by shedding light on Lynch syndrome-associated genetic variants in the Turkish population.

P01.124.D Transcriptomic profiling of cancer-associated fibroblasts: identifying key biomarkers and therapeutic targets for targeted therapy

A. Abikar[1,2], *M. Mustafa*[1], *R. Athalye*[1], *N. Nadig*[1], *N. Tamboli*[3], *V. Babu*[3], *K. Ramaiah*[1], *P. Ranganathan*[1,4];

[1]*Centre for Human Genetics, Bengaluru India, Bengaluru, India,* [2]*Manipal Academy of Higher Education, Manipal, Manipal, India,* [3]*Institute of Nephro-Urology, Bengaluru, Bengaluru, India,* [4]*Manipal Academy of Higher Education, Manipal, Bangalore, India*

Background: The characteristics of a tumor are largely determined by its interaction with the surrounding micro-environment (TME). TME consists of both cellular and non-cellular components. Cancer-associated fibroblasts (CAFs) are a major component of the TME. They are a source of many secreted factors that influence the survival and progression of tumors as well as their response to drugs. Identification of markers either overexpressed in CAFs or unique to CAFs would pave the way for novel therapeutic strategies that in combination with conventional chemotherapy are likely to have better patient outcome.

Material and methods: Fibroblasts have been derived from Benign Prostatic Hyperplasia (BPH) and prostate cancer. RNA from these has been used to perform a transcriptome analysis in order to get a comparative profile of normal and cancer-associated fibroblasts.

Results: The study has identified 818 differentially expressed mRNAs and 17 lincRNAs between normal and cancer-associated fibroblasts. Also, 15 potential lincRNA-miRNA-mRNA combinations have been identified which may be potential biomarkers.

Conclusion: This study identified differentially expressed markers between normal and cancer-associated fibroblasts that would help in targeted therapy against CAFs/derived factors, in combination with conventional therapy. However, this would in future need more experimental validation

P01.126.B BRCA1/2 population genetic screening: challenges and benefits

Zanda Daneberga[1], *Arvids Irmejs*[1], *Anneta Klujeva*[1], *Nora Krike*[1], *Elza Elizabete Liepina*[1], *Kristine Viksne*[1], *Rolands Ciematnieks*[1], *Urzula Lakuca*[1], *Kristine Kiploka*[1], *Hildegunn Hoberg-Vetti*[2], *Cathrine Bjorvatn*[3], *Ilva Kononova*[4], *Emil Syundyukov*[4], *Ieva Danovska*[4], *Agate Kalcenaua*[4], *Martins Mednis*[4], *Eva Pildegovica*[4], *Ilze Lindenberga*[5], *Edvins Miklasevics*[6], *Janis Gardovskis*[7]

[1]*Riga Stradins University, Institute of Oncology and Molecular Genetics, Riga, Latvia,* [2]*Haukeland University Hospital, Bergen, Norway,* [3]*Western Norway Familial Cancer Center, Haukeland University HospitalDepartment of Public Health and Pr, Bergen, Norway,* [4]*Longenesis Ltd, Riga, Latvia,* [5]*E. Gulbis Laboratory, Riga, Latvia,* [6]*Riga Stradins University, Department of Biology and Microbiology, Riga, Latvia,* [7]*Riga Stradins University, Department of Surgery, Riga, Latvia.*

Background: Approximately 80% of BRCA1/2 positive breast and ovarian cancers are diagnosed at stages II-IV. Despite modern treatments, morbidity, mortality, and associated costs remain significant. Early identification of BRCA1/2 carriers is critical to improving outcomes for individuals at risk of HBOC. This pilot study evaluates the feasibility of implementing a BRCA1/2 population screening program in Latvia.

Material and methods: This pilot study was conducted using the digital engagement and consent management tool "Longenesis Engage". The invitations were sent by e-mail. Eligible participants (age 25–59, without personal cancer history) who provided informed consent were included in the pilot. Saliva samples were collected and tested for BRCA1/2 SNV and CNV. Negative results were communicated digitally, while individuals with pathogenic variants were contacted personally, referred to medical geneticists, and enrolled in the surveillance program.

Results: In total, 3,438 invitation emails were sent. Of these, 49% were open, and 54% of recipients who opened the email visited the digital platform for project details. Among platform visitors, 79% provided informed consent, primarily via digital signature. Saliva samples were collected by 67% (490), yielding an overall response rate of 14.26% for this initial phase. Additionally, three gynecological practices directly invited women to participate, with a positive response from 49 women. Among the 539 analyzed cases, BRCA1/2 pathogenic variants were detected in 8, resulting in a detection rate of 1.49%.

Conclusion: The study demonstrates that BRCA1/2 population screening via digital communication channels is feasible. Findings confirm a high BRCA1/2 pathogenic variants frequency in Latvia, although screening methodology requires further refinement.

P01.127.C Molecular variant detection in non-small cell lung cancer- internal validation and external quality control

Urszula Lechowicz[1], *Magdalena Pelc*[1], *Adam Szpechcinski*[1], *Joanna Moes-Sosnowska*[1], *Paulina Skronska*[1], *Adriana Rozy*[1], *Aneta Zdral*[1], *Mateusz Polaczek*[2], *Emil Wojda*[2], *Malgorzata Szolkowska*[3], *Renata Langfort*[3], *Joanna Chorostowska-Wynimko*[1]

[1]*The Institute of Tuberculosis and Lung Diseases, Department of Genetics and Clinical Immunology, Warsaw, Poland,* [2]*The Institute of Tuberculosis and Lung Diseases, III Department of Lung Diseases and Oncology, Warsaw, Poland,* [3]*The Institute of Tuberculosis and Lung Diseases, Department of Pathology, Warsaw, Poland.*

Background: To optimize treatment for non-small cell lung cancer (NSCLC), accurate molecular characterization of tumors is essential. We validated an RNA-based NGS assay for detecting clinically significant genetic variants in NSCLC tissue samples.

Material and methods: To validate the Archer Fusion Plex Lung (AFPL) assay, 1190 NSCLC specimens were analyzed from 2023–2024. AFPL results were verified using conventional IVD tests like qPCR, FISH, and a DNA-based NGS assay. A minimum of 0.5 million reads per sample and an Internal Sample Quality Control index ≥10 were required. Seraseq FFPE Tumor Fusion RNA Reference Material was used for fusion detection control. The laboratory participated in the EMQN external quality control program (Lung Cancer: Common Biomarkers, New and Emerging Biomarkers; Oncogene Panel; and Fusions) to assess performance.

Results: Valid molecular results were obtained for 1024 (86.1%) samples; 13.9% failed NGS or data analysis quality control. Actionable variants were detected in 581 (56.7%) of valid samples. RNA concentrations ≥10 ng and PreSeq Cp values <29 defined acceptable thresholds. Validation established allele frequency reporting thresholds of ≥4.9% (≥10 altered reads at ≥100x coverage) for SNVs and ≥10% fusion site reads (≥5 supporting reads from ≥3 origins) for fusions, showing strong concordance with FISH and qPCR. Median values for Total Fragments, RNA QC, and RNA fragment length were 1,255,393; 206, and 124, respectively. All completed EMQN schemes yielded satisfactory results; the Fusion scheme is under evaluation.

Conclusion: RNA-based NGS provides a robust diagnostic solution for precise identification of therapeutically relevant variants across multiple genes in NSCLC. **Grants**:IGICHP_3.3/22

P01.128.D Prevalence of *RNF43* variants in patients undergoing genetic testing for polyposis-associated genes

Gardenia Vargas-Parra[1,2,3], *Jesús del Valle Domínguez*[1,2,3], *M. Lidia Feliubadaló Elorza*[1,2,3], *Olga Campos Mata*[1], *Nuria Dueñas Cid*[1,2,3], *Silvia Iglesias Casals*[1], *Marta Pineda Riu*[1,2,3], *Laura Valle Velasco*[4,2,3], *Conxi Lázaro García*[1,2,3]

[1]*Hereditary Cancer Program, Catalan Institute of Oncology, L'Hospitalet de Llobregat, Barcelona, Spain,* [2]*Program in Molecular Mechanisms and Experimental Therapy in Oncology (Oncobell), L'Hospitalet de Llobregat, Barcelona, Spain,* [3]*Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Madrid, Spain,* [4]*Institut d'Investigació Biomèdica de Bellvitge (IDIBELL), L'Hospitalet de Llobregat, Barcelona, Spain.*

Background: Germline pathogenic variants in *RNF43*, a negative regulator of the Wnt signaling pathway, are associated with predisposition to serrated polyposis syndrome and colorectal cancer. This gene has been recently incorporated into the diagnostic routine of patients with suspected familial polyposis. In this study, we analyzed the prevalence and distribution of *RNF43* variants in patients with a suspicion of genetic predisposition to polyposis over the past four years, and we explored the occurrence of *RNF43* variants in individuals with other hereditary cancer suspicions.

Material and methods: The *RNF43* gene was retrospectively analyzed in 6278 patients who underwent genetic testing based on personal or family history suggestive of hereditary cancer. Patients were grouped based on the primary phenotype-related genes requested for analysis: group A comprised patients with clinical indication of gastrointestinal polyposis and/or related cancer and group B the rest of individuals with hereditary cancer suspicion.

Results: No clinically actionable variants in *RNF43* were found in either group. *RNF43* VUS were identified in 1.33% (17/1282) of patients in group A. In group B, 0,58% (29/4996) of patients also carried *RNF43* VUS.

Conclusion: Although *RNF43* variants were more frequent in group A, their overall prevalence remains low and no clear association with polyposis was observed. Analysis considering the presence of different histologic polyp subtypes and functional evaluation of the identified VUS is required to obtain stronger evidence on the utility of the inclusion of *RNF43* in routine genetic testing.

P01.129.A Mutational and expression profiling of *TERT* and *CTNNB1* in hepatocellular carcinoma, cirrhotic, and non-cirrhotic liver tissues from Brazilian patients

Thaís Barbosa Sant'Anna[1], *Mariana Leonardo Terra*[1], *Leonardo Alexandre Souza Ruivo*[1], *Antonio Hugo M. Campos*[2,3], *Vera Pannain*[4], *José Junior Barros*[1], *Otacilio Cruz Moreira*[1], *Natalia Motta Araujo*[1]

[1]*Laboratory of Molecular Virology and Parasitology, Oswaldo Cruz Foundation - FIOCRUZ, Rio de Janeiro, Brazil,* [2]*Department of Anatomic Pathology, A.C.Camargo Cancer Center, São Paulo, Brazil,* [3]*Division of Pathology, Rede D'Or São Luiz, São Paulo, Brazil,* [4]*Clementino Fraga Filho University Hospital, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Hepatocellular carcinoma (HCC) is a major global health challenge with poor prognosis in advanced stages. It frequently develops in cirrhotic livers due to specific risk factors and involves genetic mutations. *TERT* and *CTNNB1* somatic mutations are prevalent in HCC but remain underexplored in Brazilian patients. This study investigates the association of *TERT* promoter mutations (-146C>T, -124C>T) and *CTNNB1* exon 3 mutations with HCC in Brazil.

Material and methods: Mutation analysis was performed on 85 liver tissue samples, including 26 tumor/surrounding tissue pairs and 33 unpaired samples (16 HCC, 9 cirrhotic, and 8 non-cirrhotic). DNA from cryopreserved or formalin-fixed tissues was analyzed by Sanger sequencing, and RNA from cryopreserved tissues was used for *TERT* expression analysis via RT-qPCR.

Results: The -146C>T mutation was rare in HCC (2.4%) and absent in cirrhotic and non-cirrhotic tissues. The -124C>T mutation was more frequent in HCC (45.2%) and cirrhotic tissues (19%) than non-cirrhotic tissues (0%), showing significant differences (HCC vs. non-cirrhotic, $P < 0.0001$; cirrhotic vs. non-cirrhotic, $P = 0.0485$). In paired samples, -124C>T was exclusive to HCC in 46.2% of cases. *CTNNB1* mutations were more common in HCC (17,24%) than cirrhotic (5,5%) and non-cirrhotic tissues (0%) and correlated with -124C>T ($P = 0.04$). Multivariate analysis identified -124C>T as a strong HCC predictor (HR = 10.23, 95% CI 2.18–48.1, $P = 0.003$). *TERT* expression was significantly higher in tumoral tissues ($P < 0.0001$) but not linked to promoter mutations.

Conclusion: *TERT* promoter -124C>T and *CTNNB1* mutations are promising biomarkers for HCC in Brazilian patients, aiding early detection, risk assessment, and potential therapeutic development.

P01.130.B Investigation of early onset breast cancer in West Africa

Alexander Ross[1,2,3], *Mohammed E. Charfi*[4,5], *Moussa Moise Diagne*[3], *Ahmadou Dem*[6,3], *Joseph Fitchett*[3], *Amadou A. Sall*[3]

[1]*Institute of Developmental Sciences, Southampton, United Kingdom,* [2]*Wessex Clinical Genetics Service, Southampton, United Kingdom,* [3]*Institut Pasteur De Dakar, Dakar, Senegal,* [4]*Hôpital Dalal Jamm, Dakar, Senegal,* [5]*Insitut Pasteur de Dakar, Dakar, Senegal,* [6]*Université Cheikh Anta Diop de Dakar, Dakar, Senegal.*

Background: Early-onset breast cancer (EOBC) is a global public health concern, with a disproportionate burden in sub-Saharan Africa. Women in this region often face late-stage diagnosis and poor survival rates, with mortality reaching 80%. The genetic contributions to EOBC in African populations are understudied, limiting opportunities for early detection and personalized care.

Materials and methods: This pilot study uses whole genome sequencing (WGS) to investigate the genetic basis of EOBC in 100 Senegalese women diagnosed at ≤30 years. Phase 1 focuses on identifying pathogenic variants in known predisposition genes (BRCA1/2, ATM, PALB2, CHEK2, RAD51C, RAD51D). Phase 2 explores novel genetic risk factors potentially unique to African populations. The study integrates capacity-building efforts, including training in genomic data analysis, sample processing, and cascade testing.

Results: The cohort includes 100 women aged 15–30 years at diagnosis. Preliminary findings reveal that 50% of cancers are triple-negative (ER/PR/HER2-). Key data on stage, treatment modality, BMI, parity, menarche, family history, medication exposure, and contraceptive use are being analyzed. Initial results identify pathogenic variants in predisposition genes and suggest potential novel variants unique to the cohort. Stakeholder engagement has begun to enhance awareness of genetic testing and personalized oncology practices.

Conclusion: This study aims to advance understanding of EOBC's genetic basis in Senegalese women and establish a genomic medicine framework. The findings will inform strategies to improve early detection, guide treatments, and reduce disparities in breast cancer outcomes across Africa.

P01.131.C Detection and characterization of BCR-ABL1 transcripts in acute and chronic leukemia: the value of molecular diagnosis and multiplex approach

M. JALTE;

faculty of sciences Dhar el Mehraz & genetics unit, central laboratory of medical analysis, CHU Hassan II, Fez, Morocco

Background: Acute and chronic leukemias are hematological malignancies associated with the translocation t(9;22)(q34;q11), which is responsible for the formation of the BCR-ABL1 fusion transcript. In chronic myeloid leukemia (CML), the majority of transcripts are e13a2 and e14a2, while in acute lymphoblastic leukemia (ALL), the predominant forms are e1a2 and, on occasion, rare variants. Precise identification of the BCR-ABL1 transcript is imperative for diagnosis, therapeutic follow-up and adaptation of treatment with tyrosine kinase inhibitors (TKIs).

Material and methods: A study was conducted on a series of 127 patients with CML and AL at the Medical Genetics and Molecular Biology Laboratory of Hassan II University Hospital in Fez. The diagnostic workflow included the following techniques: Karyotype, Fluorescence in situ hybridization (FISH), Standard RT-PCR and the Multiplex RT-PCR.

Results: the majority of CML patients exhibited the typical e13a2 and e14a2 transcripts, while the majority of ALL cases expressed e1a2. However, multiplex RT-PCR allowed the detection of rare BCR-ABL1 transcript variants that were not identified by standard RT-PCR like the transcripts e19a3 and e8a2. The principal advantage of multiplex RT-PCR lies in its capacity to detect multiple transcript variants simultaneously, thus reducing the incidence of diagnostic errors that could lead to misclassification of patients and delays in the administration of appropriate treatment.

Conclusion: This study underscores the significance of multiplex RT-PCR in the diagnosis of acute and chronic leukemias associated with BCR-ABL1. By enhancing the detection of rare transcripts and reducing false-negative results, this approach improves diagnostic accuracy and contributes to enhanced patient management.

P01.132.D MINAS involving *BRCA1*: description of two patients and considerations for genetic counseling and risk assessment

Francesco Marco Parodo[1,2], *Giovanna Traficante*[1], *Chiara Sciarretta*[3,2], *Barbara Lucherini*[1], *Marco Di Nicola*[4], *Carla Fonte*[4], *Marco Montini*[2,5], *Diletta Sidoti*[5,2], *Laura Papi*[2,5], *Angela Peron*[2,1]

[1]*Division of Medical Genetics, Neuroscience and Medical Genetics Department,Meyer Children's Hospital IRCCS, Florence, Italy,* [2]*Department of Clinical and Experimental Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy,* [3]*Division of Medical Genetics, Neuroscience and Medical Genetics Department, Meyer Children's Hospital IRCCS, Florence, Italy,* [4]*Neuro-Oncology Unit, Meyer Children's Hospital IRCCS, Florence, Italy, Florence, Italy,* [5]*Medical Genetics Unit, Maternal and Child Health Department, Careggi University Hospital, Florence, Italy.*

Background: Multilocus Inherited Neoplasia Allele Syndromes (MINAS) are an emerging concept in oncogenetics, referring to individuals carrying multiple pathogenic variants in cancer susceptibility genes (CSGs). With the rise of NGS, these patients are increasingly identified, but the impact on risk assessment remains poorly understood.

Material and methods: NGS panel analysis of CSGs was performed in two unrelated patients. MLPA was used for confirmation of an identified *MSH2* deletion.

Results: The first patient, a 46-year-old woman with breast cancer, was found to carry a pathogenic *BRCA1* variant (c.3285del,p.(Lys1095AsnfsTer14)) and a pathogenic *MSH2* variant c.(428_576)_(577_864)del, inherited from her father and mother, respectively. Family history revealed breast cancer and melanoma on the paternal side and Lynch syndrome-associated tumors on the maternal side. The second patient had two primary brain tumors (pilocytic astrocytoma at age 2 years, pleomorphic xanthoastrocytoma at age 18 years) and a family history of thyroid cancer (father), ovarian cancer (mother, deceased at 52), and ovarian, breast, and spleen cancer (maternal grandmother). Genetic testing identified a pathogenic *BRCA1* variant (c.5266dup,p.(Gln1756ProfsTer74)) and a likely pathogenic *CHEK2* variant (c.470T>C,p.(Ile157Thr)) associated with low penetrance.

Conclusion: These cases expand the knowledge on *BRCA1*-related MINAS, emphasizing the need for better risk assessment in carriers of multiple CSG variants, within this rare context. The *BRCA1-CHEK2* combination is very uncommon and may contribute to a broader tumor spectrum, despite neither gene being linked to increased brain tumor risk. Further investigation is needed to clarify potential modifying factors influencing tumor development in similar cases.

P01.133.A The effect of miR30c-2-3p on METTL14 and its role in migration inhibition in breast cancer

Zeliha Emrence[1], *Seyma Punar*[1], *Vahideh Zarerajabi*[1], *Sena Uslu*[2], *Neslihan Abaci*[1], *Sema Sirma Ekmekci*[1]

[1]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey, [2]Istanbul University, Istanbul Medical Faculty, Istanbul, Turkey.

Background: High expression of miR30c-2-3p is linked to good prognosis in breast cancer (BC). Analysis using the GEPIA2 database revealed increased METTL14(methyltransferases) expression in BC compared to healthy tissues. Considering the regulatory effects of miRNAs on m6A modifications, this study aimed to investigate miR30c-2-3p's role in regulating m6A modifications, its impact on migration, and its relationship with BC.

Material and methods: MCF12A (healthy) and MCF7 (BC) cells were transfected with miR30c-2-3p mimics. miR30c-2-3p and METTL14 RNA levels were measured by RT-PCR, while protein levels were assessed via western blot (WB). Migration was evaluated using scratch assays, and m6A levels were determined through a colorimetric method.

Results: Transfection with miRNA mimics significantly increased miR30c-2-3p expression in MCF7 and MCF12A cells ($p < 0.01$). In MCF7 cells, METTL14 expression decreased by 39.4%, 50.9% at the RNA level and 79%, 56.2% at the protein level after 24 and 48 hours, respectively ($p < 0.001$). m6A levels reduced by 28.9%, 46.2%, and migration decreased by 30%, 44%, respectively. In MCF12A cells, METTL14 expression decreased by 25.6%, 30.9% at the RNA level and 40.9%, 43.2% at the protein level at 24 and 48 hours, respectively ($p < 0.001$). m6A levels reduced by 83.7%, 63.9%, and migration inhibited by 66%, 72%, respectively.

Conclusion: miR30c-2-3p overexpression reduced METTL14 and m6A levels while inhibiting migration. Although migration results decreased in both cell lines, MCF7 demonstrated less migration compared to MCF12A, likely due to the activation of alternative pathways. These findings highlight miR30c-2-3p's role in BC biology and its potential as a therapeutic target.

P01.134.B Exploring the role of EMT genes and its regulatory microRNAs in prostate cancer risk susceptibility

Mohammad Kaleem Ahmad, *Gautam Prasad, Anveshika Manoj, Manoj Kumar, Abbas Ali Mahdi*

King George's Medical University, Lucknow, India.

Background: Epithelial-mesenchymal transition (EMT) is a crucial step in PCa invasion and metastasis. EMT is tightly regulated by multiple factors, including several miRNA. MiRNAs are essential for controlling the survival, growth, and metastasis of cells. The present study has been designed to investigate the expression and polymorphic analysis of EMT markers in PCa & CRPC and predict their targetome.

Material and methods: We have analyzed the gene expression by RT-PCR in PCa ($n = 50$), CRPC ($n = 50$), and control subjects ($n = 50$) serum and in PCa ($n = 50$) and control ($n = 50$) tissue sample. The polymorphism was investigated in serum sample by PCR-RFLP. The targetome of EMT genes was analyzed using bioinformatic tools. MiRNA profiling was carried out in both serum and tissue samples.

Results: Our results indicated significantly elevated expression of SNAIL, ZEB2, and VIM in PCa tissue and serum. Similarly, they were reported to be up regulated in CRPC serum. Moreover, a significant association was also established between VIM (rs11254434) C/T, SNAIL (rs1543442)A/C, and ZEB2 (rs13389578)T/C polymorphism with increased PCa risk. The targetome analysis reveals that EMT genes were regulated by miRNA 130b, 21, & 375 that involved in the PCa progression. The expression profiling of all miRNA were found to significantly upregulated in both serum and tissue samples.

Conclusion: Collectively these results revealed a direct link among EMT marker genes with miRNA 130b, 21, & 375 which were significantly linked to increased risk of PCa. Thus, EMT genes and its related miRNA can be exploited as a potential therapeutic target in PCa.

P01.135.C Consumer acceptability about extending the role of the victorian cancer registry into the germline genetic testing pathway

*Zoe Fehlberg[1], **Alison Trainer**[2], Maria Bechelli[3], Anu Abraham[3], Sue Evans[3], Stephanie Best[1]*

[1]University of Melbourne, Carlton, Australia, [2]Peter MacCallum Cancer centre, Parkville, Australia, [3]Cancer Council Victoria, Melbourne, Australia.

Background: In the era of precision public health, population-based cancer registries could become timely data sources to identify individuals who would benefit from germline genetic testing. To do so, may require registries to contact individuals. Assessing consumer acceptability of new service models is critical to successful implementation and delivering person-centred, value-based healthcare. We sought to examine consumer acceptability of extending the Victorian Cancer Registry into the germline genetic testing pathway.

Material and methods: Through the Victorian Cancer Registry, individuals recently diagnosed with a suspected pathogenic cancer or tumour were identified and invited to participate in a 1:1 or group interview. The interview schedule and inductive and deductive content analysis approaches were informed by the Theoretical Framework of Acceptability which covers seven constructs of acceptability: affective attitude, ethicality, perceived effectiveness, burden, intervention coherence, opportunity costs, & self-efficacy.

Results: Nine interviews with a total of 19 participants were conducted. Participants were supportive of extending the role of the registry, as utilising health data aligned with their personal values, and was perceived to effectively improve patient care. Data security, verification of the legitimacy of the registry, consideration for the timing of the contact, and suggestions for ways to reduce the emotional and mental burden on the consumer around the time of diagnosis, were discussed.

Conclusion: Optimising cancer registries to improve clinical genomics was acceptable to consumers, as it was timely, easy to understand and action, if legitimacy and data security were assured.

P01.136.D The genetic landscape of hereditary cancer syndromes in Romania: a 4 year perspective

Iulian-Andrei Hotinceanu[1,2,3], *Sebastian Ionut Toma[2], Viorica Radoi[3], Nikolaos Tsoulos[1], Angeliki Meintani[1], Eirini Papadopoulou[1], Dimitra Bouzarelou[1], Georgios Tsaousis[1], Andreea Truican[1], Diana Leonte[1], Amalia Chirnogea[1], Elena Moise[1], Irina Bucatariu[1], Lidia Munteanu[1], Alexandru Blidaru[1,3], Cornelia Nitipir[1,3], Daniela Zob[1,3], Dragos Median[1], Cristian Ervin Gal[1], Elena Gabriela Nagy[1], Vlad Manolescu[1], Andreea Mihaela Radu[1], Andrei Ungureanu[1], Milan Paul Kubelac[1], Bogdan Gafton[1], George Nasioulas[1]*

[1]Genekor Medical S.A, Bucharest, Romania, [2]Transilvania University of Brasov, Faculty of Medicine, Brasov, Romania, [3]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania.

Background: Germline pathogenic or likely pathogenic variants in well-established cancer predisposition genes contribute to hereditary cancer syndromes such as HBOC, Lynch, and Li-Fraumeni, posing a significant burden on patients and healthcare systems. The genetic landscape of hereditary cancers remains underexplored in the Romanian population.

Material and methods: Between 2020 and 2024, 1,359 Romanian patients underwent hereditary cancer genetic testing at Genekor S.A. using a 52-gene next-generation sequencing (NGS) panel. Clinical data included oncologic diagnosis, age at diagnosis, and family history. Variants of uncertain significance (VUS) were excluded from analysis.

Results: Among the tested patients, 319 (23.5%) carried pathogenic or likely pathogenic variants. Single-nucleotide polymorphisms (SNPs) were identified in 309 individuals, while 10 had copy number variations (CNVs). BRCA1 was the most frequently affected gene, followed by CHEK2 and BRCA2, together accounting for 49.1% of positive results. Lynch syndrome-related variants (MLH1, MSH2, MSH6, PMS2, and EPCAM deletions) were found in 11% of cases, while MUTYH variants were present in 6.9%

Conclusion: This study provides a comprehensive analysis of pathogenic variants associated with hereditary cancer syndromes in Romania. Findings are correlated with personal and familial cancer history, detailing the most frequent variants and variant types (missense, nonsense, frameshift) across different genes. These insights contribute to a broader understanding of hereditary cancers in Romania.

P01.137.A Germ-line pathogenic gene variants among pancreatic cancer patients

Zuzanna Frydrych, Malgorzata Lisik, Anna Fiszer-Kierzkowska, Magdalena Kalinowska-Herok, Magdalena Mazur, Aleksandra Pfeifer, Marta Cieslicka, Agnieszka Pawlaczek, Wieslaw Bal, ***Malgorzata Oczko-Wojciechowska***

Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch, Gliwice, Poland.

Background: Introduction: Pancreatic cancer is an aggressive tumor with a very high mortality rate. Genetic factors also contribute to an increased risk of pancreatic cancer. It is now considered that up to 20% of people diagnosed with pancreatic cancer have the disease linked to an inherited predisposition. Identifying germline variants makes it possible to assess the risk of an inherited form of the disease in the patient's relatives and qualify for molecularly targeted therapies. The study aimed to assess the frequency of BRCA1/2, PALB2, TP53 gene variants and mismatch repair (MMR) genes associated with Lynch syndrome in patients diagnosed with pancreatic cancer.

Methods and material: Between 2021 and 2024, 81 patients diagnosed with pancreatic adenocarcinoma received genetic testing at our genetic clinic, using Next Generation Sequencing using Illumina MiniSeq.

Results: Germline pathogenic variants were detected in 11% of patients, of which 7% of all detected variants were alterations in the BRCA1 and 2 genes. Other detected variants were in the TP53 gene (c.309C > G), MSH2 gene c.902_903del and MSH6 gene c.3226C > T.

Conclusions. The association with hereditary predisposition was demonstrated in more than 11% of pancreatic cancer patients. The study confirmed the most frequent occurrence of pathogenic variants in BRCA1/2 genes in patients with pancreatic cancer. In addition, it showed that pancreatic cancer may also be associated with variants specific for Lynch and Li Fraumeni syndrome. Therefore, genetic testing should be considered for any patient diagnosed with pancreatic cancer.

Background: *DDX41* Germline pathogenic or likely pathogenic variants (PV/LPV) are found in about 5–6% of patients with acute myeloid leukemia (AML), myelodysplastic syndromes (MDS) or idiopathic cytopenias. Unlike major germline cancer predispositions, diagnosis of hematologic malignancy for carriers is not made at an early age (median ranging from 65 to 69 years). As most reports on *DDX41* gene refer to case series of hematology patients, the risk of developing hematologic disorders in carriers is not precisely known. Thus, the attitude towards germline testing, and follow-up measures for related carriers, are not homogenous and further prospective data are needed to establish guidelines.

Material and methods: LUCID (LeUkemia in Carriers of germline *DDX41* mutation) is a French family-based multicentric cohort study designed to assess the cumulative risk of hematologic malignancies according to the age of *DDX41* PV/LPV carriers. Index cases (with clonal hematopoietic stem cell neoplasms and known or suspected to carry a *DDX41* PV/LPV) are recruited during genetics consultations (health questionnaire +/− saliva sampling). Their first, second and third degree relatives are then enlisted by

mail (questionnaire, saliva sample and CBC). A total of 910 participants are expected for a total study duration of 74 months.

Results: Here, we describe the first 14 months of the feasibility phase of the LUCID project, gathering the inclusion of more than 150 participants (≥30 families).

Conclusion: The inclusion protocol is up and running, and the LUCID study could therefore be extended by opening it up to collaboration with more investigation centers, including international centers.

P01.139.C Discovering shared gene mutations across different tumor types using Liquid biopsy

Dimitar Krasimirov Dimitrov, *Nelly Miteva-Marcheva, Hristo Ivanov, Antonia Vardeva, Aleksandar Linev, Vili Stoyanova*

Medical University Plovdiv, Department of Medical Genetics, Plovdiv, Bulgaria.

Background: Liquid biopsy is a minimally invasive approach for profiling tumor genetics through circulating tumor DNA (ctDNA). This study aimed to genotype diverse tumor types using a targeted gene panel, uncovering mutations across cancer types to evaluate their relevance in precision oncology.

Material and methods: The study enrolled 40 oncology patients: 19 with colorectal carcinoma (CRC), 12 with NSCLC, and 9 with breast cancer. ctDNA was extracted from plasma samples and subjected to targeted sequencing of 484 cancer-related genes. Bioinformatics analyses were performed to identify and interpret somatic mutations.

Results: Mutations in BRCA1 (c.1016del) were identified in 58.3% of NSCLC and 21.1% of CRC patients, as well as in breast cancer, where its role is well-documented. BRCA2 (c.9097dup) was detected in 50% of NSCLC and 47.4% of CRC cases. Mutations in GATA3 (c.404del), typically associated with breast cancer, were found in 16.7% of NSCLC and 15.8% of CRC cases. Notably, KMT2D (c.2533del), known for its role in epigenetic regulation, appeared in 26.3% of CRC, 50% of NSCLC, and 11.1% of breast cancers. PAX5 (c.963del), linked to hematologic malignancies, was unexpectedly prevalent across solid tumors (CRC: 73.7%; NSCLC: 83.3%; breast: 11.1%). Mutations in HNF1A (c.863_864insC and c.864del), commonly associated with liver cancer, were present in all three tumor types.

Conclusion: Cross-cancer mutations suggest that tumor classification may evolve from location-based to mutation-driven paradigms, enhancing precision oncology strategies.

P01.140.D Low diagnostic yield in gene panel testing of Finnish melanoma patients

Venla Ahola[1], *Minna Pöyhönen*[2,1], *Eveliina Jakkula*[2,1]

[1]*University of Helsinki, Helsinki, Finland,* [2]*Helsinki University Hospital, Department of Clinical Genetics, Helsinki, Finland.*

Background: Some melanomas are attributed to hereditary predisposition, with *CDKN2A* variants being the most significant. In other populations, diagnostic yield of gene panel testing has been 5–10%.

Material and methods: This study assessed the diagnostic yield of melanoma gene panel testing in 72 patients diagnosed with melanoma, having either multiple melanoma (≥3) and/or family members with melanoma and/or pancreatic cancer referred to Clinical Genetics Unit at the university hospital in Helsinki, Finland during 3/2019-11/2023. We also analyzed the prevalence of potentially pathogenic variants in *CDKN2A, CDK4, BAP1, POT1, ACD, TERF2IP, TERT, MITF*, and *MC1R* genes in Finnish and European ancestry group in gnomAD v4.1 database.

Results: Gene panel testing was outsourced to multiple laboratories with varying gene content. The most significant genes, *CDKN2A, CDK4, BAP1*, and *POT1* were included in all or almost all panels. The median age at the diagnosis of 1st melanoma was 58.5 years (range: 23–83). Only one patient (1.4%) was identified to have a pathogenic or likely pathogenic variant (*CDKN2A*). 14 (19.4%) patients had variants classified as variants of uncertain significance or risk alleles in other genes. Analysis of gnomAD data showed a lower frequency of pathogenic *CDKN2A* variants in the Finnish population (0%) compared to the broader non-Finnish European population (0.0545%).

Conclusion: These results suggest that clinically significant melanoma risk variants are rarer in the Finnish population compared to other European populations. The small sample size limits broader conclusions. Nonetheless, these findings support revisiting referral and testing criteria to consider inclusion of age at diagnosis.

P01.141.A Identifying the gaps in care for neurofibromatosis Type 1 patients in Singapore

Manasadevi Karthikeyan[1], *Lim Agnes Yeok-Loo*[1,2], *Chua Zi Yang*[1], *Loh Celestine*[1], *Priyadharshini Suresh*[1], *Jeanette Yuen*[1], *Zewen Zhang*[1], *Chiang Jianbang*[1], *Mark Jean Aan Koh*[1,3], *Nikki Wen Yan Fong*[3], *Ee Shien Tan*[4], *Joanne Ngeow*[1,5,6]

[1]*Cancer Genetics Service, Division of Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore,* [2]*Department of Dermatology, Singapore General Hospital, Singapore, Singapore,* [3]*Department of Dermatology, KK Women's and Children's Hospital, Singapore, Singapore,* [4]*Genetics Service, KK Women's and Children's Hospital, Singapore, Singapore,* [5]*Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore,* [6]*Oncology Academic Clinical Program, Duke-NUS Medical School, Singapore, Singapore.*

Background: Neurofibromatosis Type-1 (NF1) is an autosomal dominant inherited condition, affecting 1-in-3000 individuals globally, caused by pathogenic variants in the *NF1* gene. Patients face higher risks of malignancies like peripheral nerve sheath tumours, breast cancer, and non-malignant features like neurofibromas and café-au-lait spots. Psychosocial impact includes body image issues, low self-confidence, and pain and predominantly studied in Caucasian populations. Addressing NF1 care in a diverse cultural and economic landscape like Singapore is crucial to bridging care gaps.

Materials and methods: We conducted semi-structured interviews with clinically or genetically diagnosed NF1 patients and analysed data using thematic analysis with elements from grounded theory.

Results: 20 patients were interviewed, the mean age being 35.0 years and 40% females. Five themes emerged regarding patient experiences: 1) NF1 trajectory begins from childhood; 2) Coming to terms with body and self; 3) Expected acceptance drives disclosure patterns; 4) Need for specialized NF1 care; 5) Building local awareness and connections. Six areas of gaps identified: 1)

Optimized multidisciplinary NF1 care; 2) Management of neurological symptoms; 3) Management of cutaneous lesions; 4) Financial coverage for NF1; 5) Early NF1 screening; 6) Local awareness and support groups. Our study aligns with similar Asian findings but highlights unique cultural factors, including Traditional Chinese Medicine use, superstitions like past-life karma, and culture-specific influences on behaviour, emphasizing their importance in NF1 care.

Conclusion: There are significant gaps in care for patients with NF1 and understanding these can lead to actionable steps for improving multi-disciplinary care and enhance quality of life.

P01.142.B Application of MLPA method to FFPE samples with in-house developed probes

Daniil Ferdman, *Yulia Naumova, Natalia Isaeva, Roman Bikanov*

FIRST GENETICS' JOINT STOCK COMPANY, Moscow, Russian Federation.

Background: Alterations that affect wide genomic region often present in tumor cells but are difficult to detect by existing methods. Previous studies have shown the potential possibility of using MLPA for FFPE samples, however method has not been widely adopted. We tested the potency of using MLPA for FFPE in comparison with NGS/IHC.

Methods: 55 FFPE samples were collected for *ERBB2* amplification and *MET* exon 14 skipping detection. We used ExtractDNA FFPE kit and EK1-FAM SALSA Reagent Kit. 7 Self-developed probes consisting of DNA binding site, nonsense sequence, FAM-labeled primers site were used for hybridization. Capillary electrophoresis was perform via SeqStudio Genetic Analyzer, analysed with Coffalayzer.net software.

Results: All probes were successfully hybridized, ligated, and amplificated with FFPE DNA. All *HER2* amplification cases were matched with alternative methods results. We were faced with the problem of detecting *MET* exon 14 skipping and suggested possible causes and solutions.

Conclusion: FFPE material is fundamentally suitable for MLPA analysis and able to reliably detect *HER2* amplification. It is necessary to establish a cancer cellularity threshold for the possibility of using MLPA and introduce a correction factor. Our NGS data for *MET* ex14 skipping was based on cDNA analysis and for MLPA we used DNA, what could potentially lead to discrepancies between two methods. There is a problem of an unknown percentage of mutant cells among tumor cells. We plan to develop probes suitable for cDNA or selection into the site of alterations to make hybridization possible only in mutant cells in future studies.

P01.143.C Our first experience with the commercial MSK-Access panel for liquid biopsy

Martina Putzova, *Tomas Vanecek, Michal Michal*

Biopticka laborator, Plzen, Czech Republic.

Background: Circulating cell-free DNA of an oncology patient can be used to detect somatic tumor changes. The use of ctDNA as an analyte has its limitations, as the vast majority originate from hematopoietic cells, which exploits somatic mutations, leading to its detection in cfDNA at low concentration. The MSK-Access® panel is the first commercially available liquid biopsy (LB) panel, that uses parallel sequencing of cfDNA and reference material (white blood cells) from the same collection. This approach allows the detection of somatic non-tumor changes. Precise ctDNA testing overcomes limitations of profiling in cancer tissue and have a direct impact on patient care: allows monitoring of cancer response to therapy, reveals mechanisms of drug resistance, minimal residual disease and relapse in patients.

Material and methods: MSK-Access® test allows detection of all classes of somatic genetic alterations including SNVs, indels, CNVs and structural variants in cfDNA. The test is now powered by Sophia Genetics™, uses capture and deep sequencing in 147 key cancer-associated genes. In addition to control samples, we included to validation runs NSCLC patients with point mutations, fusions and CNVs and healthy controls.

Results and Conclusion: Previously detected mutations in these patients were mostly confirmed, but some variants (AF up to 7%) were evaluated as hematopoietic cell-derived mutations and therefore false positive. Parallel sequencing of WBC with cfDNA allows better insight into the current tumor situation in oncology patients and represents precise monitoring tool during their treatment.

M. Putzova: None. **T. Vanecek:** None. **M. Michal:** None.

P01.146.B *FH* germline testing following pathological evaluation of uterine leiomyomas with morphological features suggestive of FH deficiency: experience from a single centre

Aurélie Ayme, *Jean-Christophe Tille, Essia Saiji, Amandine Cadénes, Jean-Louis Blouin, Pierre Olivier Chappuis, Fulvia Brugnoletti*

Geneva University Hospitals, Geneva, Switzerland.

Background: Hereditary Leiomyomatosis and Renal Cell Cancer (HLRCC) syndrome is a rare entity caused by germline pathogenic variants in *FH* gene. HLRCC syndrome is characterized by multiple cutaneous and uterine leiomyomas and renal cancer. In some families, pheochromocytoma and paraganglioma have also been reported.

Pathologic evaluation of uterine leiomyoma can provide an opportunity for early detection of HLRCC syndrome. Patients with suspicious pathological features results need to be referred for oncogenetic evaluation and germline testing.

Material and methods: Between 09.2020 and 12.2024, all patients with uterine leiomyomas showing distinct morphologic features for FH-deficiency underwent immunohistochemical (IHC) analysis for FH and 2SC (2-succinocysteine) proteins. Patients with loss of FH expression and/or positive 2SC staining were referred for genetic counseling and germline analysis.

Results: A total of 110 patients showed uterine leiomyomas with histologic criteria for FH-deficient morphology and 22 (20%) exhibit loss of FH expression on IHC. Among these patients, 18 had genetic counselling: 16 patients agreed to perform germline testing, 2 refused to proceed. Genetic analysis of *FH* gene identified 3 pathogenic variants and one variant of unknown significance.

Conclusion: We observed a high rate of concordance between IHC and germline testing results among patients with uterine leiomyomas showing distinct morphologic features for FH-deficiency. Not all patients harbouring germline *FH* mutations

fulfilled criteria to recommend genetic testing. In these cases, a systematic morphologic assessment for features of FH deficiency had an essential role in the identification of HLRCC patients.

Background: It is estimated that around 10% of cancers occur through the inherited mutation in one of known cancer predisposition genes. Advances in NGS technologies have enabled a simultaneous analysis of multiple genes, resulting in increasing number of individuals diagnosed with two or more inherited genetic conditions. Among them, there are several reports of two different cancer predisposition syndromes (CPS) identified in single individuals.

Material and methods: We present the case of 19 y.o. woman with carcinoma of colon detected together with >100 polyps of large intestine. Family history was positive: her mother has had breast carcinoma and multiple polypectomy; maternal grandfather died due to colorectal carcinoma; her uncle has had colectomy due to colorectal polyposis. Based on clinical data, NGS-based Cancer panel (67 genes associated with CPS) was performed from peripheral blood in proband.

Results: The genetic analysis showed heterozygous pathogenic variants in two genes associated with CPS: c.3927_3932del (p.Glu1309Aspfs*4) in APC gene and deletion of exons 1–10 in FH gene. Target variant testing for other family members is currently ongoing.

Conclusion: Our results showed the co-occurrence of two CPS in the single individual: Familial adenomatous polyposis (FAP) and Hereditary leiomyomatosis and renal cell cancer (HLRCC). Although personal and family history was not suggestive for HLRCC, these data suggest possible benefit of multigene testing approach over target single genes analysis. All this could have important implications for improving genetic counseling, initiation of proper surveillance programs and early risk-reducing measures for all family members at risk.

P01.149.A Syndromes of predisposition to ovarian cancer in Brazilian women: insights from a case series study

Natalya Gonçalves Pereira

Hospital Sírio Libanês, Sao Paulo, Brazil.

Ovarian cancer is a major cause of mortality in gynecological cancers, largely due to late-stage diagnoses that result in low survival rates. While most cases are sporadic, 15–20% are associated with hereditary genes such as BRCA1 and BRCA2, which significantly increase the risk of cancer. Other DNA repair genes also contribute to ovarian cancer predisposition. The advent of next-generation sequencing (NGS) has facilitated broader genetic testing, enabling the identification of high-risk individuals and supporting personalized treatment approaches. This study conducted at Hospital Sírio-Libanês aims to describe genetic variants in ovarian cancer patients, emphasizing the importance of expanded genetic panels for effective disease management.

Material and methods: Data from the Hereditary Cancer Registry at Hospital Sírio-Libanês (2012–2024) was analyzed, focusing on multigene panel testing results. Among 86 ovarian cancer patients, 43 with pathogenic or likely pathogenic variants were selected. Most were from São Paulo (60.5%). Genetic testing included broad NGS panels and targeted panels for breast and ovarian cancer predisposition. Family histories were assessed using ProgenyÒ software, and data was securely stored on the REDCap platform, with ethical approval obtained.

Results: The cohort displayed various histological subtypes, predominantly high-grade serous carcinoma (79.0%). Most were diagnosed at advanced FIGO stages III and IV. P/LP variants were mainly found in *BRCA1* (40%) and *BRCA2* (33%), with others in *RAD51C, MUTYH, CHEK2*, and *TP53*. A significant 90% had a positive family history of cancer.

Conclusion: Comprehensive genetic screening using multigene panels is vital for identifying germline P/LP variants, crucial for managing ovarian cancer effectively.

P01.150.B Correction of the major epidemiogenetic risk factors lack of physical activity and daily fiber intake in a clinical genetic setting

Anatole Maloigne[1], *Anna Serova-Erard*[1], *Marie-Gabrielle Delorme-Guinand*[1], *Laury Nicolas*[1], *Noémie Demare*[2], *Simon Rey*[1], *Jacques-Olivier Bay*[1], *Johan Gagnière*[1], *Denis Pezet*[1], *Marine Jary*[1], *Morgane Helyon*[1], *Romane Muletier*[1], *Igor Tauveron*[1], *Sylvain Roumeau*[1], *Sandrine Mansard*[1], *Jacques Rouannet*[1], *Michel D'Incan*[1], *Julien Scanzi*[1], *Armand Abergel*[1], *Martine Duclos*[3], *François Cornélis*[1]

[1]*CHU Clermont-Ferrand, Clermont-Ferrand, France,* [2]*APHP, Paris, France,* [3]*CHU Observatoire National de l'Activité Physique et de la Sédentarité, Clermont-Ferrand, France.*

Introduction: Lack of physical activity (PA < 150 minutes/week) and of dietary fiber intake (DFI < 25 g/day) are major modifiable risk factors. Medical genetics offer the opportunity to correct those factors in outpatients' clinics. Our aim was to evaluate the impact of personalized advice following standardized evaluation of PA and DFI in such a setting.

Patients & methods: Genetics adult outpatients were systematically evaluated using the International Physical Activity Questionnaire-short form and an in-house questionnaire for DFI (duration: 5 minutes), starting in 2019 and 2021, respectively, up to 2024. « Severity » was defined as <75 minutes per week for PA and <15g/day for DFI. "Improvement" was defined as progression i.e. (severity to intermediate or correction). Personalized recommendation was given to individuals below the WHO (World Health Organization) target, who were to be re-evaluated at the following consultation.

Results: Evaluation of PA and DFI revealed 39,2% (n = 714) and 71.5% (n = 263) of individuals below the WHO target, respectively. Out of those, 90.7% and 86.6% were re-evaluated after a median of 268 days (range 92–1036 days): 46.1% and 33.8%, then met the WHO target, respectively. For the most « severe » subgroup, we observed improvement for 64.7% and 50.0% respectively. Subgroup analysis for onco-genetics, CCR risk, Lynch syndrome revealed no statistical difference.

Conclusion: Systematic personalised prevention in clinical genetics practice has a large impact on major modifiable risk

factors such as PA and, to a lesser extent, DFI, with asimilar magnitude in individuals at high or low CCR risk.

P01.151.C targeting cancer-cell mitochondria using tigecycline improves radiotherapy response in colorectal cancer cell line

s. hassanpour Khodaei;

Eastern Mediterranean University (EMU), Famagusta, Turkey

Background: Colorectal cancer (CRC) is the third most common cancer worldwide and causes more than 50,000 deaths in the United States each year. Due to the limited therapeutic options and poor prognosis in CRC, extensive research and development of novel therapeutic methods is essential. In this regard, the presence of cancer stem cells with unlimited division ability is the main reason for the therapeutic resistance in CRC. Tigecycline is a pharmacological mitochondria inhibitor and blocks mitochondria-related cell proliferation in cancer cells. This study investigated the effects of Tigecycline combined with radiotherapy on CRC cell apoptosis.

Material and methods: Human colorectal cancer cells (HCT-116) were treated with Tigecycline and cell viability was measured with MTT assay. In the next step, the cells were exposed to radiation using a Siemens Primus 6 MV linear accelerator at radiation doses of AA, 400 cGy, BB, and DD. Finally, we evaluated cancer cell apoptosis and apoptotic-related gene expression with Annexin V/PI and gene expression.

Results: The results showed that the IC50 value of Tigecycline is 93 µM in 48 hours. Apoptosis rate and pro-apoptotic expression genes enhanced after combination therapy. Taken together, these data indicate that Tigecycline enhanced the sensitivity of cancer cells to radiotherapy and induced cell apoptosis in CRC.

Conclusion: In summary, these findings could provide new insights into cancer therapy and might be used as a novel method to improve the current state of CRC therapy.

P01.152.D Expression of genes, connected to immunity and angiogenesis, in colorectal tumors and metastases, by Nanostring technology

Iliyan Pochileev*, Dragomira Nikolova, Svilen Maslyankov, Ivanka Dimova*

Medical University Sofia, Sofia, Bulgaria.

Background: The immune system plays a critical role in identifying and eliminating tumors. Dysregulation of the immune system is tightly connected to the development and spread of the cancer, together with the abnormal control of angiogenesis. During the metastatic process, cancer cells interact with the immune system and they influence each other, both in the tumor microenvironment and systemically. The objective of our study was to analyze the change in expression levels of genes, connected to immunity and angiogenesis, during the process of metastasis.

Material and methods: We used Nanostring technology for mRNA levels to compare the expression of 20 immunologic/angiogenesis genes in samples from colorectal cancer and their metastases.

Results: We detected >2 times increase of expression level in metastases compared to primary tumors for the following genes: *HIF1A*, encoding the alpha subunit of transcription factor hypoxia-inducible factor-1, the master transcriptional regulator of cellular and developmental response to hypoxia (4.8 times); *THBS1*, a potent inhibitor of T cell and dendritic cell activation (4.7); *KLF10*, involved in cell cycle regulation (2.7); *STAT6*, a signal transducer and activator of transcription (2.4); *AMD1*, encoding an important intermediate enzyme in polyamine biosynthesis (2.2); and *ITM2B*, an integral membrane protein (2.1).

Conclusion: NanoString technology allows complex profiling of mRNA expression in cancers and metastases to identify molecular mechanisms that govern metastasizing. By comparing mRNA expression in different stages of cancer, we can identify key molecules that can be used as prognostic markers for tumor vascularization and metastasis.

Acknowledgment: Grant BG-RRP-2.004-0004-C01.

P01.153.A The Prognostic Value of Liquid Biopsies for Benefit of Metastasis-targeted Radiotherapy in Relapsed Oligometastatic Prostate Cancer

Hoda Radmanesh*, Natalia Bogdanova, Dhanya Ramachandran, Anne Knoechelmann, Hans Christiansen, Thorsten Derlin, Christoph Klot, Roland Merten, Christoph Henkenberens*

Hannover Medical School, Hannover, Germany.

Background: Local PET/CT-guided ablative radiotherapy (RT) has been reported to improve progression-free and ADT-free survival in about 30% of patients with oligometastatic prostate cancer (OMPC) recurrence. However, no clear clinical or imaging parameters have been identified to date that allow for reliable prediction of the RT benefit. This study therefore aimed to evaluate the prognostic significance of blood-derived total RNA and circulating tumor cell (CTC)-associated mRNA for PSMA PET-guided salvage RT.

Material and Methods: A total of 44 patients were enrolled in the study between 2016 and 2020. Each patient was diagnosed with relapsed OMPC, as confirmed through PSMA- PET/CT imaging, and received RT at Radiation Oncology at Hannover Medical School. CTCs were positively enriched and RNA was extracted from liquid biopsies for real-time PCR analysis, along with miRNA sequencing for biomarker discovery.

Results: A total of 54 gene and miRNAs transcripts known to be linked to prostate cancer and treatment outcomes were selected for analysis. Significant correlations were identified between levels of these transcripts and various clinical factors, including the Gleason score, PSA levels, and UICC stage. Notably, transcript profiles of *MTCO2*, *FOXM1*, *SREBF1*, *HOXB7*, *FDXR*, and *MTRNR*, along with specific miRNAs, were associated with both temporary and long-term benefits from RT.

Conclusion: Our initial findings indicate that liquid biopsies have the potential to predict the benefits of PSMA-PET-guided salvage radiotherapy in relapsed OMPC. Further research with larger patient cohorts is required to validate these results and to establish liquid biopsy tests as a predictive tool for salvage RT.

P01.154.B Identification of the most prevalent mutations associated with metastatic non-small cell lung cancer in the Ukrainian population

Daryna Dekar[1], *Dmytro Shapochka*[2,1], *Dmytro Nehrulia*[3,1], *Nataliia Shtefan*[4], *Anna Fesenko*[1], *Anna Moskalenko*[1]

[1]*Medical Laboratory DILA, Kyiv, Ukraine,* [2]*Clinical Hospital Feofaniya, Kyiv, Ukraine,* [3]*The Institute of Molecular Biology and Genetics of NASU, Department of Protein Synthesis Enzymology, Laboratory of Innovative Biotechnology, Kyiv, Ukraine,* [4]*GeneCode Diagnostics laboratory, Kyiv, Ukraine.*

Background: Metastatic non-small-cell lung cancer (mNSCLC) has the highest mortality rates among cancer patients worldwide (approximately 18% of all cancer-related deaths as of 2022). In Ukraine these rates are 21.1% among men and 3.4% among women. Given the lack of data on the prevalence of driver genetic alterations in the Ukrainian population of mNSCLC patients, the aim was to investigate the frequencies of these clinically significant genetic changes.

Materials and methods: All studies were conducted using next-generation sequencing (NGS) on the Ion Torrent platform (Thermo Fisher Scientific, USA). Library preparation was performed using the CleanPlex OncoZoom Cancer Hotspot Kit and the AccuFusion RNA Lung Cancer Kit (Paragon Genomics, USA).

Results: Testing was performed on biopsy FFPE samples of 79 patients with mNSCLC. Actionable findings were identified in 37 samples, representing 46.8% of the total. Among these, the EML4 (6)-ALK (20) fusion was the most common, as some patients were ALK-positive according to IHC, and NGS was used to confirm the presence of ALK gene fusions in these samples. Other most frequently mutated genes were EGFR and KRAS (G12C variant), their proportion consistent with the global statistics. Mutations in HER2 (ERBB2) and BRAF genes, as well as fusions involving ROS1 and RET genes, were also identified.

Conclusions: The results are consistent with preliminary expectations. 46.8% of patients with mNSCLC have actionable findings, some of which can only be detected by NGS. This highlights the importance of expanding the use of this method in Ukraine.

P01.155.C A clinical audit to assess how a cancer genetic service further investigates the origin of a pathogenic/likely pathogenic *TP53* variant identified in multigene panel testing

Nina Vorster[1], *David Gallagher*[1], *Agnieszka Aziewicz*[1], *Emma O'Donoghue*[2], *Rosie O Shea*[1], *Claire Peyton*[3], *Niamh White*[1], *Karen Cadoo*[1]

[1]*St. James's Hospital, Dublin 8, Ireland,* [2]*Children's Health Ireland (CHI) at Crumlin, Dublin 12, Ireland,* [3]*Blackrock Health - Hermitage Clinic, Dublin 20, Ireland.*

Background: Germline *TP53* pathogenic/likely pathogenic (P/LP) variants are diagnostic of Li Fraumeni syndrome (LFS). LFS has high cancer risk requiring rigorous screening. Clonal hematopoiesis (CH) can result in *TP53* P/LP variants that are not germline in origin. It is clinically important to determine variant etiology.

Methods: A clinical database review identified individuals with diagnostic multigene panel testing (January 2021 - June 2024) and a P/LP *TP53* variant identified. Records were reviewed to assess underlying etiology.

Results: Eleven individuals with P/LP *TP53* variants were identified. See Table 1 for demographics and variant allele frequency (VAF). Table 2 summarizes outcome of investigations to determine etiology of *TP53* P/LP variant. All female patients with LFS had breast cancer. Only one patient (number 2) met Chompret criteria, while one patient with mosaic LFS (number 9) met modified Chompret criteria.

Conclusion: The etiology of a P/LP TP53 variant was resolved in all cases. Variants with VAF >40% were not further investigated, in keeping with recommendations. In our population 63,6% were heterozygous P/LP TP53, 18,2% mosaic and 18,2% CH. Individuals with germline P/LP TP53 variants often did not meet clinical LFS testing criteria.

Table 1:

Patient number	Sex assigned at birth	Cancer diagnoses at time of testing	Age of onset	OriginalSample	VAF (%)
1	Female	Papillary Thyroid	47	Saliva	46.7
		Breast	48		
2	Female	Breast	40	Saliva	53.4
3	Female	Thymoma	27	Blood	48.6
		Breast	39		
4	Male	Osteosarcoma	11	Saliva	47.5
5	Female	Bilateral breast	47	Saliva	49.0
6	Male	Colon	50	Saliva	52.0
		Leiomyosarcoma	54		
7	Female	Breast	42	Saliva	41.0
8	Female	Breast	42	Saliva	17.0
9	Female	Breast	27	Saliva	18.0
10	Female	Bilateral breast	48	Saliva	12.0
11	Female	Breast	43	Saliva	34.1

Table 2:

Patient number	Additional sample tested	Type of sample	TP53 variant detected	VAF (%)	Final diagnosis given
1	No	-	-	-	Germline LFS
2	No	-	-	-	Germline LFS
3	No	-	-	-	Germline LFS
4	No	-	-	-	Germline LFS
5	No	-	-	-	Germline LFS
6	No	-	-	-	Germline LFS
7	No	-	-	-	Germline LFS
8	Yes	Skin	Yes	10.0	Mosaic LFS
9	Yes	Hair	Yes	9.0	Mosaic LFS

P01.157.A The contribution of microarray analysis to diagnosis, risk classification, and treatment in leukemia patients

Mustafa Oguz Acar, *Sule Altiner, Hatice Ilgin Ruhi*

Ankara University Faculty of Medicine, Medical Genetics Department, Ankara, Turkey.

Background: Accurate genomic characterization is essential for leukemia classification, risk stratification, and treatment planning. However, karyotyping and FISH have limitations due to their low resolution or target specificity. We utilized SNP-array to enhance genomic characterization by identifying copy number variation (CNV) and copy-neutral loss of heterozygosity (CN-LOH). Our aim is to assess the feasibility of integrating SNP-array into routine clinical practice.

Material and methods: Archived DNA samples from 46 leukemia patients (20 ALL, 17 AML, 3 CLL, 6 other leukemia types) with inconclusive routine genetic test results were analyzed via SNP-array to identify CNV and CN-LOH.

Results: Clinically significant (tier 1 and tier 2) alterations were identified in 78.2% of cases. Diagnostic genetic markers were detected in 4 cases (8.7%), prognostic in 24 cases (52.2%), and therapeutic in 1 case (2.2%). In B-ALL cases, *IKZF1-plus* alterations (*IKZF1*, *CDKN2A*, *PAX5*), atypical iAMP21, *P2RY8::CRLF2* fusion, and *RB1* deletion were found. T-ALL cases showed *STIL::TAL1* fusion, *CDKN2A* deletion with 9p CN-LOH, and *PTEN* deletion with 10q CN-LOH. AML cases revealed *ERG* amplification, *NF1* deletion, 13q CN-LOH, 17p deletion, and chromoanagenesis-like complex changes. CLL cases showed varying sizes of 13q deletions and 2p gain. A JMML patient with a germline *CBL* mutation had two CN-LOHs with different clonality detected at 11q.

Conclusion: SNP-array enhances genetic characterization, particularly in ALL cases and AML cases with inconclusive genetic test results. However, clonal variations, low clonality amplifications, and balanced rearrangements remain undetectable. Therefore, SNP-array should be used alongside karyotyping and FISH for a comprehensive genomic profiling.

P01.158.B Cancer molecular profiling in Northern Bergamo patients: focus on the double alterations and microsatellite instability

Rea Valaperta[1], *Federica Gualandris*[1], *Marina Valeri*[1], *Silvia Freti*[1], *Ludovica Varisano*[1], *Alessandro Iaculli*[1], *Maria Grazia Sauta*[1], *Silvia Von Wunster*[1], *Andrea Crema*[1], *Michele Marini*[1], *Giuseppe Nastasi*[1], *Alice Melocchi*[2], *Alberto Cammarota*[2], *Caterina Matinato*[1], *Aurelio Sonzogni*[1]

[1]*ASST Bergamo EST, Seriate, Bergamo, Italy,* [2]*University of Milan, Milan, Italy.*

Background: Currently, the advent of precision oncology is rapidly revolutionizing both the diagnosis that the treatment of cancer through more oriented therapy. Here, we investigated the cancer molecular profiling in Northern Bergamo patients.

Material and methods: A cohort of 104 cancer patients have been the subject of this investigation.

Results: On the total individuals the 76.9% was mutated while the remaining 23.1% no mutation was identified. The number of mutations found were 82, of which the 96.3% were missense variants. The major variants identified were present in KRAS (25%), PIK3CA (11.5%) and BRAF (8.7%) genes. C.35G>T (42%) exon 2 in KRAS, c.1799T>A (44%) exon 15 in BRAF and c.263G>A (42%) exon 2 in PIK3CA genes were the three major alterations expressed. Geografic distribution investigation demonstarted that in the Upper-Valley the percentage of the mutated and the wild type samples identified were respectively of 68% and 32%. The most common type of tumor was represented by colorectal adenocarcinoma (43%) and the prevalent missense variant was represented by KRAS exon 2 c.35G>T mutation (56%). Instead, in the Lower-Valley was the melanoma (32%), with associated BRAF c.1799T>A gene mutation (50%). Finally, 63-year-old female cancer patient was selected as clinical case, reporting a double genetic alteration with associated MSI instability.

Conclusion: The knowledge of mutational spectra is very important to evaluate the most recurrent variants. The implementation of the genetic screening of different cancer populations in several areas can certainly lead benefits to the patient as an earlier diagnosis and reduction of treatment times.

P01.160.D Molecular profiling of non-small cell lung cancer in the brazilian population

Bruno da Silveira Corrêa.[1], *Anelise Baptista da Silva*[1], ***Claudia Paiva Nunes***[1], *Julia Crispim da Fontoura*[1], *Mariana Mazza Santos*[2], *Thais Assis*[2], *Maristela Ocampos, PhD*[2], *Cristina Beatriz Cazabuena Bonorino*[1]

[1]*Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil,* [2]*Mercolab Diagnósticos, Florianopolis, Brazil.*

Background: Lung cancer is the leading cause of cancer-related mortality worldwide, with 1.8 million deaths in 2022. Molecular biomarkers are crucial for clinical management in oncology. However, the mutational landscape of non-small cell lung cancer (NSCLC) in Brazil is poorly characterized. This study aims to profile NSCLC mutations in Brazil, correlate them with clinical data, and explore underlying mechanisms.

Material and methods: Samples from 182 NSCLC patients were collected at the Santa Casa de Misericórdia Hospital Complex in Porto Alegre, Brazil, and preserved in paraffin. DNA extraction was performed with Quick-DNA FFPE Miniprep kit (Zymo Research), library preparation with Library Preparation EF 2.0 kits (Twist Bioscience). Sequencing on the MiSeq platform (Illumina) used a custom panel targeting 29 clinically actionable genes. Additionally, sequencing is under way at MercoLab Diagnósticos using the Oncomine Comprehensive Assay Plus DNA panel (Thermo Fisher Scientific), with over 500 cancer-related genes. Data analysis is being carried by custom scripts to identify genetic alterations and correlate them with clinical data.

Results: Broad panel sequencing of seven patients identified mutations in cancer driver genes EGFR (2/7), KRAS (1/7), PIK3CA (1/7), and TP53 (2/7), along with pathogenic variants in ERBB2, RB1, PTEN, HRAS, RAD51B, RAD54L, PIK3CA, TERT, and MET. None had microsatellite instability, and one had an intermediate tumor mutational burden of 11.42 mut/Mb.

Conclusion: This study is among the first to comprehensively analyze the mutational profile of NSCLC in Brazil, including both common lung cancer-associated genes and other relevant molecular alterations.

P01.161.A Molecular genetics vs molecular cytogenetics in a B ALL diagnosis

Mirjam Lista[1], *Serena Albertazzi*[1], *Federica Estersini*[1], *Kokou E.A. Ayissou*[1], *Chiara Milanesi*[1], *Nicla Manes*[1], *Alessia Campagna*[2], *Rossella Caselli*[1]

[1]*Medical Genetic Laboratory, IRCCS Humanitas Research Hospital, Rozzano (MI), Italy,* [2]*Heamatology Unit, IRCCS Humanitas Research Hospital, Rozzano (MI), Italy.*

Acute B lymphoblastic leukemia is a hematological malignancy characterized by lymphoblasts uncontrolled proliferation. Advances in genomic profiling techniques have identified more specific genetic alterations and mutations driving B-ALL, leading to the development of novel therapies. In adults, common genetic alterations investigated include *KMT2A* rearrangements, *ETV6::-RUNX1, TCF3::PBX1, TCF3::HLF, BCR::ABL1* translocations [1,2].

We present the first adult case in our cohort, where a canonical *BCR::ABL1* rearrangement is identified only with genetic molecular analysis and not with FISH. FISH analysis was performed using a specific probe on uncultured material following direct nuclear extraction to search for gene targets.

FISH revealed only the presence of *HLF*, *BCR*, *PBX1*, and *KMT2A loci* in triple and quadruple copies, respectively excluding any rearrangements. These results indicated a signal pattern compatible with a ploidy alteration also investigated using oligo-SNPs array. However, for the purpose of a specific genetic characterization, the obtained information were not conclusive. Further molecular investigations, conducted via RT-PCR, were carried out to detect the BCR::ABL1 alteration, revealing the p190 canonical transcript. In contrast to all the cases we have seen, where FISH analysis yields the expected results this finding led us to hypothesize a cryptic rearrangement with probable chromothripsis.

We have not yet been able to identify the genetic-molecular cause that masked the presence of the gene fusion in the cytogenetic analysis: this is our future prospective. This case pinpoints the importance of combining cytogenetic and molecular genetic analyses in all B-ALL cases to identify all rearrangements and to ensure no alterations are missed.

P01.162.B The *BIRC5* connection: gene polymorphisms and survivin isoforms in oral and oropharyngeal squamous cell carcinoma

Ivan Mumlek[1], *Maja Sabol*[2], *Petar Ozretić*[2], *Ljubica Glavaš-Obrovac*[3], ***Vesna Musani***[2]

[1]*Bexorg, Inc., New Haven, CT, USA,* [2]*Rudjer Boskovic Institute, Division of Molecular Medicine, Zagreb, Croatia,* [3]*Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Department of Medicinal Chemistry, Biochemistry and Clinical Chemistry, Osijek, Croatia.*

Background: Oral and oropharyngeal squamous cell carcinoma are the most common head and neck cancers. The main risk factors are alcohol and tobacco use, as well as HPV infection. Most patients with early-stage cancer can be cured, but patients with advanced disease, which make two-thirds of new diagnoses still have the five-year survival rate of about 60%. Survivin, encoded by *BIRC5* gene, has been implicated in head and neck cancer development. The aim of this study was to investigate *BIRC5* polymorphisms and expression of different isoforms in head and neck cancer.

Material and methods: 48 patients (31 with oral and 17 with oropharyngeal squamous cell carcinoma) and 45 controls (patients who were treated for non-malignant diseases) were included in this study. Genomic DNA was isolated from blood, and RNA was isolated from tumors or healthy mucosa. The entire coding region of *BIRC5* gene, as well as promoter and 3'UTR regions were genotyped for polymorphisms using high resolution melting analysis and Sanger sequencing. The expression of eight different survivin isoforms were determined by qPCR.

Results: Seventeen *BIRC5* polymorphisms were found. Three were found only in patients and two only in controls. Eleven polymorphisms showed minor allele frequency (MAF) greater than 5%. All examined isoforms were detected in tumor samples, while two isoforms were not detected in healthy mucosa. All isoforms were statistically significantly more expressed in tumor tissue, with the most expressed isoforms being wild type, 2α and 2B.

Conclusion: *BIRC5* polymorphisms were associated with expression of only few isoforms.

P01.163.C Next-generation sequencing reveals multiple *ATM* gene variants in urothelial bladder cancer

Ugrinovski Dimitar[1,2], ***Slavica Josifovska***[1], *Kiril Pakovski*[1], *Saidi Skender*[3], *Panov Sasho*[1]

[1]*Laboratory for Molecular Biology, Faculty of Natural Sciences and Mathematics, Ss. Cyril and Methodius University in Skopje, Skopje, North Macedonia, The Republic of,* [2]*PathoNext GmbH, Leipzig, Germany,* [3]*Urology Clinic, Medical Faculty, SS. Cyril and Methodius University in Skopje, Skopje, North Macedonia, The Republic of.*

Background: Urothelial bladder cancer (UBC) is the most common urinary malignancy and the tenth most diagnosed cancer worldwide. Depending on the muscle infiltration, UBC can be classified as muscle-invasive bladder cancer (MIBC) and non-muscle invasive bladder cancer (NMIBC). Based on its heterogeneity, comprehensive genomic studies reveal significant molecular differences.

Material and methods: The study included 32 patients with bladder cancer, 13 with MIBC and 19 with NMIBC. Genomic DNA was extracted from fresh frozen tumor samples and sequenced by NextSeq (Illumina) using customized panel of 95 genes. Only the pathogenic, likely pathogenic and variants of unknown significance were evaluated.

Results: The most frequently affected genes, present in ≥12% of the samples are: *TP53* (44%), *FGFR3* (41%), *PIK3CA* (34%), *STAG2* (19%), *ATM* (16%), *ERBB2* (16%), *APC* (12%), *BRAF* (12%), *KRAS* (12%) and *TERT* promoter (12%). The result is in line with the previously proposed molecular stratification by mutations in *TP53/MDM2* pathway, *FGFR3*, and *RAS* genes. Interestingly, we observed *ATM* variants in five samples (26%) of the NIMBC, but none in the MIBC subgroup. In two samples we detected single variants (missense and frameshift deletion), while three samples had multiple variants in this gene. *ATM* plays a central role in cell division and DNA repair.

Conclusion: Precise pathological classification together with clarification of the molecular subtype, can significantly contribute to understanding the entity of a given tumor and, especially in early stage lead to improved individualized treatment in terms of the existing and novel therapies that would target certain molecular pathways.

P01.164.D A case report of two compound heterozygous *CHEK2* variants presenting with ovarian and breast cancer

Anna-Sophie Liegmann[1], *Bianca Greiten*[1], *Anna S. Mueller*[1], *Sophie Fitzgerald*[2], *Franziska Fick*[2], *Katharina Kaschner*[2], *Achim Rody*[2], *Yorck Hellenbroich*[1], *Malte Spielmann*[3], *Norbert Arnold*[4], *Maggie Banys-Paluchowski*[2]

[1]*Institute of Human Genetics, University Medical Center Schleswig-Holstein, University of Lübeck & Kiel University, Luebeck, Germany,* [2]*Department of Gynecology and Obstetrics, University Medical Center Schleswig-Holstein, University of Lübeck, Luebeck, Germany,* [3]*Institute of Human Genetics, University Medical Center Schleswig-Holstein, University of Lübeck & Kiel University, Luebeck and Kiel, Germany,* [4]*Oncology Laboratory Gynecology/Molecular Genetic Diagnostics, University Medical Center Schleswig-Holstein, University of Lübeck & Kiel University, Kiel, Germany.*

Background: Breast cancer remains the most prevalent cancer among women worldwide, with early diagnosis significantly improving prognosis. Genetic predisposition plays a crucial role in breast cancer risk. Mutations in *CHEK2* have been linked to a moderately increased risk of several types of cancer, particularly breast, prostate, and colorectal cancers, highlighting its role as a tumor suppressor. While monoallelic mutations in *CHEK2* and their relation to hereditary cancer syndromes are well-published, much less is known about biallelic mutations in *CHEK2* and their associated cancer risks remain under-explored.

Materials and methods: We present the case of a 66-year-old woman diagnosed with breast cancer (ER: 90%; PR: 0%) aged 62 and bilateral serous ovarian cancer at the age of 65 years. She received genetic counselling at the certified Center for Familial Breast and Ovarian Cancer at the University Medical Center Schleswig-Holstein Campus Luebeck and underwent genetic testing, revealing the following compound heterozygous variants in the *CHEK2* gene: c.(908+1_909-1)_(1095+1_1096-1)del (p.?) and c.1100delC; p.(Thr367Metfs*15). These variants were identified using next-generation sequencing, integrated CNV analysis, and Multiplex Ligation-dependent Probe Amplification. Moreover, long-range PCR and sanger-sequencing showed a *trans* configuration of the variants.

Results: The genetic profile of the patient suggests a possible increased cancer risk associated with biallelic *CHEK2* mutations, particularly in relation to breast and ovarian cancers.

Conclusion: The case highlights the importance of investigating biallelic *CHEK2* mutations in patients with multiple cancers. Further research is necessary to understand the implications of these mutations on cancer risk and clinical management.

Gral. del Rosario, 145, 38010, Santa Cruz de Tenerife, Spain.*

Background: The incidence of malignant melanoma (MM) continues to increase annually, and its prognosis rapidly worsens as the disease progresses. Single nucleotide polymorphisms (SNPs) have become key tools in the study of cancer genetics, influencing susceptibility and prognosis.

Material and methods: We analyzed the relationship between SNPs of the *PDCDL1* gene and the prognosis and tumor invasiveness of MM, considering clinicopathological characteristics in a total of 377 whole blood samples from MM cases.

Results: Patients with genotypes CG or GG at rs822336 (OR = 3.01, 95%CI = 1.53–5.92; p = 0.0017), TA or TT at rs822337 (OR = 2.45, 95%CI = 1.22–4.93; p = 0.0098) and CT or CC at rs822338 (OR = 2.23, 95%CI = 1.05–4.73; p = 0.028) had a higher risk of developing invasive melanomas compared to those with in situ melanomas. Patients with genotype AG or GG at rs2297136 had a lower risk (OR = 0.29, 95%CI = 0.11–0.75; p = 0.0038) of invasive MM. Genetic analysis at the haplotype level yielded similar results (OR = 2.95, 95%CI = 1.08–8.10; p = 0.036) for the GTCAC haplotype (rs822336 rs822337, rs822338, rs2297136, rs4143815). In addition, patients carrying the AA homozygous genotype at rs2297136 had thicker tumors than AG or GG carriers (p = 0.030). No significant association was found between the studied SNPs and melanoma-specific survival (MSS) or progression-free survival (PFS) in patients with disease progression.

Conclusion: This study suggests that SNPs rs822336, rs822337, rs822338 and rs2297136 of the PDCDL1 gene are associated with an increased risk of invasiveness and tumor thickness in MM cases. Further studies on SNPs considering genetic and epigenetic factors are needed to better understand MM susceptibility and its impact on prognosis.

P01.166.B Heritable TP53-related cancer syndrome (hTP53rc syndrome)/Li-Fraumeni syndrome (LFS) in Poland. Genotype-phenotype analysis

Dorota Nowakowska[1], *Ewa Kwiatkowska*[1], *Krzysztof Szczałuba*[1,2], *Ewa Czukiewska*[1,3], *Pawel Szyld*[4,5], *Aneta Janiec-Jankowska*[1], *Andrzej Tysarowski*[1]

[1]*The Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland,* [2]*Department of Medical Genetics and Centre of Excellence for Rare and Undiagnosed Diseases, Medical University of Warsaw, Warsaw, Poland,* [3]*St. John's Cancer Center, Lublin, Poland,* [4]*Specjalistyczna Poradnia Genetyczna, Szczytniki, Poland,* [5]*Warsaw Genomics, Warsaw, Poland.*

Background: *Li-Fraumeni syndrome (LFS; OMIM #151623) is caused by pathogenic variants in the TP53 gene*. Typical spectrum of LFS: soft-tissue sarcomas, osteosarcomas, adrenocortical carcinomas, CNS tumours and breast cancers before 31 years. If Chompret

modified criteria are met and/or a patient has been diagnosed with hypodiploid acute lymphoblastic leukaemia or otherwise unexplained sonic hedgehog-driven medulloblastoma or jaw osteosarcoma, testing for germline TP53 pathogenic variant should be offered.

Material and methods: 20 patients with germline pathogenic/likely pathogenic variants in TP53 gene have been identified. The patients received detailed genetic counselling and were offered surveillance programme, according to the guidelines. DNA had been extracted from the peripheral blood leukocytes. Causative genetics variants revealed by NGS were confirmed by Sanger sequencing in independent analysis. The pathogenicity of the variants had been assessed according to the Recommendations from the ClinGen TP53 Expert Panel.

Results: Pathogenic/likely pathogenic variants: c.455C>T, c.473G>A, c.497C>G, c.541C>T, c.631_632dup, c.637C>T, c.721T>G, c.733G>A, c.742C>G, c.743G>A, c.772G>A, c.808T>C, c.818G>A, c.845G>A. Tumor spectrum: breast cancer (12 patients, 5 cases were >31 years), soft tissue sarcoma (leiomyosarcoma, undifferentiated pleomorphic sarcoma), osteosarcoma (1), osteochondroma (1), choroid plexus carcinoma (1), melanoma (2), papillary thyroid cancer (1), serous ovarian cancer (1), lung cancer (1 adenocarcinoma).

Conclusion: We found 14 different mutations in 20 patients coming from 17 unrelated families, We were not able to prove any founder effect in this group. Our study suggests that LFS can not be excluded in breast cancer patients older than 31 years, Further studies in larger groups are needed.

P02 Reproductive Genetics

P02.001.C PGT results in double biopsied embryos - rate of inconsistency

Radostina Raynova[1,2], *Tanya Milachich*[2], *Petya Andreeva*[2], *Tanya Timeva*[2], *Maria Yunakova*[2], *Atanas Shterev*[2], *Ivanka Dimova*[2,3], *Alexey Savov*[4,3]

[1]*National Genetic Laboratory, University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria,* [2]*Shterev hospital, Sofia, Bulgaria,* [3]*Medical University, Sofia, Bulgaria,* [4]*National Genetic LaboratoryUniversity Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.*

Background: Chromosomal aberrations, such as whole-chromosome aneuploidies, segmental aneuploidies, whole-chromosome mosaicism, and segmental mosaicism, are key factors influencing embryonic development and the outcomes of fertility programs. Despite the higher probability that aneuploid embryos will arrest at the cleavage stage, embryos with chromosomal abnormalities can still form blastocysts and are often morphologically indistinguishable from chromosomally normal (euploid) embryos, especially when evaluated by static observations. The aim of our study was to analyse the chromosomes from two separate biopsies in the same embryos in order to determine the rate of concordance in chromosomal set.

Material and methods: Totally, 15 embryos were doubling biopsied and subjected to WGS chromosomal testing.

Results: Consistently euploid embryo was discovered in 4 out 15 samples (27%), in 5 samples (33%) one biopsy showed euploid and the second one - aneuploid (1 sample), mosaic (1 sample) or chaotic embryo (3 samples). In two embryos both biopsies showed aneuploidy, two were consistently chaotic and two with aneuploidy in the first biopsy and chaotic embryo from the second one. We are doing clinical follow-up for all analysed embryos.

Conclusion: There was high rate of chaotic embryos (30%) when double biopsy was performed - technical implementations should be considered. Despite the implementation of pre-implantation genetic screening and other advanced in vitro fertilization (IVF) techniques, the identification of aneuploid embryos remains complicated by high rates of mosaicism.

P02.003.A Preimplantation genetic testing without invasive embryo biopsy (Award Candidate)

Anouk E.J. Janssen[1,2], *Vanessa Verwilghen*[3], *Marion Drüsedau*[1], *Frank J.M. Snepvangers*[1], *Josien G. Derhaag*[4], *Wendy A.G. van Zelst-Stams*[1,5], *Han G. Brunner*[1,5], *Aimée D.C. Paulussen*[1,2], *Edith Coonen*[1,4], *Masoud Zamani Esteki*[1,2,6]

[1]*Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands,* [2]*Department of Genetics and Cell Biology, GROW School for Oncology and Reproduction, Maastricht University, Maastricht, Netherlands,* [3]*Department of Obstetrics and Gynaecology, Maastricht University Medical Centre, Maastricht, Netherlands,* [4]*Department of Reproductive Medicine, Maastricht University Medical Centre, Maastricht, Netherlands,* [5]*Department of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands,* [6]*Division of Obstetrics and Gynecology – Department of Clinical Science – Intervention & Technology (CLINTEC), Karolinska Institutet, Stockholm, Sweden.*

Background: Preimplantation genetic testing (PGT) is an assisted reproductive technology that requires an invasive embryo biopsy. Spent culture medium (SCM) from in vitro cultured embryos contains cell-free DNA, offering a non-invasive testing alternative. Existing non-invasive PGT (niPGT) methods focus on detection of aneuploidy and fail to address the meiotic/mitotic origin of aneuploidies and mosaicism, limiting clinical applicability. We developed an niPGT method for simultaneous detection of monogenic disorders, and aneuploidies, including their segregational origin.

Material and methods: We analyzed 90 SCM samples from 53 blastocysts (14 families) affected by monogenic disorders. Five amplification protocols were tested, followed by whole-genome sequencing. Genome-wide haplotypes were reconstructed by family-based haplotyping using haplarithmisis, optimized for cell-free DNA. Haplotypes and copy number profiles were compared to biopsy results.

Results: Genome-wide haplotypes and copy number profiles were generated and compared, allowing selection of the optimal amplification method. In 74 samples, the sex identified in medium matched biopsy, while 16 showed mismatches, suggesting (maternal) contamination. High-quality embryos assessed with the optimal amplification method had a median haplotype concordance of 92.5% ([89.83–95.27], $n = 15$). Notably, all meiotic aberrations ($n = 3$) in biopsy were also observed in medium, while mitotic aberrations were inconsistent, which is inherent to mosaicism.

Conclusion: Our niPGT method distinguishes mitotic aberrations from meiotic aberrations and tests for monogenic disorders non-invasively, offering a new paradigm for embryo selection. Future improvements in contamination control will further advance the clinical applicability of niPGT. Our approach enables

non-invasive genetic testing and could be extended to other medical disciplines, such as oncology.

P02.004.B Hereditary cancer-linked germline variants are significantly enriched in infertile men

Anu Valkna[1], *Anna-Grete Juchnewitsch*[1], *Lisanna Põlluaas*[1], *Kristiina Lillepea*[1], *Stanislav Tjagur*[2], *Avirup Dutta*[1], *Kristjan Pomm*[2], *Margus Punab*[3], *Maris Laan*[1]

[1]*Chair of Human Genetics, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia,* [2]*Andrology Clinic, Tartu University Hospital, Tartu, Estonia,* [3]*Department of Surgery, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia.*

Backgroud: Epidemiological studies show infertile men and their families have a higher tumor risk, suggesting shared genetic etiology. The aim of the study was to analyze hereditary cancer-linked germline variants in 522 infertile compared to 323 fertile men.

Material and methods: The ESTonian ANDrology (ESTAND) cohort was recruited and phenotyped at the Andrology Clinic of Tartu University Hospital. Male infertility was defined by total sperm count ≤39 million/ ejaculate; fertile men were normozoospermic and partners of pregnant women. Whole exome sequencing data was assessed for disease-causing variants in 157 hereditary cancer genes. The custom data analysis pipeline (1,2) considered in silico predictions of variant pathogenicity, previous literature, available database entries and clinical data.

Results: The ESTAND cohort revealed a nearly five-fold enrichment ($P = 2.3 \times 10E\text{-}4$) of hereditary cancer-linked variants in infertile versus fertile men. No significant difference in findings was observed between azoospermia and oligozoospermia cases. The majority of men with findings carried variants in DNA repair genes, most in Fanconi Anemia pathway genes such as *BRCA2, FANCM* and *BRIP1*. Six men had early adulthood cancers corresponding to their genetic finding, and most with pedigree data showed familial cancer incidence. Most affected genes are highly expressed in testicular cells, with mutant mouse models showing male infertility and cancer risk.

Conclusion: Hereditary cancer variants may disrupt spermatogenesis due to shared defective mechanisms responsible for genome integrity, explaining infertile men's higher cancer risk. Early knowledge of germline predisposition to cancer enables multidisciplinary management options, supporting routine hereditary cancer gene analysis in spermatogenesis disorders.

Efremov", Macedonian Academy of Sciences and Arts, Skopje, North Macedonia, The Republic of,* [6]*Department of Medical Biology and Genetics, Faculty of Medicine, University of Rijeka, Rijeka, Croatia.*

Background: Since monogenic causes of males are still largely unexplored its testing is primarily applied to research settings and has not been yet incorporated into clinical practice [1]. With the rapid accumulation of new candidate genes associated with male infertility, the question remains regarding the extent to which monogenic testing could improve the clinical diagnosis of infertile men.

Material and methods: Based on systematic literature screening, we designed a panel of candidate genes associated with severe male infertility. We tested the 420-gene panel on whole exome sequencing data from a representative multicentric cohort of 240 men with significantly impaired spermatogenesis, including men with non-obstructive azoospermia, and severe oligozoospermia (<5 million spermatozoa/ml). Identified variants were classified using the ACGS Best Practice Guidelines for Variant Classification in Rare Disease 2020 [2].

Results: We identified a potential monogenic cause in 6.7 % of infertile men. With the detection of likely pathogenic/pathogenic variants in *ADAD1, GALNTL5, MSH4, RBMXL3, RHOXF2B, SPOCD1, SSX1, STAG3, STRA8, TDRD9, TEX14*, and *TEX15* we contributed further evidence regarding the role of monogenic causes in severe idiopathic male infertility.

Conclusion: The identification of a potential monogenic cause in 6.7 % of infertile men confirmed the utility of monogenic testing in men with severely impaired fertility. Incorporation of monogenic testing into the diagnostic process of infertile men would improve both the understanding and management of infertile men. Improved diagnosis would benefit the patients, by reducing the need for unnecessary invasive tests and help inform the patients about their reproduction options.

P02.006.D LINE-1 methylation sustains telomere length : effects on pregnancy

Veronica Tisato[1,2,3], ***Elisabetta D'Aversa***[1], *Fabio Scarpellini*[4], *Roberto Marci*[1], *Francesca Salvatori*[1], *Elisa Turato*[1], *Joanne V. Vargas*[1],

Roberta Capucci[5], Bianca Antonica[1], Miriana Grisafi[1], Donato Gemmati[1,2,6]

[1]Department of Translational Medicine, University of Ferrara, Ferrara, Italy, [2]University Strategic Centre for Studies on Gender Medicine, University of Ferrara, Ferrara, Italy, [3]LTTA Centre, University of Ferrara, Ferrara, Italy, [4]Centre for Reproductive Medicine, CERM Hungaria, Rome, Italy, [5]Department of Medical Sciences, University of Ferrara, Ferrara, Italy, [6]Centre Haemostasis & Thrombosis, University of Ferrara, Ferrara, Italy.

Background: Early pregnancy loss (EPL) is defined as a spontaneous pregnancy termination within the 12th week of gestation whose exact causes remain unexplained in approximately 50% of cases. Fertility rate decreases as maternal age increases and epigenetic age-dependent conditions may favor miscarriage. We aim to investigate DNA methylation and telomere length as predictors of EPL risk.

Material and methods: Telomere length (T/S) and LINE-1 (%), as surrogate of global DNA methylation, have been assessed in a cohort of 242 pregnant women by comparing EPL (n = 129) with voluntary interruption (VPI, n = 113).

Results: Telomere size and methylation rate decreased as the age of women increased with EPL group having significantly lower values (T/S: 322.6 ± 142.0 versus 455.0 ± 290.6; $P < 0.000001$ and LINE-1 (%): 81.66 ± 4.2 versus 86.01 ± 3.7; $P < 0.000001$) characterized by stronger age-dependent lowering compared to VPI ($P < 0.001$). In correlation analysis, EPL were overrepresented in the area below the 25th percentile of the T/S and LINE-1 distribution (89.5%), while VPI controls were dramatically overrepresented in the area above the 75th percentile (94.0%). Comparing EPL/VPI ratio in these two extreme areas (EPL/$VPI_{(<25th)} = 3.12$ versus EPL/$VPI_{(>75th)} = 0.32$), a significant risk of early pregnancy failure was obtained when women carried both low telomere size and LINE-1 methylation (OR = 9.70, 3.94–23.72; $P < 0.0001$).

Conclusion: The combined effect of short telomeres and low methylation worsens the pregnancy maintenance, proposing such epigenetic age-related biomarkers as informative for pregnancy outcome and, in turn, fertility longevity. Their employment in the clinical practise has the potential to become an applicable tool also for reproduction technologies.

P02.007.A Exome sequencing of 1013 cases of disorders/differences of Sex Development (DSD) - results of a 16 year study

***Ken McElreavey[1]**, Somboon Wankanit[1], Housna Zidoune[1], Evgenia Globa[2], Maeva Elzaiat[1], Estelle Talouarn[1], Laurene Schlick[1], Laetitia Martinerie[3], Khouloud Rjiba[4], Inas Mazen[5], DSD Genetics Consortium[6], Anu Bashamboo[1]*

[1]Institut Pasteur, Paris, France, [2]Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues of the Ministry of Health of Ukraine, Kyiv, Ukraine, [3]Hôpital Robert-Debré, Paris, France, [4]Molecular Genetics and Biology of Human Reproduction, Farhat Hached University Teaching Hospital, Sousse, Tunisia, [5]National Research Center, Cairo, Egypt, [6]

Background: DSDs include a wide range of pathologies that impact gonad formation, development and function in both 46,XX and 46,XY individuals. Here, we summarize our experience of 16 years of exome sequencing performed on 1013 DSD cases.

Methods: During the period 2009–2024, WES was performed on 46,XY DSD (n = 764; gonadal dysgenesis, testicular regression sequence, anorchia, or unexplained undervirilized male) or 46,XX DSD (n = 249; ovarian dysgenesis, MURCS, cloacal extrophy, vaginal atresia, ovotesticular/testicular DSD).

Results: WES established a genetic etiology in 36.8% of the 46,XY cohort (30.9 %/non-syndromic cases and 60.4%/syndromic cases). The most common genes involved were - *GLI3, WT1, CHD7* (syndromic) and *AR, SRD5A2, NR5A1, HSD17B3* and *DHX37* (non-syndromic). 4% of individuals in 46,XY DSD cohort showed evidence for digenic/oligogenic inheritance. In the 46,XX DSD cohort the overall genetic diagnostic yield was 29.3% with 26.7% yield for ovotesticular/testicular DSD cases. In this group pathogenic variants were identified in sex-determining genes (e.g. *SRY, NR2F2, WT1, RSPO1, WNT4*) or genes required for ovarian maintenance (e.g. *NOBOX, MCM8, FILGA, TP63*).

Conclusions: WES has identified many new genetic causes of DSD (e.g *ZFPM2, ZNRF3* etc). However, pathogenic variants in each gene affect a relatively small number of individuals (e.g. *DMRT1, GATA4, ZNRF3*). Consequently, the number of genes causing DSD continues to increase without a proportionate augmentation of the overall diagnostic yield. Most children with DSD still do not have a genetic diagnosis. A significant proportion of these unexplained cases are likely due to variants in regulatory elements of genes required for gonad formation.

P02.008.B Quality control in preimplantation genetic testing for aneuploidies: beyond Vienna consensus

***Andrei Kullyev[1]**, Svetlana Avdeichik[1], Andrei Kartuesov[1], Tatiana Iunik[1], Kamola Khalilova[1], Irodakhon Shoyusupova[1], Malika Temirgalieva[1], Maftuna Islambekova[2], Lasha Nadirashvili[3], Veniamin Kazarinov[3], Sergei Sergeev[3], Yaron Goikhman[1]*

[1]Israeli Medical Center, Tashkent, Uzbekistan, [2]Consultative Medical Group, Tashkent, Uzbekistan, [3]Georgia-German Reproductive Center, Tbilisi, Georgia.

Background: Vienna consensus sets ≥90% of successfully diagnosed embryos as a competency value and ≥95% as a benchmark value in preimplantation genetic testing for aneuploidies (PGT-A). The percentage of embryos diagnosed as euploid is a critical parameter in PGT-A, as it determines the cumulative live birth rate and the efficiency of PGT-A. Yet, no benchmark has been set for this parameter. False positive results could lead to some euploid embryos being diagnosed as mosaic or aneuploid. The percentage of euploid embryos varies widely between laboratories. Published studies show that changes in the analysis of the PGT-A results could increase the percentage of embryos diagnosed as euploid, indicating that previously, some euploid embryos were diagnosed as mosaic and aneuploid.

Material and methods: 4,500 samples were analyzed with the EmbryoMap PGT-A solution on the Illumina sequencing platform. Embryo biopsy and cold chain logistics were optimized for the best sample quality. Sample processing and results analysis were optimized to avoid false positives.

Results: The percentage of successfully diagnosed embryos increased from 96.5% to 99.0%. The percentage of embryos diagnosed as euploid reached 68.2% for all age groups (up from 31.1% with our previous workflow with outsourcing to an outside

laboratory) and 73.2% for patients under 35 years old (up from 43.9%).

Conclusion: For modern PGT-A, the benchmark value for successfully diagnosed embryos could be increased from 95%. To control the efficiency of PGT-A, a benchmark for the percentage of euploid embryos in the reference group under 35 years old is needed.

Background: CHH is a heterogenous genetic disorder characterized by absent puberty and infertility. Mutations in more than 50 loci have been identified to underlie the disorder, yet 60–70% cases remain unsolved. Therefore, we performed unbiased genetic studies to discover novel CHH gene and implication in puberty.

Methods: Analysis performed: (i) gene burden test (476 CHH vs 800'000 controls from gnomAD) for gene variants with MAF< 0.01% ($p = 2.5 \times 10$^-6); (ii) screening for rare variants in *TBX3* in our CHH cohort (iii) bioinformatic screening to identify miRNA regulators of *TBX3*; and (iv) ICV injection of mimetic miRNA-137 in rats (postnatal d21-34) to evaluate pubertal status.

Results: Rare variants in *TBX3* were significantly enriched in CHH vs controls. 13 rare variants in *TBX3* were identified in 13 CHH probands, located in different protein domains. Notably, we identified 6 loss-of-function (LoF) variants in *TBX3*, including a de novo (p.R131*). Additionally, *Tbx3* is expressed in migrating GnRH neurons and inhibition of *Tbx3* by miRNA-137 in prepubertal rats led to delayed puberty.

Conclusions: Through unbiased genetics, we identified *TBX3* as a putative CHH gene, and the presence of 6 LoF variants is consistent with haploinsufficiency. *TBX3* is a transcription factor critical to POMC and KISS1 neurons and is mutated in Ulnar Mammary Syndrome (UMS). Notably, CHH and UMS appear to share clinical features (*e.g.* genital abnormalities, delayed puberty, etc.) and a potential genetic overlap. The link between *TBX3*, KISS1 neurons and miRNA-137 is currently under investigation.

P02.010.D Known and novel monogenic causes of cryptorchidism

Anna-Grete Juchnewitsch[1], *Kristjan Pomm*[2], *Kristiina Lillepea*[1], *Avirup Dutta*[1], *Erik Tamp*[3], *Anu Valkna*[1], *Stanislav Tjagur*[2], *Viljo Kübarsepp*[4,5], *Laura Kasak*[1], *Margus Punab*[1,2,4], *Maris Laan*[1]

[1]*Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia,* [2]*Andrology Clinic, Tartu University Hospital, Tartu, Estonia,* [3]*Centre of Pathology, East Tallinn Central Hospital, Tartu, Estonia,* [4]*Institute of Clinical Medicine, University of Tartu, Tartu, Estonia,* [5]*Clinic of Surgery, Tartu University Hospital, Tartu, Estonia.*

Background: Cryptorchidism (CR) is a congenital malformation where at least one testicle is missing from the scrotum. Occurring in 1–2% of newborn boys[1], it may lead to spermatogenic failure (SPGF; $<39 \times 10^6$ sperm/ejaculate) and/or testicular cancer later in life. CR has several risk factors, including likely pathogenic (LP) and pathogenic (P) variants in testicular descent genes (e.g. *INSL3*). This study aimed to identify disease-causing variants in gonadal development genes within the ESTonian ANDrology (ESTAND) cohort, including Ras/MAPK pathway genes as a novel aetiology for CR.

Material and methods: Whole-exome sequencing was performed on 844 ESTAND men (521 infertile, 323 fertile) recruited at the Andrology Clinic, Tartu University Hospital. Disease-causing variants were studied in 61 gonadal development candidate genes, applying a custom filtering pipeline, while also considering clinical, pedigree, and genotype-phenotype data of the subjects.

Results: LP/P variants were noted in 14/61 genes. Seven known gonadal development genes had 20 different LP/P variants among 18 infertile and two normozoospermic men. CR was present in 12 SPGF cases. The most prevalent genes were *NR5A1*, *DHX37*, *DMRT1*, *AR*[2].Nine SPGF and one subfertile individual carried 10 LP/P variants in seven Ras/MAPK genes[3]. None had been previously diagnosed with RASopathy. The prevalence in CR cases with RASopathies versus the general population was 40-fold higher.

Conclusion: This study shows a link between CR and LP/P variants in several gonadal development genes. Furthermore, Ras/MAPK pathway presents a novel aetiology of male infertility and congenital CR.

P02.011.A Using SNP-array based loss of heterozygosity analysis to identify candidate genes in premature ovarian insufficiency

Timothée Moyret[1], *Nicolas Rive Le Gouard*[1], *Bruno Donadille*[2], *Marion Lesieur-Sebellin*[1], *Philippe Mabboux*[1], *Eva Pipiras*[1], *Sandra Chantot-Bastaraud*[1], *Sophie Christin-Maitre*[2], *Laila El Khattabi*[1,3]

[1]*Unité de Génomique du Développement et de la Reproduction, Département de Génétique Médicale, APHP Sorbonne Université, Hôpital Pitié-Salpêtrière, Paris, France,* [2]*Service d'endocrinologie, diabétologie et médecine de la reproduction – Hôpital Saint-Antoine, AP-HP. Sorbonne Université, Paris, France,* [3]*Institut du Cerveau, Paris Brain Institute, Pitié-Salpêtrière, Sorbonne Université, Paris, France.*

Background: Premature ovarian insufficiency (POI), defined as a decline in ovarian function before age 40 evidenced by amenorrhea and hormonal criteria, affects 2–4% of women and leads to infertility, hormonal insufficiency, and various long-term

health risks. Although several genetic, autoimmune, and iatrogenic factors have been implicated, the genetic architecture of POI remains elusive. We aimed to examine the contribution of loss of heterozygosity (LOH) in women with POI, leveraging SNP-array data to identify susceptibility regions and candidate genes.

Material and methods: We analyzed, through Affymetrix 750k SNP-arrays, 393 women with POI and 759 controls consisting of pregnant women with comparable age, referred to our laboratory between 2017 and 2023. LOH segments were defined as segments of a unique genotype spanning 3 Mb or larger containing at least 25 consecutive markers. We applied Fisher's exact tests in a 1 Mb sliding window, restricting analyses to regions with a ratio of POI vs. healthy above 3.

Results: Women with POI displayed a higher mean total LOH length than controls (47.3 Mb vs. 33.1 Mb, $p < 0.01$), with an overrepresentation of chromosome 4 (6.6% vs. 3.8% in POI vs. control respectively, $p < 0.003$). Individuals presenting with a total LOH exceeding 65 Mb had a higher risk of POI (odds ratio = 3.37, [2.22–5.12], $p < 0.0001$). We identified 56 significantly overrepresented LOH regions and, using GTEx data and standardized bibliographic searches, we extracted 45 candidate genes.

Conclusion: We demonstrate significant LOH overrepresentation in POI. The identified regions and candidate genes provide valuable insights into POI candidate genes and genetic risk factors.

P02.012.B Multi-omics profiling of human ovarian granulosa cells uncovers cell type-specific regulatory landscapes

Charlotte Matton[1], *Julie Van De Velde*[2], *Quinten Mahieu*[1], *Lisa Hamerlinck*[1], *Lara Colombo*[1], *Sarah Vergult*[3], *Alexandre Segers*[1], *Mattias Van Heetvelde*[1], *Seoyeon Oh*[1], *Celine Everaert*[1], *Kelly Tilleman*[2], *Dominic Stoop*[2], *Eva D'haene*[1], *Elfride De Baere*[3]

[1]*Ghent University, Ghent, Belgium,* [2]*Ghent University Hospital, Ghent, Belgium,* [3]*Ghent University, Ghent University Hospital, Ghent, Belgium.*

Background: Granulosa cells (GCs) are key in the ovarian somatic compartment, supporting folliculogenesis and ovarian maintenance. They maintain an intricate relationship with oocytes, requiring a strict spatiotemporal regulation by GC-specific transcription factors, such as FOXL2. Dysregulation of these transcription factor genes is implicated in the pathogenesis of primary ovarian insufficiency (POI), affecting 1% of the female population and representing a major cause of female infertility. Here, we mapped 3D chromatin architecture and regulatory landscapes governing gene expression in adult human GCs.

Methods and results: Primary cumulus (surrounding the oocyte) and mural (outer layer of the follicle) GCs were collected from adult females (n = 17) who were subjected to assisted reproduction. Upon isolation, GC identity was confirmed via hormonal assays, GC-specific marker profiling (qPCR and immunocytochemistry) and FSHR+ cell flow cytometry. Short-read total RNA-seq and deconvolution analysis revealed diverse cellular composition of the primary GC samples, with GCs constituting up to 85%. Subsequently, we used an integrative multi-omics approach to profile transcriptional regulation in primary GCs. Epigenomic profiling through CUT&RUN (H3K27Ac) and ATAC-seq revealed over 60,000 candidate *cis*-regulatory elements (cCREs) active in GCs, e.g. upstream of *FOXL2*. Chromatin interaction mapping using Hi-C revealed GC-specific chromatin loops, of which 292 were differential between cumulus and mural GCs. Additionally, UMI-4C for *FOXL2* identified GC-specific promoter-CRE interactions.

Conclusion: This first comprehensive regulatory map of human GCs provides new insights into gene regulation of the ovarian somatic compartment, advancing our understanding of GC-related female infertility, such as POI.

P02.013.C Exploring the suitability of optimised, "Goldilocks" pan-ancestry carrier screening tests in endogamous and bottlenecked populations

Mia J. Gruzin[1,2], *Sarah Poll*[3], *Gannie Tzoneva*[4], *Alan R. Shuldiner*[4], *Braxton D. Mitchell*[5], *Swaroop Aradhya*[6], *Leslie Burnett*[1,2,7]

[1]*Garvan Institute of Medical Research, Darlinghurst, Australia,* [2]*School of Clinical Medicine, UNSW Medicine and Health, St Vincent's Clinical Healthcare Campus, Darlinghurst Sydney, NSW, Australia,* [3]*GeneDx, Stamford, CT, USA,* [4]*Regeneron Genetics Center, Tarrytown, NY, USA,* [5]*Department of Medicine, University of Maryland, Maryland, MD, USA,* [6]*Illumina Inc, San Diego, CA, USA,* [7]*Virtus Genetics, Virtus Diagnostics, Revesby Sydney, NSW, Australia.*

Background: Expanded reproductive genetic carrier screening ("carrier screening") assesses reproductive risk for autosomal recessive and X-linked conditions and may reduce the incidence of screened conditions in exogamous, mixed ancestry, and specific racial/ethnic/ancestry groups. However, its effectiveness in "edge cases", such as endogamous or highly bottlenecked populations, remains unclear. We developed "Goldilocks" carrier screening panels to optimize detection of heterozygotes and carrier couples across diverse ancestry groups at minimal cost. This study evaluates the performance of these Goldilocks panels in edge cases.

Material and methods: We analysed gene carrier rates for 1,350 genes using aggregated allele frequency data from exome/genome sequencing (ES/GS). For endogamous groups, we used Ashkenazi Jewish and Finnish AF data from gnomAD v4.1.0 (joint ES/GS). For bottlenecked groups, we analyzed Amish data from 7,221 Amish ES samples (including all Amish AF data in gnomAD v4.1.0). Goldilocks panels were assessed by evaluating the proportion of heterozygotes and carrier couples identified.

Results: Goldilocks panels performed well in endogamous and bottlenecked populations. A Goldilocks panel of only 200 genes was sufficient to achieve 99% detection of heterozygous individuals and carrier couples, provided those groups were adequately represented in the dataset.

Conclusion: Theoretical pan-ancestry "Goldilocks" carrier screening panels remain clinically effective in reproductive edge cases, provided frequency data adequately represents the target populations. This highlights the importance of population representation in carrier screening panel design.

P02.014.D SantPauCarriers: a pilot study for the implementation of preconceptional carrier screening

Aina Marsal-Olivan[1,2,3], *Benjamín Rodríguez-Santiago*[4,1,3], *Clara Serra-Juhe*[4,3,1], *Alicia Artigas-Baleri*[1], *Sara Bernal*[4,1,3], *Ivon Cusco*[4,3,1], *Jennifer Ortega*[1,2], *Manel Baena*[4,1], *Montse Peiró*[2,1], *Anna Abulí*[4,1], *Jordi Surralles*[1,2,3]

[1]*Institut de Recerca Sant Pau, Barcelona, Spain,* [2]*Universitat Autònoma de Barcelona, Bellaterra, Spain,* [3]*Centro de Investigación Biomédica en Red (CIBER), Madrid, Spain,* [4]*Hospital Sant Pau, Barcelona, Spain.*

Background: Severe genetic diseases entail significant emotional and financial burdens on families and the public healthcare system. Preconception carrier screening identifies at-risk couples for preventive action. In Spain, such screenings are limited to private settings, particularly in assisted reproduction, leaving the public healthcare system without equivalent options and creating inequities in access.

Material and methods: We conducted a pilot study to implement population-wide preconception carrier screening in primary care. A next-generation sequencing (NGS) panel including 350 genes associated with 450 recessive genetic disorders was designed together with complementary tests for undetectable mechanisms of pathogenicity. Of 518 contacted women, 152 met the criteria (18–38 years, male partner, and reproductive plans). Male partners (66) were tested only if the women were carriers. The process included genetic counseling, blood collection, DNA analysis, and pre- and post-test surveys to assess participants' experiences.

Results: Expression of interest was obtained from 85% of the contacted population (441/518). Among the final studied group, the carrier rate was 62% (135/218), with 4% of couples identified as high-risk (6/152). Survey analysis revealed that participants with lower anxiety levels reported higher perceived control ($p = 0.003$), as well as a positive correlation between participants' educational level and their understanding of the scientific basis of the project ($p = 0.018$).

Conclusion: This pilot study has identified bottlenecks and opportunities for improvement in the implementation of a population-wide carrier screening. It highlights the acceptance and feasibility of integrating preconception carrier screening into public healthcare as a valuable tool for informed reproductive decision-making.

P02.015.A Investigating the regulatory upstream factors of the PTPN1 gene associated with insulin resistance in women with polycystic ovary syndrome

z. Dashti[1], *N. GhasemiFiroozabadi*[2], *M. Ranjbar*[3], *S. BakhshandehBavarsad*[1], *M. Alipour*[4], ***A. MosadeghMehrjardi***[5], *N. Forouznia*[6];

[1]*Department of Genetics, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, Islamic Republic of,* [2]*Abortion Research Centre, Yazd Reproductive Sciences Institute, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, Islamic Republic of,* [3]*Department of biotechnology, School of Advanced Medical Sciences, Shiraz university of Medical Sciences, Shiraz, Iran, Islamic Republic of,* [4]*Biotechnology Department, School of Advanced Technologies in Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [5]*Medical Sciences, Tehran, Iran, Islamic Republic of,* [6]*Shahid Sadoughi University of Medical Sciences, Yazd, Iran, Islamic Republic of*

Background: Polycystic ovarian syndrome (PCOS) is a complex endocrine disorder affecting many reproductive-age women, with insulin resistance seen in 50–70% of cases. MicroRNAs (miRNAs) are small, non-coding RNAs that regulate gene expression, including Protein Tyrosine Phosphatase Non-Receptor Type 1 (PTPN1), crucial for insulin signaling. Alterations in PTPN1 expression may lead to insulin resistance. This article explores miRNAs as upstream regulators of PTPN1 in relation to insulin resistance in PCOS.

Material and methods: Bioinformatics analysis identified miRNAs targeting PTPN1. The STRING database predicted interactions of key genes with PTPN1, while three databases (miRDB, mirDIP, and miRWalk) facilitated an in-silico search for relevant miRNAs. High-scoring miRNAs were examined using TargetScan and miRBase for expression levels. Ovarian granulosa cells were collected from 36 women with PCOS and 36 age-matched controls, measuring PTPN1 and circulating miRNAs using quantitative polymerase chain reaction (qPCR).

Results: In PCOS patients, miR-22-3p and miR-6511a-3p levels were significantly higher in granulosa cells and follicular fluid compared to normal subjects. Conversely, miR-6795-5p, miR-129-2-3p, and miR-506-3p were downregulated. Additionally, PTPN1 gene expression was notably higher in PCOS patients. Bioinformatics analysis indicated that PTPN1 is a downstream target of miR-506.

Conclusion: In PCOS patients, increased levels of miR-22-3p and miR-6511a-3p were noted, while downregulated miRNAs may promote insulin resistance by targeting PTPN1, suggesting potential therapeutic targets and non-invasive biomarkers for diagnosis.

P02.016.B Comparative efficacy of cfDNA and aCGH in detecting chromosomal aberrations post-miscarriage

Vanessa Del Vitto[1], *Eloise Fraison*[2], *Anthony Atallah*[3], *Amandine Buisson*[3], *Delphine Nantois*[3], *Mathilde Pujalte*[1], *Marianne Till*[1], *Damien Sanlaville*[1], *Erdogan Nohuz*[3], ***Nicolas Chatron***[1,4]

[1]*Service de genetique, Hospices Civils de Lyon, Lyon, France,* [2]*Service de médecine de la reproduction, Hospices Civils de Lyon, Lyon, France,* [3]*Service de gynécologie-obstétrique, Hôpital Femme Mère Enfant, Hospices Civils de Lyon, Lyon, France,* [4]*Neuromyogene Institute, Pathology and Genetics of neuron and muscle, CNRS UMR 5261 INSERM U1315, University of Lyon - Université Claude Bernard Lyon 1, Lyon, France.*

Background: Miscarriages affect 10–25% of pregnancies, 1–5% of couples experiencing recurrent losses. Chromosomal abnormalities are a leading cause, yet traditional genetic testing on products of conception (POC) has limitations, including the need for intact tissue and absence of maternal DNA contamination. This study compares cell-free DNA (cfDNA)-based testing with array comparative genomic hybridization (aCGH) in diagnosing miscarriage etiology.

Material &methods: In our prospective multicenter study, we recruited 78 patients experiencing pregnancy loss between July 2023 and July 2024. Maternal blood samples collected before curettage underwent cfDNA low-depth genome sequencing

through a standard NIPT workflow, while POC samples were analyzed via aCGH post-curettage.

Results: Of the 78 participants, 13 were excluded due to missing POC samples. Among the remaining 65, 18 yielded results from only one technique (16 cfDNA, 2 aCGH), and both failed in two cases. Maternal contamination primarily caused aCGH failures. Concordance between cfDNA and aCGH was observed in 82% (37/45). Notably, cfDNA detected 6 unique chromosomal aberrations and identified 13 out of 19 aberrations found by aCGH (aneuploidies only). Sensitivity and specificity of cfDNA testing were 68.4% and 92%, respectively.

Conclusion: Our findings highlight cfDNA's potential as a robust alternative to traditional POC testing, offering advantages in scenarios where maternal contamination or sample availability/integrity is problematic. Analytic thresholds to call chromosomal aberrations from cfDNA still have to be refined to the context of pregnancy loss. These results underscore the value of incorporating cfDNA-based tests into routine miscarriage investigations, including the possibility to test patients that do not require curettage.

[1]*Department of Clinical Genetics, Maastricht University Medical Center MUMC+, Maastricht, Netherlands,* [2]*GROW Research Institute for Oncology and Reproduction, Department of Genetics and Cell Biology, Maastricht University, Maastricht, Netherlands,* [3]*Department of Obstetrics and Gynecology, Maastricht University Medical Center MUMC+, Maastricht, Netherlands,* [4]*GROW Research Institute for Oncology and Reproduction, Department of Health, Ethics, and Society, Maastricht University, Maastricht, Netherlands,* [5]*CAPHRI Research Institute for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands,* [6]*University Medical Center (UMC) Utrecht, Department of Reproductive Medicine and Gynaecology, Utrecht, Netherlands,* [7]*Department of Obstetrics and Gynecology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands,* [8]*Amsterdam UMC location University of Amsterdam, Center for Reproductive Medicine, Amsterdam, Netherlands,* [9]*Amsterdam Reproduction and Development Research Institute, Amsterdam, Netherlands.*

Background: Preimplantation genetic testing for aneuploidy (PGT-A) is widely used in in vitro fertilization for embryo selection. However, large clinical trials have questioned its efficacy, as current PGT-A may deselect viable embryos. Recent findings indicate that mosaic embryos, i.e. embryos containing both euploid and aneuploid cells, can lead to healthy live births. We evaluated the clinical utility of PGT for aneuploidy origin (PGT-AO), which determines the meiotic/mitotic origin of aneuploidies.

Material and methods: In a nationwide non-selection study, we retrospectively analyzed the genomes of 5,975 embryos sequenced for PGT for monogenic disorders (PGT-M) using either genotyping-by-sequencing (n = 2,493) or whole-genome sequencing (n = 3,482). Genome haplarithmisis determined the meiotic/mitotic origin of aneuploidies and their mosaicism. The aberrations were correlated with recorded clinical outcomes.

Results: Among 946 transferred embryos, 253 (26.7%) resulted in live birth, while 693 (73.3%) failed to reach live birth, including implantation failure (n = 546, 78.8%), early embryonic arrest (n = 104, 15.0%) and pregnancy loss (n = 43, 6.2%). None of the embryo with a meiotic trisomy resulted in live birth, while 17.0% of embryos with a mosaic mitotic trisomy did. Furthermore, only 6.8% of monosomic embryos resulted in live birth. Remarkably, different ovarian stimulation protocols influenced transfer outcomes and aneuploidy rates.

Conclusion: Embryos with meiotic trisomies and most monosomies should be considered non-viable, while those with mitotic trisomies can result in healthy live births. PGT-AO in combination with sequencing-based PGT-M will avoid unnecessary embryo transfer. PGT-AO will potentially make a paradigm-shift in embryo selection within a PGT-M and PGT for structural rearrangements (PGT-SR) context.

P02.018.D *XIST* and *FAM9A* methylation patterns as indicators of spermatogenesis status in patients with Klinefelter syndrome

Ena Vilagoš[1], *Tihana Marić*[2], *Davor Ježek*[2,3,4], *Ana Šorgić Merkler*[4], *Nino Sinčić*[1,2], *Ana Katušić Bojanac*[1,2]

[1]*Department of Medical Biology, University of Zagreb School of Medicine, Zagreb, Croatia,* [2]*Scientific Centre of Excellence for Reproductive and Regenerative Medicine, University of Zagreb School of Medicine, Zagreb, Croatia,* [3]*Department of Histology and Embryology, University of Zagreb School of Medicine, Zagreb, Croatia,* [4]*University Hospital Zagreb, Zagreb, Croatia.*

Background: In Klinefelter syndrome (KS), small testes phenotype happens due to a diminished germ cell number with two types of testicular histology, comprising of Sertoli cell-only tubules and those with focal spermatogenesis. Recently it was found that mature Sertoli cells in germ cell-containing tubules of KS patients lack the expression of XIST. Another X-chromosome related gene, FAM9A, was reported to be up-regulated in KS testes. Hereof we aimed to check whether the methylation status of these two X-related genes could be related to the presence of germ cells in KS testes.

Material and methods: Patients with azoospermia were recruited and cytogenetically screened at the University Hospital Centre Zagreb. DNA was isolated from blood and testicular tissue of 6 KS patients showing either no germ cells or focal spermatogenesis, and from 3 patients with full spermatogenesis (control). After bisulfite conversion, pyrosequencing was performed to detect the percentage of XIST and FAM9A methylation.

Results: Blood samples of Klinefelter syndrome patients showed a 50% decrease in XIST methylation, whereas in males with full spermatogenesis the XIST gene was ~100% methylated. XIST methylation in testes without germ cells was the lowest (22%) but not significantly different from control or testes with germ cells (28% and 36%, respectively). FAM9A was strongly methylated (~90%) in all samples.

Conclusion: XIST methylation status in testicular tissue indicates the immaturity of KS patient's testes, but is not a reliable marker of focal spermatogenesis. No clear differences in the inactivation of FAM9A gene in KS patients and controls were found.

P02.019.A Genetic causes of familial hypospadias in Qatar: insights from Sidra Hypospadia Biobank in Qatar and whole genome sequencing analysis

Kholoud N. Al-Shafai, *Seem Arar, Asma Jamil, Amina Azza, Luis Saraiva, Tariq Abbas*

Sidra Medicine, Doha, Qatar.

Background: Hypospadias is a common congenital anomaly in male infants and involves underdevelopment of the ventral aspect of the penile shaft. Genetic factors significantly contribute to the etiology of hypospadias. Identifying genetic contributors, especially in understudied populations, can enhance our understanding and inform targeted interventions.

Material and methods: This study utilized a structured biobank to collect and analyze biospecimens from hypospadias cases and their relatives. Whole genome sequencing (WGS) was performed on 27 subjects from seven families to identify potential genetic causes. Bioinformatics tools, including GEMINI, were used to assess the segregation of single genetic variants (SNVs) with the condition within families.

Results: Our SNV analysis identified at least four likely pathogenic variants, in four of the index patients, in genes that were not linked to hypospadias before. These variants were located in the *LHFP*, *EIF2B5*, *INO80*, and *ACADVL* genes and segregated with the hypospadias phenotype. Also, we have identified variants of uncertain significance in known hypospadias genes (DNAH12 and HOXB6) and other genes (*COL6A3)*. Two families did not reveal any potential causative variants and would require further genetic investigation, such as copy number variant (CNV) analysis. Future functional work will be necessary to establish causality between the novel SNVs identified and the hypospadias phenotype.

Conclusion: Our findings underscore the value of disease biobanking and genetic investigations in uncovering the pathogenesis of congenital conditions like hypospadias. Our findings provide a new avenue to functionally assess the identified variant(s) in relation to disease, and to better understanding disease phathophysiology.

P02.020.B Low-level mosaicism on sex chromosomes and carrier's sex in families with pregnancy pathologies

Olena Fedota[1], *Julia Gontar*[2], *Yana Lakhno*[2], *Olga Parnitskaya*[2], *Igor Ilyin*[2]

[1]*LLC "AMS", Kharkiv, Ukraine,* [2]*LLC "Medical Center IGR", Kyiv, Ukraine.*

Background: Low-level mosaicism (LLM) on sex chromosomes may remain undiagnosed and cause unpredictable reproductive disorders. Goal**:** Analysis of the association of low-level sex chromosome mosaicism in both male and female family members with tubal pregnancy (TP) and recurrent pregnancy loss (RPL).

Material and methods: Karyotypes of 4418 individuals with reproductive disorders were analyzed, cytogenetic abnormalities were identified in 809, in 415 women and in 394 men. Patients with detected mosaicism using GTG-banding underwent additional examination by FISH on uncultured peripheral blood lymphocytes.

Results: LLM up to 10% on sex chromosomes, for example, 45, X/46, XX, 45,X/47,XXX/46,XX, 47,XXY/46,XY, was found in 78 patients (9.6%). In women, it was determined 3 times more often than in men, 14.2% vs 4.8%, ($p < 0.001$). Among patients with chromosomal abnormalities, individuals from families with TP accounted for 2.1% ($n = 17$). The ratio of women (34.0 ± 5.1) and men (33.0 ± 4.3) was 1.5:1 ($p = 0.46$). Individuals from families with RPL were 5.0% ($n = 40$). The ratio of women (32.1 ± 5.0) and men (33.3 ± 9.5) is 1.5:1 ($p = 0.198$). LLM on sex chromosomes in both women and men increases the risk of TP by 7.6 times (OR = 7.59, 95% CI 1.1–52.3, $p < 0.05$), and RPL by 6 times (OR = 5.96, 95% CI 1.0–35.6, $p < 0.05$).

Conclusion: Low-level mosaicism on sex chromosomes up to 10% increases the risk of tubal pregnancy and habitual miscarriage regardless of the sex of the potential parent-carrier of the chromosomal abnormalities.

P02.021.C Optimizing non-invasive Preimplantation Genetic Testing (niPGT-A): a comparative analysis of sample collection on Day 5 vs. Day 6

Antonio Urbano[1,2], ***Marina Sánchez***[1], *Isabel Ochando*[1,2], *Ana Iris Buitrago*[1], *Joaquin Puente*[2]

[1]*Nuuma Genetics, Alicante, Spain,* [2]*Departamento de Histología. Universidad Miguel Hernández, San Juan de Alicante, Spain.*

Background: The selection of euploid embryos is a widespread practice in assisted reproduction (AR) that facilitates achieving pregnancy in a shorter time. Obtaining this selection through a completely non-invasive method represents a significant advancement. Secure Select is a new non-invasive Preimplantation Genetic Test for aneuploidies (niPGT-A) that enables embryo selection.To optimize the performance of Secure Select, it is essential to establish a proper protocol for the collection of culture medium. In this study, we aim to determine the optimal day for culture medium collection.

Material and methods: A total of 219 AR cycles were included, and 599 culture media samples from blastocyst-stage embryos were processed. The NICS kit from Yikon Genomics was used on the Illumina NGS platform (Miniseq). Analysis was performed using the Yikon Genomics ChromGo platform.

Results: The results show that the amplification failure (AF) rate is 21.05% on day 5 compared to 4.61% on day 6. This difference is statistically significant, $p < 0.001$.

Conclusion: The findings indicate that the optimal day for culture medium collection is day 6. These data demonstrate that the Secure Select technique is suitable for embryo selection in a completely non-invasive manner.

P02.022.D Benefit of the CATSPER2 gene testing in infertile couples

Martina Hruba[1,2], *Alena Vaclavikova*[3], *Martina Hajduskova*[1], *Pavel Rokyta*[3], *Petr Losan*[1]

[1]*Laboratory of Reproductive Genetics, Genetika Plzen, Plzen, Czech Republic,* [2]*University of West Bohemia, Plzen, Czech Republic,* [3]*Natalart, Plzen, Czech Republic.*

Background: The protein encoded by the CATSPER2 gene is part of an ion channel that regulates the entry of calcium ions into the sperm flagellum. Increase in the concentration of Ca^{2+} ions initiates sperm hyperactivation, which is required for the zona pellucida penetration and successful oocyte fertilization. Inactivation of the CATSPER2 gene disrupts the hyperactivation process and it has been repeatedly reported as a cause of male infertility. Affected men may have normal spermiogram, therefore the actual cause of infertility remains unrevealed.

Material and methods: The CATSPER2 gene has been examined in our laboratory since 2021 as a part of the preconception carrier screening for recessive monogenic diseases (targeting 103 genes). The test is performed using NGS by analysing both entire coding sequences and copy number variations. A cohort of 77 infertile couples underwent this examination before or during infertility treatment.

Results: A homozygous deletion of CATSPER2 was found in 2 out of 77 (2.5 %) men from the infertile cohort. In both cases, the men were found to have normo-/teratospermia and no obvious cause of infertility was revealed in their female partners. In one of the patients, a homozygous loss of the adjacent STRC gene was detected, demonstrating the genetic causality of his hearing impairment.

Conclusion: Genetic analysis of CATSPER2 can reveal the cause of (male) infertility in a significant proportion of infertile couples and thus help them start an effective treatment faster. Therefore, it would be beneficial to include CATSPER2 in routine genetic testing performed in infertile couples.

P02.023.A *CHD7* somatic mosaicism in unaffected parents can lead to underestimation of recurrence risk

Lena Rieger, *Henrike Sczakiel, Nadja Ehmke, Denise Horn*

Institut für Medizinische Genetik und Humangenetik, Charite, Berlin, Germany.

Background: CHARGE syndrome (CS) is a rare genetic condition affecting approximately 1 in 12.000–15.000 live births. In recent years an increasing number of cases with germline mosaicism has been reported. We report a female newborn with complex malformations, including four major and at least one minor clinical criteria for CS, born from healthy parents with two healthy children.

Methods: Trio genome sequencing from peripheral blood DNA was performed.

Results: We identified the heterozygous loss of function variant NM_017780.4:c.4953dup;p.(Asn1652Ter) in *CHD7*, which was also present in 10% of paternal reads. Reverse phenotyping of the father revealed mild facial dysmorphism and dysplastic ears, consistent with somatic mosaicism.

Conclusion: This case highlights the importance of thorough phenotyping, genetic counselling and genetic testing of parents, even if they seem to be unaffected. This applies in particular when they wish to have more children since this decision is largely influenced by our assessment regarding the risk of recurrence. Confirmation of a significant recurrence risk through analysis of different paternal tissues including sperm is currently underway.

P02.024.B Evaluating the predictive ability of polygenic risk score for ntrahepatic Cholestasis of Pregnancy in the Estonian Biobank

Fanny-Dhelia Pajuste[1], *Brooke Wolford*[2], *Kristi Läll*[1], *Ben M. Brumpton*[2], *Reedik Mägi*[1], *Triin Laisk*[1]

[1]*University of Tartu, Tartu, Estonia,* [2]*Norwegian University of Science and Technology, Trondheim, Norway.*

Background: Intrahepatic cholestasis of pregnancy (ICP) is a liver disorder in late pregnancy, characterized by elevated liver enzymes and severe itching. It poses significant risks to fetal health, including stillbirth and preterm birth. Genetic factors contribute to ICP susceptibility, highlighting the potential of polygenic risk scores (PRS) in predicting ICP risk.

Material and methods: Using genome-wide association study (GWAS) summary statistics (1,138 cases, 153,642 controls; Dixon et al., 2022), we calculated PRS for ICP for Estonian Biobank participants, including 1,152 ICP cases and 47,775 controls with delivery-related diagnosis codes but no ICP. Logistic regression, adjusted for birth year and the first 10 genetic principal components (PCs), assessed PRS-ICP associations. Validation was conducted in HUNT study (71 cases, 10,723 controls). A time-to-event analysis on 138 ICP pregnancies and 10,073 controls estimated the hazard of ICP onset using a Cox model adjusted for age at delivery, birth year, and first 10 PCs.

Results: ICP prevalence in Estonian Biobank increased with PRS, from 0.9% in the lowest decile to 6.1% in the highest. The odds ratio (OR) for the highest PRS decile was 3.3 (95CI 2.7–3.9, $p = 1.4 \times 10\text{^-}35$) compared to middle groups, and 1.9 (95CI 1.8–2.0, $p = 1.4 \times 10\text{^-}91$) per PRS standard deviation (SD) increase. The association was confirmed in HUNT (OR 1.7, 95CI 1.3–2.1, $p = 2.8 \times 10\text{^-}5$). Time-to-event analysis showed a hazard ratio (HR) of 2.5 (95CI 2.1–2.9, $p = 1.9 \times 10\text{^-}23$) per PRS SD increase.

Conclusion: PRS is a valuable tool for predicting ICP risk and identifying high-risk women for enhanced monitoring strategies to improve maternal and fetal outcomes.

P02.025.C A gain-of-function NANOS1 RBP variant alters early human germ cell development by redirecting signalling pathways

Matisa Alla[1], ***Bellary Lakshmi***[1], *Maciej Jerzy Śmiałek*[1,2], *Marcin Piotr Sajek*[1,3,4], *Krystyna Kwiatkowska*[1], *Żaneta Lemańska*[1], *Dorota Klaudyna Kiżewsk*[5], *Małgorzata Borowiak*[5], *Wojciech Juzwa*[6], *Kamila Kusz-Zamelczyk*[1], *Alex Rayevsky*[7,8], *Jadwiga Jaruzelska*[1]

[1]Institution of Human Genetics, Polish Academy of Sciences, Poznan, Poland, [2]Biozentrum, University of Basel, Basel, Switzerland, [3]Department of Biochemistry and Molecular Genetics, University of Colorado School of Medicine, Aurora, CO, USA, [4]RNA Bioscience Initiative, University of Colorado School of Medicine, Aurora, CO, USA, [5]Institute of Molecular Biology and Biotechnology, Adam Mickiewicz University, Poznan, Poland, [6]Department of Biotechnology and Food Microbiology, Poznan University of Life Sciences, Poznan, Poland, [7]Department of Molecular Modelling, Enamine Ltd., Kyiv, Ukraine, [8]Institute of Food Biotechnology and Genomics, National Academy of Sciences of Ukraine, Kyiv, Ukraine.

Background: NANOS is an RNA-binding protein that is specifically expressed in germ cells across species, where it plays a crucial role in inhibiting somatic fate. NANOS1 with p.[Pro34Thr; Ser78del] mutation is linked to absence of germ cells in patients. Our objective was comparing the RNP interactomes of wt- and v-NANOS1 in earliest phases of human PGC specification/development to identify pathways important for germ cell determination.

Material and methods: A PiggyBac-based, transgenic, in-vitro inducible NANOS1 expression system was established to investigate human PGC specification/early development. Human embryonic stem cell (hESC) line engineered with a NANOS3-tdTomato reporter for PGC specification enabled FACS sorting. eCLIP combined with RNA-seq/DGE analysis was performed to identify NANOS1-bound-mRNAs across the stages of pre-mesendodermal cells, and early PGCs. NANOS1-bound-proteins were identified and quantified via co-IP followed by eight-plex tandem mass tag (TMT) labelling.

Results: The v-NANOS1 gain-of-function mutation initially downregulates canonical WNT signalling, vital for pre-mesenodermal precursor induction toward PGCs. During PGC specification, v-NANOS1 fails to repress upregulated canonical WNT and TGF-ß targets, leading to increased EMT and WNT activity. This shift is reflected by higher late mesoderm marker expression and lower early germ cell marker expression, indicating a transition toward a somatic cell profile. Proteomic analysis between pre-mesenodermal and PGC stages revealed an enrichment of 17 proteins, including 10 centrosomal proteins, in the v-NANOS1 interactome. Validation of these findings is ongoing.

Conclusion: We anticipate that through upregulating mesodermal markers, v-NANOS1 acquires a gain of function. This asserts cells towards differentiation of mesodermal derivatives rather than PGCs.

P02.026.D Subpopulations of human follicular fluid extracellular vesicles differentially influence KGN granulosa cell function

Inge Varik[1], *Katariina J. Saretok*[1], *Kristine Rosenberg*[1], *Nataliia Volkova*[1,2], *Aleksander Trošin*[3], *Paolo Guazzi*[4], *Agne Velthut-Meikas*[1]

[1]Tallinn University of Technology, Tallinn, Estonia, [2]Institute for Problems of Cryobiology and Cryomedicine, Kharkiv, Ukraine, [3]Nova Vita Clinic, Tallinn, Estonia, [4]HansaBioMed Life Sciences Ltd, Tallinn, Estonia.

Background: Extracellular vesicles (EVs) are lipid-bilayered particles that play critical roles in intercellular communication. The functional differences between EV subpopulations within the human ovarian follicle remain poorly understood. In this study, we investigated the effects of small (SEV) and large EVs (LEV) isolated from preovulatory follicular fluid (FF) of in vitro fertilization (IVF) patients on mRNA and non-coding RNA expression in granulosa-like KGN cells.

Material and methods: Ethical approval was obtained from the University of Tartu Research Ethics Committee. Written informed consent was obtained from study participants. FF EV subtypes were isolated using size exclusion chromatography and tangential flow filtration. KGN cells were treated with 108/ml LEVs or 109/ml SEVs for 24 hours. RNA-sequencing and small RNA-sequencing libraries were prepared, sequenced, analyzed for differential expression using DESeq2, followed by pathway enrichment analysis using ShinyGo and miEAA.

Results: LEV treatment altered the expression of five genes: KIRREL3, CCBE1, VCAM1, C1S, and SOD2. SEV treatment triggered significant transcriptomic changes, with 692 genes upregulated and 904 downregulated. Downregulated genes were linked to cell cycle and Rho GTPase signaling, while upregulated genes were associated with extracellular matrix remodeling and MET signaling. SEV treatment also altered miRNA expression in KGN cells, upregulating 42 and downregulating 27 miRNAs compared to LEVs. Upregulated miRNAs were related to transcription, receptor tyrosine kinase signaling, and TGF-β signaling.

Conclusion: These findings highlight the functional distinctions between EV subpopulations in human FF and underscore the importance of considering EV heterogeneity in the studies of intercellular communication.

P02.027.A RNA sequencing of uterine leiomyoma tumors and control myometrium detects relationships with cancer genes and pathways

Todd L. Edwards[1], *Jacqueline Piekos*[2], *Jing Wang*[1], *Sarah Jones*[1], *Jacklyn Hellwege*[1], *Digna R. Velez Edwards*[1]

[1]Vanderbilt University Medical Center, Nashville, TN, USA, [2]NIH, Washington, DC, DC, USA.

Background: Uterine leiomyomata (UL, benign tumors of uterus) affect 77% of U.S. women by menopause and account for up to $34 billion in annual healthcare costs. Fibroid heritability ranges from 20–69%. Although studies have evaluated fibroid somatic, few studies have utilized RNA sequencing (RNAseq). Here we conduct RNAseq analyses and annotate associations at known GWAS loci.

Materials and methods: We conducted RNAseq on 35 UL tumors and 53 non-fibroid myometrium from women ages 18–50 undergoing hysterectomy with no cancer history, cancer treatment, or infectious diseases. DESeq2 modeled differential expression between fibroid and myometrial tissue controlling for race. Functional enrichment analysis was performed using GSEA using hallmark and oncogene gene sets.

Results: There were 716 genes with significant differential expression (false discovery rate [FDR]-adjusted p[P_{adj}] < 0.05, log2 fold change > |2|). The strongest association was observed at special AT-rich sequence-binding protein 2 ($p_{adj} = 4.68 \times 10^{-83}$). We observed significant associations with seven genes associated with UL in the NHGRI-EBI GWAS catalog. From GSEA, 14 gene sets show evidence of upregulation and eight show evidence of downregulation ($p_{adj} < 0.05$). Notable results were upregulated hallmark genes for MYC targets v1, oxidative phosphorylation, and E2F targets and downregulated hallmark gene sets for estrogen

response early that have been implicated in cancer, including ER+ breast cancer.

Conclusion: Using RNAseq we identified multiple genes and pathways associated with UL risk implicating tumorigenesis pathways. We also observed evidence of differential gene expression and several previously published GWAS loci, further supporting biological roles for these loci in UL risk.

P02.028.B Pregnancy loss genome-wide association study in UK Biobank replicates associations with common variants at *FAF1* and *PARG1*

Chia-Yi Chu[1], *Yevheniya Sharhorodska*[2,1,3], *Inga Prokopenko*[1]

[1]*University of Surrey, Guildford, United Kingdom,* [2]*Institute of Hereditary Pathology of National Academy of Medical Sciences of Ukraine, Lviv, Ukraine,* [3]*University of Ferrara, Ferrara, Italy.*

Background: Pregnancy losses affect 15% of recognised pregnancies. The largest genome-wide association study (GWAS) on pregnancy loss identified 10 associated loci with sporadic pregnancy loss (Reynoso et al, 2024, medrxiv:2024.03.20.24304624). Few of these loci are replicated primarily due to challenges in defining the phenotypes. This study investigated pregnancy loss susceptibility using multi-modal data from UK Biobank.

Material and methods: In UK Biobank European ancestry women, we selected 44,891 cases with self-report or electronic health record (EHR) of pregnancy loss (ICD10: O03, O02.1, N96, O26.2) and 116,060 controls with live birth and no history of pregnancy loss. We performed a GWAS with REGENIE software tool, which accounts for population structure, for 10,880,079 single nucleotide variants (SNVs) with minor allele frequency (MAF) ≥ 0.006 from the genome-wide imputed data, using a ridge regression-based model. We also examined eight previously associated loci that were available in our dataset.

Results: We identified suggestive (P-value < 10^{-5}, MAF > 0.05) associations at/near genes implicated in pregnancy loss mechanisms, including *DOCK8* (immune response), *TRIM29* (cell differentiation), and *PSMF1* gene (protein turnover). We also replicated two association signals (Bonferroni corrected P-value < 0.00625, 8 tests), at *FAF1* (rs10888690-C, effect allele frequency (EAF)=0.41, OR(95%CI) = 1.023(1.0067–1.039), P-value = 0.0052) and *PRAG1* (rs2920991-A, EAF = 0.50, OR(95%CI) = 1.023(1.0073–1.039), P-value = 0.0040).

Conclusion: We successfully replicated associations at genes involved in cell cycle regulation and cell morphology regulation, using a more stringent control definition of female participants with live birth and no EHR or self-report of pregnancy loss, despite using less than a quarter of the replication dataset sample size from the original study.

P02.029.C Methylation risk score modelling indicates potential non-genetic DNA methylation effects associated with endometriosis

Li Ying Thong[1], *Allan McRae*[1], *Marina Sirota*[2,3], *Linda Giudice*[4], *Grant Montgomery*[1], *Sally Mortlock*[5,1]

[1]*Institute for Molecular Bioscience, University of Queensland, Brisbane, Australia,* [2]*Bakar Computational Health Sciences Institute, University of California San Francisco, San Francisco, CA, USA,* [3]*Department of Pediatrics, Division of Neonatology, University of California San Francisco, San Francisco, CA, USA,* [4]*Center for Reproductive Sciences, Department of Obstetrics, Gynecology & Reproductive Sciences, University of California San Francisco, San Francisco, CA, USA,* [5]*Australian Women and Girls' Health Research Centre, University of Queensland, Brisbane, Australia.*

Background: Endometriosis is a chronic gynaecological disease characterised by endometrial-like tissue found external to the uterus. Although compelling evidence supports a genetic contribution to the disease, research on the environmental impact remains limited. DNA methylation (DNAm), influenced by genetic and environmental factors, is a valuable biomarker for understanding how genetic and environmental exposures affect complex diseases. This study aims to develop a methylation risk score (MRS) for endometriosis to improve the detection of DNAm signals linked to the disease and to gain insights into its pathogenesis.

Material and methods: Endometrium tissue samples from 318 controls and 590 endometriosis cases were collected and analysed to obtain endometrial methylation and genotyping information. Samples were first split into several independent test and training cohorts. Various MRS were generated using different models and their endometriosis case-control classification performance was assessed using the area under the receiver operating characteristic curve (AUC).

Results: The proportion of phenotypic variance in endometriosis explained by DNAm and common genetic variants was 18.25% and 23.78%, respectively. The maximum AUC obtained from the best-performing MRS was 0.68, derived from 746 DNAm sites. Additionally, combining MRS with polygenic risk scores (PRS) consistently outperformed PRS and MRS alone in classification performance.

Conclusion: Our results indicate that there are DNAm signals independent of common genetic variants associated with endometriosis, highlighting the potential role of non-genetic mechanisms in endometriosis.

P02.030.D Higher incidence of rare predicted pathogenic variants in familial spontaneous preterm birth cases suggests possible heritability risk

Tea Mladenić[1], *Aleksander Turk*[2], *Aleš Maver*[3], *Saša Ostojić*[1], *Borut Peterlin*[3], *Sanja Dević Pavlić*[1]

[1]*Faculty of Medicine, University of Rijeka, Rijeka, Croatia,* [2]*Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia,* [3]*Clinical Institute of Genomic Medicine, University Medical Centre Ljubljana, Ljubljana, Slovenia.*

Background: The maternal genetic contribution to spontaneous preterm birth (sPTB) remains poorly understood, although rare variants may influence sPTB risk, particularly in familial cases. This study aimed to evaluate the role of rare predicted pathogenic (RPP) variants in familial and sporadic sPTB, hypothesizing that RPP variants are more prevalent in familial cases.

Material and methods: Whole-exome sequencing (WES) was performed on 31 familial sPTB, 59 sporadic sPTB, and 98 controls. We conducted burden analysis of RPP variants in an sPTB gene panel, including 36 previously associated genes, and explored novel genes linked to sPTB. To explore the potential biological impact of identified RPP variants, pathway analysis using the Enrichr tool was conducted.

Results: Burden analysis revealed no significant enrichment of RPP variants in the sPTB gene panel across combined sPTB, familial, or sporadic groups ($P = 0.406$, $P = 0.309$, $P = 0.417$). However, familial cases had a significantly higher frequency of RPP variants compared to sporadic cases ($P = 0.036$). Pathway analysis identified pyrimidine metabolism as the most significantly enriched pathway ($P = 4.75 \times 10^{-4}$).

Conclusion: Although rare variants in known sPTB-associated genes do not significantly contribute to familial sPTB, familial cases exhibit a higher frequency of RPP variants across the entire exome, suggesting a potential genetic contribution beyond the sPTB gene panel. Pyrimidine metabolism is identified as a potential pathway for further investigation.

P02.031.A Endometrial fluid as a surrogate tissue for identifying methylation-based biomarkers of breast bancer risk

*González-García Bárbara[1,2], Rabanal-Núñez Aintzane[3,2,1], Arianne Uranga[1], Alba Hernangomez-Laderas[1,2], Marí Sergi[1,2], Gonzalez-Moro Itziar[1,2], Urquijo Elena[3,2], Nora Fernandez-Jimenez[1,2], Díez Santiago[3,2], Matorras Roberto[3,2,1], Jose Ramon Bilbao[1,2,4], **Iraia Garcia-Santisteban**[1,2]*

[1]University of the Basque Country (UPV/EHU), Leioa, Spain, [2]Biobizkaia Health Research Institute, Barakaldo, Spain, [3]Cruces University Hospital (Osakidetza Basque Health System), Barakaldo, Spain, [4]Center for Biomedical Research in Diabetes and Associated Metabolic Disorders (CIBERDEM), Madrid, Spain.

Background: Effective tools for risk stratification in Breast Cancer (BC) prevention are critically needed. Recent studies suggest that DNA methylation (DNAm) profiles and methylation Quantitative Trait Loci (mQTL) from cervical cytology samples could serve as surrogate hormone-responsive tissues for monitoring preventive strategies. Given that endometrial fluid represents a liquid biopsy derived from the hormone-responsive endometrium, our study aims to explore its potential as a surrogate tissue for identifying methylation-based biomarkers of BC.

Material and methods: Genotype and methylation data were generated from 145 endometrial fluid DNA samples using the Illumina GSA and EPIC arrays, respectively. Following quality control, the (epi)genomic datasets were combined with TensorQTL and corrected by endometriosis case or control status, age, menstrual cycle phase, and EPIC array batch to identify endometrial fluid mQTLs. These were then integrated with publicly available BC Genome-Wide Association Study (GWAS) summary statistics (GCST004988) using Summary data-based Mendelian Randomization (SMR).

Results: By integrating the 1,131,438 endometrial fluid mQTLs with BC GWAS data, we identified 30 CpG sites showing pleiotropic associations with the disease. Several of these CpG sites were located within or near genes known to be differentially expressed in BC (*L3MBTL3, TNNT3, EBF1, ADCY3*) or associated with aberrant methylation patterns reported in this type of cancer (*ISYNA1, GATAD2A*).

Conclusion: These findings highlight the potential of endometrial fluid as a surrogate tissue for identifying methylation-based biomarkers associated with BC risk, paving the way for innovative strategies in BC prevention and risk assessment.

P02.032.B Investigation of meiotic recombination as a potential biomarker for embryo viability and pregnancy outcomes

L. Picchetta[1], *R. Cavagnola[1], C. Ottolini[1], E. Paraboschi[1], F. Mulas[1], A. Haj Ali[2], D. Babariya[2], G. Clark[2], D. Wells[2], A. Capalbo[1];*

[1]Juno Genetics, Rome, Italy, [2]Juno Genetics, Oxford, United Kingdom

Background: The relationship between recombination and aneuploidy is well established. Our recent novel findings also show 17% of triploid embryos lack genome-wide recombination. However, despite its important role in meiosis, little is known about the impact of recombination on pregnancy outcomes in euploid embryos. This study examines whether recombination rates correlate with pregnancy outcome in putatively fertile couples undergoing IVF.

Material and methods: This retrospective multi-centre cohort study analysed recombination rates in 82 couples undergoing 94 IVF cycles with preimplantation genetic testing by SNP-array for a total of 165 transferred euploid embryos. Recombination events were assessed using a haplotyping-based algorithm, and statistical models were used to examine relationships with pregnancy outcomes and embryo morphology.

Results: On average, 33 maternal (SD:8.84) and 19.8 (SD:5.14) paternal recombination events were detected per embryo. No correlation was found between recombination and maternal age ($p = 0.9$). Recombination rates showed variation within families (maternal = 7.33(0–16.9); paternal = 4.29(0–12.02) and cycles (4.9). Smaller chromosomes exhibited statistically higher recombination events per Mb ($p < 2.2e\text{-}16$) but were also more prone to recombination absence, especially if maternal. No correlation was found between recombination and embryo morphology ($p = 0.1$). Recombination rates of transferred embryos showed no association with pregnancy outcomes (implantation: maternal p-value = 0.8-paternal p-value = 0.3; miscarriage: maternal p-value = 0.5-paternal p-value = 0.8; live birth:maternal p-value = 0.6-paternal p-value = 0.4).

Conclusion: This study provides insight into the role of recombination in embryo and oocyte health. While minimal recombination variability was observed in euploid embryos from fertile couples, further research is needed to understand its impact on meiotic integrity and reproductive success in infertility cycles.

P02.033.C Genomics of idiopathic hypogonadotropic hypogonadism in the Maltese islands

Clayton John Axiak[1], *Francesca Borg Carbott[1], Ritienne Attard[1], Karen Cassar[1], Mark Gruppetta[1,2], Josanne Vassallo[1,2], Stephanie Bezzina Wettinger[1], Rosienne Farrugia[1]*

[1]University of Malta, Msida, Malta, [2]Mater Dei Hospital, Msida, Malta.

Background: Idiopathic Hypogonadotropic Hypogonadism (IHH) is a rare and genetically heterogenous condition defined by impaired gonadal function due to insufficient or absent pulsatile secretion of gonadotropin-releasing hormone from the hypothalamus and/or gonadotropins from the anterior pituitary, often presenting with absent or incomplete sexual development and infertility by adulthood. Our objective was to characterise a cohort of 17 probands.

Material and methods: Targeted gene panel and whole exome/genome sequencing data were generated using Illumina. Bioinformatic analysis and in silico predictions were implemented to shortlist variants. Calcium mobilisation and IP1 assays were used to characterise novel *KISS1R* and *GNRHR* variants.

Results: We identified causative genetic variants in eight probands and identified potential leads in four. The findings were: (i) *FGFR1* p.Y132C in a man with cryptorchidism and micropenis, (ii) a woman with secondary amenorrhoea with a heterozygous *GNRHR* p.Q106R variant, which was also present in her (iii) hyposmic father, who had a novel *CCDC141* variant, (iv) identification of a novel *CHD7* stop variant in an anosmic man displaying two CHARGE features alongside cryptorchidism, (v) a woman with compound heterozygosity for *GNRHR* p.Q106R and a novel *GNRHR* frameshift, (vi) a woman with intellectual disability with a *SOX2* variant, and (vii) a novel *KISS1R* deletion in two brothers. Cases with potential leads included: a woman with secondary amenorrhea with accumulated heterozygous kisspeptin variants and 3 men with autosomal dominant *SOX10, SEMA3A* and *SPRY4* variants.

Conclusion: Findings show that novel *KISS1R* and *GNRHR* variants are non-functional and highlight the genetic complexity and heterogeneity of IHH.

P02.034.D Long-read sequencing enables PGT-M in de novo 16p11.2 deletion cases with limited family history: a case study

Galit Lazer Derbeko[1], *Omer Murik*[1], *David Zeevi*[1], *Gheona Altarescu*[1,2]

[1]*shaare zedek, jerusalem, Israel,* [2]*2Faculty of Medicine Hebrew University of Jerusalem, Jerusalem, Israel.*

Background: Patients with a 16p11.2 deletion are characterized by speech and language disorder, motor coordination difficulties, psychiatric conditions, and autistic features. These patients may present with a degree of developmental delay of variable severity. Additional features include obesity, seizures, vertebral anomalies, etc. 16p11.2 consists of a heterozygous ~593-kb recurrent deletion. Once detected, prenatal testing or PGT-M can be offered as a method of prevention of transmission to the next generation. PGT-M requires haplotype construction for linkage analysis, which can be challenging when first-degree family members are unavailable, in cases of de novo pathogenic variants, and when the exact breakpoints of a copy number variant (CNV) are unknown.

Materials and methods: We applied multipurpose long-read Nanopore sequencing and adaptive sampling targeting the 10 Mb spanning the deletion region. Bioinformatic analyses addressed both precise CNV breakpoint mapping and de novo variant haplotype phasing, thereby enabling the usage of PGT-M for those cases.

Results: The patient was a 43-year-old single female carrier of a 16p11.2 deletion who was treated at the PGT clinic. First-degree family members were not available. We identified precise breakpoints of the 16p11.2 deletion in the female carrier and the flanking mutant and wild-type alleles were phased by linked long read haplotype construction.

Conclusion: We demonstrate an application of long-read sequencing technology towards facilitating PGT-M for monogenic disorders in cases where traditional methods do not allow phasing and haplotype construction. This technology enables high accuracy PGT-M for unique cases in which conventional linkage methods cannot differentiate between mutant and wild-type alleles.

P02.035.A Exploring the proteomic signatures of reproductive ageing in women of South-Asian ancestry

Linda Repetto[1], *Albert Navarro-Gallinad*[1], *Maeregu Arisido*[1], *Giulia Pontali*[1], *Gianmauro Cuccuru*[1], *Alessia Mapelli*[1], *Claudia Giambartolomei*[1], *Emanuele Di Angelantonio*[1,2,3], *Luisa Zuccolo*[1,4]

[1]*Human Technopole, Milan, Italy,* [2]*British Heart Foundation Cardiovascular Epidemiology Unit at University of Cambridge, Cambridge, United Kingdom,* [3]*Victor Philip Dahdaleh Heart and Lung Research Institute at University of Cambridge, Cambridge, United Kingdom,* [4]*MRC Integrative Epidemiology Unit at the University of Bristol, Bristol, United Kingdom.*

Background: Earlier Menopause is associated with a higher risk of cardiometabolic, musculoskeletal, and cognitive disorders, and is nearly twice as prevalent in South Asia compared to Western countries. Investigating the role of proteins in its onset could provide valuable insights into actionable targets for post-menopausal health, including identifying mechanisms that contribute to accelerated aging in women after this transition.

Methods: In a South-Asian ancestry cohort with clinical, proteomic and genetic information, we: 1. GWASed age at natural menopause (ANM) (survival analysis, N = 20k women), 2. identified early menopause-predictive plasma proteins based on diverging age-trajectories comparing early to normal menopause (7kSomaScanAssay, N = 5k), 3. employed bidirectional 2-sample Mendelian Randomisation (MR) to orient the causal arrow of the relationship between protein levels and menopause.

Results: We replicated 20/283 loci from the largest ANM GWAS (ReproGen Consortium). We used genetic instruments for 88 early menopause-predictive proteins (pQTLs from our cohort), and genetic instruments for ANM as GWAS signals replicated in either the South-Asian cohort or China Kadoorie Biobank. Bidirectional 2-sample MR identified causal associations in both directions. 75% of these implicated proteins as consequences of the menopause (ANM->protein directionality), with SHGB showing the strongest effect. FSHGB showed the strongest effect in the protein->ANM direction. Both signals were expected due to these proteins' reproductive roles.

Conclusion: Our results shed light on additional biological mechanisms involved in reproductive ageing. We additionally aim to develop proteomic clocks to assess biological ageing in relation to menopause and replicate findings in a European ancestry cohort.

P02.036.B Relevance of Rare variants of the Subcortical Maternal Complex (SCMC) genes for adverse reproductive outcomes and Beckwith-Wiedemann syndrome

Silvia Russo[1], *Marco Reschini*[2], *Giada Polenghi*[2], *Valentina Alari*[1], *Alessandro Vimercati*[1], *Luciano Calzari*[3], *Davide Gentilini*[3,4], *Edgardo Somigliana*[2,5], *Paola Viganò*[2], *Pierpaola Tannorella*[1]

[1]*Research Laboratory of Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy,* [2]*Infertility Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [3]*Bioinformatics and Statistical Genetics Unit, IRCCS Istituto Auxologico Italiano, Milano, Italy,* [4]*Department of Brain and Behavioral Sciences University of Pavia, Pavia, Italy,* [5]*Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milano, Italy.*

Background: early embryonic development, before and after embryonic genome activation (EGA) is ruled by Maternal-effect genes (MEGs) coding for transcripts, exclusively expressed in oocytes. Relevant among MEGs are genes of the subcortical maternal complex (SCMC), involved in: a)formation and assembly of meiotic and mitotic spindles, b)reorganization of oocyte and zygote compartments, c)regulation of RNA metabolism, and d) zygote genome activation. A spectrum of reproductive disturbances, ranging from infertility to recurrent miscarriages and altered genomic imprinting in offspring appears related to the functions of SCMC proteins. However, the connection between variants in SCMC and reproductive outcomes remains unclear.

Material and methods: we performed whole exome sequencing (WES) analyses on 150 women from three cohorts: a) infertile women under 35 undergoing assisted reproductive technology (ART) without achieving a live birth (n = 59), b) women with recurrent pregnancy losses (n = 77), and c) healthy women with offspring affected by Beckwith-Wiedemann Syndrome (n = 52). A virtual panel of 86 genes classified as MEGs, was designed, prioritized the variants, and evaluated those with MAF <0.05.

Results: On the first subset of 57 women from the 3 cohorts (cohort 1 = 12, cohort 2 = 23, cohort 3 = 22) we found 223 variants, 30% in genes encoding the SCMC. NLRP2 was represented across all cohorts with the highest variant count (n = 18), while OOEP and PADI6 variants dominated in BWS mothers. Consistent with existing literature, NLRP7 and TLE6 variants were exclusively observed in the infertile cohort.

Conclusion: These preliminary findings indicate an enrichment of variants within SCMC genes, suggesting the need for further studies to validate our results.

P02.037.C Deconvolution of bulk endometrial tissue identifies cell type specific gene regulation associated with endometriosis

Monalisa Hota[1], *Brett McKinnon*[1], *Grant Montgomery*[1], *Allan McRae*[1], *Sally Mortlock*[1,2]

[1]*Institute for Molecular Bioscience, Univesity of Queensland, Brisbane, Australia,* [2]*School of Public Health, University of Queensland, Brisbane, Australia.*

Background: Human endometrium is a complex tissue that undergoes cyclical changes in structure and function in response to circulating steroid hormones. Traditional expression quantitative trait loci (eQTL) analysis in bulk tissue masks cell-type-specific gene regulation, limiting insights into the influence of genetic regulation on endometrial function in health and disease.

Methods: We investigated the dynamic changes in the cellular and molecular environment of the endometrium using genotype and endometrial RNA-sequencing data from 206 European women with (n = 143) and without (n = 63) endometriosis across different phases of the menstrual cycle. Computational deconvolution methods were used to estimate cell-type proportions and gene expression profiles from bulk endometrium RNA-seq, followed by differential expression and cell-type-specific eQTL analysis.

Results: Cell-type proportions in the endometrium varied across the menstrual cycle and were altered in women with endometriosis. Proportions of luminal and ciliated epithelia were significantly (FDR < 0.05) lower in women with endometriosis during the mid-secretory (MS) phase. Differential expression analysis between women with and without endometriosis in the MS phase identified differentially expressed (DE) genes in different cell-types. These included genes associated with endometrial receptivity. DE genes were enriched in RNA metabolism and biogenesis pathways that can mediate fundamental mechanisms of cell proliferation and migration. Incorporating genetic data we identified cell-type-specific eQTLs in endometrium that will be integrated with endometriosis genome-wide association data to identify target genes influencing endometriosis pathogenesis.

Conclusion: Our findings suggests that cell-type deconvolution can improve our understanding of the role of cell-type-specific gene regulation in endometrium, offering novel insights into its role in fertility and endometriosis.

P02.039.A Restrictive SNP array based PGT-SR in France: go against incidental findings

Elodie Javey[1], *Gaétan Caravello*[1], *Eric Dahlen*[2], *Mélanie Hild*[3], *Karen Levesqueau*[1], *Nathalie Gardes*[1], *Valérie Reichert*[3], *Hélène Renaud*[3], *Romain Diot*[3], *Caroline Schluth-Bolard*[3,4], *Céline Moutou*[1,4], *Philippe Gosset*[1], *Sophie Scheidecker*[3,4], *Julia Lauer Zillhardt*[1]

[1]*Laboratoire de Diagnostic Préimplantatoire, Hôpitaux Universitaires de Strasbourg, Schiltigheim, France,* [2]*Oncobiologie Génétique Bioinformatique, PCBio, Centre hospitalier universitaire de Besançon, Besançon, France,* [3]*Laboratoires de Diagnostic Génétique, Institut de Génétique Médicale d'Alsace (IGMA), Hôpitaux Universitaires de Strasbourg, Nouvel Hôpital Civil, Strasbourg, France,* [4]*Université de Strasbourg, Strasbourg, France.*

Background: Preimplantation genetic testing (PGT) involves the analysis of DNA from embryos to detect genetic abnormalities, including single-gene diseases (PGT-M), structural rearrangement (PGT-SR) and aneuploidy (PGT-A). In France, PGT is strictly regulated under Article L2131-4 of the Code de la Santé Publique, permitting only the detection of genetic abnormalities present in the parents or immediate ascendants. Consequently, PGT-A is prohibited. PGT-SR relies on fluorescence in situ hybridization (FISH), which is limited by technical and interpretative constraints. This approach contrasts with practices in many other countries using whole-genome amplification technologies, with the potential of uncovering incidental findings.To address these limitations, we aim to implement SNP array based PGT while developing a data filtration method to comply with French legislation.

Material and methods: GenomeStudio software was used and chromosome-specific filters were customized to visualize only the minimal genetic information required for diagnosis. Initial validation of these filters was conducted using postnatal SNP array results from individuals with unbalanced translocations.

Results: Five unbalanced samples were successfully confirmed with our customized filters focused near telomeres and excluding recurrent CNVs. Specific additional filters have been developed to identify pathogenic CNVs and insertions.

Conclusion: Our SNP array filtration method is able to identify chromosomal imbalances of interest, while minimizing the risk of incidental findings, according to the French legislation. Further validation is planned on 60 embryos already diagnosed by FISH based PGT-SR. Our next goal is to adapt this method to PGT-M.

Harris*[11], *JoukeJan Hottenga*[1]

[1]*Vrije Universiteit Amsterdam, Amsterdam, Netherlands,* [2]*Centre for Fertility and Health, Norwegian Institute of Public Health, Oslo, Norway, Oslo, Norway,* [3]*Qatar Genome Program, Qatar Foundation Research, Development and Innovation, Qatar Foundation, Doha, Qatar,* [4]*Amsterdam Reproduction & Development Research Institute, Amsterdam, Amsterdam, Netherlands,* [5]*Nic Waals Institute, Lovisenberg Diaconal Hospital & PsychGen Centre for Genetic Epidemiology and Mental Health, Norwegian Institute of Public Health, Oslo, Norway,* [6]*Avera McKennan Hospital & University Health Center, Sioux Falls, SD, USA,* [7]*Avera McKennan Hospital & University Health Center, Amsterdam, SD, USA,* [8]*Queensland Inst Med Res, Brisbane, Australia,* [9]*Inholland, Amsterdam, Netherlands,* [10]*8Department of Global Public Health and Primary Care, University of Bergen, Oslo, Norway,* [11]*4Centre for Fertility and Health, Norwegian Institute of Public Health, Oslo, Oslo, Norway.*

Background: Natural dizygotic twinning (DZT) results from hyperovulation and is often considered an indicator of female fertility. Paradoxically, DZT is also associated with factors linked to subfertility, such as advanced maternal age. We investigated the association between DZT and female fertility by comparing polygenic scores (PGS) for DZT in mothers of twins and singletons who conceived naturally versus those who conceived after medically assisted reproduction (MAR) and estimated genetic correlations between DZT and other fertility-related traits.

Material and methods: We applied GENESIS and SbayesS to assess polygenicity and calculated PGSs for DZT in 4381 twin mothers and 2,797 controls in the Netherlands Twin Register (NTR) and 1,299 twin mothers and 64,810 controls in the Norwegian Mother, Father, and Child Cohort Study (MoBa) based on the largest meta-analysis of DZT.

Results: DZT is not highly polygenic: ~0.20% of SNPs showed a nonzero effect and 17 SNPs contributed to 17.2% of the total predicted SNP heritability of 7.2%. The PGS for DZT captured 1.60% of the variance in DZT liability. PGSs were higher in mothers of naturally conceived twins compared to those with MAR-conceived twins, especially in mothers who used hormonal ovulation induction. Higher PGSs were associated with a shorted time to pregnancy. Genetic correlations were observed for DZT and anovulatory infertility (-0.698, $p = 5.099 \times 10\text{-}5$), PCOS ($-0.278$, $p = 0.035$), and endometriosis (0.279, $p = 0.003$).

Conclusion: A PGS for DZT is a valuable, under-recognized marker of female fertility, meriting further exploration within fertility research to improve reproductive health insights.

P02.042.D Identifying genetic markers for predicting TESE success in male infertility

Elvezia M. Paraboschi[1], *Silvia Caroselli*[1], *Laura Siciliani*[2], *Francesca Mulas*[1], *Elena Fernandez*[3], *Danilo Cimadomo*[4], *Christian S. Ottolini*[1], *Aisling Ahlstrom*[5], *Goran Westlander*[5], *Antonio Capalbo*[1,6,7]

[1]*Juno Genetics, Rome, Italy,* [2]*Università degli Studi di Roma Tor Vergata, Rome, Italy,* [3]*Juno Genetics, Valencia, Italy,* [4]*IVI RMA Global Research Alliance-Clinica Valle Giulia, Rome, Italy,* [5]*IVI RMA Global Research Alliance-Livio AB, Gothenburg, Sweden,* [6]*University of Chieti-Pescara, Chieti, Italy,* [7]*IVI Foundation, Health Research Institute La Fe, Valencia, Spain.*

Background: Nearly 75% of infertile men experience oligozoospermia, ranging from mild sperm reduction to complete azoospermia. For men with non-obstructive azoospermia (NOA), testicular sperm extraction (TESE) remains the best option for sperm retrieval, though success is largely unpredictable. Recently, genes involved in gametogenesis have been recognized as critical for male reproductive function, offering not only a potential genetic diagnosis of infertility but also a possible means to predict the presence of isolated spermatogenesis in the testes.

Material and methods: Sixty patients who previously underwent TESE were analyzed using whole-exome sequencing. A curated panel of 240 NOA-related genes was examined, considering only rare (<5% allele frequency in gnomAD NFE) variants predicted to be pathogenic by bioinformatic tools.

Results: In total, 30 patients (50.0%, 95CI%=37.7–62.3%) were identified as carriers of potentially pathogenic variants. These mutations were identified in 59% of unsuccessful TESE cases versus 44% of successful cases (Fisher test $p = 0.29$, $OR = 1.82$), indicating a trend toward sperm absence in carriers. Burden analysis identified *HFM1* and *ZMYND15* as associated with positive TESE outcomes, while *SOX30* correlated with negative outcomes. Interestingly, *SOX30* is predicted to be involved in the differentiation of male germ cells with post-meiotic arrest, as described in animal models. Principal component analysis (PCA) on mutated samples revealed clustering by sperm retrieval outcome, with a Wilcoxon test confirming a significant difference ($p = 0.006$).

Conclusion: Genetic variants may influence TESE outcomes, with specific genes impacting on success or failure. Identifying these variants may enhance personalized infertility diagnostics and improve TESE success predictions.

P02.043.A Molecular aspects of preimplantation genetic testing (PGT) for Neurofibromatosis type 1 (NF1) in three large European centers: challenges and pitfalls

Vivian Vernimmen[1,2], *Martine De Rycke*[3], *Céline Moutou*[4], *Julia Lauer-Zillhardt*[4], *Veerle Berckmoes*[3], *Jos Dreesen*[1,2], *Rien Blok*[1,2], *Masoud Zamani Esteki*[1,2], *Malou Heijligers*[1,2], *Arthur van den Wijngaard*[1,2], *Christine de Die-Smulders*[1,2], *Aimée Paulussen*[1,2]

[1]*Department of Clinical Genetics Maastricht University Medical Center, Maastricht, Netherlands,* [2]*GROW-School for Oncology and Reproduction Maastricht University, Maastricht, Netherlands,* [3]*Centre for Medical Genetics UZ Brussel, Brussel, Belgium,* [4]*Laboratoire de Diagnostic Préimplantatoire Université de Strasbourg / Hôpitaux Universitaires de Strasbourg, Schiltigheim, France.*

Background: NF1 is a neurocutaneous disorder with complete penetrance and extreme clinical variability. It is one of the most frequently requested autosomal dominant indications for PGT. The NF1 gene is large and has a high mutation rate. A high number of variants occur de novo, are mostly unique and more frequently associated with germline mosaicism. These characteristics can pose difficulties in PGT counseling, protocol set-up and treatment.

Material and methods: A retrospective, observational cohort study on PGT protocols with the indication NF1 was performed in three PGT centers (2004–2022): Maastricht University Medical Center+ (the Netherlands, n = 107), University Hospital Brussels (Belgium, n = 119) and University Hospitals of Strasbourg (France, n = 64).

Results: A PGT protocol was developed for 290 couples with 219 different sequence variants in *NF1* (n = 281 couples), of which 53 are unpublished and absent in variant databases, seven intragenic deletions of ≥1 exon(s), one 17q11.2 microdeletion and one translocation involving *NF1*. Mosaicism was detected in 14 out of 175 sporadic cases (8.0%), respectively 10/169 sporadic cases with a sequence variant (5.9%) and 4/6 sporadic cases with a deletion (66.7%, p-value <0.001). A successful PGT protocol was developed for 283 couples (97.6%) requesting PGT for NF1: 5 couples opted out during set-up and for 2 couples, PGT was technically not possible.

Conclusion: A successful protocol could be developed for the vast majority of the PGT requests for NF1. However, the impact of mosaicism is warranted in reproductive counseling and PGT for NF1, especially in *NF1* deletions of ≥1 exon(s).

P02.044.B Genetic polymorphisms of coagulation and hormonal factors in Bulgarian patients with endometriosis

Eliana Dimova[1], *Radoslava Vazharova*[2], *Atanas Syarov*[3], *Mariela Hristova-Savova*[4], *Adelina Yosifova*[5], *Nadya Magunska*[4], *Vesela Karamisheva*[6], *Tanya Timeva*[4], *Maria Yunakova*[6], *Petya Andreeva*[7], *Kaloyan Persenski*[8], *Ralitsa Lechova-Dimitrova*[6], *Ivanka Dimova*[6]

[1]*Sofia University, Sofia, Bulgaria,* [2]*Department of Biology, Medical genetics and Microbiology, Faculty of Medicine, Sofia University St K, Sofia, Bulgaria,* [3]*Sofia University St. Kliment Ohridski, Sofia, Bulgaria,* [4]*Medical Complex "Dr Shterev", Sofia, Bulgaria,* [5]*University Hospital "Lozenetz", Sofia, Bulgaria,* [6]*Medical University Sofia, Sofia, Bulgaria,* [7]*Medical Complex "Dr Shterev", South-West University, Sofia, Bulgaria,* [8]*Lozenetz University Hospital, Sofia, Bulgaria.*

Background: Endometriosis affects 2–10% of women in reproductive age. It is a chronic, inflammatory, estrogen dependent disease, and patients with endometriosis appear to be in a hypercoagulable state. The etiology and pathogenesis of endometriosis remain ambiguous. The objective of our study was to evaluate the impact of the polymorphisms in genes for coagulation factors (FV, FII and PAI-1) and in genes, related to estrogen levels and function (CYP19A1 and ESR1) on endometriosis risk.

Material and methods: We investigated the frequency of seven polymorphisms of these genes in Bulgarian patients with endometriosis (n = 30, average age = 32) and compared it with the control group (internal database with healthy Bulgarian women, n = 221 and/or population data from ensemble genome browser). Chi-square test was used for the determination of statistical significance.

Results: We established higher frequency in patients versus controls for heterozygotes of FII mutation G20210A (8.3% vs 4.5%) and for homozygotes of PAI-1 4G/4G (37.5% vs 23%), not reaching statistical significance. Regarding the polymorphism -351 A > G [XbaI] in ESR1, we found higher frequency among patients compared to controls for G allele (40% vs 31%, p < 0.15) and homozygous G/G genotype (17% vs 9%, p < 0.13). There was no markable difference in the allele or genotype frequencies for CYP19A1 between patients and controls.

Conclusion: Genetic mutations in ESR1 may lead to aberrant gene expression and may be involved in pathogenesis and development of endometriosis. It is worthy to continue this study with more patients and including expression data.

P02.045.C The contribution of the autoimmune process in the genesis of recurrent pregnancy loss

Oresta Terpyliak, *Kateryna Sosnina, Danuta Zastavna*

State Institution «Institute of Hereditary Pathology of the National Academy of Medical Sciences of Ukraine», Lviv, Ukraine.

Background: Celiac disease (CD) is an autoimmune disease and has been associated with several conditions influencing human reproduction. CD genetic components are *HLA-II* class genes known as *HLA-DQ2* and *DQ8*. The aim of study was to investigate distribution of *HLA-DQ2.5* (*HLA-DQA1*05:01 + HLA-DQB1*02*) and *HLA-DQ8* (*HLA-DQB1*03:02*) genotypes among women with recurrent pregnancy loss (RPL).

Material and methods: SSP-PCR for distribution of *HLA-DQ2.5* and *HLA-DQ8* genotypes. Pooled odds ratio (OR) and prevalence, with 95% confidence intervals were calculated.

Results: Celiac genotypes summarily are statistically significantly more often present in the group of women with RPL compared to control (46.4% vs. 25%, $p < 0.01$), but we did not establish a significant difference in the frequency of high (*DQ2.5+DQ8*) and low risk (*DQ8*) celiac genotypes ($p > 0.05$) separately in women from the RPL group compared to the control group. As for the medium-high risk genotype (*DQ2.5*), statistical calculations showed a significant ($p < 0.01$) increase of the *DQ2.5*-genotype frequency in this group compared to the control, and the OR proves 3 times increases of RPL risk.

Conclusion: An increased risk of RPL is associated with women carrying *DQ2.5*, a genotype predisposing to CD ($p < 0.01$). The OR proves 3 times increases of RPL risk in the presence of the *DQ2.5* genotype in women. Our results indicate the crucial role for the autoimmune process triggered by CD in the genesis of recurrent pregnancy loss.

P02.046.D 25 years of PGT in Strasbourg

Julia LAUER ZILLHARDT[1], *Emmanuelle KIEFFER*[1], *Julie ROOS*[1], *Sarah DONAT*[1], *Nathalie GARDES*[1], *Catherine HAMM*[1], *Karen LEVESQUEAU*[1], *Jean-christophe NICOD*[1], *Vanesha KEMPF*[1], *Elodie KIEFFER*[1], *Laetitia MOSSER*[1], *Magali BEAUGEY*[2], *Chloé SCHAMPER*[2], *Marine STREIFF*[2], *Emilie BEAU*[2], *Marion CERVANTES*[2], *Marie-Laure KELLER*[2], *Linda RAMDANI*[2], *Céline MICHEL*[1,3], *Justine RISS*[2], *Karima BETTAHAR*[2], *Olivier PIRRELLO*[2], *Catherine RONGIERES*[2], *Louise GONTARD*[2], *Arthur LUTON*[2], *Jean-Baptiste DURAND*[2], *Philippe GOSSET*[1], *Céline MOUTOU*[1,4]

[1]*Unité de Diagnostic préimplantatoire des Hôpitaux Universitaires de Strasbourg, STRASBOURG, France,* [2]*Centre de médecine de la reproduction et préservation de fertilité, Hôpitaux Universitaires de Strasbourg, STRASBOURG, France,* [3]*Centre de médecine de la reproduction et préservation de fertilité, Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [4]*Université de Strasbourg, Strasbourg, France.*

Background: Preimplantation genetic testing (PGT) was allowed in France in 1994. Strasbourg PGT center is one of the first center that was licensed in 1999. Today, PGT is performed in five authorized centers in France. The French law restricts PGT to inherited monogenic disorders (PGT-M) and structural rearrangements (PGT-SR) with previously and clearly identified abnormality in the future parent or grand-parent. It is strictly restricted to this specific disorder limiting the use of generic technologies. Aneuploidy screening (PGT-A) is thus prohibited.

Material and methods: During 25 years, we had to adapt to many legal or technical challenges and changes. PGT practice and organisation could be improved thanks to evolutions in embryology and genetics. We present key figures from 25 years of PGT in Strasbourg.

Results: We validated more than 400 specific PCR tests for 176 different genetic diseases (including de novo mutations) and more than 300 specific FISH test for several chromosomal rearrangement and sexing (for X-linked diseases). From October 1999 to October 2024, 2909 patients were referred (67% for PGT-M, 31% for PGT-SR and 1% for double indication), 3424 cycles were started leading to 3210 oocyte retrievals and 2740 biopsies. Fresh or frozen embryo transfer could be achieved in 2822 cycles (TE) resulting in 907 clinical pregnancies (32%/TE) and 854 babies born.

Conclusion: Our expertise allows us to manage more patients and indications. We are now working on generic approaches adapted to the restrictive French law in order to decrease individual set up and reduce time to cycle.

P02.047.A Preimplantation genetic testing: atypical FISH solution for an unusual translocation

Solène Doppler, *Karen Levesqueau, Catherine Hamm, Philippe Gosset, Julia Lauer Zillhardt*

Laboratoire de diagnostic préimplantatoire, Hôpitaux Universitaires de Strasbourg, Strasbourg, France.

Background: Preimplantation genetic testing (PGT) is a technique used to identify chromosomal or monogenic abnormalities before transfer of embryos created through in vitro fertilization (IVF). In France, PGT can be offered when a patient presents a high risk of transmitting a genetic disease deemed particularly serious and incurable. We report here a complex cytogenetic PGT case in the context of a familial balanced translocation t(1;17) disrupting *BRCA1*, posing a risk of both chromosomal imbalances and/or cancer predisposition.

Material and methods: At the couple's request and following approval by the local ethics committee, all unbalanced embryos and female balanced embryos at risk for *BRCA1*-related cancer were considered non-transferable. Therefore, in addition to detecting imbalances, PGT was required to identify the translocation if present. Fluorescence In Situ Hybridization (FISH) was performed using a combination of five probes. Two probes were located very close on either side of the breakpoint junction on the derivative chromosome 17 to assess the presence or absence of the *BRCA1* disruption. Validation methods confirmed that the spatial proximity of the two probes reliably identified the balanced translocation on interphase nuclei. The other probes were selected to determine imbalances and the sex of the embryo.

Results: Two embryos were analyzed after two IVF cycles. One carried a chromosomal imbalance. The other was a balanced male embryo not carrying the translocation and could be transferred.

Conclusion: This atypical PGT case using enhanced FISH analysis illustrates the ethical and technical challenges that can arise from a balanced familial chromosomal variant.

P02.048.B A six-year review of cystic fibrosis carrier testing: is it worth it?

Nicola Walsh[1], *Melissa Rogers*[2], *Rebecca Muldowney*[2], *Sally Ann Lynch*[1]

[1]*Department of Clinical Genetics, Children's Health Ireland at Crumlin, Dublin, Ireland,* [2]*Molecular Genetics Laboratory, Children's Health Ireland at Crumlin, Dublin, Ireland.*

Background: Reproductive testing for many recessive disorders is promoted widely by commercial companies to low-risk populations. Cystic Fibrosis (CF) is the most common recessive disorder for those of Irish ethnicity (1/19 carrier frequency). CF cascade carrier testing (CF-CCT) is offered to individuals with a family history where the genotype is known. The true utility of CF-CCT for family planning is unknown. We reviewed CF-CCT data to evaluate the number of high-risk couples identified and assess the benefit of carrier testing in a high prevalence disorder.

Material and methods: CF carrier tests from 2018–2024 were analysed ($n = 1006$). Carrier tests performed for parents of an affected child, assisted reproduction, or where family history was unknown were excluded ($n = 239$). Data extracted from CF-CCT reports ($n = 767$) included ascertainment (family history), relatedness of proband, and post-test reproductive risk where applicable.

Results: The largest ascertainment for CF-CCT (32.5%;n = 249) was for abnormal newborn screening (NBS) in unaffected children. 27.5% (n = 211) of CF-CCT had a family history, a quarter were first-degree relatives; the most distant were sixth-degree relatives. 190 test reports were couples reports, and testing increased CF reproductive risk for 2.6% couples (n = 5/190). Two of these couples had prenatal genetic testing. The other couples were counselled about reproductive options but their outcomes are unknown.

Conclusion: Broadly implemented CF-CCT shows increased reproductive risk in a small proportion of couples despite being the most highly prevalent recessive disorder in Ireland. Its relatively low yield raises questions about reproductive counselling strategies for disorders with lower prevalence in Ireland.

P02.049.C Endometriosis (EM) symptoms and extra-oral taste-associated genes (TGs): not only a matter of taste

Aurora Santin[1,2], *Alessandro Pecori*[2], *Giuseppe Giovanni Nardone*[1], *Beatrice Spedicati*[1,2], *Stefania Lenarduzzi*[2], *Paola Tesolin*[1,2], *Anna Morgan*[2], *Silvia Camarda*[1], *Harry Stevens*[1], *Laura Fasoli*[3], *Daniela Mazzà*[2], *Giovanni Di Lorenzo*[2], *Federico Romano*[1,2], *Francesca Buonomo*[2], *Alessandro Mangogna*[2], *Gabriella Zito*[2], *Maria Pina Concas*[2], *Giuseppe Ricci*[1,2], *Giorgia Girotto*[1,2]

[1]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy,* [2]*Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy,* [3]*Department of Life Sciences, University of Trieste, Trieste, Italy.*

Background: EM is a multifactorial gynaecological condition heavily impacting patients' well-being; to date, the mechanisms underlying EM-symptoms variability are unknown. In this context, the role of TGs in complex disorders' etiopathogenesis is emerging; indeed, beyond influencing food choices, they can modulate inflammatory processes. Hence, deepening their effect could provide novel perspectives regarding EM-symptoms development/severity.

Material and methods: A cohort of 110 Caucasian EM patients was enrolled at IRCCS "Burlo-Garofolo" (Italy). Patients underwent a careful clinical examination, comprising EM-symptoms assessment. A list of 23 variants within TGs was extracted from SNP-arrays data. Associations between EM-symptoms presence/severity and TGs were analysed with regression models.

Results: Preliminary results ($p < 0.05$) highlighted the possible impact of TGs in regulating EM-symptoms presence/severity.In particular:- C allele carriers of rs35874116 (*TAS1R2*) displayed a lower risk of dysmenorrhea development (OR = 0.12). Recent findings described that T allele carriers consume more carbohydrates (PMID:39861458); hence, C allele carriers, by consuming fewer sugars, may be protected against dysmenorrhea onset.- A allele carriers of rs224534 (*TRPV1*) had lower risk of post-menstrual pain onset (OR = 0.19). Since a) *TRPV1* encodes a channel regulating noxious stimuli detection, and b) A allele carriers of rs224534 can better respond to acetaminophen (PMID:30908574), this result could open new insights into pain processing and anti-inflammatory drugs response.

Conclusion: This is the first worldwide study investigating TGs in EM. These findings could guide a deeper understanding of EM-symptoms mechanisms, thus allowing the development of personalized strategies to improve patients' management. To further validate these results, expansion of the cohort is ongoing.

P02.050.D The DNA damage-sensing cGAS-STING pathway is critical in specific telomere Variant Sequence synthesis in men with nonobstructive azoospermia and individuals with differences of sex development

Maria Krivega, *Jutta Zimmer, Anna Slezko, Jade Kirscht, Petra Frank-Herrmann, Thomas Strowitzki*

Department of Gynecological Endocrinology and Fertility Disorders, University Hospital, Heildelberg, Germany.

Background: Increased DNA damage in men with nonobstructive azoospermia (NOA) and individuals with Differences of Sex Development (DSD) was associated with increased telomere length (TL). Autophagy inhibition elongated TL and rescued DNA damage in leukocytes, linking to the Androgen Receptor (AR) and cytoplasmic DNA-sensing cGAS-STING signaling. Recently discovered Telomere Variant Sequences (TVS) bring new focus on genome instability during infertility.

Material and methods: Lymphoblastoid lines (n = 4) and blood leukocytes of NOA groups (abnormal/normal embryogenesis after ICSI; Spermatogonia Arrest (SGA), Sertoli Cells Only (SCO) syndrome), and DSD groups (Swyer, Complete Androgen Insensitivity Syndromes (CAIS) were analyzed with PCR (n = 36) for normal Telomere Sequence (TS: TTAGGG) and TVS (TVS1: TGAGGG; TVS2: GTAGGG; TVS3: TTGGGG; TVS4: TTTGGG; TVS5: TTCGGG), TL with quantitative real-time PCR. Proteins were analyzed with immunoblotting. Unpaired t test was applied for statistics.

Results: Infertile Individuals exhibit TVS in elongated telomeres, linked to telomerase complex protein GAR1 upregulation (Swyer: p = 0,0022; Turner, p = 0,0401; abnormal ICSI group, p = 0,0270, SGA, p = 0,0176). TVS3 was present in of all infertile groups. Inhibitors of autophagy BafilomycinA1 and AR signaling Enzalutamide caused GAR1 upregulation (p = 0,0286), TL extension (p = 0,0085), but increased DNA damage marked by γH2AX on double-strand brakes (p = 0,0286) in DSD cell lines. GAR1-siRNA prevented TVS3 synthesis under Enzalutamide-induced genotoxic stress, which was rescued by Bafilomycin A1. Similarly, in contrast to fertile control, primary leukocytes from DSD patients promoted GAR1 (p = 0,0048) and TVS3 downstream from STING, upon BafA1 exposure.

Conclusion: General molecular mechanisms drive infertility-associated genome instability through AR and autophagy alteration of telomerase complex causing TVS.

P02.051.A *KIRAA*-genotype as a potential marker recurrent implantation failure after in vitro fertilization

Kateryna Sosnina, *Danuta Zastavna, Bohdan Tretiak, Oresta Terpyliak*

State Institution "Institute of Hereditary Pathology of the National Academy of Medical Sciences of Ukraine", Lviv, Ukraine.

Background: About 10% of women suffer from recurrent implantation failure (RIF) after in vitro fertilization that is generally described as the absence of pregnancy after the transfer more than four good-quality embryos in a woman under the age of 40. The etiology of RIF remains unclear in almost 50% of cases, with

considerable attention paid to the role of uterine natural killer cells and their KIR receptors. Therefore, the *aim* of the study was to analyze the frequency of *KIR*-genotypes in women with RIF compared to control.

Material and methods: *KIR*-genotyping by PCR-SSP was carried out in the 158 women with RIF and 431 women without reproductive losses.

Results: The frequency and distribution of *KIR*-genotypes in the study groups were analyzed. In women with RIF, a shifted distribution of the frequency of KIR-genotypes was observed, towards the *AA*-genotype, the frequency of which was half of all identified genotypes (50.6%). The distribution and frequency of *KIR*-genotypes in the control group corresponded to the Hardy-Weinberg equilibrium. Statistical analysis revealed a significantly higher frequency of the *KIRAA*-genotype ($\chi 2 = 26.7; p < 0.0001$) in the group of women with RIF compared to the control group of women. If a woman has *KIR-AA*, the risk of repeated failed implantations increases threefold (OR = 2.7).

Conclusion: We consider that the *KIRAA*-genotype is the optimal marker of RIF and we argue that *KIR*-genotyping is a necessary genetic test to determine the risk of embryo rejection by the maternal immune system, which will help to apply the correct medical interventions and save the pregnancy.

P02.052.B Examination of the link between mitochondrial dysfunction and common endocrine disorders in female reproductive health among Hungarian patients

Vera Várhegyi[1,2], *Barnabas Banfi*[2], *Domonkos Trager*[2], *Dora Gerszi*[1], *Eszter M. Horvath*[3], *Miklos Sipos*[1], *Maria J. Molnar*[2], *Szabolcs T. Varbiro*[1,4], *Aniko Gal*[2]

[1]*Semmelweis University, Department of Obstetrics and Gynecology, Budapest, Hungary,* [2]*Semmelweis University, Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary,* [3]*Semmelweis University, Department of Physiology, Budapest, Hungary,* [4]*University of Szeged, Albert Szent-Györgyi Clinical Centre, Department of Obstetrics and Gynecology, Szeged, Hungary.*

Background: Mitochondrial dysfunction is identified as a significant pathogenic factor in the development of prevalent reproductive endocrine disorders. This study sought to assess the relationship between female reproductive hormone levels and multiorgan involvement, their effects on plasma GDF-15 levels, and the presence of mtDNA deletions.

Material and methods: The current study involved 81 female patients who were treated for insulin resistance (IR) alone, as well as those with IR combined with polycystic ovary syndrome (PCOS), and IR with premature ovarian insufficiency (POI), alongside 41 healthy female controls.

Results: There is a significant inverse correlation between GDF-15 levels and TSH values in the overall cohort ($p = 0.023$). However, in the groups with and without mtDNA deletion, only a trend is observed. Patients with mtDNA deletion exhibited lower AMH levels compared to those without it. In the IR+PCOS subgroup, total testosterone levels rise alongside increasing GDF-15 levels. Conversely, in the IR-only subgroup, serum estradiol and testosterone levels tend to decrease as GDF-15 levels rise. The high number of affected organ systems in our group with mtDNA deletion is believed to result from more severe mitochondrial dysfunction.

Conclusion: These findings indicate that the integrity of mtDNA may be vital for sustaining normal ovarian function and hormone production. The multiorgan involvement observed in patients with mtDNA deletions highlights the systemic effects of mitochondrial dysfunction, suggesting that it could influence not only reproductive functions but also have wider implications for overall health.

P02.053.C Partial AZFc deletions in Moroccan patients with idiopathic infertility

S. Amasdl[1,2], *S. Trhanint*[2], *M. Ahsaini*[3], *A. Bouia*[1], *L. Bouguenouch*[2];

[1]*Laboratory of Biotechnology, Environment, Agri-Food and Health, Faculty of Sciences Dhar El Mahraz, Sidi Mohammed Ben Abdellah University, FEZ, Morocco,* [2]*Laboratory of Medical Genetics and Oncogenetics, Hassan II University Hospital, Fez, Morocco,* [3]*Service d'Urologie, CHU Hassan II, FEZ, Morocco*

Background: Infertility affects 10% to 15% of couples trying to conceive, with a male factor identified in nearly half of the cases. The most common molecular abnormality causing male infertility is microdeletion of the long arm of the Y chromosome (MCY). These deletions impact the Azoospermia Factor (AZF), a group of genes involved in spermatogenesis, spread across three distinct regions: AZFa, AZFb, and AZFc.This study aimed to evaluate the prevalence of AZF microdeletions in infertile men from Morocco.

Material and methods: We present a series of 30 infertile Moroccan patients with severe oligospermia (n = 10) or azoospermia (n = 20), who underwent clinical and paraclinical investigations as well as molecular analysis of the AZF regions using the MLPA technique. In parallel, 20 normozoospermic men were analyzed as controls.

Results: Partial AZFc microdeletions were identified in four patients (4/30). However, no AZFa or AZFb deletions were found. The four deletions were observed in two patients with severe oligospermia and two with azoospermia. No deletions were detected in the control group.

Conclusion: According to this study, the frequency of MCY is estimated at 13%. This frequency is comparable to that reported in other studies but higher than previously documented in Moroccan populations. The management strategy for male infertility should systematically include testing for MCY in all patients with azoospermia or severe oligospermia before proceeding with assisted reproductive techniques.

P02.054.D Expanded carrier screening during pregnancy, reproductive follow-up of 100 consanguineous couples

Juliette Schuurmans[1], *Suming Sun*[1], *Liesbeth Van Osch*[1,2], *Celine Frank*[2,3], *Katelijne Bouman*[4], *Robert-Jan Galjaard*[5], *Jeske van Harssel*[5], *Sara Joosten*[6], *Phillis Lakeman*[7], *Vyne Van der Schoot*[8], *Manon Suerink*[9], *Christine de Die*[1], *Malou Heijligers*[1], *Arthur van den Wijngaard*[1], *Sander Stegmann*[3], *Aimée Paulussen*[3]

[1]*MUMC+, Maastricht, Netherlands,* [2]*Maastricht University, Maastricht, Netherlands,* [3]*MUMC, Maastricht, Netherlands,* [4]*UMC Groningen, Groningen, Netherlands,* [5]*UMC Utrecht, Utrecht, Netherlands,* [6]*Radboud UMC, Nijmegen, Netherlands,* [7]*Amsterdam UMC, Amsterdam, Netherlands,* [8]*Erasmus MC, Rotterdam, Netherlands,* [9]*LUMC, Leiden, Netherlands.*

Background: Preconception carrier testing (PCT) for autosomal recessive (AR) and/or X-linked conditions can be offered to enhance couples' reproductive decision-making. Consanguineous couples have an increased risk to be a carrier couple for AR conditions. Ideally, testing is performed before conception, but is often requested during pregnancy. Our aim for this study was twofold: 1) to determine diagnostic yield for PCT in consanguineous couples during pregnancy and 2) to gain insight into reproductive decision-making by examining reproductive follow-up.

Subjects and methods: A hundred pregnant consanguineous couples (aged ≥ 18), referred and counselled for PCT by clinical geneticists were included. Exome-based PCT for AR conditions with a large gene panel (>2000 genes) was performed. Diagnostic yield was defined as the percentage of couples who were identified as carrier couples for a condition they were not yet aware of. Reproductive decisions were extracted from patients' medical files.

Results: Diagnostic yield was 25% (25/100). AR conditions couples were carriers of were diseases with a range in severity and variable expressivity; examples were Familial Mediterranean Fever and Joubert Syndrome. Pregnant couples made different decisions after test results, including invasive prenatal testing, continuation and termination of affected pregnancies, postnatal genetic testing and decisions regarding peripartum care. In two cases the PCT resulted in explanations for foetal abnormalities that were not explained by prenatal testing.

Conclusion: These results show that expanded carrier testing during pregnancy in consanguineous couples has a high diagnostic yield. Couples use these PCT results to make different reproductive decisions.

P02.055.A Age-related trends in embryo eupoidy, aneuploidy, and mosaicism: refining the indications for preimplantation genetic testing (PGT-A)

Mariia Alekseevna Ishchuk, *Elena A. Lesik, Olga V. Malysheva, Valeriia Yu Zhilyaeva, Yanina M. Sagurova, Kseniia V. Obedkova, Alexander M. Gzgzyan, Natalia I. Tapilskaya, Olesya N. Bespalova, Evgeniia M. Komarova*

Research Institute of Obstetrics and Gynecology named after D.O. Ott, Saint Petersburg, Russian Federation.

Background: Aneuploidy, mosaicism, and euploidy in embryos significantly impact the success rates of in vitro fertilization (IVF). Understanding their distribution across different maternal age groups is crucial for optimizing treatment strategies.

Material and methods: Data on aneuploid, mosaic, and euploid embryos (n = 1010) were collected from patients (n = 451) undergoing Preimplantation Genetic Testing for Aneuploidy (PGT-A) at an IVF clinic. The study included 13 age groups ranging from 20–21 years to 46–47 years. Proportions of each embryo type were calculated for each group.

Results: The proportion of aneuploid embryos increased significantly with maternal age, peaking in older age groups. Euploid embryos predominated until the age of 38 years. In the 38–39 year group, the proportions of euploid and aneuploid embryos were approximately equal, after which the proportion of aneuploid embryos surpassed that of euploid ones. Mosaic embryos remained relatively stable up to the age of 36–37 years, showing a slight increase thereafter but not as pronounced as the rise in aneuploid embryos.

Conclusion: Maternal age critically influences embryo quality, with increasing aneuploidy rates observed with advancing age. We propose revising the recommended age for PGT-A from 35 to 38–39 years based on these findings. This adjustment could optimize patient selection for genetic testing and improve IVF outcomes. Clinicians should consider these trends when advising patients on fertility treatments and associated risks.

The results of PGT-A of embryos from patients of different age groups

AGE GROUPS	ANEUPLOID, %	MOSAIC, %	EUPLOID, %
20–21	22.22	22.22	55.56
24–25	16.67	0	83.33
26–27	0	30.77	69.23
28–29	47.37	10.53	42.11
30–31	40.74	11.11	48.15

P02.056.B Chromosomal aberrations and Y Chromosome microdeletions in infertile men: a retrospective study in Eastern Morocco

Fatima Ezzahra Aouni[1,2], *Fatima zahra Smaili*[1,2], *Khawla Zerrouki*[1,2], *Jihane Ahmidi*[1,2], *Sara Meziane*[1,2], *Kaoutar Ahmidouch*[1,2], *Ali Barki*[3,2], *Hafsa Taheri*[4,2], *Ahmed Mimouni*[4,2], *Mariam Tajir*[1,2]

[1]*Medical Genetics Laboratory, Central Laboratory, Mohammed VI University Hospital, Oujda, Morocco,* [2]*Faculty of Medicine and Pharmacy, Mohammed Premier University, Oujda, Morocco,* [3]*Urology Department, Mohammed VI University Hospital, Oujda, Morocco,* [4]*Medically Assisted Procreation Unit, Mohammed VI University Hospital, Oujda, Morocco.*

Background: Male infertility accounts for 50% of infertile couples. Genetic factors are identified in 15–30% of infertile men. Chromosomal aberrations and AZF microdeletions are the most important genetic causes of male infertility. Our objective is to evaluate, for the first time in the Eastern region of Morocco, the frequency of chromosomal abnormalities and AZF microdeletions in infertile men.

Material and methods: This is a 4-year retrospective study involving 113 patients (70 non-obstructive azoospermic and 43

oligozoospermic men) referred to our medical genetic laboratory at Mohammed VI University Hospital Center of Oujda for genetic exploration. We performed postnatal constitutional karyotyping on venous blood in all patients in our series. Multiplex PCR of the AZF regions of the Y chromosome was performed on 38 patients.

Results: Cytogenetic analysis identified chromosomal aberrations in 13% of cases (14/113), with a frequency of 15.94% in patients with azoospermia and 6.97% in those with severe oligozoospermia. Klinefelter syndrome was the most frequent chromosomal abnormality (n = 9). Structural chromosomal aberrations were observed in four patients: three Robertsonian translocations and one mosaic deletion of the long arm of the Y chromosome. AZF microdeletions were detected in 10.52% of tested cases (4/38), two patients with AZFc microdeletion and two concerning AZFbc. All patients in our series with genetic abnormalities benefited from genetic counseling.

Conclusion: Study of chromosomal aberrations and Y chromosome microdeletions remains a good first-line strategy in the public health system for an accurate diagnosis, appropriate genetic counseling, and improved infertile men management.

P02.057.C Study of genomic biomarkers associated with preterm birth

Laura Pranckėnienė[1], *Alina Urnikytė*[1], *Svetlana Dauengauer-Kirlienė*[2], *Austėja Letukienė*[1], *Ingrida Domarkienė*[1]

[1]*Translational health research Institute, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Department of Human and Medical Genetics, Biomedical Science Institute, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.*

Background: Spontaneous preterm birth (PB), defined as delivery before 22–37 weeks of gestation without medical or surgical induction, is a significant public health challenge with substantial impacts on neonatal mortality and long-term morbidity. Genetic predisposition plays a critical role in PB, with maternal and fetal genetic variants influencing susceptibility through pathways involved in inflammation, immunity, uterine contractility, and cervical remodeling. Fetal genetic variations responsible for crucial organogenesis, affecting placental development and maternal-fetal immune interactions further contribute to PB risk and may lead to adverse health outcomes, especially attention-deficit/hyperactivity disorder and autism spectrum disorders. Additionally, gene-environment interactions, where genetic predisposition amplifies sensitivity to external factors like infection, maternal stress, or smoking, exacerbate the condition's complexity. Advances in genetic studies, such as genome-wide association studies (GWAS), provide valuable insights into PB's underlying mechanisms, paving the way for identifying at-risk individuals and developing targeted interventions. This project aims to identify potential biomarkers for PB on women and preterm infants, to investigate their functional mechanisms, and to understand the early molecular pathways leading to PB.

Material and methods: The study included 25 healthy trios (full-term newborn, mother, and father) and 16 PB trios (mother, father, and preterm newborn). Whole-genome genotyping was performed using the Illumina Infinium Global Diversity 1.8 M Array. Data processing included imputation, annotation, de novo SNPs and GWAS analysis.

Results: Further genotyping and detailed data analysis are currently ongoing and results will be presented at the conference.

Background: Common fragile sites (CFS) are genomic regions prone to breakage under DNA replication stress, therefore impairments in DNA damage repair pathways may exacerbate this fragility. While CFS are known to be involved in various genetic disorders, aside from the fragile X premutation, their role in primary ovarian insufficiency (POI) is not fully understood. Chromosome band 16q22.1 contains two CFS, whose connection to infertility is uncertain. This study aims to investigate whether POI patients may exhibit higher chromosome instability (CI) due to impaired NHEJ, HR, and ATM DNA repair pathways.

Material and methods: CI was evaluated on blood samples from 7 POI patients with negative exome and *FMR1* premutation to analyze the DNA repair pathways. A control was included for each sample. Analysis was performed on 100 metaphases from each experiment. Each cell was scored for the number and type of CI abnormalities.

Results: No statistically significant differences were found in NHEJ, HR, or ATM-dependent DNA repair pathways between POI patients and healthy controls. Intriguingly, among the POI patients, the sample displaying the greatest number of breaks across all experimental conditions exhibited a fragile site at 16q22.1, as revealed by conventional cytogenetic analysis.

Conclusion: While our sample size limits definitive conclusions, the observed correlation between the fragile site and increased genomic instability deserves further investigation. It is important to determine whether these breaks in POI patients, both with and without the fragile site, consistently occur at 16q22.1. A compromised DNA repair gene in this region may contribute to POI.

P02.059.A Detection of a novel small non-coding RNA in seminal plasma of fertile men

K. Shahabi[1], *Y. Ghaffari*[2], *F. Piryaei*[1];

[1]*Research Center for Molecular Medicine, Institute of Cancer, Avicenna Health Research Institute, Hamadan University of Medical Sciences, Hamadan, Iran, Islamic Republic of,* [2]*Department of*

Molecular Genetics, Faculty of Biological Sciences, Tarbiat Modares University, Tehran, Iran, Tehran, Iran, Islamic Republic of

Background: Small non-coding RNAs (ncRNAs) in seminal plasma are known as potential biomarkers for diagnosing and differentiating types of male infertility. This study focuses on detection of a novel ncRNA, namely novel_seq32, in seminal plasma of normal fertile men for the first time. This sequence was firstly identified by authors in the previous research in human testis tissue.

Material and methods: Twenty seminal plasma samples were collected in accordance with WHO guidelines. The total RNA was isolated using a column kit (Pars Toos, Iran), yielding concentrations between 130 and 250 ng with a 260/280 absorption ratio of 1.7 to 2. Quantitative Real-Time PCR (qRT-PCR) was utilized to validate the presence of this novel sequence in seminal plasma. U6 was selected as the reference gene, and miR-888-5p was utilized to validate qRT-PCR accuracy. Bioinformatics analysis was performed.

Results: The mature sequence of novel_seq32 is GTCACAAATTCGTATCTAGGGGA (- strand on Chr17, Start: 46657214, End: 46657303). The sequence was detected in all samples by qRT-PCR. It also was blatted to a region human genome including HOXB3 and HOXB-AS3 genes. This finding indicates a gene regulatory cluster involving in cell growth and differentiation.

Conclusion: These findings suggest that novel_seq32 has potential as a biomarker for impaired parameters in semen analysis and forensic studies in the future.

P02.060.B A novel homozygous *PSMC3IP* variant in a patient with hypergonadotropic hypogonadism and short stature

Zehra Yavas Abali[1], *Esra Dirimtekin*[2], *Mehmet Eltan*[3], *Ilknur Kurt*[1], *Tulay Guran*[1], *Abdullah Bereket*[1], *Geckinli Bilgen Bilge*[2], *Demircioglu Serap*[1]

[1]*Marmara University School of Medicine Department of Pediatric Endocrinology, Istanbul, Turkey,* [2]*Marmara University School of Medicine Department of Medical Genetics, Istanbul, Turkey,* [3]*Sancaktepe Research and Training Hospital, Department of Pediatric Endocrinology, Istanbul, Turkey.*

Background: The *PSMC3IP* gene on chromosome 17q21.2 encodes a protein crucial for meiotic recombination. Biallelic pathogenic variants in *PSMC3IP* are linked to ovarian dysgenesis (OD), a genetically heterogeneous disorder causing amenorrhea and streaked gonads. Despite advances in next-generation sequencing (NGS), the etiology of OD remains unknown in most cases.

Case report: An 11-year-7-month-old girl presented with short stature. She was born at term with a birth weight of 3000g, and her parents were first-degree cousins with no history of premature menopause or infertility in the family. Her height and weight were 137.4 cm(−1.9SDS), and 39.1 kg(−0.3SDS), respectively. Midparental height was -2.3SDS. She was prepubertal with no systemic abnormalities, and bone age was delayed (10 years). Gonadotropins were elevated with, low estradiol, and reduced AMH. Pelvic ultrasonography failed to visualize the uterus and ovaries. Hearing and cardiac assessments were normal. GH stimulation testing revealed GH deficiency (GHD). The pituitary MRI was normal. Due to poor growth velocity, rGH therapy was commenced. Puberty progressed to Tanner stage 3 spontaneously. Chromosome analysis was 46,XX. Clinical exome sequencing identified a novel homozygous *PSMC3IP* variant, NM_016556:c.261dup/p.(Val88-Serfs*12), classified as likely pathogenic and not found in gnomAD. Both parents were heterozygous.

Conclusion: We report a novel variant in *PSMC3IP* causing OD and GHD by expanding the phenotypic spectrum of this condition, suggesting short stature as a novel feature. Additional cases are needed to refine the phenotype, and wider use of NGS will improve diagnostic accuracy.

P02.061.C Recurrent pregnancy loss and chromosomal anomalies: insights from a single-center analysis in Turkey

Cisem Cinar, *Senol Demir, Ceren Alavanda*

Department of Medical Genetics, SBU. VAN EDUCATION AND RESEARCH HOSPITAL, VAN, Turkey.

Background: Recurrent pregnancy loss (RPL), defined as the loss of two or more consecutive pregnancies before the 20th to 24th week of gestation, affects approximately 1–5% of couples. Constitutive chromosomal abnormalities are a significant cause of RPL, as chromosomal imbalances in the gametes of carriers may lead to embryonic lethality. This study aimed to investigate chromosomal abnormalities in couples with a RPL history.

Material and methods: We conducted a retrospective analysis of the medical records of 678 couples(1356 patients) who were admitted to Van Education and Research Hospital between 2017 and 2024. Peripheral blood lymphocyte karyotyping was performed using GTG banding techniques following standardized protocols.

Results: Chromosomal aberrations were detected in 4.12% (28/678) of couples, aligning with the 2–5% prevalence range reported in the literature for RPL populations. Among affected individuals, 57.1% (16/28) had structural abnormalities, including 12 balanced translocations, two inversions, and two Robertsonian translocations. Numerical chromosomal abnormalities were detected in 12 individuals (42.9%, 12/28), including four cases of 47,XYY, 47,XXX, or marker chromosome abnormalities. The remaining eight cases exhibited mosaicism, with sex chromosome mosaicism observed in females and marker chromosome mosaicism in one male and one female. These findings are consistent with previously reported data in Turkey.

Conclusion: Chromosomal anomalies, particularly translocations and rare mosaicisms, play a critical role in RPL etiology. Cytogenetic analysis is essential for genetic counseling and optimizing reproductive outcomes. These findings emphasize the necessity of comprehensive genetic investigations to elucidate RPL pathogenesis and develop targeted management strategies.

P03 Prenatal Genetics

P03.001.D Whole exome sequencing (WES) increases the molecular diagnosis of 106 foetuses with structural anomalies negative at chromosomal microarray analysis

Vanessa Rebecca Gasparini[1,2], *Beatrice Spedicati*[1,2], *Giulia Pianigiani*[1,2], *Aurora Santin*[1,2], *Ilaria Falcomer*[1], *Daniela Mazzà*[2], *Elisa Paccagnella*[2], *Domizia Pasquetti*[2], *Elisa Rubinato*[2], *Claudio Granata*[3], *Flora Maria Murru*[3], *Maurizio Pinamonti*[4], *Rossana Bussani*[4], *Ilaria*

Fantasia[5], Tamara Stampalija[1,5], Paolo Gasparini[1,2], Stefania Zampieri, PhD[2], Giorgia Girotto[1,2]

[1]Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy, [2]Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy, [3]Radiology Department, Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy, [4]Department of Pathology, University of Trieste, Trieste, Italy, [5]Unit of Fetal Medicine and Prenatal Diagnosis, Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy.

Background: Foetal structural abnormalities (3% of all pregnancies) range from isolated to multisystemic malformations. WES analysis has recently provided an accurate molecular diagnosis when chromosomal microarrays (CMA) failed to identify their genetic aetiology.

Material and methods: 106 foetuses presenting structural malformations and negative to CMA analysis were recruited. After multidisciplinary consultation and detailed phenotypical characterisation, in trio WES analysis on genomic DNA extracted from chorionic villi, amniotic fluid or fetal tissue obtained after pregnancy termination was performed. Minigene assay was conducted to functionally characterise selected splicing variants of uncertain significance (VUS).

Results: 51% of the foetuses in our cohort presented with multisystemic malformation, while 49% presented a single major malformation (i.e. fluid accumulation, urogenital, cardiac, skeletal and central nervous system anomalies). WES analysis, based on clinical features according to the human phenotype ontology terms, identified 37 variants in 31 genes, the majority (46%) being classified as likely pathogenetic. Two selected splicing variants in *INPPL1* and *RHOA* genes, initially classified as VUS, were functionally characterised by minigene assay thus confirming their pathogenetic effect. Notably, a novel missense variant in *ZNF292* gene was firstly detected in a prenatal setting. Altogether, the WES diagnostic yield was 34.9% (37/106 foetuses), with the highest rate for urogenital and skeletal anomalies.

Conclusion: This study supports the utility of an integrated clinical and molecular approach in the challenging Italian prenatal setting, offering couple counseling and recurrence risk estimation. Furthermore, the implementation of minigene assay in the laboratory routine could improve the characterisation of clinically relevant non-coding variants.

P03.002.A Targeted long-read sequencing of native DNA for genetic disease diagnostic and screening research

***Sarah Bowman Kingan[1]**, Jocelyne Bruand[2], Jeff Zhou[1], Tom Mokveld[1], Guilherme De Sena Brandine[3], Egor Dolzhenko[1], Michael A. Eberle[2], Duncan Kilburn[1]*

[1]PacBio, Menlo Park, CA, USA, [2]PacBio, San Diego, CA, USA, [3]PacBio, London, United Kingdom.

Background: Despite enormous advances in DNA sequencing, the causal mutations of many human diseases remain challenging to characterize with standard methods. Examples include fragile X syndrome and Friedreich's ataxia, caused by expansion of short tandem repeats, congenital adrenal hyperplasia (associated with a segmental duplication) and hemophilia A (caused by large inversions). The adoption of long-read sequencing has the potential to improve and simplify sequencing and analysis of these complex regions. In addition, the ability to detect methylation enables simultaneous generation of sequence-level and epigenetic data. We present new panel content for the PureTarget assay, which uses the CRISPR/Cas9 system to generate targeted sequencing libraries of native DNA, sequenced with long and accurate HiFi sequencing.

Material and methods: Coriell DNA samples with known mutations were prepared with the PureTarget assay and sequenced on Revio and Vega systems. Samples were analyzed with a novel pipeline which relies on the TRGT and Paraphrase genotyping tools.

Results: PureTarget allows for the evaluation of a panel of targets in multiplexed samples in a single assay and analysis workflow. In samples with known pathogenic mutations, we demonstrate the ability to define and resolve structurally complex repeat alleles (as needed for *RFC1*) and resolve structural variants in genes relevant for carrier screening such as *CYP21A2*. For *FMR1* this approach can simultaneously size repeat expansion, detect methylation, and identify AGG interruption sequences.

Conclusion: The PureTarget assay and software pipeline allows for a comprehensive characterization of repeat expansions and other challenging targets.

Background: Placental epigenomics provides valuable insights on maternal-fetal interactions in relation to pregnancy outcomes, and health later in life. This study aimed to explore the relationship between maternal and fetal genomic data, and placental DNA methylation (DNAm) patterns by identifying *trans* and *transgenome* methylation quantitative trait loci (*trans*/*trangenome*-mQTLs).

Material and methods: We analyzed 337 placenta samples from the INMA project with the EPIC and GSA arrays from Illumina. We also genotyped the DNA extracted from the blood of the donor mothers, using the GSA array. mQTLs were generated using TensorQTL, with placental DNAm modelled as a function of genotype and covariates including DNAm and genotype principal components, cell type estimations and fetal sex. T*rans*-mQTLs, defined as associations between fetal genotype and placental DNAm (SNP-CpG distance >0.5 Mb); and *transgenome*-mQTLs, defined as associations between maternal genotype and placental DNAm, were identified.

Results: After Bonferroni correction ($p = 1.57 \times 10^{-14}$), we identified 98,553 *trans*-mQTLs, comprising 1,618 CpGs and 61,172 SNPs. The *transgenome*-mQTL analysis revealed 2,731 associations, including 107 CpGs and 2,682 SNPs. Interestingly, 82 mQTLs found in the *transgenome*-mQTL dataset did not appear in the *trans*-mQTL results, with six unique CpGs under exclusive maternal control. These CpGs were located on active chromatin and promoter regions of genes related to brain development, stress response and cell cycle.

Conclusion: These findings underscore the role of the maternal genetic background in the regulation of placental DNAm, with particular impact on key processes such as brain development and cell cycle regulation.

P03.004.C Technical advances in non-invasive pre-implantation genetic screening at Zan Mitrev Clinic

Marija Gjorgjievska[1], *Daniela Hristov*[2], *Sanja Mehandziska*[1], *Djansel Bukovec*[1], *Ivan Kungulovski*[1], *Zan Mitrev*[1], *Goran Kungulovski*[1]

[1]*Zan Mitrev Clinic, Skopje, North Macedonia, The Republic of,* [2]*Remedika Hospital, Skopje, North Macedonia, The Republic of.*

Background: Non-invasive pre-implantation genetic screening (niPGS) is an advanced reproductive medicine technique that enables embryo analysis for chromosomal abnormalities without biopsy. Using cfDNA extracted from the culture medium in which embryos develop, niPGS offers a safer, non-invasive alternative to traditional PGS methods which involve extracting cells from the embryo.

Material and methods: After intracytoplasmic sperm injection, the fertilized oocytes were cultured individually from day-1. On day-3, the embryos were transferred in a 10 µl blastocyst medium and cultured until day-5/6. Readapting the Ion ReproSeq PGS kit, originally designed for biopsied material, we analyzed 33 spent-medium samples from 33 pre-selected cultured embryos, plus 4 negative controls (cultured-medium blank and water).

Results: Over 100,000 sequencing reads were obtained for 76% of the samples, while negative controls had a median of 8,853 reads per sample. Data acquisition failed for 24% of samples. Using the ReproSeq kit, we detected 52% euploid, and 48% aneuploid and/or mosaic samples, demonstrating its effectiveness in identifying diverse chromosomal abnormalities in embryos. The median time from sample collection to result was 3 days.

Conclusion: Traditional PGS kits can be readapted for use in non-invasive settings with an acceptable failure rate. However, cross-validation studies with biopsied material, are essential to confirm the method's accuracy and reliability. To enhance the cost-effectiveness of niPGT, novel approaches such as Nanopore sequencing can eliminate the need for streamlining the large number of samples per sequencing run. NiPGS holds great potential as a valuable tool to increase the success rate of in vitro pregnancies.

P03.005.D Placental mosaicism for autosomal trisomies and structural variants (Award Candidate)

Simon Horsholt Thomsen[1,2,3], *Ida C. B. Lund*[1,2,4], *Iben Bache*[5], *Naja Becher*[1,2,4], *Ida Vogel*[1,6]

[1]*Center for Fetal Diagnostics, Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark,* [2]*Dept. of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark,* [3]*Dept. of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark,* [4]*Dept. of Biomedicine, Aarhus University, Aarhus, Denmark,* [5]*Dept. of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark,* [6]*Dept. of Obstetrics and Gynaecology, Aarhus University Hospital, Aarhus, Denmark.*

Background: Mosaicism, the presence of two or more cell lines originating from the same zygote, is identified in 2–4% of chorionic villus samples (CVS). Estimating fetal prognosis based on a mosaic CVS result is challenging. Mosaicism may indicate true fetal mosaicism (TFM), potentially causing fetal disease, or confined placental mosaicism (CPM), which can lead to placental dysfunction. This study aimed to provide aberration-specific risk estimates for TFM and adverse outcomes in cases of CPM.

Material and methods: We analysed all Danish singleton pregnancies with mosaicism involving an autosome (trisomies and structural variants) detected in CVS from 1983 to 2021 using data from the Danish Cytogenetic Central Registry and the Danish Fetal Medicine Database. Information on pre- and postnatal cytogenetic analyses and pregnancy outcomes was collected. Risk estimates for TFM, preterm birth (<37 weeks), and low birth weight (<2.3 percentile) were calculated.

Results: Among 948 identified cases, 779 (82%) had follow-up analyses.The overall TFM risk was 18% (95%CI: 15.3;20.9) and varied by aberration: common trisomies (13, 18, 21): 25% (17.2;33.2), rare autosomal trisomies (RAT): 10% (6.9;12.9) structural variants (SV): 28% (22.8;34.3). For CPM-pregnancies, 13% (10.3;16.5) gave birth before 37+0 (common trisomies: 10% (4.0;19.0), RAT: 16% (12.1;21.2), SV: 9% (5.0;15.1)) and 12% (8.9;14.8) had low birth weight (common trisomies: 4% (0.9;12.0), RAT: 16.6% (12.4;21.6), SV: 6% (2.5;10.9)).

Conclusion: Risk of TFM is highly dependent on the specific aberration, which should be communicated to pregnant couples along with the substantial risk of adverse outcomes in CPM for specific aberrations.

[1]Centre de Génétique, FHU-TRANSLAD, CHU Dijon Bourgogne, Centre de Référence Maladies Rares Anomalies du Développement et Syndromes Malformatifs, Dijon, France, [2]Inserm – Université Bourgogne Europe UMR1231 GAD, Dijon, France, [3]Service de Génomique Médicale, Laboratoire de Génomique Médicale, CHU Dijon Bourgogne, Dijon, France, [4]Centre de Référence Maladies Rares Anomalies du Développement et Syndromes Malformatif, Service de génétique, CHU Montpellier, Montpellier, France, [5]Pédiatrie, Centre de Référence Maladies Héréditaires du Métabolisme Hépatique, Hôpital Antoine Béclère, APHP Université Paris-Saclay, Clamart, France, [6]Service de Génétique, CHU Angers, Angers, France, [7]Service de Génétique Médicale, Institut de Génétique Médicale d'Alsace, Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [8]Génétique Clinique, Centre de Référence Maladies Rares CLAD-Ouest, ERN-ITHACA, FHU GenOMedS, CHU de Rennes, Rennes, France, [9]Centre de Genetique CHU de DIJON, DIJON, France, [10]Service de gynécologie-obstétrique, CPDPN Paris Saclay, hôpital Antoine-Béclère, AP-HP, université Paris Saclay, Clamart, France, [11]Service de génétique, CHU de Bordeaux, Bordeaux, France, [12]Service Gynécologie Obstétrique, Hôpital Louis Mourier, Hôpitaux Universitaires Paris Nord Val de Seine, Paris, France, [13]Laboratoire Eurofins Biomnis, Département de génétique, Lyon, France.

Background: Prenatal management of congenital malformations (3% of pregnancies) relies on rapid causal diagnosis. Chromosomal microarray (CMA) and exome sequencing (ES) face delays of 2–6 weeks and are often used sequentially, which remains burdensome for couples. Since genome sequencing (GS) can simultaneously identify single, copy number, and structural variants, its use in prenatal diagnosis as a first-line test with suitable turnaround-time (TAT) could be of great interest. A French pilot study evaluates the feasibility and diagnostic yield of GS as a first-line test with a TAT of ≤7-workdays.

Methods: Ultra-rapid GS was performed alongside CMA/ES in 90 pregnancies (8 centers) with either two anomalies or one with strong suspicion of genetic cause. Only ACMG class 4/5 variants were considered as positive diagnosis.

Results: To date, GS TAT of ≤7-workdays was met for 49/68 (72%) (median 6.5 workdays without 2 outliers caused by variant validation to exclude false-positive, compared to a median of 10 and 15 workdays for CMA and ES, respectively). The transport and wet lab phase was the most common cause of delay, although other limitations were encountered: excessive bioinformatics step (2), report generation (2). The diagnostic rate was 17/68 (25%). In addition, 11 interesting variants of uncertain significance were reported to clinicians. GS was highly concordant with CMA/ES (98.5%).

Conclusions: These preliminary results demonstrate that prenatal GS is feasible with a TAT of ≤7-workdays and similar diagnostic yield to ES/CMA combined. However, such ultra-rapid TAT presents significant constraint. All inclusions will be completed by the time of ESHG.

P03.007.B Redefining pre-conception screening: rare disease detection and equity through couple whole exome sequencing

***Hadas Ityel**[1,2,3], Ortal Barel[4,3], Elisheva Javasky[4], Yulia Khavkin[4], Tal Zinger[4], Ifat Bar-Joseph[4], Nitzan Kol[4], Tamar Shohat[2], Motti Shohat[2,4,5]*

[1]The Institute for Rare Diseases, Danek Gertner Institute of Human Genetics, Sheba Medical Center, Ramat Gan, Israel, [2]Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel, [3]Equally contributing authors, -, Israel, [4]The Genomic Unit, Sheba Cancer Research Center, Ramat Gan, Israel, [5]The Genetic Institute of Maccabi Health Services, Rehovot, Israel.

Background: The standard ethnicity-based carrier screening (EBS) in Israel has successfully reduced the prevalence of diseases, such as Tay-Sachs in Ashkenazi Jews and Infantile neuroaxonal dystrophy in Israeli Bedouin. However, this targeted approach is

Table 1. P/LP variants detected by pre-conception couple exome screening (pCCE) across 483 families from diverse ethnic groups in Israel.

	Number of pCCE-detected events	% of events missed by standard ethnic-based carrier screening	Number of pCCE-detected genes	% of Genes missed by standard ethnic-based carrier screening	Number of Couples/ Individuals with pCCE-detected Event	% of Couples /Individuals missed by standard ethnic-based carrier screening
Shared AR (OMIM)	75 (bi-allelic P/ LP variants)	73/75 (97.3%)	36	26/36 (72.2%)	67 (Couples)	65/67 (97%)
Autosomal Recessive (AR)	1,335	1,102/1,335 (82.5%) (genes missing in EBS)	386	255/386 (66.1%)	480 (Couples)	426/480 (88.7%) (genes missing in EBS)
X-linked (XL)	10	10/10 (100%)	8	8/8 (100%)	10 (Couples)	10/10 (100%)
Expanded secondary findings panel	155	NA	60	NA	147 (Individuals)	NA

Shared AR (OMIM) includes all P/LP mutations across all recessive OMIM genes. **Autosomal Recessive (AR)** includes P/LP mutations detected in either parent among the Israeli Extended Gene Panel. **X-linked (XL)** includes clinically significant XL disorders. **Expanded secondary findings panel** of 180 actionable genes, including the American College of Medical Genetics and Genomics secondary finding list (ACMG SF v3.2).

inherently limited, overlooking rare variants and genetic risks in diverse populations.

Methods: We developed a pre-conception couple exome screening (pCCE) approach screening for pathogenic (P) and likely pathogenic (LP) variants in the autosomal recessive (AR) and X-linked (XL) disorders, and additionally reporting expanded secondary findings panel with potential health implications for the couple.

Results: We retrospectively analyzed 483 consecutive couples of diverse ethnicities collected at a single center between 12/2023-01/2025 using the pCCE approach. Our results, summarized in Table 1, highlight the inclusiveness of detectable P/LP variants by pCCE compared to previously used EBS. Our pCCE detected 75 shared carrier status in AR disorders, spanning 36 different genes. Notably, EBS has no representation for 26/36 (72.2%) of these genes, and 73/75 (97.3%) of the specific variants detected. Additionally, EBS missed all XL variants 10/10 (100%) and 155 expanded secondary findings pCCE results.

Conclusion: pCCE offers three critical advantages: (1) Detecting rare diseases that limited-gene panels fail to detect; (2) Facilitating ethnicity-agnostic variant screening of genetic risks across all populations; (3) Providing couples with actionable insights about their health through the secondary findings. Taken together, our approach enables informed reproductive choices while alleviating ethnicity bias and allowing for a higher yield in capturing P/LP in diverse populations.

P03.008.C Analysis of DNA methylation abnormalities in chorionic villi in obstetric syndromes

Andrew Zuev[1], *Daniil Shevtsov*[1,2], *Victoria Demeneva*[1], *Oksana Vasilyeva*[1], *Elena Sazhenova*[1], *Ekaterina Tolmacheva*[1], *Tatiana Nikitina*[1], *Stanislav Vasilyev*[1,2]

[1]*Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation,* [2]*National Research Tomsk State University, Tomsk, Russian Federation.*

Background: The physiological course of pregnancy is supported by the functioning of many cell types, among which the chorion performs functions that ensure normal placentation. Aberrant DNA methylation, shown in some obstetric syndromes, is another factor that disrupts this process. Given the pathogenetic similarity of the syndromes, it is assumed that there are common methylation patterns for these pathologies, with unique patterns observed in spontaneous abortions (SA) representing an extreme phenotype.

Material and methods: Chorionic DNA methylation profiles of spontaneous (n = 7) and induced abortions (n = 7) were analyzed using reduced representation bisulfite sequencing. Methylation data for preterm labor, preeclampsia and intrauterine growth restriction were obtained using Genome Expression Omnibus public data repository - GSE100197, GSE74738, GSE115508, GSE197795. Differentially methylated genes (DMGs) were obtained for each syndrome. Common and specific DMGs were then identified and annotated. Expression of selected genes was confirmed by immunohistochemistry.

Results: *CLEC16A* was hypermethylated for all pathologies and 237 DMGs were specific for SA. The functional annotation of these specific DMGs revealed a cluster involved in the genesis and function of primary cilia and another cluster associated with epidermal growth factor. DMGs involved in embryonic development (*CMIP, EGFR, FBN2, GLI3* and *PBRM1*) showed different expression in chorionic villi of SA compared to induced abortions.

Conclusion: The analysis revealed a substantial number of DMGs specific to SA. The identification of gene clusters may indicate a functional relationship with impaired embryonic development, and changes in gene expression in SA suggest a potential role in the formation of a lethal phenotype.

P03.009.D Ultrasound and genetic diagnosis of fetal skeletal dysplasias in a fetal cohort

Giulia Vitetta[1], *Isabelle Bacchi*[1], *Sara Calabrese*[1], *Luca Caramanna*[1], *Emanuele Coccia*[1], *Lucrezia Giannini*[1], *Agnese Luglio*[1], *Elena Luppi*[1], *Andreina Minicucci*[1], *Adelaide Peruzzi*[1], *Andrea Pietra*[1], *Eliana Zacchi*[1], *Antonella Tanzariello*[1], *Maria Carla Pittalis*[1], *Luca Sangiorgi*[2], *Antonio Novelli*[3], *Giulia Lanzoni*[1]

[1]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy,* [2]*Department of Medical Genetics and Rare Orthopaedic Diseases, and CLIBI Laboratory, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy,* [3]*Laboratory of Medical Genetics, Translational Cytogenomics Research Unit, Bambino Gesù Children Hospital IRCCS, Rome, Italy.*

Background: Skeletal dysplasias are a heterogeneous group of genetic disorders resulting from mutations in more than 500 genes involved in bone formation, mineralization, and cartilage development. We report the ultrasound and genetic results of 27 cases of fetal skeletal dysplasias, retrospectively collected from 2019 to 2024.

Material and methods: Selection was based on women who underwent prenatal genetic counseling at the Policlinico S. Orsola Genetics Unit for ultrasound findings revealing skeletal dysplasia. Genetic tests including karyotype, CMA analysis, targeted gene testing and NGS panels were performed.

Results: The average gestational age at the first suspicion of skeletal dysplasia was 20+6 days, though severe cases showed abnormalities such as hydrops and micromelia since the first trimester. Among the 21 women who underwent invasive procedures, 15 (71.4%) received a molecular diagnosis. Five cases had pathogenic mutations in type I and II collagen genes. Three cases involving *KIAA0753, HSPG2, DYNC2H1* genes were recessive, with heterozygous variants inherited from both parents. One fetus carried a maternally inherited X-linked pathogenic variant in the *EBP* gene, while the remaining diagnoses were de novo mutations.

Conclusion: Skeletal dysplasias are primarily genetic disorders, however their large number and phenotypic variability makes diagnosis complex. The combination of detailed ultrasound assessment and advanced genetic analyses enhances diagnostic accuracy. Early detection allows for more informed reproductive choices, and a confirmed genetic diagnosis can impact recurrence risk assessments for affected couples.

[1]Rare Diseases Unit, ASST Papa Giovanni XXIII, Bergamo, Italy, [2]Medical Genetics Laboratory, ASST Papa Giovanni XXIII, Bergamo, Italy, [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [4]IRCCS San Gerado dei Tintori, Monza, Italy, [5]Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milano, Italy, [6]Medical Genetics Unit, ASST Fatebenefratelli Sacco, Milano, Italy, [7]Department of Obstretics and Ginecology, ASST Papa Giovanni XXIII, Bergamo, Italy, [8]Genomics and Clinical Genetics Unit, IRCCS Istituto G. Gaslini, Genova, Italy, [9]Pediatric Department, ASST Lariana - S. Fermo della Battaglia, Como, Italy, [10]Medical Genetics Laboratory, IRCCS San Gerardo dei Tintori, Monza, Italy.

Background: Whole Exome Sequencing (WES) and Whole Genome Sequencing (WGS) are becoming more widely available in genetic disease diagnosis. However, data on their clinical utility and integration into clinical management during pregnancy remain limited.

Material and methods: We report our 9-year experience implementing prenatal WES and WGS in a retrospective cohort of 322 fetuses with ultrasound anomalies, both in ongoing pregnancy (43,5%) and terminated pregnancy (56,5%). Two hundred thirty-five trio-WES and 87 trio-WGS were performed on DNA extracted from fetal samples and parents' peripheral blood. Fetal phenotypes were classified into predefined subgroups based on the sonographic findings at the time of sample collection and/or autopsy findings.

Results: The overall diagnostic yield was 32.4%, varying between different clinical categories. We evaluated the integration and timing of WES/WGS into the prenatal diagnostic care pathway, the clinical utility, the potential impact on pregnancy management, the outcome (especially regarding continuation or interruption of pregnancy on the result), and parents' reproductive decisions.

Conclusion: Our experience supports using WES/WGS in ongoing pregnancies, confirming their high potential for identifying the molecular etiology of fetal ultrasound anomalies. However, it also shows several challenges associated with their use in a prenatal setting, including complexities associated with clinical phenotyping, technical considerations, timing, and interpretation of results. Both pre- and post-test genetic counseling in the context of a multidisciplinary team remains crucial in giving indications for analysis and in communicating the test results with implications for the fetus and the couple.

P03.012.C The diagnostic yield and genetic findings of prenatal whole exome sequencing of fetal sonographic abnormalities: A retrospective study from Qatar

***Mashael Al-Shafai[1]**, Heba Almaghrbi[1], Sumaya Abib[1], Karen El-Akouri[2], Maria Farag[2], Zoulikha Rezoug[1], Tawfeg Omran[2], Sara Musa[2]*

[1]Qatar University, Doha, Qatar, [2]Sidra Medicine, Doha, Qatar.

Background: Prenatal karyotype (KT) and chromosomal microarray (CMA) are diagnostic in ~9% and ~6% of cases with fetal sonographic abnormalities, respectively. An additional 20% to 47% of cases could be diagnosed using prenatal whole exome sequencing (WES). We aim to investigate the diagnostic yield of prenatal WES in Qatar, since its implementation in 2014.

Material and methods: More than 2,150 patients registered in the prenatal genetic clinic in Qatar from Oct 2014 to Dec 2023 were screened. Cases were eligible if they underwent prenatal WES after nondiagnostic KT and/or CMA. WES findings were reviewed and classified.

Results: A confirmed genetic diagnosis was observed in 65/143 cases (45.5%). A total of 68 different pathogenic or likely pathogenic variants in 49 genes were identified, of these, 73.8% were AR. The most common condition was Nemaline Myopathy, seen in 21.5% (n = 14) of solved cases. Ten of those cases belonged to consanguineous Qatari families from the same tribe and were caused by the same homozygous pathogenic variant in the *NEB* gene, supporting a potential founder effect. The reassessment of variants of uncertain significance resulted in the re-consideration of three variants in *CLEC16A, VTA1 and ATP1A2* as being likely clinically relevant.

Conclusion: Prenatal WES has significant potential as a diagnostic tool in the prenatal setting in Qatar, with one of the highest reported diagnostic yields worldwide. Our study also recommends offering optional targeted testing for the *NEB* variant at premarital screening, considering the notable incidence of this variant in Qatar compared to elsewhere.

P03.013.D Diagnostic and clinical utility of prenatal exome sequencing: an Italian experience

***Anna Carrer[1,2]**, Chiara Dordoni[1], Anna Meroni[3,4], Angelica Fiorini[5], Jessica Garau[6], Ilaria Palmieri[6], Sara Benini[5,7], Marta Carboni[6,4], Alessia Arossa[3], Arsenio Spinillo[3], Marta Valsecchi[3], Mara Giacchè[1], Laura Franceschetti[5], Chiara Platto[5], Anna Fichera[5,7], Marino Signorelli[5], Enza Maria Valente[6,4], Fabio Sirchia[4,6], Claudia Izzi[1,8]*

[1]Clinical Genetics Unit, Maternal-Infantile Department, ASST Spedali Civili, Brescia, Italy, [2]Genetics and Med Biotech Hub and Competence Centre, Department of Medical Biotechnologies, University of Siena, Siena, Italy, [3]Department of Obstetrics and Gynecology, IRCCS San Matteo Foundation, Pavia, Italy, [4]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [5]Department of Obstetrics and Gynecology, ASST Spedali Civili, Brescia, Italy, [6]Medical Genetics Unit, IRCCS San Matteo Foundation, Pavia, Italy, [7]Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy, [8]Dep of Molecular and Translational Medicine, University of Brescia, Brescia, Italy.

Background: Ultrasound scans detect fetal structural abnormalities in approximately 3% of pregnancies. Exome sequencing (ES) identifies a monogenic disorder in 26–36% of cases. Few studies have explored the clinical utility of ES in the prenatal setting.

Material and methods: This retrospective study involved two enrolling centers and a single laboratory; 131 pregnancies with single or multiple fetal anomalies, with uninformative karyotype and chromosomal microarray results, were analyzed with ES at any gestational age. Cases were categorized into 13 phenotypic subgroups. 59 pregnancies were terminated and 72 resulted in live births. The primary endpoints were assessing diagnostic utility (diagnostic yield and clinical diagnosis reclassification) and clinical utility (prognosis definition, impact on pregnancy management,

postnatal care, and familial counseling), evaluated using a questionnaire completed by healthcare professionals before and after the analysis.

Results: The overall diagnostic yield was 29.8% (39/131). ES had an impact in both positive and negative cases: positive results led to diagnostic reclassification in 59% of cases (23/39) and prognosis definition in 51.3% of cases (20/39); negative results impacted diagnosis and prognosis in 18.9% (17/90) and 36.7% (33/90) of cases, respectively. Familial counseling was modified in 92.3% of positive cases (36/39) and 57.8% of negative cases (52/90). Postnatal care was modified in 85.7% of positive cases (12/14). Pregnancy management was less influenced by ES results.

Conclusion: The use of ES in the prenatal setting offers significant clinical utility, regardless of the results (positive or negative), mainly by aiding in diagnosis classification, prognosis definition, improving postnatal care, and enhancing familial counseling.

P03.014.A Investigating mosaicism for monosomy X in the placenta and fetus: a registry-based study of cases from Denmark 1983–2021

Johanne Berntsen[1], *Simon Horsholt Thomsen*[1,2,3], *Ida Charlotte Bay Lund*[1,2,4], *Anne Skakkebæk*[2,5], *Ida Vogel*[1,5,6]

[1]*Center for Fetal Diagnostics, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,* [2]*Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark,* [3]*Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark,* [4]*Department of Biomedicine, Aarhus University, Aarhus, Denmark,* [5]*Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,* [6]*Department of Obstetrics and Gynaecology, Aarhus University Hospital, Aarhus, Denmark.*

Background: Mosaicism, defined by a mix of chromosomally normal and abnormal cells, is detected in up to 4% of chorionic villus samples (CVS). When detected in CVS, the abnormal cells can either be generalized to the fetus (true fetal mosaicism, TFM) and potentially cause fetal disease or confined to the placenta (confined placental mosaicism, CPM) which may lead to placental dysfunction.

This study examines the potential outcomes following the detection of monosomy X mosaicism in CVS.

Material and methods: We collected data on all singleton pregnancies with mosaicism for monosomy X in CVS between 1983–2021 from two nationwide registries: Danish Cytogenetic Central Registry and Danish Fetal Medicine Database.

Results: During the study period 90,973 CVSs were registered. Of these we identified 204 cases of mosaicism for monosomy X; 111 cases were CPM and 93 cases were TFM. The overall risk of TFM was 46% (93/204, 95% CI: 39;53). In cases with CPM, the risk of SGA was 7% (6/84, 95% CI: 3;15) and the risk of preterm birth was 10% (8/82, 95% CI: 4;18). The mean level of mosaicism in the CVS was 38% (95% CI: 33;44, n = 74) in case of CPM and 55% (95% CI: 47;62, n = 52) in case of TFM.

Conclusion: Mosaicism for monosomy X detected in CVS carries a high risk of TFM. The risk of SGA and/or preterm birth in relation to CPM is, however, low. As expected, the mean level of mosaicism found in the CVS is higher in cases with TFM compared to CPM.

P03.015.B Non-invasive prenatal testing: a retrospective analysis of confirmatory cytogenomic findings in high-risk pregnancies

Feodora Stipoljev[1], *Maja Oroz*[2], *Tamara Vuk*[2], ***Ana Mustapic***[2]

[1]*Cytogenetic Labaratory, Deptartment of Obstetric & Gynecology, Clinical Hospital Sveti Duh, Zagreb, Croatia,* [2]*Clinical Hospital "Sveti Duh", Zagreb, Croatia.*

Background: Non-invasive prenatal testing (NIPT) based on the analysis of cell-free fetal DNA in maternal plasma has sensitivity rate of approximately 99%, with false positive results below 1%. However, the positive predictive values (PPVs) have been shown to be much lover, except for trisomy 21.

Material and methods: In a five-year period a total of 201 women where referred for invasive prenatal diagnosis due to high risk or uninformative results obtained after NIPT. Chorionic villus sampling was performed in 70 cases, and amniocentesis in 131 cases. Cytogenomic analysis was performed by karyotyping, fluorescence in situ hybridization and chromosomal microarray analysis (CMA).

Results: The PPVs for detection of the most common trisomies -T21, T18 and T13 were 96.5% (110/114), 76.5% (13/17) and 46.5% (6/13), respectively. For the sex chromosome aneuploidies including 45,X, 47,XXY, and 47,XXY, PPVs were 12.5%, 100% and 100%, respectively. Among 7 cases with inconclusive results for sex chromosomes, in only one case a sex discrepancy between ultrasonography and cytogenomic analysis was found. In the case of rare chromosomal aneuploidies (RCAs) PPV was 14,3% (1/7), and in the case of structural copy number variations (CNVs) was 13.3% (2/15). There were 15 uninformative NIPT results and the cytogenomic analysis revealed normal results in all cases.

Conclusion: NIPT provides high PPVs in screening for T21, thereby increasing its prenatal detection and reducing the number of invasive procedures. On the contrary, a low proportion of confirmed results for 45,X, RCAs and CNVs strongly implies confirmatory diagnostics, and cautious management of such pregnancies.

Background: Congenital adrenal hyperplasia (CAH) is an autosomal recessive disorder with an incidence of 1 in 10,000–15,000 live births. In 90–95% of cases, it is caused by 21-hydroxylase deficiency due to *CYP21A2* mutations, leading to increased adrenal androgens. Affected females may present with ambiguous genitalia, while males often exhibit precocious puberty. Non-invasive prenatal testing (NIPT) using cell-free fetal DNA (cffDNA) has been applied to monogenic diseases since 2012, demonstrating diagnostic potential. Our case involved a fetus classified as female and low-risk for aneuploidies via NIPT but born with ambiguous genitalia, raising suspicion of CAH.

Material and ethods: Karyotyping confirmed a 46,XX genotype, consistent with the NIPT result. We performed PCR and reverse dot-blot analysis of *CYP21A2* on DNA from the patient and both parents. Retrospective next-generation sequencing (NGS) of stored maternal plasma from the time of NIPT assessed the feasibility of detecting the mutation in cffDNA.

Results: The c.290-13A/C>G (I2 splice) mutation was identified in homozygosity in the patient and in heterozygosity in both parents. NGS of cffDNA detected the same mutation with a Variant Allele Frequency (VAF) of 67% and a fetal fraction of 5%.

Conclusion: The high VAF suggests cffDNA can identify point mutations and small insertions/deletions in monogenic disorders, providing a non-invasive alternative for prenatal diagnosis. Early identification of pathogenic variants affecting sexual development could enable timely interventions, including potential in utero therapy, improving neonatal outcomes.

P03.017.D Clinical experience with use of cffDNA for non invasive identification of POC chromosomal abnormalities in early pregnancy loss

Monica Ianniello, *Giovanni Savarese, Raffaella Ruggiero, Luisa Circelli, Antonella Di Carlo, Marika Casillo, Maria Rosaria Fantuz, Rossana D'Angelo, Mariasole Bruno, Cristina Ramiro, Rossella Castiello, Nadia Petrillo, Luigia De Falco, Evangelista Eloisa, Alessio Mori, Roberto Sirica, Francesca Del Peschio, Siriana De Falco, Teresa Suero, Davide Cino, Maria Barbato, Federico Capone, Emanuela Pescatore, Simone Marcella, Piero Sabbatino, Umberto Lazzaro, Tonia Miraglia, Veronica Feola, Alessandro Ottaiano, Antonio Fico*

AMES s.r.l., Casalnuovo di Napoli (NA), Italy.

Background: Around 25% of pregnancies result in miscarriage, with 50% caused by chromosomal abnormalities. Identifying these causes has prognostic value for couple's and mother's reproductive health, as euploid miscarriages are associated with maternal dysfunctions. However, obtaining products of conception (POC) is invasive, and traditional methods like karyotyping have low success rates and high costs. Genetic analysis is typically performed after multiple miscarriages, highlighting the need for non-invasive diagnostic alternatives. This study aimed to evaluate the use of circulating free fetal DNA (cffDNA) for genome-wide screening of chromosomal abnormalities in early miscarriages.

Material and methods: Plasma samples from women with POC retained or expelled within 24 hours were processed using the VeriSeq NIPT Solution v2 and sequenced on the NextSeq 550Dx. Data were analyzed with the VeriSeq NIPT Assay Software v2 and an in-house bioinformatics algorithm.

Results: A total of 366 samples were analyzed: 202 euploid and 164 aneuploid. Among the aneuploid samples, 20 had trisomy 15, 38 had trisomy 16, 21 had trisomy 22, and other rare autosomal aneuploidies (RAAs) were detected, including trisomies of chromosomes 2, 3, 4, 5, 6, 9, 10, 14, and 20.

Conclusion: Chromosomal abnormalities were found in 45% of cases, with trisomy 15, 16, 22, and monosomy X representing 28% of these. The non-invasive nature of this method offers diagnostic opportunities even after the first miscarriage, improving the diagnostic process and aiding in the development of new preventive and therapeutic strategies.

P03.018.A Incremental yield of exome sequencing in fetuses with isolated polyhydramnios: diagnostic insights and clinical impact

Michal Levy[1], *Vered Offen Glasner*[1], *Adi Mory*[2], *Adi Reches*[1], *Karina Krajden Haratz*[3], *Britannia Fleming*[1], *Hagit Baris Feldman*[4], *Liron Malki*[5], *Lena Sagi-Dain*[6], *Shohat Mordechai*[7], *Adi Botvinik*[1], *Yuval Yaron*[1]

[1]*Prenatal Genetic Diagnosis, Tel Aviv Sourasky Medical Center, Tel Aviv Yafo, Israel,* [2]*The Genetics Institute and Genomic Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Tel Aviv Yafo, Israel,* [3]*Lis Maternity Hospital - Division of US in OBGyn, Tel Aviv Sourasky Medical Center, Tel Aviv Yafo, Israel,* [4]*Genetics Institute and Genomic Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel,* [5] *The Genetics Institute and Genomic Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Tel Aviv Yafo, Israel, Tel Aviv Yafo, Israel,* [6]*Carmel Medical Center, Haifa, Israel,* [7]*1The Genetic Institute of Maccabi Health Services, Rehovot, Israel, Tel Aviv Yafo, Israel.*

Background: Exome sequencing (ES) shows potential in identifying genetic causes of polyhydramnios, but systematic evaluation and guidelines are lacking. This study aimed to assess the diagnostic yield of ES in isolated polyhydramnios.

Material and methods: This retrospective multicenter study included 40 cases of isolated polyhydramnios (AFI ≥25 cm or SDP ≥8 cm). Mild cases were defined as AFI ≥25 and <30 or SDP ≥8 and <10 cm; moderate-severe cases as AFI ≥30 or SDP ≥10 cm. All cases were screened for gestational diabetes mellitus (GDM) and underwent chromosomal microarray analysis (CMA). ES was offered for CMA-negative cases, along with targeted tests for spinal muscular atrophy, myotonic dystrophy type 1, and Prader-Willi syndrome.

Results: Pathogenic or likely pathogenic variants were identified in seven cases (17.5%), including four cases of Bartter syndrome (variants in *KCNJ1*, *BSND*, and *MAGED2*), one case of Noonan syndrome (*RIT1*), one case of Osteopathia Striata with Cranial Sclerosis (*AMER1*), and one case of autism/intellectual disability syndromes (*AUTS2*). Two cases had variants of uncertain significance, and one case was positive for myotonic dystrophy. Among the 17 mild cases, 2 (12%) had positive ES results. Notably, two ES-positive cases also had gestational diabetes mellitus (GDM). Postnatal follow-up revealed normal development in 89% of live-born infants, with isolated instances of global developmental and speech delays.

Conclusions: ES significantly enhances diagnostic yield in isolated polyhydramnios, even in mild or late-diagnosed cases and with GDM, supporting its integration into the diagnostic workflow.

P03.019.B iMedImage: an end-to-end foundational model for medical image recognition and its application in chromosome analysis

*Zhixiong Lan[1], ran wei[1], Qing Yan[1], Ming Lv[1], **Desheng Liang**[2], Ning Song[1]*

[1]Hangzhou Diagens Biotechnology Co., Ltd., Hangzhou, China, [2]Central South University, Changsha, China.

Background: Karyotyping, the gold standard for detecting chromosomal abnormalities, remains critical for diagnosing genetic and hereditary diseases. While AI effectively identifies numerical abnormalities, detecting structural abnormalities remains challenging. Leveraging advances in large foundation models, which integrate multimodal medical images for robust feature extraction and accurate diagnoses, we developed iMedImage, an end-to-end model for medical image recognition. Applied to chromosomal abnormality detection, iMedImage demonstrated promising performance.

Material and methods: We constructed a comprehensive medical image dataset encompassing diverse modalities from common medical fields, including chromosome, cellular, pathological, ultrasound, X-ray, CT, and MRI images. Based on this dataset, we developed iMedImage, which incorporates the following key features: (1) a unified representation for diverse modal inputs and medical imaging tasks, and (2) multi-level (case-level, image-level, and patch-level) image recognition capabilities, enhanced by chain of thought (CoT) embedding and mixture of experts (MoE) strategies.

Results: A prospective and retrospective, multicenter, stratified block-randomized, crossover clinical trial with a "gold standard" control, enrolling 1,518 participants, was conducted at three Class III A hospitals in China. The model achieved fully automated chromosome analysis, including segmentation, arrangement, and abnormality detection, with a diagnostic accuracy rate of 99.59%, sensitivity of 95.83%, and specificity of 100%.

Conclusion: We present iMedImage, an innovative end-to-end foundation model for medical image recognition and demonstrates its capability to significantly enhance performance in chromosomal abnormality detection tasks. Our proposed iMedImage can provide clinicians with an effective tool for identifying chromosomal abnormalities and potentially contribute to reducing birth defects.

P03.020.C Cell-based NIPT: one test for reliable detection of the most common prenatal syndromes, including Down syndrome, 22q11 deletion syndrome, and cystic fibrosis

Ida Vogel[1,2], *Maria Bach Laursen[3], Maibritt Nørgaard Lauridsen[3], Ripudaman Singh[3], Lars Henning Pedersen[1,4], Lotte Hatt[1]*

[1]Aarhus University, Department of Clinical Medicine, Århus N, Denmark, [2]Aarhus University Hospital, Department of Clinical Genetics, Århus N, Denmark, [3]Arcedi Biotech, Århus N, Denmark, [4]Aarhus University Hospital, Department of Obstetrics and Gynecology, Århus N, Denmark.

Background: Currently, the most common prenatal syndromes—Down syndrome, 22q11 deletion/duplication syndrome, and cystic fibrosis (CF) —are typically assessed separately, often requiring multiple - and potentially invasive tests - per pregnancy. The isolation of extravillous trophoblasts from maternal blood provides a pure fetal DNA source, free from maternal DNA, enabling comprehensive non-invasive prenatal genetic analysis. However, this study comprises multiple smaller cohorts focusing on different aspects of testing.

Material and methods: Using a newly ISO 15189-accredited methodology, trophoblasts were isolated from maternal blood of pregnancies (GA 10–15 weeks) via magnetic-activated and fluorescence-activated cell sorting. Genetic analysis (ACGH, WGS (4x), Sanger seq) following whole-genome amplification enabled:- Aneuploidy detection- Pathogenic CNVs: >2 Mb for deletions and >5 Mb for duplications genome-wide- Smaller CNVs (>0.4 Mb) associated with known microdeletion/duplication syndromes- Targeted analysis of the 50 most common CF-causing CFTR variants- A bespoke setup for monogenic disorders

Results: Validated in a public-private collaboration in Denmark 500+ pregnancies have been analyzed across different study arms:- cbNIPT screening for 50 common CFTR variants demonstrated 27/28 (96%) concordance with invasive testing, one without trophoblasts.- Chromosome 22q11.2 CNVs (0.4–2.8 Mb) was the most common CNV and was identified in eight pregnancies, highlighting genomic instability from low-copy repeats (LCRs A-H) and the phenotypic importance hereof.- 15 monogenic disorders (20 cases) were successfully tested in pregnancy

Conclusion: cbNIPT is ready for clinical use, providing a non-invasive alternative for aneuploidy and CNV detection. Soon follows a CFTR screening and bespoke setup, reducing the need for multiple tests per pregnancy.

P03.021.D The clinical significance of prenatal whole genome sequencing

Erik Iwarsson[1,2], *Peter Conner[3,4], Ellika Sahllin[1,2], Maria Pettersson[1,2], Nikos Papadogiannakis[5,6], Anna Lindstrand[1,2], Eini Westenius[1,2]*

[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden, [2]Karolinska University Hospital, Department of Clinical Genetics and Genomics, Stockholm, Sweden, [3]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden, Stockholm, Sweden, [4]Karolinska University Hospital, Center for Fetal Medicine, Stockholm, Sweden, [5]Karolinska Institutet, Department of Laboratory Medicine, Stockholm, Sweden, [6]Karolinska University Hospital, Department of Pathology, Stockholm, Sweden.

Background: This study investigated the diagnostic yield of short-read whole genome sequencing (WGS) in prenatally detected congenital malformations and the consequences of the results.

Material and methods: A prospective study of 100 fetuses with various malformations, negative for trisomies and copy number variants, which were analyzed with fetal parental trio WGS.

Results: A molecular diagnosis was achieved in 26/100 (26%). The phenotypes were divided into different groups with the following diagnostic yields: multisystem 10/25 (40%), CNS 9/25 (36%), skeletal 4/13 (31%), thorax 2/20 (10%), abdominal 1/11 (9%) and other isolated anomalies 0/6 (0%). Of the cases with a causative variant, 18 (69%) were terminated due to the prenatal ultrasound findings before the results from WGS were available, one was terminated after the pathological WGS result, four ended in perinatal death and three resulted in a live-birth. 19/26 (73%) of the causative variants were de novo. However, 7/26 (27%) of the causative variants had a significant recurrence risk with 3/26 (12%) variants being autosomal recessive, 3/26 (12%) autosomal dominant with a carrier parent and 1/26 (4%) X-linked. 5/7 (71%) of the couples with a significant recurrence risk chose PGT for their next pregnancy.

Conclusion: We demonstrate an additional diagnostic yield of 26% with WGS in prenatally detected congenital malformations where chromosome aberrations were previously excluded. 27% of the detected variants had a significant recurrence risk. Hence, WGS increases the diagnostic yield in current pregnancies, but also increase the number of couples with a known significant recurrence risk in future pregnancies.

Van Deutekom*[6], *Gijs W.E. Santen*[1], *Manon Suerink*[1]

[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Radboud University Medical Center, Nijmegen, Netherlands,* [3]*Maastricht University Medical Center, Maastricht, Netherlands,* [4]*Amsterdam University Medical Center, Amsterdam, Netherlands,* [5]*University Medical Center Groningen, Groningen, Netherlands,* [6]*Utrecht University Medical Center, Utrecht, Netherlands.*

Genomic diagnostics are increasingly requested in pregnancies with congenital anomalies. Identifying the causal variant while minimizing Variants of Uncertain Significance (VUS) and Unsolicited Findings (UF) is challenging since variant interpretation is complicated by limited fetal phenotypes. Artificial intelligence (AI) variant interpretation software might aid prioritizing variants.

Prenatal Exome Sequencing cases were prospectively included between February 2022 and October 2024 in a Dutch nationwide study. Exome data with HPO-terms were reanalysed using AION by Nostos Genomics. The validity of the AI platform was evaluated and rates of VUS and UF were compared with the DDG2P gene panel.

Overall, 133 samples from 131 pregnancies (two dizygotic twins) were reanalyzed. During routine care, variants related to the prenatal phenotype were reported in 24 cases (18%) of which $n = 3$ VUS and UF in 5 cases (4%) of which $n = 1$ VUS. The mean number of allocated HPO-terms per case was 2.5 (SD 1.7), with AI prioritizing 11.0 variants (SD 5.2) per case. Linear regression showed no significance between the number of HPO-terms and prioritized variants ($p = 0.792$). AI ranked the diagnostic variant in the top 5 in 96.6%. The total number of VUS did not significantly differ between usage of the DDG2P panel and AI ($p = 0.250$), however significantly more UF were detected with AI ($p = 0.039$).

AI is a promising add-on in the often-laborious interpretation of variants and has the potential to make curating gene panels redundant. This is crucial in prenatal care, where the increasing number of referrals and time pressure of advancing gestation are challenging.

P03.024.C Exome sequencing in structurally normal fetuses - yield, lesson learned and complexities

Hagit Daum[1], *Rivka Birnboum*[1], *Shiri Shkedi-Rafid*[1], *Tamar Harel*[2], *Shiri Gershon-Naamat*[1], *Adily Basal*[1], *Vardiella Meiner*[1], *Hagar Mor-Shaked*[2]

[1]*Hadassah, Jerusalem, Israel,* [2]*Hadassah-Hebrew University Medical Center, Jerusalem, Israel.*

Background: Exome sequencing (ES) is a highly effective and well-established method for detecting disease-causing single nucleotide variations (SNVs) and small indels in postnatal cases. In prenatal situations, where the clinical characteristics of the affected fetus can often be vague and non-specific, ES plays a crucial role in diagnosis. However, for structurally normal fetuses, the benefits are less well-defined. There is limited information available on the utility and complexities of exome sequencing in this population.

Material and methods: From February 2017 to June 2024, ES was performed in 1608 structurally normal fetuses. Analysis included SNV, copy number variations and uniparental disomy. Only pathogenic/likely pathogenic variants, based on ACMG classification criteria, were reported.

Results: ES was carried out between 16–22 weeks of pregnancy. 12 of the 1608 fetuses (0.75%) were found to have pathogenic variants in genes related to moderate to severe diseases. Autosomal recessive diseases were diagnosed in three fetuses (25%). Autosomal dominant diseases were diagnosed in eight fetuses (67%), all of which de-novo. An X-linked inherited disease was diagnosed in one fetus (8%). Most of the diagnosed diseases have a prominent neurodevelopmental phenotype, hence not detected by ultrasound. There were another two groups of results, related to a phenotype with an actionable importance related to fetal and child health (five fetuses) or a mild phenotype (four fetuses).

Conclusion: With restrictive analysis and careful management of the results, prenatal ES might be beneficial when offered in adjunct to genetic counseling in structurally normal fetuses. Neurodevelopmental phenotypes were enriched in this cohort.

P03.026.A Investigation of *SIK3* and *CEP164* variant pathogenicity in human fetuses with severe skeletal defects

Eliana Stanziano[1,2], *Vicki Wilczek*[1,2], *Dylan Harnas*[1,2], *Pawanrat Tangseefa*[1,2], *Sandy Piltz*[3], *Melissa White*[3], *Paul Thomas*[3], *Caleb Lushington*[2], *Peer Arts*[4,5], *Thuong Ha*[4,5], *Matilda Jackson*[4,5], *Hamish Scott*[4,5], *Christopher Barnett*[6], *Ashfaqul Hoque*[7], *Jon Oakhill*[7], *Benjamin Kamien*[8], *Melissa Cantley*[1,2], *Kate Vandyke*[1,2], *Andrew Zannettino*[1], *Stephen Fitter*[1,2]

[1]*The University of Adelaide, Adelaide, Australia,* [2]*South Australian Health and Medical Research Institute, Adelaide, Australia,* [3]*SA Genome Editing Facility, Adelaide, Australia,* [4]*Centre for Cancer Biology, Adelaide, Australia,* [5]*Genetics and Molecular Pathology Research SA Pathology, Adelaide, Australia,* [6]*Paediatric and Reproductive Genetics Unit Women's and Children's Hospital, Adelaide, Australia,* [7]*St Vincent's Institute of Medical Research, Melbourne, Australia,* [8]*Genetic Services of Western Australia, Perth, Australia.*

Background: This research is part of the Genomic Autopsy study, an Australian initiative investigating the genetic cause of perinatal deaths. Two homozygous VUS were identified in *SIK3* (c.1178G>A, p.Arg393His) and *CEP164* (c.393+6T>G) in two human fetuses presenting with polydactyly, shortened long bones and severe ossification irregularities. SIK3 regulates long bone growth. Disruption of SIK3 kinase activity causes skeletal abnormalities. Mutations within *CEP164* give rise to ciliopathies, which have broad clinical phenotypes, including skeletal. The aim of this study was to investigate the VUS using mouse genetics and NGS, to provide evidence for variant causation or benign re-classification.

Material and ethods: Homozygous *SIK3* mutant mice were assessed by whole-mount skeletal staining, histology and micro-CT. RNA sequencing of parental PBMCs was performed to assess *CEP164* transcript splicing. The *CEP164* variant was introduced in human and murine cells using Prime Editing (PE), and *CEP164* splicing assessed by RT- PCR.

Results: No differences in gross skeletal morphology or bone micro-architecture were observed in pre- and post-natal *SIK3* mutant mice relative to controls. RNA-seq revealed 50% non-canonical *CEP164* splicing in the parents, with exon 5 skipping introducing a premature stop codon. *CEP164* PE in HEK293T cells revealed transcript splicing consistent with the parental RNA-seq data.

Conclusion: These findings suggest the *SIK3* variant is likely benign, and the *CEP164* intronic mutation is likely pathogenic and causative of the skeletal deformities in the fetuses. This important work contributes to variant classification in rare genetic diseases to inform prenatal screening, genetic counselling, and ultimately reduce perinatal deaths globally.

P03.027.B Prenatal variants of uncertain significance (VUS): to report or not to report?

Maayke de Koning[1], *Malgorzata Srebniak*[2], *Esther Oldekamp*[1], *Denise Hahn*[1], *Karin Diderich*[2], *Hennie Bruggenwirth*[2], *Gijs Santen*[1], *Mariette Hoffer*[1], ***Manon Suerink***[1]

[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Erasmus MC, Dept. of Genetics, Rotterdam, Netherlands.*

Background: Prenatal Exome Sequencing (pES) has a significant diagnostic yield but time pressure and limited phenotypic information make interpretation of Variants of Uncertain Significance (VUS) more challenging than in a postnatal setting. We share our experiences of prenatal reporting of highly suspicious VUS.

Material and methods: We retrospectively analyzed pregnancies in which VUS identified by pES were reported to parents during pregnancy in two Dutch academic medical hospitals.

Results: During the study period, 31 VUS in 29 genes were reported in 27 pregnancies. Cases were assigned to one of five groups based on consistency of prenatal phenotypes with gene-associated diagnoses. The implications of VUS included clinical evaluation of parental carriers ($n = 4$), additional screening of proband ($n = 2$), influencing parental decision-making ($n = 11$) and/or prompting confirmatory testing ($n = 10$). Reanalysis with currently available data resulted in reclassification of seven variants, five of which were upgraded to (likely) pathogenic.

Conclusion: Although we do not recommend routine disclosure, our data suggest that prenatal reporting of VUS can be valuable in exceptional cases. Stringent selection was applied and only a minority of reported VUS was reclassified as (likely) pathogenic. Therefore, a careful individual assessment of each VUS case remains imperative and multidisciplinary meetings should be an integral part of prenatal VUS management.

P03.028.C Prenatal trio exome sequencing for fetuses with isolated nuchal translucency thickness above the 95th percentile but below 3 mm

Nicolina Zjacic[1], *Anaïs Begemann*[1], *Ivan Ivanovski*[1], *Yalda Baradaran*[1], *Michael Papik*[1], *Tilo Burkhardt*[2], *Angela Bahr*[1], *Anita Rauch*[1]

[1]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [2]*Clinic of Obstetrics, University Hospital Zurich, Zurich, Switzerland.*

Background: Increased nuchal translucency (NT) thickness is associated with a higher risk of chromosomal abnormalities, as well as monogenic developmental disorders, which can be detected during pregnancy via exome sequencing. Currently, recommendations for referral to prenatal exome sequencing vary between countries, such as requiring the additional presence of fetal structural malformations, or an isolated NT above the 95th or 99th percentile, or above an absolute value of 3 or 3.5 mm. Our aim was to evaluate the diagnostic yield of exome sequencing in fetuses with NT above the 95th percentile, but below 3 mm, both with and without further structural anomalies.

Material and methods: Trio exome sequencing was performed on fetal DNA and blood collected from both parents. There were five cases of increased NT < 3 mm with further structural anomalies, and 56 cases of isolated NT < 3 mm.

Results: In 1 out of 5 of the NT cases with further anomalies, a (likely) pathogenic variant for a monogenic developmental disorder was determined. In comparison, in the isolated NT group, 11% of cases had (likely) pathogenic variants in genes causing monogenic developmental disorders, with an additional 4% showing "hot" variants of uncertain significance (VUS) and 12% showing regular VUS.

Conclusion: Given the high incidence of (likely) pathogenic variants for monogenic developmental disorders found in fetuses with isolated increased NT thickness, our findings support the use of exome screening for NT cases above the 95th percentile,

independent of the absolute measure values, and even in the absence of further structural anomalies.

P03.029.D The utility of non invasive prenatal testing in early diagnosis of tetrasomy 12p

Sara Duca, *Donatella Viola, Pasquale Savarese, Rossella Falcone, Monica Faieta, Vanessa De Paolis, Alessandra Cammareri, Arianna Polverari, Elena Corsetti, Ilenia Intini, Clarissa Locci, Angelina Pranteda, Francesca Pizzuti, Mariateresa Sessa, Laura Gigante*

Eurofins Genoma, Rome, Italy.

Background: Non-invasive prenatal testing (NIPT) for detection of rare chromosomal imbalances has been extensively used in past years. Pallister-Killian syndrome (PKS) is a rare disorder due to tissue-limited mosaicism for isochromosome of the short arm of chromosome 12: i(12)(p10). PKS prenatal diagnosis is challenging as manifestations are variable and nonspecific (i.e. increased nuchal translucency, polyhydramnios, etc.). The utility of NIPT in the diagnosis of PKS was never explored.

Material and methods: We reviewed a subset of a previously published cohort (Faieta 2024) with NIPT positive results for 12p duplication using the CE-IVD certified Veriseq NIPT Solution V2 (Illumina, Inc. San Diego, CA, USA), together with an in-house developed algorithm. All patients were offered follow-up: karyotype on amniotic fluid (AF) and maternal lymphocytes.

Results: NIPT revealed dup(12)(p13.33q11) in 9 patients, definite follow-up was available for 6: fetal karyotype on AF confirmed the presence of isochromosome 12p [47,XX,iso(12)(p10->pter)] in 2 cases, the remaining 4 showing a normal fetal karyotype (≥50 metaphases analyzed). In one case a supernumerary marker chromosome was identified on maternal lymphocytes (mos47,XX,+mar[28]/46,XX[72]). Notably, among cases without available follow-up one declined amniocentesis and gave birth to a baby referred for neurodevelopmental abnormalities (post-natal investigation were refused). None showed ultrasound abnormalities.

Conclusion: This study demonstrates NIPT can detected 12p duplication related to PKS in early pregnancy without ultrasound abnormalities. The main limitation of the study is represented by the small number of cases, and extension of the cohort is needed to reliably assess the detection rate of NIPT for 12p tetrasomy.

P03.030.A Secondary findings from prenatal exome-sequencing: prevalence, types of conditions and variants

Shiri Shkedi-Rafid[1], *Hagar Mor-Shaked*[2], *Rivka Birnbaum*[1], *Sarah Weissman*[1], *Tamar Harel*[1], *Vardiella Meiner*[1], *Hagit Daum*[1]

[1]*Hadassah Hebrew University Medical Center, Jerusalem, Israel,* [2]*Hadassah-Hebrew University Medical Center, Jerusalem, Israel.*

Background: Clinical use of exome sequencing for prenatal diagnosis is on the rise. Exome analysis may (or may not) include a list of genes, recommended by the American College of Medical Genetics (ACMG), predominantly associated with adult-onset conditions for which prevention/treatment/early detection exists (currently 81 genes). Guidance regarding these secondary-findings and disclosure in a prenatal setting is lacking.

Material and methods: Our in-house database of exome-sequencing data was analyzed for the prevalence of pathogenic variants in the ACMG secondary-findings genes, the type of variants identified, and related conditions.

Results: In 2023–2024, 2235 fetal exomes were performed at our tertiary center. Seventeen pathogenic variants in the ACMG secondary-findings genes were reported in prenatal testing (0.8%). Nine variants (53%) were in genes associated with cardiovascular phenotypes (APOB, LDLR, MYBPC3, RYR2, PKP2, PCSK9), and eight variants (47%) were in genes related to cancer phenotypes (BRCA1, BRCA2, MAX, TMEM127). Seven variants (41%) were founder mutations (mainly the Ashkenazi-Jewish BRCA1/2 mutations), six variants (35%) were previously reported as disease-causing, and four loss-of-function variants (24%) were not previously reported.

Conclusion: Although there are challenges in implementing secondary-findings disclosure in the prenatal setting, such findings can have positive clinical impact on parents and on their family members. Chances of identifying pathogenic variants are greater in populations with founder mutations. Pre-test counseling regarding prenatal exome-sequencing should include discussion of the inclusion or exclusion of secondary findings.

P03.032.C Detection of copy number variations (CNVs) on chromosome 18 by non-invasive prenatal testing (NIPT): case reports of partial deletions

Sujeong Eom[1], *Minyeon Go*[1,2], *Hyunjin Kim*[1], *Hee Yeon Jang*[1,2], *Ji Eun Park*[1], *Jong Chul Kim*[1], *So Hyun Yang*[1], *Sung Han Shim*[1,3], *Young Jin Lee*[1], *Dong Hyun Cha*[1,3]

[1]*Center for Genome Diagnostics, CHA Biotech Inc., Molecular Genetics Laboratory, Seoul, Korea, Republic of,* [2]*College of Life Science, CHA University, Department of Biomedical Science, Gyeonggi-do, Korea, Republic of,* [3]*CHA Gangnam Medical Center, CHA University, Department of Obstetrics and Gynecology, Seoul, Korea, Republic of.*

Background: NIPT is a screening test used to detect trisomy of chromosomes 21, 18, and 13 through the analysis of cell-free DNA. Recently, increasing interest has been in detecting CNVs based on NIPT results. In this context, we report two cases of CNVs on chromosome 18 identified through NIPT.

Material and methods: NIPT, chromosomal microarray analysis (CMA), and karyotyping were performed.

Results: Case 1: A 33-year-old woman (G2P0) at 12+3 weeks' gestation was subjected to NIPT due to an increased nuchal translucency and a short nasal bone of her fetus. The NIPT results indicated partial deletions in 18p11.32p11.21 (15.4 Mb) and 18q21.2q23 (25.8 Mb). At 14 weeks' gestation, intrauterine fetal death was diagnosed, and the CMA results performed on the fetal tissue were consistent with the NIPT findings.

Case 2: A 33-year-old woman (G2P0) underwent NIPT at 12+1 weeks' gestation. In NIPT, partial deletions in 18q21.2q23 (25.8 Mb) were detected, and CMA and karyotyping were performed on both the fetus and the parents. The results were consistent with the NIPT findings. Additionally, CMA of the fetus revealed duplications in 8p23.2 (2.2 Mb) and deletions in 12p11.22p11.21 (2.6 Mb), while karyotyping revealed 9p12q13 inversions. Comparison with the parents' results confirmed that the deletions in chromosomes 18 and 12 were de novo pathogenic variants. Following genetic counseling, the pregnant woman chose to terminate the pregnancy.

Conclusion: NIPT may be used as a screening tool for CNVs. However, confirmatory tests, such as CMA or karyotyping, are still necessary to ensure accurate genetic counseling.

P03.035.B Positive NIPT for trisomy 16 in an euploid fetus - the unmasking of maternal UPD 16

Irena Bradinova[1,2], *Kameliya Kercheva, MD*[1,3], *Radostina Raynova*[1], *Zhivka Genova*[4], *Silvia Andonova*[4], *Nadezhda Yaneva*[1], *Dimiter Markov*[5], *Albena Todorova*[4,3], *Alexey Savov*[1,2]

[1]*National Genetic Laboratory, UHOG "Maichin dom", Sofia, Bulgaria,* [2]*Medical University- Sofia, Faculty of Medicine, Department of Obstetrics and Gynecology, Sofia, Bulgaria,* [3]*Medical University- Sofia, Faculty of Medicine, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria,* [4]*GMDL "Genica" and IMDL "Genome Center Bulgaria", Sofia, Bulgaria,* [5]*MC "Markovs", Sofia, Bulgaria.*

Background: The widespread clinical use of noninvasive prenatal testing (NIPT) has led to increase in unexpected findings. Trisomy 16 occurs in approximately 1–2% of all clinically recorded pregnancies and is a common finding in spontaneous abortions. While full trisomy 16 is typically lethal, mosaic trisomy 16 can be viable. Postzygotic trisomic rescue may result in uniparental disomy (UPD), with diverse possible clinical outcomes. Maternal UPD 16 is associated with a spectrum of phenotypic variability, with intrauterine growth retardation (IUGR) being the most common manifestation.

Material and methods: A young couple's first pregnancy was investigated following a positive NIPT result for trisomy 16 and sonographic fetal anomalies. Microsatellite (QF-PCR) and Chromoseq analysis of amniotic fluid were performed, along with trio microsatellite analysis for UPD 16. Post-termination QF-PCR analysis was conducted on placental and fetal samples.

Results: NIPT detected trisomy 16 and male fetal sex. Genetic amniocentesis by QF-PCR demonstrated a normal male fetal chromosomal profile, while ultrasound revealed IUGR in a female fetus. Subsequent Chromoseq analysis showed a normal chromosomal result and male sex. Trio microsatellite analysis revealed absence of paternal alleles at three informative chromosome 16 markers, confirming the diagnosis of upd(16)mat. Post-termination analysis demonstrated full to low-grade mosaic trisomy 16 in the placenta, with normal fetal result. In addition to IUGR ambiguous genitalia and finger anomalies were observed.

Conclusion: This case highlights the challenges in interpreting rare trisomies detected via NIPT and underscores the critical role of interdisciplinary collaboration between clinicians and geneticists for accurate diagnosis and pregnancy management.

P03.036.C Prenatal diagnosis of Smith-Lemli-Opitz syndrome : the critical role of multidisciplinary collaboration in a rare case

Kameliya Kercheva[1,2], *Irena Bradinova, MD PhD*[1,3], *Elena Pavlova*[4], *Lubomir Balabanski*[5,6], *Maya Atanasoska*[5,7], *Slavyana Yaneva Staykova*[5], *Sylvia Savova*[8], *Alexey Savov*[1]

[1]*National Genetic Laboratory, UHOG "Maichin dom", Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria,* [3]*Department of Obstetrics and Gynecology, Medical University Sofia, Sofia, Bulgaria,* [4]*MC "Markovs", Sofia, Bulgaria,* [5]*CellGenetics Laboratory, Sofia, Bulgaria,* [6]*Genetic Laboratory, Polymed Hospital, Sofia, Bulgaria,* [7]*Laboratory of Biology and Immuology of Reproduction, Bulgarian Academy of Sciences, Sofia, Bulgaria,* [8]*Pathologic pregnancy clinic, UHOG "Maichin dom", Sofia, Bulgaria.*

Background: Smith-Lemli-Opitz syndrome (SLOS) is a rare autosomal recessive disorder caused by pathogenic variants in the DHCR7 gene, leading to defects in cholesterol biosynthesis. The syndrome is characterized by facial dysmorphism, microcephaly, intellectual disability, limb abnormalities (polydactyly, syndactyly, bone shortening), multiorgan malformations. Prenatal diagnosis is challenging due to its variable phenotype.

Material and methods: An 18-week pregnant woman was referred for genetic counseling due to ultrasound findings of postaxial polydactyly in one hand and both feet, along with shortening of all long bones in the fetus. Amniocentesis was performed at 19 weeks of gestation, and whole-genome sequencing (WGS) was initiated, followed by targeted analysis of 841 genes associated with skeletal dysplasias. Additionally, genome-wide screening for variants with an expected loss of function (pLoF) was conducted. Segregation analysis was performed for the identified variants in both parents. Free estriol levels were measured at 22 weeks of gestation.

Results: WGS revealed a known pathogenic variant (c.452G>A) and a likely pathogenic variant (c.1364A>G) in DHCR7, both in heterozygous states, suggesting a diagnosis of SLOS. Segregation analysis confirmed that the c.452G>A variant was paternally inherited and c.1364A>G maternally. Maternal serum estriol levels were significantly reduced, as expected in SLOS pregnancies. Following genetic counseling, the couple opted for pregnancy termination.

Conclusion: Prenatal diagnosis of SLOS is rare due to its heterogeneous presentation and limited awareness of its early ultrasound features. This case underscores the importance of collaboration between experienced fetal morphologists and geneticists in recognizing and confirming such cases, enabling informed decision-making for affected families.

P03.037.D Diagnostic strategy for unsolved miscarriages - results from a pilot study

Isabell Schumann[1], *Elias Greiner-Bär*[2], *Anne-Christin Teichmann*[2], *Vincent Strehlow*[3], *Anja Weise*[4], *Philipp Jaecks*[4], *Julia Hentschel*[5]

[1]*Department of Medical Genetics, Münster, Germany,* [2]*Institute of Human Genetics, Leipzig, Germany,* [3]*Universitatsklinikum LeipzigInstitut fur Humangenetik, Leipzig, Germany,* [4]*Institute of Human Genetics, Jena, Germany,* [5]*Universitatsklinikum Leipzig, Leipzig, Germany.*

Background: About 50% of miscarriages are caused by several risk factors, such as embryo aneuploidy, anatomical abnormalities, immune response or genetic dispositions. The other 50% remain unexplained. This study uses exome sequencing (ES) to explore genetic causes, particularly in families with recurrent miscarriages, as we presume to find variants that are lethal in embryonic state and have not been found in living individuals so far.

Material and methods: We retrospectively analyzed miscarriages that previously had an unremarkable karyotype, no growth in cell culture or no clear cytogenetic evaluation. Female samples with unremarkable karyotypes were tested for maternal contamination. A total of 80 unresolved cases underwent ES, with strict filtering of single nucleotid variants and HPO terms.

Results: Here, we highlight one family with three miscarriages might linked to a maternally transmitted hemizygous variant NM_002049.4:c.919C>T, p.(Arg307Cys) in *GATA1*. This gene plays an important role in erythroid development by regulating the switch from fetal to adult hemoglobin. Several OMIM morbid conditions caused by *GATA1* variants are known. The variant segregated with all male miscarriages, leading us to classify it as likely pathogenic. Further evaluation of the healthy male child in the family is ongoing.

Conclusion: In summary, we recommend the immediate integration of ES into the diagnosis of unresolved abortions in form of trio-ES to address the limitations shown by our retrospective pilot study (1) copy-number variant analysis is not feasible in old (stored) material, (2) inheritance of new variants is not traceable and (3) phenotypic data are missing in older cases.

P03.038.A An incidental finding in prenatal exome sequencing: a case report and ethical implications of a novel variant in Wolcott Rallison Syndrome

Ekin Cemre Bayram Tokac*, Elif Kubar, Haluk Akin, Asude Durmaz, Ayca Aykut*

Ege University, Department of Medical Genetics, Izmir, Turkey.

Background: Targeted molecular tests in prenatal diagnosis enable early detection in families with a history of genetic disease. Wolcott-Rallison syndrome (WRS) is a rare autosomal recessive disorder caused by *EIF2AK3* mutations, with a prevalence of <1 in 1,000,000. This study evaluates clinical and ethical considerations when incidental findings lack phenotypic evidence in utero.

Material and methods: A 42-year-old pregnant woman and her consanguineous husband sought genetic counseling counseling due to a previous deceased child from congenital lactic acidosis at 14 months. In 2015, an inherited disease panel found no causative variant. During the current pregnancy (7 weeks' gestation), clinical exome sequencing (CES) was performed on the parents, their healthy child, and preserved DNA from their deceased child. No ultrasound abnormalities were detected. Genomic DNA from peripheral blood and fetal DNA from CVS underwent Next-Generation Sequencing (NGS). Quantitative PCR (qPCR) confirmed copy number variations (CNVs).

Results: CNV analysis identified a heterozygous *G6PC1* deletion in both parents and also homozygous in deceased child, associated with Glycogen Storage Disease Type IXc. Additionally, a novel heterozygous 38.4 kbp deletion of *EIF2AK3* was incidentally identified in both parents. CES on the fetal sample revealed homozygous *EIF2AK3* deletion, confirming WRS. qPCR performed to validate findings. Following genetic counseling, the couple decided for termination at 24 weeks.

Conclusion: This case highlights the utility of prenatal exome sequencing and CNV analysis. The incidental diagnosis of WRS underscores its clinical value, while the ethical complexities of incidental results emphasize the need for comprehensive genetic counseling in reproductive decision-making.

P03.040.C Exploring socio-demographic factors in a 2-year cohort of patients offered rapid prenatal exome sequencing across the North East of England and Yorkshire (NEY)

Aliza Z. Imam[1,2], *Sunayna Best*[2], *Leila Amel Riazat Kesh*[2], *Alison Stewart*[3], *Richard Sayers*[3], *Laura Yates*[4], *Patricia Wells*[4], *Martin McClatchey*[4], *Kate Richardson*[4], *Stephanie Allen*[5], *Kirsty Fogg*[5], *Denise Barnes*[1], *Andrew Michaelson*[1], *Jennifer Campbell*[1,2]

[1]*North East and Yorkshire Genomic Service, Newcastle upon Tyne, United Kingdom,* [2]*Leeds Clinical Genomics Service, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom,* [3]*Sheffield Clinical Genomics Service, Department of Clinical Genetics, OPD2, Northern General Hospital, Sheffield, United Kingdom,* [4]*Northern Genetics Service, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom,* [5]*West Midlands Regional Genetics Laboratory, Birmingham Women's and Children Foundation Trust, Birmingham, United Kingdom.*

Background: In England, the national prenatal exome sequencing (pES) service offers rapid genetic testing for pregnancies with significant fetal anomalies with a likely monogenic cause. The NEY region serves a diverse population, including some of the most socio-economically deprived areas in England, rural communities, and urban areas, such as Bradford with a large ethnic minority population where consanguineous marriage is common[1]. We examined all pES cases between 01/08/2021 and 31/12/2023 to identify patterns in the use of and the impact of this specialist testing.

Methods: Retrospective analysis of patient records was undertaken in the 3 Clinical Genomics services: Leeds, Sheffield, and Newcastle. Patients were identified through genomics laboratories and clinical databases.

Results: 109 pES were completed, with 29 pathogenic or likely pathogenic variants reported. Overall 12.8% of couples were consanguineous. Diagnostic yield was higher within the consanguineous group than the non-consanguineous group (35.7% vs 26.1%). Geographical analysis showed samples received from rural and urban areas. Lower than expected test rates were observed in some areas corresponding to those with higher consanguineous populations and rates of congenital anomalies[1]. Socio-economic deprivation was not associated with low testing rates.

Conclusion: Testing rates were lower, but the diagnostic yield was higher in areas with high levels of consanguinity. Further work is required to understand if testing is not being offered or accepted, and to ensure equity of access to pES across NEY. We will explore the potential barriers and enablers of access to pES

testing that may help understand different patterns across the region.

P03.041.D Prenatal characterization of a pathogenic variant in enoyl Coenzyme A hydratase short chain 1 (ECHS1): a case report

Elisabeth B.M.P. Vandendriessche[1], *Ingrid Krapels*[2], *Maud Tijssen*[1], *Christine Willekes*[1]

[1]*MUMC+, Maastricht, Netherlands,* [2]*Maastricht University Medical CenterClinical Genetics, Maastricht, Netherlands.*

Background: Pathogenic variation in ECHS1 gene is described as causative for autosomal recessive mitochondrial short-chain enoyl-CoA hydratase 1 deficiency (ECHS1D, OMIM#616277). Disturbed metabolism of branched-chain amino acids leads to lactic acidosis and is known to cause neurodegenerative Leigh-like syndrome in neonates and infants. Data on prenatal features are scarce, although abnormal corpus callosum, facial dysmorphic features and cardiomyopathy were described before. In this case of ECHS1D we describe severe neurodevelopmental delay prenatally determined by ultrasonography and MRI.

Material and methods: Case report highlighting the diagnostic pathway in a singleton pregnancy from mid-trimester ultrasound scan to prenatal diagnosis of ECHS1D.

Results: Patient was referred at 19 weeks of gestation with single umbilical artery for a detailed mid-trimester ultrasound scan. Additionally a thin, though intact, corpus callosum and interhemispheric cystic lesion were visualized. Routine follow-up ultrasound scan at 28 weeks of gestation revealed 8 weeks of delay in gyration pattern, which was confirmed by MRI; pachygyria, polymicrogyria and cysts in basal ganglia were noted, next to hepatomegaly. MRI was repeated with only minimal progression of gyration pattern. Amniocentesis was performed. Whole Exome Sequencing (WES) with trio-analysis led to the identification of a homozygous pathogenic variant in ECHS1 gene c.817A>G p.(Lys273Glu) in the fetus, causative for ECHS1D. Both parents were found to be heterozygous carriers. Pregnancy was terminated at 32 weeks of gestation.

Conclusion: Prenatal abnormal gyration pattern, cysts in basal ganglia and fetal hepatomegaly were the main features in this case leading to the prenatal diagnosis of mitochondrial short-chain enoyl-CoA hydratase 1 deficiency.

P03.042.A Prenatal diagnosis and neonatal phenotype of a newborn with a de novo heterozygous LZTR1 gene variant

Federica Lo Bascio[1,2], *Valentina Pinna*[3,4], *Maria Lisa Dentici*[2], *Lorenzo Sinibaldi*[2], *Maria Grazia Di Gregorio*[3], *Gerarda Mastrogiorgio*[3], *Rossella Capolino*[2], *Sarah Cetola*[4], *Giorgia D'Ortenzi*[1], *Laura Tirrito*[1,3], *Federico Casciani*[1,2], *Miriam L. Carriero*[1,2], *Alessio Ludovico Del Popolo*[1,2], *Alessia Micalizzi*[3,4], *Giuseppe Novelli*[1], *Antonio Novelli*[4,5], *Maria Cristina Digilio*[2]

[1]*Department of Biomedicine and Prevention, Tor Vergata University of Rome, 00133, Rome, Italy, Rome, Italy,* [2]*Medical Genetics Unit Translational Pediatrics and Clinical Genetics Research Area, Bambino Gesù Children's Hospital, IRCCS, 00146 Rome, Italy, Rome, Italy,* [3]*Medical Genetics Unit, San Pietro Fatebenefratelli Hospital, Rome, Italy, Rome, Italy,* [4]*Laboratory of Medical Genetics, Translational Cytogenomics Research Unit, Bambino Gesù Children's Hospital, IRCCS, 00146 Rome, Italy., Rome, Italy,* [5]*UniCamillus, Saint Camillus International University of Health Sciences, 00131 Rome, Italy, Rome, Italy.*

Background: Pathogenic variants in LZTR1 are associated with schwannomatosis, a hereditary tumor predisposition syndrome, and Noonan syndrome (NS), characterized by facial anomalies, cardiac defects, developmental and growth delay, following autosomal dominant or recessive inheritance. This study reports neonatal clinical features of a NS patient with a de novo heterozygous variant in LZTR1 gene identified during pregnancy following ultrasound detection of fetal hydrops.

Material and methods: Genetic tests were performed on amniotic fluid.

Results: Fetal ultrasound at the 28th week revealed severe fetal hydrops and bilateral pleural effusion. Karyotype and array-CGH analysis were normal. NGS-based trio testing identified a de novo heterozygous missense variant, c.742G>A p.(Gly248Arg), in the LZTR1 gene, classified as pathogenic according to the ACMG criteria, causing NS. At birth, the baby presented chylothorax, large patent ductus arteriosus, renal failure, left vocal cord paralysis, severe obstructive apnea, hypothyroidism, redundant skin on the neck, hypertelorism and dysmorphic ears.

Conclusion: Fetal hydrops was the prenatal clinical sign driving specific genetic testing during pregnancy. The present case is supporting the evidence that also autosomal dominant NS caused by LZTR1 may manifest with fetal hydrops, previously reported only in the autosomal recessive form. Prenatal detection of thoracic effusion and cystic hygroma has been reported previously in two fetuses with the c.742G>A LZTR1 variant. The present report is highlighting clinical difficulties in identifying the classic NS phenotype in newborns with LZTR1 variant when cardiac defect is not present and fetal hydrops is masking characteristic facial features.

P03.043.B Insights in underlying pathophysiology of brain malformations associated with *VRK1*-related syndrome derived from fetal neuropathology

Aude Tessier[1], *Olivier Monestier*[1], *Debray Francois Guillaume*[2], *Vanthier Frederic*[1], *Valerie Benoit*[1], *Kim van Berkel*[3], *Ghassemi Leila*[4], *Brock Stefanie*[5]

[1]*IPG, Gosselies, Belgium,* [2]*Sart-Tilman University Hospital, Liège, Belgium,* [3]*VUB - UZ Brussel, Brussel, Belgium,* [4]*Hôpital Citadelle, Liège, Belgium,* [5]*UZ-VUB, Bruxelles, Belgium.*

Biallelic variants in *VRK1* have been described in patients with heterogeneous phenotypes with childhood or adult-onset of progressive upper and lower motor neuron disease. Prenatal onset and neurodevelopmental disorders associated with *VRK1* have rarely been described in the literature. Here, we report on the first fetal cases and first neuropathological examination of the brain in patients with pathogenic variants in *VRK1*. Two fetuses from consecutive pregnancies of second-degree consanguineous parents presented with microcephaly prenatally during the early second trimester. Termination of pregnancy was performed for

both cases. Post-mortem examination showed overlapping features including facial dysmorphisms, microencephaly, agenesis of the corpus callosum, absent gyration and reduced neuronal density of the cortex, suggesting a simplified gyral pattern. One of the two fetuses showed an unusual macroscopic appearance of muscle hypertrophy that could underlie a neuromuscular disease, in the absence of histological anomalies. No visceral malformations were observed. Whole exome sequencing identified a homozygous likely pathogenic variant in *VRK1* (NM_003384.3, GRCh38):c.238C>G p.(Leu80Val) in both fetuses. The variant is located in a previously reported cluster close to the ATP-binding site. The parents were heterozygous carriers of the variant. Neuropathological examination in these cases provides first insights in the underlying pathophysiological process of biallelic pathogenic variants in *VRK1* in humans. Our findings are evocative of a combination of impaired neuronal proliferation, of a neuronal migration deficit, and abnormal axon guidance.

P03.044.C Diagnosing mosaic variants by trio exome sequencing in termination of pregnancy fetuses

Liron Malki[1], *Alina Kurolap*[1], *Yuval Yaron*[1,2], *Hagit Baris Feldman*[1,3]

[1]*The Genetics Institute and Genomics Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel,* [2]*Prenatal Genetic Diagnosis Unit, Genetics Institute, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel,* [3]*School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel.*

Background: Genetic analysis in fetuses can pose different diagnostic challenges in variant discovery and interpretation. We present mosaic variants detected by trio exome sequencing (tES) in fetuses with major anomalies.

Material and methods: The cohort included three fetuses following termination of pregnancy due to major anomalies. The first fetus (male) was presented with abnormal embryonic development, abnormality of the nose, abnormal hip bone morphology, and abnormal morphology of female internal genitalia. The second fetus (female) presented with sonographic non-visualized fetal bladder and cleft lip and palate. The third fetus (male) presented with abnormal brain morphology and mild malformation of cortical development.

Results: tES analysis identified two CNVs and one SNV de novo mosaic variants:The first fetus carried a de novo mosaic duplication (70%) of chromosome 12p, suggesting Pallister Kilian syndrome. The second fetus carried a de novo likely pathogenic mosaic variant (21%) in the MED12 gene (c.2238C>A; p.Cys746*), consistent with X-linked autosomal dominant Hardikar syndrome. The third fetus carried a de novo mosaic duplication (50%) of chromosome 21, diagnostic of Down syndrome.

Conclusion: These data suggest that tES may be considered as a first-tier test for prenatal diagnosis of major fetal anomalies, detecting both CNV and SNV variants, even in mosaic form. This is of particular importance in the time-frame constraints of an ongoing pregnancy.

P03.045.D De novo *FBN2* variant in exon 33 associated with complex congenital heart disease and hydrops fetalis: expanding the prenatal phenotype

Elisa Nizzetto[1,2], *Elena Andreucci*[2], *Francesco Marco Parodo*[3,2], *Maria Cristina Stefano*[2,3], *Rosangela Artuso*[2], *Marilena Pantaleo*[2], *Silvia Guarducci*[2], *Lucia Tiberi*[2], *Debora Vergani*[2], *Samuela Landini*[2], *Elia Dirupo*[2], *Laila Zaroili*[2], *Roberto Biagiotti*[4], *Giorgia Monti*[4], *Angela Peron*[2]

[1]*University of Padova, Department of Women's and Children's Health SDB, Padova, Italy,* [2]*Division of Medical Genetics, Neuroscience and Medical Genetics Department, Meyer Children's Hospital IRCCS, Florence, Italy,* [3]*Department of Clinical and Experimental Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy,* [4]*Prenatal Diagnosis Unit - Meyer Children's Hospital IRCCS, Florence, Italy.*

Background: The *FBN2* gene encodes fibrillin-2, a key structural component of connective tissue expressed in the heart. *FBN2* pathogenic variants cause congenital contractural arachnodactyly (CCA), which is characterized also by the presence of cardiac disease (primarily atrial and ventricular septal defects, aortic root dilation and valvulopathy) with no prenatal phenotype reported so far.

Material and methods: We present a case of a complex congenital heart disease detected in a fetus at 20 weeks of gestation. Ultrasonography identified cardiomegaly, right ventricular dysfunction, hypoplastic pulmonary valve with regurgitation, tricuspid valve insufficiency, abnormal ductus venosus, reversed ductus arteriosus flow, severe intra-uterine growth restriction, asymmetric cerebral ventriculomegaly and hydrops fetalis. Maternal infectious disease screening showed positive IgM and IgG against Parvovirus B19. Genetic analyses were performed on DNA from abortive tissue and from the couple's blood samples: Array-CGH ruled out genomic imbalances in a female fetus; targeted exome sequencing identified a *FBN2* de novo variant: p.(Thr1428Ile), absent in GnomAD and previously unreported in the scientific literature.

Results: Recent reports suggest that *FBN2* variants in exons 31–35 may be associated with an increased risk of structural heart disease, along with CCA. The variant we found is located in exon 33 and for this reason is strongly suspected to be associated with fetal anomalies and classified as likely pathogenic.

Conclusion: This report provides further evidence of genotype-phenotype correlation for *FBN2* and suggests a possible role of exons 31–35 pathogenic and likely pathogenic variants in the fetal presentation of structural heart disease.

Camillus International University of Health Sciences, 00131, Rome, Italy, [6]Medical Genetics Unit, Tor Vergata University Hospital, 00133, Rome, Italy.

Background: Enlarged parietal foramina (EPF) (OMIM *609597) are rare, symmetric, oval defects of parietal bones located on each side of sagittal suture. Although EPF are usually asymptomatic, some patients show symptoms such as headache, vomiting, pain over the exposed cerebral cortex and seizures. Prenatally diagnosed EPF are typically incidental findings, with encephalocele or myelocele being the most common differential diagnoses. We report a prenatal case with pathological ultrasound findings suggestive for occipital meningocele. Fetal MRI showed a rounded appearance of the cranial profile in the bilateral parieto-occipital area with possible meningeal herniation and without evident herniation of brain tissue.

Material and methods: Genetic tests were performed on amniotic fluid.

Results: Karyotype analysis and array-CGH analysis were normal. NGS-based analysis identified a de novo heterozygous c.653G>A (p.Arg218Gln) variant in the ALX4 gene. At birth, the infant was noted to have fluctuating masses at the bilateral parietal region. Brain MRI revealed the "presence of two areas of osseous discontinuity at biparietal region, associated with meningoencephalocele".

Conclusion: Case reports on EPF are crucial for advancing our understanding of this condition, especially since prenatal diagnosis remains exceedingly rare. Dominant heterozygous mutations in the ALX4 (OMIM *605420) gene is associated with EPF with high penetrance and phenotipic variability. EPF is often a benign disorder; knowledge on this condition can prevent performance of unnecessary tests and treatments, reducing the anxiety of parents. Furthermore, this work underlines the value of NGS analysis as an essential component in prenatal diagnosis, in medical management and parental decision making.

P03.048.C Is a large deletion always pathogenic? 8p23.2 deletion in a healthy family

Michal Barzily Rokni[1], *Sharon Zeligson*[1], *Miriam Patt*[1], *Malka BenUziyahu*[1], *Tal Dror*[1], *Tali Yuditsky*[1], *Lihi Amit*[1], *Omri Weiss*[1], *Reeval Segel*[1,2]

[1]*Genetic institute, Shaare Zedek Medical center, Jerusalem, Israel,* [2]*Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel.*

Background: Chromosomal 8p23.2-pter microdeletions are extremely rare and to date only twelve patients have been reported. Clinical manifestations include mild-to-moderate cognitive impairment, dysmorphism, and neurobehavioral issues[1]. Recently, an individual with 8p23.2-pter microdeletion and normal development was reported[2]. We present a family with three asymptomatic individuals with 8p23.2-pter microdeletions identified as part of follow up testing after a prenatal diagnosis.

Objectives: To expand the clinical knowledge of individuals with 8p23.2-pter microdeletions to provide better genetic counseling to families with this finding.

Results: Amniocentesis was performed on a healthy 32-year-old female at 20 weeks gestation due to low b-HCG detected in a triple screen test (0.11 MOM). Chromosomal microarray (CMA) showed a female fetus with 6,025 KB deletion at 8p23.3-8pter.

The microdeletion was inherited from the fetus's healthy, normally developed mother, who had only mild toe malformations. Further testing done via fluorescent in situ hybridization (FISH) revealed that the microdeletion was also present in two of the fetus's siblings, both healthy children with normal development, ages 2 and 10 years. Additional testing established the microdeletion as de-novo in the mother. The couple opted to continue with the pregnancy. At age 4 months, the baby girl is a beautiful baby, with normal development.

Conclusion: We present a healthy female and her three children with normal development all carrying an 8p23.2-ter microdeletion. Together with the current information available in the literature regarding individuals with this large deletion, this report may help genetic counseling in future cases.

P03.049.D Identification of a new phenotype combining anencephaly and fronto-nasal dysplasia associated with *ZIC2* pathogenic variants

Mathieu Philippe[1], *Christele Dubourg*[1,2], *Wilfrid Carre*[1,2], *Valérie Dupe*[2], *Sylvie Odent*[3,2], *Chloé Quelin*[3,4], *Marie Faoucher*[1,2]

[1]*Service de Génétique Moléculaire et Génomique, CHU de Pontchaillou, Rennes, France,* [2]*Univ Rennes, CNRS, INSERM, IGDR, UMR 6290, ERL U1305, Rennes, France,* [3]*Service de Génétique Clinique, Centre de Référence Maladies Rares CLAD-Ouest, ERN ITHACA, CHU de Pontchaillou, Rennes, France,* [4]*Anatomie et cytologie pathologiques, CHU de Pontchaillou, Rennes, France.*

Neural tube defects (NTDs) are congenital malformations that arise during the third week of embryogenesis, characterized by the incomplete closure of the neural tube, the precursor of central nervous system (CNS). Anencephaly represents the cephalic form of NTDs. The transcription factor *ZIC2* plays a crucial role in CNS patterning during development and is known contributor to holoprosencephaly, a congenital brain malformation caused by the incomplete division of the forebrain into two hemispheres during early development. Here, we report the first two cases of anencephaly associated with fronto-nasal dysplasia (FND) related to pathogenic variant in *ZIC2*.

The first patient was diagnosed with anencephaly by ultrasound during pregnancy, and autopsy additionally revealed FND. The pregnancy was a monozygote twin gestation. The second fetus was diagnosed with semi-lobar holoprosencephaly after birth. The second case also involved anencephaly and FND. In the first family, SANGER sequencing identified a de novo heterozygous frameshift pathogenic variant in *ZIC2*, p.(Cys398Argfs*18) which was also present in the twin. In the 2nd case, exome sequencing identified a heterozygous de novo missense variant in *ZIC2*, p.(Asn349Ser), with pathogenic predictions from in silico *analysis*.

We report here for the first time a novel phenotype associated with ZIC2 by describing two cases of anencephaly associated with FND. Our findings suggest that mutations in ZIC2 can lead to diverse phenotypic outcomes, ranging from holoprosencephaly to abnormal neural tube closure with FND. Consistent with this, Zic2 mutant mice exhibit, in addition to the holoprosencephaly, delayed neurulation, which results in neural tube closure defects.

P03.050.A Rare prenatal finding : *AKT1* somatic variant for which phenotype ?

Alice BOURGES[1,2], *Françoise Boussion*[3], *Clarisse Battault*[1,2], *Randa Benarbia*[1,2], *Florence Biquard*[3], *Celine Bris*[1,2], *Antoine Civit*[1,2], *Benoit Delorme*[4], *Clara Houdayer*[1,2], *Magalie Lodin-Pasquier*[1,2], *Didier Loisel*[4], *Mathilde Pacault*[1,2], *Vincent Procaccio*[1,2], *Patrick Van Bogaert*[5], *Agnes Guichet*[1,2], *Paul Kuentz*[6], *Estelle Colin*[1,2]

[1]*University Hospital of Angers, Genetics, Angers, France,* [2]*2University of Angers, Mitovasc Unit, UMR CNRS 6015 INSERM 1083, Angers, France,* [3]*University Hospital of Angers, Gynecology and Obstetrics, Angers, France,* [4]*University Hospital of Angers, Paediatric Radiology, Angers, France,* [5]*University Hospital of Angers, Paediatric Neurology, Angers, France,* [6]*University Hospital of Besancon, Genetics, Besancon, France.*

Background: Prenatal reports of pathogenic *AKT1* (OMIM*164730) variants are extremely rare, with limited descriptions of prenatal manifestations. The most frequently reported features include limb malformations, grey matter heterotopia, brain parenchymal anomalies, and megalencephaly.

Material and methods: A woman was referred to our center at 23 weeks of gestation (WG) for macrocrania exceeding the 99th percentile. A finding confirmed at 23 WG+5, along with a pronounced parieto-occipital sulcus. At 31 WG+5, fetal MRI revealed megalencephaly, temporal polymicrogyria, and atypical operculization of the Sylvian fissures. The pregnancy was continued.

Results: The array performed on native amniotic fluid (AF) was normal. Trio exome sequencing on native AF revealed a de novo heterozygous mosaic missense variant of unknown significance in *AKT1* (NM_001382430.1:c.235C>A, p.(Gln79Lys)) with a variant allele frequency of 26%. Deep NGS sequencing confirmed post-zygotic transmission. Cultured AF cells revealed a selective advantage, allowing the variant to be reclassified as likely pathogenic.

Conclusion: We report this *AKT1* somatic variant at a prenatal stage for the first time. Previously, it was described as pathogenic in a child with AKT1-related overgrowth syndrome without any reported cerebral manifestations, and differs from the recurrent *AKT1* variant (c.49G>A, p.(Glu17Lys)) in Proteus syndrome. While the clinical and molecular correlation remains uncertain, pathogenicity cannot be excluded. Could the variability of AKT1-related disorders indicate a broader spectrum of overgrowth syndromes ? Given the identification of a mosaic *AKT1* variant, we highlight the importance of analyzing both native AF and cultured AF cells for accurate variant classification.

P03.052.C Genomic and epigenomic analysis of fetal hydrocephalus in ARID1A-associated BAFopathy: potential role of aberrant non-sense mediated RNA decay

Kenjiro Kosaki[1], *Yuya Tanaka*[1], *Mamiko Yamada*[1], *Fuyuki Miya*[1], *Noboru Inagaki*[2], *Toshimitsu Otani*[1], *Yoshifumi Kasuga*[1], *Mamoru Tanaka*[1]

[1]*Keio University School of Medicine, Tokyo, Japan,* [2]*Saint Women's Clinic, Saitama, Japan.*

Germline variants in *ARID1A* have been associated with the so-called BAFopathies, including Coffin-Siris syndrome, which is characterized by microcephaly, hirsutism, and small nails and is associated with a unique episignature. Hydrocephalus has not been considered part of BAFopathy until recently, when *ARID1A* variants were implicated in prenatal-onset hydrocephalus. It remains unknown whether *ARID1A*-associated hydrocephalus is linked to a specific class of variants and whether it exhibits an episignature comparable to that of BAFopathies. We conducted genomic and epigenomic analyses on a fetus diagnosed with severe hydrocephalus on prenatal ultrasound at 19 weeks. After detailed counseling, the pregnancy was terminated at 21 weeks. The delivered fetus exhibited hirsutism and small nails. With approval from the ethics committee and appropriate consent, exome sequencing using umbilical cord blood identified a de novo heterozygous frameshift variant in the last exon of ARID1A (NM_006015.6:c.5259_5262dupGTCT, p.(Ser1755Valfs*2)). In parallel, episignature analysis was conducted using nanopore sequencing and a support vector machine-based classifier. The epigenetic profile was consistent with BAFopathy. The frameshift variant in the last exon is expected to escape nonsense-mediated decay (NMD). Although NMD has not been previously linked to ARID1A-related hydrocephalus, a retrospective review of published cases identified at least three fetuses with hydrocephalus who likely had disrupted NMD due to truncating ARID1A variants in the last or penultimate exons. In conclusion, ARID1A-associated hydrocephalus occurs within the broader clinical and epigenomic spectrum of BAFopathy but involves a distinct genetic mechanism, including aberrant NMD surveillance, which had not previously been recognized as a potential contributing factor.

P03.053.D Socioeconomic Status and Termination of Pregnancy for Trisomy 21

Sofie Ølgaard, *Ellen Hollands Steffensen, Ida Vogel, Lars Henning Pedersen*

Aarhus University Hospital, Aarhus, Denmark.

Background: Socioeconomic status (SES) influences the use of the health-care system. The potential association between SES and the propensity for choosing to terminate a pregnancy following a prenatal diagnosis of trisomy 21 is, however, not well-documented. Knowledge on such associations may help us provide unbiased information to all patients regardless of SES.

Material and methods: Registry-based study including all pregnant women with a trisomy 21 diagnosis based on prenatal invasive test from 1995–2018. The study population was defined from the Danish Fetal Cytogenetic Register. Exposure was defined as SES one year prior to the invasive test. Outcome was either termination or continuation of pregnancy, extracted from The Danish Fetal Medicine Database, The National Patient Register, The Medical Birth Registry and The Danish Cytogenetic Central Register.

Results: Of 2 591 women, 4.3% chose to continue their pregnancy after a trisomy 21 diagnosis based on an invasive test. Socioeconomic status was associated with the choice of continuing or terminating pregnancy, e.g, OR of continuing pregnancy was 4.45 [2.26 ; 8.74] for women or families with low occupational classification compared to women or families with high occupational status. The association was modified by age, ethnicity and parity of the women, but an association remained in adjusted analyses.

Conclusion: SES was associated with the propensity of choosing to continue a pregnancy with a trisomy 21 diagnosis. The result is of clinical and public health significance even though

the direction of the association, may be limited to health care systems similar to Denmark.

P03.054.A Characterization of two cases of pyruvate dehydrogenase E1-alpha deficiency with prenatal presentation

Raquel G. Silva[1], *Márcia Rodrigues*[1], *Catarina Macedo*[1], *Lucília Carvalho*[2], *Vera Mourinha*[3], *José C. Ferreira*[4], *Teresa Loureiro*[4], *Ana B. Sousa*[1]

[1]*Serviço de Genética, Departamento de Pediatria, ULS Santa Maria, Lisboa, Portugal,* [2]*Serviço de Anatomia Patológica, ULS Lisboa Ocidental, Lisboa, Portugal,* [3]*Serviço de Obstetrícia e Ginecologia, ULS Algarve, Algarve, Portugal,* [4]*Departamento de Obstetrícia, Ginecologia e Medicina da Reprodução, ULS Santa Maria, Lisboa, Portugal.*

Background: Pyruvate dehydrogenase E1-alpha deficiency (PDHAD) is a X-linked neurometabolic disorder caused mostly by variants in PDHA1 gene encoding the E1-alpha subunit. The clinical spectrum is broad, ranging from fatal neonatal lactic acidosis to chronic neurologic dysfunction with structural brain malformations. There is a high proportion of heterozygous females with severe phenotypes. Only a few prenatal case reports have been published.

Material and methods: We describe two cases of PDHAD presenting prenatally. In the first case, both monozygotic female fetuses of a dichorionic twin pregnancy (with prior family history and prenatal diagnosis of classic simple virilizing adrenal hyperplasia) presented at 21 weeks with bilateral cavitations of the ganglionic eminence, partial agenesis of the corpus callosum (cc) and cerebellar hypoplasia. The second case was a single female fetus presenting with growth restriction at 23 weeks, who at 27 weeks showed cc atrophy and extensive periventricular destructive lesions with brain volume reduction, compatible with neuronal migration anomalies, confirmed by MRI. Both couples decided for TOP.

Results: Quad (first case) and trio (second case) WES were performed, revealing, respectively, a de novo heterozygous likely pathogenic missense variant, and a de novo heterozygous pathogenic frameshift variant in PDHA1 gene, leading to a diagnosis of PDHAD in both cases. Fetal autopsies corroborated the prenatal findings.

Conclusion: The brain abnormalities detected in our cases have been previously described. These cases highlight the relevance of performing WES in fetuses with CNS abnormalities, and allow further characterization of the rare prenatal presentation of PDHAD. This may help establish genotype-phenotype correlations.

P03.055.B Prenatal diagnosis of MSL2-related ventriculomegaly in association with an inherited 15q13 microduplication

Omar Zgheib[1], *Thomas Rio Frio*[1], *Jean-Marie Pellegrinelli*[1], *Stefania Gimelli*[1], *Delphine Le Mercier*[1], *Mónica Rebollo Polo*[2], *Céline Habre*[1], *Joël Fluss*[1], *Russia Ha-Vinh Leuchter*[1], *Marc Abramowicz*[1], *Rosalinda Giannini*[1], *Siv Fokstuen*[1]

[1]*Geneva University Hospital, Geneva, Switzerland,* [2]*Hospital Sant Joan de Dèu, Barcelona, Spain.*

The Male-Specific Lethal 2 Homolog (MSL2) gene was recently reported to be responsible of a novel neurodevelopmental syndrome, with two reports describing 28 patients all showing some form of developmental delay, around half of whom with brain MRI abnormalities, including ventriculomegaly. Reported mutations were mostly nonsense or frameshift, arguing for haploinsufficiency and loss-of-function intolerance. We hereby report the first prenatal diagnosis of a MSL2-related pathology, notably a male fetus with a priori isolated bilateral moderate ventriculomegaly, harboring a de novo heterozygous splice mutation in *MSL2*, the first splice mutation to be reported for this gene: c.142+1G>T, r.142_143ins[u;142+2_142+88], p.(Gly48-Valfs*53). The mutation was characterized through an RNA study on amniotic fluid cells and shown to lead to a non-functional truncated protein, consistent with loss-of-function intolerance. The patient also harbored a paternally inherited 1.97-Mb recurrent microduplication at 15q13.2-q13.3, known to be of incomplete penetrance and variable expressivity, but not associated with ventriculomegaly. Postnatally, the proband presented with persistent triventricular dilatation, a narrowed aspect of the aqueduct of Sylvius, square-shaped lateral ventricle frontal horns, but favorable 6-month clinical outcome. Clinical and radiological follow up will be crucial to better define the impact of the *MSL2* mutation and 15q13 microduplication on his development. This case illustrates the challenges in predicting postnatal outcomes for genetic anomalies linked to recently characterized phenotypes with limited documented cases. Characterization of more patients with *MSL2* mutations will contribute to better understanding of penetrance and phenotypic diversity. Genetic counselling in this case is further complicated by a second distinct genetic anomaly.

P03.056.C Demographics influence on Down syndrome incidence and prenatal screening in Saint-Petersburg

T. K. Kascheeva[1], *E. S. Shabanova*[2];

[1]*D.O. Ott Institute of Obstetrics Gynecology and Reproductology, Saint-Petersburg, Russian Federation,* [2]*D.O. Ott Institute of Obstetrics Gynecology and Reproductology & I.I. Mechnikov Northwestern State Medical University, Saint-Petersburg, Russian Federation*

Background: The total first trimester Down's syndrome screening (FTS) in Saint-Petersburg was performed since 2012. An original bioinformatics algorithm for NIPT is used in contingent screening for women with DS risk from 1/101 to 1/1000 since 2021. **Aim**. To study the influence of migration, maternal age and screening strategy on the frequency of Down syndrome outcomes and to characterize problems that should be taken into account in city prenatal service.

Material and methods: The results of a survey of 2,083 women in the case of pre- and postnatal trisomy 21 detection in St. Petersburg from 2013 to 2023 were analyzed. Statistical processing was carried out using standard software.

Results: In 2013 the share of mothers aged 25–29 was 38.6% and decreased to 24.7% in 2023, and the group of 35–39 years were doubled (from 12.8 to 24.3%). In 11 years, the proportion of mothers aged 40 and over has been raised in 3 times. An efficiency of the city prenatal service has been increased from 60% to 94%. There is a trend in increase of gestational age at invasive

testing. 16% of women among prenatally diagnosed cases and 9% - among Down syndrome newborns did not undergo the FTS. The average incidence of Down syndrome cases (detected pre- and postnatally) increased from 1/412 to 1/258 newborns.

Conclusion: It is necessary to transfer invasive diagnostics to earlier pregnancy. An increase in the maternal age and migration processes affected the frequency of Down syndrome in Petersburg.

P04 Sensory disorders (Eye, Ear, Pain)

P04.001.D Insights into the role of long noncoding RNA in inherited retinal disorders

Maria Magdalena Zawadzka, *Paola Brandi, Filomena Capolongo, Santiago Negueruela, Mariateresa Pizzo, Sandro Banfi*

Telethon Institute of Genetics and Medicine, Pozzuoli, Italy.

Background: Inherited retinal diseases (IRDs) are genetic disorders characterized by retinal degeneration and progressive visual impairment. The main feature of these disorders is the high clinical and genetic heterogeneity that represent a limitation for the application of gene specific therapies. For this reason, mutation-independent therapeutic approaches are gaining interest. In this direction, we focused our attention on noncoding RNAs, and in particular on long noncoding RNAs (lncRNAs). In recent years there has been an increasing amount of data suggesting their role in ocular diseases. For this reason, we aimed at generating a lncRNA expression atlas in the retina in different mouse models of inherited retinal diseases using Next Generation Sequencing-based approaches.

Material and methods: We performed single cell isolation from the retinas of rd10, RHO-P347S and WT mice using Fluorescence Activated Cell Sorting. Next we carried out RNAseq analysis on the main stages of retinal degeneration mainly focusing on rods.

Results: We identified a dataset of lncRNAs displaying the highest expression levels at the analyzed stages and identified some of them being differentially expressed between wild type and degenerating retina.

Conclusion: Different expression levels of lncRNAs between healthy and diseased retina at different stages of disease may indicate their involvement in pathological processes in IRDs. Some of the identified lncRNAs or their coding partners have been already reported in retinal development and degeneration (e.g., Rncr4, Fgf2os, Prox1os), highlighting the need for further studies on their precise role in IRDs.

P04.002.A Loss of the Golgi stacking protein GRASP65 (GORASP1) causes glycosylation and mitotic defects associated with deafness, muscle cramps, vitreoretinopathy and white matter abnormalities (Award Candidate)

Sophie Lebon[1], *Arnaud Bruneel*[2,3,4], *Séverine Drunat*[5], *Alexandra Albert*[1], *Zsolt Csaba*[1], *Monique Elmaleh*[6], *Alexandra Ntorkou*[6], *Yann Ténier*[7], *François Fenaille*[7], *Pierre Gressens*[1], *Sandrine PASSEMARD*[1,8], *Odile Boespflug Tanguy*[1,8], *Imen Dorboz*[1,8], *Vincent El Ghouzzi*[1]

[1]*Université Paris Cité, NeuroDiderot, Inserm UMR1141, Paris, France,* [2]*Université Paris Saclay, Saclay, France,* [3]*Inserm UMR1193, Faculté de Pharmacie, Paris, France,* [4]*AP-HP Département de Biochimie Métabolique et Cellulaire, Hôpital Bichat, Paris, France,* [5]*AP-HP Département de Génétique, Hôpital Robert Debré, Paris, France,* [6]*AP-HP Département de Radiologie Pédiatrique, Hôpital Robert Debré, Paris, France,* [7]*Université Paris Saclay, CEA, INRAE, Département Médicaments et Technologies pour la Santé, MetaboHUB, Gif-sur-Yvette, France,* [8]*AP-HP Département de Neurologie Pédiatrique, Hôpital Robert Debré, Paris, France.*

Background: GRASP65 is a Golgi-associated peripheral protein encoded by the GORASP1 gene and is required for Golgi ribbon integrity in mammals. In vitro and in vivo models suggest that the protein also plays a key role in glycosylation and in regulating the entry of cells into mitosis, but the gene has never been associated with any human pathology.

Material and methods: Trio WGS identified a human pathogenic variant in the GORASP1 gene in a patient with a neurodevelopmental disorder combining white matter abnormalities, progressive deafness, myalgia episodes with muscle cramps but without rhabdomyolysis, severe myopia with vitreoretinopathy, and skeletal abnormalities. Cognitive assessments revealed poor verbal performance with severe dyslexia, and attention deficit hyperactivity disorder. Patient fibroblasts as well as RPE cells in which a similar mutation was introduced by CRISPR/Cas9 were used for functional studies.

Results: The variant is homozygous and causes a frameshift resulting in a stable transcript but a total absence of the GRASP65 protein. The structure of the Golgi apparatus did not show fragmentation, but glycosylation anomalies such as hyposialylation of membrane glycoproteins were detected in patient cells. Mitosis analyses revealed an excess of prometaphases and metaphases with polar chromosomes, suggesting a delay in cell cycle. These cellular defects were recapitulated in mutant RPE cells.

Conclusion: Together, these findings indicate that loss of GRASP65 in humans causes a novel Golgipathy associated with defects in glycosylation and mitotic progression. The identification of new patients will provide a better understanding of the pathology and the GRASP65 functions involved.

P04.003.B Clinical applications of long-read sequencing: enhancing diagnosis and guiding decision-making in inherited retinal disorders (Award Candidate)

Elena Fernández-Suárez[1,2], *María González-del Pozo*[1,2], *Cristina Méndez-Vidal*[1,2], *Belén de la Morena-Barrio*[3], *Javier Corral*[3], *Salud Borrego*[1,2], *Guillermo Antiñolo*[1,2]

[1]*Department of Maternofetal Medicine, Genetics and Reproduction, Institute of Biomedicine of Seville (IBiS)/Virgen del Rocío University Hospital/CSIC/University of Seville, Seville, Spain,* [2]*Center for Biomedical Network Research on Rare Diseases (CIBERER), Seville, Spain,* [3]*Department of Haematology and Medical Oncology, Morales Meseguer University Hospital, Regional Hemodonation Center, University of Murcia, IMIB-Pascual Parrilla, CIBERER, Murcia, Spain.*

Background: Inherited retinal disorders (IRD) are a heterogeneous group of rare diseases that cause progressive and irreversible vision loss. Despite advances in next-generation sequencing (NGS), 30–40% of IRD cases remain without a definitive genetic diagnosis, limiting clinical decision-making. This study aims to

implement a long-read sequencing (LRS) approach to improve diagnostic yields in selected IRD cases previously studied by short-read sequencing with negative or inconclusive results. In addition, the challenging ORF15 region of *RPGR* was also examined in X-linked cases.

Material and methods: Different LRS approaches using MinION or PromethION devices were applied to study 45 individuals from 27 IRD families, including amplicon sequencing (22 families), adaptive sampling (3 families), and whole-genome sequencing (2 families). Tertiary data analyses were conducted using an in-house bioinformatics pipeline. Candidate variants detected were validated through PCR and Sanger sequencing.

Results: This approach enabled a new genetic diagnosis in three previously unsolved families by identifying challenging structural variants (SVs), including retrotransposon insertions and duplications. Additionally, LRS confirmed biallelism in 11 families, suggesting an autosomal recessive inheritance, and enhanced detection while facilitating family segregation studies of *RPGR*-ORF15 variants in 11 families. One straightforward clinical application of these findings has been enabling access to Luxturna gene therapy for a patient with *RPE65* variants.

Conclusion: Our results highlight the potential of LRS to improve genetic diagnostics, facilitate targeted treatments, and support informed clinical and reproductive decision-making for IRD patients and their families.

P04.004.C Mobile element insertions in vision disorders case descriptions in a diagnostic setting

Maartje J. Geerlings[1], *Robin Wijngaard*[1], *Carel B. Hoyng*[2], *Dzenita Smailhodzic*[3], *Patrick Rump*[4], *Jordi Corominas*[1], *Christian Gilissen*[1], *Lonneke Haer-Wigman*[1]

[1]*Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands,* [2]*Department of Ophthalmology, Radboud university medical center, Nijmegen, Netherlands,* [3]*Rotterdam Eye Hospital, Rotterdam, Netherlands,* [4]*Department of Genetics, University Medical Center Groningen, Groningen, Netherlands.*

Background: Genome sequencing is becoming part of routine diagnostics, providing a powerful tool for comprehensive variant calling. Many complex and intronic genomic variations have been overlooked previously, including mobile elements insertions (MEI). MEIs have been shown to play a role in disease mechanisms however, they have been identified in only a small fraction of patients.

Material and methods: Here, we describe the identification of MEIs in multiple cases with vision disorders, as detected by our diagnostic pipeline and integrated tool Mobile Element Locator Tool (MELT). Variants were confirmed using long-range amplicon sequencing.

Results: In 2024, our diagnostic laboratory implemented genome sequencing as the standard technique for analyzing gene panel for vision disorder. We have performed approximately 750 analyses of differential vision disorder. In these analyses, we identified multiple cases where MEIs explained the clinical symptoms of patients. Among these, we found a heterozygous Alu insertions in exon 8 of ZEB1, resulting in autosomal dominant posterior polymorphous corneal dystrophy (OMIM #609141). Additionally, two cases from the same family with heterozygous Alu insertions in exon 45 of USH2A, which, together with different heterozygous SNVs, cause Usher syndrome (OMIM #276901). Lastly, a homozygous retrotransposon LINE-1 insertion in exon 8 of IQCB1, resulting in Senior-Loken syndrome (OMIM #609254).

Conclusion: Our case descriptions demonstrate that genome sequencing, which allows for complex variation detection, such as MEIs, enhances the diagnostic yield for patients with vision disorders. In this cohort we detected a causal MEI in 0.5% of analyses, which is higher than currently reported in literature

Background: Inherited retinal diseases (IRDs) are amongst the most common Mendelian human disorders in humans. Their clinical and molecular diversity is increasingly being unveiled, with more than 346 disease genes and loci identified to date. This study

aimed to characterize the phenotypic spectrum of a cohort of patients with IRD associated with mutations in genes encoding different subunits of the vesicular Fifth Adaptor Protein (AP-5) complex, a newly-identified cause of IRD.

Material and methods: Retrospective analysis of clinical data focused on ophthalmic findings from a cohort of patients with IRD attributed to biallelic mutations in *AP5Z1*, *AP5M1*, or *AP5B1*, including retinography, optical coherence tomography, and fundus autofluorescence imaging.

Results: A total of 22 patients representing 19 families were analyzed. Initial symptoms were mostly related with central vision. Younger individuals presented with asymptomatic or paucisymptomatic macular deposits, while older patients demonstrated variable areas of outer retinal and retinal pigment epithelium atrophy, with significant visual acuity loss. Retinal imaging revealed progressive enlargement of the atrophic area in cases with available follow-up data. Additionally, 10 patients exhibited concomitant neurological findings.

Conclusion: Ocular findings in our cohort illustrate a phenotypic continuum consistent with both the maculopathy described in Kjellin syndrome and sporadically reported *AP5Z1*-associated retinal findings. SPG11, SPG15, and AP-5 complex are known to interact in order to maintain endolysosomal homeostasis. We therefore propose to designate this novel IRD phenotype, resulting from molecular defects within this functional complex, Lysosomal Macular Dystrophy.

P04.006.A Efficacy of FACS-based dual fluorescence reporter assay in developing antisense oligonucleotide therapy of novel *PRPF3* intronic splice variant

V. Dolgin[1,2], *E. Eremenko*[3], *G. Narkis*[2], *M. Mazor Oring*[2], *L. Gradstein*[4,5], *O. Birk*[1,2,6];

[1]*The Morris Kahn Laboratory of Human Genetics, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel,* [2]*Genetics Institute, Soroka University Medical Center, Beer Sheva, Israel,* [3]*Zlotowski Neuroscience Center and Regenerative Medicine and Stem Cell Research Center, Ben-Gurion University of the Negev, Beer Sheva, Israel,* [4]*Department of Ophthalmology, Soroka Medical Center and Clalit Health Services, Beer Sheva, Israel,* [5]*Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel,* [6]*The Danek Gertner Institute of Human Genetics, Sheba Medical Center, Tel Hashomer, Israel*

Background: The development of antisense oligonucleotide (AON) therapy for monogenic diseases such as retinitis pigmentosa (RP) is effective but labor-intensive. There is an urgent need for rapid, efficient technologies to select optimal AONs. We herein introduce a novel methodology to efficiently test and select therapeutic AONs, focusing on intronic splicing mutations.

Material and methods: We identified a novel heterozygous intronic non-canonical splice variant in *PRPF3* causing dominant RP in a four-generation pedigree. Using a Dual Fluorescence Reporter Assay, we transfected HEK273T cells with a reporter plasmid containing either the wildtype intron (resulting in GFP fluorescence due to normal splicing) or the mutant intron (showing no green fluorescence due to splicing defects). As an alternative to standard AONs, we used uridine-rich 7 (U7) small nuclear RNA (snRNA) derivatives with optimized Sm protein-binding site and a modified antisense sequence (U7 Sm OPT snRNA) as modulators of pre-mRNA splicing.

Results: Eight AONs were designed to target the aberrant *PRPF3* transcript, to restore normal splicing and gene function. To evaluate treatment efficacy, HEK273T cells with the reporter GFP plasmid were co-transfected with U7snRNA cassettes, each containing an incorporated AON sequence. FACS analysis quantified splicing modulation and gene expression rescue, identifying the most effective AON.

Conclusion: Our findings demonstrate the potential of the FACS-based Dual Fluorescence Reporter Assay in selecting AONs for treating splice site mutations, exemplified by a novel *PRPF3* mutation. This study broadens genetic understanding and highlights the significance of personalized medicine in treating genetic disorders.

P04.007.B 400 families' whole genome sequencing in early onset hearing loss: the French Reference Center's experience

Margaux Serey Gaut[1], *Ralyath Balogoun*[1], *Sophie Achard*[1], *Natalie Loundon*[1], *Isabelle Rouillon*[1], *Marine parodi*[1], *Souad Gherbi-Halem*[1], *Thomas Smol*[2], *Camille Porteret*[3], *Laurence Jonard*[1], *Pierre Blanc*[4], ***Sandrine marlin***[1,5]

[1]*Hopital Necker, Paris, France,* [2]*Institut De Génétique Médicale, Lille, France,* [3]*SeqOIA, Paris, France,* [4]*SeqOIA, PARIS, France,* [5]*INSERM UMR1163, Imagine Institute, Paris, France.*

Background: Up to recent years, diagnosis of the genetic aetiology of early onset hearing loss(EOHL) relied on targeted gene panel analyses, with a diagnosis rate of about 50%. French clinical geneticists have now access to trio Whole Genome Sequencing (WGS) through the Plan France Medecine Genomique 2025 sequencing platforms for most patients presenting with EOHL.

Material and methods: Testing criteria for WGS differ according to the subgroup of EOHL indications. The strategy is genome-first for syndromic hearing loss (HL), WGS after normal array-CGH for HL associated with malformation(s) and WGS after normal GJB2/GBJ6 and HL gene panel for patients presenting with isolated HL. From 2020 to mid-2024, 400 families assessed in the French Reference Center forgenetic HL underwent whole genome sequencing on the SeqOIA platform.

Results: The diagnosis yield was 40%. We will present the main genes identified, the diagnostic rate according to subgroups of the EOHL indication, clinical vignettes, along with the advantages and limitations of our strategy.

Conclusion: WGS allows for identification of additional causes (class 4 and 5 variants) and candidate genes, but variants interpretation is more complex than exome or gene panel analysis. We show with our four-and-a-half years' experience that WGS is an enticing new tool for patient diagnosis, with its advantages and setbacks.

P04.008.C *Nr2f1* mutant mouse models of Bosch-Boonstra-Schaaf optic atrophy syndrome reveal retinal ganglion cell dysfunction and optic nerve alterations

Dominik Kamionek[1], *Sarah K. Williams*[2,3], *Johann Georg Maaß*[1], *Henning Fröhlich*[1], *Christian P. Schaaf*[1], *Richard Fairless*[2,3]

[1]*University Clinic Heidelberg, Institute of Human Genetics, Heidelberg, Germany,* [2]*University Clinic Heidelberg, Department of Neurology, Heidelberg, Germany,* [3]*Clinical Cooperation Unit (CCU) Neurooncology, German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, Germany.*

Background: Bosch-Boonstra-Schaaf optic atrophy syndrome (BBSOAS) is a rare autosomal dominant neurodevelopmental disorder, caused by heterozygous pathogenic variants in the transcription factor *NR2F1*, resulting, among others, in optic nerve hypoplasia and visual impairments. To explore the underlying mechanisms of BBSOAS, we generated a mouse model carrying a patient-specific missense variant (*Nr2f1*$^{+/R139L}$). Here, we performed a comprehensive characterisation of the visual system to evaluate the phenotypic impact of this mutation, alongside the previously established *Nr2f1*$^{+/-}$ mouse strain.

Material and methods: A novel *Nr2f1*$^{+/R139L}$ mouse model, harbouring a critical patient-specific missense variant in the *Nr2f1* DNA-binding domain, was introduced. Visual function was assessed in this strain in comparison to *Nr2f1*$^{+/-}$ and wild-type mice. Full-field flash and flicker electroretinograms (ffERGs) under photopic and scotopic conditions were performed to evaluate photoreceptor, bipolar cell and amacrine cell function. Pattern ERGs (pERGs) were additionally performed to ascertain retinal ganglion cell (RGC) functionality. Furthermore, retinas and optic nerves were histologically analysed to correlate functional impairments with structural changes.

Results: Mice carrying a variant exhibit significant alterations in pERG recordings compared to wild-type littermates, indicative of RGC dysfunction, while ffERGs reveal intact photoreceptor and bipolar cell function. This is supported by decreased survival of RGCs in *Nr2f1*$^{+/R139L}$ retinas, as well as compromised integrity of the optic nerves.

Conclusion: Our findings highlight selective disruptions in RGC survival and function in *Nr2f1* mutant mice, recapitulating key features of BBSOAS. These results provide new insights into the structural and functional pathology of BBSOAS, offering a platform for testing novel therapies.

P04.009.D *STRC* findings in 670 Danish probands with hearing impairment and improved genetic testing using long-read sequencing

Nanna D. Rendtorff[1], *Lone S. Hindbæk*[1], *Anne A. M. H. Lauridsen*[1], *Lisbeth Tranebjærg*[1,2], *Mette Bertelsen*[1,2]

[1]*The Kennedy Center, Department of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark,* [2]*Institute of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: Hearing impairment (HI) is genetically heterogeneous with >140 genes for non-syndromic HI. Pathogenic variants in *STRC* encompassing the DFNB16 locus is now considered the most common cause of autosomal recessive mild-to-moderate HI across populations. However, interpreting *STRC* sequence data based on short-read NGS methodologies is challenging due to existence of the pseudogene, *STRCP1*, with 98% identity with *STRC*. Furthermore, a majority of *STRC*-associated HI is associated with CNV events (partial, whole, and multi-gene deletions).

Methods: From 2017–2025, 670 index cases with HI and variable additional clinical features underwent custom-made SureSelect gene panel analysis or Whole Genome Sequencing (WGS) in clinical settings. The samples were analyzed using virtual gene-panels of 35–196 genes or 101–506 genes, for patients suspected of having non-syndromic and syndromic HI, respectively. Long-range PCR, MLPA, and long-read sequencing using Oxford Nanopore Technologies were used to further evaluate SNVs and deletions.

Results: In this cohort the prevalence of *STRC*-associated hearing loss was 7% (48/670). Thirty-four patients (71%) had homozygous *STRC* deletions, also involving the entire *STRC-CATSPER2* region on one or both alleles, four patients (8%) were homozygous or partial homozygous for deletion of *STRC* only, and ten patients (21%) had a deletion in combination with a *STRC* SNV, six are novel. Nanopore sequencing was used to confirm that variants mapped with certainty to *STRC* and not *STRCP1*.

Conclusion: The results show a major contribution of DFNB16 to non-syndromic HI in the Danish population. Selected cases/families are presented. Further studies to characterize the *STRC* deletion breakpoints are in progress.

P04.010.A Functional characterization of splicing variants in syndromic and non-syndromic hereditary hearing loss using minigene splicing assays

Lara Emily Rosso[1], *Anna Morgan*[2], *Elisa Rubinato*[2], *Beatrice Spedicati*[1,2], *Giorgia Girotto*[1,2], *Giulia Pianigiani*[1,2]

[1]*University of Trieste, Trieste, Italy,* [2]*IRCCS Burlo Garofolo, Trieste, Italy.*

Background: Hereditary hearing loss (HHL) is a genetically heterogeneous disorder, with over 150 genes implicated in non-syndromic forms and more than 400 syndromes linked to syndromic cases. Even if whole-exome sequencing (WES) has significantly improved the diagnostic rate, many cases remain unsolved due to missing heritability, partly from overlooked splicing variants. Integrating WES with functional assays can enhance variant classification, improve diagnostic accuracy and reveal hidden splicing defects in HHL.

Material and methods: This study used the SpliceAI tool to assess the impact on splicing of intronic variants identified by WES in HHL patients. Then, in vitro validation through minigene splicing assays has been performed.

Results: Eight novel intronic variants in *OTOF*, *ADGRV1*, *ATP11A*, *GSDME*, *OTOGL*, *PPP1R12A* and *USH2A* genes were identified in 8 HHL patients by WES. Minigene assays confirmed SpliceAI predictions, showing that the variants disrupted normal splicing inducing exon skipping or the selection of cryptic splice sites (ss). Notably, two *OTOF* (NM_001287489.2) variants were particularly significant: the c.5533+13G>T variant activated a cryptic 5′ss, causing partial intron retention, while the c.5104-3C>G variant led to complete exon skipping. Both variants resulted in a shift of the open reading frame and the generation of a premature termination codon.

Conclusion: This study identifies and functionally validates eight splicing variants in HHL genes, all of which disrupt RNA

splicing. These findings enhance our understanding of HHL's molecular basis and are particularly relevant to the *OTOF* gene research, given recent advancements in gene therapy.

P04.011.B What was once unseen is now crystal clear: *CHAF1A* is a novel gene for OAVS

Naz Guleray Lafci[1], *Nesibe Saliha Bulut*[1], *İbrahim Vargel*[2]

[1]*Hacettepe University Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [2]*Hacettepe University Faculty of Medicine, Department of Plastic, Reconstructive and Aesthetic Surgery, Ankara, Turkey.*

Background: Oculoauriculovertebral spectrum (OAVS) is a developmental disorder primarily characterized by hemifacial microsomia and asymmetric ear anomalies, including microtia and preauricular skin tags. Its pathogenesis is complex, involving both environmental and genetic factors. In recent years, *MYT1* and *SF3B2* have been identified as monogenic causes of OAVS, while *CHAF1A*, a gene involved in chromatin assembly, has only recently been proposed as a novel contributor to this spectrum. Here, we present the second family in the literature with multiple affected individuals, consisting of a father and his three daughters, demonstrating autosomal dominant inheritance of a novel *CHAF1A* mutation.

Results: All four affected individuals presented with OAVS features, including hemifacial microsomia, microtia, and hearing loss, with the father and the youngest daughter exhibiting the most severe phenotypes. Notably, this daughter displayed striking middle ear abnormalities, such as agenesis of the malleus, incus dysplasia, and absence of the stapedial crura, along with malocclusion, and required multiple ear reconstruction surgeries. Whole-exome sequencing in 2018 failed to reveal a causative variant. However, periodic reanalysis in 2024, incorporating updated literature, identified a novel heterozygous *CHAF1A*(NM_005483.3) frameshift mutation (c.922_931dup;p.Pro311GlnfsTer16) in the father, subsequently confirmed in all affected daughters by Sanger sequencing.

Conclusion: This study not only concretely establishes *CHAF1A* as a novel gene responsible for OAVS but also expands its phenotypic spectrum to include middle ear abnormalities, a feature not previously associated with this gene. Furthermore, our findings underscore the transformative power of periodic reanalysis, even after extended periods, in uncovering hidden genetic etiologies in unresolved cases.

Background: Inherited retinal dystrophies (IRDs) are a group of rare diseases characterized by the progressive degeneration of the photoreceptors and/or the retinal pigment epithelium. Biallelic variants in genes involved in the biosynthesis of the coenzyme Q10 (coQ10) have been associated with coQ10 deficiency, leading to different clinical features, including syndromic and non-syndromic IRD in some patients. This work focuses on the *PDSS2* gene, which is part of this biosynthesis pathway, and whose association with retinitis pigmentosa remains largely unexplored.

Material and methods: Patients were studied by next-generation sequencing, and clinical data were obtained from self-reported ophthalmic history recorded from questionnaires, ophthalmic examinations and their clinical reports. ChimeraX was used to visualize the 3D PDSS2 structure predicted by AlphaFold for novel missense variants.

Results: We have identified six *PDSS2* biallelic patients, who had been diagnosed with retinitis pigmentosa with/without hearing loss, ataxia and/or nephrotic syndrome. This study reports eight *PDSS2* variants (four of them novel), including five missense, two splicing and one stop-gain variants. The identified missense variants are located at the end of certain alpha-helixes of the protein, and are predicted to destabilize the protein structure. Additionally, most missense variants are located in a nearby region in the predicted 3D structure of the PDSS2 protein. Interestingly, the novel variant NM_020381.4:c.365C>G is recurrent in this cohort.

Conclusion: These findings could improve clinical management of patients and allow families to receive genetic counselling. Additionally, this work supports the inclusion of *PDSS2* in screening gene panels for patients with retinal disorders.

P04.013.D Implementation of a polygenic risk score in diagnostic genetic testing for age-related macular degeneration

Lonneke Haer-Wigman[1], *Bert L. van den Heuvel*[1], *Silke Kats*[2], *Caroline C. Klaver*[1], *Yara Lechanteur*[1], *Marieke van Mullem*[1], *Rick de Reuver*[1], *Helger Yntema*[3], *Arjen Mensenkamp*[1]

[1]*Radboudumc, Nijmegen, Netherlands,* [2]*Maastrichtumc+, maastricht, Netherlands,* [3]*Dept Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Age-related macular degeneration (AMD) is a major cause of vision loss in older adults. Genetic factors greatly contribute to AMD risk. Polygenic risk score (PRS) combines multiple frequent genetic variants to predict AMD risk and development.

Methods: Baits for the intronic variants of the AMD-PRS, as described by Fritsche et al. (2016, PubMed:26691988), were included in the Twist Exome 2.0 plus Comprehensive Exome Spike-in Kit (TWIST Bioscience). Exome sequencing was conducted on an Illumina NovaSeq 6000. Zygosity and quality of all 52 PRS variants were assessed using an in-house developed tool. Variants were genotyped as homozygous wild-type (VAF < 20%), heterozygous (VAF = 20–80%), or homozygous alternative (VAF>80%). The risk score for each variant was calculated by multiplying the zygosity (0, 1, or 2) by its associated risk. If quality criteria were not met (total reads <10 or alternative reads <5), risk was estimated using allele frequency. The final PRS was the sum of all variant risks.

Results: The AMD-PRS test was evaluated in 1000 random samples. This cohort had an average PRS of 0.42 and the PRS follows a normal distribution. The allele frequencies of the 52 variants are similar to those in the European population of GnomAD v4.1.0. In 0.5% of samples, PRS could not be reliably determined due to <95% of variants passing quality criteria.

Conclusion: The developed genetic test can reliably determine the AMD-PRS in a diagnostic setting. The PRS has been incorporated into our gene panel analysis for AMD to provide a comprehensive genetic test for AMD.

P04.014.A Overcoming challenges in the sequencing of *RPGR* ORF15 in X-Linked Retinitis Pigmentosa

Ornella Rondinone[1], *Martina Miceli*[2], *Daniela Rusconi*[2], *Marzia Gianò*[1], *Giada Moresco*[1], *Giovanna Bevilacqua*[1], *Claudia Farè*[2], *Gianluca Tolva*[2], *Roberta Villa*[2], *Leonardo Colombo*[3], *Luca Rossetti*[3], *Monica Rosa Miozzo*[1,2], *Laura Fontana*[1,2]

[1]*Medical Genetics, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy, Milano, Italy,* [2]*Medical Genetic Unit, ASST Santi Paolo e Carlo, Milano, Italy, Milano, Italy,* [3]*Eye Clinic, ASST Santi Paolo e Carlo, Università degli Studi di Milano, Milano, Italy, Milano, Italy.*

Background: Retinitis pigmentosa (RP) represents the prevalent form of retinal dystrophy, with X-linked RP (XLRP) accounting for 10–20% of cases. XLRP are characterized by progressive vision loss in males and wide range of severity in female carriers. The *RPGR* gene is implicated in over 70% of XLRP cases, with the ORF15 exon representing the primary mutational hot-spot. Due to the highly repetitive and purine-rich sequence of ORF15, conventional short-read NGS techniques often fail to accurately detect variants in this critical region.

Material and methods: To establish an efficient diagnostic workflow for retinal dystrophies, we employed WES targeting 332 genes, including coding and hotspot non-coding variants associated with RP. Long-range PCR (LR-PCR) coupled to Sanger sequencing of the *RPGR* ORF15 was used to enhance the amplification and overcome the analysis of this problematic region, ensuring comprehensive coverage and increased diagnostic accuracy.

Results: This approach was applied to a cohort of 281 previously undiagnosed RP patients, achieving a diagnostic rate >60%. Notably, we identified causative ORF15 variants in ten patients (six males and four females), significantly improving the diagnostic yield through this method. XLRP females exhibit a milder phenotype compared to the affected males. All ORF15 variants were initially detected by WES despite at very low coverage and subsequently confirmed by LR-PCR. Among these, three were novel, contributing to the expansion of the *RPGR* mutational spectrum.

Conclusion: Our study emphasizes the need of a comprehensive molecular diagnostic approach for retinal dystrophies, combining WES with targeted Sanger sequencing to address complex genomic regions.

P04.015.B Genetic profile of inherited retinal diseases in 497 Finnish patients

Joni A. Turunen[1], *Julia Krootila*[1], *Maria Kaukonen*[2], *Eeva-Marja Sankila*[3], *Maarjaliis Paavo*[3], *Pauliina Repo*[1], *Michael P. Backlund*[1], *Sanna Seitsonen*[3], *Anna Majander*[3], *Päivi Lindahl*[3], *Kristiina Vasara*[3], *Robert E. MacLaren*[4], *Tero T. Kivelä*[3]

[1]*Folkhälsan Research Center, Helsinki, Finland,* [2]*University of Helsinki, Helsinki, Finland,* [3]*Helsinki University Hospital, Helsinki, Finland,* [4]*University of Oxford, Oxford, United Kingdom.*

Background: Population isolates like Finland have a unique genetic background shaped by population bottlenecks and geographical isolation, enriching certain gene variants while eliminating others. We investigated genetic findings in Finnish patients with inherited retinal diseases (IRDs).

Material and methods: We retrospectively collected data from patients with IRDs treated between 2012 and 2020 at the Helsinki University Hospital Eye Clinic. We collected the age, clinical diagnosis, mode of inheritance, and genetic findings.

Results: Of the patients who underwent genetic testing, 78% (497/639) received a likely genetic diagnosis. Most of them (90%) were native Finns. The genetic findings corresponded to autosomal recessive inheritance in 48% (239/497), X-linked in 30% (148/497), autosomal dominant in 17% (84/497), and mitochondrial inheritance in 4% (19/497) of patients. X-linked retinoschisis (*RS1*) was the most common diagnosis in 17% (83/497) of patients. The following most common causative variants were in the genes *CERKL* (8.7%, 44/497), *RPGR* (6.2 (31/497), *ABCA4* (5.4%, 27/497), *EYS* (5.2%, 26/504), *CHM* (5%, 25/497), and *CLRN1* (3.2% 16/497). *RS1*, *CERKL, CHM, EYS*, and *CLRN1* included Finnish founder mutations, explaining high variant frequencies.

Conclusion: Pathogenic variants in *RS1* (X-linked retinoschisis) and *CERKL* (cone-rod dystrophy) are the most common findings in our cohort, while Stargardt disease is less prevalent than in other Western countries. Enriched founder mutations likely contribute to the high diagnostic yield. Over one-fifth of cases remain undiagnosed, potentially due to testing limitations, non-coding variants, structural variants, or novel causative genes. Future research will leverage the Finnish population isolate to identify new IRD genes.

Background: Albinism is a heterogeneous genetic disease characterized by altered melanogenesis. To date, 21 albinism-related genes have been identified. The *DCT* gene has been associated with albinism for the first time in 2022, delineating the oculocutaneous albinism type 8 (OCA8) (PMID:33100333). Only three patients have been reported so far. Here, we present data on seven patients, including six previously unreported cases with bi-allelic variants in *DCT*, and provide detailed clinical and genetic information to enhance understanding of OCA8.

Methods: Patients with a clinical suspicion of albinism underwent targeted gene panel high-throughput sequencing. Those found to have bi-allelic variants in the *DCT* gene were included. Parental segregation was performed by Sanger sequencing. A splicing reporter minigene assay was used to assess the effect on splicing of the intronic variant c.1180-12A>G. Demographic and clinical data were retrospectively collected from geneticists, dermatologists, and ophthalmologists for each patient.

Results: Seven patients from 6 unrelated families were identified. Most exhibited no or mild cutaneous hypopigmentation and classical ocular features of albinism. All patients carried bi-allelic *DCT* variants, including missense variants, intragenic deletions, and one intronic variant. The latter altered RNA splicing according to the minigene assay.

Conclusion: Here, we describe the largest series of patients with *DCT* variants. Based on the description of seven additional patients, OCA8 appears to be primarily associated with ocular features rather than significant cutaneous hypopigmentation. This study contributes to a more precise characterization of the phenotype associated with this rare form of albinism.

Background : Ocular coloboma is a congenital disorder resulting from the incomplete closure of the embryonic ocular fissure. It can arise in isolation or as part of a syndrome, exhibiting significant genetic heterogeneity. Despite advances in genetic research, the diagnostic yield remains below 30%, underscoring the need for further investigation. Mutations in the Wnt receptor FZD5, a key regulator of ocular development, have been implicated in both isolated and syndromic coloboma. These mutations often exert a dominant-negative effect, disrupting WNT signaling by sequestering WNT ligands.

Materials and methods : We describe a case of syndromic bilateral ocular coloboma with microcornea, bone anomalies, and mild intellectual disability. Whole exome sequencing identified a homozygous rare missense variant in *FZD5*. To assess its impact, we performed zebrafish embryo overexpression assays, in vitro TOPFlash assays, and in silico structural modeling.

Results: Consistent with a loss-of-function effect, overexpressing of *fzd5* mRNA harboring the missense variant in zebrafish embryos does not influence embryonic development, whereas overexpression of wild-type *fzd5* mRNA results in body axis duplications. However, in vitro TOPFlash assays revealed that the missense variant caused partial loss-of-function, behaving as a hypomorphic mutation. We further showed that the mutant protein still localized to the cell membrane and maintained proper conformation when modeled in silico, suggesting that the impairment lies in signal transduction

Conclusion : Overall, these findings mark the first reported recessive *FZD5* disease-causal variant and expand the *FZD5* disease spectrum to include syndromic complex ocular coloboma.

P04.018.A The genetic architecture of retinal ciliopathies in the Irish Target 5000 cohort

Anna R. Ridgeway[1], *Laura Finnegan*[1], *Matthew Carrigan*[1], *Adrian Dockery*[1], *Laura Whelan*[1], *Ella Kopčić*[1], *Claire Kirk*[2], *Jacqueline Turner*[3], *David Keegan*[3], *Giuliana Silvestri*[2], *Naomi Chadderton*[1], *Paul F. Kenna*[1,4,5], *Emma Duignan*[4,5], *G. Jane Farrar*[1]

[1]*Trinity College Dublin, Dublin, Ireland,* [2]*The Royal Victoria Hospital, Belfast, United Kingdom,* [3]*Mater Misericordiae University Hospital, Dublin, Ireland,* [4]*The Research Foundation, Royal Victoria Eye and Ear Hospital, Dublin, Ireland,* [5]*Royal Victoria Eye and Ear Hospital, Dublin, Ireland.*

Background: Retinal ciliopathies (RCs) comprise syndromic and non-syndromic inherited retinal degenerations (IRDs) caused by pathogenic variants in genes required for cilia morphogenesis and function. Cilia are hair-like projections on the surface of many cell types and when defective, can cause a spectrum of clinical phenotypes including vision loss, hearing impairment, renal pathology, polydactyly, and obesity amongst others. Thus far, >100 genes have been implicated. This study aims to characterise the genetic architecture of these conditions in the Irish Target 5000 cohort.

Material and methods: Following informed consent, blood was obtained, DNA isolated according to standard protocols and next-generation sequencing undertaken. Candidate variants were interpreted according to ACMG guidelines and phased where possible. Novel missense variants were modelled using AI-powered AlphaFold and splice-altering variants of uncertain significance investigated by midigene functional assays.

Results: In total, >200 candidate variants were detected in 34 different RC-associated genes in 345 participants. Notably, 45 variants were novel. Variants of all types were identified. The most common syndromic disease was Usher syndrome followed by Bardet-Biedl syndrome, whilst variants in RPGR represented the largest number of non-syndromic IRD cases. In total, IRDs caused by RC-associated genes accounted for ~20% of solved cases in this cohort.

Conclusion: Given the clinical and genetic heterogeneity of RCs, it is of utmost importance that patients and their families obtain a molecular diagnosis in this era of precision medicine. This study illuminates the mutational profile in RCs with 45 novel variants identified and classified undoubtedly aiding the diagnostic process for future patients.

P04.019.B Functional analysis of splicing variants located in the Proline-Serine-Threonine transactivation domain of *PAX6*

Carolina Ruiz Sánchez[1,2], *Alba Martín Mota*[1], *Carmen Ayuso García*[1,2], *María José Trujillo Tiebas*[1,2], *Marta Cortón Pérez*[1,2]

[1]*Health Research Institute-Fundación Jiménez Díaz University Hospital, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, Spain,* [2]*Center for Biomedical Network Research on Rare Diseases (CIBERER), ISCIII, Madrid, Spain.*

Background: PAX6 is a transcription factor essential for ocular and neural development, whose alterations are associated with congenital aniridia. The PST transactivation domain, encoded by exons 10–13, plays a vital role in regulating gene expression. Variants altering splicing in this domain, causing exon skipping or cryptic splice sites activation, may disrupt its structure and function contributing to disease pathology. This study evaluated the spliceogenic effects of specific variants in PST-coding exons.

Material and methods: From our aniridia cohort or mutational databases, we selected variants located in PST-related exons or introns. After in silico analysis, potential spliceogenic variants were in vitro assessed through exon-trapping minigenes containing the genomic sequences of *PAX6* exons 10–13. Selected variants were introduced through site-directed mutagenesis, and both wild-type and mutated minigenes were transfected into HEK293 cells. Subsequently, splicing patterns were determined after the RNA extraction, RT-PCR and long-read sequencing with an Oxford Nanopore MinION device.

Results: Finally, fourteen variants with potential splicing effects were analysed in vitro. All variants disrupted normal splicing, resulting in complete or partial exon skipping as well as small insertions caused by the activation of cryptic exonic or intronic splice sites.

Conclusion: Splicing variants in exons 10–13 of *PAX6* can alter the structure of the PST domain. This may result in a loss or decrease of its transactivation function, potentially affecting *PAX6*-regulated pathways essential for ocular development. Therefore, in vitro minigene assays are an effective tool for evaluating the splicing impact and pathogenicity of these types of variants in aniridia.

P04.020.C Employing a cost-effective smMIPs panel 'IRD25' to identify causative variants in known and candidate inherited retinal disease genes

Zelia Corradi[1], *Rebekkah J. Hitti-Malin*[1], *Daan M. Panneman*[1], *Lara K. Holtes*[1], *Erica G.M. Boonen*[1,2], *Bernhard H.F. Weber*[3,4], *Alaa AlTalbishi*[5], *Carmen Ayuso*[6], *G. Jane Farrar*[7], *Susanne Roosing*[1], *Frans P.M. Cremers*[1]

[1]*Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Rotterdam Ophthalmic Institute, Rotterdam, Netherlands,* [3]*Institute of Human Genetics, University of Regensburg, Regensburg, Germany,* [4]*3Institute of Clinical Human Genetics, University Hospital Regensburg, Regensburg, Germany,* [5]*St John of Jerusalem Eye Hospital Group, East Jerusalem, Palestinian Territory,* [6]*Department of Genetics, IIS-Fundación Jiménez Díaz, CIBERER, Madrid, Spain,* [7]*The School of Genetics and Microbiology, Trinity College Dublin, Dublin, Ireland.*

Background: Inherited retinal diseases (IRDs) are clinically and genetically heterogeneous which makes reaching a clear diagnosis challenging. Effective genetic screening is crucial to identify the causes of disease and in guiding diagnosis and treatment avenues.

Material and methods: The IRD25 panel consists of 51,245 probes targeting 358 genes associated with IRDs, SNPs associated with age-related macular degeneration, the complete *ABCA4* and *RPE65* genes, the mitochondrial genome, as well as recently published and candidate IRD genes. Probes cover all exonic regions as well as known causal intronic variants and non-coding regions of interest such as the RP17 locus. Each targeted position was covered by at least seven probes. Sequencing was performed using NovaSeq SP technology and variant analysis was performed using the Franklin by Genoox platform.

Results: A cohort of 120 IRD probands was analysed to assess the panel, and an average coverage of 294X was obtained. A 52% (83/160) of the affected individuals carried pathogenic variants (ACMG class 3-4-5) and were considered likely or possibly solved. Amongst the (likely) solved cases, the identification of deep intronic variants, variants in candidate genes, as well as potentially novel genotype-phenotype correlations highlighted the effectiveness of the panel.

Conclusion: The use of smMIPs technology to target IRD associated genes is a flexible and cost-effective approach that can be continuously updated. The IRD25 panel enables a genotype-first analysis of IRD patients that promises to bring to light novel genotype-phenotype correlations and improves the clinical diagnosis for affected individuals.

Background: *KITLG* pathogenic variants have been associated to three distinct clinical presentations with different combinations of hearing loss and/or pigmentation abnormalities. However, its involvement in isolated hearing loss has not been confirmed since its initial description in two families. Besides, *KITLG* is so far the only gene prevailingly involved in unilateral isolated hearing loss.

Material and methods: We therefore conducted a retrospective study of patients with *KITLG* alterations in the French national Reference Network for Genetic Hearing Loss and one case was added through the Genematcher exchange platform.

Results: We describe a series of monoallelic *KITLG* deletions and variations in a cohort of 14 symptomatic patients from eight unrelated families. All patients presented with unilateral, bilateral symmetric or asymmetric sensorineural hearing loss. When not profound, hearing loss was predominant on low frequencies. Most *KITLG* alterations are likely to result in loss-of-function and aggregate in the extracellular region, disrupting the KIT-binding domain or its structure. Penetrance is not complete, and unspecific pigmentation alterations were observed in only three patients.

Conclusion: The present study confirms *KITLG* involvement in isolated unilateral, bilateral symmetric or asymmetric hearing loss. This confirmation indicates that genetic testing can be relevant in early-onset, non-sudden, isolated unilateral hearing loss.

P04.022.A Long-read adaptive nanopore sequencing reveals a novel pathogenic structural variant in the *PRPH2* gene in patients with macular dystrophy

Michael P. Backlund[1], *Suzie A. Gasparian[2], Pauliina Repo[1,3], Harri Kangas[4], Kati Donner[4], Heidi Putkuri[1], Sanna Seitsonen[3], Maarjaliis Paavo[3], Tero T. Kivelä[3], David I. Sierpina[2], Joni A. Turunen[1,3]*

[1]Eye Genetics Group, Folkhälsan Research Center, Helsinki, Finland, [2]Department of Ophthalmology, Loma Linda University, Loma Linda, CA, USA, [3]Department of Ophthalmology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, [4]Institute for Molecular Medicine Finland (FIMM), Helsinki Institute of Life Science (HiLIFE), University of Helsinki, Helsinki, Finland.

Background: The peripherin 2 (*PRPH2*) gene is involved in photoreceptor organization. Pathogenic variants in *PRPH2* are associated with retinal and macular dystrophies with a wide degree of clinical variability. Here, we report three individuals from two families with macular dystrophy caused by exon 2 duplication of *PRPH2*.

Material and methods: Two affected members (P1, P2) from one family were treated at Helsinki University Hospital, Finland, and one unrelated individual (P3) at Loma Linda University Eye Institute, USA. The patients underwent comprehensive ophthalmic examination, and their genomic DNA was subjected to macular (P2) and retinal (P3) dystrophy gene panels or targeted genetic testing (P1). The gene panels indicated a structural variant in *PRPH2*, which was characterized by nanopore sequencing.

Results: The patients were clinically diagnosed with different forms of macular dystrophy. Exome-based genetic testing indicated all patients as heterozygous for a 482 bp duplication, covering exon 2 of *PRPH2*, with unknown breakpoints (BP). Nanopore sequencing revealed the duplication to be ~4 kb in size. They share the same 3′BP adjacent to an intronic Alu element. For P1 and P2, the 5′BP resides in a novel Alu element (AluYa5) lacking from the hg38 reference genome. P3 is negative for the novel AluYa5, and the 5′BP resides some 300 bp upstream in another known Alu element.

Conclusion: Long-read sequencing revealed that macular dystrophy in two families is caused by a 4 kb duplication involving *PRPH2* exon 2, likely due to non-allelic homologous recombination between Alu elements at the breakpoints.

P04.024.C Screening for *SLC26A4*-related hearing loss, enlarged vestibular aqueduct and Pendred syndrome and functional characterization of novel variants in the *SLC26A4* gene

Silvia Borecka[1], *Marek Sklenar[1], Lukas Varga[1,2], Emanuele Bernardinelli[3], Juraj Stanik[1,4], Martina Skopkova[1], Diana Ugorova[2], Silvia Dossena[3], Daniela Gasperikova[1]*

[1]Institute of Experimental Endocrinology, Biomedical Research Center SAS, Bratislava, Slovakia, [2]Department of Otorhinolaryngology – Head and Neck Surgery, Medical Faculty of Comenius University and University Hospital, Bratislava, Slovakia, [3]Institute of Pharmacology and Toxicology, Paracelsus Medical University, Salzburg, Austria, [4]Department of Pediatrics, Medical Faculty of Comenius University and National Institute of Children's Diseases, Bratislava, Slovakia.

Background: Pathogenic variants in the *SLC26A4* gene are associated with non-syndromic hearing loss with enlarged vestibular aqueduct (NSEVA) and Pendred syndrome. In the Caucasian population, the CEVA haplotype plays an important role in diagnostics of NSEVA. The aim of the study was identification of genetic etiology in 37 probands with hearing loss, EVA or Pendred syndrome and functional characterization of novel variants in the *SLC26A4* gene.

Material and methods: For determination of genetic etiology, Sanger sequencing, WES and KASP genotyping assay were used. The Nanopore sequencing of nasopharyngeal swab samples was performed to confirm the pathogenic effect of potential splice site variant. Functional characterization of *SLC26A4* variants involved determination of iodide influx, total and plasma membrane pendrin expression level and subcellular localization of pendrin by confocal imaging.

Results: Biallelic variants in the *SLC26A4* gene were identified in 10 probands and a complete CEVA haplotype was confirmed in three probands harbouring *SLC26A4* monoallelic variants. Sixteen variants in the *SLC26A4* gene were identified in total, three of which are novel. The functional characterization of novel variants and variants which were not functionally characterized yet confirmed pathogenic potential of five out of six tested variants. Analysis of nasopharyngeal swab samples confirmed exon 4 skipping due to novel variant *SLC26A4*:c.415G>A.

Conclusion: The genetic etiology of hearing loss associated with EVA was determined in 13 out of 37 probands (35%). Functional studies are important for the accurate diagnosis, as well as for a better understanding of the function of *SLC26A4* variants.

P04.025.D Exploring the genetic background of autosomal dominant hearing loss

Dominika Ozieblo[1], *Marcin L. Leja*[1], *Nina Gan*[1,2], *Natalia Baldyga*[1,2], *Anna Sarosiak*[1], *Henryk Skarzynski*[1], *Monika Oldak*[1]

[1]*Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*Doctoral School of Translational Medicine, Centre of Postgraduate Medical Education, Warsaw, Poland.*

Introduction: Autosomal dominant hearing loss (ADHL) is the second most common form of hereditary HL, typically manifesting after the first decade of life. It primarily affects high frequencies and worsens over time. Autosomal-dominant genes account for about 20% of prelingual non-syndromic deafness cases, with 63 genes identified to date.

Materials and methods:

This study included 110 ADHL families. Targeted next-generation sequencing (NGS) of 237 HL-related genes was performed in all probands. In six large unsolved families, linkage analysis and whole genome sequencing (WGS) were conducted. Presence of the selected probably pathogenic variants and their segregation with HL within the family were confirmed by standard Sanger sequencing.

Results: A genetic cause was identified in 51% (56/110) of families. Among 56 HL variants, 27% (15/56) were previously reported, while 73% (41/56) were novel. Variants included missense (35/56, 62%), splice site (8/56, 14%), frameshift (6/56, 11%), nonsense (6/56, 11%), and one synonymous variant (1/56, 2%). The most frequently affected genes were *MYO6* (n = 11), *TBC1D24* (n = 6), *WFS1* (n = 6), *GSDME* (n = 5), *POU4F3* (n = 5), and *KCNQ4* (n = 4). Variants in *NLRP3*, *LMX1A*, *FGFR3*, *CD164*, *GRHL2*, *TMC1*, *COCH*, *ATP2B2*, and *CEACAM16* were found in single families. Linkage analysis and WGS identified non-coding variants in *EYA4* and *ATP11A* and novel candidate genes.

Conclusions:

Our custom multigene panel demonstrated good diagnostic performance. Given the frequent discovery of novel variants, clinical assessment and segregation analysis are essential. Linkage analysis and WGS improve variant detection, particularly in non-coding regions, and help identify new HL genes.

Background: Consanguinity provides a unique opportunity to identify novel gene-phenotype correlations. Consanguineous children have an average genomic homozygosity 10-fold higher than outbred individuals. This facilitates the identification of high-impact genomic variants for autosomal recessive inherited retinal disorders (IRDs). Pakistan and Iran are among the most consanguineous countries in the world, with consanguineous marriages accounting for up to 70% and 38%, respectively. The purpose of this study was to identify novel candidate genes for IRDs by studying consanguineous families.

Methods: This study presents the genetic analysis of 609 consanguineous multiplex families from Pakistan and Iran. WES was performed on the affected individuals, and in some unsolved families, SNP-arrays were used for homozygosity mapping.

Results: Overall, the diagnostic yield was ~70%. The most frequently implicated genes were CRB1 (18-families), AIPL1 (11-families), and ABCA4 (11-families). In addition, pathogenic variants were identified in LCA5 (10-families), RPE65 (7-families), RPGR (3-families), MYO7A (3-families), CNGA3 (7-families), and CNGB3 (3-families), all of which are treatable targets for gene therapy that is either currently available or undergoing clinical investigation. Among the undiagnosed families, likely pathogenic variants in 37 novel candidate genes were identified, and these findings will be presented at the conference.

Conclusion: This study demonstrates the power of investigating consanguineous multiplex families to identify novel genes,

thereby expanding our understanding of the molecular pathways underlying IRDs. These discoveries are of paramount clinical importance not only for specific families or geo-ethnic groups, but also for patients worldwide, as they improve diagnostic possibilities and therapeutic interventions in diverse clinical settings.

P04.027.B Major impact of *USH2A* variants on the development of mild to moderate hearing loss

Natalia Baldyga[1,2], *Dominika Ozieblo*[1], *Magdalena Pankowska*[1], *Henryk Skarzynski*[1], *Monika Oldak*[1]

[1]*Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*Doctoral School of Translational Medicine, Centre of Postgraduate Medical Education, Warsaw, Poland.*

Background: The most common genetic cause of mild to moderate hearing loss (HL) is *STRC* copy number variants (CNVs). Many patients with mild to moderate HL require further genetic testing due to the lack of molecular diagnosis. Literature indicates that, besides *STRC, USH2A, MPZL2*, and *OTOG* may also be responsible for mild to moderate HL. This study aimed to identify the genetic basis of isolated mild to moderate HL in patients without *STRC* CNVs.

Material and methods: The study included 47 patients with isolated mild to moderate HL without detected *STRC* CNVs or with one identified heterozygous *STRC* CNV. Genomic DNA was isolated from peripheral blood and NGS with a custom panel of HL-related genes (n = 237) was performed. Selected variants were confirmed by Sanger sequencing.

Results: NGS revealed the genetic cause of HL in 51% (24/47) of patients. Among these, 25% (6/24) of causative variants were found in *USH2A*, linked to Usher syndrome. In 17% (4/24) of variants, mutations in *OTOG* were considered as the cause of HL. The remaining causative variants were detected in: *ADGRV1, GATA3, MPZL2, OTOA, POU3F4, PTPRQ, REST, STRC, TBC1D24*, and *WFS1*.

Conclusions: NGS revealed that, in addition to *STRC*, a significant proportion of patients with mild to moderate HL have causative variants in *USH2A*. Patients with *USH2A* pathogenic variants are likely to develop Usher syndrome type 2A, which includes both HL and retinitis pigmentosa. Identifying the genetic cause is crucial for providing personalized care from an early age.

Sperimentale Ricerche Immunologia Clinica e Reumatologia, IRCCS Istituto Auxologico Italiano, Milano, Italy,* [6]*Centro de Biología Molecular Severo Ochoa CSIC-UAM, Madrid, Spain.*

Background: Syndromic microphthalmia-3 (MCOPS3, #206900) is a rare disorder, characterized by anophthalmia microphthalmia and esophageal atresia. Genital anomalies are common in male patients associated with central nervous system developmental abnormalities, cardiac defects, vertebral anomalies, growth failure, sensorineural hearing loss, pituitary hypoplasia, and hypogonadotropic hypogonadism. Intellectual development is very variable. MCOPS3 is an autosomal dominant disorder, due to mutations in the SOX2 gene (MIM#184429), which plays a crucial role in nervous system development and stem cell maintenance.

Material and ethods: induced pluripotent stem cells (iPSCs) were generated using Sendai virus from peripheral blood of 2 patients heterozygous for a SOX2 truncating variant, respectively NM_003106.4:c.70_89del (case 1 with right anophthalmia, left microphthalmia, and neurological symptoms) and NM_003106.4:c.53C>A (case 2 with bilateral anophthalmia/microphthalmia, hypogenitalism, and epilepsy). Using CRISPR/Cas9 isogenic clones were generated from case 2's IPSCs.

Results of the iPSCs from both cases properly expressed stemness markers. Cytofluorimetry in the IPSCS proved a reduced SOX2 expression when compared with healthy controls and isogenic edited clones. Retinal Ganglion cells(RGCs), cortical neuronal cells, and cortical organoids were differentiated by specific protocols. Immunofluorescence and RT-qPCR confirmed the cellular identity of the models. We are defining the genomic pattern of SOX2 binding to DNA by CUT&RUN, to identify targets for which SOX2 dosage reduction results in reduced or lost binding, plausibly relevant for SOX2-dependent pathology.

Conclusion: We proved that the haploinsufficiency of SOX2 does not preclude obtaining iPSCs and maintaining their stemness. For the first time, we generated human 2D and 3D models with heterozygous SOX2 variants.

P04.029.D Identification of the RPGR gene pathogenic variants in a cohort of Greek male patients with retinitis pigmentosa phenotype

Smaragda Kamakari[1], *Stavrenia Koukoula*[2]

[1]*Ophthalmic Genetics Unit, Athens, Greece,* [2]*2Ophthalmica Institute of Ophthalmology and Microsurgery, Thessaloniki, Greece.*

Background: X-linked Retinitis Pigmentosa (XLRP) is one of the most severe retinal phenotypes accounting for about 20% of all RP patients. RPGR is the most commonly implicated gene and its variants account for more than 70% of XLRP. The aim of the study was to report the molecular basis of RPGR related retinitis pigmentosa in 16 Greek unrelated patients.

Material and ethods: Genetic testing of 441 independent Greek patients with suspected retinal dystrophies was performed using a Next Generation Sequencing panel of retinal dystrophy genes as described (PMID: 34985506).

Results: The molecular background was established in 374 patients of the total 441 tested. RPGR pathogenic variants were detected in 16 unrelated, male patients (4.27%) in this cohort.

Demographic data including family history and reported diagnosis were available. 10 patients were simplex, 3 had an affected brother, 1 had an affected sister and 2 had numerous male and female affected relatives resembling an autosomal dominant inheritance. Variants in ORF15 accounted for 68.75% (11/16) of the diagnoses, the remaining variants were detected in exons 2 and 9 (missense), 4 and 9 (frameshift) whereas a deletion of exons 1–11 of the RPGR gene was detected in 1 case.

Conclusion: This study provides the first molecular genetic characteristics of patients with RPGR pathogenic variants from the previously unexplored Greek population. Our study expands the mutational spectrum as we report novel variants in the RPGR gene and allows for the formation of a cohort for current and emerging therapeutic opportunities for this disorder.

P04.030.A Novel genetics findings using WES and WGS and implications of these in optic nerve atrophy

Katrine M. Johannesen[1], *Karen Grønskov*[1], *Line Kessel*[2,3], *Steffen Hamann*[2,3,4], *Marianne Wegener*[2], *Mette Bertelsen*[1]

[1]*Department of Genetics, University Hospital of Copenhagen Rigshospitalet, Copenhagen, Denmark,* [2]*Department of Ophthalmology, Copenhagen University Hospital - Rigshospitalet, Glostrup, Denmark,* [3]*Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark,* [4]*Neuro-Ophthalmology Department, Rothschild Foundation Hospital, Paris, France.*

Background: Optic atrophy is a severe eye condition in which the retinal ganglion cells degenerate, causing vision loss and a pale optic nerve when visualized though fundoscopy. Optic atrophy can be genetic; Autosomal dominant optic atrophy (ADOA) is caused by pathogenic variants in *OPA1*, and Leber's hereditary optic neuropathy (LHON) is caused by specific pathogenic mitochondrial variants. More rare genetic causes of optic atrophy may be uncovered using non-biased genetic testing, such as whole exome/genome sequencing (WES/WGS). Uncovering the genetic cause can have great implications for patients and families, including more knowledge about the expected visual prognosis, possible extraocular manifestations, and the hereditary mode. Here, we investigated a cohort of patients with optic atrophy with WES/WGS to estimate the diagnostic yield of unbiased genetic testing in optic atrophy and uncover more uncommon causes.

Material and methods: WES or WGS analysis in patients with optic atrophy.

Results: 68 patients had WGS (15) or WES (53) performed. 22/68 had a genetic diagnosis (yield 32%). Genetic findings included *OPA1* (50%) but also rare variants in genes such as *WFS1* (9,3%), *NR2F1* (6,2%), and *ACO2* (6,2%). For 22 patients the genetic finding implicated more than optic atrophy, e.g., intellectual disability (*NR2F1, ACO2, COQ2)*, hearing loss (*NR2F1, ACO2, COQ2, WFS1*) and other features (*UCHL1, COQ2, WFS1*).

Conclusion: This study illustrates that un-biased genetic testing have clinical implications in patients with optic atrophy that are not limited to ADOA and LHON but includes other rare genetic causes that may have diagnostic implications.

P04.031.B Single-center experience on genotype-phenotype correlation in retinitis pigmentosa cases in the Marmara Region

Sehime G. Temel[1], *Duygu Erdem*[2], *Duygu G. Aracı*[3], *Lamiya Aliyeva*[4], *Sebnem Özemri Sag*[1], *Selim Doganay*[1]

[1]*Bursa Uludag University, Bursa, Turkey,* [2]*Elazıg Fethi Sekin City Hospital, Elazıg, Turkey,* [3]*Akdeniz University, Antalya, Turkey,* [4]*Acıbadem Hospital, İstanbul, Turkey.*

Background: Retinitis pigmentosa (RP) is a genetically heterogeneous retinal disorder characterized by progressive vision loss. Next-generation sequencing (NGS) is essential for identifying causative mutations, establishing genotype-phenotype correlations, and improving clinical management. This study aims to characterize the genetic spectrum of RP in the Turkish population using NGS.

Material and methods: A total of 118 unrelated Turkish RP patients were recruited at Bursa Uludag University Hospital, and clinical or whole-exome sequencing was performed using the Illumina NextSeq system, with variants classified per ACMG guidelines. Clinical evaluations, including fundoscopic examination, OCT, ERG, and visual field analysis, were conducted, and statistical analyses assessed genotype-phenotype correlations.

Results: Pathogenic or likely pathogenic mutations were detected in 94 patients, spanning 48 genes, with a total of 84 mutations, including 16 novel variants. Clinically relevant variants were identified mostly in *MYO7A* (n = 7), *CDHR1* (n = 6), *NR2E3* (n = 5), *RDH12* (n = 5), *RPGR* (n = 5), and *USH2A* (n = 5). Mutation inheritance patterns included 61 homozygous, 19 heterozygous, 10 compound heterozygous, and 4 hemizygous variants. According to ACMG criteria, among the 84 identified variants, 37 were pathogenic, 21 likely pathogenic, and 26 variants of uncertain significance (VUS). *MYO7A* mutations were associated with earlier disease onset ($P = 0.001$) and higher cystoid macular edema frequency in the right eye ($P = 0.021$) compared to *CDHR1* mutations.

Conclusion: This study provides the most comprehensive multidisciplinary molecular analysis of RP in the Turkish population, identifying 16 novel variants and expanding the known RP mutation spectrum. The high diagnostic yield of 79.6% underscores the clinical value of NGS-based molecular testing for RP.

P04.032.C Identification of susceptible mutations and digenic pathogenic combinations of Retinitis Pigmentosa in Chinese families cohort

Z. Wang, *D. Han, X. Chen;*

BGI research, Shenzhen, China

Background: Retinitis pigmentosa (RP; MIM: #268000) is a group of inherited retinal dystrophies caused by the loss of retinal photoreceptors. It is a clinically and genetically heterogeneous disorder. Understanding the genetic mutations and their combinations can aid in identifying pathogenic mechanisms and improving diagnosis for RP.

Material and methods: The study analyzed 339 trios of RP families using genetic analysis, including the Transmission Disequilibrium Test (TDT). Bonferroni correction was applied to identify significant mutations. ORVAL software was utilized to predict the pathogenicity of digenic combinations of mutations. Statistical, machine learning, and genetic methods were employed to analyze and validate the findings.

Results: Seven significant mutations associated with RP were identified after Bonferroni correction: *MSH2* c.212-16delT, *LRP5* c.58_60del, *FOXE3* c.211A>G, *PRX* c.4077_4079del, *DMD* c.8810A>A, *GP1BA* c.1322_1344del, *SYNE2* c.1170A>C, and *SMPD1* c.573T>C. In addition, 26 combinations of highly correlated susceptible loci were identified, involving 31 genes. Two digenic

combinations were predicted as pathogenic: *COL3A1* c.2092G>A~*TWIST1* c.295A>G and *CNNM4~WFS1*. The *COL3A1* c.2092G>A~*TWIST1* c.295A>G combination was classified within the Disease Causing 99% zone and could explain the RP phenotype in four families.

Conclusion: The study identified *COL3A1* c.2092G>A~*TWIST1* c.295A>G as a novel digenic combination associated with RP, demonstrating the utility of integrating statistical, machine learning, and genetic methods in uncovering pathogenic genetic interactions. These findings provide new insights into the genetic basis of RP and potential targets for diagnosis and treatment.

P04.033.D Identification of a novel heterozygous OPA3 mutation in a large Italian family with cataract and progressive sensorineural deafness

Fjorilda Caushi[1], *Andrea Zonta*[2], *Lucia Corrado*[1], *Martina Tosi*[1], *Nadia Barizzone*[1], *Benedetta Bartilomo*[1], *Marco Seri*[3], *Cesare Danesino*[4], *Claudia Scotti*[4], *Andrea Guala*[5], *Sandra D'Alfonso*[1]

[1]*Università degli Studi del Piemonte Orientale, Novara, Italy,* [2]*AOU Città della Salute e della Scienza di Torino, Torino, Italy,* [3]*Medical Genetics Unit, Sant'Orsola-Malpighi HospitalDepartment of Medical and Surgical Sciences, Uni, Bologna, Italy,* [4]*Dipartimento di Medicina Molecolare, Università di Pavia, Pavia, Italy,* [5]*SOC Pediatria, Ospedale Castelli Verbania, Novara, Italy.*

Background: Co-occurrence of cataracts and sensorineural hearing loss in the young was initially documented by Nadol and Burgess in 1982 in a large family (MIM120040). We described a second large Italian family including 11 affected members spanning 4 generations, with a similar phenotype (PMID:1623624).

Aim: To identify the genetic cause in the Italian family with cataract and sensorineural hearing loss syndrome.

Material and methods: WES and SNP array was performed on 11 family members on 4 generations, including both healthy (N = 5) members and those with syndrome (N = 6). Ten linkage regions (LOD>1) were identified. WGS was performed on one affected member to investigate the linkage regions for structural variants, tandem repeats, and non-coding regions.

Results: We found a novel heterozygous missense mutation (p.Lys10Asn, chr19:46087993 C>A, hg19) in OPA3 gene, segregating in all family members. OPA3 mutations are associated with ADOAC (autosomal dominant optic atrophy and cataract), whose clinical manifestations overlap with our patients except for the absence of optic atrophy. Notably, another research group reported the same mutation in a separate family with the same peculiar clinical presentation as ours (https://doi.org/10.1002/ajmg.a.63846).

Conclusion: We found the likely genetic cause of a rare syndrome in a large Italian family, a missense mutation in OPA3. Dominant mutations in OPA3 cause ADOAC, whose clinical manifestations partially overlap with our affected family members, despite the absence of optic atrophy. Interestingly, another group found the same mutation in a second family with same symptoms, suggesting that our finding could expand the spectrum of OPA3-associated diseases.

P04.034.A Ophthalmic genetics service in a tertiary center: diagnostic yield, insights and challenges

Dalia Eli[1], *Israel Finkelstein*[2], *Daphna Landau Prat*[1,2,3], *Odelia Chorin*[4,2], *Shelly Lev-Hochberg*[4,2], *Hadas Ityel*[4,2], *Oriel Spierer*[5,2], *Dar Shay Levanon*[2], *Neta Feinstein-Goren*[6,2], *Avner Hostovsky*[3,2], *Tamara Wygnanski-Jaffe*[3,2], *Aviva Eliyahu*[4,2], *Lior Greenbaum*[6,2,7], *Guy Ben-Simon*[3,2], *Annick Rein*[4,2], ***Ben Pode-Shakked***[4,2]

[1]*The Ophthalmo-Genetics Clinic, Department of Ophthalmology, Goldschleger Eye Institute, Sheba Medical Center, Ramat Gan, Israel,* [2]*Faculty of Medical and Health Sciences, Tel-Aviv University, Tel Aviv, Israel,* [3]*Department of Ophthalmology, Goldschleger Eye Institute, Sheba Medical Center, Ramat Gan, Israel,* [4]*The Institute for Rare Diseases, Danek Gertner Institute of Human Genetics, Sheba Medical Center, Ramat Gan, Israel,* [5]*Department of Ophthalmology, Wolfson Medical Center, Holon, Israel,* [6]*Danek Gertner Institute of Human Genetics, Sheba Medical Center, Ramat Gan, Israel,* [7]*The Joseph Sagol Neuroscience Center, Sheba Medical Center, Ramat Gan, Israel.*

Background: Ophthalmic genetics is a rapidly evolving field, with over 600 genes implicated in inherited eye disorders in the past three decades. The growing accessibility of Next Generation Sequencing (NGS) technology has revolutionized this field, shortening the diagnostic odyssey for countless pediatric and adult patients. The diagnostic yield of NGS-based genetic testing in patients with ophthalmological conditions suspected to have a monogenic etiology varies greatly depending on the phenotype.

Methods: We established a referral ophthalmo-genetics clinic in a large tertiary center, led by a single dedicated genetic counsellor, supervised by a medical geneticist. We sought to characterize the patient population and evaluate the overall and phenotype-specific diagnostic yield of NGS-based genetic testing.

Results: Between 2021–2023, a total of 141 unrelated probands (age range, 2.5 weeks to 84 years) were evaluated at the Ophthalmic Genetics Clinic, 73 (51.8%) of whom under 18 years of age. The most common clinical presentations were Retinitis Pigmentosa and suspected hereditary retinopathies/viteroretinopathies (37.6%), followed by high myopia (13.5%), congenital cataract (9.9%) and suspected ocular albinism (9.2%). Fourty-three probands (30.5%) completed at least one comprehensive genetic test (most often, gene panel sequencing) by the time of analysis. Of these, the overall diagnostic yield was 51.2% (22/43), with an additional 32.5% (14/43) cases in which genetic testing resulted in variants of uncertain significance (VUS). Diagnostic yield differed between clinical presentations.

Conclusions: Our findings underscore the importance of NGS-based genetic testing in individuals with suspected inherited eye disorders. Furthermore, we present a cost-effective model for a referral ophthalmo-genetics clinic.

P04.035.B Screening of the DNAJC30 gene causing autosomal recessive Leber hereditary optic neuropathy in a Finnish cohort

Ronja Hotakainen[1], *Reetta-Liisa Vainiomäki*[1], *Kaisa Kettunen*[1], *Eveliina Jakkula*[2,3], *Anna-Kaisa Anttonen*[1,2,3]

[1]*Laboratory of Genetics, HUS Diagnostic Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [2]*Department of Clinical Genetics, Helsinki University Hospital, University of Helsinki, Helsinki, Finland,* [3]*Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland.*

Background: Leber hereditary optic neuropathy (LHON) is a rare mitochondrial disease characterized by vision loss, typically manifesting in the second or third decade of life. While most cases of mitochondrial LHON are associated with three common mitochondrial DNA variants, autosomal recessive LHON (arLHON) has been recently linked to biallelic variants in the DNAJC30 gene. DNAJC30 has a gene carrier frequency of 1% in the Finnish population, mainly caused by the NM_032317.3(DNAJC30):-c.152A>G p.(Tyr51Cys) variant. Notably, the Finnish population has the highest allele frequency of this variant in gnomAD v4.1.0 and 3.1.2.

Material and methods: As part of the R&D of a clinical laboratory test we screened anonymized Finnish patients, who had tested negative for mitochondrial LHON point mutation analysis during 2004–2024, for the NM_032317.3(DNAJC30):-c.152A>G p.(Tyr51Cys) variant. This variant site was analyzed by Sanger sequencing in total 133 patients from the Helsinki University Hospital.

Results: We identified three DNAJC30 c.152A>G p.(Tyr51Cys) homozygotes and three heterozygotes. Using the Hardy-Weinberg equation, gnomAD allele frequencies and population of 5.6 million, we estimated that 100 Finns would have the c.152A>G p.(Tyr51Cys) variant in homozygous state at population level. FinnGen genotyping data from 500,348 Finnish individuals shows 14 homozygotes and in recessive analysis, association with binocular visual impairment was observed (p-value = 2.34e-4).

Conclusion: A recent study reporting two Estonian arLHON cases hypotized that this variants prevalence would be even higher among Finns. We thereby expected to find more homozygotes. However, DNAJC30 c.152A>G p.(Tyr51Cys) does not seem to be very common cause of LHON in Finnish patients.

P04.036.C Molecular diagnosis of hereditary optic neuropathy : retrospective next-generation sequencing study in 51 cases

Fatma Zehra Yalçin, *Haktan Erdem, Hanife Saat, Abdullah Sezer, Abdullatif Bakir, Elifcan Tasdelen*

Ankara Etlik City Hospital, Ankara, Turkey.

Background: Hereditary optic neuropathy is best known for its two most common phenotypes; autosomal dominant optic atrophy and Leber hereditary optic neuropathy. These disorders belong to a group of diseases arising from mitochondrial dysfunction caused by defects in both the nuclear and mitochondrial genomes.

Material and methods: We present a retrospective evaluation of 51 patients assessed between 2022–2024 with a diagnosis of hereditary optic neuropathy. 38 were male, and 13 were female, with an average age of 31(range:3–61 years). We performed clinical exome sequencing to evaluate nuclear and mitochondrial genomic alterations.

Results: Five patients were identified with pathogenic or clinically uncertain homoplasmic genomic changes in the mitochondrial genome. Two of these patients were female, and three were male, with an average age of 27 years. Consistent with the literature, the most frequently detected mitochondrial variant was m.11778 (MTND4).Pathogenic/likely pathogenic or clinically uncertain (VUS) changes in the nuclear genome were identified in 24 patients. The most frequently detected genomic alterations were found in the *OPA1* gene(14 patients) and the *WFS1* gene(3 patients). Other genes in which nuclear genomic alterations were identified included *LRP5*, *KCNJ13 NDUFAF5*, *EYS*, and *NXNL1*. Three patients had retinal diseases in addition to optic nerve disease. Retinal dystrophy-related variants were identified in two patients, specifically in *EYS* and *LRP5*.

Conclusion: In our study evaluating patients with optic neuropathy, nuclear genomic alterations were more frequently detected. However, we recommend a comprehensive assessment of both the nuclear and mitochondrial genomes in these patients.

P04.037.D Identification of the genetic background of Polish pediatric patients with suspected oculocutaneous albinism using next-generation sequencing

Beata Chalupczynska[1], *Elzbieta Ciara*[1], *Agata Maria Cieslikowska*[1], *Katarzyna Iwanicka-Pronicka*[1], *Dorota Siestrzykowska*[1], *Paulina Halat*[1], *Marzena Gawlik*[1], *Ewelina Bielska*[1], *Agnieszka Pollak*[2], *Małgorzata Rydzanicz*[2], *Krystyna Chrzanowska*[1], *Agnieszka Madej-Pilarczyk*[1]

[1]*The Children's Memorial Health Institute, Department of Medical Genetics, Warsaw, Poland,* [2]*Medical University of Warsaw, Department of Medical Genetics, Warsaw, Poland.*

Background: Albinism is a phenotypically and genetically heterogeneous condition characterized by absent or reduced pigmentation of the skin, hair, eyes. Seven genes are associated with different types of autosomal recessive OCA (*DCT, LRMDA, OCA2, SLC45A2, SLC24A5 TYR, TYRP1*) and *GPR143* gene is associated with X-linked OA.

Material and methods: We analyzed 25 Polish pediatric children from unrelated families with clinical suspicion of OCA/OA, searching for molecular changes in the causative genes using NGS based multi-gene targeted panel.

Results: Molecular analysis provides a genetic diagnosis in approximately 52% of individuals with clinical OA/OCA. The most commonly mutated gene was *TYR*, associated with OCA1. In this group we found common functional polymorphisms p.(Ser192Tyr) and p.(Arg402Gln) as pathogenic haplotype, which segregates consistently with an autosomal recessive inheritance pattern in various configurations with other pathogenic variants i.e.: one novel: p.(Asp305Glufs*12) and five known p.(Arg217Gln), p.(Pro406Leu), p.(His367Gln), p.(Met1Val), p.(Thr373Lys). The remaining patients had pathogenic variants in genes: *OCA2, GPR143, SLC24A5, SLC45A2* and *TYRP1*, among them the novel ones were: *TYRP1*: p.(Lys141Profs*38); *OCA2*: p.(Ala433Val); *SLC24A5*: p.(Met114Ile). Three patients were heterozygous for a causative variation in *OCA2* or *SLC45A2*.

Conclusion: Haplotype formed by two common, functionally-relevant variants in *TYR*: p.(Ser192Tyr) and p.(Arg402Gln) is associated with a high probability of receiving an albinism diagnosis. Reporting this variants in individuals in whom only a single deleterious *TYR* variant has been identified could permit a uplift in confirmatory molecular diagnoses. The combined analysis of rare and common variants can increase diagnostic yield and enables genetic counselling in families with albinism.

P04.038.B Congenital cataract in two unrelated individuals explained by *CRYBB2* gene conversion

Amandine Smail[1], *Lisa Chanourdie*[1], *Marjolaine Willems*[2], *Marion Serrand*[3], *Bertrand Chesneau*[1], *Nora Chelloug*[1], *Véronique Gaston*[1], *Julie Plaisancié*[4], *Nicolas Chassaing*[5]

[1]Service de Génétique Médicale, CHU Toulouse, Toulouse, France, [2]Service de Génétique Médicale, CHU de Montpellier, Montpellier, France, [3]Service d'Ophtalmologie, CHU Montpellier, Montpellier, France, [4]Laboratoire de Référence (LBMR) des Anomalies Malformatives de l'oeil, Toulouse, France, [5]Centre de Référence des Affections Rares en Génétique Ophtalmologique, Toulouse, France.

Background: Congenital cataract are opacities of the lens that develop within the first year of life. A genetic cause is found in around 50% of cases. Among about 50 causative genes described, with various modes of inheritance, those encoding crystallins are frequently involved. This includes *CRYBB2* gene, whose monoallelic pathogenic variants are associated with autosomal dominant isolated congenital cataracts. We report herein two individuals with a conversion involving *CRYBB2* and its pseudogene.

Materials and methods: Two unrelated individuals (a 4-month-old female and a 38-year-old female) with isolated congenital cataract were analysed using a targeted panel of 187 ocular development genes. An exon 5 deletion of *CRYBB2* was suspected and further investigated using custom CGHa (180 k) and long-range PCR.

Results: A heterozygous deletion of exon 5 of the *CRYBB2* gene (NM_000496.2) was suspected in both individuals but not confirmed by high resolution CGHa. Gene-specific Long-Range amplification and Sanger sequencing revealed three heterozygous missense variants in exon 5 of *CRYBB2*: p.(Arg145Trp), p.(Gln147Arg) and p.(Thr150Met). These variations matched the reference sequence of the pseudogene *CRYBB2P1* exon 4, supporting a conversion event between exon 5 of *CRYBB2* and exon 4 of *CRYBB2P1*.

Conclusion: Molecular studies in these patients identified a gene conversion involving *CRYBB2*. Such *CRYBB2* gene conversions, previously described in 3 patients with congenital cataract, may explain part of patients without molecular diagnosis as they could easily be missed by short-read sequencing. Recognizing gene conversion mechanisms is crucial for improving molecular diagnoses, as other genes may also be affected by similar events.

P04.039.A Genetic analysis of 387 independent otosclerosis patients

Laura Nagel, *Sophia Hollander, Sarah Amann, Ralf Birkenhager*

Univ Freiburg, Freiburg, Germany.

Backround: Otosclerosis is a disease affecting the middle and inner ear, which manifests in a slowly developing, intermittent hearing loss eventually leading to deafness. Hearing loss increases as the transmission of sound via the eardrum and ossicular chain is increasingly impaired because of inflammation-like remodelling processes of the bone with fixation of the stapes footplate to the oval window caused by genetic, viral and hormonal influences. Three different types of Otosclerosis can be distinguished. The classic middle ear type with pure conductive hearing loss. The pure inner ear type, capsular Otosclerosis with sensorineural hearing loss. The affection of both the middle and inner ear with a combination of conductive and sensorineural hearing loss. So far, eight different gene locations for Otosclerosis have been identified in single families and four genes that have so far only been described in individual patients. However, a clearly responsible gene has not been idetified yet.

Material and methods: The aim of the research project is to identify genes responsible for Otosclerosis in a larger sample collection of around 387 independent clinically clearly characterized patients. DNA sequencing techniques and Q-PCR methods will be used to analyse whether the genes FOXL1, MEPE, SMARCA4 and SERPINF1 are involved in Otosclerosis.

Results: The investigated samples do not show any mutations in the FOXL1 gene, no alterations were detected in MEPE so far.

Conclusion: In contrast to literature, involvement of the FOXL1 gene in Otosclerosis was excluded, while the impacts of the MEPE gene cannot be conclusively assessed yet.

P04.040.C Gene variant spectrum in a cohort of 94 patients with familial exudative vitreoretinopathy

Sarah Renae van der Ende, *Christopher R. McMaster, Johane M. Robitaille*

Dalhousie University, Halifax, NS, Canada.

Background: Familial exudative vitreoretinopathy (FEVR) is a rare genetic disease that impedes the vascularization of the retina. Early treatment before the development of complications is critical for the prevention of vision loss in moderate to severe cases. For this, a genetic diagnosis is essential, however, only 50% of FEVR patients have a variant in a known FEVR gene. Over 25 genes have been associated with the FEVR phenotype, with most cases being in *FZD4*, *LRP5*, *TSPAN12*, and *NDP*.

Material and methods: Probands clinically diagnosed with FEVR were enrolled and clinical information and DNA collected. An expanded FEVR panel was used, including six recognized FEVR genes (*FZD4, NDP, LRP5*, *TSPAN12*, *ZNF408*, and *CTNNB1*) and 19 genes previously associated with ocular features overlapping FEVR (FEVR-associated genes). Variants identified using targeted next-generation sequencing were analyzed and classified using the ACMG and ClinGen SVI working group recommendations to detect disease-causing variants (DCV).

Results: Analyses of data from a cohort of 94 probands provided a molecular diagnosis for 40 (42.6%) probands: 35 (87.5%) had a single DCV while five (12.5%) harboured more than one. Of 42 total DCV, 33 (78.6%) were in four of the six recognized genes (*LRP5*, *FZD4*, *TSPAN12*, *NDP*) while eight were found in FEVR-associated genes—six in *KIF11* and two in in association with another DCV.

Conclusion: The expanded FEVR gene panel detected DCV in nearly half of our cohort. Four FEVR genes account for most cases, and the role of rare FEVR genes and candidate genes requires further study.

P04.041.D Identification of two pathogenic splice variants, in the *HPS5* gene, associated with Hermansky-Pudlak Syndrome 5

Francesca Peluso[1], *Neri Alberto*[1], *Niki Ionadi*[1], *Isabelle Bacchi*[2], *Stefano Giuseppe Caraffi, PhD*[3], *Chiara Cattani*[4], *Roberta Zuntini*[3], *Livia Garavelli*[5]

[1]IRCCS Azienda USL di Reggio Emilia, Reggio Emilia, Italy, [2]Universita degli Studi di Bologna, Bologna, Italy, [3]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Medical Genetics Unit, AUSL-IRCCS of Reggio Emilia, Reggio Emilia, Italy, [5]AUSL IRCCS Reggio Emilia, Reggio Emilia, Italy.

Background: The *HPS5* gene codes for two isoforms: isoform A (NM_181507.2) (full-length), which consists of 23 exons encoding

a protein of 1129 amino acids, while isoform B (NM_007216.4) has a different 5' UTR and lacks exon 2, resulting in the usage of downstream ATG and in a protein that lacks the first 114 amino acids. Pathogenic variants, in the *HPS5* gene, are associated with Hermansky-Pudlak syndrome 5, which causes oculocutaneous albinism and a bleeding diathesis due to dysfunction of lysosome-related organelles (RLOs) and absence of dense platelet bodies.

Material and method: Whole exome sequencing filtered for genes associated with oculocutaneous albinism was performed. In vitro RNA analysis was carried out to clarify the effects of variants on splicing.

Results: We detected two new variants in three probands with oculocutaneous albinism. The first two probands are two sisters of consanguineous Pakistani parents. A homozygous variant was identified in the *HPS5* gene considering isoform A as reference, (NM_181507.2):c.108G>A that does not result in amino acid change p.(Lys36=). The third proband, a girl from a non-consanguineous Italian family, was compound heterozygous for the known pathogenic variant c.543del, inherited from her father, and for the novel variant c.1784+1G>A inherited from her mother. In the three patients, haematochemical examinations were normal and they have no history of bleeding problems. RNA analysis was carried out for both variants and revealed transcript alterations that can explain the clinical presentation.

Conclusion: We have identified two new splicing variants that cause a milder haematological phenotype of Hermansky-Pudlak syndrome 5.

P04.042.A Genotype and phenotype characteristics of patients with familial exudative vitreoretinopathy: first report on a Turkish cohort

Fulya YAYLACIOGLU TUNCAY[1], *Burak ACAR*[2], *Gulsum KAYHAN*[3], *Mehmet Ali ERGUN*[3], *Sengul OZDEK*[2]

[1]*University of Health Sciences, Gulhane Medical Faculty, Ankara, Turkey,* [2]*Gazi University Faculty of Medicine, Department of Ophthalmology, Ankara, Turkey,* [3]*Gazi University Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey.*

Background: We aimed to investigate genetic and clinical characteristics of patients with familial exudative vitreoretinopathy (FEVR) in a large single-center Turkish cohort.

Material and methods: The genetic test results of 95 patients diagnosed with FEVR in the ophthalmology department of Gazi Medical Faculty were retrospectively evaluated. The reported gene variants and clinical findings were recorded. Clinical severity was evaluated in patients with a reported variant in known FEVR genes (L*RP5, FZD4, NDP, TSPAN12, ZNF408, KIF11, DOCK6*, and *CTNNB1*).

Results: The genetic test results were conclusive in 33 patients (34.7%) with pathogenic/likely pathogenic variants, inconclusive for 17 patients (17.9%) with variants of uncertain significance (VUS), and negative for the remaining patients (47.4%) with no variants in known FEVR genes. Forty-five variants were reported in 38 unrelated patients, 19 of them (42.2%) were novel. *LRP5* variants were most prevalent (16/38), followed by *FZD4* (6/38), *TSPAN12* (5/38), *CTNNB1* (3/38), *NDP* (2/38), *KIF11* (2/38), *ZNF408* (1/38), and *DOCK6* (1/38). Two patients had more than one variant in more than one FEVR gene. Asymmetry was most prevalent in patients with *FZD4* variants (50%). However, patients with *LRP5* (37,5%), *TSPAN12, ZNF408*, and *CTNNB1* variants also showed asymmetric eye findings. Our cohort included six families with more than two patients, and four had younger family members with more severe findings.

Conclusion: This study represents one of the largest cohorts from Europe and the first cohort from Turkey investigating genotype-phenotype characteristics in FEVR patients. Our study supported the phenotypic variability in FEVR, even in the same family members.

P04.043.B Newly described *LRP2* pathogenic variants in a patient with Donnai-Barrow syndrome without congenital malformations

Sara Bargiacchi[1], *Lucia Tiberi*[1], *Giacomo M. Bacci*[2], *Francesco Marco Parodo*[3], *Chiara Quisisana*[4], *Roberto Caputo*[2], *Debora Vergani*[1], *Elia Dirupo*[1], *Ilaria Sani*[1], *Marilena Pantaleo*[1], ***Rosangela Artuso***[1], *Angela Peron*[1,3]

[1]*Division of Medical Genetics, Meyer Children's Hospital IRCCS, Florence, Italy,* [2]*Pediatric Ophthalmology Unit, Meyer Children's Hospital IRCCS, Florence, Italy,* [3]*Department of Experimental and Clinical Biomedical Sciences 'Mario Serio', Università degli studi di Firenze, Florence, Italy,* [4]*Eye Clinic, ASST Santi Paolo e Carlo Hospital, University of Milan, Milan, Italy.*

Background: Donnai-Barrow syndrome (DBS), also known as facio-oculo-acoustico-renal (FOAR) syndrome, is characterized by multiple congenital malformations with distinctive facial features, myopia and other ocular findings, hearing loss, agenesis of the corpus callosum, low-molecular-weight proteinuria and variable intellectual disability. Congenital diaphragmatic hernia (CDH) and/or omphalocele are common. Fewer than 60 individuals from about 20 families have been reported. DBS is an autosomal recessive disorder caused by loss of function variants in *LRP2* (low-density lipoprotein receptor-related protein 2 gene, chr 2q31.1) encoding the protein megalin, expressed in multiple absorptive epithelia, notably in the brain, kidney, and eye.

Material and methods: Few reports in the literature mention that a milder phenotype was observed in some patients. Here we describe a 6-years-old patient with a phenotype characterized only by high myopia, esotropia and minimal behavioral differences. We also describe the ocular phenotype in detail.

Results: On trio exome sequencing, we identified two compound heterozygous pathogenic variants in *LRP2*: a missense variation, c.9014G>A (p.Cys3005Tyr), and a deletion involving the entire gene. Both variants have not been previously reported in literature and entire gene deletions, in particular, have not been described thus far in association with DBS.

Conclusion: We describe the detailed phenotype of a patient with DBS showing no congenital malformations and we report for the first time a deletion of the entire *LRP2* gene. This information helps better understand genotype-phenotype correlations of this rare condition.

P04.044.C Genetic background of inner ear malformations

Natalia Baldyga[1,2], *Nina Gan*[1,2], *Dominika Ozieblo*[1], *Marcin Leja*[1], *Mariusz Furmanek*[1], *Henryk Skarzynski*[1], ***Monika Oldak***[1]

[1]Institute of Physiology and Pathology of Hearing, Warsaw, Poland, [2]Doctoral School of Translational Medicine, Centre of Postgraduate Medical Education, Warsaw, Poland.

Background: Inner ear malformations (IEMs) can occur in isolation or as part of genetically determined syndromes. Enlarged vestibular aqueduct (EVA) is the most frequently observed IEM, often accompanied by incomplete partition type 2 (IP2) of the cochlea and a dilated vestibule. *SLC26A4* is the major gene associated with IEMs, with 50% of EVA/IP2 patients carrying either two pathogenic *SLC26A4* variants or one *SLC26A4* pathogenic variant together with the CEVA haplotype. The genetic background of other IEMs is more diverse and remains poorly understood.

Material and methods: DNA was isolated from blood samples of 40 hearing loss (HL) patients with bilateral IEMs. Sequencing was performed using a custom multigene panel (237 or 263 genes).

Results: Genetic testing identified the cause of IEMs in 67.5% (27/40) of individuals. Among EVA/IP2 patients, six carried two pathogenic variants in *SLC26A4*, while another six had one *SLC26A4* pathogenic variant together with the CEVA haplotype. The genetic cause still remains unknown in six EVA/IP2 patients. In patients with other IEMs, pathogenic variants were identified in *POU3F4* as well as genes associated with CHARGE (*CHD7*), BOR (*EYA1*, *SIX1*), Waardenburg (*SOX10*), and Kabuki (*KMT2D*) syndromes. Additionally, a novel pathogenic variant in *HOXA2* was identified in a single patient.

Conclusion: Mutations in *SLC26A4* and the CEVA haplotype account for more than half of EVA/IP2 cases. Patients with other IEMs are frequently diagnosed with syndromic forms of HL. Further research is needed to identify pathogenic variants in noncoding regions of known HL genes or in novel genes.

P04.045.D The burden of combined sensory impairment and two distinct genetic diseases in a single patient

Evlampia Tsentemidou[1], *Konstantina Kosma*[1], *Nikolaos M. Marinakis*[1,2], *Faidon N. Tilemis*[1,2], *Vasileia Christodoulaki*[1,3], *Afroditi Kampouraki*[1], *Simoni Saranti*[4], *Stavroula Kostaridou*[4], *Joanne R. Traeger-Synodinos*[1], *Periklis Makrythanasis*[1,5,6]

[1]Laboratory of Medical Genetics, Medical School, National and Kapodistrian University of Athens, Athens, Greece, [2]Research University Institute for the Study and Prevention of Genetic and Malignant Disease of Childhood, St. Sophia's Children's Hospital, National and Kapodistrian University of Athens, Athens, Greece, [3]First Department of Pediatrics, St. Sophia's Children's Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece, [4]Department of Pediatrics, Penteli Children's Hospital, Athens, Greece, [5]Department of Genetic Medicine and Development, Medical School, University of Geneva, Geneva, Switzerland, [6]Biomedical Research Foundation of the Academy of Athens, Athens, Greece.

Background: Waardenburg syndrome refers to a group of rare genetic disorders characterized by congenital sensorineural hearing loss (SNHL) and defects in neural crest-derived structures, including pigmentation anomalies of the eyes, hair and skin. Waardenburg syndrome type 1 (WS1, MIM#193500) is the second most common subtype and is distinguished by eye dysmorphology, such as dystopia canthorum, which is typically not associated with visual impairment. This case presents the concomitance of WS1 and Stargardt 1 disease or Retinitis Pigmentosa (RP).

Material and methods: A 6-year-old boy with unilateral, *GJB2*-negative SNHL and a family history suggestive of autosomal dominant inheritance was referred for genetic evaluation. His phenotype was consistent with WS1, exhibiting four major and two minor criteria. Whole Exome Sequencing (WES) was performed to confirm the clinical diagnosis.

Results: WES confirmed WS1 diagnosis, identifying a novel likely pathogenic variant in *PAX3* [NM_181459.4:c.688C>A, p.(Gln230Lys)]. Additionally, compound heterozygosity was detected in *ABCA4* [NM_000350.3:c.5882G>A, p.(Gly1961Glu)/NM_000350.3:c.5917del, p.(Val1973*)]. Both of these variants are known causative for Stargardt 1 (MIM#248200) or RP (MIM#601718).

Conclusion: This case underscores the value of WES in revealing both expected and incidental findings. The patient's congenital SNHL is compounded by the risk of future visual impairment, which will significantly affect his quality of life, particularly in communication and social integration. Genetic diagnosis has altered the clinical follow up and management, with the primary goal being the deceleration of disease progression. Depending on the eventual manifestation of Stargardt 1 or RP, optical aids or therapeutic interventions may substantially improve his daily life.

P04.046.A Novel copy number variation and coding variants in Saudi patients with X-linked retinitis pigmentosa

Basamat Almoallem

Department of Ophthalmology, King Saud University, Riyadh, Saudi Arabia.

Background: X-linked retinitis pigmentosa (XLRP), a severe form of progressive retinal degeneration, accounts for 15% of RP cases. It is primarily caused by mutations in two genes: RPGR (OMIM #300455), responsible for most cases, and RP2 (OMIM #312600). This study investigates four unrelated XLRP Saudi families.

Material and methods: Six male patients from four Saudi families, ranging between 5–51 years, were recruited for this study. Whole exome sequencing (WES) NGS based copy number variation (CNV) analysis and was performed in the four index cases of each family followed targeted mutation screening in the affected ones.

Results: All studied patients displayed typical clinical features of profound visual loss, nyctalopia nystagmus and variable presentation of retinal dystrophy in the fundus. WES revealed hemizygous likely causative variants in all studied patients. Three distinct known variants in *RPGR* were found in five patients as follows: a nonsense mutation (c.1544T>G; p.(Leu515*) in (1/4 family; 25%), and a frameshift mutations (c.2236_2237del; p.(Glu746Argfs*23) in (2/4 family; 50%) including four affected males that might suggest a founder effect in the Saudi population. In one family we identified a hemizygous likely pathogenic by NGS CNV analysis a deletion of chromosomal region chrX:46712889-46719557, encompassing exons 2–3 of the *RP2* gene.

Conclusion: Our study broadens the genetic spectrum of RPGR-related XLRP, identifying known variants in 75% of families (five patients) and discovering a novel CNV in the RP2 gene. This emphasizes the value of NGS-based CNV analysis in uncovering missing heritability.

P04.047.B Familial steep corneas in posterior polymorphous corneal dystrophy 3 due to a novel ZEB1 gene mutation

Ehud Banne[1,2,3], *Tal Koval*[1,2,4], *Eli Neimark*[1,4,5], *Oriel Spierer*[1,4,2]

[1]*Wolfson Medical Center, Holon, Israel,* [2]*School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel aviv, Israel,* [3]*Department of Medical Genetics, Edith Wolfson Medical Center, Holon, Israel,* [4]*Department of Ophthalmology, Edith Wolfson Medical Center, Holon, Israel,* [5]*School of Medicine, Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel.*

Background: Posterior Polymorphous Corneal Dystrophy (PPCD), particularly PPCD3 caused by ZEB1 mutations, affects the corneal endothelium and Descemet's membrane, with features including vesicular corneal opacification, potential corneal ectasia, and steep curvature in some cases.

Material and methods: Ophthalmic examinations and corneal curvatures analyses were performed for all patients. Whole exome targeted gene panel sequencing was performed for one patient. Pathogenic variant confirmation and segregation of variant was performed for all four patients using Sanger sequencing.

Results: A mother and her 3 children presented with bilateral diffuse corneal opacities, vesicular aggregates at the Descemet's membrane level and endothelial stippling, compatible with the diagnosis of posterior polymorphous corneal dystrophy. All patients had steeper than average keratometry readings with normal globe axial lengths and refractive moderate to extremely high myopia, ranging from −2 diopters to −16.5 diopters (spherical equivalent). The younger patients had more severe findings, with the youngest, an 11-months old female, presenting with keratometry readings of 66.72 × 69.48 @ 132° and 66.10 × 67.32 @ 34° in the right and left eyes, respectively. The *ZEB1*:c.794-1G>A;chr10-31809053G>A; NM_001174096.2 mutation was detected in all patients.

Conclusion: We describe a novel *ZEB1* mutation associated with posterior polymorphous corneal dystrophy, steep non-keratoconic corneas and myopia. Posterior polymorphous corneal dystrophy 3 should be considered not only as an endothelial pathology but also as an ectatic disorder and ruled out in young children presenting with high myopia.

P04.048.C Evaluation the effect of *COL4A1*R1656S mutation on the progressive retinopathy

Kunka Kamenarova[1,2], *Stefani Petrova*[3], *Kirilka Mladenova*[3], *Kalina Mihova*[1,2], *Martin Georgiev*[1,2], *Nevyana Veleva*[4], *Veselina Moskova-Doumanova*[5], *Pavel Videv*[3], *Jordan Doumanov*[3], *Radka Kaneva*[1,2]

[1]*Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical University - Sofia, Sofia, Bulgaria, Sofia, Bulgaria,* [2]*Laboratory of genomic diagnostics, Department of Medical Chemistry and Biochemistry, Medical University - Sofia, Sofia, Bulgaria, Sofia, Bulgaria,* [3]*Department of Biochemistry, Faculty of Biology, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria, Sofia, Bulgaria,* [4]*Department of Ophthalmology, University Hospital Alexandrovska, Medical University - Sofia, Sofia, Bulgaria, Sofia, Bulgaria,* [5]*Department of Cell and developmental biology, Faculty of Biology, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria, Sofia, Bulgaria.*

Background: Mutations in collagen type IV alpha 1 (*COL4A1*) are associated with multisystem abnormalities affecting mainly the brain and the retinal vasculature. We identified a pathogenic variant R1656S in *COL4A1* in patients with retinopathy, anterior segment dysgenesis, and cataract, and aimed to evaluate the molecular effect of R1656S-mutation in MDCKII cells.

Material and methods: MDCKII cells were transiently and stably transfected using Effectene Transfection Reagen (Qiagen) with expression vectors containing WT *COL4A1* and mutant R1656S along with GFP (pCMV-eGFP, Genecopea). ZO-1 (Tight junction protein) and GM-130 (Golgi marker) immunofluorescence, as well as TRITC-Phalloidin staining of actin cytoskeleton and cell nuclei with DAPI was performed on confluent cells.

Results: Using mammalian expression system based on transient and stably transfected MDCKII cells, we assessed the colocalization of F-actin cytoskeleton, ZO-1, GM-130, and COL4A1 proteins. No changes were found in cell morphology, ZO-1, GM130 and actin cytoskeleton structure but we observed differences in cell growth, mitotic index, and distribution of WT and R1656S-COL4A1. In cells expressing WT-COL4A1, its colocalization with F-actin filaments and ZO-1 close to the cell periphery was detected. This localization was less pronounced or absent In cells expressing R1656S-mutant. A strong signal for the *COL4A1*-R1656S was detected in close proximity to the Golgi apparatus.

Conclusion: Our findings explain the mixed phenotype of epithelial changes used as model system, which could be related to the retinal epithelial changes associated with optic nerve dysgenesis and secondary glaucoma observed in our patients, and suggest that carriers of *COL4A1*-R1656S may be at elevated risk of retinopathy.

P04.049.D InsightRP2: a global patient registry for *RP2*-associated X-linked retinitis pigmentosa

Nina Bögershausen[1], *Barbara Vona*[1,2], *Lukas Cyganek*[3,4,5], *Alisa Fedorenko*[1], *Patricia Take*[6], *Carolin Strohmeyer*[6], *Hans Hoerauf*[6], *Bernd Wollnik*[1,7]

[1]*Institute of Human Genetics, University Medical Center Göttingen, Göttingen, Germany,* [2]*Institute for Auditory Neuroscience and InnerEarLab, University Medical Center Göttingen, Göttingen, Germany,* [3]*Stem Cell Unit, Department of Cardiology and Pneumology, University Medical Center Göttingen, Göttingen, Germany,* [4]*Translational Neuroinflammation and Automated Microscopy, Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Göttingen, Germany,* [5]*DZHK (German Centre for Cardiovascular Research), partner site Lower Saxony, Göttingen, Germany,* [6]*Department of Ophthalmology, University Medical Center Göttingen, Göttingen, Germany,* [7]*Else Kröner Fresenius Center (EKFZ) for Optogenetic Therapies, University Medical Center Göttingen, Göttingen, Germany.*

Background: Retinitis pigmentosa (RP) represents a genetically heterogeneous group of inherited retinal dystrophies (IRD) characterized by progressive photoreceptor degeneration leading to visual impairment. Mutations in the *RP2* gene account for approximately 20% of X-linked retinitis pigmentosa, a particularly severe and early-onset form of the disease (1,2). RP collectively qualifies as a rare disorder, which, by definition, affects less than 5 in 10,000 people. However, *RP2*-associated RP by itself is much rarer and this aspect hinders participation in rare disease studies and access to evolving treatments such as gene therapies. Patient registries serve as important tools to engage patients who may otherwise face hurdles in connecting with rare disease studies.

Material and methods: We have created a collaborative online registry database within the REDCap® framework. A clinical questionnaire, specific to *RP2* related medical issues, as well as online consent forms were created.

Results: The InsightRP2 registry is tailored to document detailed clinical and genetic data of individuals with *RP2*-associated RP. It entails a clinical questionnaire to be filled out by the participant and / or their physician, and allows for storage of medical reports, genetic reports, and imaging files for further analysis, thus facilitating natural history studies, as well as research into pathogenesis and therapy.

Conclusion: By implementing a disease specific patient registry, we aim to help linking individuals affected by *RP2*-associated RP from Germany and around the world with physicians and researchers intending to better understand the clinical manifestations and progression of the disease and eventually treat this rare condition.

P04.050.A A novel splice variant in *COL4A1* results in retinal arterial tortuosity and HANAC syndrome in a multi-generational family

Ehsan Misaghi, *Alina Radziwon, Narin Sheri, Peter Kannu, Matthew Benson*

University of Alberta, Edmonton, AB, Canada.

Background: *COL4A1*-related disorders are multisystem diseases characterized by aberrant collagen IV fibers and disrupted basement membranes. We identified a novel splice-site variant (c.3876+5G>A) in *COL4A1* in a multi-generational family with intracerebral vasculopathy and retinal arterial tortuosity.

Material and methods: Ophthalmic exams, imaging and clinical genetic tests were performed for the proband, her affected father and son, and unaffected daughter. Dermal fibroblasts from the proband were harvested and used for RNA and protein analysis. RT-PCR and Sanger sequencing were performed on fibroblast-derived RNA to evaluate whether the variant in *COL4A1* disrupted normal splicing. Western blotting was used to assess protein expression using a COL4A1 antibody.

Results: Molecular testing identified a *COL4A1* splice-site variant in affected family members but not in the unaffected daughter. RNA analysis revealed skipping of exon 43 (of 52), resulting in a frameshift and premature termination codon ten amino acids downstream of the variant. Further RNA analysis using a nonsense-mediated RNA decay (NMD) inhibitor indicated that the mutant transcript is likely degraded by NMD. The absence of the predicted truncated protein on Western blotting provided further support for this hypothesis.

Conclusion: We highlight a *COL4A1*-related disorder, diagnosed by ophthalmology, in a family presenting with retinal arterial tortuosity and intracerebral vasculopathy. Functional analyses enabled upgrading the variant to likely pathogenic, solidifying the diagnosis of this rare disorder in this family and enhancing our understanding of basic genetic mechanisms underlying *COL4A1*-related disorders.

P04.052.C Diagnosis of an overlooked rare disease: a case of Bardet-Biedl syndrome

Huseyin Sonat Simsir, *Hande Kucuk Kurtulgan, Malik E. Yildirim*

Sivas Cumhuriyet University, Faculty of Medicine, Department of Medical Genetics, Sivas, Turkey.

Background: Bardet-Biedl Syndrome (BBS) is a rare autosomal recessive ciliopathy due to primary ciliary dysfunction and is characterised by multisystemic involvement. The major features of the syndrome include retinal rod-cone dystrophy, obesity, polydactyly, intellectual disability, hypogonadism and renal anomalies. Additionally, minor findings related to various systems have been reported.

Case Presentation: A 55-year-old woman whose parents had consanguineous marriage was referred to our department from ophthalmology clinic with a pre-diagnosis of retinitis pigmentosa due to visual loss. The patient's medical history revealed that she had progressive visual loss, recurrent nephrolithiasis and haematuria since the age of 10 years. The patient's family history included visual impairments, renal problems, and obesity at various degrees. Brachydactyly, abdominal obesity, and hallux valgus were noted on physical examination. The patient was screened for additional abnormalities using imaging techniques and blood tests. Whole exome sequencing analysis revealed a homozygous c.479G>A variant in the *BBS1* gene. The patient met sufficient diagnostic criteria for BBS, received genetic counseling about the disease and referred to the appropriate departments.

Conclusion: Although the early-onset retinitis pigmentosa is one of the distinguishing features of BBS, the patient's diagnosis was delayed because the symptoms were evaluated separately and the association with the syndrome was overlooked on previous assessments. The diagnosis of BBS could have been missed if the patient had only been examined with genetic testing based solely on the referral pre-diagnosis. This case highlights the importance of multidisciplinary approach and genetic analyses in the diagnosis and management of a rare hereditary disease.

Early-onset, severe retinal dystrophy can be isolated or syndromic, presenting as part of an underlying systemic disease. Mainzer-Saldino syndrome, a rare systemic ciliopathy characterized by skeletal and renal disease, is caused by recessive mutations in the intraflagellar transport 140 chlamydomonas homologue (IFT140) gene. We present a series of 13 cases of early-onset retinal dysfunction with confirmed IFT140 mutations from 8 unrelated Saudi families belonging to 3 well-known tribes. All carried the same homozygous missense IFT140 mutation (c.1990G>A; p.Glu664Lys) except for a single family, which included 4 affected subjects, 3 of whom were aborted fetuses, with compound heterozygous pathogenic IFT140 variants (c.1525-1G>A and c.1990G>A; p.Glu664Lys). Severe retinal dystrophy was present in all living subjects, phenotypically apparent as hyperopia, nystagmus, nyctalopia, poor vision and nonrecordable full-field electroretinography. All affected individuals had skeletal

abnormalities, and neurological abnormalities were common, but there was no evidence of chronic renal failure.

P04.055.B Genetic diagnosis in sensorineural hearing loss: clinical outcomes following cochlear implantation in two patients with Zimmerman-Laband syndrome (case series)

Sarah Chamieh

Hôpital Necker-Enfants Malades, Paris, France.

Background: The gold standard recommendation for congenital sensorineural hearing loss (SNHL) care is cochlear implantation (CI). Adjusting for confounding factors such as developmental comorbidities is crucial when assessing expected outcomes of the procedure for the patients, their families, and their medical teams.

Case series: We describe two clinical cases of Zimmerman-Laband syndrome associated with two different ATP6V1B2 pathogenic variants and highlight the benefit of molecular diagnosis in a context of overlapping syndromic phenotypes.

Conclusion: Through the case study of CI in congenital syndromic SNHL, we demonstrate the importance of genotype-phenotype relationships in assessing clinical outcomes, and present genetic molecular diagnosis as a crucial tool in managing patient and family expectations.

C.O.I. Disclosure:

P04.056.C Unveiling the genetic landscape of visual impairment in North Macedonia: insights from whole exome sequencing

Emilija Shukarova Stefanovska[1], *Ivana Maleva Kostovska*[1], *Predrag Noveski*[1], *Stefan Pandilov*[2], *Bekim Tateshi*[2], *Natasha Trpevska Shekerinov*[2], *Galina Dimitrova*[3], *Dijana Plaseska-Karanfilska*[1]

[1]*Macedonian Academy of Sciences and Arts, Research Centre for Genetic Engineering and Biotechnology, Skopje, North Macedonia, The Republic of,* [2]*University Clinic for Eye Diseases, Faculty of Medicine, Ss. Cyril and Methodius University in Skopje, Skopje, North Macedonia, The Republic of,* [3]*Department of Ophthalmology, City General Hospital "September 8th", Skopje, North Macedonia, The Republic of.*

Background: Visual impairment encompasses a highly heterogeneous group of disorders, with inherited retinal dystrophies being the most common cause of severe, irreversible vision loss. Over 300 genes contribute to the molecular basis of visual impairment, making genetic testing essential for diagnosis, genetic counselling and prognosis.

Material and methods: Whole Exome Sequencing (WES), followed by bioinformatics analysis and ACMG classification, was performed on 44 patients referred to RCGEB for molecular diagnosis of various types of visual impairment.

Results: Causative pathogenic variants were identified in 34 (77.3%) of the patients. Among the 35 distinct pathogenic variants, nine were novel. In two patients (4.5%), variants of uncertain significance (VUS) in autosomal dominant (AD) genes (RP1L1/UNC119) were detected, while in four patients (9.1%) only a single pathogenic variant in an autosomal recessive (AR) gene was found. The *ABCA4* gene was the most frequently affected AR gene (4/34; 11.8%), followed by *FAM161A* and *PCARE* (2/34; 5.9% each). Pathogenic variants in the X-linked *RPGR* gene were identified in two male patients. Additionally, thirteen different AR genes (*ALMS1; CDHR1, CYP1B1, CNGB3, EYS, MERTK, NRL, RDH12; RP1, PDE6C, SPATA7, TSPAN12, USH2A)* and 3 AD genes (*BEST1, CRX* and *PAX6)* were causative in only one patient each.

Conclusion: The implementation of WES led to the identification of disease-causing variants in 77.3% of patients with visual impairment, enabling more accurate prognoses, optimized therapeutic approaches, and appropriate genetic counselling. Further analysis is required for patients where VUS variants or a single pathogenic variant in AR conditions were identified.

P04.057.D A novel, recurrent, population-specific variantp.(Lys232*) in the *CACNA1F* genein Familial type 2 X-linked incomplete congenital stationary night blindness

Nataša Teran*, Barbara Golob, Aleš Maver, Karin Writzl, Marija Volk, MD PhD, Mihael Rogač, Borut Peterlin*

UMC Ljubljana, Centre for Mendelian Genomics, Clinical Institute of Genomic Medicine, Ljubljana, Slovenia.

Background: X-linked congenital stationary night blindness (CSNB) is a nonprogressive retinal disorder characterized by decreased visual acuity and impaired night vision, with an estimated prevalence ranging from 1:5,000 to 1:25,000. We report a novel recurrent pathogenic variant in the *CACNA1F* gene, identified in two Slovenian families with a total of four affected male family members.

Material and methods: All four patients were referred for whole-exome sequencing (WES) due to impaired retinal function, suspected to be an incomplete form of X-linked CSNB. Segregation analysis was performed to determine the origin of the identified variant.

Results: A pathogenic hemizygous frameshift variant NM_005183.4:c.694A>T, p.(Lys232*), was identified in all four patients. In the first family, the variant segregated with the X-linked inherited clinical phenotype in three males. However, segregation analysis could not be performed in the second family.

Conclusion: Here, we report a novel, recurrent, population-specific pathogenic variant c.694A>T, p.(Lys232), in the CACNA1F gene, associated with X-linked congenital stationary night blindness.

C.O.I. Disclosure:

P04.058.A Disrupted *GRHL2* transcriptional activity as a mechanism of autosomal dominant hearing loss development (DFNA28)

Natalia Baldyga[1,2], *Dominika Ozieblo*[1], ***Marcin Leja***[1], *Henryk Skarzynski*[1], *Monika Oldak*[1]

[1]*Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*Doctoral School of Translational Medicine, Centre of Postgraduate Medical Education, Warsaw, Poland.*

Background: *GRHL2* is one of over 50 genes linked to autosomal dominant hearing loss (ADHL) and is also implicated in cancers. It encodes a transcription factor. Only few ADHL-related *GRHL2* pathogenic variants have been reported and their mode of action

remains unclear. This study aimed to identify the genetic basis of ADHL in a multigeneration family with progressive hearing loss (HL) and explore the molecular mechanism of DFNA28 *GRHL2* mutations.

Material and methods: Genomic DNA from the proband and family members (n = 8) was analyzed using a 237-gene HL panel and Sanger sequencing. Expression vectors for four ADHL-related *GRHL2* variants were generated, and their transcriptional activity was assessed in HEK293T cells using a luciferase reporter assay.

Results: A novel heterozygous *GRHL2* variant (c.1061C>T; p.Ala354Val) segregating with HL was identified within the DNA-binding domain. Functional assays showed reduced transcriptional activity for this variant and two others (c.1258-1G>A, p.Gly420Glufs*111; c.1276C>T, p.Arg426*). In contrast, a variant affecting the dimerization domain (c.1609_1610insC, p.Arg537-Profs*11) strongly activated the GRHL-responsive promoter.

Conclusions: The pathogenicity of novel missense variant was supported by functional assays. *GRHL2* mutations can suppress or activate transcription depending on variant location—DNA-binding domain variant causes haploinsufficiency, while dimerization domain variant shows gain-of-function effect. This study provides new insights into *GRHL2*-related hearing loss mechanisms.

P05 Internal organs and endocrinology (Lung, Kidney, Liver, Gastrointestinal)

P05.001.B A broader genetic testing approach in Nephropathies: towards a better diagnosis

Ana Patrícia Jesus[1], *Diana Antunes*[1,2,3], *Catarina Silveira*[1], *Yuri Chiodo*[1], *Sofia Jorge*[4], *Sara Gonçalves*[4], *José Nuno Fonseca*[4], *Márcia Rodrigues*[5], *Joaquim Calado*[6], *Maria Carmo-Fonseca*[7]

[1]*GenoMed - Diagnósticos de Medicina Molecular, Lisbon, Portugal,* [2]*Medical Genetics Department, ULS São José (HSMarta), Lisbon, Portugal,* [3]*Medical Genetics Department, ULS São José (HDEstefânia), Lisbon, Portugal,* [4]*Nephrology and Transplantation Department, ULS Santa Maria (HSM), Lisbon, Portugal,* [5]*Medical Genetics Department, ULS Santa Maria (HSM), Lisbon, Portugal,* [6]*Nephrology Department, ULS São José (HCCabral), Lisbon, Portugal,* [7]*Gulbenkian Institute of Molecular Medicine, Lisbon, Portugal.*

Background: Kidney diseases (KD) have a high incidence in Portugal. Whole exome sequencing (WES) is widely used to determine the genetic etiology of KD. However, KD's high genetic and phenotypic heterogeneity poses a challenge.

Material and methods: We present an overview of genetic testing by WES, from 2010 to 2024. Our cohort of 487 patients displays a wide range of phenotypes.

Results: Until mid-2023, genetic panels ≤85 genes were requested. 21.6% (n = 88) of the patients (n = 406) presented pathogenic (P) or likely pathogenic (LP) variants. The remaining either presented variants of uncertain significance (VUS) or a single pathogenic variant in a gene with an autosomal recessive inheritance (n = 148), or rendered a negative result (n = 170). All reported VUS were reinterpreted and 21 presented a different classification: 6 patients with a VUS received an upgrade in classification (LP), while 15 were downgraded to benign. In 2023, besides Copy Number Variation (CNV) analysis, we implemented broader panels. Since then, 29.6% (n = 24) of the 81 index cases, in which a broader first analysis was requested, had LP/P variants. We detected a deletion and a microduplication, which would fail to be reported without CNV analysis. Moreover, reanalysis of 24 negative samples employing broader genetic panels rendered a positive result in four of them (17%).

Conclusion: Our findings emphasize the significance of reevaluating variant classification and using a larger number of genes in nephropathy genetic testing. Effective treatment of the patients, as well as adequate screening and family counseling, are made possible by an accurate initial diagnosis.

Background: In normal human anatomy, the position and orientation of thoraco-abdominal organs and major blood vessels exhibit a distinct asymmetry along the body's left-right axis. Disruption of the left-right patterning process during embryogenesis gives rise to laterality disorders, characterized by abnormal arrangement of internal organs and great vessels, often combined with congenital malformations. We aimed to characterize the genetic defect in two infants with left isomerism heterotaxy, caused by bi-allelic loss-of-function variants in a novel disease-causing gene.

Methods: Trio genome sequencing was performed for each family. Primary dermal fibroblasts from *Patient 1* were generated and used for RNA extraction to study the detected splice variant in *PIH1D2*, for immunofluorescence staining and for in vitro ciliogenesis assays.

Results: We characterize a novel laterality syndrome of disrupted left-right asymmetry, including dextrocardia, polysplenia and biliatry atresia. Genome sequencing revealed bi-allelic loss-of-function variants in the *PIH1D2* gene in each patient. Immunofluorescence staining confirmed protein loss in *Patient 1* fibroblasts. A ciliary defect was supported by a low nasal nitric oxide level in *Patient 2*, and by a significant reduction in ciliogenesis of *Patient 1* fibroblasts upon serum starvation ($p = 0.0004$).

Conclusion: This study provides evidence of a novel left isomerism heterotaxy syndrome caused by bi-allelic loss-of-function variants in *PIH1D2*. Our data is supported by previous studies in mutant zebrafish exhibiting heart-looping defects, and other primary ciliary dyskinesia syndromes caused by genes belonging to the PIH protein family. Additional patients will provide better characterization of the full phenotypic spectrum and natural history of this disorder.

P05.003.D Functional assessment of *NPHS2* pathogenicity - the world of interallelic interactions

Violetta Antal-Kónya[1,2], *Gusztáv Schay*[3,2], *Máté Kétszeri*[1,2], *Dániel Seidl*[1,2], *Eszter Balogh*[1,2], *Ágnes Mikó*[1,2], *Anita Ungvári-Veres*[1,2], *Miklós Kellermayer*[3], *Dóra Karancsiné Menyhárd*[4], *Kálmán Tory*[1,2]

[1]*Semmelweis University, Pediatric Center, MTA Center of Excellence, Budapest, Hungary,* [2]*MTA-SE Lendület Nephrogenetic Laboratory, Budapest, Hungary,* [3]*Semmelweis University, Department of Biophysics and Radiation Biology, Budapest, Hungary,* [4]*MTA-ELTE Protein Modeling Research Group and Laboratory of Structural Chemistry and Biology, Eötvös Loránd University, Budapest, Hungary.*

Background: *NPHS2*, encoding podocin, is the most frequently mutated gene in podocytopathies. The pathogenicity of its most frequent R229Q variant depends on the trans-associated variant, which makes the pathogenicity assessment of unknown R229Q-associations particularly challenging. We previously showed that podocin shortens the distance between neighboring nephrin molecules, and here aimed to determine its potential in the pathogenicity assessment of unknown associations.

Material and methods: HEK293 cells were transfected with nephrin constructs labelled extracellularly with YPet or mCherry encoded in pEGFP-N1 plasmids, and a pKK-BI16 plasmid expressing two different podocin variant. FRET efficiency was measured between YPet and mCherry in living cells, 48h after transfection. Measurements were repeated nine times in three experiments.

Results: While all benign podocin associations (R229Q-wt, R229Q-R138Q, R229Q-R229Q, R229Q-V290M) increased the FRET efficiency between nephrin molecules ($p < 0.005$), none of the pathogenic associations (R229Q-A248V, R229Q-A297V, R229Q-F344Lfs, R229Q-R291W) exerted such an effect. The difference between benign and pathogenic variants/associations was highly significant ($p = 1.19 \times 10^{-33}$), and a cut-off value could distinguish them in 100% of the measurements.

Conclusion: Benign R229Q podocin oligomers significantly shorten the distance between nephrin molecules in cis, while pathogenic oligomers are unable to do so. This mechanism explains the molecular basis of the interallelic interactions, and is also specific enough to help the distinction of pathogenic and benign R229Q associations.

P05.004.A Genome-wide aggregated *trans*- effects analysis implicates deficient Type III interferon signalling as a key cause of inflammatory bowel disease

Paul M. McKeigue[1], *Andrii Iakovliev*[1], *Buddhiprabha Erabadda*[1], *Helen Colhoun*[1], *Athina Spiliopoulou*[2]

[1]*University of Edinburgh, Edinburgh, United Kingdom,* [2]*Usher Institute, Edinburgh, United Kingdom.*

Background: The "omnigenic" sparse effector hypothesis postulates that the polygenic effects of common SNPs on a typical complex trait are mediated by trans- effects that coalesce on expression of core genes. The objective of this study was to identify core genes and core pathways for inflammatory bowel disease.

Material and methods: We tested for association of inflammatory bowel disease with genome-wide aggregated trans-effects (GATE) scores for gene expression in 7907 cases and 451198 non-cases in UK Biobank.

Results: Inflammatory bowel disease was inversely associated with predicted expression of six interferon-stimulated genes - I*FIT1, IFI44, HERC5, MX1, IFI44L, RSAD2* - that were regulated by the same trans-eQTLs, and with predicted levels of the Type III interferon IFN-λ1 encoded by *IFNL1*. Ten other genes were identified as possible core genes based on GATE score associations with inflammatory bowel disease, of which three were supported by a reported GWAS hit within 200 kb of the transcription site, and three - *CCDC50, VCAM1, HAVCR2* - by effects on colitis in a mouse model. Of these ten genes, three have roles in the innate immune system, one in the adaptive immune system, and one in leucocyte trafficking.

Conclusion: These results establish a key role of deficient Type III interferon signalling in the aetiology of inflammatory bowel disease, supported by other evidence including previously reported GWAS associations, monogenic disease caused by rare variants, clinical studies of gene expression and experimental perturbation in a mouse model. More generally, these results identify possible therapeutic targets.

P05.005.B Early diagnosis of Wolfram syndrome type 1: insights into diabetes insipidus presentation and genotype-phenotype correlation

Ozge B. Gundogdu Ogutlu, *Oguzhan Yarali, Atilla Cayir*

Erzurum City Hospital, Erzurum, Turkey.

Background: Wolfram syndrome type 1 (WS1) is a neurodegenerative disorder caused by biallelic WFS1 mutations, primarily characterized by the association of diabetes mellitus (DM), optic atrophy (OA), diabetes insipidus (DI), and hearing loss (HL). Early DI diagnosis in WS1 may be missed as its polyuria and polydipsia symptoms overlap with those of DM. This study used a structured questionnaire to detect DI and examined genotype-phenotype correlations in a Turkish Type 1 DM cohort.

Material and methods: We retrospectively analyzed 1,278 pediatric patients with Type 1 DM. A polyuria/polydipsia questionnaire was administered during follow-ups to identify DI symptoms masked by DM. Eighteen patients with positive results underwent WFS1 genetic testing. The identified variants were assessed by ACMG criteria.

Results: Six patients (33%) were diagnosed with WS1, carrying seven different *WFS1* variants: four missense mutations, one in-frame duplication, and two frameshift variants, including two novel variants (c.2104G>T and c.1727_1744dup). The median age at diagnosis of WS1 was 9 years 1 month. Three patients had OA, and one had HL, reflecting phenotypic variability. Two siblings with the same frameshift mutation showed different ages of onset and different phenotypic presentations, suggesting intra-familial variability.

Conclusion: DI may precede OA in WS1, and early detection by a simple questionnaire could enable early diagnosis. The present study emphasizes the importance of genetic screening in patients with Type 1 DM presenting with symptoms of DI and highlights the need for functional studies and longitudinal follow-up to

better define genotype-phenotype correlations in order to improve clinical management.

P05.006.C Genetic and clinical characteristics of familial pulmonary fibrosis patients and relatives

Nathalie Veyt[1,2], *Tinne Goos*[2,3], *Marie Vermant*[2,3], *Tine Follet*[2,3], *Stefan Gogaert*[2,3], *Evelien Van Hoof*[1], *Karen Rosier*[1], *Anniek Corveleyn*[1], *Isabelle Cleynen*[1], *Sascha Vermeer*[1], *Wim A. Wutys*[2,3]

[1]*Department of Human Genetics, University Hospitals Leuven-KU Leuven, Leuven, Belgium,* [2]*Laboratory of Respiratory Diseases and Thoracic Surgery (BREATHE), Department of Chronic Diseases and Metabolism, KU Leuven, Leuven, Belgium,* [3]*Unit for interstitial lung diseases, Department of Pulmonology, University Hospitals Leuven, Leuven, Belgium.*

Background: In the majority of familial pulmonary fibrosis (FPF), defined as the presence of fibrotic interstitial lung disease in at least two first- or second-degree relatives, the underlying genetic cause remains unknown, complicating the screening approach for relatives.

Material and methods: We included 132 families (155 patients and 213 relatives) and performed in-depth genetic and clinical characterization of this cohort. Analysis of the pulmonary fibrosis gene panel, genotyping of the *MUC5B* promoter polymorphism (rs35705950) and telomere length (TL) assessment (using flow-FISH) was done in patients. For families with a negative gene panel result, the whole exome data were analyzed for variants in candidate genes. Relatives took part in a multimodal screening program (pulmonary function test and high-resolution CT-scan, besides genetic testing).

Results: A (likely) pathogenic (LP/P) variant was detected in 23/132 (17,4%) families, mostly in the telomere-related genes (*RTEL1*, *TERT*, *PARN*, *TERC*). In 2 families we found a LP/P variant in a surfactant-related gene (*SFTPC*, *SFTPA2*). In 28/132 (21.2%) families a variant of unknown significance (VUS) was detected. The c.308T>C p.(Leu103Pro) VUS in the *TERT* gene (NM_198253.2) was seen in 3 independent families and might be a founder variant, which we will verify by haplotype analysis. Furthermore, we detected rare variants in the *KIF15* candidate gene segregating with the phenotype in 5 families. A common *KIF15* variant, thought to be a risk allele, was overrepresented in our cohort. About 12% of relatives had interstitial lung abnormalities/disease on screening.

Conclusion: In-depth genetic characterization will facilitate follow-up and early detection in relatives.

P05.007.D Burden of potential kidney failure in apparently asymptomatic patients

Michel Bader[1,2], *Giorgio Signori*[1,2,3], *Antoine Dahine*[1,2], *Nicoletta Mancianti*[4], *Guido Garosi*[4], *Flavia Tinella*[2,3], *Miriana Danelli*[1,2], *Chiara Fallerini*[1,2,3], *Anna Maria Pinto*[1,2,3], *Alessandra Renieri*[1,2,3]

[1]*Department of Medical Biotechnologies, Med Biotech Hub and Competence Center, University of Siena, Siena, Italy,* [2]*Medical Genetics, University of Siena, Siena, Italy,* [3]*Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy,* [4]*Nephrology, Dialysis and Transplantation Unit, Department of Emergency-Urgency and Transplantation, University Hospital of Siena, Siena, Italy.*

Background: Chronic Kidney Disease (CKD) is a major health concern due to its high morbidity and asymptomatic nature in early stages. Early detection is essential for timely intervention, reducing complications and mortality. Despite its prevalence, only a small percentage of affected individuals are aware of their condition. Genetic screening offers a promising approach for identifying at-risk individuals before symptoms arise.

Material and methods: This study analyzed 8,376 exomes from patients evaluated for conditions unrelated to kidney disease. To determine the prevalence of genetic predisposition among asymptomatic individuals, we searched for pathogenic and likely pathogenic (P/LP) variants in 67 CKD-associated genes.

Results: P/LP variants were identified in 6.4% of individuals across 60 genes associated with CKD. Among the most notable findings, variants in the Collagen type IV genes were present in 1.4% of cases, underscoring their significant role in CKD pathogenesis. Additionally, variants in autosomal dominant *ACTN4, TRPC6, INF2, LMX1B, WT1, APOL1, PAX2, ANLN, FN1* and *MYH9* accounted for another 0.84%. These findings suggest a significant genetic contribution to CKD development and highlight many individuals carrying genetic risks without clinical manifestation.

Conclusion: The genetic predisposition to CKD in asymptomatic individuals is underestimated. Integrating genetic screening into clinical practice can enhance early diagnosis, allowing for personalized treatment strategies and improved patient outcomes. Future research should focus on optimizing screening protocols and evaluating the long-term benefits of genetic risk assessment in CKD management. Genetic characterization may become a key tool in preventing disease progression and advancing precision medicine in nephrology.

P05.008.A Investigation of the molecular mechanism underlying IBD phenotypes through a large meta-analysis of scRNAseq data

Paola Pibiri[1], *Roy Oelen*[1], *Werna T.C. Uniken Venema*[1], *Emilia Bigaeva*[1], *Monique G.P. van der Wijst*[1], *Maria D. Paraskevopoulou*[2], *Xinghao Zhang*[2], *Klaas N. Faber*[1], *Lude Franke*[1], *Eleonora A.M. Festen*[1]

[1]*University Medical Center Groningen, Groningen, Netherlands,* [2]*Takeda Pharmaceuticals, Cambridge, MA, USA.*

Background: Inflammatory Bowel Disease (IBD) is one of the most prevalent gastrointestinal diseases worldwide. However, despite the advent of new therapeutic agents, patients deal with debilitating symptoms and a high non-response rate. Studies such as Martin et al. (Cell 2019) and Smillie et al. (Cell 2019) have provided insights into the disease mechanism, yet their limited statistical power due to small cohort sizes impedes a comprehensive understanding. To overcome these limitations, we propose a large-scale meta-analysis by combining and harmonizing independent IBD scRNAseq and genotype studies.

Material and methods: We developed a standardized pipeline on gut mucosa scRNAseq and genotype data to align quality control, preprocessing, cell type annotation, differential proportion analysis, differential expression, and eQTL mapping.

Results: We harmonized and integrated two Chron's Disease (CD) and two Ulcerative Colitis (UC) scRNAseq datasets. We obtained extensive datasets comprising over 485,000 cells from 150+ individuals for CD and over 290,000 cells from 30+ individuals for UC. Moreover, we performed cell abundance

analysis of inflamed vs non-inflamed samples in both UC and CD datasets. The analysis shows a concordant behavior between UC and CD upon inflammation in 67% of cell types, while some disconcordant cells include CD8 T cells, immature enterocytes, and glial cells.

Conclusion: We created a standardized pipeline for harmonizing scRNAseq and genotype data applied to four IBD datasets. Our preliminary analysis shows the presence of some relevant differences among the diseases. Further investigation will deepen our understanding of IBD pathomechanisms, aiming to improve therapeutic strategies for patients.

Background: Focal segmental glomerularsclerosis (FSGS) is a clinically and genetically heterogeneous glomerular disease that manifests itself by proteinuria. About 15% of FSGS patients progress to renal failure. A portion of the FSGS cases is of a monogenic etiology. The prevalence of adult-onset genetic FSGS is considered underestimated and its clinical, genetic and histological features have not been clearly described.

Material and methods: Multicentric study, cohort: FSGS adult patients steroids resistant, kidney biopsy confirmed.

Methods: whole exome sequencing, whole genome sequencing, bioinformatics, clinical data analysis, re-analysis of kidney biopsies Columbia classification.

Results: The analysis of 225 families cohort yielded 16% (n = 35) index patients with genetic FSGS, out of these, 50% probands carried causal variant in Alport syndrome phenocopy genes *COL4A3,4,5* and 50% in various podocyte-specific genes. We divided the patients according to genotype into 3 groups: with podocyte variants (P), Alport variants (A) and without genetic variant (N) and correlated them with the clinical and histologic phenotype. We established statistically significant differences among the groups in manifestation age (P 23y/A 37y/N 39y), edemas presence (P 18%/A 0%/N 60%) and frequency of kidney failure (P 45%/A 29,4%/N 15%). Kidney biopsies re-analysis using Columbia Classification showed the majority of NOS lesions and highest fibrosis level (42,9% level 2) in P group. Tip lesion prevailed in N group (61,1%).

Conclusion: This is the first large-scale adult-onset genetic FSGS study in Czech population. It brings new insights into genetic and clinical features of the FSGS in adults and the results will improve personalized medical care.

P05.010.C Epidemiology of monogenic diabetes in the Czech Republic

Michaela Cermakova[1], *Petra Dusatkova*[1], *Marketa Pavlikova*[2], *Klara Vesela*[1], *Katerina Kolarova*[1], *Zdenek Sumnik*[1], *Jan Lebl*[1], *Stepanka Pruhova*[1]

[1]*Department of Paediatrics, Second Faculty of Medicine and Motol University Hospital, Charles University, Prague, Czech Republic,* [2]*Department of Probability and Mathematical Statistics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic.*

Background: Monogenic diabetes results from a single-gene defect affecting pancreatic beta cells. Accurate diagnosis enables personalized treatment. While precise European prevalence data are lacking, the U.K., a global leader in monogenic diabetes research, reports an estimated prevalence of 24.8/100,000 and an observed prevalence of 5.8/100,000. This study assessed diagnostic trends and determined the minimum prevalence of monogenic diabetes in the Czech Republic.

Material and methods: Clinical and genetic data were collected from individuals suspected of having monogenic diabetes referred for genetic testing and registered in the National Registry for Monogenic Diabetes between 1999 and 2023. Covariates were analysed using the t-test, and categorical variables with $\chi 2$.

Results: By 2023, we registered 1,879 families (i.e., probands) with suspected monogenic diabetes, and 728 (39 %) received a confirmed diagnoses (1,473 individuals from the Registry in total). The causative variant was identified in 13 different genes, most commonly in *GCK* (69 %), *HNF1A* (15 %), and *HNF4A* (8 %). The minimum prevalence of monogenic diabetes was 13.6/100,000. The number of referred probands increased from 42 between 1999–2001 to 142 in 2023. The detection rate has stabilized since

2011 at 30–40 %. The average age of diabetes diagnosis was 15.5 (± 9.4) years, with 76 % of probands having a family history of diabetes.

Conclusion: We reported an increasing referral rate and stable detection rate of monogenic diabetes in the Czech Republic. However, considering the U.K. prevalence estimates, about half of the Czech patients with monogenic diabetes remain un- or misdiagnosed.

P05.011.D The role of the ciliary TRIM8 protein in focal segmental glomerulosclerosis and neurodevelopmental syndrome

Giorgia Gemma[1,2], *Eleonora Di Venere*[1], *Gabriella M. Squeo*[2], *Flora Cozzolino*[3], *Paolo Salerno*[1], *Valentina Tretola*[1], *Utsa Bhaduri*[1], *Leopoldo Staiano*[4], *Maria Monti*[3], *Giuseppe Merla*[1,2]

[1]*Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples, Italy,* [2]*Laboratory of Regulatory and Functional Genomics, Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy,* [3]*CEINGE Advanced Biotechnologies s.c.a.r.l. Franco Salvatore, Naples, Italy,* [4]*Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli, Italy.*

Background: TRIM8 is an E3 ubiquitin ligase involved in cell cycle progression, that interacts with master regulators of mitotic spindle assembly. Our recent transcriptomics and proteomics studies demonstrated that TRIM8 localizes at centrioles and regulates centrosomal protein CEP170. Also, it is a novel ciliary protein located at the basal body, and TRIM8 depletion causes a significant reduction in primary cilia number and length. Notably, heterozygous dominant variants on *TRIM8* cause a neuro-renal syndrome (FSGSNEDS), characterized by developmental delay and podocytopathy.

Material and methods: We engineered human podocytes using CRISPR/Cas9 mimicking patients' variants, and then fully characterized them morphologically and functionally, studying cellular permeability, endocytosis, viability and apoptosis. Then, we performed RNASeq to highlight deregulated genes and pathways associated with TRIM8 variants.

Results: Heterozygous TRIM8 podocytes displayed lower viability and increased apoptosis compared to their isogenic controls. Also, they showed altered cytoskeletal network, increased prolapse between cell-cell junctions with higher endosomal escape. Interestingly, our transcriptomics analysis confirmed among the most deregulated pathways those involved in cell adhesion, with a significant down-regulation of several cadherins, along with catenin complex, inflammation and synaptic organization.

Conclusion: Although preliminary, our data present a new role for TRIM8 in cell adhesion and cytoskeletal integrity, that we are deepening to understand FSGSNEDS patients' podocytes dysfunction. To this aim, we are generating patients' hiPSCs-derived kidney organoids to analyze them by scRNAseq and proteomics.

P05.012.A Pathogenic mechanisms in Hirschsprung's Disease: insights from transcriptomic analysis

Cristina Tous[1,2], *Mª Jose Moya*[3], *Juan Antiñolo*[1], *Rocio Granero*[3], *Guillermo Antiñolo*[1,2], *Salud Borrego*[1,2]

[1]*Department of Maternofetal Medicine, Genetics and Reproduction, Institute of Biomedicine of Seville, University Hospital Virgen del Rocío/CSIC/University of Seville, Sevilla, Spain,* [2]*Center for Biomedical Network Research on Rare Diseases (CIBERER), Sevilla, Spain,* [3]*Department of Pediatric Surgery, University Hospital Virgen del Rocío, Sevilla, Spain.*

Background: Hirschsprung's disease (HSCR) is a congenital disorder arising from an impaired migration and differentiation of neural crest cells (NCCs), resulting in the absence of enteric neurons in the distal colon. While mutations in the *RET* proto-oncogene are recognised as contributing factors, the potential role of extracellular matrix (ECM) remodeling and transcriptional regulation remain poorly understood.

Material and methods: Intestinal tissues from ganglionic (HG) and aganglionic (HA) regions were collected from 13 male patients with short-segment HSCR (S-HSCR). RNA sequencing identified differentially expressed genes (DEGs) (fold-change >1.5, FDR <0.05), and pathway enrichment analysis was performed to explore molecular mechanisms underlying HSCR pathogenesis.

Results: Results suggest disruptions in ECM components (*FERMT1, MMP2*, and *ITGA6)*, which may impair NCC adhesion and migration, thus contributing to the absence of enteric neurons in the distal colon. In addition, downregulation of the transcription factors *SOX9* and *HOXB5*, key regulators of RET signalling and NCC differentiation, was also observed. Furthermore, the study identified deficiencies in *FGFR4* expression and MAPK/ERK signaling, which may further impair pathways critical for the development of the enteric nervous system (ENS). The analysis also revealed alterations in Wnt signaling, axon guidance, and inflammatory responses, highlighting their roles in HSCR.

Conclusion: This study proposes that ECM remodeling, transcriptional dysregulation, and signaling pathway impairments collectively contribute to HSCR. These findings reveal therapeutic targets, such as restoring ECM integrity or enhancing RET signaling. While further validation is required, this work provides a suitable framework to explore novel interventions and advancing our understanding of HSCR pathophysiology

P05.013.B Reverse phenotyping and genetic stratification in Cystic Kidney Disease: new perspectives for diagnosis and personalised therapy

Giulia Nutile[1], *Michela Murgia, MSc*[1], *Celeste Sanna*[1], *Federico Marongiu*[1], *Laura Serventi*[1], *Federica Cannas*[1,2], *Stefano Mocci*[1,2], *Caterina Mereu*[1], *Michela Lorrai*[1], *Chiara Cocco*[1], *Gaia M. Tosone*[1], *Alessia Mascia, PhD student*[1,3], *Sara Lai*[4], *Erika Giuressi*[4], *Andrea Perra*[3], *Roberto Littera*[4], *Sabrina Giglio*[5,2,4]

[1]*Medical Genetics, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy,* [2]*Centre for Research University Services (CeSAR, Centro Servizi di Ateneo per la Ricerca), University of Cagliari, Monserrato, Cagliari, Italy,* [3]*Unit of Oncology and Molecular Pathology, Department of Biomedical Sciences, University of Cagliari, Cagliari, Italy,* [4]*Medical Genetics, R. Binaghi Hospital, Local Public Health and Social Care Unit (ASSL) of Cagliari, Cagliari, Italy,* [5]*Director of Medical Genetics Unit, University of Cagliari, Department of Medical Sciences and Public Health, Cagliari, Italy.*

Background: Cystic kidney disease (CKD) comprises a heterogeneous group of disorders characterised by the formation of renal cysts and progressive deterioration of kidney function. While variants in tubular genes such as *PKD1* and *PKD2* are well

established in autosomal dominant and recessive polycystic kidney disease (ADPKD and ARPKD), emerging evidence suggests that additional genes involved in renal morphogenesis may contribute to disease pathogenesis. This study investigates the role of reverse phenotyping in the genetic stratification of CKD patients, emphasising how genotypic characterisation can refine differential diagnosis, prognosis, and therapeutic decision-making.

Methods and results: Variants in *PKD1* were identified in 59.3% of cases (seven males and nine females). Additionally, pathogenetic variants were detected in collagen type IV genes (*COL4A3*, *COL4A4*, *COL4A5*) in 18.5% of cases, *ALG8* in 7.4%, and *HNF1B* in 3.7%. One female harboured two biallelic variants in *PKHD1*. Among individuals with *PKD1* mutations, variants were also found in *CFHR3* and *GANAB* genes. In three cases, no mutations were identified despite a clear polycystic phenotype.

Conclusion: Reverse phenotyping mitigates the limitations of phenotype-based diagnosis alone in CKD, facilitating improved prognostic stratification and personalised treatment approaches. The identification of novel genes implicated in CKD pathogenesis may pave the way for targeted therapies and optimised clinical management of affected individuals.

P05.014.C Comprehensive diagnostic approach to identifying pathogenic variants in *SLC34A1* and *SLC34A3* genes in patients with suspected NPT2 damage

Margarita Sharova[1], *Svetlana Papizh*[2], *Anatoly Tulpakov*[1], *Olga Levchenko*[3], *Alexandra Filatova*[3], *Mikhail Skoblov, Head of the Department*[3]

[1]*Federal State Budgetary Scientific Institution "Research Centre for Medical Genetics", Moscow, Russian Federation,* [2]*Veltishev Research and Clinical Institute for Pediatrics and Children Surgery of Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [3]*Research Centre for Medical Genetics, Moscow, Russian Federation.*

Background: Phosphate metabolism is primarily regulated by phosphate reabsorption via NPT2a (*SLC34A1*) and NPT2c (*SLC34A3*) transporters. Pathogenic variants in these genes are associated with recessive hypercalcemia, infantile 2 (IHC2), dominant nephrolithiasis/osteoporosis, type 1 (NOH1), and hereditary hypophosphatemic rickets with hypercalciuria (HHRH). The existence of a dominant phenotype for *SLC34A3* currently remains under question.

Material and methods: 55 unrelated patients with suspected NPT2 damage underwent molecular genetic testing (WGS or WES). NGS data for 36 patients were reanalyzed, followed by functional analysis or WGS.

Results: Initial NGS analysis identified biallelic variants in 29% (7/24) of IHC2 patients and 35% (11/31) of HHRH patients. Further reanalysis, functional studies, allelic imbalance investigation, or WGS were performed for undiagnosed cases. Reanalysis detected a second variant in 7 IHC2 and 5 HHRH patients, including a recurrent pathogenic *SLC34A1* variant initially filtered due to high frequency and a synonymous *SLC34A1* variant in 3 patients, prompting a minigene assay. In HHRH, a complex allele and a synonymous *SLC34A3* variant were identified, with RNA analysis on fibroblasts clarifying pathogenicity. WGS was performed for 9 IHC2 and 15 HHRH patients, revealing 6 monoallelic *SLC34A1* cases reclassified as dominant phenotype NOH1. In 5 patients, we found missed intronic variant in *SLC34A3* confirming HHRH, 10 remained monoallelic, requiring further investigation.

Conclusion: A comprehensive diagnostic strategy with NGS data reanalysis and functional studies is crucial for accurate clinical diagnosis and can substantially enhance genetic diagnostic outcomes.

P05.015.D Activation of hypoxia signalling favours somatic mutation in normal kidney cells

Jean Piero Margaria[1], *Giovanni Battista Pipitone*[2], *Alessandro Larcher*[3], *Sipontina Faienza*[1], *Isaline Rowe*[3], *Francesca Corea*[3,2], *Gianfranco Distefano*[4], *Umberto Capitanio*[3], *Paola Carrera*[2], *Andrea Salonia*[3], *Alessandra Boletta*[4], *Irene Franco*[1]

[1]*Somatic Mutation Mechanisms Unit, Division of Genetics and Cell Biology, IRCCS Ospedale San Raffaele/ Università Vita-Salute San Raffaele, Milan, Italy,* [2]*Unit of Genomics for human disease diagnosis and Lab. of Clinical Molecular Biology, IRCCS O San Raf, Milano, Italy,* [3]*Urological Research Institute (URI), IRCCS Ospedale San Raffaele, Milan, Italy,* [4]*Cystic Kidney Disorders Unit, Division of Genetics and Cell Biology, IRCCS Ospedale San Raffaele, Milan, Italy.*

Background: Somatic genetic alterations are progressively engraved in normal tissues with age and known to drive cancer initiation, but the molecular mechanisms determining somatic mutation accumulation are not fully elucidated. In the kidneys, 90% of clear cell renal cell carcinomas (ccRCCs) harbour mutations that inactivate the negative regulator of adaptation to low oxygen (hypoxia), i.e. the product of the *Von Hippel Lindau (VHL)* gene.

Material and methods: To assess a possible causal relationship between hypoxia signalling activation and mutation accumulation, we investigated normal kidney cells from VHL-disease patients (*VHL+/−) and* controls *(VHL+/+)*. The pattern of somatic mutations acquired in vivo was analysed by WGS of clonally amplified cells, while the in vitro pattern upon hypoxia exposure was analysed by duplex sequencing.

Results: We found in vivo accumulation of COSMIC signatures SBS1, SBS5 and SBS8 in all kidney cells. However, a subset of *VHL +/−* cells also bore the marks of SBS40b, a signature specifically found in ccRCC. These normal kidney cells showed molecular features of adaptation to hypoxia, including nuclear translocation of the HIF (Hypoxia Inducible Factor) 1 alpha transcription factor, usually repressed by VHL, and upregulation of HIF target genes. Similarly, we discovered that when *VHL+/+* normal kidney cells were subjected to in vitro hypoxia, HIF1A underwent nuclear translocation and the SBS40b signature accumulated.

Conclusion: Through the analysis of somatic mutations acquired in vivo and in vitro, we provide evidence that accumulation of the ccRCC-specific, mutational signature SBS40b can be triggered by activation of hypoxia signalling in normal kidney cells.

P05.017.B Biallelic canonical splice site variant in *FMNL2* underlies an autosomal recessive form of renal tubulopathy

Prince Jacob[1], *Deepha Sekar*[2], *Shilpa Rao*[2], *Rashmi Santoshkumar*[2], *Bevinahalli Nanjegowda Nandeesh*[2], *Siddarmappa J. Patil*[3], *Madhu Nagappa*[4], *Periyasamy Govindaraj*[2]

[1]*Department of Medical Genetics, JSS Medical College, JSS Academy of Higher Education and Research, Mysuru, India,* [2]*Department of Neuropathology, National Institute of Mental Health and Neurosciences (NIMHANS), Bengaluru, India,* [3]*Division of Medical Genetics, Mazumdar Shaw Medical Centre, Narayana Hrudayalaya Hospitals, Bengaluru, India,* [4]*Department of Neurology, National Institute of Mental Health and Neurosciences (NIMHANS), Bengaluru, India.*

Background: Renal tubulopathies (RTs) are a rare and heterogeneous group of genetic diseases that often result in electrolyte imbalances, metabolic acidosis, and impaired growth. Despite significant advances in molecular diagnosis, many RTs remain genetically undiagnosed. *FMNL2* gene encoding Formin-like 2 protein is known to be highly expressed in kidney tissues and is associated with mitochondrial proteins. However, its role in renal and mitochondrial pathology remains largely unexplored.

Material and methods: A 3-year-old male with renal tubular acidosis (RTA) and developmental delay was evaluated clinically and genetically (Exome sequencing). Minigene assay was performed in patient-derived fibroblasts whereas mitochondrial respiratory chain complex assay (RCC) and TEM were performed on muscle tissue to evaluate the effect of disease-causing variation in mitochondrial function and structure.

Results: The proband presented with polyuria, polydipsia, failure to thrive, and facial dysmorphism since the age of 1 year. He had elevated serum lactate levels (3.8 mmol/L), and the biochemical profile suggested distal RTA. Exome sequencing analysis revealed a canonical splice-site variant in *FMNL2*:c.783-1G>A (NM_052905.4) in homozygous state. The splice variant resulted in the deletion of exon 9, producing an aberrant transcript and likely leading to a truncated protein. RCC assay showed normal enzyme activity for C-I to C-IV, whereas ultrastructural analysis revealed abnormal mitochondria with loss of cristae.

Conclusion: Our study provides the first evidence of *FMNL2* as a novel candidate gene for renal tubulopathy and highlights its putative role in mitochondrial structure. Further, functional analysis is needed to decipher the pathological mechanism of *FMNL2*-related renal tubulopathy.

P05.018.C Re-analysis of NGS data for Copy Number Variations (CNVs) detection greatly increases the diagnostic yield in patients with growth disorders

Giulia Borgonovi[1], *Simona Mellone*[1,2], *Denise Vurchio*[1,2], *Giulia Paglino*[1,2], *Alessandro Ugonotti*[1], *Tatiana Scagliotti*[1], *Sara Ronzani*[2], *Maurizio Sciancalepore*[2], *Caterina Lonati*[2], *Mara Gagliardi*[1], *Ivana Rabbone*[1,3], *Simona Bellone*[3], *Flavia Prodam*[1,4], *Alice Spano*[2], *Umberto Dianzani*[1,2], *Mara Giordano*[1,2]

[1]*University of Eastern Piedmont, Department of Health Sciences, Novara, Italy,* [2]*Genetics Laboratory, SCDU Clinical Biochemistry, AOU Maggiore della Carità Hospital, Novara, Italy,* [3]*SCDU Pediatrics, AOU Maggiore della Carità Hospital, Novara, Italy,* [4]*SCDU Endocrinology, AOU Maggiore della Carità Hospital, Novara, Italy.*

Background: Growth defects frequently originate from genetic factors, involving variations in genes that influence GH secretion, skeletal development, or cellular metabolism.

Materials and methods: Using a 107-gene NGS panel targeting growth disorder-related genes, we analyzed a cohort of 362 patients (212 males and 150 females) with idiopathic and syndromic short stature. To improve the diagnostic yield, we retrospectively reanalyzed NGS FASTQ data from a subset of 65 patients, tested negative for point mutations, using enGenome eVai software (v3.5) to detect copy number variations (CNVs).

Results: Pathogenic/Likely Pathogenic (P/LP) variants were identified in 61 patients (16.8%), with *ACAN, COMP, FGFR1, FGFR2, FGFR3, GNAS, GNRHR, LZTR1, NF1, NPR2, PTPN11, SLC26A2* and SOS1 being the most frequently mutated genes. The detection rate was similar in males and females (16.5% and 17.3%, respectively). Additionally, we identified 221 Variants of Uncertain Significance (VUS) in 81 genes, whose roles require further investigation. The CNV bioinformatics analysis identified clinically relevant alterations in 9 patients, suggesting that the diagnostic rate could be increased by 13.8%. Specifically, four patients carried whole-gene deletions (*GH, NF1, GLI2, LHX3*), while three had intragenic deletions: one affecting 9 exons of *GLI3*, another 7 exons of *PHIP* and the last 1 exon of *KRAS*. Two patients exhibited intragenic duplications: one involving 2 exons of *ANOS1* and the other 7 exons of *FGFR3*. These CNVs were confirmed by MLPA.

Conclusion: These findings emphasize the added value of CNV detection in the molecular screening of growth disorders, uncovering additional pathogenic variants that are undetectable by standard variant calling.

P05.019.D A Sibling case *with AGR2* variant causing severe respiratory and digestive symptoms

Noriko Miyake[1], *Sanami Takada*[1], *Silvanna Gallo*[2], *Sebastian Silva*[2], *Hiroki Tanaka*[1], *Oscar Pincheira*[2], *Juan Zúñiga*[2], *Marcela Villarroel*[3], *Ximena Hidalgo*[2], *Joel Melo-Tanner*[4], *Hidefumi Suzuki*[5], *Shinichi Machida*[1], *Hidehisa Takahashi*[5]

[1]*National Center for Global Health and Medicine, Tokyo, Japan,* [2]*Hospital de Puerto Montt, Puerto Montt, Chile,* [3]*Hospital de Puerto Montt, Puerto Montt, Chile,* [4]*Instituto Nacional del Tórax, Santiago, Chile,* [5]*Yokohama City University Graduate School of Medical Science, Yokohama, Japan.*

Background: Anterior gradient 2 (AGR2) is a protein disulfide isomerase that is important for protein processing in the endoplasmic reticulum and is essential for mucin production in the digestive and respiratory tracts. Bi-allelic *AGR2* variants are known to cause recurrent respiratory infections and failure to thrive with or without diarrhea (RIFTD; MIM # 620233), although the mechanisms behind this condition remain unclear. To date, at least six pathogenic *AGR2* variants have been reported.

Material and methods: We analyzed two affected siblings in a consanguineous family who had recurrent respiratory infections and digestive symptoms, one of whom needed lung transplantation. We performed exome to identify the genetic cause of their symptoms and functional studies to investigate the effect of this variant.

Result: We identified a novel homozygous missense variant in *AGR2* (NM_006408.4, c.250A>C, p.(Ser84Arg)) in both affected siblings. Both parents had the identical variant in a heterozygous state. This variant is quite rare in the general population and is clinically compatible with RIFTD, substituting a highly conserved CXXS motif with CXXR. Through transient overexpression, Ser84Arg AGR2 decreased protein stability, and promoted aberrant dimerization under non-reducing conditions. AGR2 functions in a monomer-dimer equilibrium. Size-exclusion chromatography showed that the Ser84Arg mutant had a larger molecular size than the wild-type protein under non-reducing, but not reducing conditions, indicating that Ser84Arg enhanced intermolecular disulfide bonds.

Conclusion: We identified a novel pathogenic *AGR2* variant and indicated its abnormal monomer-dimer equilibrium as a possible mechanism involved in the pathogenesis of RIFTD.

P05.020.A Whole-exome sequencing in kidney transplant patients: implications for chronic kidneydiseaseandprecision medicine in transplantation

Dias Malik[1], *Mirgul Bayanova*[1], *Aida Zhenissova*[1], *Aizhan Abdikadirova*[1], *Malika Sapargalieyva*[1], *Lyazzat Nazarova*[1], *Sholpan Altynova*[1], *Aidos Bolatov*[1,2], *Yuriy Pya*[1]

[1]*"University Medical Center" Corporate Fund, Astana, Kazakhstan,* [2]*Shenzhen University, Shenzhen, China.*

Background: Chronic kidney disease (CKD) is influenced by genetic factors that affect disease progression and transplant outcomes. This study investigates genetic variants associated with CKD in kidney transplant recipients and donors using whole-exome sequencing (WES).

Material and methods: Kidney transplant donors and recipients were recruited between 2023 and 2024 from the "University Medical Center" CF and National Center for Oncology and Transplantology (Astana, Kazakhstan). The study included 14 pediatric recipients, 55 adult recipients, and 67 kidney transplant donors, all of whom underwent WES on Illumina NovaSeq 6000.

Results: Genetic variants associated with CKD were identified in 16 adult recipients (29%), including MUC1 (4 cases, with insertions and deletions in non-canonical transcripts), COL4A3 (3 cases), and rare variants in UMOD, TBC1D8B, PAX2, ANLN, PIGA, ROBO2, NOTCH2, and ACTN4. One individual had compound heterozygous variants in LAMA5. Among pediatric recipients, 4 (29%) had significant variants in SLC3A1, MUC1, COL4A3, and GREB1L. In the donor cohort, pathogenic and likely pathogenic variants associated with autosomal dominant kidney diseases were identified in 10 donors (15%), affecting genes such as COL4A3 (2 cases), UMOD (2 cases), HNF4A, WT1, CFHR5, SEC63, COL4A5, and SLC3A1. The high frequency of the APOE:c.388T>C variant, associated with lipoprotein glomerulopathy, observed among both recipients and donors (20%), necessitates further clinical evaluation.

Conclusion: WES is a valuable tool for identifying genetic causes of CKD, providing insights for family counseling and assessing risks of kidney disease development in recipients and donors, thus underscoring the importance of genetic screening in transplant medicine.

P05.021.B Phenotype-genotype comparison of three Czech families with Heřmanský-Pudlák syndrome

Jakub Trizuljak[1,2,3], *Zuzana Vrzalová*[1,3], *Ivona Blaháková*[1,3], *Paulína Likavcová*[2], *Kateřina Staňo Kozubík*[2,3], *Jiří Štika*[3], *Martina Doubková*[4], *Šárka Pospíšilová*[1,2,3], *Michael Doubek*[1,2,3]

[1]*Department of Internal Medicine - Hematology and Oncology, Faculty of Medicine, Masaryk University and University Hospital Brno, Czech Republic, Brno, Czech Republic,* [2]*Department of Medical Genetics and Genomics, Faculty of Medicine, Masaryk University and University Hospital Brno, Brno, Czech Republic, Brno, Czech Republic,* [3]*Central European Institute for Technology, Masaryk University, Brno, Czech Republic, Brno, Czech Republic,* [4]*Department of Pulmonary Diseases and Tuberculosis, Masaryk University Faculty of Medicine and University Hospital, Brno, Czech Republic, Brno, Czech Republic.*

Background: Heřmanský-Pudlák syndrome (HPS) is an autosomal recessive disorder associated with oculocutaneous albinism, bleeding diathesis, granulomatous colitis, and highly penetrant pulmonary fibrosis in some subtypes. Homozygous or compound heterozygous pathological variants in AP3B1, AP3D1, BLOC1S3, BLOC1S5, BLOC1S6, DTNBP1, HPS1, HPS3, HPS4, HPS5, and HPS6 genes lead to clinical manifestation of the disease. We present a phenotypic series of four patients from three distinct families in the Czech Republic.

Material and methods: We performed whole exome sequencing (WES) in affected patients. The detected variants were confirmed by Sanger sequencing.

Results: We detected causal pathogenic variants in all three families. The proband in family one carried compound heterozygous *HPS1* variants p.(Gln503*); p.(Gln397Serfs*2); two sisters in the second family carried homozygous p.(Gln397Serfs*2) *HPS1* variant, while the proband from the third family carried homozygous p.(Arg217*) *HPS4* variant. All four patients were affected by oculocutaneous albinism and functional platelet defect. At the time of investigation, 3 out of 4 patients (75%) developed pulmonary fibrosis, with the median of onset being 50 years. None of the patients developed cytopenias, granulomatous colitis, chronic kidney failure or cardiomyopathy.

Conclusion: We present the largest phenotypic series of patients with Heřmanský-Pudlák syndrome from the Czech Republic. Early detection of HPS is essential for correct management of pulmonary fibrosis.

P05.022.C Gitelman and Bartter syndromes: insights from a longitudinal cohort study on salt-wasting tubulopathies

María García-Murias[1], *Laura Núñez González*[2], *Adela Urisarri Ruiz de Cortázar*[3], *Marta Gil Calvo*[3], *Ana Barcia de la Iglesia*[2], *Raquel Martínez Pulleiro*[2], *Eloísa Sánchez Cazorla*[4], *Cándido Díaz Rodríguez*[3], *Noa Carrera Cachaza, PhD*[4], *Miguel García Gonzalez*[1]

[1]*Health Research Institute of Santiago de Compostela- Genetics and Developmental Biology of Kidney Diseases, Santiago de Compostela, Spain,* [2]*Research Institute of Santiago de Compostela- Genetics and Developmental Biology of Kidney Diseases, Santiago de Compostela, Spain,* [3]*Clinical Hospital of Santiago de Compostela, Santiago de Compostela, Spain,* [4]*Health Research institute of Santiago de Compostela- Genetics and Developmental Biology of Kidney Diseases, Santiago de Compostela, Spain.*

Background: Inherited kidney tubulopathies are genetic disorders affecting tubular transporter proteins, disrupting homeostasis and

causing renal and extrarenal symptoms.Gitelman syndrome (GS) and Bartter syndrome (BS) are monogenic diseases with overlapping clinical features, including hypokalemia, hypochloremic metabolic alkalosis, hyperreninism, and secondary hyperaldosteronism due to renin-angiotensin-aldosterone system activation. Given their clinical similarities, genetic studies are essential for differential diagnosis.Despite their significance, GS and BS remain poorly understood, with limited population studies on prognosis and patient follow-up.

Methods: The cohort of patients with suspected GS and BS diagnoses underwent analysis using NGS techniques. Integrated DNA Technologies (IDT, Illumina®) platforms were employed until a definitive diagnosis was reached, confirming identified variants via Sanger sequencing. Clinical assessment of this cohort occurred at the time of diagnosis, and ongoing follow-up evaluations are being conducted to monitor disease progression, particularly focusing on treatment requirements.

Results: Preliminary studies identified 39 individuals diagnosed with GS, 9 diagnosed with BS, and 5 carrying mutations in both disease-related genes. Additionally, some heterozygous GS mutation carriers exhibited clinical symptoms. All individuals underwent genetic analysis. At the time of diagnosis, potassium levels emerged as the most affected clinical parameter, with a median of 3.1 Eq/l.Significant phenotypic variability was observed, ranging from mild to severe cases, suggesting potential differences in clinical outcomes based on treatment regimens.

Conclusion: While GS is often considered asymptomatic and BS more severe, both syndromes are frequently misdiagnosed. This highlights the need for accurate genetic diagnosis, careful prognosis assessment, and continuous patient monitoring to optimize disease management and treatment strategies.

P05.023.D Recurrent genetic variants and molecular diagnostic strategies for hereditary nephropathies in the Moroccan population

Nada BENYAHYA[1], *Ourayna BATTA*[1], *Jaber Lyahyai*[1], *Kenza Soulami*[2], *Imane CHERKAOUI*[3], *Abdelaziz SEFIANI*[1]

[1]*Faculty of Medicine and Pharmacy, University Mohammed V of Rabat, Rabat, Morocco, RABAT, Morocco,* [2]*Private medical office, Casablanca, Morocco,* [3]*Faculty of Medicine and Pharmacy, Rabat, Morocco, RABAT, Morocco.*

Background: Hereditary nephropathies are a major cause of end-stage renal disease in Morocco, requiring dialysis or transplantation in ~50% of children and >15% of adults. These disorders, inherited in autosomal dominant, recessive, or X-linked patterns, present diagnostic and management challenges. Recurrent mutations play a crucial role in disease understanding and are particularly prevalent in populations with high consanguinity, such as Morocco.

Material and methods: A strategic diagnostic approach was developed, prioritizing recurrent mutation screening through targeted Sanger sequencing or multiplex PCR before utilizing nephropathy-specific gene panels via Next-Generation Sequencing (NGS).

Results: Based on the experience of the Department of Medical Genetics at the National Institute of Hygiene, in collaboration with nephrologists and pediatric nephrologists from different regions of the Kingdom, a diagnostic strategy was established for key nephropathies:

- **Primary Hyperoxaluria Type 1:** *AGXT* c.731T>C (p.Ile244Thr)
- **Infantile Cystinosis:** *CTNS* c.922G>A (p.Gly308Arg)
- **Distal Renal Tubular Acidosis Type 1b:** *ATP6V1B1* c.1155dupC
- **Hereditary Nephropathies:** *TTC21B* c.626C>T
- **Nephronophthisis:** Large deletions in *NPHP1*

Conclusion: Identifying recurrent variants is essential for improving diagnosis, personalizing care, and advancing research. Artificial intelligence (AI) integration in molecular diagnostics offers a promising approach to analyzing large genomic datasets for mutation detection. Developing innovative strategies and incorporating new technologies will help overcome challenges posed by these complex diseases

P05.024.A Genomic and metabolomic signatures of metabolic dysfunction-associated steatotic liver disease (MASLD) subjects

Benedetta M. Motta[1], *Martina Lombardi*[2], *Mariano Festa*[1], *Tommaso Sarcina*[1], *Jacopo Troisi*[2], *Marcello Persico*[1]

[1]*University of Salerno, Salerno, Italy,* [2]*Theoreo Srl Spin Off Company, Pontecagnano Faiano (SA), Italy.*

Background: Metabolic dysfunction-associated steatotic liver disease(MASLD, formerly known as NAFLD) is the leading cause of liver diseases, ranging from simple steatosis to steatohepatitis. Environmental and genetic factors influence the susceptibility to MASLD. Several non-invasive methods aim at diagnosing and predicting significant/advanced fibrosis, including untargeted metabolomics and genomics approaches. NAFLD-susceptibility is highly associated with four genetic variants:rs738409, rs58542926, rs641738, rs1260326. We aimed to identify metabolomics signatures according to the severity of the disease combining metabolomics and genetics analyses data.

Material and methods: 106 MASLD patients attending our Hepatology Unit department were genotyped by TaqMan5′-nuclease assays. We categorized patients in High-Risk and Low-Risk groups by a weighted polygenic risk score. As well, we divided patients into three severity levels to evaluate liver disease progression. Untargeted metabolomics analysis was performed through Gas Chromatography-Mass Spectrometry (Shimadzu2010SE), after metabolome extraction, purification and derivatization using MetaboPrep GC-kit.

Results: For disease severity analysis, Partial Least Squares Discriminant Analysis (PLS-DA) demonstrated progressive separation, with key metabolites including urea, lactic, pyroglutamic, hydroxydecanoic, 2-hydroxyisocaproic, and acetoacetic acids. Pathway analysis highlighted alterations in starch, sucrose, galactose, and amino sugar metabolism. PLS-DA model focused on genetic risk, revealed significant separation between High- and Low-Risk groups. Key metabolites include palmitic, mandelic, pyroglutamic, lactic, and ribonic acids. Altered pathways involved phenylalanine, tyrosine, tryptophan biosynthesis, as well as valine, leucine, isoleucine metabolism.

Conclusion: Untargeted metabolomic analysis demonstrated that patients exhibit progressive metabolic alterations according to the severity of the disease. Notably, a marked separation emerged between high- and low-genetic-risk groups, indicating potential for early diagnostics and stratified patient management.

P05.025.B Genetic predisposition, dietary risk factors and intestinal microbiota in obese individuals with colorectal tumors

*Marta La Vecchia[1], **Gloria Sala**[1], Marta Potenza[1], Marika Sculco[1], Denise Marradi[2,3], Marta Mellai[1,3], Nico Pagano[4], Renzo Boldorini[1], Barbara Azzimonti[1,3], Elisa Bona[3,5,6], Flavia Prodam[1,7], Daniela Ferrante[2], Emilia Ghelardi[8], Marcello Manfredi[2,3], Anna Aspesi[1], Irma Dianzani[1]*

[1]Department of Health Sciences, University of Eastern Piedmont, Novara, Italy, [2]Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy, [3]Center for Translational Research on Autoimmune and Allergic Diseases, Univeristy of Eastern Piedmont, Novara, Italy, [4]Department of Gastroenterology, University Hospital "Maggiore della Carità", Novara, Italy, [5]Department for Sustainable Development and Ecological Transition, University of Eastern Piedmont, Novara, Italy, [6]Simple Departmental Structure Research Laboratories - Integrated Activities Research and Innovation Department, Azienda Ospedaliera SS. Antonio e Biagio e Cesare Arrigo, Alessandria, Italy, [7]SCDU Endocrinology, University Hospital "Maggiore della Carità", Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy, [8]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy.

Background: Genetic predisposition, intestinal dysbiosis, obesity, and an unhealthy diet are well-known risk factors for colorectal cancer (CRC).

Material and methods: To examine the interplay of these cofactors in colon carcinogenesis, we recruited 120 patients with colorectal polyps and collected blood samples for genetic analyses, mucosa-associated microbiota (MAM), lumen-associated microbiota (LAM), mucosa- and lumen-associated metabolome, and lifestyle/dietary habits (using validated EPIC questionnaires). Germline DNA from peripheral blood was analyzed by targeted-NGS using a custom panel of 107 genes involved in inherited cancer syndromes. MAM and LAM were analyzed by 16S rDNA sequencing. Metabolites were analyzed by bidimensional gas chromatography mass spectrometry. Patients were classified according to their body mass index and waist circumference in 75 normal-weight and 45 overweight/obese subjects.

Results: Twenty patients, 13 normal-weight and seven overweight/obese, carried germline pathogenic variants (PVs) in genes involved in colorectal cancer syndromes. No statistically significant difference was observed in genetic predisposition between normal-weight and obese patients. Dietary habits data revealed a statistically significant higher consumption of processed meat in obese patients. Both MAM and LAM 16S rDNA sequencing and mucosal and luminal metabolome analyses revealed different signatures in the two groups. Importantly, we found an enrichment of the pathogenic species *Finegoldia magna* in MAM of obese patients.

Conclusion: These data support the hypothesis that different risk factors may contribute to tumorigenesis in obese and normal-weight patients.

P05.026.C Mitochondrial dysfunction in Alpha-1 antitrypsin deficiency models

***Sara Gil Martin**[1,2], Nerea Matamala[1], Carlos Benítez Buelga[1], Gema Gómez Mariano[1], Sheila Ramos del Saz[1], Marta Fernández Prieto[1], Juliana Manosalva[3], Diego Megías[3], Félix Docando[4], María C. Terrón[4], Javier Alonso García de la Rosa[1,2], Beatriz Martinez-Delgado[1,2]*

[1]Institute of Health Carlos III (ISCIII), Rare Disease Research Institute (IIER), Majadahonda, Spain, [2]Biomedical Research on Rare Diseases Network Centre (CIBERER), Madrid, Spain, [3]Institute of Health Carlos III (ISCIII), Advanced Optical Microscopy Unit (MOA), Majadahonda, Spain, [4]Institute of Health Carlos III (ISCIII), Electron Microscopy Unit, Majadahonda, Spain.

Background: Alpha-1 Antitrypsin Deficiency (AATD) is a rare genetic disorder caused by mutations in the *SERPINA1* gene. The most common pathogenic mutation, known as the Z allele, results in the production of a dysfunctional AAT protein that accumulates as polymers within hepatocytes, leading to both lung and liver damage. The aim of this study is to investigate the metabolic differences induced by the Z allele in both cell models and liver organoids of AATD.

Material and methods: We studied a HepG2 cell line expressing the Z allele of *SERPINA1*, in parallel with a control HepG2 cell line, and hepatic organoids derived from both ZZ AATD patients and control individuals. These models of AATD were used to assess mitochondrial activity and integrity. Mitochondrial markers such as TOM20 antibody and MitoSOX were employed for immunofluorescence assays. Mitochondrial integrity was examined using transmission electron microscopy, and mitochondrial metabolism was evaluated through Seahorse metabolic assays.

Results: Both Z allele-expressing models (hepatic cell lines and organoids) exhibited an increase in mitochondrial mass, with altered mitochondrial activity under basal conditions. HepG2-Z cells and patient-derived organoids showed a significantly lower spare respiratory capacity compared to control HepG2 cells and organoids, which indicates mitochondrial dysfunction. Additionally, electron microscopy revealed irregular cristae and alterations in the mitochondrial lumen of both models.

Conclusion: The Z allele-expressing models show an alteration of the mitochondrial function and structure that could be related to the accumulation of AAT polymers within the cells. These alterations may contribute to the cellular dysfunction characteristic of AATD.

P05.027.D Genotype-phenotype variability in adult cystic kidney diseases: evidence from seven cases

***Ramona G. Babici**[1,2], Cristina Rusu[2,3], Stela Racoviță[4,5], Gianina Dodi[6], Irina L. Mititiuc[7,6], Bogdan D. Agavriloaei[7,6], Adrian C. Covic[7,6]*

[1]Dr. C.I. Parhon University Hospital, Iasi, Romania, [2]University of Medicine and Pharmacy, Grigore T.Popa Iasi, Medical Genetics Department, Iasi, Romania, [3]Department of Medical Genetics, Saint Mary Emergency Children's Hospital, Iasi, Romania, [4]Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova, Republic of, [5]Genetics Laboratory of the Center for Personalized Medicine, Nicolae Testemitanu SUMP, Chisinau,

Moldova, Republic of, [6]University of Medicine and Pharmacy Grigore T. Popa, Iasi, Romania, [7]Nephrology Clinic, Dialysis and Renal Transplant Center, Dr. C.I. Parhon University Hospital, Iasi, Romania.

Background: Cystic kidney diseases represent a group of disorders with overlapping phenotypes. While many are linked to primary cilium dysfunction (ciliopathies), others involve distinct non-ciliary mechanisms. This study examines seven clinical cases, focusing on genotype-phenotype correlations to guide personalized management approaches.

Material and methods: Seven cases from the Rare Renal Diseases Center in Iași, Romania, were analyzed using NGS (gene panels, whole-exome sequencing, or single-gene testing). The aim was to correlate genetic findings with clinical phenotypes and demonstrate how molecular analysis improves patient care.

Results: Pathogenic mutations were identified in four patients:

- *PKD1* associated ADPKD in a patient with bilateral polycystic kidney but no family history.
- *VHL*-related Von Hippel-Lindau disease with an increased risk of clear-cell carcinoma.
- Contiguous gene deletion syndrome involving *TSC2* and exons 31–46 of *PKD1* in a 50-year-old patient.
- X-linked Alport syndrome without hearing loss caused by a *COL4A5* mutation.

Key measures included: initiating Tolvaptan treatment for ADPKD; assessing the potential use of mTOR inhibitors and vasopressin receptor antagonists for *TSC2-PKD1* syndrome; implementing family screening for early prevention; providing genetic counseling for reproductive decisions. The patient with VHL was informed about a phase 2 clinical trial using Belzutifan.

Three additional cases involved missense variants of uncertain significance (*HNF1B, PKHD1, TTC21B*), highlighting the need for further studies to clarify pathogenicity.

Conclusion: This case series underlines the importance of genetic testing and phenotypic correlation in refining diagnoses, optimizing management, and guiding personalized therapies. These results emphasize the transformative potential of integrating molecular data into clinical practice of Nephrology.

P05.028.A Comprehensive genomic and cytogenomic analysis reveals *C4B* deletion and mutation in wild-type *C4A* pediatric lupus nephritis: a case report of two siblings

Edoardo Spagnolo[1,2], *Carmelo M. Romeo*[1,2], *Giulia M. Brach Del Prever*[1,2], *Maria Luca*[1,2], *Davide Caldo*[1,2], *Angelo C. Faini*[1,2], *Fiorenza Mioli*[1,2], *Claudia Saglia*[1,2], *Caterina Scolari*[1,2], *Tullia Carradori*[1,2], *Francesca Arruga*[1,2], *Valeria Bracciamà*[1,2], *Tiziana Vaisitti*[1,2], *Diana Carli*[1,2], *Licia Peruzzi*[3], *Silvia Deaglio*[1,2]

[1]SC Immunogenetica e Biologia dei Trapianti, AOU Città della Salute e della Scienza, Turin, Italy, [2]Dipartimento di scienze mediche, Università di Torino, Turin, Italy, [3]SC Nefrologia Pediatrica, AOU Città della Salute e della Scienza, Turin, Italy.

Background: Systemic lupus erythematosus (SLE) is a chronic, multifactorial disorder with variable clinical manifestations. Among the most common and serious manifestations is lupus nephritis (LN), affecting >50% of patients, with 20% progressing to end-stage renal disease.

Material and methods: We present the case of a sixteen-year-old girl and her younger sister, born to consanguineous parents. The older sister developed early-onset SLE at age 3 with LN, severe persistent hypocomplementemia (C3+C4), thrombotic microangiopathy, nephrotic syndrome relapses, arthralgia, and serositises, reaching ESRD and receiving a kidney transplant by age 13. The younger sister presented milder SLE starting at age 9 with hemolytic anemia, cutaneous and articular symptoms, normal renal function, normal C3, and low C4.

Results: NGS genetic testing revealed three VUS in *C4B* (p.L1120P, p.S1121C, and p.H1125=), previously reported in SLE patients and presumed inherited as a haplotype, in both sisters and their healthy parents. Via SNP-array analysis and qRT-PCR, a heterozygous de novo whole-gene *C4B* deletion was identified in the older sister, while *C4A*-loss-CNVs were excluded.

Conclusion: Deficiencies in early complement components are often present in SLE patients: although the specific association between lower total *C4* CNV, lower *C4A* CNV, lower *C4B* CNV, and SLE is a matter of debate, C4A- and C4B-null phenotypes often result from gene deletions. While the pathogenic role of the three variants is unconfirmed, the co-occurrence of a whole-gene *C4B* deletion and a complex haplotype with three VUS on the second allele appears compatible with the more prominent partial C4 deficit exhibited by the proband.

P05.029.B Assessment of the clinical diagnostic potential of NGS-based panel tests in 100 cases with renal disease pre-diagnoses

Ilknur Suer[1], *Tugba Kalayci*[2], *Ahmet Burak Dirim*[3], *Seda Safak*[3], *Sema Sirma Ekmekci*[4], *Murat Kaya*[2], *Neslihan Abaci*[4], *Kivanc Cefle*[2], *Halil Yazici*[3], *Savas Ozturk*[3], *Alaattin Yildiz*[3], *Sukru Ozturk*[2]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Medical Genetics, Istanbul, Turkey, [3]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Nephrology, Istanbul, Turkey, [4]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey.

Background: This study aimed to determine the contribution of next-generation sequencing-based panel tests to clinical diagnosis by evaluating the genetic data of 100 patients who applied to the Division of Medical Genetics of Istanbul Faculty of Medicine with various renal disease pre-diagnoses between 2019 and 2024.

Material and sethods: DNA samples were extracted from the peripheral blood of patients. NGS analysis of the targeted gene panel was performed using the Nephropathies Solution Kit (Sophia Genetics) on the NovaSeq 6000 sequencing platform (Illumina). The exons and exon-intron boundary regions of 44 genes linked to renal disorders in the panel were sequenced. Segregation analyses were performed by Sanger sequencing. Sophia-DDM software was used to detect disease-related SNPs and CNVs.

Results: In 51% of cases, pathogenic (57.5%), likely pathogenic (6.3%), or variants of unknown clinical significance (VUS, 36.2%) were detected in targeted genes. Variant classification was performed according to the ACMG guidelines.

Conclusion: Many renal diseases exhibit genetic heterogeneity. Unfortunately, our panel test was limited to genes with the most frequently reported pathogenic variants in renal diseases.

According to our data, 49% of the cases were negative. This situation may be caused by a variation in another gene that is associated with the pre-diagnosis but is not included in the panel test. Therefore, we would like to emphasize that choosing a more comprehensive and powerful diagnostic test, such as CES/WES, instead of a panel test with limited gene content in diseases with genetic heterogeneity will significantly contribute to both rapid diagnosis and cost-effectiveness.

P05.030.C Paternal *PEG10* deletion in a familial case of Silver-Russell Syndrome

Alessandro Vimercati[1], *Pierpaola Tannorella*[1], *Luciano Calzari*[2], *Davide Gentilini*[2,3], *Melissa Bellini*[4], *Giuseppa Patti*[5,6], *Mohamad Maghnie*[5,6], *Lidia Larizza*[1], *Silvia Russo*[1]

[1]*Research Laboratory of Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milan, Italy,* [2]*Bioinformatics and Statistical Genomic Unit, IRCCS Istituto Auxologico Italiano, Milan, Italy,* [3]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy,* [4]*Pediatrics and Neonatology Unit, Gugliemo da Saliceto Hospital, Piacenza, Italy,* [5]*Paediatric Endocrinology Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy,* [6]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genoa, Genoa, Italy.*

Background: Silver-Russell syndrome (SRS, MIM#180860) is an imprinting disorder, characterized by prenatal and postnatal growth retardation, relative macrocephaly at birth, prominent forehead, feeding difficulties, and body asymmetry. Clinical diagnosis is based on at least 4 out of 6 clinical signs (Netchine-Harbison clinical scoring system). The main molecular mechanisms are loss of methylation at the paternal *H19/IGF2:IG-DMR* (30–60%) localized in the 11p15 chromosomal region and maternal uniparental disomy of chromosome 7 (5–10%). While it is well known that deregulation of 11p15 imprinted genes (*IGF2*, *H19*, and *CDKN1C*) contribute to the SRS phenotype, those on chromosome 7 (*GRB10*, *PEG10*, and *MEST*) are still in discussion.

Case Reports: We report two brothers clinically diagnosed with SRS (postnatal growth delay, relative macrocephaly at birth, feeding difficulties, and SRS facies). One proband also has myoclonus dystonia and underwent growth hormone treatment.

Results: CGH-array revealed a deletion of 112 Kb including *PEG10* and *SGCE* genes, inherited from their unaffected father. Whole Exome Sequencing did not disclose other causative variants. PEG10 functions as a transcriptional repressor of cyclin-dependent kinase inhibitors, including *CDKN1C*, for which maternal gain-of-function variants are linked to SRS and IMAGe syndrome. Real-time PCR, performed on RNA from blood samples of probands and their healthy relatives, displayed a down-regulation of *PEG10* and an upregulation of *CDKN1C* expression only in the two brothers. Interestingly, *IGF2* was upregulated in the treated proband.

Conclusion: For the first time, we associate deregulation in the *PEG10* gene with the SRS phenotype, mediated by a gain-of-function effect on the *CDKN1C* expression.

P05.031.D Molecular analysis of the *AGXT* gene in Moroccan patients with primary Hyperoxaluria Type 1: a study of 132 Cases

Ourayna Batta[1], *Jaber LYAHYAI*[1], *Yasmina RAHMUNI*[1], *Kenza Soulami*[2], *Najat Oulhiyane*[1], *Ait Ouamar Hassan*[1], *Omar Askander*[3], *Zineb Rchiad*[3], *Abdelaziz Sefiani*[1], *Imane Cherkaoui Jaouad*[1]

[1]*Mohamed V university, Faculty of Medecine and Pharmacy, Rabat, Morocco,* [2]*private medical office, Casablanca, Morocco,* [3]*University Mohamed VI polytechnic, Benguerir, Morocco.*

Background: Primary hyperoxaluria type 1 (PH1) is one of the most common genetic diseases in the Moroccan population and is likely underdiagnosed. PH1 is an autosomal recessive disorder caused by a deficiency of alanine-glyoxylate aminotransferase due to a defect in the *AGXT* gene which contains 11 exons. The HGMD database reported 299 mutations. This study aims to identify recurrent mutations in Moroccan PH1 patients.

Material and methods: A series of 132 unrelated patients were recruited, based on clinical diagnosis, including elevated oxalate levels in blood and urine, and the presence calcium oxalate monohydrate (whewellite) of kidney stones confirmed through spectrophotometric analysis. Molecular studies were conducted using direct sequencing of recurrent mutations in the *AGXT* gene or through clinical exome sequencing.

Results: Eleven pathogenic mutations were identified, with the most frequent being *AGXT*(NM_000030.3): c.731T>C (p.Ile244Thr); c.697C>T(p.Arg233Cys) in exon 7 and c.976delG(p.Val326Tyrfs*15) in exon 10. Genetic analysis identified AGXT gene mutations in over 60% of cases. All mutations were found in exons 7; 10; 2 and 1 of the *AGXT* gene.

Conclusion: These findings support the development of a standardized diagnostic protocol, beneficial in low-to-middle incomes countries, including Morocco. Optimal treatment involves combined liver and kidney transplantation in addition to promising therapies based on RNA interference. This optimized approach enhances clinical management and provides a cost-effective framework for genetic counseling, benefiting both affected individuals and their families.

P05.032.A A novel genetic variant in chronic intestinal pseudo-obstruction expands the *ACTG2*-related pathophysiological spectrum

Marcella Catania[1], *Daniele Cartelli*[1], *Federica Chiappori*[2], *Ilaria D'Amato*[1], *Alessia Strippoli*[1], *Erika Salvi*[1], *Guido Basilisco*[3], *Marina Coletta*[3], *Maurizio Vecchi*[3,4], *Giuseppe Lauria*[1,5], ***Margherita Marchi***[1]

[1]*Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy,* [2]*Institute for Biomedical Technologies, National Research Council (ITB-CNR), Segrate, Italy,* [3]*Gastroenterology and Endoscopy Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [4]*Department of Pathophysiology and Transplantation, University of Milan, Milano, Italy,* [5]*Department of Medical Biotechnology and Translational Medicine, Università degli Studi di Milano, Milano, Italy.*

Background: Pathogenic variants in the *ACTG2* gene are linked to a spectrum of intestinal motility disorders ranging from congenital megacystis-microcolon-intestinal hypoperistalsis syndrome (MMIHS) to late-onset chronic intestinal pseudo-obstruction

(CIPO). However, the molecular mechanisms underlying these phenotypic differences remain unclear. This study aims to (1) characterize a novel missense variant of *ACTG2* in a familial case of late-onset CIPO and (2) compare its functional impact with the R178H mutation, which causes MMIHS.

Methods: Two adult male siblings with late-onset CIPO (ages 26 and 61 years) and their unaffected offspring underwent whole-exome sequencing (WES). Wild-type and mutant ACTG2 proteins were expressed in experimental models. Functional effects were evaluated by in silico modelling and confocal microscopy, comparing the new variant with wild-type and mutant R178H.

Results: WES identified a novel *ACTG2* c.209A>G (Y70C) variant in both affected siblings. In silico modelling predicted divergent behaviours for the two variants: Y70C is more prone to monomeric form, while R178H shows a tendency toward aberrant aggregation. Confocal microscopy confirmed these predictions, showing widespread monomeric actin G2 in cells transfected with Y70C plamids, while R178H induced G2 actin precipitation into amorphous aggregates.

Conclusions: the novel Y70C mutation induced misfolding of actin monomers, impairing their integration into filaments and aligning with loss-of-function behaviour consistent with the less severe late-onset phenotype. In contrast, the R178H mutation exerted a dominant-negative effect on the wild-type allele, promoting aberrant polymerization and bundle aggregation, altering the cytoskeletal architecture of enteric myocytes, consistent with the defective intestinal development observed in MMIHS.

P05.033.B Autosomal recessive polycystic kidney disease and mimicking phenocopies in a retrospective Slovak single centre cohort

Gabriela Hrčková, *Veronika Krajčovičová, Lucia Janečková, Ľudmila Podracká, Katarína Skalická*

National Institute for Children´s Diseases, Bratislava, Slovakia.

Background: Autosomal recessive polycystic kidney disease (ARPKD) leads to early onset kidney failure and liver impairment. Biallelic pathogenic PKHD1 gene variants are mostly responsible for the disease. However, large genetic heterogeneity must be taken into consideration when ordering genetic analysis.

Material and methods: The aim of the study was to characterize retrospectively the manifestations, clinical course and the results of genetic testing in the group of patients with initial suspicion on ARPKD according to the renal ultrasound.

Results: The cohort of 29 patients was examined between the years 2012–2022. Manifestation was prenatal in 8 patients, neonatal in 13 and postnatal in 8 patients. Prenatal disease onset had the highest mortality, with the total mortality in the cohort reaching 20.7%. Genetic testing confirmed ARPKD in 22 patients, in negative cases the TMEM67, HNF1ß, NPHP3, NPHP4, and PKD1 gene variants were identified.

Biallelic protein truncating PKHD1 gene variants had perinatally lethal phenotype, representing the only known genotype-phenotype correlation in ARPKD. Patients with the NPHP-genes associated disease suffered from an equally severe condition, either. Conversely, a milder course was observed in TMEM67-associated disease, although renal failure and hepatic fibrosis occurred in the first decade. Disease due to PKD1 hypomorphic alleles was on the modest edge.

Conclusion: ARPKD is a severe disease with high mortality, renal and hepatic morbidity. In addition to the PKHD1 gene, many other genes produce a similar phenotype. Whole exome sequencing is an adequate diagnostic tool with a reliable result for genetic counseling in affected families.

P05.034.C Highly variable expressivity of a CNV deletion involving *TBX4* in three siblings with lethal lung developmental disorder and their mildly affected mother and grandfather

Pawel Stankiewicz[1], *Tomasz Gambin*[2], *Gail Deutsch*[3], *Nahir Cortes-Santiago*[4], *Salmo Raskin*[5], *Przemyslaw Szafranski*[1]

[1]*Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA,* [2]*Institute of Computer Science, Warsaw University of Technology, Warsaw, Poland,* [3]*Department of Laboratory Medicine and Pathology, University of Washington School of Medicine, Seattle, WA, USA,* [4]*Department of Pathology & Immunology, Baylor College of Medicine, Houston, TX, USA,* [5]*Laboratorio Genetika, Curitiba, Brazil.*

Background: In addition to pulmonary arterial hypertension and ischiocoxopodopatellar syndrome, single nucleotide variants (SNVs) and copy-number variant (CNV) deletions involving the dosage sensitive (pLI score = 1.0) T-box transcription factor *TBX4* gene have been associated with lethal lung developmental disorders (LLDDs) in neonates, including acinar dysplasia (AcDys) and congenital alveolar dysplasia (CAD). In contrast to missense SNVs, CNV deletions encompassing entire *TBX4* have been found exclusively as de novo events.

Material and methods: Whole-genome sequencing (WGS), RT-qPCR, luciferase reporter assay, computational analyses.

Results: We present a 3-generation family with three neonate siblings who died within 35–66 days after birth due to respiratory distress. Histopathological evaluation of the lung biopsy from one neonate showed pronounced alveolar simplification in the spectrum of CAD without hypertensive changes of the pulmonary arteries. WGS identified an ~ 108 kb CNV deletion encompassing *TBX4* in all three deceased infants. The deletion was also detected in their mother who has a history of pneumonia episodes and persistent thick upper airway secretions, and in the maternal grandfather who had surgically corrected genu valgum. RT-qPCR from the available lung biopsy showed a significant decrease in TBX4 expression. Computational analyses of the *TBX4* distant enhancer region in the affected and unaffected family members revealed 13 noncoding potentially hypomorphic SNVs, transmitted to the children from their father. We tested some of these variants using an in vitro luciferase reporter assay in fetal lung fibroblast cell line.

Conclusion: Our data further demonstrate complex compound inheritance of LLDDs and challenges in genetic counseling.

[1]Somatic Mutation Mechanisms Lab, IRCCS Ospedale San Raffaele/ Università Vita-Salute San Raffaele, Milan, Italy, [2]Division of Nephrology, Dialysis and Hypertension, IRCCS Ospedale San Raffaele, Milan, Italy, [3]Cystic Kidney Disorders Unit, IRCCS Ospedale San Raffaele, Milan, Milan, Italy, [4]Laboratory of Clinical Molecular Genetics, IRCCS Ospedale San Raffaele, Milan, Italy, [5]Urological Research Institute (URI), IRCCS Ospedale San Raffaele, Milan, Italy, [6]Unit of Genomics for human disease diagnosis and Lab. of Clinical Molecular Biology, IRCCS O San Raf, Milano, Italy.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD), caused by inherited mutations in one allele of *PKD1* or *PKD2*, is characterized by progressive kidney cyst formation. Most cysts clonally expand from single cells that acquire somatic mutations in the wild-type copy of the *PKD* gene. We tested whether a higher rate of somatic mutation accumulation at the whole genome level might be a mechanism that favors cystogenesis in ADPKD.

Material and methods: We detected somatic mutations in single genomes by clonally expanding normal kidney cells from the urines of 6 ADPKD patients (aged 25–55) and 6 controls (aged 24–53). Clones were subjected to concomitant qPCR measurement of gene expression (n = 119), RNAseq (n = 16), and WGS (n = 46).

Results: High *PAX2* and *PAX8* expression revealed that all cultured clones originated from the kidney tubule epithelium, but the number of clones was higher (36 vs 8 colonies/urine sample, $p = 0.002$) and there was an upregulation of alanine-aspartate-glutamate metabolism in ADPKD vs controls. No somatic second hits in *PKD1* or *PKD2* were found in our normal cell clones. Somatic SNVs and indels linearly increased with age, with similar rates in both cohorts. However, a rare *VCAM1+* cell subset, described as mutation-prone in our previous study [1], was more prevalent in ADPKD (7.02% vs 0.89% of clones, $p = 0.003$). We will analyze somatic mutations in this subset.

Conclusion: In normal kidney cells from ADPKD patients, the age-related accumulation of somatic mutations is similar to control, but *VCAM1+* cells that may accelerate cyst growth are more common.

P05.037.B Molecular findings in children with intrahepatic cholestasis

Natalia Semenova[1], *Elena Gusarova[1], Natalia Taran[2], Tatiana Strokova[2], Andrey Marakhonov[1], Olga Shchagina[1], Oksana Ryzhkova[1], Ekaterina Nuzhnaya[1], Ekaterina Zakharova[1]*

[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Federal Research Centre of Nutrition and Biotechnology, Moscow, Russian Federation.

Background: cholestatic liver disease is a condition that is commonly referred to in pediatric liver transplant centers. During the first months of life, inherited disorders are the second most common cause of cholestasis.

Material and methods: between 2017–2023 years, 213 pediatric patients (male- 117/45.1%) with suspected inherited intrahepatic cholestasis were evaluated by Sanger sequencing and/or NGS-sequencing (panel/WES/WGS/ WGS trio). The age of onset of cholestasis varies widely, from 0 months to 14 years, with a median age of 2 months [0;10].

Results: we identified disease-causing variants in 60% (128/213) of our study participants. Causative variants were identified in 39 different genes of monogenic diseases, top genes were: *JAG1* (Alagille syndrome; 21/128; 16.4%), *SERPINA1* (alpha-1 antitrypsin deficiency; 17/128; 13.3%), *ABCB11* (type 2 PFIC; 14/128; 10.9%), *ATP7B* (Wilson disease; 11/128; 8.6%), *AGL* (glycogenosis type 3; 7/128; 5.5%), *PKHD1* (polycystic disease type 4 (Karoli syndrome); 3.1%) and *ABCB4* (PFIC type 3; 4/128; 3.1%). In total, that genes account for more than half of the cases (60.93%) of monogenic forms of cholestasis syndrome. The majority of inherited cholestatic diseases are autosomal recessive (78.9%). Only 19.53% are monogenic diseases with an autosomal dominant inheritance pattern, and most of these are represented by Alagille syndrome.

Conclusion: in a single-center pediatric study, we identified monogenic variants in 39 known human's intrahepatic cholestasis genes. These findings support the usefulness of comprehensive multigene testing for diagnosing cholestasis and emphasize the evolving understanding of genetic variants contributing to the pathogenesis of this condition.

P05.038.C Refining the diagnosis of Renal Hypouricemia: genetic and biochemical insights

Noa Carrera Cachaza[1], *Adela Urisarri Ruiz de Cortaza[2], Pedro Fortes González[1], Eloísa Sánchez Cazorla[1], Ana María Barcia de la Iglesia[1], Cándido Díaz Rodríguez[3], María García Murias[1], Miguel A. García González[1]*

[1]Fundación Pública Instituto de Investigación Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain, [2]Servicio de Pediatría - CHUS, SANTIAGO DE COMPOSTELA, Spain, [3]Servicio de Nefrología - CHUS, Santiago de Compostela, Spain.

Background: Renal hypouricemia (RHUC) is caused by pathogenic mutations in *SLC22A12* and *SLC2A9*. Current clinic diagnostic criteria (SUA <2 mg/dL and FEUA >10%) exclude cases of mild hypouricemia (2<SUA < 3 mg/dL and FEUA >10%), which may be caused by monoallelic pathogenic mutations in these genes and could still pose health risks.

Material and methods: We studied individuals with suspected RHUC, identifying monoallelic and biallelic carriers of disease-causing mutations (DCMs). Additionally, for co-segregation and genotype-phenotype analysis, we recruited relatives of RHUC probands and additional individuals carriers of any DCM and not suspected of having RHUC. We ask for clinical data of all participants.

Results: Among 21 RHUC-suspected probands, 15 carried DCMs (71% diagnostic yield), including 3 biallelic and 12 monoallelic carriers. Ten distinct mutations were found, including 3 previously unlinked to RHUC. Many mutations were initially classified as VUS by automated classifiers but were reclassified as likely-pathogenic after incorporating published data, genotype-phenotype correlation and cosegregation results. Biochemical data revealed biallelic

individuals having SUA around 1 mg/dL and FEUA >20%. Monoallelic subjects showed SUA mostly between 2–3.3 mg/dL and FEUA >10%, consistent with mild hypouricemia. Significant SUA differences were found among non-carriers, monoallelic, and biallelic carriers.

Conclusion: Monoallelic carriers of *SLC22A12* or *SLC2A9* mutations may present with mild hypouricemia. The diversity of mutations found and the poor classification by automated classifiers highlight the need for specialized geneticists and personalized diagnostics. Revised diagnostic criteria, including adjusted SUA thresholds, are essential. Further research is needed to clarify the pathogenicity of mild hypouricemia and management strategies.

P05.039.D Optimization of the diagnostic workflow for genetic liver diseases in pediatric and adult patients through Next Generation Sequencing

Angelo Corso Faini[1,2], *Michele Pinon*[3], *Giulia Margherita Brach Del Prever*[1,2], *Carmelo Romeo*[1,2], *Maria Luca*[1,2], *Fiorenza Mioli*[1,2], *Claudia Saglia*[1,2], *Caterina Scolari*[1,2], *Tullia Carradori*[1,2], *Francesca Arruga*[1,2], *Diana Carli*[1,2], *Pier Luigi Calvo*[3], *Tiziana Vaisitti*[1,2], *Silvia Deaglio*[1,2]

[1]*Department of Medical Sciences, University of Turin, Turin, Italy,* [2]*Laboratory of Immunogenetics, Città della Salute e della Scienza Hospital, Turin, Italy,* [3]*Pediatric Gastroenterology Division, Regina Margherita Children's Hospital, Turin, Italy.*

Background: Genetic testing for liver diseases faces significant challenges, including variant interpretation and genotype-phenotype correlation. Moreover, limited evidence exists on its role in the diagnostic workflow of patients with hepatopathies. Clinical exome sequencing (CES) has emerged as a promising tool, offering flexibility and cost-effective workflows. This study aims at designing an algorithm to efficiently implement genetic testing in the diagnostic workup of hepatopatic patients.

Material and methods: We analyzed 197 pediatric and adult patients with liver disease referred to the Città della Salute e della Scienza Hospital, Turin, between July 2003-October 2024. CES was performed and analyzed using in silico gene panels. When available, pre-existing genetic reports were reviewed. Data were analyzed for diagnostic yield and stratified by patient characteristics, age and clinical suspicion.

Results: The cohort consisted of both pediatric and adult patients. Marked differences in diagnostic yield were observed between children and adults. Summarized data are reported in Table 1. In pediatric patients, genetic testing provided a high diagnostic rate and supported its use even for minor signs of liver disease. In contrast, genetic testing in adults showed limited utility, being most valuable for selected cases with unexplained liver disorders that had already undergone extensive routine testing without a diagnosis.

Conclusion: This study highlights CES as a valuable tool for diagnosing liver diseases, particularly in children. Additionally, the findings enabled the design of a diagnostic algorithm to guide genetic testing in liver diseases, optimizing diagnostic workflows and cost-efficiency.

Table 1. *Cohort description and result summary*.

FEATURE	PEDIATRIC	ADULTS	TOTAL

P05.040.A Expanded clinical phenotype of RINT1: infantile-onset recurrent acute liverfailure and neutropenia

Ekaterina Nuzhnaya[1], *Natalia Semenova*[1], *Anna Efremova*[1], *Polina Tsygankova*[1], *Andrey Marakhonov*[1], *Nikolai Prokhorov*[2], *Nelly Kan*[3], *Yulia Rodina*[3], *Anna Shcherbina*[3], *Nina Demina*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Indiana University, Bloomington, Bloomington, IN, USA,* [3]*Dmitry Rogachev National Research Center, Moscow, Russian Federation.*

Background: Infantile-onset recurrent acute liver failure is a rare and life-threatening condition in pediatric patients, often triggered by febrile illnesses or infections. Genetic factors underlying RALF include mutations in genes involved in intracellular trafficking and autophagy. Variants in *RINT1*, a key component of the NRZ complex, have been implicated in RALF, but data on their clinical spectrum remain limited.

Material and methods: We present a case of an 8-year-old girl from the Chuvash population with RALF and neutropenia. Clinical data, biochemical evaluations, and genetic analyses were conducted, including whole-exome sequencing (WES) and 3D structural modeling of the identified *RINT1* variant (NM_021930.6:c.1435G>C, p.Ala479Pro). Population-specific analysis investigated the variant's origin.

Results: The homozygous *RINT1* variant was identified in the proband and associated with febrile and infection-induced liver failure episodes, elevated AST/ALT levels, hepatomegaly, and fibrosis. Neutropenia was consistently observed. Siblings with similar phenotypes succumbed to severe liver failure, supporting an autosomal recessive inheritance pattern. Structural modeling demonstrated that the p.Ala479Pro substitution disrupts alpha-helical stability, impairing RINT1 function. Population analysis revealed a shared ancestral origin within the Chuvash population.

Conclusion: This study expands the clinical phenotype of RINT1-related disorders to include RALF and neutropenia, emphasizing the importance of early genetic diagnosis and monitoring. The findings suggest a population-specific disorder with implications for genetic counseling and future therapeutic research. Functional insights into the mutation underscore the role of *RINT1* in vesicular trafficking, autophagy, and immune regulation, offering new avenues for understanding and managing RALF.

P05.041.B MEFV mutational spectrum and clinical manifestations in Georgian FMF patients

Christian Oberkanins[1], *Mamuka Khvedelidze*[2], *Otar Zhvania*[3], *Gernot Kriegshäuser*[4], *Davit Tatoshvili*[3], *Karaman Pagava*[3]

[1]*ViennaLab Diagnostics, Vienna, Austria,* [2]*Molecular Medicine Research Center - Primax, Tbilisi, Georgia,* [3]*Department of Child & Adolescent Medicine, Tbilisi State Medical University, Tbilisi, Georgia,* [4]*Department of Medical Genetics, Yerevan State Medical University, Yerevan, Armenia.*

Background: Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disorder caused by mutations in the *MEFV* gene. Despite a known high carrier rate of 15% and its neighbourhood to endemic countries Armenia and Turkey, the overall situation concerning FMF in Georgia is still largely inextricable.

Material and methods: Over 300 Georgian subjects with FMF symptoms or/and family history have so far been recruited. Genotyping for twelve *MEFV* mutations plus three *SAA1* isoforms is performed using FMF-SAA1 StripAssay (ViennaLab Diagnostics). To date, full medical records and genotypes are available for 136 patients matching Tel-Hashomer criteria.

Results: 71 (52.21%) patients were female and 65 (47.79%) were male, with a mean age of 28.66 ± 16.63 years. We distinguished 16 different genotypes, M694V (66.44%), V726A (11.64%) and E148Q (8.90%) being the most frequent *MEFV* mutations. *SAA1* 1.1, 1.3 and 1.5 was present in 47.79%, 1.84% and 50.37% of alleles, respectively. Reported clinical manifestations included periodic attacks of fever (87.50%), abdominal pain (84.56%), arthralgia (71.32%), chest pain (45.59%), myalgia (44.12%) and skin rash (21.32%). A family history of FMF was reported by 50 (36.76%) subjects. Currently only 46 (33.82%) FMF patients receive colchicine therapy. Among the most striking observations was an extensive delay between the reported FMF onset (median: 9.00 years of age) and confirmed diagnosis (median: 25.50 years of age).

Conclusion: The *MEFV* mutational spectrum in Georgia is heterogenous, with similarities to neighbouring Armenia and Turkey. Awareness, as well as accessible diagnostic and therapeutic options for FMF, seem still insufficient and widely unavailable.

P05.043.D Investigation of PNPLA3 rs738409 and TM6SF2 rs58542926 functional gene variants in patients with metabolic syndrome and non alcoholic fatty liver disease

Fatima Ceren Tunçel[1], *Celalettin Küçük*[2], *Yasemin Oyacl*[1], *Murat Köse*[3], *Sevde Hasanoglu Sayin*[1], *Tufan Tükek*[3], *Servet Tunoğlu*[4], *Sacide Pehlivan*[5]

[1]*Institute of Graduate Studies in Health Sciences, Istanbul University, Istanbul, Turkey,* [2]*Department of Internal Medicine, Biruni University Faculty of Medicine Hospital, Istanbul, Turkey,* [3]*Department of Internal Medicine, Faculty of Medicine, Istanbul University, Istanbul, Turkey,* [4]*Department of Molecular Biology and Genetics, Faculty of Arts and Sciences, Demiroğlu Science University, Istanbul, Turkey,* [5]*Istanbul University, Istanbul Faculty of Medicine, Department of Medical Biology. Istanbul/TURKIYE, Istanbul, Turkey.*

Background: This study aimed to investigate the relationship between PNPLA3-rs738409 and TM6SF2-rs58542926 functional gene variants with both genetic and clinical parameters in patient groups diagnosed with Metabolic syndrome (MetS) and Non-alcoholic fatty liver (NAFLD).

Material and methods: A total of 159 MetS, 120 NAFLD and 80 healthy individuals were included in the study. Variant analyses were performed using PCR-RFLP from genomic DNAs.

Results: While PNPLA3-rs738409 genotype frequencies did not show significant differences in both disease groups compared to controls, TT genotype of TM6SF2-rs58542926 variant was found to be higher in Mets patients. In the Mets group, the PNPLA3-rs738409-CC genotype was associated with increased platelet (PLT) count and high Diabetes Mellitus (DM) rate, the GG genotype with increased waist circumference and high free triodothyronine (fT3) levels, and the GC genotype with low weight and short stature. The TM6SF2-rs58542926-TC genotype was associated with decreased Alkaline phosphatase (ALP) levels. In the NAFLD group, the PNPLA3-rs738409-CC genotype was associated with high BMI, the GC genotype with advanced age, narrow leg/arm circumferences. The TM6SF2-rs58542926-CC genotype with weight gain and high blood pressure, TC genotype with low weight, low blood pressure and low gamma-glutamyl transferase (GGT) levels, and TT genotype was associated with narrow leg/arm circumference and high GGT levels.

Conclusion: Our study is the first to examine rs738409 and rs58542926 missense mutations together in MetS and NAFLD patients, and these results suggest that these functional gene variants may be important biomarkers in the etiopathogenesis of both MetS and NAFLD.

P05.044.A Identification of type 2 diabetes-associated polymorphisms in DOCK7, ABCG8, UBE2E2, and SYN2 genes in the Uzbek population

Darya Zakirova[1], *Fazliddin Khonboev*[1], *Dilbar Dalimova*[1], *Guzal Abdullaeva*[2], *Feruza Takhirova*[3], *Anastasiya Punko*[1], *Nodira Alikhanova*[3], *Shahlo Turdikulova*[1], *Alisher Abdullaev*[1]

[1]*Center for Advanced Technologies, Tashkent, Uzbekistan,* [2]*Republican Specialized Scientific and Practical Medical Center of Cardiology, Tashkent, Uzbekistan,* [3]*Republican Specialized Scientific And Practical Medical Center Of Endocrinology, Tashkent, Uzbekistan.*

Background: Diabetes is a leading cause of death, affecting nearly half a billion adults worldwide. With projections indicating a significant increase in prevalence, understanding the genetic factors contributing to diabetes, particularly type 2, is crucial.

Materials and methods: This study include 165 individuals: 125 patients with type 2 diabetes and 40 controls. PCR was performed using Real-Time PCR. A logistic regression analysis was conducted using the R programming language and the SNPassoc software package to identify statistically significant associations between genetic variants and disease risk under an additive genetic model.

Results: Genetic analysis showed an association between the rs4299376 variant and type 2 diabetes (OR:0.52, 95% CI: 0.32–0.84, $p = 0.008375$), as well as between the rs6780569 (OR:3.25, 95% CI: 0.99–10.64, $p = 0.021334$), rs7616006 (OR:1.8, 95% CI: 1.06–3.05, $p = 0.02316$), and rs12749263 (OR:0.50, 95% CI: 0.31–0.82, $p = 0.006540$) variants and type 2 diabetes. After Bonferroni correction, only rs4299376 and rs12749263 remained significant. Other gene variants rs7957197 and rs4402960 did not show an association with the disease ($p > 0.05$).

Conclusion: The findings underscore the importance of ethnic and geographical diversity in genetic studies and contribute to the understanding of type 2 diabetes in the Uzbek population. Further research is needed to explore the clinical implications of these genetic associations.

P05.045.B Predicted loss of function variants in exons 20 and 21 of *OFD1* cause X-linked primary ciliary dyskinesia: a case report

Fuad Chowdhury, *Ashish Marwaha*

University of Calgary and Alberta Children's Hospital, Calgary, AB, Canada.

Background: Primary ciliary dyskinesia (PCD) is the most common motile ciliopathy characterized chiefly by early-onset sinopulmonary disease and variably present situs anomalies, subfertility, hydrocephalus, and congenital heart anomalies. PCD is genetically heterogenous; *OFD1* is an emerging cause of an X-linked recessive form. This gene encodes a pleiotropic protein found in basal bodies that functions in ciliogenesis and left-right patterning. Variants in this gene also cause Oral-Facial-Digital syndrome type 1, Joubert syndrome type 10, and retinitis pigmentosa type 23. To date, 15 individuals/kindreds with *OFD1*-related PCD have been reported and all have variants creating a premature termination codon (PTC) in exons 20 or 21 (total of 23).

Methods: Commercial NGS-based testing of 47 PCD-related genes was performed on proband peripheral blood DNA.

Results: We report an 8-year-old boy with recurrent sinopulmonary infections (pneumonia, sinusitis, and otitis media), chronic wet cough, and situs inversus consistent with PCD. He is neurodevelopmentally typical and presents with mild dysmorphisms including hypertelorism and brachydactyly. Genetic testing revealed a likely pathogenic de novo hemizygous *OFD1* c.2725C>T, p.(Arg909*) variant. This variant was reported previously in a family with two affected males with PCD.

Conclusion: These findings provide further clinical evidence that X-linked PCD belongs in the phenotypic spectrum of *OFD1*. A review of reported cases establishes a clear correlation with PTC-causing variants in exons 20 or 21 which were previously shown to escape nonsense-mediated decay. Additional variable features include intellectual disability, macrocephaly, obesity, polydactyly and distinctive facial features. Importantly, similar variants in these exons also cause Joubert syndrome.

P05.046.C A case of gastrointestinal defects and immunodeficiency syndrome-1 (GIDID1) in a 3-month-old Bulgarian girl with two variants in *TTC7A* gene: diagnostic challenges and implications

Gabriela Kovacheva[1,2], *Tihomir Todorov*[2], *Slavena Atemin*[2], *Mila Sleptsova*[2], *Zornitsa Pavlova*[2], *Mila Baycheva*[3], *Paulina Taushanova*[4], *Vanyo Mitev*[1], *Albena Todorova*[1,2]

[1]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria,* [2]*GMDL "Genica" and IMDL "Genome Center Bulgaria", Sofia, Bulgaria,* [3]*University Children's Hospital, Department of Paediatric Gastroenterology, Hepatology and Nutrition, Sofia, Bulgaria,* [4]*Department of Immunobiology of Reproduction, Institute of Biology and Immunology of Reproduction, BAS, Sofia, Bulgaria.*

Background: Gastrointestinal defects and immunodeficiency syndrome-1 (GIDID1) is a complex rare autosomal-recessive disorder with a range of intestinal abnormalities (including apoptotic enterocolitis, intestinal atresias at multiple locations throughout the small/large intestines, intestinal stenosis), along with immune deficiency. This condition is associated with pathogenic variants in the tetratricopeptide repeat domain 7A (*TTC7A*) gene; homozygous state is correlated with poor prognosis and short life expectancy. Genetic testing for *TTC7A* gene abnormalities associated with GIDID1 is advised for patients with multiple gastrointestinal issues and frequent infections in order to offer effective treatment, prenatal screening, and genetic counseling. We present a case of a 3-month-old girl diagnosed with intestinal atresia, severe hypotrophy and chronic diarrhea, with a suspected diagnosis of congenital enteropathy.

Material and methods: Genomic DNA was extracted from peripheral blood of the proband and both parents and analyzed using whole exome sequencing (WES).

Results: WES analysis revealed two heterozygous variants in the *TTC7A* gene: c.315_318del, p.(Tyr105Ter) and c.1027G>A, p.(Glu343Lys) - classified as pathogenic and a variant of uncertain significance (VUS) in the ClinVar database, respectively. Sanger sequencing and segregation analysis in the family revealed one paternally and one maternally inherited variant, which validated the suspected diagnosis GIDID1.

Conclusion: This case highlights the critical role of genetic testing for complex congenital disorders like GIDID1. Considering the significant morbidity and mortality associated with this condition, clinicians should maintain a high level of awareness

to recognize this syndrome and to be familiar with the benefits of genetic testing due to the treatment scarcity.

P05.047.D Incidental findings in HHT-related genes in prenatal unindicated exome sequencing: implications of reclassification

Efrat Sofrin-Drucker[1], *Yael Goldberg*[2], *Vered Shkalim Zemer*[3], *Gabriel Lidzbarsky*[4], *Naama Orenstein*[1], *Lina Basel-Salmon*[4], *Liat Chamma*[4], *Mordechai Pollak*[1], *Meir Mei-Zahav*[1]

[1]*Schneider hospital, Petah Tikva, Israel,* [2]*RMC, Petah Tikva, Israel,* [3]*Clalit health service, Petah Tikva, Israel,* [4]*Beilinson hospital, Petah Tikva, Israel.*

Background: Hereditary Hemorrhagic Telangiectasia (HHT) is a highly penetrant vascular disorder that can lead to severe complications, many of which are preventable through proactive surveillance. Since 2013, the American College of Medical Genetics and Genomics (ACMG) has provided guidelines for reporting secondary findings (SF) in clinical exome and genome sequencing. In May 2021, HHT-related genes ACVRL1 and ENG were incorporated into ACMG SF v3.0, while SMAD4 had been included earlier due to its link with juvenile polyposis.

Material and methods: We reviewed data from the HHT National Center, focusing on families in which incidental HHT-related variants were identified during unindicated prenatal trio-exome sequencing.

Results: HHT-related variants in ACVRL1 and ENG were identified in 15 individuals across five families. The testing was conducted in various laboratories. Initially all five variants were considered potentially disease-causing and were classified as either warm VUS, likely pathogenic or pathogenic. Following the 2024 ClinGen Hereditary Hemorrhagic Telangiectasia Expert Panel Specifications, all five variants were downgraded to VUS. Clinical findings ranged from asymptomatic presentations to epistaxis and/or telangiectasias, but no individuals had known AVMs or met the Curaçao criteria at the time of molecular diagnosis.

Conclusion: We anticipate a growing number of prenatal exome tests as the test becomes more feasible, underscoring the importance of accurate variant classification. Genomic variants identified in asymptomatic population have a higher chance of being false positives. Adherence to the latest ClinGen guidelines assists in classification of variants and the appropriate management of individuals with HHT.

P05.048.A Homozygous pathogenic variant c.922G>A in the *CTNS* gene: a recurrent mutation in Moroccan patients with nephropathic cystinosis

Imane Cherkaoui Jaouad[1,2], *Ourayna Batta*[1,3], *Ilham Ratbi*[1,2], *Abdelaziz Sefiani*[1,3], *Jaber Lyahyai*[1]

[1]*Research Team in Genomics and Molecular Epidemiology of Genetic Diseases, GENOPATH Center, Faculty of Medicine and Pharmacy of Rabat, University Mohammed V, Rabat, Morocco,* [2]*Medical Genetics Unit, Ibn Sina CHU, Rabat, Morocco,* [3]*Department of Medical Genetics, National Institute of Health, Rabat, Morocco.*

Background: Nephropathic cystinosis is a rare autosomal recessive lysosomal storage disorder characterized by an accumulation of cystine in the lysosomes leading to progressive renal failure and extra-renal comorbidity. It is caused by pathogenic variants of the cystinosin gene (*CTNS*). The spectrum of mutations in the *CTNS* gene is not well defined in Moroccan population.

Material and methods: Here, we investigated five families with at least one child affected by nephropathic cystinosis. Molecular analysis was performed by clinical exome sequencing in two families and by targeted Sanger sequencing of the *CTNS* gene in three families.

Results: We report a known mutation c.922G>A in these families which seems to be a recurrent mutation in the Moroccan population. This mutation was first found in two families by clinical exome sequencing. This result allowed us to search for this mutation by Sanger sequencing in the three other families.

Conclusion: We propose first line genetic testing based on screening of the c.922G>A mutation in the *CTNS* gene. This strategy will allow cost-effective diagnosis confirmation as well as early administration of treatment with oral cysteamine and will improve genetic counseling in families.

P05.049.B Xq26.3 Microduplication as a Genetic Cause of Pituitary Macroadenoma and Gigantism

S. Ketenci İşlek[1], *G. Ürel Demir*[1], *P. Şimşek Kiper*[1], *Z. Özön*[2], *G. Utine*[1];

[1]*Hacettepe University, Division of Pediatric Genetics, Department of Pediatrics, Ankara, Turkey,* [2]*Hacettepe University, Division of Pediatric Endocrinology, Department of Pediatrics, Ankara, Turkey*

Background: Excessive growth hormone (GH) levels before the closure of the epiphyseal plates lead to gigantism, which is characterized by tall stature. The most common cause is GH-producing pituitary adenomas, while pituitary hyperplasia is less frequently observed. In a study by Trivellin et al. (2014), 43 nonsyndromic gigantism cases without known genetic causes associated with pituitary tumors, were examined. Among them, 14 patients with gigantism in early childhood and symptoms in late infancy were found to have microduplications in the Xq26.3 region. Subsequent studies identified similar cases, leading to the classification of X-linked acrogigantism (XLAG; OMIM #300942). XLAG is an X-linked dominant disorder characterized by advanced bone age, accelerated growth velocity, tall stature, and elevated GH, IGF-1, and prolactin levels. We present a 5-year-old girl with gigantism and a pituitary macroadenoma, in whom a microduplication in the Xq26.3 region was detected.

Methods: Microarray analysis was performed.

Results: Microarray analysis revealed a 606 kb microduplication in the Xq26.3 region, encompassing the ARHGEF6, CD40LG, RBMX, and GPR101 genes. *GPR101* (OMIM *300393) is known to be associated with growth hormone-secreting pituitary adenomas. The alteration was classified as pathogenic and considered to clarify the patient's symptoms.

Conclusion: In this study, we present a patient diagnosed with XLAG resulting from Xq26.3 microduplication. Chromosome Xq26.3 microduplication syndrome associated with pituitary adenoma should be considered in patients with early growth hormone elevation and significant height increase.

P05.050.C Genotype-phenotype correlation in patients with 17q12 microdeletion and *HNF1B* point alterations

Eloísa Sánchez Cazorla[1], *Pedro Fortes González*[1], *Adela Urisarri Ruiz de Cortaza*[2], *María García Murias*[1], *Ana María Barcia de la Iglesia*[1], *Laura Núñez González*[1], *Cándido Díaz Rodríguez*[2], *Noa Carrera Cachaza*[1], *Miguel Ángel García González*[1]

[1]*Fundación Instituto de Investigación Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain,* [2]*Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain.*

Background: The *HNF1B* gene encodes a transcription factor crucial for the development of multiple organs, including kidneys, pancreas, liver, intestines, and neurons. It regulates key biological processes such as nephrogenesis, ion transport, and cellular polarity, among others. Pathogenic *HNF1B* variants disrupt these functions, leading to a broad spectrum of renal and extrarenal manifestations. Patients can be classified into three groups based on their genetic alteration: 17q12 microdeletion, truncating point mutations, and missense point mutations. This study aims to establish genotype-phenotype correlations for *HNF1B* variants in a closed cohort predominantly from Galicia (region in western Europe characterized by unique geographical, ethnic, and consanguinity patterns, which enhance the genetic value of this population).

Material and methods: This retrospective, observational, multicenter study analyzed a large cohort of patients with suspected hereditary kidney diseases. Genetic analysis was conducted via Next-Generation Sequencing (NGS) and/or Sanger sequencing. 31 individuals (27 probands, 4 relatives) carrying *HNF1B* variants were selected, and detailed clinical data were collected and analyzed.

Results: Among probands, 55.55% carried the 17q12 microdeletion, 18.52% truncating mutations, and 25.93% missense mutations. Over 60% of probands presented renal cysts, hyperechogenicity, and/or hypomagnesemia. Other manifestations observed were hyperuricemia, Congenital Anomalies of the Kidney and Urinary Tract (CAKUT), diabetes/Maturity-Onset Diabetes of the Young (MODY), and hepatic or neurological anomalies. Clinical features varied among genetic variants.

Conclusion: This study highlights the broad and variable multisystemic impact of *HNF1B* variants, reinforcing the need for accurate genetic diagnosis to guide personalized genetic counseling and patient management based on the specific mutation type.

P05.051.D A novel *COL4A1* truncating variant in an Italian family mimicking Alport syndrome

Chiara Dordoni[1], *Diego Toso*[2,3], *Eva Sestagalli*[4,3], *Laura Econimo*[4], *Roberta Cortinovis*[4], *Letizia Zeni*[4], *Gianfranco Savoldi*[5], *Cinzia Mazza*[5], *Zito Alessandra*[6,7], *Enza Maria Valente*[6,7], *Federico Alberici*[4,3], *Francesco Scolari*[3,4], *Claudia Izzi*[1,8]

[1]*Clinical Genetics Unit, ASST Spedali Civili Brescia, Brescia, Italy,* [2]*Division of Nephrology and Dialysis, ASST Spedali Civili Brescia, Brescia, Italy,* [3]*Radiological Sciences, and Public Health, University of Brescia, Brescia, Italy,* [4]*Division of Nephrology and Dialysis, ASST Spedali Civili of Brescia, Brescia, Italy,* [5]*Medical Genetics Laboratory, ASST Spedali Civili of Brescia, Brescia, Italy,* [6]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [7]*Medical Genetics Unit, IRCCS Mondino Foundation, Pavia, Italy,* [8]*Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy.*

Background: Alport syndrome (AS) is the prevalent genetic diagnosis in patients with microhematuria and chronic kidney disease (CKD). However alternative monogenic disease should be considered in genetically unresolved patients. Rare *COL4A1* missense variants are associated with Hereditary angiopathy, nephropathy, aneurysms, and muscle cramps (HANAC syndrome) characterized by renal cysts, thus this gene is not routinely investigated in suspicion of AS. Intriguingly, here we describe a novel truncating *COL4A1* variant in an Italian family with AS-phenotype, vascular malformation without renal cysts.

Material and methods: The proband was diagnosed with AS given the association of microhematuria, hearing loss and CKD. Similar features were observed in other relatives and a brother underwent renal biopsy revealing thin glomerular basement membranes overlapping the pattern observed in AS. Pathogenic variants in *COL4A3-A5* genes were not identified and the family was genetically unresolved since the son of the proband underwent Whole Exome Sequencing (WES) analysis for congenital spastic paraplegia identifying a heterozygous pathogenic truncating *COL4A1* variant in NC1 domain (c.1186C>T, p.Arg396Ter)

Results: Segregation analysis revealed *COL4A1* p.Arg396Ter variant in all affected relatives: mother, sister, aunt, uncles. Moreover, genotype-driven further clinical assessments delineated in the family extra-renal clinical features related to *COL4A1*-disease, i.e. cerebrovascular and retinal vascular malformations and elevated CK levels.

Conclusion: This report add insights into *COL4A1*-spectrum disease and usufulness of wide genetic approach. *COL4A1* gene should be investigated in genetically unresolved AS patients. The genetic diagnosis is even more crucial for accurate clinical management preventing misdiagnoses and to guide managment of extrarenal manifestations.

P05.052.A In Pursuit of a novel variant in LIPI gene: a rare case of hypertriglyceridemia and hepatosteatosis

Nurdamla Sandal Filikci[1], ***Zehra Manav Yigit***[1], *Mehmet Altay Unal*[2]

[1]*Aydin Adnan Menderes University, Faculty of Medicine, Department of Medical Genetics, Aydin, Turkey,* [2]*Ankara University, Stem Cell Institute, Ankara, Turkey.*

Background: *LIPI* gene, located on chromosome 21q11.2, plays a crucial role in maintaining lipid homeostasis. Genetic studies suggest that *LIPI* mutations may lead to dyslipidemia in humans and hypertriglyceridemia in mice. Presented case is a 27-year-old male who was admitted with elevated triglyceride levels and subsequently developed hypertriglyceridemia and hepatosteatosis during follow-up. Genetic analysis identified a novel, likely pathogenic variant in *LIPI*.

Material and methods: DNA was isolated from peripheral blood leukocytes obtained from the patient, and a clinical exome panel covering 6380 disease-associated genes was analyzed. The

analyses were performed using the Illumina NextSeq platform with the SOPHIA Clinical Exome Solution (CES) v3.

Results: The c.335A>G (p.Asp112Gly) missense variant was identified at heterozygous state in *LIPI* and classified as likely pathogenic based on ACMG criteria (PM2, PP3_Strong). Human Splicing Finder (HSF) analysis suggested potential splicing alterations due to changes in the ESE/ESS motif ratio and cryptic donor site activation. The variant's REVEL score of 0.957 further supports its high pathogenicity potential. When WT and D112G structures were examined using molecular dynamics methods, findings were obtained that the D112G change affected the protein function.

Conclusion: To the authors knowledge, this is the first hypertrigliseridemia case with a novel mutation in *LIPI*. Dyslipidemia is a major public health risk and a leading cause of preventable mortality. This case underscores *LIPI*'s role in lipid metabolism and dyslipidemia. Given the limited genetic studies on *LIPI*, further research is needed to expand its genetic spectrum and develop new therapeutic approaches.

P05.054.C Novel ATP7B variants in pediatric hepatic Wilson disease from Northern India

***Amresh Kumar Mishra**, Moinak Sen Sarma, Anchal Dubey, Anshu Srivastava, Ujjal Poddar*

Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background: Most ATP7B mutation variants found globally do not match the Indian population, possibly due to the mixed anthropology and ethnic diversity. The hepatic manifestation of Wilson disease (WD) is an aggressive phenotype in children. Due to the paucity of exclusive literature, we aimed to assess the novel variants of ATP7B mutation and its correlation with the hepatic phenotype.

Material and methods: Children with hepatic WD diagnosed by modified Leipzig criteria having bona fide symptoms, on chelators underwent molecular confirmation by whole-exome sequencing. Known and novel variants were identified.

Results: 50 WD patients (aged 15.2 ± 4.5 years, 37 boys) had 71 ATP7B variants (45 heterozygous, 26 homozygous), located on exons 2(32%), 18 (13%), 8(10%), 13(10%) and 14(9%). Most common variants were c.813C>A(p.C271X) and c.3809A>G(p.N1207S). Deep intronic changes were found in three patients. The presentation was chronic hepatitis (64%), decompensation [ascites and/or encephalopathy] (26%) and acute liver failure (10%) with an overall mean pediatric end-stage liver disease (PELD) score of 11.4 ± 9.2. Of the entire cohort, 15 novel variants were identified in 11 patients (Table 1) with 100% endogamy or third-degree consanguinity. Of this subset, three patients had one variant each that was known pathogenic. Over a follow-up of 7.1 ± 3.8 years, six and three patients developed renal tubular dysfunction and neurological involvement respectively. Liver dysfunction improved in all.

Conclusion: Novel ATP7B variants are seen in 21% of Northern Indian cohort. Though liver functions recover on chelation, other systemic phenotypes may ensue in follow-up

P05.055.D Genome analysis of situs inversus with and without primary ciliary dyskinesia

Meng-Yun Wang[1,2], *Simon E. Fisher*[1,2], *Guy Vingerhoets*[3], *Clyde Francks*[1,2,4]

[1]*Language & Genetics Department, Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands,* [2]*Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands,* [3]*Department of Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium,* [4]*Department of Cognitive Neuroscience, Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Situs inversus (SI) or left-right mirror reversal of the visceral organs is a developmental condition occurring in roughly 1 out of every 6000 to 8000 people. SI can occur together with the recessive disorder Primary Ciliary Dyskinesia (PCD) in the context of disrupted motile ciliary function in the early embryonic node, during specification of the left-right axis. However, most people with SI do not have PCD, and the etiology of their condition remains poorly studied. Although a general reversal of functional brain asymmetry in SI was not observed, they showed a marginally increased prevalence of atypical lateralization [1].

Material and methods: We previously sequenced the genomes of 15 people with SI, of which 6 had PCD, as well as 15 unaffected controls [2]. Now, we have sequenced the genomes of a further 23 SI individuals (of which 2 have PCD) and 23 controls.

Results: In the first wave of data collection, we found that while the 6 people with SI and PCD all had likely causal recessive mutations in genes already known to cause PCD, we only found 4 out of the 9 non-PCD SI cases had likely causative mutations.

Conclusion: We are now analyzing the new 23 SI individuals and 23 controls and will integrate with the first wave to better understand the genetic contributions to non-PCD SI and their possible relevance to brain asymmetry. This may provide clues to developmental mechanisms of left-right axis formation beyond motile cilia at the embryonic node.

P05.056.A Longer leukocyte telomere length increases the risk of lung injury in children with COVID-19

Tetiana Harashchenko[1], *Tetiana Umanets*[1], *Yuriy Antypkin*[1], *Alexandra Gorodna*[2], *Ludmila Livshits*[1,2,3], *Dmytro Krasnienkov*[3]

[1]*SI «Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine», Kyiv, Ukraine,* [2]*Institute of Molecular Biology and Genetics National Academy of Sciences of Ukraine, Kyiv, Ukraine,* [3]*SI "D.F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine.*

Background: The global pandemic of COVID-19 caused a significant impact on society, and emphasized the need to understand the factors that determine individual susceptibility to various forms of the disease. The susceptibility factors to lung injury of COVID-19 are not yet fully understood. Leukocyte telomere length (LTL) is sensitive to reactive oxygen species damage and inflammatory processes. Our study aimed to investigate the association between LTL and lung injury among children with COVID-19.

Material and methods: The relative average length of chromosome regions was studied in the groups of children (n = 210) with COVID-19. The analysis uses a method of multiplex monochrome quantitative real-time PCR on DNA samples isolated from the peripheral blood leukocytes.

Results: 210 children were divided into 2 groups: group 1 - children with lung injury (all types of pneumonia) (n = 156), group 2 - without injury (n = 54). Among children with lung injury during COVID-19 were detected statistically significantly longer telomere length according to the nonparametric Mann-Whitney test, compared to children without lung damage ($p < 0.05$ $p = 0{,}0196$).

Conclusion: It is one of the first studies to evaluate the role of LTL as a predictive biomarker in pediatric patients with COVID-19. In the current study, the association of longer relative telomere length with lung injury comparatively to shorter telomere in children without lung injury has been demonstrated. Thus, relative telomere length can be proposed as a risk marker of lung injury in children with COVID-19.

P05.057.B First report of a novel *FLNA* long isoform missense mutation causing late-onset Chronic Intestinal Pseudobstruction (CIPO)

Ilaria D'Amato[1], *Enrico Ganguzza*[2], *Guido Basilisco*[2], *Alessia Strippoli*[1], *Elkadia Mehmeti*[1], *Erika Salvi*[1], *Maurizio Vecchi*[2,3], *Giuseppe Lauria*[1,4], *Margherita Marchi*[1]

[1]*Neuroalgology Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [2]*Gastroenterology and Endoscopic Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [3]*Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milan, Italy,* [4]*Department of Medical Biotechnology and Translational Medicine, Università degli Studi di Milano, Milan, Italy.*

Background: CIPO is a rare intestinal motility disorder that can be associated with systemic diseases or genetically determined. X-linked CIPO (CIIPX) results from *FLNA* gene mutations. This gene encodes filamin A, which is crucial for cytoskeletal integrity and smooth muscle function. Previous CIPO cases linked to *FLNA* involved early-onset and often extra-intestinal manifestations.

Material and methods: Following a comprehensive clinical assessment of the proband, genomic DNA was subjected to WES analysis; variant segregation analysis within the family was conducted using Sanger Sequencing.

Results: A 36-year-old male presented with late-onset CIPO characterized by progressive constipation, vomiting, and weight loss. Genetic screening through WES was performed. Sequencing analysis in the patient revealed a hemizygous c.56G>T variant in the long-isoform of the *FLNA* gene (NM_001110556.2). Sanger sequencing confirmed the variant and demonstrated its segregation within the family: heterozygous in the mother and absent in the father and brother. This novel missense variant (p.Gly19Val) was classified as VUS according to ACMG guidelines.

Conclusion: This study reports the first case of late-onset CIIPX associated with a novel missense mutation (p.Gly19Val) in the *FLNA* gene. Located exclusively within the long isoform of filamin A, predominantly expressed in intestinal smooth muscle, this variant highlights the crucial role of this isoform in intestinal motility. Our findings expand the phenotypic spectrum of filaminopathies and provide insights into the pathogenesis of late-onset genetic CIPO.

P05.058.C Alport syndrome associated with a novel COL4A3 variant: clinical and genetic findings

Aydan Mengubas Erbas[1], *Zehra Manav Yigit*[1], *Ridvan Savas, MD*[1], *Dilek Yilmaz*[2], *Gokay Bozkurt*[1]

[1]*Aydin Adnan Menderes University, Faculty of Medicine, Department of Medical Genetics, Aydin, Turkey,* [2]*Aydin Adnan Menderes University, Faculty of Medicine, Department of Pediatric Nephrology, Aydin, Turkey.*

Background: Alport syndrome (AS) is caused by mutations in type IV collagen genes, leading to hematuria, progressive renal failure, hearing loss, and ocular abnormalities. Most cases have mutations in *COL4A5* (X-linked), while mutations in *COL4A4* and *COL4A3* cause the autosomal recessive form and, rarely, the autosomal dominant form. In this study, we report the variable clinical manifestations in seven individuals from the same family with consanguineous marriages, including four homozygous and three heterozygous carriers of a novel *COL4A3* variant.

Methods: Genetic analysis was conducted using next-generation sequencing and targeted variants were analyzed by Sanger sequencing.

Results: Seven patients were examined, four homozygous and three heterozygous for a novel, likely pathogenic c.2347_2370del variant in *COL4A3*. No ocular lesions were identified in any of the patients. Homozygous individuals, diagnosed at ages ranging from 2 to 8 years, all exhibited with early-onset nephrotic syndrome and hearing loss in two of them. Among the heterozygous individuals, one had been monitored for hematuria since age 10. Segregation analysis was performed on the parents of a patient, revealing that both were heterozygous carriers. Subsequent clinical evaluation detected microscopic hematuria in the mother (aged 31), whereas no renal pathology was observed in the father (aged 38). These findings suggest a more severe clinical course in homozygous individuals compared to heterozygous carriers.

Conclusion: This study provides additional evidence for the expanding phenotypic spectrum associated with the novel *COL4A3* variant, contributing to a better understanding of its clinical variability and implications for patient management.

P05.059.D Targeted sequencing of dyshormonogenesis-associated genes in congenital hypothyroidism cases with gland-in-situ from North Macedonia

Nikolina Zdraveska[1], *Violeta Anastasovska*[1], *Mirjana Kocova*[2]

[1]*University Children's Hospital, Faculty of Medicine, Ss Cyril and Methodius University in Skopje, Skopje, North Macedonia, The Republic of,* [2]*Faculty of Medicine, Ss Cyril and Methodius University in Skopje, Skopje, North Macedonia, The Republic of.*

Background: The prevalence of congenital hypothyroidism (CH) in the Republic of North Macedonia is approximately 1 in 1,670 live births, with over fifty percent presenting as "gland-in-situ" (GIS CH). GIS CH includes CH cases with dyshormonogenesis; however, the proportion of GIS CH cases harboring mutations in CH-associated genes has rarely been investigated. This research represents the first investigation into the genetic basis of CH in Macedonia.

Material: A phenotype-driven approach was used to screen known dyshormonogenesis-associated genes (TG, TPO, DUOX2, DUOXA2, SLC26A7, SLC5A5 (NIS), IYD, and TSHR in GIS cases and TSHR and PAX8 in cases with thyroid hypoplasia. The cohort included non-syndromic, iodine-sufficient CH cases ($n = 40$) exhibiting a range of biochemical thyroid dysfunction ranging from severe permanent to mild transient and subclinical CH, along with 11 familial cases.

Results: All CH cases were term-born, with birth weight >3,000 g, and thyroid morphologies included goiter ($n = 11$), thyroid hypoplasia ($n = 6$), and apparently normal-sized thyroid. Potentially pathogenic variants were identified in 14 cases, of which four were definitively causative. Oligogenic variants were detected in three cases. Seventeen variants (nine novel) were identified in TPO ($n = 4$), TG ($n = 3$), TSHR ($n = 4$), DUOX2 ($n = 4$), and PAX8 ($n = 2$) genes. No mutations were detected in DUOXA2, NIS, IYD, and SLC26A7.

Conclusion: The low mutation frequency observed in our cohort suggests that factors beyond established genetic causes, such as environmental influences or novel genetic etiologies, may contribute to the pathogenesis of CH.

P05.060.A Effects of long-term glucose and fructose consumption on liver ageing and Epigenetic changes

Mert Pekerbas[1,2], *Bilgesu Ak*[1], *Alper Baysal*[1], *Berrin Ozdil Bay*[3], *Huseyin Aktug*[3], *Erhan Pariltay*[1], *Ayca Aykut*[1], *Lutfiye Kanit*[4], *Haluk Akin*[1]

[1]*Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey,* [2]*Izmir Biomedicine and Genome Center, Izmir, Turkey,* [3]*Ege University Faculty of Medicine, Department of Histology and Embryology, Izmir, Turkey,* [4]*Ege University Faculty of Medicine, Department of Physiology, Izmir, Turkey.*

Background: Calorie restriction is well-known for slowing ageing and extending lifespan. White sugar, composed of glucose and fructose, is processed differently in liver cells. Glucose metabolism is tightly controlled by the enzyme phosphofructokinase-1 (PFK-1), while fructose bypasses this regulation. Consuming glucose and fructose together for a long time may promote an anabolic state, leading to senescence in liver cells.

Material and methods: Standard chow diet-fed rats were divided into four groups: a control group (water), a glucose group (20% glucose), a fructose group (20% fructose), and a mixed group (10% glucose + 10% fructose). Blood biochemical values, weight gain were measured and open field and rotarod tests were performed. Liver steatosis and senescence were assessed using hematoxylin-eosin and s-β-galactosidase staining. Expression and methylation-specific PCR analyses were performed for the genes related to ageing and metabolism.

Results: The glucose group gained the most weight and had the best performance in the open field test, while the mixed group had the poorest results in the rotarod test. Triglyceride levels were significantly higher in the glucose and mixed groups. Steatosis and cell senescence were only observed in the fructose and mixed groups. Methylation analysis revealed increased FOXO4 methylation in the mixed group, while *PKLR*, *PFKL*, and *DNMT1* methylation levels were elevated in both the fructose and mixed groups.

Conclusion: We found that prolonged glucose+fructose consumption leads to liver fat accumulation and cellular senescence, but methylation analyses did not fully explain the underlying mechanisms. Further research is needed to uncover the molecular pathways involved.

Istanbul/TURKIYE, Istanbul, Turkey,* [6]*Istanbul University, Istanbul Faculty of Medicine, Department of Medical Biology. Istanbul/TURKIYE, Istanbul, Turkey.*

Background: Lymphocyte Cytosolic Protein 1 (LCP1) is one of the important genes under investigation in NAFLD, but these studies are limited in adolescents. This study aimed to investigate the relationship between the LCP1 gene and obesity-NAFLD in adolescents.

Material and ethods: We included 86 obese and 45 healthy adolescents. We assessed hepatostatosis with ultrasonography and measured anthropometric features. Minisequencing was performed for LCP1 rs7324845 variant using genomic DNA isolated from samples and performed with detection primers using SnaPshot Multiplex Ready Reaction Mix and run on an automated capillary electrophoresis. Multiplex peaks were analyzed with GeneMapper 5 Software. We used Bayesian Kendall's tau test to assess the evidence for H0 (independence) and H1 (correlation) hypothesis, and frequentist statistics.

Cortisole	0.156	0.514	0.168	4.467	0.156	0.514	−0.053	0.238

Results: Adolecents (53.1% male) had a mean age of 169 ± 32 months. The frequency of AA, AG, and GG genotypes were 78.6%, 19.1%, and 2.3%, respectively. Hepatosteatosis was present in 46.9% among obese group. The obese group had more AG/GG genotypes ($p = 0.038$), however, genotypes were independent from clinical and laboratory features with anecdotal evidence (total bilirubin, TSH, triglyceride, birth weight, systolic blood pressure) and moderate evidence (BMI-SDS, WC-SDS, diastolic blood pressure). Also, hepatosteatosis was independent from LCP1 gene among obese group (BF_{10}:0.316) and among all cases (BF_{10}:0.171) with moderate evidence.

Conclusion: GG and AG genotypes were more frequent among obese group; however, these variants were independent from blood pressure, BMI, laboratory, and especially hepatosteatosis with anecdotal and moderate evidence.

Table 1. LCP1 rs7324845 Gene Variant distribution among groups

AA vs G	Control n(%)	Obese n(%)	Total	p
AA	40 (88.9)	63 (73.3)	103	0,038
AG / GG	5 (11.1)	23 (26.7)	28	
Total	45	86	131

P05.062.C Novel variant in the activin A receptor like type 1 *ACVRL1* gene associated with hereditary hemorrhagic telangiectasia

Hiroyuki Shimada[1], *Yasuto Sano*[2,3], *Yoshihiko Kawano*[1], *Junichiro Machida*[4], *Akiko Ota*[4], *Toru Iwasa*[5], *Shinya Hara*[1], *Hiroko Morisaki*[6], *Yoshihito Tokita*[3]

[1]*Department of Pediatrics, Toyota Memorial Hospital, Toyota, Aichi, Japan,* [2]*Department of Maxillofacial Surgery, School of Dentistry, Aichi-Gakuin University, Nagoya, Aichi, Japan,* [3]*Department of Disease Model, Institute for Developmental Research, Aichi Developmental Disability Center, Kasugai, Aichi, Japan,* [4]*Department of Genome Medicine, Toyota Memorial Hospital, Toyota, Aichi, Japan,* [5]*Department of Pediatric Cardiology, National Cerebral and Cardiovascular Center Research Institute, Suita, Osaka, Japan,* [6]*Department of Medical Genetics, Sakakibara Heart Institute, Fuchu, Tokyo, Japan.*

Background/objectives: Hereditary hemorrhagic telangiectasia (HHT) is an autosomal dominant vascular disorder characterized by recurrent epistaxis, skin/mucocutaneous telangiectasia, and organ/visceral arteriovenous malformations. Mutations in the *ENG*, *ACVRL1*, and *SMAD4* genes mainly cause HHT. *ACVRL1* is a type I receptor for TGF-beta family members and is important in vascular development.

Patients and methods: A 14-year-old female was clinically diagnosed with HHT. Saliva samples were obtained from the patient and her family members, followed by genomic DNA extraction. The proband's HHT-related genes were sequenced using an Illumina platform. Then, Sanger sequencing was employed to confirm the variant of *ACVRL1* detected in other family members with HHT.

Results: Genomic analysis revealed a novel missense variant in the extracellular domain coding region of the *ACVRL1* gene. No other genetic abnormalities were detected. Then, we confirmed that the family members with HHT shared the variant. Biochemical analyses demonstrated that the variant gene product impaired the function of the ALK1 receptor, suggesting that the amino acid substitution affects BMP ligands' binding to the receptor. In silico structural analysis further supported the pathogenic nature of the variant.

Conclusion: Identifying this novel missense mutation in the *ACVRL1* gene corroborated the patient's clinical diagnosis of HHT. We revealed that the mutation results in a loss of function of the *ACVRL1*, likely contributing to the development of HHT. These findings suggest that this variant is a causative mutation for HHT, expanding the mutation spectrum of the *ACVRL1* gene and providing insights into its molecular pathology.

P05.063.D Investigation of new genetic variants by whole exome Sequencing (WES) in Turkish MODY-X families

Mustafa Ozen[1,2], ***Betul Kesriklioglu***[1]

[1]*Istanbul University-Cerrahpasa Department of Medical Genetics, Istanbul, Turkey,* [2]*Baylor College of Medicine, Houston, TX, USA.*

Background: Maturity-onset diabetes of the young (MODY) is the most common type of monogenic diabetes. Different subtypes associated with 14 different genes have been described. For genetic diagnosis of MODY, NGS based multigene targeted panels for known genes are commonly applied. The genetic etiology, however; remains unexplained in approximately 20–30% of patients (MODY-X). In this study, we aimed to identify additional genes and novel variants in the MODY-X families.

Material and methods: WES was performed in at least two related patients in 5 families ($n = 10$) who were admitted to our clinic between 2020 and 2023 with a prediagnosis of MODY and whose genetic diagnosis could not be established by multigene targeted panels for the etiology of MODY.

Results: Two novel variants in *GIGYF1* gene in 2 different families and 1 novel variant in *SLC30A8* gene in 3 individuals from 2 different families were detected. Individual family analysis showed variants considered to be significant in previously reported genes of monogenic diabetes. In addition, novel variants in *GCKR*, *RFX7*, *RAP1GAP*, *EXOC7* genes, which were not previously shown in diabetic patients were identified.

Conclusion: WES contributes to deepen genetic research, identify new genes and variants and better understand the molecular pathogenesis of this disease. In addition to genes previously associated with diabetes, this study identified new candidate genes that may be associated with MODY. This is the first WES study of this scale in the MODY-X group in the Turkish population.

P05.065.B Investigation of absolute mtdna copy number and gene variants associated with mtdna function in obese adolescents

Sevde Hasanoglu Sayin[1], *Aylin Yetim Şahin*[1], *Yasemin Oyacı*[1], *Mustafa Pehlivan*[2], *Sacide Pehlivan*[3]

[1]*Institute of Graduate Studies in Health Sciences, Istanbul University, Istanbul, Turkey,* [2]*Department of Hematology, Istanbul Basaksehir Cam and Sakura City Hospital, Istanbul, Turkey,* [3]*Istanbul University, Istanbul Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey.*

Background: Obesity in adolescents is the most challenging public health problem of the twenty-first century and is associated with increased morbidity and premature death. This study aimed to investigate the absolute mtDNA copy number and peroxisome proliferator-activated receptor family (PPARs) and Peroxisome proliferator-activated receptor-γ coactivator-1-α (PPARGC1A) gene variants in obese adolescents.

Material and methods: A total of 183 individuals, 121 adolescents diagnosed with obesity and 62 healthy adolescents as the control group, were included in the study. PPARA, PPARG, PPARD and PPARGC1A gene variants in DNA samples isolated from the peripheral blood of the individuals were analyzed quantitatively using the PCR-RFLP method, and absolute mtDNA copy number was analyzed quantitatively using real-time PCR.

Results: When obese adolescents and healthy controls were compared, no statistically significant relationship was found in mtDNA copy number. No significant difference was found in genotype and allele frequencies of PPARA rs1800206, PPARG rs1801282, PPARD rs2016520 and PPARGC1A rs8192678 gene variants. However, PPARGC1A rs8192678 variant GG genotype was found significantly higher in obese adolescents and GA genotype was found significantly higher in healthy controls ($p = 0.033$, $p = 0.041$, respectively).

Conclusion: This is the first study in the literature to investigate absolute mtDNA copy number and PPARs and PPARGCA1 gene variants in obese adolescents. It has been shown that the high frequency of PPARGC1A-rs8192678 missense mutation GG genotype may be associated with adolescent obesity. However, larger study groups and evaluation of clinical data in patient groups of different ethnic origins will provide better clarification of this relationship.

P05.066.C Variant in *RAF1* in a patient with 46,XY differences of sex development (DSD)

Nadine Hornig[1], *Inga Nagel*[1], *Maj-Britt Salewski*[1], *Olaf Hiort*[2], *Almuth Caliebe*[1], *Malte Spielmann*[3]

[1]*Institute of Human Genetics, University Hospital Schleswig-Holstein, Kiel, Germany,* [2]*Division of Paediatric Endocrinology and Diabetes, Department of Paediatrics and Adolescent Medicine, University of Lübeck, Lübeck, Germany,* [3]*Institute of Human Genetics, University Hospital Schleswig-Holstein, Lübeck, Germany.*

Background: *RAF1* (Raf-1 proto-oncogene, serine/threonine kinase) encodes a kinase involved in the MAPK/ERK signaling pathway, crucial for cell growth, differentiation, and survival. Activating pathogenic variants in *RAF1* often result in hyperactivation of signaling pathways, leading to developmental abnormalities or uncontrolled cell proliferation and are associated with Rasopathies, like Noonan syndrome (OMIM #611553) as well as Noonan syndrome with multiple lentigines (OMIM #611554). Clinical features of Noonan syndrome with multiple lentigines include multiple lentigines typically from the age four, café-au-lait spots, craniofacial dysmorphisms, cardiovascular anomalies, sensorineural hearing loss, short stature, and genital anomalies.

Material and methods: We acquired the patient's family history and clinical as well as hormonal data. Chromosome banding analysis and exome sequencing were performed using blood samples. The disease's severity of our patient was assessed and literature search for similar patients was performed.

Results: The patient was born following in vitro fertilization to non-consanguineous parents. The family history was uneventful. He presented with penoscrotal hypospadias, multiple Café-au-lait spots, pronounced axillary freckling and proximal placement of the thumbs. Chromosome banding analysis showed a 46,XY karyotype. Whole-exome sequencing revealed a heterozygous variant of unknown significance in *RAF1* (NM_002880.4:c.1687C>G; p.Arg563Gly). The variant was not present in the gnomAD database and was located in a conserved protein domain involved in protein-protein interaction (CADD score: 28). A segregation analysis is pending.

Conclusion: We report a patient with 46,XY DSD carrying a variant in RAF1. So far only a few patients with pathogenic variants in *RAF1* and a DSD phenotype have been described.

Introduction: Wolfram Syndrome 1 (WFS1) is characterized by diabetes insipidus, diabetes mellitus, optic atrophy (OA), deafness, along with additional multisystem manifestations. Wolfram-like syndrome (WLS) is heralded by hearing impairment sharing many WFS1 manifestations. Both conditions are caused by pathogenic *WFS1* variations, inherited in an autosomal recessive (WFS1) and autosomal dominant (WLS) manner. Prevalence of WFS1 spectrum disorders varies worldwide, while a founder variant: c.1672C>T, p.(Arg558Cys), present in 1.34% of Ashkenazim, leads to high local prevalence with unique manifestations. We describe herein the national Israeli registry of WFS1 spectrum disorders.

Materials and methods: Individuals attending the WFS1 designated clinic at Sheba Medical Center were enrolled, along with individuals referred from centers nationwide. Ongoing clinical data, based on a designated questionnaire was updated at regular intervals.

Results: Since 2021, 32 individuals (10 males, age range 4–75 years), were enrolled (WFS1:$n = 28$, WLS $= 4$), representing 22 families. Homozygotes ($n = 22$) or compound heterozygotes ($n = 4$) of the c.1672C>T founder variant, were significantly older at diagnosis, with delayed OA compared to individuals harboring other variants ($n = 6$, $p < 0.01$). Among the former, females were diagnosed at a significantly older age ($n = 14$) ($p < 0.01$). Hearing loss was present among all WLS ($n = 3$), and least common among homozygotes for the c.1672C>T variant ($n = 4$, 18%). Additional symptoms included urinary ($n = 18$), psychiatric ($n = 6$), impaired balance ($n = 5$), cognitive decline ($n = 3$) among others.

Conclusions: The Israeli registry represents the unique national landscape of WFS1 spectrum disorders. This registry may enhance

our understanding, improve patient care, and serve as an infrastructure for clinical trials and drug development.

P05.068.A Novel biallelic Splicing variant identified in PKHD1 gene in a consanguineous Iranian pedigree with autosomal recessive polycystic kidney disease

Razieh Ebrahimi Askari[1], *Sara Sadeghzadeh*[2], *Nasrin Ghasemi*[1,3]

[1]*Department of Medical Genetics, faculty of Medicine, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, Yazd, Iran, Islamic Republic of,* [2]*Department of Molecular Medicine, faculty of Medicine, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, Yazd, Iran, Islamic Republic of,* [3]*Abortion Research Center, Yazd Reproductive Sciences Institute, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, Yazd, Iran, Islamic Republic of.*

Background: Variants of the polycystic kidney and hepatic disease 1 (PKHD1) gene are associated with polycystic kidney disease 4, with or without hepatic disease (PKD4). The most typical disease expression occurs in neonates and includes a history of oligohydramnios, massively enlarged kidneys, and the 'Potter' sequence with pulmonary hypoplasia that leads to respiratory insufficiency and perinatal death in approximately 30% of affected newborns. This study aimed to identify the genetic cause in an Iranian consanguineous pedigree with apparently autosomal recessive polycystic kidney disease (ARPKD).

Material and methods: The genomic DNA was extracted from the affected fetal tissue. Whole-exome sequencing (WES) and bioinformatic analysis were used to identify the potential genetic cause. The identified variant in PKHD1 gene was confirmed in the fetus and peripheral blood samples of the parents bysanger sequencing.

Results: Novel biallelic variant, chr6:51890981 T>G, was identified in the PKHD1 gene (NM_138694.4, c.3629-2A>C) by WES; that has not been previously reported. Based on the analysis performed on the data obtained from sanger sequencing, the couple were carriers. Bioinformatic splice prediction tools revealed that the variant strongly impacts splice site function. Based on the ACMG guidelines, this variant is categorized as likely pathogenic.

Conclusion: A novel likely pathogenic variant of PKHD1, chr6:51890981 T>G, was found in an Iranian consanguineous pedigree with ARPKD, which enriches the variant spectrum of the PKHD1 gene and provides a basis for genetic counseling and the diagnosis of ARPKD.

P05.069.B A mutation in exon 1 of the androgen receptor gene results in complete androgen insensitivity syndrome

Maria Balzo[1], *Eriselda Profka*[1,2], *Alessandra Mangone*[1,2], *Mariarosa Ferrara*[3], *Ilaria Bestetti*[3], *Palma Finelli*[3,4], *Giovanna Mantovani*[1,5], *Silvia Maria Tabano*[3,4]

[1]*Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [2]*Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy,* [3]*Laboratory of Medical Genetics, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [4]*Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy,* [5]*Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy.*

Background: Androgen insensitivity syndrome is an X-linked recessive disease due to loss-of-function mutations of the *AR* gene (Xq 11–12). The disease affects individuals phenotypically females with 46, XY karyotype. Different *AR* mutations lead to diverse impairment of protein function, thus determining a wide spectrum of phenotypes: mild, partial, complete (CAIS) insensitivity to androgens (OMIM#300068). Currently, about 1000 mutations have been identified in *AR* and linked to AIS, mainly located in the hormone-binding domain.

Material and methods: We describe a female with CAIS, diagnosed at 18 years old due to primary amenorrhea, with 46, XY karyotype and absence of Müllerian structures. Gonadectomy was performed, confirming testicular tissue without signs of malignancy. We performed a clinical exome using next-generation sequencing (SureSelect CDCFE, Agilent-Technologies), using Illumina Platform.

Results: The proband showed a small insertion in exon 1 of the *AR*: (NM_000044.6): c.195_196insTAGCAGCAG, p.Gln65_Gln66insTerGlnGln. The variant has never been described; it was classified as likely pathogenic in databases (e.g. Varsome). Indeed, this variant introduces a stop codon, likely leading to a premature protein truncation, and consequent loss of function.

Conclusion: We identified a small insertion within exon 1 of *AR* gene, near to the start codon. To our knowledge, a similar genetic anomaly was only described once in a proband with clinical manifestations similar to the present case (https://doi.org/10.1016/j.steroids.2019.02.007). Our findings reinforce the role of exon 1 insertions in determining AIS and further expand the database of *AR* gene mutations.

P05.070.C An atypical case of Alström Syndrome: challenging the Classic phenotype

Merve Tanrisever Turk, *Gizem Ürel Demir, Gulen Eda Utine, Pelin Ozlem Simsek Kiper*

Hacettepe University Faculty of Medicine, Department of Pediatric Genetics, Ankara, Turkey.

Background: Alström syndrome (AS, MIM#203800) is an autosomal recessive disorder caused by biallelic pathogenic variants in the ALMS1 gene. AS is characterized by rod-cone dystrophy, sensorineural hearing loss (SNHL), obesity, cardiomyopathy, non-alcoholic fatty liver disease and chronic renal disease. Affected individuals may also exhibit developmental delay and endocrine problems including insulin resistance, type 2 diabetes mellitus, hypertriglyceridemia, hypothyroidism, hypogonadism and obesity. Although there is wide clinical variability among affected individuals, even within the same family, rod-cone dystrophy, obesity, short stature, insulin resistance, and SNHL are typical findings observed in most patients, aiding in the prediagnosis of the disease. Here, we present a male patient whose body weight was below −2 SD, in contrast to the commonly observed obesity in patients with AS.

Material and methods: Exome sequencing was performed.

Results: The patient presented with microcephaly, failure to thrive (BMI: −1.44 SD), dysmorphic features, bilateral SNHL, astigmatism, hypothyroidism, adrenal insufficiency, intellectual disability, and a history of acute rheumatic fever carditis. Abdominal ultrasound, liver function tests, and renal function

tests were normal. Karyotype analysis and chromosomal microarray were normal. Exome sequencing identified a novel, de novo homozygous variant c.1223_1237+1del in *ALMS1*, classified as "likely pathogenic" according to ACMG criteria.

Conclusion: Although AS presents with a broad spectrum of clinical findings, obesity is the most common feature after rod-cone dystrophy across all age groups. However, it is important to recognize that AS can also occur in non-obese individuals who exhibit other characteristic findings.

P06 Skeletal, connective tissue, ectodermal and skin disorders

P06.001.D Cellular senescence in pseudoxanthoma elasticum

Robbe Derudder[1], *Daniela Quaglino*[2], *Lukas Nollet*[1], *Matthias Van Gils*[1], *Mohammad Jakir Hosen*[3], *Janina Tiemann*[4], *Paul Coucke*[1], *Olivier Vanakker*[1]

[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Life Science, University of Modena and Reggio Emilia, Modena, Italy,* [3]*Department of Genetic Engineering and Biotechnology, School of Life Sciences, Shahjalal University of Science and Technology, Sylhet, Bangladesh,* [4]*Institut für Laboratoriums-und transfusionsmedizin, Herz-und Diabeteszentrum Nordrhein-Westfalen, Universitätsklinik der Ruhr-Universität Bochum, Bad Oeynhausen, Germany.*

Background: Pseudoxanthoma elasticum (PXE) is a rare hereditary disorder caused by bi-allelic *ABCC6* mutations, leading to pathological calcification in the skin, arteries, and eyes. Increasing evidence suggests that cellular senescence—a state of irreversible cell cycle arrest triggered by DNA damage, oxidative stress, and telomere shortening—plays a key role in PXE pathophysiology. Senescent cells contribute to tissue dysfunction through the senescence-associated secretory phenotype (SASP), which promotes chronic inflammation and extracellular matrix (ECM) remodeling. NF-κB, a central regulator of SASP, accelerates senescence, while IL-6 amplifies pro-inflammatory signaling and exacerbates disease progression. Furthermore, excessive activation of the DNA damage response (DDR) may further drive pathological changes in PXE. This study investigates the roles of NF-κB, IL-6, and DDR activation in PXE to identify potential therapeutic targets.

Material and methods: Skin tissue (n = 4) and dermal fibroblasts (n = 9) from PXE patients and matched controls (n = 9) were analyzed. NF-κB was assessed via immunofluorescence, and calcium deposits were visualized using Von Kossa staining. RT-qPCR was used to evaluate differential gene expression of *NF-κB*, *IL6*, DDR targets like *PARP1* and downstream targets.

Results: NF-κB was highly expressed in PXE skin, co-localizing with osteogenic markers and calcium deposits. PXE fibroblasts showed increased *NF-κB*, *PIK3CA*, *AKT1*, *PARP1*, *ATM*, *p21*, *p53*, *RUNX2* and *IL6* mRNA levels, while *SIRT1* mRNA levels were decreased.

Conclusion: Disrupted pathways in PXE, including DNA damage response, PARP1 activation, and NF-κB upregulation, link PXE to cellular senescence. Targeting senescence pathways and SASP may provide new therapeutic strategies to slow disease progression and improve patient outcomes.

P06.002.A Body site-specific transcriptomic signature in psoriatic lesions

Martina Krušič[1], *Maruška Marovt*[2], *Mario Gorenjak*[1], *Uroš Potočnik*[1,3,4]

[1]*Center for Human Molecular Genetics and Pharmacogenomics, Faculty of Medicine, University of Maribor, Maribor, Slovenia,* [2]*Department of Dermatovenerology and Venereology, University Medical Centre Maribor, Maribor, Slovenia,* [3]*Faculty of Chemistry and Chemical Engineering, University of Maribor, Maribor, Slovenia,* [4]*Department for Science and Research, University Medical Centre Maribor, Maribor, Slovenia.*

Background: Non-invasive methods like tape-stripping have been increasingly used to identify response biomarkers in psoriasis. Some psoriatic lesions show resistance to biological therapies and respond differently. This study aimed to investigate molecular differences between individual psoriatic lesions.

Material and methods: Tape-stripping method was used to obtain skin samples from active lesions. RNA from psoriatic skin was extracted of 24 adult Slovenian patients with plaque psoriasis. Skin samples were obtained from four different body parts (trunk, scalp, upper, and lower extremities), depending on the patient's clinical presentation. All patients were naïve to biological therapy. Additionally, both lncRNA and mRNA 100 bp paired-end libraries were constructed. Furthermore, RNA-seq analysis was performed to compare different anatomical sites, followed by gene ontology analysis.

Results: RNA-seq analysis revealed distinct miRNA expression patterns across different anatomical psoriatic lesions. Our results highlight several miRNAs that may play pivotal roles in psoriasis pathogenesis and lesion-specific molecular differences. Notably, miR-4323, miR-203a, miR-4274, *MIRLET7A1*, *MIRLET7G*, miR-205, and miR-200b were identified across multiple comparisons, suggesting their involvement in the regulation of psoriasis lesions. These miRNAs show potential as key regulators of the molecular divergence between different lesion types; however, their exact roles in the disease's pathophysiology remain to be fully elucidated.

Conclusion: The present study highlights the importance of our results in elucidating molecular pathways in different anatomical psoriatic lesions. These findings provide valuable insights into psoriatic lesion heterogeneity and could aid in identifying novel biomarkers and therapeutic targets for difficult-to-treat psoriasis cases.

Background: IGF1R, a ubiquitous cell-surface receptor belonging to the insulin receptor (INSR) sub-family of receptor tyrosine kinases, mediates IGF-I's growth-promoting actions. Most pathogenic *IGF1R* variants are heterozygous loss-of-function mutations causing haploinsufficiency and moderate growth impairment. Very rare biallelic hypomorphic variants lead to severe growth impairment and microcephaly. To date, only 10 patients with homozygous or compound heterozygous *IGF1R* variants have been reported. Here we report a novel homozygous *IGF1R* pathogenic variant in two siblings with microcephalic dwarfism and additional comorbidities, demonstrating its pathogenicity through various functional studies.

Material and Methods: Whole-exome sequencing was performed in two siblings presenting with microcephalic dwarfism, mild intellectual disability, deafness, congenital cardiac malformations, partial vermis hypoplasia, dysmorphic features, and skeletal abnormalities. Functional studies included patient-derived fibroblasts analysis, 3D protein modeling, generation of a CRISPR/Cas9 gene-edited $Igf1r^{KI/KI}$ knock-in mouse model, and patient-based iPSC models.

Results: A homozygous *IGF1R* c.2132_2143del variant was identified. This in-frame deletion in the extracellular region did not reduce receptor expression or alter cell surface localization but significantly compromised IGF-I-induced signaling. The $Igf1r^{KI/KI}$ mouse model recapitulated severe growth impairment, IGF-I resistance, and impaired skeletal integrity, including reduced bone strength and defective anterior fontanel calcification. Patient-derived iPSCs showed reduced bone mineralization, partly due to RUNX2 dysregulation, which was reversed upon gene-editing to wild-type.

Conclusion: This study report a rare novel homozygous hypomorphic *IGF1R* variant and highlights the critical importance of IGF1R in osteogenesis and skeletal maturation through analyses of patient-derived fibroblasts, the first viable knock-in mouse model, and human iPSC models.

P06.004.C Zebrafish as a model for Myhre syndrome: growth deficits and vascular narrowing (Award Candidate)

Eva Vanbelleghem[1,2], *Michiel Vanhooydonck*[1], *Maxim Verlee*[1], *Patrick Sips*[1], *Bert Callewaert*[1,2]

[1]*Ghent University, Center of Medical Genetics Ghent, Ghent, Belgium,* [2]*Ghent University Hospital, Department of Medical Genetics, Ghent, Belgium.*

Background: Myhre syndrome (MS, MIM 139210) is a rare multisystemic disorder caused by recurrent pathogenic missense variants in SMAD4. The clinical features comprise variable neurocognitive development, autism, recognizable craniofacial features, short stature, hearing loss, a thickened skin, joint limitations, diverse cardiovascular and airway manifestations including arterial stenosis, and increased fibrosis often following trauma or surgery.

Material and methods: We developed a zebrafish model for Myhre syndrome. Using CRISPR technology, we generated heterozygous and homozygous smad4a p.Ile495Thr knock-in (KI) zebrafish, which correspond to the known human SMAD4 p.Ile500Thr variant. The knock-in was crossed with the transgenic Tg(kdrl:EGFP) zebrafish line to visualize the ventral aorta and aortic branches.

Results: At 5 days post-fertilization (dpf), vasculogenesis was not different in p.Ile495Thr KI versus wild type controls. At 10 dpf, heterozygous and homozygous KI zebrafish exhibited a significant reduced diameter of the ventral aorta between aortic arch two and three, as well as a decreased aorta diameter adjacent to the bulbus arteriosus compared to wild-type controls. Cardiac ultrasounds of 6-month-old zebrafish showed no significant abnormalities. Measurements of 4-month-old zebrafish revealed decreased body length in homozygous mutants compared to wild type controls. Mortality at three months post fertilization seems higher in homozygous KI zebrafish (up to 50%).

Conclusion: Our zebrafish model for MS exhibits reduced body length, narrowing of the ventral aorta, and potentially increased mortality. Further phenotypic assessment and multi-omic analyses are underway to elucidate the underlying disease mechanisms.

Background: Approximately 200 genetic skeletal disorders can present prenatally, detectable through ultrasound abnormalities during pregnancy. Severe forms are typically identified during the first or second trimester, whereas milder phenotypes are recognized later, in the third trimester. Diagnosing skeletal dysplasia prenatally is challenging due to the large number of disorders and the frequent overlap in clinical findings that can be detected by ultrasound.

Material and methods: This study, conducted at Karolinska University Hospital between 2015 and 2022, examines the genetic and radiographic findings in 32 fetuses (14 female and 18 male, from unrelated families) with skeletal abnormalities detected on prenatal ultrasound and confirmed by radiographs either at birth or after pregnancy termination. Fetal DNA samples underwent genome sequencing using an in silico skeletal dysplasia gene panel as singletons for all fetuses. As a second step, trio genome sequencing was performed for six fetuses with unsolved molecular diagnoses, involving both the fetus and parents.

Results: The diagnostic yield of genome sequencing was 72%, with pathogenic or likely pathogenic variants identified in 23 of the 32 fetuses. Additionally, four variants of uncertain significance, strongly suspected to be causative based on clinical and radiographic features, as well as structural protein analyses, were identified in four fetuses with autosomal recessive conditions. The molecular diagnoses for five fetuses remain unsolved.

Conclusion: By combining detailed phenotypic data with singleton genome sequencing, we achieved a genetic diagnosis in 72% of the 32 cases of fetal genetic skeletal disorders investigated at the Karolinska University Hospital.

P06.006.A Functional and clinical significance of splicing variants in patients with osteogenesis imperfecta

Iuliia Viakhireva, *Elena Merkurieva, Maksim Ivanov, Tatyana Nagornaya, Nadezhda Moiseeva, Tatyana Cherevatova, Viktoria Zabnenkova, Tatyana Markova, Mikhail Skoblov, Head of the Department*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Osteogenesis imperfecta types I-IV (OI) represents a group of inherited bone disorders. Splicing variants constitute a significant proportion of all pathogenic variants, yet they remain among the most challenging to interpret due to their diverse mechanisms of altering mRNA structure and function.

Material and methods: For molecular diagnostics of patients, WES or WGS was performed. SpliceAI tool was used to predict splicing variants. The SpliceAI tool was utilized to predict the impact of splicing variants. To investigate splicing alterations, we constructed 12 minigenes encompassing all exons of *COL1A1* and 7 minigenes containing 20 out of 52 exons of *COL1A2*. To assess splicing patterns, HEK293T cells were transfected with variant-containing vectors, and splicing alterations were analyzed using RT-PCR, Sanger sequencing, and fragment analysis.

Results: We collected a cohort of 184 patients with various types of osteogenesis imperfecta (OI). Among them, 133 harbored variants in COL1A1, and 51 had variants in COL1A2. Bioinformatic analysis identified 29 variants in COL1A1 and 9 variants in COL1A2 as potentially affecting splicing. Additionally, we selected 40 variants from the literature, including 12 exonic variants, 19 lethal variants, and 13 splice site region deletions. We also included 10 frequent variants from gnomAD with high-confidence predictions. Overall, 68 of 71 variants showed splicing changes, including exon skipping causing in-frame deletions or out-of-frame shifts, leading to frameshifts and premature stop codons.

Conclusion: In total, we analyzed 71 splicing variants in patients with OI, revealing how diverse splicing alterations correlate with the severity of clinical presentations.

P06.007.B Knock-in mice harbouring an auriculocondylar syndrome-causing *PLCB4* variant display anomalies of the jaw skeleton and of neonatal breathing

*Nancy Vegas[1], Nelina Ramanantsoa[2], **Charlotte Guillouet**[1], Amelia Madani[2], Nabila Djaziri[1], Nathaly Romero[2], Thomas Bourgeois[2], Jorge Gallego[2], Jeanne Amiel[3], Boris Matrot[2], Chris Gordon[4]*

[1]Genetics of Developmental Disorders, Imagine institut, Paris, France, [2]NeuroDiderot-Inserm UMR 1141, Robert Debré Hospital, Paris, France, [3]Necker Hospital, INSERMGenetics, Paris, France, [4]Imagine Institute, Paris, France.

Background: Auriculocondylar syndrome (ACS) is a rare mandibulofacial dysostosis characterized by "question mark" ear dysplasia and homeotic transformation of the lower jaw into an upper jaw-like structure, probably due to deregulation of the endothelin pathway during development of the branchial arches. Some ACS patients display hypoventilation during sleep. Heterozygous missense variants clustered in the catalytic domain of *PLCB4* are the most frequent cause of ACS. Here we analysed the developmental consequences of an ACS-causing variant in *Plcb4* knock-in mice.

Material and methods: Mice harbouring the recurrent *Plcb4* variant p.Arg621Cys (R621C) were generated by targeted replacement. Craniofacial structures were examined at embryonic day 18.5 by skeletal staining. Respiratory flow and abdominal movements were measured for one hour at birth. Obstructive breaths were revealed by abdominal movements during apnoea.

Results: $Plcb4^{R621C/R621C}$ mice have a shorter mandible and hypoplasia of the mandibular processes, as observed in other mouse models with reduced endothelin signalling in the mandibular prominence. $Plcb4^{R621C/R621C}$ and $Plcb4^{R621C/+}$ mice have an ectopic bone on either side of the basisphenoid that variably extends from the pterygoid process to the tympanic ring. Homozygous pups die within 12 hours of birth due to severe hypoventilation, apnoeas and obstructive breaths, accompanied by loss of chemosensitivity to hypercapnia. Heterozygotes show normal ventilation in air and a reduced chemosensitivity to hypercapnia that normalizes by 8 days of life.

Conclusion: Our data suggest a negative effect of the *Plcb4* variant on endothelin signalling in the mandibular prominence and an important role for *Plcb4* in the control of breathing.

P06.008.C Unraveling the complex NOTCH1-SERCA2 interplay in Darier's Disease: insights into genotype-phenotype correlations and pathogenic mechanisms

Valeria Barili[1], *Erika De Sensi[1], Barbara Moschella[1], Ilenia Rita Cannizzaro[1], Antonietta Taiani[1], Anita Luberto[1], Sabrina Busciglio[1], Elisa Perlangeli[1], Sara Zanelli[1], Luigi Giorgio Sergi[1], Enrico*

Ambrosini[2], Davide Martorana[2], Patrizia Caggiati[2], Bruno Lorusso[1], Vera Uliana[2], Giovanni Roti[1], Antonio Percesepe[1]

[1]University of Parma, Parma, Italy, [2]University Hospital of Parma, Parma, Italy.

Background: Darier's Disease(DD) is a rare dominantly inherited genodermatosis caused by *ATP2A2* variants, leading to loss of desmosomal adhesion and abnormal keratinization. *ATP2A2* encodes the SERCA2 transporter for calcium trafficking to the endoplasmic reticulum. The molecular mechanism underneath *ATP2A2* alterations is not understood. Interestingly, in other disease models, SERCA2 regulates NOTCH1 signaling, and its inhibition inactivates the pathway.

Material and methods: we collected patients' blood and skin biopsies: i)to perform transcriptomic RNA-sequencing analysis and Spatial transcriptomics on affected and unaffected subjects; ii)to generate keratinocytes primary cells for expression analysis of the NOTCH1-downstream effector targets(*HES1*,*HEY1*,*c-MYC*); iii)to investigate NOTCH1 signaling deregulations through immunohistochemistry on FFPE bioptic samples. Furthermore, we generated variant specific-*ATP2A2* overexpression plasmid library to evaluate variant impact on the NOTCH1 signaling by performing in vitro functional and biochemical assays(Western-blot,qPCR,Luciferase-assays).

Results: The project successfully identified a pathogenic role of NOTCH1 receptor-mediated pathway deregulations which correlate with the genetic and the histological features observed in patients with Darier's disease. Different variants were found to have distinct effects on NOTCH1 signaling, highlighting different impacts on disease manifestations. Moreover, we define a DD transcriptomic gene signature and spatial profiles, focused on metabolic, ribosomal and immunological deregulations. We pointed out a molecular dependency of NOTCH1 pathways and *ATP2A2* defects through the effects evaluation of patient-specific variant overexpression and by ex vivo assays based on patient-derived primary cell lines and tissue IHC.

Conclusion: Gaining insight into the molecular network between SERCA2 and NOTCH1 in DD could pave the way for the development of novel and effective therapeutic approaches.

P06.009.D A novel form of autosomal dominant spondylocostal dysostosis in three unrelated families caused by the same heterozygous pathogenic variant in *MESP2*

Aneta Malesa[1], *Maria I. Arismendi[2], Gabriela A. Vasques[2], Alexander A. L. Jorge[2], Enrique Galán-Gómez[3], Karen E. Heath[4], Wim Van Hul[5], Geert Mortier[1,6], Gretl Hendrickx[1]*

[1]Laboratory for Skeletal Dysplasia Research, Department of Human Genetics, KU Leuven, Leuven, Belgium, [2]Division of Endocrinology and Genetic Endocrinology, University of São Paulo School of Medicine, São Paulo, Brazil, [3]Clinical Genetics Unit. University Children's Hospital, Badajoz, Spain, [4]Institute of Medical & Molecular Genetics (INGEMM), Hospital Universitario la Paz and UMDE-ERN BOND, Madrid, Spain, [5]Department of Medical Genetics, Antwerp University Hospital and University of Antwerp, Antwerp, Belgium, [6]Center for Human Genetics, University Hospital Leuven, Leuven, Belgium.

Background: Spondylocostal dysostosis (SCD) is a rare genetic bone disorder characterized by disproportionate short stature, scoliosis, and defects of vertebrae and rib formation occurring during embryonic development. SCD typically shows a recessive inheritance and several causal genes have been identified. These genes play a crucial role in somitogenesis and the subsequent formation of the vertebral column. Only in one family with a dominant inheritance a heterozygous mutation in TBX6 was identified.

Material and methods: Genome sequencing was performed on three TBX6-negative unrelated families with dominant SCD. Prediction programs were used to assess the impact of the identified mutation. The effect of the mutation on Notch signaling and subcellular protein localization was verified by immunostaining and luciferase reporter assays.

Results: Genome sequencing on a Belgian family with dominant SCD led to the identification of a heterozygous pathogenic MESP2 variant (c.268G>A; p.Glu90Lys). The same mutation was identified in a Brazilian and a Spanish family with a dominant form of SCD. The p.Glu90Lys variant was evaluated as disease-causing in silico and affects a highly-conserved amino acid in the bHLH domain of the MESP2 transcription factor, responsible for DNA binding. Functional studies demonstrated an impaired regulation of LFNG expression and a more dominant nuclear localization of p.Glu90Lys MESP2. These data strongly suggest a dominant negative effect.

Conclusion: We provide the first evidence that a heterozygous mutation in MESP2 can cause a dominant form of SCD. Ongoing studies aim to further determine the effects of this mutation on somitogenesis and vertebral segmentation.

P06.010.A Familial hidradenitis suppurativa linked to GJB3 mutation: disruptions in keratinocyte proliferation and differentiation

Elena Maria Nardacchione[1], *Ronald Rodrigues Moura[2], Blendi Ura[2], Eduardo Sommella[3], Nour Balasan[2], Barbara Vergani[4], Giorgia Cardinali[5], Daniela Kovacs[6], Hassan Riad[7], Sergio Crovella[7], Paola Maura Tricarico[2]*

[1]University of Trieste, Trieste, Italy, [2]IRCCS Burlo Garofolo, Trieste, Italy, [3]University of Salerno, Salerno, Italy, [4]University of Milano-Bicocca, Monza, Italy, [5]San Gallicano Dermatological Institute - IRCCS, Rome, Italy, [6]San Gallicano Dermatological Institute - IRCCS, Roma, Italy, [7]Hamad Medical Corporation, Doha, Qatar.

Background: Mutations in key genes can profoundly impact skin health, altering fundamental biological processes and contributing to the development of chronic conditions. Among these, familial hidradenitis suppurativa (fHS) remains a particularly challenging disorder, with its complex genetic and environmental interactions still not fully understood.

Material and methods: To explore potential genetic contributions to fHS we performed WES on DNA from multiple affected members, looking for new or rare heterozygous variants with a significant predicted impact on protein function. To investigate the functional impact, we introduced the SNV of interest into the keratinocyte cell line using CRISPR/Cas9 genome editing, generated a 3D human epidermal equivalents and performed RT-PCR, western-blot, microscopy assays, cell-proliferation assays and proteomic analysis.

Results: WES analysis revealed a shared heterozygous frameshift SNV in the GJB3 gene, the first instance of a GJB3 mutation being linked to fHS. The GJB3 gene encodes a connexin protein, which plays a crucial role in gap junctions, the structures

responsible for enabling communication between keratinocytes. This mutation appears to significantly change GJB3 gene and protein expression, alter the gap junction morphology and significantly increase the proliferation rate. Gene ontology enrichment analysis of proteomic data highlighted significant alterations in molecular functions and biological processes related to cell adhesion, skin structure, and epidermal maintenance.

Conclusion: This study provides the first evidence linking a variation in GJB3 gene to fHS, opening new avenues for understanding the molecular mechanisms of the disease. Our functional investigation revealed that variation compromises cell-cell communication channels, potentially leading to dysregulated keratinocyte proliferation and impaired differentiation.

P06.011.B THBS2 gene variants as a putative emerging molecular cause for hypermobile Ehlers Danlos Syndrome/ Hypermobility spectrum disorders. A case series

Niccolò Di Giosaffatte[1,2], *Alessandro Ferraris*[2], *Filippo Camerota*[3], *Francesca Clementina Radio*[2], *Valentina Lodato*[2], *Michele Valiante*[2], *Chiara Todini*[4,2], *Marianxhela Dajko*[4,2], *Daniela Formicola*[2], *Irene Bottillo*[4,2], *Paola Grammatico*[4,2]

[1]*Department of Molecular Medicine, "Sapienza" University of Rome, Rome, Italy,* [2]*Division of Medical Genetics, San Camillo-Forlanini Hospital, Rome, Italy,* [3]*Physical Medicine and Rehabilitation Division, Sapienza University, Umberto I University Hospital, Rome, Italy,* [4]*Department of Experimental Medicine, "Sapienza" University of Rome, Rome, Italy.*

Background: The Ehlers Danlos syndromes (EDS) are a group of hereditary connective tissue disorders with common features including joint hypermobility, hyperextensible skin and tissue fragility. Genetic testing is informative for a definitive diagnosis in EDS subtypes with a known causative gene, but some patients with a clinical diagnosis, especially those with the hypermobile type (hEDS), still lack confirmation at molecular analyses. Moreover, clinical distinction between hEDS and Hypermobility Spectrum disordes (HSD) can be challenging. Recently, a novel dominantly inherited EDS-like phenotype has been described in association with a missense variant in the *THBS2* gene. Main reported features were joint dislocations, atrophic scarring, prolonged bleeding time and age-related aortic dilatation and rupture.

Material and methods: Negative whole exome sequencing analyses of 209 patients with a clinical diagnosis of hEDS or HSD were revaluated for variants in THBS2. Clinical features at first referral and those resulted from reverse phenotyping of the identified cases were collected and compared to those already reported.

Results: We identified 7 patients (3%) carrying a missense variant in *THBS2*. In silico predictions indicated a likely disruptive effect for each variant. Although our case series has not yet revealed major vascular complications, we did observe the presence of vascular malformations and/or aortic ectasia.

Conclusion: Given its recent identification, this new putative form of EDS necessitates further validation in larger cohorts. Considering the late onset of aortic rupture in the initial family described, our findings suggest that precautionary surveillance for vascular complications should be considered for patients harbouring *THBS2* variants.

P06.012.C Further evidence that bi-allelic pathogenic variants in IFT74 are a novel cause of skeletal ciliopathy and implications for diagnostic testing

Tessi Beyltjens[1], *Tjakko van Ham*[2], *Nikolas Kuehn*[2], *Wim Wuyts*[3], *Marjan De Rademaeker*[3]

[1]*Center for Medical Genetics Ghent, Ghent University Hospital, 9000 Ghent, Belgium,* [2]*Department of Clinical Genetics, Erasmus MC, University Medical Center Rotterdam, PO Box 2040, 3000 Rotterdam, Netherlands,* [3]*Department of Medical Genetics, University of Antwerp and University Hospital of Antwerp, 2650 Edegem, Belgium.*

Background: Skeletal ciliopathies are autosomal recessive disorders sharing characteristic clinical and radiographic features. Genes involved frequently encode intraflagellar transport proteins. Bi-allelic *IFT74* variants are rare causes of Bardet-Biedl and Joubert syndrome, and isolated spermatogenic failure (OMIM: 608040). Bakey et al. recently showed that putative truncating variants in *IFT74* can also present with a predominant skeletal phenotype.

Methods: Trio exome sequencing (ES) followed by analysis of a filtered skeletal dysplasia gene panel was performed. RNA-sequencing was done on patients' skin fibroblasts to detect pathogenic expression outliers for a ciliopathy gene panel. Confirmation of RNA- sequencing result at the DNA- level was achieved using Multiplex Amplicon Quantification (MAQ).

Results: A male fetus presented at 22 weeks with ultrasonographic findings of a skeletal ciliopathy. Parents were consanguineous. Postmortem evaluation confirmed long narrow thorax with short ribs, handlebar clavicles, brachydactyly and trident acetabula. ES revealed no variants of interest in *IFT80* or *KIAA0586*, located in ROHs. Only a mono-allelic pathogenic variant in *IFT81* was detected. Subsequent RNA-sequencing was performed and revealed absent expression of *IFT74* exon 2. Re-analysis of exome data showed no coverage for this region and MAQ confirmed a homozygous pathogenic exon 2 deletion.

Conclusion: Our results further establish the role of *IFT74* as a novel cause of skeletal ciliopathy, most resembling the short-rib thoracic dysplasia subtype (formerly asphyxiating thoracic dysplasia). Exon 2 deletions are recurrent and may be readily missed on routine ES. Diagnostic work-up for skeletal ciliopathies should include *IFT74* sequencing and targeted CNV- analysis.

P06.013.D Arylsulfatase L (ARSL) controls Glycosaminoglycan Sulfation during skeletal development

Marianna Maddaluno[1], *Chiara De Leonibus*[1], *Eugenio Del Prete*[1], *Francesco Giuseppe Salierno*[1], *Daniela Intartaglia*[2], *Diego Carrella*[1], *Ivan Conte*[3], *Nicola Volpi*[4], *Carmine Settembre*[1]

[1]*Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli, Italy,* [2]*CNR, Institute of Applied Sciences and Intelligent Systems "Eduardo Caianiello" (ISASI), Pozzuoli, Italy,* [3]*5 Department of Biology, Federico II University, Naples, Italy,* [4]*Department of Life Sciences, UniMORE, Modena and Reggio Emilia, Italy.*

Background: Proteoglycans, key components of the cartilage extracellular matrix (ECM), are decorated with glycosaminoglycan (GAG) chains whose sulfation patterns are tightly regulated during

biosynthesis. Aberrant GAG sulfation has been implicated in multiple skeletal disorders. Among them, X-linked chondrodysplasia punctata (CDPX) is a rare skeletal dysplasia characterized by abnormal cartilage development and impaired endochondral ossification. The disease is caused by mutations in the ARSL gene, encoding arylsulfatase L, a unique Golgi-localized enzyme. To date, however ARSL role in skeletal development remains unknown.

Material and methods: We combined in vitro biochemical assays, bioinformatic analyses, and unbiased LC-MS (Liquid chromatography - Mass Spectrometry) to identify ARSL substrates. Additionally, we developed a Medaka fish model lacking the *ARSL* ortholog (*Ol-Arsd*) to investigate the in vivo effects of ARSL deficiency through biochemical and morphological analyses, including μCT imaging.

Results: We demonstrate that ARSL desulfates chondroitin sulfate (CS) specifically at the 4-O-position, establishing CS as a bona fide substrate of ARSL. Loss of *Ol-Arsd* in Medaka fish resulted in hypersulfated CS at the 4-O-position, leading to defective perichondral and intramembranous ossification and skeletal abnormalities that mimic those observed in CDPX patients, including nasal hypoplasia and shortened skeletal elements

Conclusion: Our findings identify ARSL as a regulator of GAG desulfation in the Golgi and suggest a direct link between proteoglycan sulfation and CDPX manifestations.

P06.014.A Diagnostic challenges in Neurofibromatosis type 1: an Italian cohort study between parental testing and cell line models generation

Elena Luppi[1,2], *Francesca Montanari*[2], *Giulia Severi*[2], *Alessandro Vaisfeld*[1,2], *Giovanni Innella*[1], *Luigi Monti*[1], *Andrea Pietra*[1], *Luca Caramanna*[1,2], *Andreina Minicucci*[1,2], *Pamela Magini*[2], *Ivana Kurelac*[1], *Cesare Rossi*[2], *Daniela Turchetti*[1,2], *Giuseppe Gasparre*[1]

[1]*University of Bologna, Bologna, Italy,* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: Neurofibromatosis type 1 (NF1) presentation is highly variable, and overlapping signs to other Rasopathies make differential diagnosis challenging, especially in incomplete phenotypes. We aimed to define the diagnostic rate of genetic analysis in NF1 patients and its improvement by parental testing and functional studies.

Material and methods: We reviewed data from 230 probands who underwent Rasopathies NGS panel and *NF1* MLPA testing for NF1 differential diagnosis between 2018 and 2024.

Results: 126 probands (55%) harboured *NF1* pathogenic/likely pathogenic (LP) variants, including 15 cases (6.5%) whose variants were upgraded from uncertain significance (VoUS) to LP due to their de novo nature. The disease spectrum ranged from mild to severe, with truncating/splicing variants enriched in the latter (68% vs 87%; $p = 0.007$). 31 patients (25%) did not fulfil the revised NF1 criteria (mean age:10.6y vs 18y for clinical diagnosis; $p = 0.02$). 12 probands (5.2%) displayed *NF1* VoUS, whereas alternative diagnoses were possible in 11 (4.7%) cases (5 *SPRED1*, 4 *LZTR1*, 2 *PTPN11*). For VoUS clarification, *NF1* cell models are critical when biopsies of affected tissues are unavailable. We demonstrated an EGF-inducible RAS pathway in immortalized non neoplastic hTERT RPE-1 and N-thy ori3-1 cells (up to 3-fold increase in RAS-GTP signal; $p = 0.002$) and used N-thy cells to generate NF1 H1348P mutant models via CRISPR/Cas9-mediated knock-in approach.

Conclusion: Our results widen the NF1 genotypic spectrum and underline the relevance of parental testing in the molecular diagnosis of incomplete phenotypes. We also defined a cell line suitable for VoUS functional studies, generating an NF1 mutant model.

Background: Vascular Ehlers-Danlos syndrome (vEDS) is a rare connective tissue disorder caused by heterozygous deleterious variants in COL3A1. Affected individuals have an increased risk of early death due to rupture of arteries, large intestine, and gravid uterus. The pathogenesis of vEDS is only partially understood and the disease remains without treatment. Three-dimensional (3D) spheroids represent an innovative cell culture model mimicking connective tissue-like properties to more effectively replicate of the in vivo cellular environment.

Material and methods: Transcriptomic, proteomic, ultrastructural analysis and high content imaging analysis on 2D fibroblast cultures and/or 3D spheroids from ten vEDS patients and four controls; computational drug repositioning on a set of FDA/EMA approved drugs.

Results: Transcriptomic analysis revealed upregulation of genes related to mitochondrial function, organellar ribosomal subunits and biosynthesis processes, indicating an enhanced adaptive metabolic response, whereas downregulation of genes involved in cell migration, differentiation and stress response highlighted abnormalities in cellular signalling and extracellular matrix maintenance. Proteomic analysis revealed that induced proteins were enriched for the mitochondrial matrix, minichromosome maintenance complex and biological processes involving low-density lipoprotein particles. Ultrastructural analysis and high

content imaging have documented an endoplasmic reticulum dilatation, increased autophagosomes and lipofuscin deposits. Computational drug repositioning analysis on a set of FDA/EMA drugs that are able to correct the defects associated to mutated COL3A1 is ongoing.

Conclusion: Our findings delineate a cellular pathogenesis for vEDS. The therapeutic potential of drugs identified as modulators of pathological cellular phenotypes will be evaluated in vitro in vEDS fibroblasts for future human application.

P06.016.C SMAD7: a novel gene in Sclerosing bone dysplasia

*Alice Goldenberg[1], Anaik Previdi[2], Thomas Pinna[3], Valérie Cormier-Daire[4], **Corinne Collet**[4]*

[1]Genetic department, University Hospital Charles-Nicolle, Rouen, France, [2]inserm U1163 Imagine institute CHU Necker, Paris, France, [3]inserm U1132, Lariboisière Hospital, Paris, France, [4]Hopital Necker Department of Genetics and INSERM U1163, Paris, France.

Background/objectives: Sclerosing bone dysplasia is a heterogeneous group of disorders caused by different genes that result in decreased bone resorption or, conversely, increased bone formation. Different signalling pathways involved in these pathologies can lead to an excessive increase of bone formation. The present case study concerns a patient with an atypical and generalised hyperostosis for whom targeted panel sequencing was negative. We used Whole Exome Sequencing (WES) and functional studies to find molecular basis of this disease.

Methods: WES, functional studies using primary fibroblast cells from the patient and controls (Western-Blot (WB); RNA-seq, RT- qPCR).

Results: This woman displays a severe facio-mandibular hyperostosis and diaphyseal sclerosis of the long bones. The first signs appeared in early childhood and worsened with age. WES revealed compound heterozygous missense variants in *SMAD7* gene, an inhibitor of SMADs pathways. Using primary fibroblasts, we found that the RNA and protein expressions of *SMAD7* were decreased in the patient cells compared with control cells. WB results showed that SMAD2/3 and p-SMAD3 levels were higher in mutated fibroblast cells than in control cells after TGF-β1 treatment. Furthermore, SMAD7-mutated cells showed increased RNA expression of ALPL, with reduced expression of RUNX2 and its target genes SP7 and COL1A1. Moreover, RANKL expression was abolished in SMAD7 mutated cells and OPG expression was slightly increased. RNAseq showed that genes involved in wnt and PI3K-AKT signalling pathways were upregulated.

Conclusion: Functional studies support the pathogenicity of SMAD7 variants in sclerosing bone dysplasia.

P06.017.D Improving the diagnostic yield of skeletal dysplasia through targeted systematic re-analysis of known disease genes

***Megan F. Baxter**[1], Musculoskeletal (MSK) Genomics England Clinical Interpretation Partnership (GeCIP)[2]*

[1]Guy's and St Thomas' Hospital, London, United Kingdom, [2]

Background: Identifying the underlying genetic cause of a patient's rare disease is critical to provide appropriate counselling and access to novel treatments. Currently a prolonged diagnostic odyssey exists and often the underlying cause is never identified. Collectively 1 in 5000 individuals are affected by a skeletal dysplasia for which there are 552 known disease genes published in The Nosology of genetic skeletal disorders:2023 revision. More than 900 individuals with skeletal dysplasia were recruited for the 100,000 Genomes Project however at present only 27.3% (256/937) of the cases are listed as solved.

Material and methods: Utilising a targeted approach, systematic re-analysis of all genes present in Skeletal Nosology was completed for individuals enrolled in the 100,000 Genomes Project with an overarching diagnosis of skeletal dysplasia, currently listed as unsolved. Analysis was completed assessing both SNV and/or structural variants, respective of the disease genes inheritance pattern.

Results: Strong candidate variants in known disease genes were found for more than 3% of the currently listed as unsolved skeletal dysplasia cases. This included variants that for a myriad of reasons were not originally tiered at a level to be identified on original analysis including recent novel disease genes, splice site variants, and structural variants.

Conclusion: This project significantly improved the diagnostic yield of unsolved skeletal dysplasia cases and highlighted the diverse landscape of molecular mechanisms that underly skeletal dysplasia. It also demonstrated the potential for continued re-analysis of available data and the need for similar approaches to be utilised across other rare disease domains.

P06.018.A Enhancing polygenic risk score accuracy for adolescent idiopathic scoliosis through an international GWAS meta-analysis

***Takuro Iwami**[1,2], Nao Otomo[1,2,3], Ming Yue[4], Yoshiro Yonezawa[2], Kazuki Takeda[2], Jason Pui Yin Cheung[5], Jonathan Rios[3,6,7], Shiro Ikegawa[1], Morio Matsumoto[2], Masaya Nakamura[2], You Qiang Song[4], Carol Wise[3,6,7], Kota Watanabe[2], Chikashi Terao[1]*

[1]Laboratory for Statistical Analysis, Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan, [2]Department of Orthopedic Surgery, Keio University School of Medicine, Tokyo, Japan, [3]Center for Translational Research, Scottish Rite for Children, Dallas, TX, USA, [4]School of Biomedical Sciences, The University of Hong Kong, Hong Kong SAR, China, [5]Department of Orthopaedics and Traumatology, The University of Hong Kong, Hong Kong SAR, China, [6]Department of Orthopaedic Surgery and Pediatric, University of Texas Southwestern Medical Center, Dallas, TX, USA, [7]McDermott Center for Human Growth and Development University of Texas Southwestern Medical Center, Dallas, TX, USA.

Background: Adolescent idiopathic scoliosis (AIS) is a complex, three-dimensional spinal deformity affecting 2–3% of adolescents worldwide. Although genetic factors play a significant role in AIS susceptibility, the predictive accuracy of polygenic risk scores (PRS) remains limited. To improve PRS performance, we conducted an international meta-analysis of genome-wide association studies (GWASs) for AIS.

Materials and methods: We performed a meta-analysis of GWAS data from cohorts in Japan (5,427 cases and 155,983 controls), Hong Kong (977 cases and 2,085 controls), the US (1,503 cases and 20,153 controls), and Iceland (146 cases and 255,191 controls). Using these results, we inferred AIS-associated cell types

through heritability enrichment analysis and developed a polygenic risk score (PRS)-based prediction model.

Results: We identified 41 susceptibility loci, including 22 novel loci. The genetic background of AIS was strongly enriched in the regulatory regions of rhabdomyosarcoma, chondrocytes and myoblasts. By combining the regions with significant associations, 74.7% of AIS heritability could be explained by 9.8% of the genome. In a PRS analysis, we demonstrated that including more populations improved the AUC, a measure of predictability. Notably, the model prioritizing SNPs within significantly enriched regions achieved the highest AUC of 0.734 among all models.

Conclusion: We identified 22 novel AIS susceptibility loci by the meta-analysis. Three-quarters of AIS heritability could be attributed to the regulatory regions of specific musculoskeletal cell types. Our PRS-based prediction model incorporating global populations with these regions showed the highest predictability to date.

P06.019.B Predictive factor of malignant tumoral development in multiple enchondromatosis

Mevyn Nizard[1], *Genevieve Baujat*[1], *Caroline Michot*[1], *Sophie Monnot*[2], *Valérie Cormier-Daire*[1,3]

[1]*Service de médecine génomique des maladies rares, Hôpital Necker - Enfants Malades, Assistance Publique - Hôpitaux de Paris, Paris, France., Paris, France,* [2]*Service de médecine génomique des maladies rares, Hôpital Necker - Enfants Malades, Assistance Publique - Hôpitaux de Paris, Paris, France., PARIS, France,* [3]*Université Paris Cité, INSERM UMR 1163, Imagine Institute, Paris, France, Paris, France.*

Background: Ollier disease (OD) and Maffucci syndrome (MS) are extremely rare and complex disorders characterized by the abnormal development of multiple benign tumors in bones or soft tissues. These two disorders share identical clinical and histopathological features, leading to their classification under multiple enchondromatoses. Current knowledge on these pathologies is derived from sporadic case reports, genetic analyses of biopsies and retrospective studies. This accumulated knowledge higlighted a high risk of malignant transformation in patients, while the exact prevalence remains unknown. It is now demonstrated that somatic mutations in isocitrate dehydrogenase-1 (IDH1) or 2 (IDH2) are present in tumor tissues and hemangiomas

Methods: Observational cross-sectional study of 44 patients (37OD, 7MS)

Results: We found that the diagnosis remains radioclinical. Somatic mutations in IDH1 or IDH2 have been identified in affected tissues and rarely also in blood sample (4 patients). The prevalence of malignant tumoral lesions was 22% in OD patients, and 43% in MS patients. Multivariate analysis revealed that the localization of enchondromas in the axial skeleton, upper limbs, or when one side of the body was more affected than the other, was positively correlated with the development of malignant lesions.

Conclusion: Our study describes for the first time that patients with enchondromas localized in the axial skeleton, upper limbs, or with asymmetric body involvement have a higher risk of developing malignant lesions and should undergo more frequent follow-ups. Furthermore, the systematic search fro IDH1/IDH2 variant will be needed for future therapeutics including the possible use of IDH inhibitors.

P06.020.C Whole genome association analysis in 450,000 individuals identifies rare and common variants associated with severe shoulder pathologies

Harry D. Green[1], *Robin Beaumont*[1], *Gareth Hawkes*[2], *Michael Weedon*[1], *Jonathan P. Evans*[1]

[1]*University of Exeter, Exeter, United Kingdom,* [2]*University of Exeter Medical School, Exeter, United Kingdom.*

Background: Shoulder pathologies encompass a spectrum from soft tissue injuries to joint degeneration, impacting quality of life and often requiring surgery. Despite high prevalence, the genetic aetiology of shoulder pathologies remains under explored.

Material and methods: Using the UK Biobank (N = 448,436), we performed a whole-genome sequencing-based association analysis for five ICD10-defined shoulder pathologies: adhesive capsulitis, shoulder arthrosis, rotator cuff syndrome, shoulder calcific tendinitis, shoulder impingement, and three OPCS4-defined operations: shoulder replacement, subacromial decompression and rotator cuff repair. Genome-wide significant variants were followed up using a phenome-wide association study (PheWAS) including common disease, blood biomarkers, and plasma protein levels. FinnGen was used for replication where possible.

Results: We identified 2 common loci associated with severe shoulder conditions at $p < 1e\text{-}8$. We report a novel association with rs4326370 (MAF 22%) and shoulder replacement operation (OR 1.36 [1.30–1.43], $p = 4e\text{-}11$). The top two associations for this variant in the PheWAS were hip circumference ($p = 2e\text{-}7$) and shoulder arthrosis ($p = 4e\text{-}5$ in UKBB, $p = 0.003$ in the FinnGen replication). We replicated a well-known adhesive capsulitis association (rs62228066, $p = 8e\text{-}15$). We also found 3 novel rare variants for adhesive capsulitis (intronic in RBFOX3, intronic in ZNF516, and an intergenic variant on chromosome X) 2 for subacromial decompression (both intergenic on chromosomes 9 and 17) and 1 for shoulder replacement (intronic in PLEKHH2).

Conclusion: This is the first whole-genome sequencing-based analysis of these common shoulder pathologies. We confirm known genetic associations and report novel common and rare genetic loci. These findings improve our understanding of the aetiology of shoulder pathologies.

P06.021.D Evaluation of mitochondrial DNA copy number and telomere length in patients with knee osteoarthritis in the Turkish population

Yasemin Oyacı[1], *Ayşe Feyda Nursal*[2], *Demirhan Dıraçoğlu*[3], *Serbülent Yiğit*[4], *Mustafa Pehlivan*[5], *Dicle Rotinda Özdaş Sevgin*[3], *Sacide Pehlivan*[6]

[1]*Institute of Graduate Studies in Health Sciences, Istanbul University, Istanbul, Turkey,* [2]*Department of Medical Genetics, Faculty of Medicine, Hitit University, Corum, Turkey,* [3]*Department of Physical Medicine and Rehabilitation, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey,* [4]*Faculty of Veterinary, Department of Genetics, Ondokuz Mayıs University, Samsun, Turkey,* [5]*Department of Hematology, Basaksehir Cam and Sakura City Hospital, Istanbul,*

Turkey, [6]Istanbul University, Istanbul Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey.

Background: Osteoarthritis (OA) is a degenerative joint disease that causes chronic joint pain and physical disability. Knee osteoarthritis (KOA) is a degenerative arthritis. Recent studies have demonstrated that mitochondrial DNA copy number (mtDNACN) is associated with OA and may contribute to its pathological development. Leukocyte telomere length (LTL) has been accepted as a clinical indicator of the risk of age-related diseases, such as OA. Therefore, we evaluated mtDNACN and LTL in Turkish patients with KOA.

Material and methods: A total of 228 subjects, including 147 patients with KOA and 81 healthy controls, participated in the study. The analyses were performed using quantitative real-time PCR (qPCR). The comparative Cq method was used to calculate the absolute $mtDNA_{CN}$ and LTL.

Results: Absolute $mtDNA_{CN}$ was increased in KOA patients compared with healthy controls ($p = 0.001$). The mean LTL was lower in patients with KOA than in controls ($p = 0.001$). Patients with $mtDNA_{CN}$> 286.8 had a longer symptom duration than those with less than 286.8 ($p = 0.009$). When we divided the patients according to grade, $mtDNA_{CN}$ and average LTL did not show a statistically significant difference in KOA patients.

Conclusion: Our results that mtDNACN levels may increase to compensate for mitochondrial dysfunction in KOA patients. Average LTL reduction also supported LTL reduction in patients with chronic diseases. These results should be replicated in different and larger ethnic groups.

P06.022.A Genomic and transcriptomic profiles of osteoporotic vertebral fractures in postmenopausal women

Ondrej Šeda[1], *Josef Včelák*[2], *Blanka Chylíková*[1], *Helena Peková*[3], *Eva Račochová*[3], *Lucie Šedová*[1]

[1]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and the General University Hospital in Prague, Prague, Czech Republic,* [2]*Department of Orthopaedics, First Faculty of Medicine, Charles University, University Hospital Na Bulovce, Prague, Czech Republic,* [3]*GNTlabs by GENNET, Prague, Czech Republic.*

Background: Osteoporotic vertebral fractures (OVF) represent a major health concern in aging postmenopausal women. This pilot study aimed to characterize the unique genomic and transcriptomic profiles associated with OVF compared to non-osteoporotic controls.

Material and methods: Bone tissue samples were acquired from the vertebral bodies during surgery on postmenopausal women with OVF (n = 41) and those undergoing elective surgery of the thoracolumbar spine without osteoporosis (control, n = 29). DNA was extracted from whole blood and genotyped using the Illumina InfiniumTM Global Screening Array-24 v3.0 BeadChip. Pilot association analysis was performed using PLINK2 with genomic control-corrected p-values. RNA was extracted from vertebral bone tissue and sequenced using Illumina NovaSeq6000 as 150-bp paired-end reads. RNASeq-based differential expression and gene ontology analyses were performed (TMM normalization) comparing OVF and control samples.

Results: The OVF and control groups did not differ in age, BMI, or prevalence of concomitant diabetes, cancer, hyperuricemia, dyslipidemia, hypertension, inflammation, smoking status or medication. Top nominally associated single nucleotide polymorphisms included variants in *VIT, ANK3, SCN9A* and multiple regulatory intergenic regions. Transcriptomic analysis revealed 243 differentially expressed genes after false-discovery rate correction, with 231 downregulated and 13 upregulated in OVF. Gene ontology analysis identified enrichment in extracellular matrix organization, skeletal system development, collagen fibril organization and osteoblast differentiation (all Bonferroni-corrected $p < 10^{-4}$). KEGG pathway analysis showed the top enriched pathways differentiating OVX from controls to be extracellular matrix-receptor interaction ($q = 3.11 \times 10^{-15}$), protein digestion and absorption ($q = 1.47 \times 10^{-10}$).

Conclusion: This study has identified a distinct genomic and transcriptomic signature associated with OVF.

P06.023.B A new multisystem disorder, TIMES syndrome, reveals unexpected roles of Volume-Regulated anion channels

Mathieu Quinodoz[1,2,3], *Sonja Rutz*[4], *Virginie Peter*[1,2], *Livia Garavelli*[5], *Micheil A. Innes*[6], *Sheila Unger*[7,8], *Carlo Rivolta*[1,2,3], *Raimund Dutzler*[4], ***Andrea Superti-Furga***[7,8]

[1]*Institute of Molecular and Clinical Ophthalmology Basel (IOB), 4031, Basel, Switzerland,* [2]*Department of Ophthalmology, University of Basel, 4031, Basel, Switzerland,* [3]*Department of Genetics and Genome Biology, University of Leicester, Leicester, United Kingdom,* [4]*Department of Biochemistry University of Zurich, 8057, Zurich, Switzerland,* [5]*Medical Genetics Unit, Azienda USL-IRCCS of Reggio Emilia, 42123, Reggio Emilia, Italy,* [6]*Department of Medical Genetics and Pediatrics and Alberta Children's Hospital Research Institute, Cumming School of Medicine, University of Calgary, AB, T3B 6A8, Calgary, AB, Canada,* [7]*Division of Genetic Medicine, Lausanne University Hospital (CHUV), and University of Lausanne, 1011, Lausanne, Switzerland,* [8]*Genetica AG, Zurich and Lausanne, Switzerland.*

We describe two individuals with a congenital disorder including Teleangiectasia, Intellectual disability, Microcephaly, Metaphyseal bone dysplasia, Eye anomalies and Short stature (TIMES syndrome) and a specific facial appearance. The unrelated patients had different never-seen de novo variants (a missense and a fs/stop) in a region of the *LRRC8C* gene, encoding the boundary between the pore and a cytoplasmic domain, that is depleted of sequence variations in control subjects. The LRRC8C gene codes for a subunit of Volume-Responsive Anion Channels (VRACs) channels of the cell membrane that are activated by external hypotonic conditions and allow the cell to discharge water and solubles and protect itself from osmotic swelling. Although molecular structure and functioning of VRACs are well known, their specific physiologic roles in the body have remained elusive. We found that LRRC8C proteins with the patients' variants were incorporated into mature VRACs but the VRACs showed destabilization of subunit interaction and, importantly, enhanced activation, resulting in channel activity even at isotonic conditions in which wild-type channels are closed. The pathogenetic chain between constitutive VRAC activation and the pleiotropic clinical phenotype is still unclear at present; potentially affected cell types are endothelial cells, neurons in the developing brain, growth-plate chondrocytes, and others. Thus, the TIMES syndrome is a pleiotropic, clinically recognizable condition produced by mono-allelic dominant LRRC8C variants leading to constitutional activation and gain-of-function of VRAC channels. It highlights first links between VRAC function and health and disease and might be amenable to pharmacologic treatment in the future.

P06.024.C Silent doesn't mean harmless: pathogenic role of a synonymous *WRN* variant

Nesibe Saliha Bulut, *Ceren Damla Durmaz, Naz Guleray Lafci*

Department of Medical Genetics, Faculty of Medicine, Hacettepe University, Ankara, Turkey.

Background: Werner Syndrome (OMIM:277700) is a rare progeroid disorder caused by biallelic pathogenic *WRN* variants, disrupting RecQ helicase function essential for DNA repair. Here, we present a synonymous *WRN* variant in a 25-year-old proband from Turkish Werner Syndrome Registry.

Clinical Report: The proband presented with early-onset diabetes-mellitus, with additional findings of early hair greying, bird-like facies, and hepatosteatosis—features raising suspicion for premature aging. Clinical exome sequencing identified a novel homozygous synonymous *WRN* variant (c.504G>A, p.Lys168=), residing at the last nucleotide of exon 5. Suspecting a splicing defect, we performed cDNA sequencing, yet intriguingly, no aberrant splicing was detected. However, RT-PCR expression analysis revealed a striking 99.6% reduction in mRNA levels, indicating transcript degradation via nonsense-mediated decay (NMD), with only a small fraction escaping NMD and being amplified in cDNA sequencing. To further elucidate the pathomechanism, expression studies following NMD inhibition are currently planned.

Discussion and Conslusion: This study highlights the importance of recognizing clinical signs of premature aging in patients with atypical presentations as a potential early manifestation of premature aging syndrome but also challenges conventional assumptions about synonymous variants as de facto benign. To the best of our knowledge, this is the first *WRN* synonymous variant with proven pathogenicity, highlighting how silent mutations can have consequences. Recognizing these noncanonical disease mechanisms underscores the necessity of a comprehensive approach that integrates clinical, genetic, and functional insights. This enables timely diagnosis, optimizes patient management, and contributes to the prevention of complications in rare aging disorders such as Werner Syndrome.

P06.025.D Deciphering the phenotypic spectrum associated with *MIA3*-relaed odontochondrodysplasia

Mohamed S. Abdel-Hamid[1], *Rasha Elhossini*[2], *Sherif Fawzy*[1], *Mennat Mehrez*[1], *Mona Aglan*[1], *Nehal Hassib*[1]

[1]*National Research Centre, Cairo, Egypt,* [2]*National Research centre, Cairo, Egypt.*

Odontochondrodysplasia (ODCD) is a rare skeletal dysplasia characterized by short stature, skeletal deformities, and dentinogenesis imperfecta (DI). Although the majority of cases were associated with biallelic variants in *TRIP11*, one study described a homozygous truncating variant in *MIA3*, encoding TANGO1, in four sibs with ODCD in association with insulin-dependent diabetes, hearing loss, obesity, and intellectual disability. Subsequently, a homozygous truncating variant in the luminal domain of TANGO1 was identified in a fetus with a lethal skeletal dysplasia and fetal hydrops. Herein, we describe two unrelated patients with a distinct phenotype including severe short limbs, short stature, metaphyseal dysplasia, dysmorphic facies, lax joints, and DI. Other variable features were scoliosis, squint, and cardiac problems. Exome sequencing revealed two homozygous *MIA3* variants in the luminal domain of TANGO1, c.354+2T>G and p.Cys38Phe. The c.354+2T>G variant was confirmed by investigating the patient's mRNA to result in exon 3 skipping and an inframe deletion of 28 amino acids. Our patients lacked the extra-skeletal manifestations noted in the four sibs with *MIA3* variant. However, they had more severe skeletal deformities closely resembling those observed in patients with *TRIP11* variants. Our study suggests the presence of a phenotypic spectrum associated with *MIA3* variants including ODCD with milder skeletal deformities, a classic ODCD with severe skeletal deformities, and a lethal skeletal dysplasia at the severe end of the spectrum. Although the striking phenotypic variability appears to be related to the type and or the location of the *MIA3* variants, the influence of other factors cannot be ruled out.

Simple bone cysts are benign fluid-filled lytic lesions, which can be unicameral (UBC) or partially separated. UBC can be asymptomatic and typically resolve spontaneously or they can cause pathological fractures. Only one case of familial polycystic bone disease (PCBD), associated with recurrent fractures, has been described to date (PMID: 10457258, 10703941). Here, we report a second familial case, providing new insights into this ultra-rare disease. Patient 1 presented at 16 years of age with recurrent fractures (left femur and, subsequently, left tibia). Skeletal radiological survey, CT and MRI confirmed the presence of multiple bone cysts (femurs, tibias, calcaneus and ulna). Pamidronate treatment showed no efficacy and she had multiple orthopedic interventions (intra-medullary nails, bone graft). Histological examination revealed a thin, fibrous cyst wall with no epithelial lining, consisting of fibroblasts and irregular bands of fibrin-like material mimicking odontogenic cement. She did not show any other health problem (normal stature, vision and hearing) except steatotic liver disease and polycystic ovary syndrome. Her father had a fracture of his upper limb and multiple cysts of long bones. Her younger brother showed a similar radiological picture. Genetic assessment including gene panel for skeletal dysplasias (including *FGFR1*), chromosomal microarray and quatuor whole genome sequencing, could not characterize the cause of this condition. In conclusion, we

report the second case of PCBD, providing new insights into the clinical, radiological and pathological characterization of this ultra-rare disease. We hope that the report of further cases will let the characterization of the molecular basis of this condition.

P06.027.B Syndrome-informed phenotyping reveals a polygenic basis for connective tissue disorder variation in the general population and identifies novel loci for aortopathies

Jay Devine[1], *Seppe Goovaerts*[1], *Hanne Hoskens*[2], *Jose D. Aponte*[2], *Meng Yuan*[1], *Nina Claessens*[1], *Michiel Vanneste*[1], *Craig T. Jacobs*[2], *Elizabeth C. Barretto*[2], *Hilde Peeters*[1], *Kim L. McBride*[2], *Ophir D. Klein*[3], *Scott M. Damrauer*[4], *Francois P. Bernier*[2], *Benedikt Hallgrimsson*[2], *Peter Claes*[1]

[1]*KU Leuven, Leuven, Belgium,* [2]*University of Calgary, Calgary, AB, Canada,* [3]*University of California, San Francisco, CA, USA,* [4]*University of Pennsylvania, Philadelphia, PA, USA.*

Background: Thoracic aortic aneurysms and dissections (TAADs) are a class of life-threatening aortic pathologies that can be syndromic (e.g., Marfan syndrome (MFS), Loeys-Dietz syndrome (LDS), and vascular Ehlers-Danlos syndrome (vEDS)) or non-syndromic. Compared to syndromic TAADs, non-syndromic TAADs are more common but less understood and thus harder to screen.

Material and methods: Following previous work that has suggested Mendelian disorders are phenotypic extensions of the general population, we use facial shape to establish axes of variation between controls (N = 8,246) and individuals with MFS, LDS, and vEDS. We then subject control scores along these axes, or syndrome-informed phenotypes (SIPs), to genome-wide association studies. Next, we investigate whether the discovery of TAAD (i.e., ascending aorta diameter) loci can be boosted by leveraging pleiotropy with SIPs via the conditional false discovery rate (FDR). We additionally implement the conjunctional FDR to examine shared loci between TAADs and SIPs.

Results: We recovered 32, 50, and 11 genome-wide significant loci for the LDS, MFS, and vEDS SIPs, respectively, which were primarily enriched for processes related to embryonic and skeletal system development, as well as limb morphogenesis. The loci common to all SIPs implicate key craniofacial transcription factors, including known loci near *TBX15*, *KLF4*, and the *HOXD* cluster, as well as *DCHS2*, which likely also regulates cardiomyocyte proliferation and cardiac growth. Using the FDR (1%) approaches, we found 112 novel loci for TAAD, 46 of which were shared across all SIPs.

Conclusion: Our results show that the face can yield novel genetic insights into TAADs.

P06.028.C Severe malnutrition masking a well-defined skeletal dysplasia: a case of achondroplasia with coexisting *BRAF* variant

Nesligul Hasibe Gonen[1], *Demet Teker Duztas*[2], *Ceren Damla Durmaz*[3]

[1]*Department of Medical Genetics, Sanliurfa Training and Research Hospital, Sanliurfa, Turkey,* [2]*Pediatric Gastroenterology Clinics, Sanliurfa Training and Research Hospital, Sanliurfa, Turkey,* [3]*Department of Medical Genetics, Faculty of Medicine, Hacettepe University, Ankara, Turkey.*

Background: Rare diseases, which currently exceed 7,000 in number and constitute a significant workload in Medical Genetics clinics, affect approximately 6% to 8% of the worldwide. Although distinct dysmorphic features can guide specialists toward a specific diagnosis, presence of overlapping findings across different diseases, blended phenotypes, and environmental factors etc. pose challenges in establishing a clinical diagnosis.

Methods-Results: A female proband, followed for prenatal long bone shortening, was born to non-consanguineous parents with an unremerkable family history. Postnatally, she exhibited severe growth and developmental delay. At 7-months-old, physical examination revealed that height: 52.5 cm (SDS: −5.73), weight: 3800 gr (SDS: −5.61), head circumference: 41.5 cm (SDS: −1.34), hypotonia, frontal bossing, flattened nasal bridge, macrostomia, severe loss of adipose tissue and rhizomelia. Radiographs showed iliac bone hypoplasia, epi-metaphyseal changes in the femur, and loss of vertebral body height in the lumbar spine. In a case that lipodystrophy and skeletal dysplasia were prominent, c.1138G>A(p.Gly380Arg) in FGFR3 consistent with achondroplasia and c.1774A>G(p.Ile592Val) in BRAF heterozygous changes were detected in the clinical exome sequencing. Segregation study is ongoing.

Conclusion: Here, we present how severe malnutrition can obscure a well-defined syndrome such as achondroplasia and complicate clinical diagnosis. BRAF V600E mutation is known to influence plasma lipid profiles (PMID: 35565240). BRAF mutation identified in our case has been previously associated with cancer; however, its relation with lipid metabolism remains unclear. This case underscores the importance of comprehensive genomic analysis in atypical presentations and highlights the potential interplay between genetic and environmental factors in shaping phenotypic outcomes.

P06.029.D Long-read sequencing cracks unsolved cases and further improves genome diagnostics in epidermolysis bullosa

Eddy N. de Boer[1], *L. Agnes Grutters*[1], *Rosalie Baardman*[2], *Daniëlle Schoonhoven*[1], *Jeroen Bremer*[2], *Rindert R. Venema*[2], *Femke Boorsma*[1], *Jelkje J. de Boer-Bergsma*[1], *Gilles F.H. Diercks*[3], *Henny H. Lemmink*[1], *Sabrina Z. Commandeur-Jan*[1], *Lennart F. Johansson*[1], *Marieke C. Bolling*[2], *Cleo C. van Diemen*[1], ***Peter C. van den Akker***[1]

[1]*University Medical Center Groningen, Department of Genetics, Groningen, Netherlands,* [2]*University Medical Center Groningen, Department of Dermatology, Groningen, Netherlands,* [3]*University Medical Center Groningen, Department of Pathology, Groningen, Netherlands.*

Background: Standard genetic diagnostics of Epidermolysis Bullosa (EB) using short-read sequencing has a diagnostic yield of ~95%, leaving 5% of patients in uncertainty about their genetic diagnosis. Here, we applied Oxford Nanopore Technologies long-read sequencing (LRS) to diagnose unsolved cases.

Material and methods: Nine patients were selected with either no causal variant identified or only one variant in a presumed recessive form of EB. Libraries were generated and 24 EB-related genes were sequenced.

Results: In four patients, intermediate-sized (2.5–8 kb) multi-exon deletions were detected that were not found in public databases. Two *COL7A1* deletions were found in patients with dominant dystrophic EB (DDEB) in whom no previous variant was

identified, explaining the phenotypes. The same *ITGB4* deletion was identified in two patients. For one patient with junctional EB-localized, a heterozygous pathogenic frameshift variant had been identified previously, completing the genetic diagnosis. In the other patient, no additional variant was found, leaving the EB simplex-localized phenotype yet unexplained. In a fifth patient with DDEB, we found a likely pathogenic intronic splice-variant in *COL7A1*. RT-PCR confirmed alternative splicing leading to the in-frame insertion of seven amino acids to the triple-helical region. The variant was found to co-segregate with the disease in the patient's family.

Conclusion: Long-read sequencing yielded a genetic diagnosis for four of nine patients, highlighting its added value to EB diagnostics. Interestingly, four of five variants identified were intermediate-sized deletions, a class of variants that is missed with routine diagnostics due to shortcomings of current whole exome sequencing methods.

P06.030.A Study of the splicing variants in the *FBN1* gene of patient with Marfan syndrome

Yana Fedotova, *Darya Sherstyukova, Petr Sparber, Dmitrii Subbotin, Researcher, geneticist, Evgeniya Melnik, Darya Gorodilova, Kseniya Zabudskaya, Ekaterina Solodovnikova, Vyacheslav Tabakov, Tatyana Nagornova, Tatyana Markova, Alexandra Filatova, Mikhail Skoblov, Head of the Department*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Marfan syndrome is caused by pathogenic variants in the *FBN1* gene, primarily through two main mechanisms: haploinsufficiency, caused by loss-of-function variants associated with an increased risk of aortic complications, and dominant-negative effects, resulting from missense variants or in-frame deletions/insertions. Splicing variants can contribute to disease pathology through either mechanism, and elucidating the underlying mechanism requires experimental investigation of the specific splicing defects they induce.

Material and methods: Variants in *FBN1* were identified in patients with Marfan syndrome through either targeted NGS panel or WGS sequencing. Splice-altering variants were predicted using SpliceAI. Total RNA was isolated from patient-derived fibroblasts using the Trizol method. RT-PCR followed by deep next-generation sequencing was performed to detect splicing alterations and allelic imbalance.

Results: We studied a cohort of 230 Marfan syndrome patients diagnosed by clinical criteria, carrying pathogenic or VUS variants in *FBN1*. SpliceAI predicted the potential impact on splicing for 42 variants. We performed splicing analysis on patient-derived RNA samples isolated from fibroblasts for 15 variants: 11 splice-site variants, 2 exonic variants, and 2 deep intronic variants. Numerous splicing alterations were analyzed in the context of their impact on reading frame preservation or disruption. The resulting interpretation of splicing variants was correlated with the clinical presentation of the patients.

Conclusion: Splicing variants in *FBN1* require further study to clarify their pathogenic mechanisms. Improved understanding will enhance genotype-phenotype correlations and advance diagnostic and therapeutic approaches for Marfan syndrome patients.

P06.031.B Exploring the genetics of molar incisor hypomineralization (MIH): a molecular study on candidate genes involved in human dental enamel development

Simone Frisari[1], *Stefania Zampieri*[2], *Valentina Luppieri*[2], *Maria Pina Concas*[2], *Beatrice Spedicati*[1,2], *Aurora Santin*[1,2], *Alessandro Pecori*[2], *Milena Cadenaro*[1,2], *Giorgia Girotto*[1,2]

[1]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy,* [2]*Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy.*

Background: MIH is a worldwide-spread qualitative developmental defect of dental enamel. It affects some or all permanent molars and incisors, with variable colour demarcated opacities. From a genetic perspective, MIH is a multifactorial disorder, and, to date, its precise aetiology remains unclear and contentious.

Methods: Eighteen subjects aged 6 to 18 years attending the dental clinic of the IRCCS Burlo Garofolo (Trieste, Italy) and affected by MIH, diagnosed according to Lygidakis et al. (PMID:34669177), were enrolled in the study. Genetic analysis was performed by Whole Exome Sequencing (WES).

Results: Upon WES analysis, in 9/18 patients, 7 novel heterozygous missense variants were identified in the following genes: *HMCN1*, involved in dentinogenesis; *MMP2* and *TFIP11*, implicated in enamel formation; *LAMB3*, associated with amelogenesis imperfecta; *TTLL12* and *RMI1*, linked to MIH. Moreover, in two affected siblings, a large pathogenic deletion was identified in the *ENAM* gene, encompassing the first four exons. ENAM plays a crucial role in enamel development and pathogenic variants within *ENAM* gene were reported to cause enamel hypomineralization.

Conclusions: For the first time in Italy, we deepened the genetic bases of MIH, identifying novel variants in genes involved in enamel formation and development. This work emphasises the significance of genetic investigations for disease characterisation and prevention, and the choice of a suitable treatment for each patient, thereby enhancing their quality of life. In the future, it may be possible to identify new genes implicated in the condition by expanding the patient cohort and involving more Italian centres in the study.

P06.032.C Evaluation of clinical and molecular features and oxidative stress parameters in ciliopathies with skeletal Involvement

Gizem Ürel Demir, *Yaman Muşdal, Gülen Eda Utine, Pelin Özlem Şimşek Kiper*

Hacettepe University, Ankara, Turkey.

Background: Ciliopathies encompass a broad spectrum caused by variants in genes associated with ciliogenesis and ciliary trafficking. Among these, ciliopathies with predominant skeletal involvement are classified as a subgroup of genetic skeletal disorders. The aim of our study was to clarify the molecular etiology in patients with skeletal ciliopathies, establish genotype-phenotype

correlation, and investigate the relationship between ciliary dysfunction and oxidative stress.

Material and methods: A total of 20 patients with a preliminary diagnosis of skeletal ciliopathy were included in the study and whole exome sequencing was performed to elucidate the molecular etiology. Additionally, oxidative stress parameters were compared between the patient and control groups.

Results: Molecular etiology was identified in 16 (80%) of the patients, while no causal variants were detected in four (20%). Based on clinical and molecular findings, six patients were diagnosed with Ellis-van Creveld syndrome, six with oral-facial-digital syndrome, five with short-rib thoracic dysplasia, one with Meckel-Gruber syndrome, one with cranioectodermal dysplasia, and one with an undefined ciliopathy with skeletal involvement. The most frequently detected variants were in the *EVC* gene, followed by *DYNC2H1*. Among the identified variants, nine novel variants were described in the *EVC*, *EVC2*, *DYNC2H1*, *FAM149B1*, *KIAA0586*, *IFT80*, and *WDR35* genes. Oxidative stress parameters were found to be elevated in the skeletal ciliopathy patient group compared to the control group; however, statistical analyses did not show a significant difference.

Conclusion: This study has detailed the clinical, radiographic, and molecular characteristics of skeletal ciliopathies and contributed to the expansion of the mutational spectrum.

P06.033.D A longitudinal study to evaluate the advantages of HR-pQCT to assess bone mineral density in patients with Osteogenesis Imperfecta

Alice Moroni, *Francesca Gurioli, Rebecca Sassi, Alberto Bazzocchi, Marco Miceli, Giulia Fraterrigo, Fulvia Taddei, Enrico Schileo, Elena Pedrini, Davide Scognamiglio, Luca Sangiorgi*

IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy.

Background: Osteogenesis Imperfecta (OI) is a rare disease characterized by bone fragility. This ongoing prospective study aims to test if High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT), a high-resolution low-dose technique, can complement the current standard for quantitative bone assessment, i.e. areal bone mineral density(aBMD) measured by Dual-energy-X-ray Absorptiometry(DXA).

Methods: DXA scans are performed at lumbar spine, hip, total body, and forearm. HR-pQCT images are acquired at distal radius and tibia, measuring volumetric BMD(vBMD) and microarchitectural parameters.

Results: To date, 35 patients have been enrolled: 6 children, 29 adults; 19 females, 16 males; 32 OI Type I, 2 Type III and 1 Type IV. For 21 patients 12-months follow-up has been performed, data analysis is ongoing. Preliminary results demonstrate significant site-specific correlations of DXA-aBMD with HR-pQCT-vBMD ($r = 0.89$) and HR-pQCT cortical parameters (cortical vBMD, $r = 0.83$, cortical thickness $r = 0.87$) at the ultradistal radius. Cortical areas measured by HR-pQCT, at both radius and tibia, are correlated with DXA-aBMD at all sites. However, there is almost no significant correlation between DXA-aBMD (all sites) and trabecular HR-pQCT parameters (vBMD, number, thickness, separation).

Conclusion: There is preliminary evidence that DXA-aBMD cannot explain HR-pQCT trabecular measurements and may thus not be able to identify specific trabecular bone phenotypes/deficits in OI patients. HR-pQCT imaging therefore warrants further testing to identify patients at higher risk of fracture and target therapies. With this aim, ERN BOND supported the establishment of an international working group for the development of HR-pQCT standardized protocols and guidelines for the clinical management of OI patients.

P06.034.A Whole-body MRI in a cohort of adult patients affected by Nurofibromatosis type 1: suggestions for appropriate follow-up

Silvia Kalantari[1,2], *Luisa Carone*[3], *Marta Carboni*[1], *Simone Carbonera*[1], *Gaia Visani*[1], *Chiara Maizza*[1], *Alberto De Rosa*[1], *Enza Maria Valente*[1,4], *Lorenzo Preda*[3,5], *Fabio Sirchia*[1,6]

[1]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [2]*Medical Genetics Unit, Department of Diagnostic Medicine, Fondazione IRCCS Policlinico San Matteo, Pvia, Italy,* [3]*Radiology 1 Unit, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy,* [4]*Neurogenetics Research Center, IRCCS Mondino Foundation, Pavia, Italy,* [5]*Diagnostic Imaging and Radiotherapy Unit, Department of Clinical, Surgical, Diagnostic, and Pediatric Sciences, University of Pavia, Pavia, Italy,* [6]*Medical Genetics Unit, Department of Diagnostic Medicine, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy.*

Background: The care of adults with genetic disorders has been under the radar due to improved survival rates, but specific guidelines are often lacking. Neurofibromatosis type 1 (NF1) patients require life-long care for cancer screening, and current guidelines recommend a whole-body MRI (wbMRI) during transition from adolescence to adulthood. However, this is still not standard-of-care in many centers and there are no clear indications regarding how often to repeat it. We hereby describe our recent experience in Pavia, where collaboration with the radiologists allowed to perform wbMRI for the first time in a cohort of adult NF1 patients.

Material and methods: Since July 2024, we recruited adult NF1 patients routinely followed at the Medical Genetics Department of San Matteo hospital in Pavia for wbMRI. All imaging results were reviewed by a multidisciplinary team composed of clinical geneticists and radiologists to establish appropriate follow-up.

Results: 16 patients were recruited (3F/13M, mean age 37 years) and a wbMRI was performed for 11/16 patients.Plexiform neurofibromas (PNs) were identified in 7/11 patients (63%) and in most cases (6/7; 86%) new previously unknown internal PNs were detected. Based on multidisciplinary evaluation, a follow-up wbMRI was suggested for four patients (4/7; 57%) while either ultrasound or targeted MRI were planned for the others. In one patient wbMRI identified an unexpected lung adenocarcinoma allowing for timely surgery.

Conclusion: WbMRI is a valuable tool in assessing internal tumor burden, a precious information considering the newly available targeted therapeutic strategies (i.e. MEK-inhibitors) in NF1.

P06.035.B The dual role of IRF7 in immunodeficiencies and autoinflammatory diseases

Samantha Minetto[1,2], *Flavia Tinella*[1,2,3], *Miriana Danelli*[1,2], *Carla Gaggiano*[4,5], *Antonio Vitale*[4,5], *Laura Calonaci*[1,2], *Giulia Casamassima*[1,2], *Giulia Rollo*[1,2], *Jurgen Sota*[4,5], *Claudia Fabiani*[6,5,7], *Chiara*

*Fallerini[1,2,3], Caterina Lo Rizzo[3], Luca Cantarini[4,5,7], **Alessandra Renieri**[1,2,3]*

[1]Medical Genetics, University of Siena, Siena, Italy, [2]Department of Medical Biotechnologies, Med Biotech Hub and Competence Center, University of Siena, Siena, Italy, [3]Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy, [4]Department of Medical Sciences, Surgery and Neurosciences, Research Center of Systemic Autoinflammatory Diseases and Behçet's Disease Clinic, University of Siena, Siena, Italy, [5]Azienda Ospedaliero-Universitaria Senese [European Reference Network (ERN) for Rare Immunodeficiency, Autoinflammatory and Autoimmune Diseases (RITA) Center], Siena, Italy, [6]Ophthalmology Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy, [7]Rheumatology Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy.

Background: The role of Interferon Regulatory Factor 7 (*IRF7*) is well established in recessive immunodeficiencies due to loss of function mutations. However, gain of function mutations in this gene are not described despite the fact that the pro-inflammatory function of this gene is well known.

Material and methods: Exome analysis in 198 autoinflammatory patients, negative for variants in known genes and 8,037 patients coming for different clinical questions.

Results: In one autoinflammatory family (0,5%) we identified a *IRF7* truncating variant c.738_750delCGGGCCCCAGCCC, p.Gly247fs, segregating in the proband with Still disease and in affected members. Transactivation assay demonstrates that removing of C-terminal domain from position 246 results in 100-fold increase activity. We identified 2 additional close *IFR7* truncating variants in 6 patients from a larger cohort, coming for different clinical purposes: c.749_750delCC, p.Pro250fs and c.839delC, p.Ala280fs. Active recontact of those patients showed the presence of joint pain, diarrhoea or arthritis (often requiring knee prosthesis) in all of them.

Conclusion: We report here new *IRF7* variants in autoinflammatory patients, which suggest to include *IRF7* in either autosomal dominant autoinflammatory or autosomal recessive immunodeficiency diseases depending on loss/gain variant effect. Since *IRF7* is unable to stimulate interferon gene expression in vitro in the absence of virus infection, we believe that the variability of clinical outcome in patients is strongly dependent on environmental factors such as the timing and type of viral infections. Further validation in larger cohort of patients is necessary to confirm the exact prevalence of *IRF7* variants in autoinflammatory disorders.

P06.036.C Diagnostic challenges in skeletal dysplasia: a clinical overview based on a 10-year retrospective study of single genetic department

Marija Mijovic[1,2], *Goran Cuturilo[1,2], Jelena Ruml Stojanovic[1], Aleksandra Miletic[1], Brankica Bosankic[1], Maja Dedovic[1], Marija Brankovic[1]*

[1]University Children's Hospital, Department of Clinical Genetics, Belgrade, Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Background: Genetic skeletal dysplasia is heterogeneous group of 771 disorders associated with 552 genes affecting bone and cartilage. Given that some skeletal dysplasia can be caused by several different genes, and also that some genes can cause a variety of different phenotypes, achieving a molecular diagnosis can be challenging.

Materials and methods: Our 10-year retrospective study (2014–2024) includes 252 probands from the skeletal dysplasia database of Department of Clinical Genetics, University Children's Hospital from Belgrade, Serbia. We conducted a clinical overview of tested probands with analysis of the diagnostic approach.

Results: Out of 252 probands, 217 were tested using next-generation sequencing (clinical exome sequencing or whole exome sequencing in first step, and whole genome sequencing in second step in selected negative probands) and 35 were tested using targeted gene/mutation analysis. Next generation sequencing showed a high detection rate of the causative gene variant(s) of 61.21% (131/217). Additionally, in 5.52% (12/217) of a non-diagnosed probands gene variant(s) of unknown significance were identified. In the targeted tested group, result was positive for 75.67% (27/35) of them. We monitored whether the diagnosis was made with the first genetic test or if more steps were required. Some of the probands went through diagnostic odyssey before establishing the molecular diagnosis.

Conclusion: Our results showed that combination of next generation sequencing and gene/mutation targeted testing could achieve a high diagnostic rate for probands with skeletal dysplasia. We learned from analyzing diagnostic challenges in patients in whom the diagnosis was achieved with difficulty.

P06.037.D Unraveling the genetic landscape of rare Ichthyosis in Tunisian patients: advancing molecular diagnosis and uncovering novel variants through whole exome sequencing

Hamza CHOUK[1,2], *Hane LEE[3], Sarra SAAD[4], Haifa EL MABROUK[1], Lobna BOUSSOFARA[4], Yongjun SONG[3], Moez GRIBAA[1], Ali SAAD[1], Mohamed DENGUEZLI[4], Dorra H'MIDA[1]*

[1]Laboratry of Human Cytogenetics, Molecular Genetics and Reproductive Biology, Sousse, Tunisia, [2]Higher Institute of Biotechnology of Monastir, Monastir, Tunisia, [3]3billion Inc, Seoul, Korea, Republic of, [4]Department of Dermatology, Farhat Hached Hospital, Sousse, Tunisia.

Background: Over 50 genes are associated with ichthyoses, contributing to the broad spectrum of clinical manifestations. The genetic diversity and overlapping phenotypes raise challenges in diagnosing ichthyoses in many Tunisian patients. This study aimed to assess the effectiveness of Whole Exome Sequencing (WES) in identifying genetic variations in Tunisian patients with different subtypes of ichthyosis to improve molecular diagnosis and management.

Material and methods: WES was performed on 46 patients suspected of having various forms of ichthyoses.

Results: Mutations were detected in 38 (83%) patients, while no variants were found in 8 (17%) patients. Overall, variants were identified in 14 distinct genes. In a subgroup of 23 patients with autosomal recessive congenital ichthyosis (ARCI), 4 variants were identified in *CYP4F22*, 2 in *NIPAL4*, 1 in *CERS3*, 1 in *ALOXE3*, 1 in *ALOX12B*, and 5 in *TGM1* gene. A new variant in the *KRT1* gene was discovered in a patient with epidermolytic hyperkeratosis. In contrast, another patient with the same phenotype had a heterozygous pathogenic c.467G>A (p.Arg156His) variant in the *KRT10* gene. Twelve patients carry *LORICRIN*, *ABHD5*, *SLC27A4*, *RAG1*, *FLG* and *STS* genes variants, associated with syndromic and

commun ichthyosis, whereas they were clinically suspected of having the ARCI phenotype.

Conclusion: The high detection rate of pathogenic variants (83%) highlights the utility of WES in improving molecular diagnosis. Additionally, discovering new variants highlights the importance of population-specific genetic characterization, which deepens the understanding of the genetic landscape of ichthyoses, aiding in better diagnostic accuracy and the potential development of targeted therapies.

P06.038.A Systematic use of WES improves the diagnostic yield for skeletal dysplasia conditions within the national healthcare system

Ana Peterlin[1,2], *Dorra Najjar*[3,2], *Ales Maver*[2], *Helena Jaklic*[2], *Borut Peterlin*[2]

[1]*Faculty of Medicine, University of Ljubljana, LJUBLJANA, Slovenia,* [2]*Clinical Institute of Genomic Medicine, University Medical Centre Ljubljana, Ljubljana, Slovenia,* [3]*Laboratory of Biomedical Genomics and Oncogenetics, LR16IPT05, Institut Pasteur de Tunis, Tunis El Manar University, El Manar I, Tunis, Tunisia.*

Background: Skeletal dysplasia (SD) is a large and heterogeneous group of rare genetic disorders that affects bone and cartilage growth. These disorders are diagnosed on the basis of clinical, radiographic, and molecular criteria. We present the yield of genetic testing and molecular epidemiology of SD in the Slovenian national health care system.

Material and methods: We retrospectively reviewed the records of 470 patients with clinical features of SD, including prenatal, childhood, and adult patients referred to the national genetic reference center over a ten-year period. In 262 patients, next-generation sequencing (NGS) was performed either as whole-exome sequencing (WES) or whole-genome sequencing (WGS). Targeted sequencing was performed in 208 patients with a clear-cut clinical diagnosis.

Results: A definitive genetic diagnosis using NGS was achieved in 50% (n = 131) of patients. Among the positive cases, 49.61% initially presented with a nonspecific diagnosis of SD and genetic testing contributed to establishing the diagnosis. Moreover, we demonstrated high genetic heterogeneity in our SD cohort, with 66 distinct causative genes, resulting in different types of SD. We detected 132 SD-causing variants, of which 29 were novel.

Conclusion: With the systematic use of WES and WGS, we significantly improved the diagnostic yield of SD in the Slovene national health care system. Moreover, we found significant genetic heterogeneity and reported the genetic epidemiology of SD in the Slovenian population.

P06.039.B Mitochondrial skeletal disorders: a retrospective cohort of 9 French cases

Caroline Michot[1], *Geneviève Baujat*[1], *Tania Attié-Bitach*[2], *Giulia Barcia*[2], *Lucile Boutaud*[2], *Véronique Ivashchenko*[3], *Olivier Patat*[3], *Sophie Rondeau*[1], *Celine Huber*[4], *Valérie Cormier-Daire*[1]

[1]*Reference Center for Skeletal Dysplasias, INSERM UMR1163, Paris Descartes - Sorbonne Paris Cité University, Imagine Institute, Necker-Enfants Malades Hospital, Paris, France,* [2]*Department of Genomic Medicine of Rare Diseases, Paris Descartes - Sorbonne Paris Cité University, Necker-Enfants Malades Hospital, Paris, France, Paris, France,* [3]*Genetics Department, Reference Center for Developmental Anomalies, Purpan Hospital, Toulouse, France, Paris, France,* [4]*INSERM UMR1163, Laboratory of molecular and physiopathological bases of osteochondro-dysplasia, Institut Imagine, Paris, France, Paris, France.*

Background: Mitochondrial disorders (MD) result from primary mitochondrial dysfunction leading to multisystemic manifestations. However, bone disorders are uncommon in MD. A group of autosomal recessive skeletal dysplasias linked to mitochondrial dysfunction is yet emerging, involving *LONP1*, *HSPA9*, *IARS2*, *PAM16*, *AIFM1* and *PISD* genes. We aim to describe and compare the skeletal presentation of these mitochondrial skeletal disorders (MSD).

Material and methods: We recruited 9 cases (6 families), including 5 females and 4 males of diverse ethnicities; 4 fetuses and 5 patients (8 to 15 years old).

Results: We identified biallelic *LONP1* mutations in 3 fetuses and 1 patient, *AIFM1* (2 brothers) and *PISD* (1 fetus; 2 patients). Common symptoms include growth retardation and absence of microcephaly. *PISD* fetus displayed neuronal alterations, platyspondyly, short ribs, curved femora and metaphyseal spurs. *LONP1* fetuses, but not the living patient, harbour cardiopathies and diaphragmatic hernias. All MSD patients display motor developmental delay, eye abnormalities, spondyloepimetaphyseal dysplasia and maxillofacial anomalies. Distal femoral epiphysiodesis and patellar dislocation affect the *LONP1* patient. *AIFM1* and *PISD* patients display brachy-metacarpy/-phalangy. Metaphyseal alterations and enlarged knees are observed in *AIFM1*, whereas joint dislocations and coxa vara are seen in *PISD*.

Conclusion: Growth retardation, severe epiphyseal dysplasia, spine involvement and maxillofacial anomalies are common to MSD. Together with the shared extra-skeletal signs, this supports a common clinicoradiological presentation linked to genes involved in mitochondrial protein homeostasis and transport. However each genotype displays some specific signs: we recommend to assess joint laxity in *LONP1* and coxa vara in *PISD*.

P06.040.C Not only reverse phenotyping: reverse genotyping in Bazex-Dupré-Christol syndrome

S. Morlino[1], *M. Capurso*[2], *O. Palumbo*[1], *M. Castori*[1];

[1]*Division of Medical Genetics, Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy,* [2]*Laboratory of Medical Genetics, Department of Biomedical Sciences and Human Oncology (DIMO), University of Bari "Aldo Moro", Bari, Italy*

Background: The ACMG standards and guidelines for reporting copy number variations provide for not considering those that are small, inherited, and not containing OMIM disease-genes. Although generally valid, these criteria have limitations such as in cases due to small duplications falling in desert-gene/intergenic regions, which regularly escape filtering for clinical reporting. Bazex-Duprè-Christol syndrome (BDCS) is an X-linked dominant genodermatosis recently associated with a ~100 Kb microduplication spanning between the IGSF1 and ARHGAP36 genes in Xq26.1. Before the identification of its genetic cause, BDCS has been defined by the combination of congenital hypotrichosis, atrophoderma follicularis and basal cell carcinomas.

Material and methods: Two unrelated families with multiple affected individuals presenting atrophoderma follicularis of dorsum of hands/elbows/knees, facial milia and hypotrichosis and acrocordons underwent genetic testing for an unclassified genodermatosis. In both families the phenotype was transmitted from the affected mother.

Results: After initial negative results at SNParray, precise clinical diagnosis guided re-analysis and prompted to the identification of the recurrent microduplication in Xq26.1 in both families. Affected individuals did not present basal cell carcinomas, while facial milia and atrophoderma follicularis were the only features occurring with full penetrance.

Conclusion: Presented families illustrate the crucial role of deep phenotyping before prescribing molecular testing in apparently attenuated presentations such as BDCS. Our experience put forward the opportunity to identify in atrophoderma follicularis, facial milia and lack of male-to-male transmission the minimum set of criteria for array-based data re-analysis in the suspicion of BDCS.

P06.041.D Unraveling novel genetic markers and transcriptional regulator of osteoporosis

T. Koromila[1,2], *M. Vlachou*[3], *F. Kaliakou*[1], *M. Doumou*[1], *C. Oikonomopoulou*[3], *N. Pantazi*[3], *G. Mimikos*[3], *P. Kollia*[3];

[1]*School of Biology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*Department of Biology, University of Texas at Arlington, Arlington, TX,* [3]*Department of Biology, School of Science, National and Kapodistrian University of Athens, Athens, Greece*

Background: Osteoporosis is the most common bone-related disease, driven by a combination of environmental and genetic factors. The aim of our study is to investigate the underlying gene expression mechanisms and characterize the genetic profile of affected individuals in order to identify correlations between genetic background and osteoporosis symptoms, low bone mass and osteoporotic fractures.

Material and methods: We analyzed gene expression profiles in bone samples from 75 osteoporotic and 25 control post-menopausal Greek women. Bone mineral density (BMD) was measured using dual X-ray absorptiometry (DXA), and serum bone markers were assessed. Total RNA was isolated from bone tissue and analyzed via TGFβ-BMP signaling pathway microarray. Additionally, we performed ChIP-seq binding analysis at loci associated with low bone density and increased fracture risk.

Results: The gene expression analysis revealed significant molecular distinctions between osteoporotic patients and controls. Specific SNPs, including rs3736228 (LRP5) and rs1286083 (RPS6KA5), were linked to reduced BMD, whereas rs6465508 (SHFM1) and rs7851693 (FUBP3) correlated with higher fracture risk. Notably, the CTCF-dependent SNP in *DKK1* emphasize genetic influences on bone health and remodeling. Lastly, overexpression of *CDKN1A* in peripheral blood and bone tissue underscores its role in osteoporosis pathophysiology. Elevated *ENG* expression at fracture sites suggests its involvement in healing processes, while increased *FOS* levels in peripheral blood highlight its potential as an early diagnostic biomarker.

Conclusion: Genetic profiling in osteoporosis can uncover key biomarkers for early diagnosis. Knowledge of specific SNPs that affect gene regulation can pave the way for personalized approaches in treating bone diseases.

P06.042.A Homozygous LRP6 variant in a patient with multiple birth defects and ectodermal dysplasia

Maria Luisa Garau[1], *Rebecca Affuso*[1], *Elona Shkoza*[1], *Eva Trevisson*[1,2,3], *Matteo Cassina*[1,3]

[1]*University of Padova, Department of Women's and Children's Health SDB, Padova, Italy,* [2]*Istituto di Ricerca Pediatrica-IRP, Fondazione Città della Speranza, Padova, Italy,* [3]*University Hospital of Padova, Clinical Genetics Unit, Padova, Italy, Padova, Italy.*

Background: *LRP6* plays a crucial role in embryogenesis, cell signaling, and tissue development processes. Heterozygous loss-of-function variants in *LRP6* gene have been associated with non-syndromic dental agenesis, while some heterozygous and homozygous missense mutations have been linked to increased risk of coronary artery disease. Notably, homozygous loss-of-function variants have never been reported in human population. However, experimental studies on mouse embryos have demonstrated that homozygous mutations can result in a complex phenotype encompassing multiples congenital anomalies and early mortality.

Material and methods: we report a case of an 8-year-old male with a complex phenotype characterized by ectodermal dysplasia, bilateral cleft lip and palate, split hand-foot and vertebral anomalies. A panel of genes associated with ectodermal dysplasia and hypodontia was analyzed by next generation sequencing.

Results: a homozygous variant in *LRP6* gene was identified (NM_002336.3: c.2280-3T>G). The variant has never been reported in the literature nor in the available databases, is not present in databases aggregating exome and genome sequencing data from large-scale sequencing projects, and is predicted to alter the transcript splicing by multiple lines of computational evidence.

Conclusion: the clinical characteristics of our patient overlap the phenotypic spectrum observed on *lrp6* knock-out animal models; however, until now, no other human patients carrying homozygous splicing variants in this gene have been described in the literature. Ongoing functional studies aim to characterize the effect on splicing and confirm the pathogenicity of the variant detected in our proband.

Metabolic Bone Diseases Department and ERN BOND, ULS Santa Maria, Lisbon, and Faculty of Medicine, University of Lisbon, Lisbon, Portugal, [7]Medical Genetics Unit and ERN-BOND, ULS Coimbra, and Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Background: Except for monogenic disorders with significant fractures and/or extra-skeletal features, such as osteogenesis imperfecta (OI), bone fragility is usually considered a multifactorial disorder. Our aim was to molecularly evaluate a cohort of patients with mild bone fragility in order to identify its monogenic causes and/or genetic risk factors.

Material and methods: We evaluated a cohort of 38 unrelated patients with bone fragility and absence of extra-skeletal signs of OI or significant bone deformities. Genetic analysis was performed using a skeletal dysplasia NGS panel and MLPA for *COL1A1* and *COLA1A2*.

Results: The cohort included 22 females and 16 males. Twenty patients were children or adolescents and 18 were adults. A monogenic cause was identified in three patients (7.9%), namely a duplication of exons 6 to 9 of *PLS3*, a complete deletion in mosaic state of *COL1A1*, and a frameshift variant in *LRP5*. No relevant variants were detected in 24 cases (63.2%). In the remaining cases (9/38, corresponding to 23.7%), variants that have been previously associated with increased risk of recurrent fractures and/or osteoporosis (including common polymorphisms) were found, namely *LRP5*, *WNT1*, and *DKK1*. Six patients carried more than one such variants.

Conclusion: These results highlight that mild bone fragility can, in rare cases, be monogenic, which is important for genetic counselling. While knowledge of genetic risk factors contributing to bone fragility is increasing, they explain only a portion of cases, indicating that other genetic and environmental factors should be involved.

P06.044.C Probable founder effect for rare variants of the *P3H1* gene in Bashkirs (Russia)

Yulia Karpova[1], *Elena Merkureva*[2], *Anton Turin*[3], *Rita Khusainova*[1]

[1]*Endocrinology Research Center, Moscow, Russian Federation,* [2]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [3]*Bashkir State Medical University, Ufa, Russian Federation.*

Background: Prolyl-3-hydroxylase-1 (P3H1) is part of a complex that hydroxylates proline residues in type 1 collagen. About 70 pathogenic variants in the *P3H1* gene are linked to autosomal recessive forms of osteogenesis imperfecta (OI) type III/VIII. This paper reports three *P3H1* gene variants identified in Bashkir patients with OI and evaluates their prevalence in Bashkir ethnic groups.

Material and methods: The study included 65 OI patients, 125 family members, and 731 individuals of Bashkir ethnicity from six districts in Bashkortostan, along with Bashkirs from other regions of Russia. NGS sequencing of a target 664-gene panel was performed on the DNBSEQ-G400 platform, validated by Sanger sequencing. Three *P3H1* gene variants were screened using TaqMan technology.

Results: Two unrelated Bashkir families with OI were identified: one child with a homozygous c.1051G>T (p.Glu351*) mutation in *P3H1* died at age of 3 months, while another patient had a non-lethal form with compound-heterozygous variants c.1051G>T (p.Glu351Ter) and 1948G>A (p.Gly650Arg). A heterozygous c.1720+4G>A variant was found in a patient not fitting OI type VIII. Screening in the Bashkir population three *P3H1* detected variants revealed the 1948G>A variant in one individual in a heterozygous state, while c.1051G>T (p.Glu351Ter) appeared in three unrelated individuals, indicating a potential founder effect. The 1720+4G>A variant had a frequency of 0.007, significantly higher than in available databases.

Conclusion: These results underscore the importance of studying the genetic basis of OI across ethnic groups to identify specific pathogenic variants. Further research on their prevalence will clarify their clinical significance in OI formation.

P06.045.D Investigating the pre- and postnatal phenotypic spectrum and prognosis of ARCN1-related disorder

Jacqueline Ritz[1], *Pascal Joset*[1], *Gabor Szinnai*[2,3], *Gwendolin Manegold-Brauer*[4], *Isabel Filges*[1,3]

[1]*Institute of Medical Genetics and Pathology, University Hospital Basel, Basel, Switzerland,* [2]*Pediatric endocrinology, University Children`s Hospital Basel, Basel, Switzerland,* [3]*Department of Clinical Research, University of Basel, Basel, Switzerland,* [4]*Department of Obstetrics and Prenatal Medicine, Division of Gynecologic and Prenatal Ultrasound, University Hospital Basel, Basel, Switzerland.*

Background: *ARCN1*-related condition is rare and caused by defective collagen transport. To date, 21 cases were described with a clinical spectrum ranging from fetal death to a milder phenotype including intrauterine growth restriction (IUGR), short stature and micrognathia. The challenge remains to predict the severity and postnatal outcome based on the prenatal phenotype and genotype. We describe a one-year-old girl diagnosed prenatally with a favorable outcome and compare the clinical findings to previously reported cases.

Material and methods: Prenatal Trio-Exome sequencing, full clinical examination and phenotype-genotype comparison based on the literature were performed.

Results: Ultrasound at 24 weeks of gestation showed mild IUGR and rhizomelic shortening. Trio-Exome sequencing revealed a novel de novo *ARCN1*-variant c.1091G>A (p.Trp364Ter), classified as pathogenic (ACMG criteria). The patient was born prematurely with micrognathia and a ventricular septal defect. At one year she had normal development. Including our patient to the previously reported postnatal cohort rhizomelia was observed in 56% (9/16), prematurity in 75% (12/16), development delays in 69% (11/16) and congenital heart disease in 38% (6/16). Additional 6 prenatal cases had been published, which all showed rhizomelia (6/6) and skeletal anomalies in the early second trimester. Outcomes included 3 fetal demises and 3 terminations of pregnancy.

Conclusion: Prenatal lethal or severe cases had a higher proportion of rhizomelia, skeletal anomalies and other ARCN1-related features which were detected earlier during pregnancy than in liveborn cases, including ours. Onset and severity during pregnancy may help to predict prognosis, but further patients are needed to assess genotype-phenotype correlation.

P06.046.A A novel deep-intronic variant in HES7 unveils a poison exon mechanism underlying spondylocostal dysostosis type 4

Elsa Lucas-Castro[1,2], *Francisca Díaz-González*[1,2], *Natalia Gallego-Zazo*[1,3], *Alejandro Parra*[1,3], *María Palomares*[1,3], *Manuel Parrón-Pajares*[4,2], *Pablo Lapunzina, MD, PhD*[1,3], *Karen Elise Heath*[1,3,2]

[1]INGEMM, IdiPAZ, Hospital Universitario La Paz, Madrid, Spain, [2]European Research Network on Rare BONe Disorders (ERN-BOND), Madrid, Spain, [3]CIBERER, Madrid, Spain, [4]Department of Radiology, Hospital Universitario La Paz, Madrid, Spain.

Background: Spondylocostal dysostosis (SCD) is an ultra-rare autosomal recessive disorder caused by pathogenic variants in *HES7*. To date, only six causative variants have been identified, all affecting coding or canonical splicing regions.

Materials and methods: Whole-genome sequencing (WGS) was performed on a patient with clinical features of SCD. The impact of the identified variant was assessed using bioinformatic tools, transcriptomic analysis of publicly available RNA-seq data, and splicing assays in patient and control samples.

Results: WGS revealed a novel homozygous deep-intronic variant in *HES7*, absent from population databases. It is predicted to enhance the strength of a cryptic intronic acceptor site, which would result in aberrant inclusion of a 49 base-pair pseudoexon and the introduction of a premature termination codon. This transcript is likely to be exposed to nonsense-mediated decay (NMD) and to subsequently cause loss of *HES7* function. Transcriptomic analysis revealed that pseudoexon inclusion occurs at low levels in a tissue-specific manner in healthy individuals, suggesting an underlying physiological role as a poison exon. However, splicing assays in lymphocyte-RNA revealed significantly increased pseudoexon inclusion in the patient compared to controls.

Conclusion: This is the first report to implicate a poison exon in the regulation of a somitogenesis-related gene. The patient's homozygous variant likely disrupts normal *HES7* splicing across multiple tissues, leading to biallelic loss of function and the SCD phenotype. These findings expand the genetic spectrum of SCD and emphasize the value of WGS and transcriptomic approaches in uncovering causal non-coding variants.

P06.047.B Genetic aspects of pediatric genodermatosis cases from a center for rare diseases

Susanne Leidescher[1], *Birgit Anwald*[1], *Jana Rohde*[1], *Moneef Shoukier*[1], *Désirée Dunstheimer*[2], *Andreas B. Weins*[2,3]

[1]Eurofins Humangenetik und Pränatal-Medizin MVZ GmbH, München, Germany, [2]Klinik für Kinder- und Jugendmedizin, Universitätsklinikum Augsburg, Augsburg, Germany, [3]KIDZ SKIN Praxis für Kinder und Jugenddermatologie, Ulm, Germany.

Background: Genodermatoses encompass a broad spectrum of genetic disorders that involve the skin, and may or may not involve other organ systems. Therefore, the clinical identification of uncommon genodermatoses is challenging and many patients remain without a molecular diagnosis, even though more than 500 causative genes have been discovered. The presented cases highlight the importance of interdisciplinary approaches in the diagnosis of rare skin disorders.

Material and methods: More than 20 cases with different dermatological conditions from an interdisciplinary dermatological and genetic consultation for pediatric and juvenile dermatology were examined for the presence of causative molecular genetic changes via (targeted) NGS analysis.

Results: We present a heterogeneous collective of rare pediatric/juvenile genodermatoses with regard to symptomatology and underlying molecular genetic alterations. Among others, we report on a previously undescribed de novo missense alteration in the *NSDHL* gene in an 8-year-old female patient who presented with inflammatory linear verrucous epidermal naevus (ILVEN). Furthermore, we describe a previously undescribed de novo frameshift alteration in the *ATP2A2* gene (Darier's disease) in a 9-year-old female patient who presented with acrokeratosis verruciformis and moderate neurodevelopmental disability.

Conclusion: The described cases show that molecular genetic diagnostics is a useful addition to dermatological or pediatric consultation, which often contributes to timely diagnosis of pediatric/juvenile genodermatoses. This in turn enables the best possible patient care at an early age and can considerably improve treatment outcome.

P06.048.C Development of an S2k Guideline for Ehlers-Danlos Syndrome (EDS) in Germany, Austria, and Switzerland

Bernd Auber[1], *Heinz Gabriel*[2], *Brock Isabelle*[3], *Martin Leinen*[4], *Bettina Brossart*[4]

[1]Department of Human Genetics, Hannover Medical School, Hannover, Germany, [2]CeGaT Tuebingen, Tuebingen, Germany, [3]Department of Connective Tissue, Nova Combian Research Institute, New York, NY, USA, [4]Ehlers-Danlos Organisation e.V., Isernhagen, Germany.

Background: Ehlers-Danlos syndrome (EDS) comprises a group of genetically determined connective tissue disorders characterized by joint hypermobility, skin fragility, and systemic manifestations. Despite the significant burden on affected individuals and the diversity of subtypes, no comprehensive evidence-based guidelines exist in the German-speaking region. To address this gap, the development of an S2k guideline for EDS diagnosis and treatment was initiated under the auspices of the Association of Scientific Medical Societies in Germany (AWMF).

Material and methods: The guideline is being developed under the coordination of the Society for Human Genetics (GfH) in collaboration with 16 professional societies and 4 patient organizations from Germany, Austria, and Switzerland. The process involves reviewing available evidence, conducting expert discussions, structured consensus rounds (e.g., Delphi method), and incorporating feedback from patient organizations. Additionally, recommendations for therapeutic interventions are being drafted in cooperation with physiotherapy experts.

Results: The ongoing guideline development focuses on establishing standardized criteria for EDS diagnosis, including clinical and genetic diagnostics, and creating evidence-based recommendations for medical and therapeutic care. The inclusion of patient perspectives ensures a practical and patient-centered approach. This initiative aims to create a unified standard for EDS care across the German-speaking region.

Conclusion: The development of the S2k guideline represents an essential step toward improving EDS diagnosis and treatment. Its interdisciplinary and patient-focused approach ensures that the final guideline will meet high-quality standards, enhance collaboration among healthcare professionals, and address the needs of affected individuals.

P06.049.D A novel PIK3R1 germline splice variant in a multi-generation family with overgrowth, vascular malformations, lipomas, and developmental delay

Stanley John Neufeld[1], *Anita E. Beck*[2], *Audrey E. Squire*[2], *Emily Pao*[2], *Micheil A. Innes*[3], *Ghayda M. Mirzaa*[2]

[1]*University of Calgary and Alberta Health Services, Calgary, AB, Canada,* [2]*Univ Washington & Seattle Children's Hospital, Seattle, WA, USA,* [3]*Department of Medical Genetics, Alberta Children's Hospital Research Institute, Calgary, AB, Canada.*

Background: PIK3R1 encodes a regulatory component of the PI3K/AKT signalling pathway which is critical for growth. Pathogenic germline PIK3R1 variants are associated with SHORT syndrome, characterized by short stature, lipodystrophy, and insulin resistance, or an immune phenotype (Activated PI3K-Delta syndrome) depending on the molecular mechanism. Recently, mosaic PI3KR1 variants have been associated with overgrowth and vascular malformations. We present a 3-generation family with a variable phenotype associated with neurodevelopmental, cutaneous and growth issues with a germline variant previously reported in PIK3R1-related mosaic overgrowth.

Material and methods: Trio exome sequencing of a family with vascular malformations, lipomas, macrocephaly, and neurodevelopmental issues was performed. Gene-specific RNA-sequencing of the proband was also performed to functionally validate the identified variant.

Results: Exome sequencing identified PIK3R1 c.1746-2A>C, a variant in the proband, father and paternal grandmother. The proband had neurodevelopmental delays, unilateral hearing loss and sensory processing disorder. His father has multiple cutaneous hemangioma, lipomas and early developmental delays that have since resolved. The paternal grandmother has macrocephaly. Its pathogenicity is supported by absence in population databases, position at a splice site acceptor junction, and abnormal splicing as demonstrated by RNA-seq. This variant has been reported once before in the mosaic state in an individual with overgrowth.

Conclusion: We report the first association of a rare germline variant in PIK3R1 with vascular malformations, overgrowth, and developmental delay, similar to activating PIK3R1 somatic variants. We will review these findings in the context of our expanded understanding of genotype-phenotype correlations with PIK3R1-related disorders.

P06.050.A Clinical heterogeneity in *GNAS*-related disorders:experience of a single center

Yusuf Can Dogan[1], *Türkan Turkut Tan*[1], *Zehra Burcu YILMAZ, Pediatric Specialist pre-doc genetics researcher*[1], *Deniz Özalp Kizilay*[2], *Özlem Nalbantoglu*[3], *Tahir Atik*[1], *Ozgur COGULU*[1], *Esra Isik*[1]

[1]*Ege University, Department of Pediatric Genetic Diseases, İzmir, Turkey,* [2]*Ege University, Department of Pediatric Endocrinology, İzmir, Turkey,* [3]*Dr. Behçet Uz Children's Hospital, Pediatric Endocrinology Department, İzmir, Turkey.*

Background: Pseudohypoparathyroidism (PHP), pseudopseudohypoparathyroidism (PPHP), and McCune-Albright syndrome (MAS) are disorders associated with mutations in the GNAS gene, which encodes the alpha subunit of the stimulatory G protein (Gsα). Due to the complex expression of the GNAS gene, these conditions present a broad clinical spectrum. Loss-of-function mutations cause PHP or PPHP phenotypes, characterized by hormone resistance or Albright hereditary osteodystrophy (AHO) features, respectively. Activating mutations lead to MAS with fibrous dysplasia and endocrine abnormalities. This study describes the phenotypic and molecular spectrum of six cases diagnosed with GNAS-related disorders.

Material and methods: Six Ege University Pediatric Genetics Department patients were selected. Hospital records were reviewed for clinical and molecular data.

Results: The study included six patients (4 females, 2 males) aged 5–16 years, presenting with seizures, developmental delay, short stature, obesity, hypocalcemia, and premature menarche. Physical examination revealed AHO features in four patients, café-au-lait spots in one, obesity in two, and intellectual disability in three. TSH resistance was observed in four cases, and PTH resistance in three. Molecular analysis identified pathogenic GNAS variants in five cases, four of which were novel. One patient also had a maternally inherited 22q11.2 duplication, explaining their dysmorphic features. For a patient with premature menarche and fibrous dysplasia, skin biopsy-based high-read-depth NGS was planned. Diagnoses included PHP type 1a (4 cases), PPHP (1 case), and MAS (1 case).

Conclusion: *GNAS*-related disorders demonstrate diverse clinical features influenced by mutation type and inheritance. Molecular studies from affected tissues are critical for diagnosing MAS cases with suspected mosaicism.

P06.051.B X-chromosome inactivation patterns and clinical manifestations in Russian females with *EDA* mutations

Valeriia Kovalskaia*, Tatiana Cherevatova, Elena Zinina, Anna Stepanova, Olga Schagina, Aleksander Polyakov, Oxana Ryzhkova, MD, PhD*

FSBSI Research Centre for Medical Genetics, Moscow, Russian Federation.

Background/Objective: X-linked hypohidrotic ectodermal dysplasia (XLHED) is a rare disorder affecting various ectodermal derivatives due to pathogenic variants in the EDA gene. Female carriers of EDA deleterious mutations typically exhibit milder or no clinical signs compared to affected males. This study aimed to determine whether a correlation exists between HED manifestations and X-chromosome inactivation (XCI) patterns.

Material and methods: XCI patterns were analyzed in the blood of 47 Russian female patients carrying pathogenic or likely pathogenic EDA variants using an assay that targets the polymorphic CAG repeats of the AR gene. Peripheral blood DNA was digested with the HpaII enzyme, which cleaves only the restriction sites on the active X chromosome, leaving the methylated X-chromosome intact. XCI patterns were classified as random if the ratio was ≤75:25, moderately skewed if between 75:25 and 80:20, and highly skewed if >80:20.

Results: The analysis of XCI patterns in 47 females with causative EDA variants revealed no significant differences between the individuals ($p = 0.277$), indicating no clear link between preferential XCI patterns and clinical XLHED manifestations. In most cases, blood X-inactivation was random. Notably, in one family, female subjects displayed almost opposite XCI patterns, yet both exhibited HED-related clinical features.

Conclusion: Our findings indicate no evidence of preferential X-inactivation in blood among female XLHED Russian patients and EDA female carriers. Consequently, blood X-inactivation testing should not be widely used in clinical practice for predicting XLHED severity or for refining the pathogenicity of variants of uncertain significance (VUS) in the EDA gene.

P06.052.C A family with new X-linked overgrowth syndrome caused by *SPIN4* gene defect

Lisanna Põlluaas[1,2], *Stella Lilles*[1,3], *Aleksandr Peet*[1,3], *Youn Hee Jee*[4,5], *Ülle Murumets*[2], *Mihkel Ilisson*[1,2], *Katrin Õunap*[1,2]

[1]*University of Tartu, Institute of Clinical Medicine, Tartu, Estonia,* [2]*Genetic and Personalized Medicine Clinic, Tartu University Hospital, Tartu, Estonia,* [3]*Children's Clinic, Department of General Paediatrics and Neurology, Tartu University Hospital, Tartu, Estonia,* [4]*Division of Endocrinology and Center for Genetic Medicine Research, Children's National Hospital, Washington, DC, USA,* [5]*Department of Pediatrics, George Washington University School of Medicine and Health Sciences, Washington, DC, USA.*

Background: Spindlin Family Member 4 (*SPIN4*) is an epigenetic reader, located on the X-chromosome and recently reported to negatively regulate body growth. Normally SPIN4 binds to modified histones, promotes canonical WNT signaling, and inhibits cell proliferation. The loss of SPIN4 function is associated with overgrowth syndrome in mice and humans, hemizygous males being more affected.

Material and Methods: 14-year-old male was assessed for suspected overgrowth syndrome. Within the family, next-generation sequencing (NGS), Sanger sequencing, familial segregation analysis, and skewed X-inactivation (androgen receptor (AR)-CAG trinucleotide repeat length) were used.

Results: The male proband presented tall stature (+3.5SD), thick joints, and normal intelligence. He was born large for gestational age with birth weight of +3SD and length of +2SD. At presentation, puberty was at Tanner stage 5 with testicular volume >25 ml. Ultrasound revealed splenomegaly. Bone age was consistent with the chronological age. Low bone mineral density was detected in the spine and the entire body (L1-L4 BMD HAZ −1.08 SD; TBLH BMD HAZ: −3.29 SD). Clinical biochemical evaluations (IGF-1, IGFBP-3, PTH, 25-OH vitamin D, Ca, P, Mg, thyroid function tests, and creatinine) were in the normal range.NGS identified a previously described hemizygous frameshift variant in the *SPIN4* gene (NM_001012968.3(SPIN4):c.312_313del p.(Arg104Serfs*24)). The variant was present in the proband's mother and maternal grandmother, although they both had skewed X-deviation (80% and 20%) and no height gain to their midparental height.

Conclusion: We report a second family with a newly identified X-linked overgrowth syndrome caused by a loss-of-function variant in the *SPIN4* gene.

P06.053.D Identification of novel recurrent gross deletion in *COL9A3* gene in Russian patients with multiple epiphyseal dysplasia

Maria Orlova, *Timofei Vizerov, Tatiana Markova, Daria Gorodilova, Oxana Ryzhkova*

FSBSI Research Centre For Medical Genetics, Moscow, Russian Federation.

Background: Multiple epiphyseal dysplasia (MED) is a heterogeneous chondrodysplasia with autosomal dominant or recessive inheritance characterized by joint pain and stiffness, waddling gait and/or mild short stature in childhood. The disorder is associated with mutations in several genes, including *COL9A3*, which encodes one of the three alpha chains of Type IX collagen. Heterozygous variants in *COL9A3* have been implicated in MED pathogenesis.

Material and methods: Whole-genome sequencing (WGS) was performed to 6 families of Russian descent with MED using the DNBSEQ-T7 platform. The obtained data achieved an average coverage depth of 35×.

Results: WGS revealed a previously unknown gross deletion, chr20:62817899_62818755del, spanning 857 nucleotides length and including exon 3 of gene *COL9A3*. This deletion was detected in 18 patients with MED across all six families and segregated with the disease in each case. All families were of Russian origin but represented diverse regions within the country. Importantly, this variant has not been published before and not present in the population frequency databases, such as DGV Gold and gnomAD SV. Based on established criteria, the deletion was classified as a pathogenic variant.

Conclusion: Pathogenic variants affecting splicing and leading to skipping of exon 3 in patients with MED have been repeatedly reported in this gene, highlighting the functional importance of this region. The newly identified gross deletion in *COL9A3* gene represent a frequent recurrent pathogenic variant among Russian patients with MED. These findings expand the mutational spectrum of *COL9A3* and emphasize the need for targeted genetic screening in affected patients.

P06.054.A Exploring *EDA*gene splicing variants: functional insights, clinical implications and therapeutic opportunities

Federica Perino[1], *Giulia Pianigiani*[2,1], *Domizia Pasquetti*[2], *Elisa Paccagnella*[2,1], *Elisa Rubinato*[2], *Stefania Zampieri, PhD*[2], *Vanessa Rebecca Gasparini*[1,2], *Giorgia Girotto*[1,2]

[1]*University of Trieste, Trieste, Italy,* [2]*IRCCS Burlo Garofolo, Trieste, Italy.*

Background: X-linked hypohidrotic ectodermal dysplasia (XLHED), characterized by hypotrichosis, hypohidrosis, hypodontia, is caused by *EDA* (NM_001399.5) pathogenic variants, which alter ectodermal morphogenesis. To date, 416 *EDA* mutations have been reported and approximately 10% of them affects normal splicing process.

Material and methods: Whole exome sequencing (WES) was performed in one family, highly suggestive of XLHED. In vitro splicing assay using *EDA* minigenes was used to evaluate splicing variant effects.

Results: Our proband presented with hypodontia, sparse hair and dry skin, while his mother and sister showed milder XLHED phenotypes. In trio-WES analysis identified a hemizygous c.924+6T>G *EDA* variant in the proband, with the mother and the sister being heterozygous for the same variant. The variant, located near the splice donor site in intron 7, was predicted to be damaging by in silico tools. The minigene assay showed that mutant construct produced one correctly spliced transcript and a shorter one due to a cryptic donor splice site activation. This led to a 42 bp deletion in exon 7, causing a 14-amino-acid loss in the functional TNF domain.

Conclusion: This study underscores the importance of integrating WES data with functional assays to elucidate the role of splicing variants in *EDA* gene, especially those involving the exon 7 mutational hotspot. Functional validation provides critical insights into the XLHED's molecular basis and serves as a valuable tool for determining the significance of variants of unknown significance. Furthermore, promising outcomes from both preclinical and clinical studies on targeted therapeutic strategies for XLHED emphasize the need to improve advanced genomic approach.

P06.055.B A de novo 1.7 Mb interstitial deletion upstream of *SOX9* in a patient with acampomelic form of campomelic dysplasia

Anna Szoszkiewicz[1,2], *Ewelina Bukowska-Olech*[3], *Anna Sowinska-Seidler*[1], *Aleksander Jamsheer*[1,4]

[1]*Department of Medical Genetics, Poznan University of Medical Sciences, Poznan, Poland,* [2]*Doctoral School, Poznan University of Medical Sciences, Poznan, Poland,* [3]*Poznan University of Medical Sciences, Poznan, Poland,* [4]*Diagnostyka GENESIS, Poznan, Poland.*

Background: Acampomelic campomelic dysplasia (ACD) is a rare autosomal dominant skeletal disorder classified as a milder form of campomelic dysplasia (CD). ACD typically results from heterozygous de novo pathogenic variants in *SOX9* and is characterized by distinct clinical features, including spinal malformations, cleft palate, facial dysmorphism, and an absence of long bone bowing, which differentiates it from classic CD. Approximately two-thirds of patients with ACD exhibit 46,XY sex reversal, often due to disruptions in *SOX9* regulatory elements. We report a case of ACD with 46,XY sex reversal caused by a de novo ~1.7 Mb interstitial deletion at chromosome 17q24.3.

Material and methods: High-resolution 1M array comparative genomic hybridization (aCGH) identified the chromosomal aberration, which was subsequently validated and refined using quantitative real-time polymerase chain reaction followed by Sanger sequencing to map the exact breakpoints.

Results: The analysis revealed a de novo 1.671 Mb deletion upstream of *SOX9* in a 3-year-old female patient with a 46,XY karyotype. The deleted region encompassed key *SOX9* enhancers, including F2, SOX9cre1, enh3, enh4, enh5, enh6, enh7, F8, E1, and E3. Clinically, the patient presented with a short neck, thoracic kyphoscoliosis, widely spaced nipples, sandal gap deformity, cleft palate, gonadal dysgenesis, and mild facial dysmorphism.

Conclusion: This case represents the second-largest deletion upstream of the *SOX9* gene associated with ACD reported to date. It underscores the role of *SOX9* enhancers in modulating the clinical variability of ACD and expands the spectrum of chromosomal abnormalities linked to *SOX9*-related disorders. Our findings provide valuable insights into genotype-phenotype correlations in ACD.

P06.056.C Unveiling *IL11RA* variants in craniosynostosis and dental anomalies: insights from exome sequencing

Volkan Karaman[1], *Mehmet Akif Yücesoy*[1], *Kübra Demir*[2], *Güven Toksoy*[1], *Esra Yıldız*[2], *Bülent Kara*[3], *Zehra Oya Uyguner*[1], *Ayça Dilruba Aslanger*[1]

[1]*Department of Medical Genetics, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey,* [2]*Department of Restorative Dentistry, Institute of Health Sciences, Istanbul University, Istanbul, Turkey,* [3]*Division of Pediatric Neurology, Department of Pediatrics, Faculty of Medicine, Kocaeli University, Kocaeli, Turkey.*

Background: Craniosynostosis (CS) is the second most common craniofacial birth defect after orofacial clefts, affecting approximately 1 in 2,250 live births. This condition results from the premature fusion of one or more cranial sutures, causing abnormal skull development. CS is genetically heterogeneous, presenting as either rare syndromic or more commonly nonsyndromic forms. Bi-allelic pathogenic variants encoding the interleukin 11 receptor alpha (*IL11RA*) gene have been implicated in CS and dental anomalies (CRSDA), a Crouzon-like craniosynostosis disorder.

Material and methods: Exome sequencing (ES) was conducted in two cases. Variants in genes associated with CS, based on the Human Phenotype Ontology and literature data, were analyzed. Rare variants' pathogenicity was assessed and segregations were performed using Sanger sequencing.

Results: Two cases presenting with craniosynostosis and dental anomalies were clinically evaluated. Additionally, one of the cases exhibited symptoms of epilepsy. Following the clinical assessments, ES was performed on both cases. ES identified two different homozygous variants in the *IL11RA*(NM_001142784). The first case revealed a previously reported nonsense variant (p.(Arg237*)), while the second case identified leading to a novel frameshift alteration (p.(His289Profs*70)). Both variants were confirmed as homozygous in the affected individuals, with their parents identified as heterozygous carriers.

Conclusion: Craniosynostosis is a genetically heterogenous condition with a complex etiology involving monogenic, polygenic, and chromosomal factors. This study underscores the value of ES in uncovering the genetic basis of CS. Identifying *IL11RA* variants in two CRSDA cases expands the spectrum of known pathogenic variants and enhances the understanding of the genetic mechanisms underlying the condition.

P06.057.D A Novel pathogenic variant in the PDE4D gene in a case of metaphyseal acroscyphodysplasia

Anna Morgul[1], *Evgeniy Melchenko*[2], *Maria Orlova*[1], *Tatiana Milovidova*[1], *Tatiana Markova, MD*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*H. Turner National Medical Research Center for Children's Orthopedics and Trauma Surgery, St. Petersburg, Russian Federation.*

Background: Metaphyseal acroscyphodysplasia (OMIM 250215) is an ultra-rare skeletal dysplasia classified within the group of metaphyseal dysplasias. Acroscyphodysplasia includes radiological findings, facial dysmorphism, obesity and mental retardation. This condition is also characterized by significant brachydactyly and the presence of cone-shaped epiphyses in the hands. To date, five clinical cases of metaphyseal acroscyphodysplasia caused by pathogenic variants in the *PDE4D* gene have been published.

Material and methods: The patient, a 7-year-old, underwent an extensive evaluation involving pedigree analysis, clinical and X-ray, Whole-genome sequencing, and direct Sanger sequencing to establish a precise diagnosis.

Results: We present a sixth clinical case of metaphyseal acroscyphodysplasia featuring a previously unreported pathogenic variant in the *PDE4D* gene: c.934C>T (p.Leu312Phe) in exon

7. A variant in the PDE4D gene characterized by an alternative amino acid substitution has been previously described in acrodysostosis type 2. The clinical characterization reveals distinct features of the facial phenotype, obesity, disproportionate short stature accompanied by limb shortening, pronounced brachydactyly affecting both hands and feet, as well as intellectual disability. Radiographic examinations of the upper and lower extremities reveal the presence of cone-shaped epiphyses accompanied by cup-shaped enlarged metaphyses in the knee regions, along with notable humeral bowing and brachydactyly with cone-shaped epiphyses.

Conclusion: The identification of a novel variant in the *PDE4D* gene expands the existing mutational spectrum and offers important insights for future investigations into the genotype-phenotype correlations associated with Metaphyseal acroscyphodysplasia.

P06.058.A Report on a new splice variant in *ACAN* in a well-characterized family

Veronika Benend[1], Moneef Shoukier[1], Franziska Reschke[1], Cornelia Daumer-Haas[1], Daniela Liebrecht[2], ***Dennis Witt***[1]

[1]Eurofins Humangenetik und Pränatal-Medizin MVZ GmbH, Munich, Germany, [2]Prenatal Medicine Munich, Munich, Germany.

Background: Spondyloepiphyseal dysplasia is a rare disorder caused by variants in several genes; among others, more than 100 different alterations in the ACAN gene (missense, nonsense and splice variants) have been identified as causative. In general, identification of new splice variants is often complex, as the effect of a variant in the exon/intron transition is difficult to predict. Therefore, the family presented here, in which a causal splice alteration can be segregated over several generations with a clear phenotype, is helpful.

Material and methods: The reported family introduced themselves due to the short stature of the youngest daughter (p3). The initial diagnosis was conducted using a multigene panel in our DAkkS accredited laboratory. Subsequently, the identified variant was segregated in the rest of the family. Additionally, a transcriptome analysis was performed.

Results: In the index patient, a novel variant was identified in the intron of the 5' UTR (NM_001369268.1: c.-7-1G>T), which is shared by sister and mother. The clinical-genetic examination of the extended family revealed that the sister and the mother of the index were also affected by spondyloepiphyseal dysplasia; in addition to short stature. Both suffer from osteochondrosis dissecans. We expect that the transcriptome analysis, which is still pending, will provide further insights into the functional mechanisms of the variant.

Conclusion: The symptoms of several affected individuals in combination with the segregation results allow the variant to be assessed as probably pathogenic and expands the group of known disease-causing variants and diagnostics.

P06.059.B Expanding the phenotypic and genetic spectrum of *PIEZO2*-related distal artrogryposis type 5: a single center experience

Evgeniya Melnik[1], *Tatiana Markova, MD[1], Sergei Nikitin[1], Inna Sharkova[1], Oksana Ryzhkova[1], Olga Agranovich[2], Elena Dadali[1]*

[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]H. Turner National Medical Research Center for Children's Orthopedics and Trauma Surgery, Saint Petersburg, Russian Federation.

Background: Distal arthrogryposis type 5 (DA5) is a rare autosomal dominant *PIEZO2*-related disease, characterized by congenital contractures, ophthalmoparesis, ptosis and restrictive respiratory disorders. We studied the phenotypic manifestations of 9 patients from 8 unrelated families with DA5 caused by four previously described and one novel heterozygous nucleotide variants in the *PIEZO2* gene.

Material and methods: All patients underwent comprehensive clinical, radiological examinations and electromyography study. Trio WGS was conducted for three families, and WES for 5 patients. Almost all cases (7 families) have de novo status, which was confirmed by Sanger sequencing.

Results: The most severe clinical manifestations with respiratory failure and tracheal stenosis were found in patients with novel variant c.8238G>A (p.Trp274Ter) and another c.7095G>T (p.Trp2365Cys), which hadn't been revealed in heterozygous state. While in patients with other previously described variants c.8181_8183delAGA (p.Glu2727del), c.2134A>G (p.Met712Val) and c.8555C>T (p.Ser2852Leu) the clinical phenotype was more moderately expressed. Our cohort included patients with different ages (from 1 to 24 years) to successfully identify a number of previously not reported symptoms of DA5, such as uneven distribution and thickening of subcutaneous fat in the abdomen and thighs, poor temporal hair growth, elongated second toe and short first toe, as well as to assess the formation of the disease phenotype in dynamics.

Conclusion: It has been shown that spectrum of DA5 clinical manifestations depends on the localization of amino acid substitution in a protein molecule and the disease progression may occur as the child grows, which requires monitoring of this group of patients.

P06.062.A A Novel SOX9 variant leading to Mild campomelic dysplasia

Elif Yilmaz Gulec*, Beyza Adacoglu*

Istanbul Medeniyet University Medical School Goztepe Prof. Dr Suleyman Yalcin City Hospital Departmant of Medical Genetics, Istanbul, Turkey.

Background: Campomelic Dysplasia is a congenital genetic disorder caused by mutations in the SOX9 gene, characterized by skeletal deformities, respiratory distress, and other systemic features. This disorder typically manifests with growth and developmental delay and facial dysmorphisms. We aim to present a novel case of midly affected Campomelic Dysplasia expanding the clinical spectrum.

Material and methods: The patient presented with respiratory distress at birth, requiring intubation for one month and then tracheostomy at 3 months of age. At the age of two years, the patient developed gait abnormalities, leg length discrepancy and knee deformities and was referred to us. A multigene panel test was performed.

Results: On physical examination, the patient exhibited macrocephaly, a long triangular face, wide forehead, periorbital edema, scoliosis, pes planus and short fingers. X-ray radiography revealed scoliosis and metaphyseal enlargement of long bones

and flat acetabular roof. We identified a heterozygous de novo novel variant in the SOX9 gene (c.440_445del). These findings, combined with the clinical presentation, led to the diagnosis of Campomelic Dysplasia.

Conclusion: We consider this case as a mild campomelic dysplasia due to milder skeletal involvement and missing genitourinary abnormalities. Early identification through NGS allows for accurate diagnosis and better management in such mild phenotypes. Genetic counseling plays a key role in guiding affected families.

E. Yilmaz Gulec: None. **B. Adacoglu:** None.

P06.063.B Expanding phenotype Of oral-facial-digital syndrome caused by a homozygous putative pathogenic variant in the *INTU* Gene

Britta Hanker[1], *Kirstin Hoff*[2], *Guido Stichtenoth*[3], *Malte Spielmann*[1,2], *Inga Nagel*[2]

[1]*Institute of Human Genetics, University of Lübeck, Lubeck, Germany,* [2]*Institute of Human Genetics, University of Kiel, Kiel, Germany,* [3]*Department of Pediatrics, University of Lübeck, Lubeck, Germany.*

Background/objectives: To date, more than 15 genetic causes of oral-facial-digital (OFD) syndrome have been described. This syndrome is associated with abnormalities of the face (hypertelorism), oral cavity (lingual hamartoma) and extremities (polydactyly). Renal and cerebral malformations are also associated with OFD. OFD syndrome belongs to the ciliopathies. In 2017, Bruel et al. reported the first patient with OFD with a homozygous pathogenic variant in *INTU*. To date, few pathogenic variants in *INTU* are known.

Methods: We report a newborn boy of consanguineous parents with facial features including hypertelorism, broad nasal root and malformation of the extremities consisting of pre- and postaxial hexadactyly and syndactyly. He had respiratory difficulties due to laryngeal stenosis (retrolaryngeal mass, notched epiglottis, severe laryngomalacia). Laser supraepiglottoplasty of the large retrolaryngeal space-occupying lesion (plus tissue) was performed to avoid aspiration of the arytenoid cartilage and epiglottis. A tracheostomy tube was required to stabilise the patient due to vocal cord paresis.

Results: On suspicion of OFD syndrome, trio exome sequencing revealed a homozygous putative pathogenic variant (NM_015693.4:c.2428G>C p.(Gly810Arg)) in the gene *INTU* in the newborn. Both parents were heterozygous carriers of this variant. The variant is predicted to be protein-damaging according to prediction tools (e.g. CADD score 27.4).

Conclusion: A systematic review of the literature showed that only a few patients with putative pathogenic variants in *INTU* are known. The patient's phenotype overlaps with the clinical features reported in the literature. Severe upper airway obstruction with laryngomalacia and rigid vocal cord paresis is a previously undescribed association.

P06.065.D Twelve years to diagnosis: *MCRS1*as a cause for Klippel-Feil syndrome

Elis Tiivoja[1,2], *Rita Teek*[1,2], *Sander Pajusalu*[1,2], *Kaisa Teele Oja*[1,2], *Monica H. Wojcik*[3,4], *Ikeoluwa Osei-Owusu*[4], *Katrin Ounap*[1,2]

[1]*University of Tartu, Tartu, Estonia,* [2]*Tartu University Hospital, Tartu, Estonia,* [3]*Boston Children's Hospital, Boston, MA, USA,* [4]*Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, USA.*

Background: MCRS1 is a multifunctional protein essential for cellular processes. Research has shown that it is required for branchial arch and cranial cartilage development. Notably, Mcrs1 functionally interacts with Six1 in the embryo, playing a critical role in craniofacial tissue development, including the formation of the otic vesicle. Klippel-Feil syndrome is a congenital disorder characterized by fusion of cervical vertebrae, often accompanied by a short neck, scoliosis, hearing loss, and other skeletal abnormalities. We hypothesize that variants in *MCRS1* could be an additional etiologic factor for the syndrome.

Material and methods: Trio-genome and RNA sequencing from skin fibroblasts were performed. Identified variant was validated by Sanger sequencing.

Results: We report a 13-year-old boy with a potentially deleterious heterozygous 406 bp de novo deletion in *MCRS1* gene. His features include a short neck, dysmorphic facial features, missing ribs, spine abnormalities (including scoliosis), congenital hearing loss, bilateral *n. vestibulocochlearis* aplasia, and microcephaly. He has a clinical diagnosis of Klippel-Feil syndrome but no molecular diagnosis was identified until recently. Underexpression of the *MSCRS1* gene was found in RNA sequencing analysis, corresponding to a heterozygous loss-of-function defect. Reanalysis of genome sequencing data revealed a deletion in *MCRS1*.

Conclusion: We describe a patient with a clinical diagnosis of Klippel-Feil syndrome and a deletion in *MCRS1*. Given the gene's important role in craniofacial and branchial arch development, we hypothesize it could be the cause for the patient's clinical picture. We are planning to conduct additional studies in order to determine the functional impact of the variant.

P06.066.A When icthyosis reveals a rare metabolic disorder: a case of Chanarin-Dorfman syndrome

D. Singh, *D. Kaur, P. Panigrahi, D. Mahajan, D. Bhatia;*

PGIMER, Chandigarh, India

Background: Chanarin-Dorfman syndrome (CDS) is a rare autosomal recessive disorder caused by mutations in the ABHD5 gene, leading to intracellular triacylglycerol accumulation in various organs. It presents with ichthyosis, multisystem involvement, and lipid-filled vacuoles in neutrophils, known as Jordan's anomaly.

Material and Methods: A 19-month-old female, born of a third-degree consanguineous marriage, presented with xerotic, scaly skin since birth, progressive abdominal distension, and hepatosplenomegaly. Clinical examination revealed lamellar scales, ectropion, dysplastic auricles, and hypohidrosis. Laboratory investigations indicated elevated transaminases, hypertriglyceridemia, and lipid vacuoles in neutrophils. Genetic confirmation through whole-exome sequencing identified a homozygous pathogenic variant in the ABHD5 gene [c.810T>A: p.(Tyr270*)].

Results: The diagnosis of CDS was confirmed. Multidisciplinary management, including dietary fat restriction, medium-chain triglyceride supplementation, skincare, and supplementation with ursodeoxycholic acid and vitamin E, improved growth, metabolic markers, and imaging findings. Follow-up showed reduced AST and ALT levels, lower triglycerides, and decreased liver size.

Conclusion: This case highlights the characteristic clinical, laboratory, and genetic findings in CDS, emphasizing the

importance of a multidisciplinary approach to management. Early diagnosis and intervention improve outcomes, while genetic counseling and prenatal diagnostic testing are essential to prevent recurrence in future pregnanciesFigure 1: Peripheral smear analysis demonstrating cytoplasmic vacuolation of neutrophils and eosinophils.Figure 2: Finer, grayish, semi-adherent scales on the trunk

P06.067.B Recurrent FGFR3 splicing variant in a case of atypical achondroplasia: a case report

*Daniele Vitale[1,2], **Milena Mariani**[1], Marzia Giagnacovo[3], Silvia Scupilliti[2], Laura Pezzoli[4], Daniela Marchetti[4], Maria Iascone[4], Angelo Selicorni[1]*

[1]Centro Fondazione Mariani per il Bambino Fragile – S.C. Pediatria, ASST Lariana, Como, Italy, [2]Università degli Studi di Milano, Milano, Italy, [3]SSD Genetica, ASST Lariana, Como, Italy, [4]Medical Genetics Laboratory, Papa Giovanni XXIII Hospital, Bergamo, Italy.

Background: Pathogenic variants in *FGFR3* gene are associated with a broad range of skeletal dysplasias, ranging from achondroplasia to thanatophoric dysplasia. Despite highly suggestive clinical features, some cases lack a definitive molecular diagnosis, with routine diagnostic testing failing to identify a pathogenic variant.

Material and methods: Clinical assessment of a patient with a de novo *FGFR3* variant presenting with a clinical phenotype compatible with an atypical form of achondroplasia.

Results: An 8 year-old girl patient presented with disproportionate short stature, rhizomelic shortnening of the limbs, *genu varum*, and lumbar hyperlordosis. Cognitive development was adequate for her age, whereas a mild gross motor delay was described. No particular dysmorphic features were present; a relative macrocephaly was described. Radiographic features were highly suggestive for *FGFR3* spectrum. Prior sequencing of *FGFR3* (performed on both blood and buccal swab samples), NGS-based gene panel for skeletal dysplasias, Whole Exome Sequencing, and exome-based arrayCGH failed to identify any pathogenic variant. Whole Genome Sequencing identified a pathogenic intronic heterozygous de novo variant in *FGFR3* (*FGFR3*:c.1075+95C>G), previously reported in three patients with atypical achondroplasia (or severe hypochondroplasia), and one patient with hypochondroplasia.

Conclusion: We identified the *FGFR3*:c.1075+95C>G variant in a girl presenting with disproportionate short stature and typical skeletal phenotype of *FGFR3* spectrum. Consistently with previous reports, the variant appears to be associated with an atypical form of achondroplasia or severe hypochondroplasia. Our results provide an additional pediatric report of the clinical phenotype associated with this recurrent splicing variant, reaffirming the necessity to include it in diagnostic setting.

P06.070.A Long-term impact of spondylometaphyseal dysplasia, corner fracture type (SMD-CF) caused by heterozygous pathogenic variant in *FN1* gene

Elis Riin Tars-Hurt[1,2], *Mare Lintrop[3,4], Riina Zordania[2], Laura Mauring[2,5,6], Katrin Ounap[2,5]*

[1]Faculty of Medicine, University of Tartu, Tartu, Estonia, [2]Department of Clinical Genetics, Genetics and Personalized Medicine Clinic, Tartu University Hospital, Tartu, Estonia, [3]Radiology Clinic, Tartu University Hospital, Tartu, Estonia, [4]Department of Radiology Clinic, University of Tartu, Tartu, Estonia, [5]Institute of Clinical Medicine, University of Tartu, Tartu, Estonia, [6]Eye Clinic, Tartu University Hospital, Tartu, Estonia.

Background: Spondylometaphyseal dysplasia, corner fracture type (SMD-CF; OMIM#184255, ORPHA:93315) is a rare skeletal dysplasia presenting with short stature, developmental changes in vertebrae, corner fracture-like lesions and metaphyseal abnormalities with sparing of the epiphyses. The disease has large phenotypic diversity and identified causative genes are *COL2A1* and more recently discovered *FN1*. Less than 20 cases of *FN1* associated SMD-CF have been described in the literature. We seek to improve understanding of SMD-CF long term course by retrospectively analyzing one patient's lifetime medical data.

Material and methods: We conducted a retrospective study on the medical data, including radiological images, of a 54-year-old patient with clinical suspicion of SMD-CF and assessed the clinical phenotype at the age of 53. Molecular diagnosis was confirmed by next generation sequencing (NGS).

Results: Most notable findings included short stature (−3.5SD), short trunk, waddling gait, scoliosis, *pectus excavatum*, F2-5 clinodactyly, left foot T2-3 clinodactyly, flat feet, overpronating knees, myopia and optic disc drusen associated with visual field defect. Radiological images revealed corner fractures present since childhood and progressive osteoarthritis, ultimately leading to the endoprostheses of two joints (right knee at 52y, and left hip at 49y). NGS analysis detected a heterozygous pathogenic variant in the *FN1* gene; NM_212482.3(FN1):c.693C>G p.(Cys231Trp).

Conclusion: Our study demonstrates the long-term course of SMD-CF and provides valuable information to clinicians regarding prevention and treatment, as well as to patients and their families regarding prognosis. Since *FN1* pathogenic variants in SMD-CF patients have been rarely described, this study offers invaluable insight into the phenotype-genotype correlation.

P06.071.B Atypical glutamic acid to lysine substitution in the triple helix of type III collagen manifests as overlap between classical and vascular Ehlers-Danlos syndrome

***Margot Callens**, Delfien Syx, Shana Verschuere, Sofie Symoens, Fransiska Malfait*

Department of Medical Genetics University Hospital Ghent, Ghent, Belgium.

Background: Vascular Ehlers-Danlos syndrome (vEDS) is caused by pathogenic variants in *COL3A1*. The most frequently reported pathogenic variants are glycine substitutions within the triple-helical domain of type III procollagen and splice site variants leading to an exon skip. A 34-year-old man was referred because of suspected connective tissue disorder. At birth, bilateral congenital clubfeet were observed. Joint hypermobility was present in childhood, and recurrent shoulder dislocations began at the age of 29 after a fall. There was a history of delayed wound healing and wound dehiscence, but no signs suggestive for vascular fragility. Clinical examination showed hyperelastic, translucent, doughy skin, generalized joint hypermobility (Beighton score 9/9), facial features (hypotelorism, deep-set eyes and epicanthal folds), a flattened back and mild pedes plani. An

atrophic scar with hemosiderin deposition was observed on his left leg.

Methods and materials: Due to the combination of skin fragility and joint hypermobility, classical EDS was suspected. Whole exome sequencing of known EDS-associated genes was performed.

Results: A variant of unknown significance in *COL3A1* in the triple helix (p.(Glu730Lys)) was identified. Segregation analysis revealed the variant in the younger brother (33y), with a comparable phenotype. Hence the variant was reclassified as likely pathogenic.

Conclusion: We describe two patients with a novel glutamic acid-to-lysine substitution in *COL3A1*, currently without complications related to tissue fragility. The clinical presentation of our patient shows overlap with previously reported cases, often suspected as classical EDS, with some exhibiting vEDS-like features. Additional cases are needed to clarify complication risks and the underlying pathophysiology.

P06.073.D Gonadal mosaicism as a rare inheritance pattern in recessive genodermatoses: report of two cases with Pseudoxanthoma Elasticum and literature review

Lisa Dangreau[1,2], *Mohammad J. Hosen*[3], *Julie De Zaeytijd*[4], *Bart P. Leroy*[4,5], *Paul J. Coucke*[1,2], *Olivier M. Vanakker*[6,2]

[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Biomolecular Medicine, Ghent University, Ghent, Belgium,* [3]*Department of Genetic Engineering and Biotechnology, Shahjalal University of Science and Technology, Sylhet, Bangladesh,* [4]*Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium,* [5]*Division of Ophthalmology, The Children's Hospital of Philadelphia, Philadelphia, PA, USA,* [6]*Ghent University HospitalCenter for Medical Genetics, Ghent, Belgium.*

Background: Gonadal mosaicism, the presence of genetically distinct cell populations in the gonads, is well-documented in autosomal dominant genodermatoses but rarely reported in autosomal recessive diseases. We describe two families with Pseudoxanthoma Elasticum (PXE), an autosomal recessive genodermatosis caused by biallelic ABCC6 mutations, and systematically review gonadal mosaicism in recessive skin disorders.

Material and methods: Genetic analyses, including direct sequencing and MPLA, were conducted on both families. A systematic literature review was performed following PRISMA-P guidelines.

Results: The first male proband, diagnosed with PXE at age 11, exhibited characteristic skin and ocular findings and was compound heterozygous for the c.3506 + 2T > C variant (maternal) and a whole ABCC6 gene deletion (uncertain paternal origin). The second female proband, diagnosed at 16, had typical PXE features and was compound heterozygous for p.R1141* (maternal) and a whole ABCC6 deletion, with evidence suggesting paternal germline mosaicism. Asymptomatic family members carried one pathogenic variant, and analyses ruled out UPD16, high-level mosaicism, and non-paternity. The literature review identified 16 additional gonadal mosaicism cases in recessive skin disorders, including cutis laxa, epidermolysis bullosa, Cockayne syndrome, and Vici syndrome, with paternal mosaicism more frequent.

Conclusion: Recognizing gonadal mosaicism is crucial for genetic counseling, as recurrence risk may be significantly lower than the typical 25%, impacting reproductive planning and genetic testing accuracy. Expanded carrier screening may overlook gonadal mosaicism, leading to misinterpretations. These findings highlight gonadal mosaicism as a possible inheritance mechanism in PXE and emphasize the need for expert interpretation of genetic results.

P06.074.A A novel pathogenic variant in FBN1 gene identified in a patient with MFS

Susanna Gastaldi[1], *Miriam Carriero*[1], *Monia Magliozzi*[2], *Antonio Novelli*[3], *Federica Sangiuolo*[1,4], *Leila Baghernajad Salehi*[1], *Giuseppe Novelli*[1,4]

[1]*Department of Biomedicine and Prevention, Tor Vergata University, 0133 Rome, Italy, Rome, Italy,* [2]*Laboratory of Medical Genetics, Translational Cytogenomics Research Unit, Bambino Gesù, Rome, Italy,* [3]*Bambino Gesù Children Hospital, Rome, Italy,* [4]*Medical Genetics Unit., Tor Vergata University Hospital, 00133 Rome, Italy, Rome, Italy.*

Introduction: Mutations in the fibrillin-1 (FBN1) gene are linked to Marfan syndrome (MFS) and MFS-related disorders (MFS-RD), which exhibit a range of overlapping phenotypes. MFS is an autosomal dominant disorder affecting connective tissue, primarily in the heart, eyes, and skeleton. Despite its well-established clinical features, factors influencing phenotypic severity remain unclear. Molecular analysis of the FBN1 gene, located on chromosome 15 and containing 65 coding exons, helps reduce diagnostic uncertainty in MFS and MFS-RD. To date, more than 2700 mutations in FBN1 have been documented, with up to 25% of cases arising from de novo variants.

Case Report: We describe a 53-year-old man diagnosed with congestive heart failure at 32, secondary to severe mitral insufficiency from mitral valve prolapse. He underwent mitral and tricuspid valvuloplasty and was later diagnosed with aortic bulb dilatation. His physical exam revealed a height of 188 cm, arm span of 210 cm, small joint hyperextensibility, positive bilateral thumb and wrist signs, arachnodactyly, and scoliosis with right convexity.

Discussion: Informed consensus was obtained from patient and Next Generation Sequencing analysis was performed on patient's peripheral blood sample. A novel heterozygous FBN1 variant, c.6865T>A, resulting in a cysteine-to-arginine substitution (p.Cys2289Arg), was identified. The identified variant is a novel VP, not so far been reported in the scientific literature in individuals with Marfan syndrome.

Conclusions: Present work enriches the mutations profile in FBN1 gene associated with MFS and underlines the importance of updating clinical criteria considering the complexity of cardiological clinical status.

P07 Cardiovascular disorders

P07.001.B Generation and characterization of two novel knock-in models: insights into arrhythmogenic cardiomyopathy

Francesca Gasparella[1], *Chiara Romanato*[1], *Sara Vencato*[1], *Alessandra Ghigo*[2], *Nicola Facchinello*[1], *Dario Bizzotto*[1], *Giulia Arcuri*[1], *Carlo*

Guglielmini[1], Paola Braghetta[1], Libero Vitiello[1], Alessandra Rampazzo[1], Martina Calore[3]

[1]Università degli Studi di Padova, Padova, Italy, [2]University of Torino, Torino, Italy, [3]Padova University, Department of Biology, Padova, Italy.

Background: Arrhythmogenic cardiomyopathy (ACM) is a genetic disorder characterized by nonischemic ventricular arrhythmias and sudden death. ACM is generally caused by pathogenic variants in genes encoding for proteins of intercalated discs and it is defined by a progressive myocardial dystrophy resulting in fibro-adipogenic substitution.

Material and methods: To investigate the molecular mechanisms underlying ACM, two novel murine knock-in models were generated harboring the p.G105R mutation in the *Dsg2* gene (DSG2_KI) and the p.del765L in-frame deletion in the *Ctnna3* gene (CTNNA3_KI), in both homozygous and heterozygous forms. The mice were analyzed at ultrastructural, molecular and functional level. Specifically, transmission electron microscopy images were analyzed, real-time PCR, echocardiography and electrocardiogram (ECG) were performed.

Results: Knock-in models displayed a reduction of desmosome length at different ages; in particular, in homozygous DSG2_KI animals desmosomes were even shorter compared to the heterozygous ones. Moreover, homozygous DSG2_KI mice also exhibited a greater expression of transcripts associated to fibrosis. The same increase in fibrosis markers were observed in the heterozygous CTNNA3_KI model. Functionally, in 9-month-old heterozygous DSG2_KI mice, fractional shortening, ejection fraction and left ventricular internal diameter at end-diastole (LVIDd) were elevated, while left ventricular internal diameter at end-systole (LVIDs) was decreased. Finally, by means of ECG, extrasystole events were observed in 12-month-old heterozygous animals.

Conclusion: Altogether, these results suggest that the two knock-in lines exhibited typical features of ACM, such as shorter desmosomes, fibrosis and functional alterations. Therefore, these models provide valuable tools to explore the molecular mechanism behind the disease and explore potential therapeutic interventions.

P07.002.C DNA methylation in *ABCG1* mediates an effect of lipoproteins on atherosclerotic markers

M. Kamal Nasr*[1,2], *Marcus Dörr[1,2], Ann-Kristin Henning[1], Birte Holtfreter[1], Clemens Jürgens[1], Matthias Nauck[1,2], Uwe Völker[1,2], Henry Völzke[1], Alexander Teumer[1,2]

[1]University Medicine Greifswald, Greifswald, Germany, [2]DZHK (German Centre for Cardiovascular Research), Partner Site Greifswald, Greifswald, Germany.

Background: Atherosclerosis, linked to cardiovascular disorders like myocardial infarction and stroke, involves chronic low-grade inflammation, though its mechanisms remain unclear. This study explores the role of blood lipids and DNA methylation in atherosclerosis and its influence on cardiovascular outcomes.

Material and methods: We analyzed 112 serum NMR lipoprotein subfractions in 4,010 individuals from the SHIP-TREND cohort, examining associations with subclinical atherosclerosis markers (e.g., carotid intima-media thickness, periodontitis, retinal microcirculation, and inflammatory cytokines). An epigenome-wide association study (EWAS) was conducted in 479 individuals using the EPIC array to identify CpG sites linked to lipoproteins and atherosclerosis. We tested the association of DNA methylation levels of the significant CpG sites with atherosclerotic markers and cardiovascular outcomes.

Results: There were significant associations between lipoproteins and atherosclerotic traits, particularly low-density lipoproteins (LDL) and inflammatory markers, potentially mediated by DNA methylation. Two CpG sites, cg05325763 (chromosome 11) and cg06500161 (chromosome 21 in *ABCG1*), were strongly associated with LDL ($p < 4.73E\text{-}10$). Methylation at cg06500161 correlated with increased soluble tumor necrosis factor receptor 2 (sTNFr2) levels ($p = 0.024$) and myocardial infarction risk, while cg05325763 methylation was linked to reduced IL-10 levels ($p = 0.044$). Both gene expression and DNA methylation levels at *ABCG1* showed association signals with myocardial infarction occurrence in the analyzed population, supporting its role in cardiovascular outcomes.

Conclusion: These findings highlight the interplay between lipoproteins, DNA methylation, and inflammation in atherosclerosis, suggesting *ABCG1*'s potential role in myocardial infarction risk. This study advances understanding of atherosclerosis' inflammatory processes and its epigenetic regulation.

P07.003.D LncRNA H19: promoter and circulating biomarker of human carotid atherosclerotic plaque development

Iolanda Veneruso*[1,2], *Valeria D'Argenio[2,3], Vasilis F. Ntasis[4], Maria Donata Di Taranto[1,2], Giovanna Cardiero[1,2], Umberto Marcello Bracale[5], Silvia Pérez-Lluch[4], Giuliana Fortunato[1,2], Roderic Guigó[4], Francesco Salvatore[1,2]

[1]Department of Molecular Medicine and Medical Biotechnologies, University of Naples Federico II, Naples, Italy, [2]CEINGE-Biotecnologie Avanzate Franco Salvatore, Naples, Italy, [3]Department of Human Sciences and Quality of Life Promotion, San Raffaele Open University, Rome, Italy, [4]Centre for Genomic Regulation (CRG), The Barcelona Institute for Science and Technology (BIST), Barcelona, Catalonia, Spain, [5]Department of Public Health, Vascular Surgery, University of Naples Federico II, Naples, Italy.

Background: Long non-coding RNAs (lncRNAs) have been increasingly involved in several diseases, including atherosclerosis; however, their specific role in plaque development is still under investigation. This study aimed to investigate the involvement of lncRNAs as potential effectors and biomarkers of carotid atherosclerosis in humans.

Methods: Carotid atherosclerotic plaques, their adjacent regions (AR) and plasma samples were collected from 15 patients and analyzed via total RNA-Seq by Next Generation Sequencing. Bioinformatic analysis was performed on R. Additionally, plasma samples from other 35 atherosclerotic patients and 19 healthy controls (50 cases, 19 controls) were collected. Circulating RNA was extracted and quantitative real-time PCR (qRT-PCR) was performed using SYBR Green, with GAPDH as housekeeping gene. Statistical analysis was performed using SPSS software.

Results: Among the 915 differentially expressed genes in plaques versus AR, lncRNA H19 was significantly overexpressed in plaques ($logFC = 4.3, p = 0.00004$) and detected in plasma. qRT-PCR confirmed H19 upregulation in plaques [16.5(6.5–40.5)] versus AR [0.1(0.07–1.8), $p = 0.001$]. Circulating H19 levels were higher in atherosclerotic patients [1.15(0.7–2.43)] than in controls

[0.7(0.3–1),p = 0.004] and were associated with lipid-rich plaques (Gray-Weale grade 2,p = 0.022), smoking (p = 0.028), and dyslipidemia (p = 0.020). Gray-Weale resulted independently negatively associated to H19 levels (beta-coeff.=−0.498 - p = 0.004).

Conclusion: Our findings suggest that lncRNA H19 is overexpressed in human carotid atherosclerotic plaques rather than in the adjacent lower-grade regions, confirming its implication in atherosclerotic plaques development in humans. Higher levels of H19 were found in plasma from atherosclerotic patients, associated with plaque instability, thus supporting its potential as a circulating biomarker (AUC = 0.73) for unstable carotid atherosclerosis.

P07.004.A Genetic crossroads of cardiovascular disease and its comorbidities

Pashupati Prasad Mishra, *Binisha Hamal Mishra*

Tampere University, Tampere, Finland.

Background: With rising life expectancy, the prevalence of cardiovascular disease (CVD) patients with comorbidities is also increasing, complicating healthcare and outcomes. This highlights the need for improved prevention, treatment and management strategies. Understanding the genetic links between CVD and its comorbidities could advance research in this area. We aimed to assess the genetic correlation (r_g) between CVD and its comorbidities.

Material and methods: We used FinnGen R12 GWAS summary statistics for 24 CVD and its comorbidities related endpoints. Quality control steps in the GWAS involved exclusion of participants with ambiguous gender, high genotype missingness (>5%), excess heterozygosity (+-4SD) and non-Finnish ancestry. SNPs with high missingness (>2%), low HWE p-value (<1e-6) and low minor allele count (MAC < 3) were excluded. We estimated heritability for each endpoint and assessed the genetic correlations between them using linkage disequilibrium score regression (LDSC). Disease endpoints with heritability z-score below 4 were excluded because genetic correlation estimates for these diseases are generally noise and therefore unreliable, leaving 19 diseases for analysis. Genetic correlations with Bonferroni-adjusted p-values (adj.pval) < 0.05 were considered significant.

Results: Out of the 19 diseases, five CVDs (coronary atherosclerosis, transient ischemic attack, atrial fibrillation, myocardial infarction and heart failure) and seven comorbidities (type 2 diabetes, asthma, obesity, depression, chronic obstructive pulmonary disease, gingivitis and hypertension) showed significant genetic correlations (adj.pval < 0.05).

Conclusion: We found significant genetic correlations between CVD and its comorbidities, suggesting shared genetic variants. The findings may aid in developing joint risk stratification tools for CVD and comorbidities.

P07.006.C Genetic findings in a cohort of over 2300 individuals with clinically suspected heritable thoracic aortic disease

Emma Mårtensson, *Julie Hathaway, Johanna Huusko, Saija Ahonen, Johanna Tommiska, Kimberly Gall, Janica Djupsjöbacka, Mikko Muona, Inka Saarinen, Eija Seppälä, Tiia Kangas-Kontio, Lotta Koskinen, Pertteli Salmenperä, Samuel Myllykangas, Juha Koskenvuo*

Blueprint Genetics, Espoo, Finland.

Background: Heritable thoracic aortic disease (HTAD) is associated with high morbidity and mortality; sudden death due to aortic dissection may be the first presenting feature. Establishing a molecular genetic cause of HTAD allows for management based on the causative gene and identifying at-risk family members. In this study, we reviewed the genetic findings in a large cohort of individuals with suspected HTAD to assess the value of genetic testing in this population.

Material and methods: A total of 2,358 individuals were tested with an NGS panel including up to 53 genes associated with HTAD. Gene content varied due to the addition of genes to the panel over time. Sequencing and copy number variant (CNV) interpretation was performed following ACMG guidelines.

Results: Pathogenic (P) or likely pathogenic (LP) variants consistent with the individual's phenotype and disease inheritance were identified in 280 (11.9%) cases. The yield of testing was similar in children (12.8%[36/281]) and adults (11.7%[244/2,077] but was higher in deceased individuals (23.5%[8/34]). A total of 284 LP/P variants were identified; 19 of these were CNVs. 97.9% of LP/P variants (278/284) identified were in genes associated with extracardiac features in addition to HTAD. The most common diagnostic finding was an LP/P sequence variant in *FBN1*, and the most common LP/P CNV was a duplication involving the *ABCC6* and *MYH11* genes.

Conclusion: This work further demonstrates the importance of comprehensive genetic testing in individuals with suspected HTAD, especially in those with relevant findings on autopsy, to inform management for at-risk family members.

P07.008.A Mitral valve prolapse caused by TLL1 gain-of-function mutation

N. Agam[1], *V. Dolgin*[1,2], *A. Star*[2], *O. Freund*[1], *M. Jean*[1], *A. Safran*[1], *T. Poleg*[1], *D. Zahger*[1,2], *O. Birk*[1,2,3];

[1]*Ben-Gurion University of the Negev, Beer-Sheva, Israel,* [2]*Soroka Medical center, Beer-Sheva, Israel,* [3]*Sheba Medical Center, Ramat Gan, Israel*

Background: Mitral valve prolapse (MVP) is a common cardiac valvular anomaly that can be caused by mutations in genes of various biological pathways. We set out to identify the molecular basis of apparently dominant heredity of isolated MVP in a three generation kindred.

Material and methods: Clinical evaluation and echocardiography for all complying family members (n = 13). Whole exome and genome sequencing of two affected individuals, delineating shared heterozygous variants, further tested for segregation within the kindred. Wild type versus mutant Tolloid Like 1 (TLL1) enzymatic activity assays in media of transfected HEK293 cells.

Results: The only heterozygous variant segregating in the affected kindred as expected for dominant heredity of MVP was p.T253A, within the catalytic domain of TLL1. Of eight heterozygotes, six had MVP and two had trivial mitral regurgitation. Activity assay in extracellular media of HEK293-transfected cells demonstrated that over time, the enzymatic activity of the mutated TLL1 protein was ~3-fold higher than that of the wildtype.

Conclusion: *TLL1* encodes an extracellular metalloprotease regulating ECM composition and maintenance. Heterozygous Loss-of-Function *TLL1* mutations have been previously shown to cause autosomal dominant atrial septal defects. We now show through genetic and biochemical studies that a TLL1 Gain-of-Function mutation, prolonging the half-life of TLL1 active protein in the extracellular matrix (ECM), causes a different cardiac phenotype: autosomal dominant MVP with variable expressivity. Our findings enable novel insights into molecular pathways of valvular physiology and disease, and the differing phenotypes of Loss-of-Function and Gain-of-Function mutations of the same gene.

P07.010.C Single nucleus transcriptomic profiling of cardiac cells in a novel transgenic mouse model of arrhythmogenic cardiomyopathy

Sara Vencato[1], *Stefano Cagnin*[1], *Chiara Romanato*[1], *Karthik Murali*[1], *Angelo Velle*[1], *Gabriele Sales*[1], *Chiara Romualdi*[1], *Agata Rakszewska*[2], *Christian Conrad*[2], *Nicola Facchinello*[3], *Paola Braghetta*[1], *Libero Vitiello*[1], *Alessandra Rampazzo*[1], *Martina Calore*[1,4]

[1]*Università degli Studi di Padova, Padova, Italy,* [2]*Center for Digital Health, Berlin Institute of Health, Berlin, Germany,* [3]*Neuroscience Institute, National Research Council (CNR), Padova, Italy,* [4]*CARIM School, Maastricht University, Maastricht, Netherlands.*

Background: Arrhythmogenic cardiomyopathy (ACM) is one of the most commonly inherited cardiomyopathies, characterized by the progressive substitution of the myocardium with fibrofatty tissue. Clinically, ACM is characterized by ventricular arrhythmias, syncope, and sudden cardiac death and shows wide phenotypic heterogeneity. Approximately half of ACM cases are attributed to inherited mutations in one or more genes encoding cardiac intercalated disc components. Among them, those encoding for plakophilin-2 (*PKP2*), desmoplakin (*DSP*), and desmoglein-2 (*DSG2*) are most commonly mutated.

Material and methods: In order to study the pathogenic mechanisms underlying the disease, we generated transgenic mice with a cardiomyocyte-specific overexpression of human *DSG2* carrying the p.G100R mutation (Tg-hG) found in an affected patient. To establish the transcriptomic ACM signature, we performed bulk and single nucleus-RNA seq on cardiac samples from 6 month-old Tg-hG and control mice.

Results: Tg-hG mice presented several clinical features of ACM, such as fibrous replacement, increased inflammatory markers, and cardiac dysfunction. Accordingly, enrichment analysis and network construction performed on bulk RNA seq data identified upregulation of immune- and extracellular matrix-related processes. Moreover, single nucleus-RNA seq analysis dissected the cellular composition of wild-type and transgenic hearts. In agreement with phenotypic data and bulk RNA-seq, interactome analyses highlighted the involvement of fibroblast-secreted factors in three key ACM-related networks: extracellular matrix accumulation, inflammation, and Wnt signaling.

Conclusion: Collectively, these findings identified numerous processes and cell populations potentially altered in Tg-hG mice that could shed light on ACM pathogenic mechanisms.

P07.011.D Targeted mRNA sequencing improves classification of splicing variants in hypertrophic cardiomyopathies

L. Rialland[1,2], *E. Blin*[2], *C. Perret*[1], *F. Ader*[2], *P. De la grange*[3], *P. Charron*[4,1], *E. Villard*[1], *P. Richard*[2,1];

[1]*UMRS 1166, Paris, France,* [2]*APHP, UF Cardiogénétique et Myogénétique Moléculaire et Cellulaire, Paris, France,* [3]*Genosplice, Paris, France,* [4]*APHP, Centre de Référence des Maladies Cardiaques héréditaires ou rares, Paris, France*

Background: Hypertrophic cardiomyopathies (HCM) are inherited cardiac diseases with an autosomal dominant transmission, among which MYBPC3 is the main causal gene responsible for haplo-insufficiency. RNA splicing variants in MYBPC3 appears to be a prevalent cause of HCM, however RNA analysis is not developed for these diseases because of cardiac tissue unavailability. Thus, these variants are often classified as Variant of Unknown Significance (VUS) and can't be use for clinical purposes. We propose an enrichment method to detect splicing aberrations in MYBPC3 causing cardiomyopathies from blood cells mRNA.

Material and methods: We selected 26 variants (16 intronics and 10 exonics) detected on DNA potentially affecting splicing. polyA+ RNA purified from venous blood cells were retro-transcribed, captured with optimized design and sequenced on NextSeq550. A specific bio-informatic pipeline was developed to automatically detect splicing events.

Results: The gene *MYBPC3* was very well covered and interpretable (RPM~6809, Mean depth~2947X). We detected a splice aberration for 19/26 (73%) of cases, consistent with their respective predictive score, among which 6 (32%) creates a novel junction; 8 (42%) modifies the proportional usage of annotated junctions and 5 (26%) leads to the retention of the entire intron. Then, we performed bio-informatic screening that was able to detect all pathogenic events, including intron retention even without abnormal junction.

Conclusion: Targeted mRNA sequencing from blood cells helps to classify splice affecting variants, thus improving the yield of molecular diagnostic. This method, associated with a specific bio-informatic pipeline can be used as a screening approach expanded to other cardiomyopathy genes.

P07.012.A Unravelling shared pathomechanisms in syndromic thoracic aortic aneurysm disorders using single-cell RNA sequencing

Irene Valdivia-Callejon[1], *Sofie Daemen*[1], *Silke Peeters*[1], *Josephina Meester*[1], *Bart Loeys*[1,2], *Aline Verstraeten*[1]

[1]Centre of Medical Genetics, Antwerp University Hospital/University of Antwerp, Edegem, Belgium, [2]Radboud University Medical Center, Nijmegen, Netherlands.

Background: Thoracic aortic aneurysm (TAA) is characterized by progressive enlargement of the aorta, increasing the risk of dissection. Current pharmacological treatments are limited and patients often require high-risk surgical procedures. This highlights the need for better understanding of the disease mechanisms to develop new therapies to stop or reverse TAA.

Material and methods: We analysed single-cell RNA sequencing data from aortic samples (ascending aorta and root) of the TAA mouse models C57Bl6J *Fbn1*$^{C1041G/+}$ and C57Bl6N *Ipo8*$^{-/-}$, and their respective wild-type (WT) littermates to identify convergent mechanisms. Samples were collected before and after aneurysm development to distinguish driving from compensatory mechanisms.

Results: Prior to the aneurysm formation, a few top shared DEGs were identified in vascular smooth muscle cells (VSMCs), including *Tnc, Sncg, Wif1, Rbp4*, and *Smad6*, and both models showed downregulation of the "Signaling by TGF-β family members" pathway. When the aneurysm was present, enrichment analysis in the VSMC cluster of both models revealed the involvement of focal adhesion, extracellular matrix (ECM), and cytoskeleton pathways, pointing towards mechanotransduction dysregulation. Additionally, we pinpointed a shared VSMC subcluster enriched in aneurysmal aortas, which showed a greater upregulation of ECM and focal adhesion genes (*Tnc, Fn1, Itga5*), along with higher expression of TGF-β-related genes (*Bmp4*, *Tgfb1*, *Tgfb2, Serpine1*) and lower expression of contractile genes (*Myh11*, *Cnn1*).

Conclusion: Dysregulation of mechanotransduction may be an important shared pathomechanism in *FBN1*- and *IPO8*-related TAA. Furthermore, a subset of VSMCs with a more extreme phenotypic switch might be involved in the pathogenesis of both TAA conditions.

P07.013.B Trait based partitioned polygenic risk scores for biologically informed risk stratification of common cardiovascular diseases

Tigist D. Adane, *Joyce B.J. van Meurs, André G. Uitterlinden, Jeroen G.J. van Rooij*

Department of Internal Medicine, Erasmus MC, Rotterdam, Netherlands.

Background: Cardiovascular diseases (CVDs) remain a major global health burden. Coronary artery disease (CAD), stroke, heart failure (HF), peripheral arterial disease (PAD), and atrial fibrillation (Afib) are among the most common CVDs, exhibiting both shared and distinct genetic and biological components. This study aims to elucidate these genetic mechanisms and their potential to predict CVD subtypes using partitioned polygenic risk scores (PRS).

Material and methods: We employed trait-based partitioning on genetic variants clusters derived from distance-based hierarchical clustering of their associations with CVD-related traits. Variants were identified from genome-wide association studies for CAD, stroke, HF, PAD, and Afib. Genome-wide significant variants were clustered into 10 partitions, reflecting shared and unique genetic influences across these diseases. Partitioned PRS are evaluated on their associations with common CVDs and subtypes.

Results: This study revealed a structured genetic architecture of CVDs, with 10 partitions capturing unique and overlapping genetic associations underlying biological mechanisms. For instance, a partition shared among CAD, PAD, and stroke is anticipated to predict those diseases and comorbid patients. In contrast, a CAD-specific partition with no association with PAD or stroke is expected to predict CAD only. Similarly, an Afib-specific partition is expected to predict Afib.

Conclusion: This study demonstrates that trait-based hierarchical partitioning identifies shared and unique genetic contributions to common CVDs. The 10 distinct partitions could provide a framework for developing partitioned PRS and enhance genetic risk prediction for individual and overlapping CVDs. These findings could offer valuable insights for improving precision medicine in CVD risk assessment and treatments.

P07.016.A Impact of rapid Exome sequencing on pediatric patients with cardiomyopathies and acute Heart failure

Tameemi Abdalla Moady[1], *Tova Hershkovitz*[2], *Clair Habib*[1], *Ori Attias*[3], *Amir Hadash*[3], *Galit Tal*[4], *Asaad Khoury*[5], *Josef Ben-Ari*[6], *Tamar Paperna*[1], *Danny Eytan*[3], *Karin Weiss*[1]

[1]Genetics Institute, Rambam Health Care Center, Haifa, Israel, [2]Genetics institute, Galilee Medical Center, Nahriya, Israel, [3]Pediatric Intensive Care Unit, Rambam Health Care center, Haifa, Israel, [4]Metabolic Clinic, Ruth Rappaport Children's Hospital, Rambam Health Care Center, Haifa, Israel, [5]Pediatric Cardiology and Congenital Heart Disease in Adults, Rambam Health Care center, Haifa, Israel, [6]Pediatric intensive care unit, Rambam health care center, Haifa, Israel.

Intoduction: Exome Sequencing (ES) is a comprehensive tool for the diagnosis of rare monogenic disorders, but scarce studies address its clinical impact on pediatric cardiomyopathies (PCM) in urgent settings.

Materials and methods: Data was collected retrospectively from medical records of pediatric patients presenting with acute heart failure and cardiomyopathy who underwent singleton rapid ES between 2021 and 2023 at Rambam Medical Center.

Results: A total of nine patients were included. Eight patients (88.8%) presented in the first year of life. Age range 5days-11years, median-6 weeks. Family history was positive in only one case (11.1%). Turnaround Time was 5–14 days (median 9 days). The diagnostic yield was 5/9 (55.5%) confirming primary cardiomyopathy. The majority had dominant disorders (*ACTC1, MYBCP3, TNNI3, NKX2-5*) with two (22.2%) occurring de novo. One patient (11.1%) had a recessive condition (*MYBPC3)*. In Three patients (33.3%) who rapidly deteriorated during admission, a major impact on immediate medical management was imposed: palliative care in one and referral for heart transplantation in two. In most patients, the diagnosis led to avoidance of further metabolic or expert consultations, cardiac magnetic imaging or vitamin treatment. At-risk relatives in three families (33.3%) started cardiac follow-up. In five families accurate recurrence risk was provided.

Conclusions: Our results show a high clinical impact of rapid ES in isolated PCM presenting in urgent settings, including shorter time to diagnosis, high diagnostic yield, improved patient management, and therapeutic approach. In addition to family members at risk segregation and genetic counseling regarding family planning.

P07.017.B The association between donor-derived cell-free DNA and acute rejection in heart transplant patients

Bianca De Nicolo[1,2], *Laura Borgese*[2], *Laura Giovannini*[2], *Arianna Orsini*[1], *Antonio Russo*[2], *Marco Masetti*[2], *Paola Prestinenzi*[2], *Mario Sabatino*[2], *Elena Bonora*[1,2], *Luciano Potena*[2]

[1]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy,* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: Lifelong noninvasive rejection monitoring in heart transplant (HT) patients is a therapeutic need still inadequately provided. The historical and still current gold standard for assessment of cardiac acute cellular and antibody-mediated rejection (ACR and AMR) is the endomyocardial biopsy (EMB). Developments in NGS technologies have allowed the concept of liquid biopsy to evolve, with the development of cell-free DNA (cfDNA) analysis in the context of organ transplantation. This study aims to assess the relationship between donor-derived cfDNA (dd-cfDNA) levels, ACR and AMR in a cohort of HT recipients.

Material and methods: dd-cfDNA was extracted from plasma derived from blood EDTA-tubes among the patients subjected to EMB. dd-cfDNA was measured and sequenced on MiSeq (Illumina) platform at >1000X coverage, according to AlloSeq cfDNA protocol (CareDx), which evaluated 202 genomic polymorphisms estimating the percentage of dd-cfDNA, compared to recipient patient, as an index of rejection.

Results: dd-cfDNA assessment was performed in 75 recipients. Starting from 30 days after HT, ACR was detected in 25 (33.3%) patients in whom median dd-cfDNA levels were 0.36% (IQR 0.23 to 0.66%) and AMR was detected in 15 (20.0%) patients, in whom median dd-cfDNA levels were 0.6% (IQR 0.395 to 1.045%). dd-cfDNA levels were higher in recipients with ACR ($p = 0.0169$) and AMR ($p = 0.0002$) *vs*. those without rejection.

Conclusion: In conclusion, starting from 30 days after HT, ACR and AMR were associated with higher dd-cfDNA levels, indicating that this technology can be relevant in detecting HT rejection with minimal invasive tests *vs*. classic EMB.

P07.019.D Improving genetic testing for heart disease with targeted consideration of population linkage patterns

Grace Elizabeth Tietz[1], *Sairam Behera*[1], *Jonathan R. Belyeu*[2], *Richard A. Gibbs*[1], *Fritz J. Sedlazeck*[1], *Elizabeth G. Atkinson*[1]

[1]*Baylor College of Medicine, Houston, TX, USA,* [2]*Pacific Biosciences, Menlo Park, CA, USA.*

Background: Cardiovascular Disease (CVD) is the leading cause of death globally, making it an important target for genetic prediction. Towards this, *LPA* is a promising gene as it influences CVD though Lipoprotein A (Lp(a)), a hereditary blood lipid that is rarely measured in-clinic. Two variants within *LPA* are now used to predict Lp(a) levels, however these have poorer performance in Latin American individuals (LAT). This suggests that these variants are not causal, but rather differentially tagging a causal locus due to differences in linkage disequilibrium across populations. In this case, the putatively causal locus in *LPA* is KIV-2, a repetitive domain rarely included in clinical care or genetic datasets due to inherent challenges in ascertaining repeats. To improve Lp(a) clinical predictions, this motivates us to identify variants tagging KIV-2 well to improve actionability of genetic testing when KIV-2 or Lp(a) data is unavailable.

Material and methods: We identified KIV-2 tagging variants through a generalized linear model correlating *LPA* variants with KIV-2 copy numbers in 1,000 Genomes Project LAT. From this, we designed an improved risk model accounting for a variant tagging KIV-2 plus a Lp(a) polygenic risk score (PRS) built from the UK Biobank.

Results: This method showed a 70% increase in predictive performance for LAT as compared to the standard pruning and thresholding PRS.

Conclusion: Our findings show promise in our ancestry-informed approach, improving Lp(a) genetic testing in the populations most neglected by the current test and providing a framework for more equitable genetic risk prediction overall.

P07.020.A Unraveling the enigma of DSG2 p.(N266S): a culprit in Arrhythmogenic Cardiomyopathy

Serena Pinci, *Rudy Celeghin, Maria Bueno Marinas, Marco Cason, Cristina Basso, Barbara Bauce, Kalliopi Pilichou*

University of Padua - Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy.

Background: Desmoglein-2 (*DSG2*) truncating variants are major cause of arrhythmogenic cardiomyopathy (ACM), which is an autosomal dominant disease characterized by electrical instability and myocardial fibro-fatty replacement. The clinical significance of rare *DSG2* p.(N266S) missense variant remains an open question (ACMG criteria: PP3, PM2, BP1). The purpose of this study is to explore pathognomonic features of the DSG2-p.(N266S) to support a damaging effect on the gene product (PS3 rule).

Material and methods: An in vitro system based on HL-1 cells and 2 plasmids, carrying either DSG2 Wild-type (Wt) or the p.(N266S) variant, were used to established HL-1-Wt and HL-1-Mut cell lines. Transfection was obtained by 4-D Nucleofector System (Lonza©). For a patient-tailored in vitro system, CD34+ cells were isolated, reprogrammed into induced pluripotent stem cells (iPSCs) and later differentiated into cardiomyocytes (iPSC-CMs).

Results: DSG2 p.(N266S) missense variant was identified in four families exhibiting ACM phenotypes with biventricular involvement, arrhythmias and ECG abnormalities. Transfected HL-1 cells were able to continuously divide, spontaneously contract and expressed both plasmids. Confocal and TEM imaging revealed the insertion of the DSG2 mutated protein into cardiac desmosomes and evidence of gap widening in HL-1 Mut. Calcium flux and the beating phenotype were significantly altered in HL-1 Mut. Desmosomal widening and electrophysiological alterations were confirmed subsequently in iPSC-CMs derived from one proband.

Conclusion: We provided strong evidence to support DSG2 p.(N266S) pathogenicity in ACM through a combination of clinical observations in four independent affected families and further experimental findings in two different in vitro models, HL-1 and iPSC-CMs.

P07.021.B Familial hypercholesterolaemia: prevalence and discrepancy between genotype and phenotype - results from the population-based Hamburg City Health Study

Cristian Riccio[1], *Natalie Arnold*[2,3,4], *Georgios Koliopanos*[1], *Vivian Link*[1], *Linlin Guo*[2,3,4], *Raphael Betschart*[1], *Tanja Zeller*[5], *Stefan Blankenberg*[2,3,4], *Andreas Ziegler*[1,2,3], *Raphael Twerenbold*[2,3,4]

[1]*Cardio-CARE, Medicine Campus Davos, Davos, Switzerland,* [2]*Department of Cardiology, University Heart & Vascular Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [3]*German Center for Cardiovascular Research (DZHK), partner site Hamburg/Kiel/Lübeck, Hamburg, Germany,* [4]*Center for Population Health Innovation (POINT), University Heart and Vascular Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [5]*Institute for Cardiogenetics, University of Lübeck, Lübeck, Germany.*

Background: Familial hypercholesterolaemia (FH) is one of the most common monogenic diseases, affecting genes involved in low-density lipoprotein (LDL) metabolism. In Germany, there is limited population-based data on the prevalence of genetically confirmed FH (genFH) and genotype-phenotype associations. This study aimed to address this gap using whole-genome sequencing data from the Hamburg City Health Study.

Material and methods: Pathogenic mutations in five FH-associated genes were analysed in 7,373 participants aged 45–74 years. Genotypes were compared to LDL cholesterol (LDL-C) levels, adjusted for lipid-lowering medication. Severe hypercholesterolaemia was defined as LDL-C ≥190 mg/dL.

Results: Heterozygous FH was identified in 23 individuals (0.31%; 1 in 321), all due to *LDLR* mutations. Median treatment-adjusted LDL-C levels were higher in genFH individuals (191 mg/dL [149–210]) than in those without genFH (128 mg/dL [105–153], $p < 0.001$). Severe hypercholesterolaemia was observed in 6.5% of participants, of whom only 2.3% ($n = 11$) had genFH. LDL-C levels were below 130 mg/dL in 9.1% of genFH individuals, below 160 mg/dL in 31.8%, and only 50% had severe hypercholesterolaemia. Screening using LDL-C thresholds of ≥190 mg/dL, ≥160 mg/dL, or ≥130 mg/dL yielded sensitivities of 50.0%, 68.2%, and 90.9%, respectively, with 43, 98, and 175 individuals requiring screening to identify one genFH case.

Conclusion: The prevalence of genFH in this cohort was 0.31%, aligning with global estimates. Significant discrepancies between genFH and LDL-C levels highlight the limitations of genetic FH screening.

P07.022.C DNA methylation signature in pulmonary arterial hypertension, a potential molecular diagnostic tool

Natalia Gallego-Zazo[1], *Mario Cazalla*[1], *Lucia Miranda*[1], *Mónica Mora*[1], *Alejandro Cruz-Utrilla*[2], *Nuria Ochoa*[2], *Manuel Jesús Rodriguez-Canó*[1], *Sergio Ramos*[1], *Valeria Vasquez*[1], *Pedro Arias*[1], *Cristina Silvan*[1], *María Jesús Del Cerro*[3], *Mathis Hildonen*[4], *Spanish PAH Consortium*[5], *METILPREC Consortium*[5], *Zeynep Tuemer*[4], *Julián Nevado*[1], *Vinicio De Jesús*[6], *Pablo Lapunzina*[1], *Pilar Escribano*[2], ***Jair Antonio Tenorio***[1]

[1]*Institute of Medical and Molecular Genetics (INGEMM) - HOSPITAL UNIVERSITARIO LA PAZ, MADRID, Spain,* [2]*Hospital Universitario 12 de Octubre, MADRID, Spain,* [3]*Hospital Universitario Ramón y Cajal, MADRID, Spain,* [4]*Department of Clinical Genetics, Kennedy Center, Copenhagen University Hospital, Glostrup, Spain,* [56]*Stanford University, Stanford, CA, USA.*

Introduction: Pulmonary arterial hypertension (PAH) is a rare, life-threatening disorder characterized by increased pulmonary arterial pressure, leading to right heart failure and potential mortality. The incidence ranges from 15 to 50 cases per million annually. Clinical symptoms include fatigue, syncope, chest pain, and edema. While PAH has a multifactorial etiology, genetic and epigenetic contributions play a critical role in its pathogenesis. The diagnostic utility of DNA methylation (DNAm) patterns has emerged as a novel approach to classify and validate genetic variants of uncertain significance (VUS), particularly in genes like **BMPR2, SOX17**, and **EIF2AK4**.

Materials and methods: Using Illumina 950K Methylation Microarray, we analyzed DNAm profiles from 23 patients with pathogenic variants in ***BMPR2*** and 41 controls. Differentially methylated probes (DMPs) were identified, and a support vector machine (SVM) model was employed for classification.

Results: We identified 842 DMPs, with 752 hypomethylated and 90 hypermethylated CpG sites, predominantly outside well-known PAH-associated genomic regions. PCA revealed distinct DNAm profiles between patients and controls. SVM analysis achieved 90% specificity and 100% sensitivity in differentiating patients based on DNAm patterns, with promising results for subclassification among other PAH-related genes.

Discussion: DNAm signatures offer a robust tool for validating VUS in PAH-associated genes, improving diagnostic accuracy. Preliminary data highlight a unique epigenetic signature for ***BMPR2***, distinct from ***SOX17*** and ***EIF2AK4***. Further validation with external cohorts and diverse gene sets is essential to enhance the utility of DNAm profiling as a molecular diagnostic adjunct in PAH.

P07.023.D The impact of the pro-atherogenic MRAS gene in smooth muscle cells

Pashmina Wiqar Shah[1], *Tobias Reinberger*[1], *Malte Spielmann*[2], *Tanja Zeller*[1]

[1]*Institute of Cardiogenetics, Lubeck, Germany,* [2]*Institute of Human Genetics, Lubeck, Germany.*

A study by Erdmann *et al*. in 2009, revealed a region on 3q22.3, encompassing the *MRAS* gene as a risk factor for CAD. *MRAS* encodes muscle Ras, a GTPase acting as a signal transducer in TNF signalling and other acute phase response pathways. eQTL data suggests *MRAS* risk variants for CAD increase *MRAS* mRNA levels primarily in the arterial tissue in vascular smooth muscle cells (SMCs). However, *MRAS's* exact role in atherogenesis is still elusive. The function of *MRAS* in vascular SMCs was investigated. Human

primary aortic SMCs transfected with *MRAS*-specific siRNA and murine SMCs derived from our *Mras*$^{-/-}$*ApoE*$^{-/-}$ double knockout (dKO) mouse model were subjected to functional assays including proliferation, migration and apoptosis. *MRAS* siRNA knockdown in human SMCs and *Mras* deficient mice SMCs showed increased migration, proliferation and reduced apoptotic activity with and without stimulation of TNF, IL6 and IL1ß. Stimulation with TNF, IL6 and IL1ß enhanced the proliferative effect of *Mras* deficiency, indicating an interplay of these cytokines and MRAS pathways. Bulk RNA sequencing revealed *Mras* KO in murine SMCs led to differential gene expression of numerous genes involved in cGMP/cAMP signalling, suggesting that SMCs upregulate cGMP/cAMP signalling to compensate for the loss of *Mras*. The in vivo atherosclerosis study on plaque characteristic revealed that the impact of *Mras* deficiency was sex-specific as significant differences in plaque size, collagen content and macrophage staining were only observed in male mice. Conclusively, lower MRAS levels in SMCs protects against CAD by enhancing plaque stability and decreasing rupture risk.

P07.025.B Elucidating the pathomechanisms of Meester-Loeys syndrome: insights from a *Bgn*$^{-/0}$ mouse model

Anne Hebert[1], *Jarl Bastianen*[1], *Sofie Daemen*[1], *Jolien Schippers*[1], *Maaike Bastiaansen*[1], *Aline Verstraeten*[1], *Bart L. Loeys*[1,2], *Josephina A.N. Meester*[1]

[1]*Center of Medical Genetics, University of Antwerp, Edegem, Belgium,* [2]*Department of Clinical Genetics, Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Pathogenic loss-of-function biglycan (*BGN*) variants are associated with Meester-Loeys syndrome, a thoracic aortic aneurysm and dissection syndrome. To study its pathomechanisms, a *Bgn*$^{-/0}$ mouse model was developed.

Material and methods: Aortic dissection/rupture was induced in *Bgn*$^{-/0}$ mice using a non-hypertensive dose of angiotensin-II (AngII) (400 ng/kg/min). Animals were sacrificed after five days of AngII-infusion, before the occurrence of an aortic dissection/rupture. Descending aortic tissues from AngII- and vehicle-treated *Bgn*$^{-/0}$ and wildtype mice were analysed macroscopically and with histological stainings, transmission electron microscopy, and RNA-sequencing.

Results: Macroscopic and histological analyses revealed red blood cell accumulation within the aortic wall of AngII-treated *Bgn*$^{-/0}$ mice, indicating aortic damage. Verhoeff-Van Gieson and Masson's Trichrome stainings showed no consistent differences in elastin fiber organization or collagen content between groups. Exploratory assessment by transmission electron microscopy revealed variability in collagen fibril diameter, with an overall smaller fibril diameter in *Bgn*$^{-/0}$ mice relative to wildtype mice, regardless of the treatment. This suggests that reduced fibril diameter may reflect a genetic predisposition caused by the biglycan variant, but it does not explain the dissection/rupture phenotype. To further explore the underlying pathomechanisms, bulk and single-cell RNA-sequencing have recently been performed. Principal component analysis highlighted AngII-challenge as the greatest source of variation between samples, suggesting a more heterogeneous response to the environmental challenge compared to the relatively modest effect of the biglycan deficiency. Differential expression analysis is ongoing.

Conclusion: The (preliminary) findings from the *Bgn*$^{-/0}$ mouse model offer valuable insights for further mechanistic studies to unravel drivers of biglycan-related aortopathy.

P07.026.C Spatial transcriptomics reveal gene expression signature in arterial fibromuscular dysplasia lesions

Yilong Lin[1], *Patrick Bruneval*[2], *Margaux-alison Fustier*[1], *Corinne Lesaffre*[1], *Adrien Georges*[1], *Nabila Bouatia-Naji*[1]

[1]*Inserm UMR970 Paris Cardiovascular Research Center, Paris, France,* [2]*Hôpital européen Georges-Pompidou, Paris, France.*

Background: Fibromuscular dysplasia (FMD) is a group of arterial lesions (stenosis and aneurysms), which present in hypertension, stroke and spontaneous coronary artery dissection (SCAD), an under-studied form of myocardial infarction. With ~50% of SCAD patients present extra-coronary FMD, in both conditions cardiovascular risk factors and high proportion of women are found. Here we aimed to explore gene expression signatures in human arteries to delineate FMD specific arterial remodeling.

Material and methods: We selected 6 FMD and 2 non-FMD formalin-fixed paraffin-embedded arterial samples for 10X Visium spatial transcriptomic sequencing (Illumina). FASTQ files were processed using Space Ranger (v3.0.0), differential expression using Seurat (v5.0.3) in R (v4.3.3), and enrichment analyses using clusterProfiler (v4.10.1). Cell types were inferred using public human artery single-cell RNAseq datasets.

Results: After quality control, we analyzed six samples (4 FMD, 2 non-FMD) with an average of 2,787 spots per sample and mapping rates above 97%. Clustering identified 10 groups, with M1-M5 in the media and A1-A5 in the adventitia, with intima layer virtually uncaptured. M1, M2, M3 and M5 were enriched in smooth muscle cells (SMCs) expressing *MYH11* and *TAGLN*. Collagen-enriched M3 was predominant in FMD lesions (7.5% vs. 0.3% in non-FMD). M4, unique to FMD, displayed a macrophage-like signature (*CD68*). Pathway analyses revealed upregulation of genes linked to extracellular matrix biology in FMD lesions while contractile fiber genes were downregulated.

Conclusion: Our findings suggest increased fibrosis and impaired SMC function in FMD. Ongoing histological validation will further elucidate SMCs remodeling mechanisms, in comparison to atherosclerosis.

P07.027.D In vivo interrogation of the contribution of *Igfbp2* upregulation to thoracic aortic aneurysm development

Katrien De Roeck[1], *Jotte Rodrigues Bento*[1], *Jarl Bastianen*[1], *Sofie Daemen*[1], *Maaike Bastiaansen*[1], *Erik Fransen*[1], *Josephina Meester*[1], *Bart Loeys*[1,2], *Aline Verstraeten*[1,2]

[1]*Center of Medical Genetics, University of Antwerp, Edegem, Belgium,* [2]*Antwerp University Hospital, Edegem, Belgium.*

Background: Thoracic aortic aneurysm (TAA), the abnormal widening of the thoracic aorta, can occur in isolation or as part of a connective tissue disorder like Marfan syndrome (MFS). Insulin-growth factor binding protein 2 (Igfbp2) regulates cell proliferation, growth, and extracellular matrix remodeling. Our lab identified significant upregulation of *Igfbp2* in the aortic wall of three independent TAA mouse models (including *Fbn1*$^{C1041G/+}$ (MFS)), with an 8- to 30-fold increase prior to aneurysm development, suggesting that it might drive TAA establishment.

Material and methods: We explored the role of upregulated *Igfbp2* on TAA development and progression by crossbreeding *Igfbp2*$^{+/-}$ and *Fbn1*$^{C1041G/+}$ mice. This breeding yielded pups belonging to four genotype groups (N = 14 per group): *Fbn1*$^{+/+}$/*Igfbp2*$^{+/-}$, *Fbn1*$^{C1041G/+}$/*Igfbp2*$^{+/+}$, *Fbn1*$^{C1041G/+}$/*Igfbp2*$^{+/-}$, and *Fbn1*$^{+/+}$/*Igfbp2*$^{+/+}$. Aortic root and ascending aorta diameters of male mice were determined every 4 weeks from 4 to 28 weeks of age via transthoracic echocardiography utilizing a Vevo-2100 system with MS550D transducer (VisualSonics). Aortic root and ascending aorta data were analyzed separately using likelihood ratio tests and chi-squared statistics. Post-hoc analysis involved a Tukey's HSD test.

Results: Our analysis confirmed exaggerated aortic growth both at the level of the aortic root and the ascending aorta in male *Fbn1*$^{C1014G/+}$ versus wildtypes. In contrast, haplo-insufficiency for *Igfbp2* alone showed no measurable effect on aortic diameter, nor did it have an impact in combination with an *Fbn1*$^{C1041G/+}$ background.

Conclusion: Haplo-insufficiency for *Igfbp2* in *Fbn1*$^{C1041G/+}$ mice has no significant impact on TAA development and progression, suggesting that it may not be sufficient to mitigate aneurysm progression.

P07.028.A Development and characterization of an HHT-iPSCs model for drug testing

Claudia Cantarini[1], *Elisavet Koutala*[2], *Laura Lorente-Herraiz*[3], *Carla Olivieri*[1], *Karine Raymond*[2], *Franck Lebrin*[2]

[1]*Universita degli Studi di Pavia, Pavia, Italy,* [2]*Leiden University Medical Center, Leiden, Netherlands,* [3]*Centro de Investigaciones Biológicas Margarita Salas, CIB-CSIC, Madrid, Spain.*

Background: The latest gene editing technologies and the use of iPSCs is leading to the development of novel cell-based disease models that allow to reproduce and characterize the phenotypic alterations implied in the pathogenesis of specific disorders. Hereditary Hemorrhagic Telangiectasia (HHT) is a rare genetic vascular disease caused by mutations in *ENG*, *ACVRL1*, *SMAD4*, or *GDF2*, leading to an impairment of the TGFβ/BMPs pathway. Here we present an iPSCs-based cell line carrying a homozygous truncating variant in *ENG*, obtained by CRISPR-Cas9 technology.

Material and methods: CRISPR-Cas9 was performed on the iPSCs LUMC0072 line. The quality of the gene editing was attested by restriction enzyme digestion, Sanger sequencing, Short Tandem Repeats, karyotyping, pluripotency and multi-lineage assays. The lines were mycoplasma free. Angiogenesis studies were performed on both parental and mutated lines, which were further differentiated in endothelial cells and blood vessels organoids (BVOs). Proliferation assays and migration under laminar flow were conducted.

Results: The quality assessment of LUMC0072-F5 *ENG*$^{mut/mut}$ line, carrying the *ENG* c.1A>G truncating variant, was successful. The in vitro HHT model showed defective angiogenic features, including flow-induced cell migration and response to VEGFR2 signalling, comparable to the already published data on Eng-KO mice retina.

Conclusion: The development of a reliable and highly characterized in vitro HHT model represents an important tool for deepening the cellular and molecular processes modulating angiogenesis, leading to the pathological phenotype. Furthermore, this may provide a valuable support for drug testing.

Background: Neonatal arterial ischemic stroke (NAIS) is a cerebrovascular condition characterized by a localized disruption of cerebral blood flow due to artery obstruction, which can yield prolonged neurological consequences. Despite research aimed at elucidating the genetic basis of stroke in pediatric and adult populations, the precise contribution of genetic factors in the pathogenesis of NAIS remains unknown.

Material and methods: Genetic analysis of newborns with NAIS was performed using WES-trio. A personalized workflow was applied for filtering, analyzing, and interpreting genetic variants in de novo dominant and autosomal recessive models. Functional studies included plasmid recombination, cell culture, western blot, and confocal microscopy.

Results: In the WES-trio analysis of 23 newborns with idiopathic NAIS we identified 28 unique de novo variants in 28 genes. No variant was diagnostic quality. The *PIK3CD* variant c.1292A>G/p.[Gln431Arg], from a patient with perforant stroke, was selected as the strongest candidate possibly linked to NAIS. Functional studies overexpressing both wild type and p.Gln431Arg PIK3CD proteins suggested this variant might disrupt protein function. However, no significant PI3K/Akt signaling pathway changes were detected. WES-trio analysis under the autosomal recessive model did not allow the identification of candidate genes.

Conclusion: The study did not provide conclusive evidence for a genetic cause of idiopathic NAIS. However, it suggested that genetic variations, particularly in *PIK3CD*, might still play a role in perforant stroke. We cannot completely rule out a genetic basis, as relevant variants may lie outside protein-coding regions, requiring alternative genomic approaches, including whole genome sequencing (short/long reads) and RNA-seq.

P07.030.C Analysis of the *MYBPC3* spectrum in hypertrophic cardiomyopathy with a focus on splicing variants

Giulia Margherita Brach del Prever[1,2], *Donatella Marsalla*[1], *Tullia Carradori*[1,2], *Carmelo Romeo*[1,2], *Maria Luca*[1,2], *Angelo Corso Faini*[1,2], *Claudia Saglia*[1,2], *Caterina Scolari*[1,2], *Fiorenza Mioli*[1,2], *Francesca Arruga*[2], *Diana Carli*[1,2], *Tiziana Vaisitti*[1,2], *Deaglio Silvia*[1,2]

[1]*Department of Medical Sciences, University of Turin, Turin, Italy,* [2]*Immunogenetics and Transplant Biology Service, Città della Salute e della Scienza University Hospital, Turin, Italy.*

Background: a genetic etiology is present in ~30% of patients with hypertrophic cardiomyopathy (HCM), *MYBPC3* being the most frequently involved gene. We analyzed a cohort of molecularly characterized HCM patients, focusing on the spectrum and impact of *MYBPC3* variants.

Material and methods: between 2018 and 2024, 520 HCM patients underwent next-generation sequencing (NGS) of a panel of HCM-related genes. *MYBPC3* genotype-phenotype correlations were assessed. Selected *MYBPC3* splicing variants were studied using cDNA sequencing.

Results: Genetic analysis identified variants in 286 patients (55.0%): 133 (46.50%) carried pathogenic (C5)/likely pathogenic (C4) variants, and 153 (53.50%) had variants of uncertain significance (VUS). A total of 109 *MYBPC3* variants were detected in 102/520 (19.6%) patients, 83 of whom presented with classic HCM phenotype and 19 with an atypical phenotype. Of the 109 *MYBPC3* variants, 62 (56.9%) were causative (C4/C5), and 47 (43.1%) were VUS. In total, 68/109 (62.39%) *MYBPC3* variants were truncating, 41 (37.61%) were missense without predicted splicing impact. Furthermore, 24 intronic and 34 exonic *MYBPC3* variants (58/109, 53.2%) were predicted to affect splicing. Although statistical significance was not reached, truncating *MYBPC3* variants were often associated with a more severe phenotype and earlier onset than other variants. Cloning and sequencing from mRNA obtained from peripheral blood mononuclear cells determined defective splicing for 3 variants, previously classified as C3/C4, allowing variant reclassification.

Conclusion: NGS is a powerful tool for molecular diagnosis in HCM, but VUS remain a challenge. Functional studies play a critical role in reclassifying VUS, improving the clinical utility of genetic testing.

P07.031.D Panel-negative cases diagnosed with WGS in patients with cardiomyopathy and arrhythmia

Valerio Rhodio[1,2], *Philip Harrer*[1,2], *Elisabeth Graf*[1,2], *Cordula Wolf*[3,4,5], *Teresa Trenkwalder*[4,5,6], *Stefan Kääb*[4,5,7], *Sebastian Clauss*[4,5,7], *Eimo Martens*[4,5,8], *Marie Arens*[4,5,8], *Susann Badmann*[1,2], *Maureen Jacob*[1,2], *Melanie Brugger*[1,2], *Theresa Brunet*[1,2], *Matias Wagner*[1,2], *Thomas Meitinger*[1,2], *Juliane Winkelmann*[1,2], *Dominik Westphal*[1,2,8]

[1]*Institute of Human Genetics, TUM University Hospital, School of Medicine and Health, Technical University of Munich, Munich, Germany,* [2]*Bavarian Genome Network, Munich, Germany,* [3]*Department of Pediatric Cardiology and Congenital Heart Disease, TUM University Hospital, School of Medicine and Health, Technical University of Munich, Munich, Germany,* [4]*Member of the European Reference Network for rare, low prevalence and complex diseases of the heart (ERN GUARD-Heart), Amsterdam, Netherlands,* [5]*DZHK (German Centre for Cardiovascular Research), Partner site Munich, Munich Heart Alliance, Munich, Germany,* [6]*Department of Cardiology, TUM University Hospital, School of Medicine and Health, Technical University of Munich, Munich, Germany,* [7]*Department of Medicine I, LMU Hospital, LMU Munich, Munich, Germany,* [8]*Department of Internal Medicine I, TUM University Hospital, School of Medicine and Health, Technical University of Munich, Munich, Germany.*

Background: Current cardiological guidelines emphasize the use of targeted gene panels in diagnostics focused on known disease-associated genes, potentially overlooking diagnostically relevant variants in other genomic regions. In contrast, whole-genome sequencing (WGS) offers a comprehensive approach, enabling targeted analysis of genes linked to a patient's phenotype and the broad detection of genetic variants.

Methods: We employed WGS to investigate a cohort of 21 patients with suspected monogenic cardiovascular disease (CVD), in which previous gene panels failed to identify (likely) pathogenic variants between 01/2015 and 03/2022. The analysis included a comprehensive search for variants across the entire genome, focusing on genes relevant to the clinical phenotypes. The patients were classified according to the following phenotypes: cardiomyopathy (n = 18) and arrhythmia (n = 3).

Results: WGS identified variants in 71.4% (15/21) of cases. 53% (8/15) were classified as (likely) pathogenic, implicating them as causative of the patients' phenotype. The remaining 47% (7/15) were categorized as variants of uncertain significance. In 66.6% (10/15) of cases, the affected gene was not included in the panel analysis. In 20% (3/15) of cases, the variant was also reported but considered causative for the phenotype. In a single instance, the affected gene was included in the panel but the variant was not reported. In the remaining case, the unreported variant was located in an intronic region.

Conclusion: This study highlights the enhanced diagnostic yield of WGS compared to conventional gene panels for patients with suspected monogenic CVD. Our results support the routine use of genome wide analysis.

P07.032.A Mutations in angiogenesis-related genes, revealed by whole exome sequencing in patients with congenital cutaneous arterial, capillary and lymphatic malformations

Dimitar Bakalov, *Kalina Mihova, Kunka Kamenarova, Darina Kachakova, Radka Kaneva, Ivanka Dimova*

Molecular Medicine Center, Medical University-Sofia, Sofia, Bulgaria.

Background: Cutaneous vascular malformations (CVMs) are congenital anomalies resulting from errors in vascular development, often presenting as capillary, venous, lymphatic, or mixed malformations. While the genetic basis of CVMs is increasingly recognized, many causative mutations remain unidentified. This study aimed to uncover novel genetic mutations associated with CVMs using advanced genomic techniques in a cohort of affected individuals.

Material and methods: Whole-exome sequencing (WES) was performed on 9 patients diagnosed with CVMs.

Results: In 7 out of 10 patients (70%) the following genetic variants were detected: pathogenic/likely pathogenic (*FLT4* [c.3341C>T], *VEGFC* [c.148-3_148-2delCA]; *EIF2AK4* [c.4065+1G>T];

JAG1 [c.3003_3006dupTTGC]) and VOUS (*NOTCH1* [c.7583A>T], *RASA1* [c.1583A>G]; *FLT4* [c.3002C>T]). We identified 3 novel missense mutations in the following genes: *NOTCH1* - a critical regulator of arterial differentiation and blood vessel (BV) sprouting; *RASA1* - gene functioning downstream of the Ephrin B4 receptor to control BV development; and *FLT4* - gene regulating the development and maintenance of the lymphatic system. EIF2AK4 mutation, classically found in pulmonary capillary hemangiomatosis and hereditary pulmonary arterial hypertension was found in a patient with cutaneous hemangiomatosis. The segregation analysis was performed in the healthy parents and none of them was a carrier of the corresponding variants, confirming they are de novo.

Conclusion: This study highlights novel genetic mutations associated with CVMs, advancing our understanding of their molecular etiology. These findings underscore the potential for genomic approaches in enhancing diagnostic accuracy and informing therapeutic development. Further research is needed to investigate the functional consequences of these mutations.

P07.033.B A Retrospective analysis of *MYBPC3* variants - optimized bioinformatics pipeline reveals pathogenic intronic variants in Former Genotype-Negative HCM cases

*Mélcar Collodetti[1], Patrícia Oliveira[2,3], Diana Pinho[2,3], **Márcia Baixia**[2,3], Raquel Borges[2,3], Gonçalo Vale[2,3], Elisabete Martins[4,5], Bernardo Cruz[5], Marisa P. Silva[6], Rita Faria[6], Sérgio Castedo[2,3], Joana Rosmaninho-Salgado[7]*

[1]Laboratory of Medical Research in Liver Pathology - Clinics Hospital - Faculty of Medicine of the University of São Paulo, São Paulo, Brazil, [2]Ipatimup, Oporto, Portugal, [3]i3S - Institute for Innovation and Health Research, Oporto, Portugal, [4]Faculty of Medicine - University of Porto, Oporto, Portugal, [5]Department of Cardiology, Centro Hospitalar Universitário São João, Oporto, Portugal, [6]Department of Cardiology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia, Portugal, [7]Medical Genetics Unit, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Background: Genetic variants in the *MYBPC3* gene are among the most common genetic causes of hypertrophic cardiomyopathy (HCM). Recent studies have identified causal intronic variants, introducing cryptic splice-sites located in outside the standard regions of interest of genetic testing. By default, intronic regions outside the canonical splice site (± 8 bp) are not analyzed in the daily practice of our diagnostic laboratory. The aim of this work was to conduct a retrospective analysis and optimize the workflow used in routine cardiogenic testing to include the study of important intronic regions.

Material and methods: A retrospective study was conducted on a cohort of 658 HCM probands, through the development of a bioinformatics pipeline that allowed us to search for five known intronic *MYBPC3* relevant variants (c.1224-19G>A, c.1224-52G>A, c.1224-80G>A, c.1224-21A>G, and c.906-36G>A).

Results: This analysis allowed the detection of 4 cases with splicing variants (0.6%) that were previously missed using the conventional approach. All cases were otherwise genotype-negative.

Conclusion: These results emphasize the importance for laboratories to regularly update their bioinformatics pipelines, incorporating the study of well covered intronic regions, in genes like *MYBPC3*. This strategy can increase the detection of pathogenic/likely pathogenic variants, improving HCM diagnostic yield, without increasing costs or turnaround time for genetic testing.

P07.034.C Copy number analysis in Czech patients with the inherited cardiac diseases by next generation sequencing

***Jana Zídková**[1], Tereza Kramářová[1], Rastislav Beharka[2], Tomáš Novotný[3], Lenka Fajkusová[1]*

[1]Centre of Molecular Biology and Genetics, University Hospital Brno, Brno, Czech Republic, [2]Institute of Medical Genetics and Genomics, University Hospital Brno, Brno, Czech Republic, [3]Department of Internal Medicine and Cardiology, University Hospital Brno, Brno, Czech Republic.

Background: Copy Number Variants (CNVs), including exon deletions and duplications, are significant contributors to the pathogenesis of various genetic diseases. These structural alterations can disrupt gene function, dosage, or regulation, leading to a wide spectrum of disorders, including cardiomyopathies and arrhythmogenic syndromes. Recent advances in genetic testing technologies, particularly next-generation sequencing (NGS), have enhanced the detection of these variants, improving diagnostic accuracy and risk assessment.

Material and methods: Our study involved targeted sequencing of genes associated with inherited cardiac diseases, along with bioinformatics analysis for detecting small-scale gene variants and CNVs.

Results: We present genetic findings in Czech patients with cardiomyopathies and arrhythmogenic syndromes. Pathogenic or likely pathogenic variants were identified in 104 unrelated patients (26.3%). CNVs - specifically whole-exon deletions within genes - were detected in 4 patients in the genes *RYR2*, *JUP*, *NEXN*, and *SNTA1*. Notably, exon deletions in *JUP* and *SNTA1* have not been previously described. Deletions involving the entire *NEXN* gene have been reported in the literature; however, we detected a novel deletion involving exons 2–5 in a homozygous state in a patient with heart failure in infancy. This finding broadens the spectrum of patients with recessive inheritance in the *NEXN* gene.

Conclusion: The identification of novel CNVs in genes such as *JUP*, *SNTA1*, and *NEXN* expands our understanding of the genetic basis of inherited cardiac diseases. These results underscore the importance of comprehensive genetic testing, including CNV analysis, in improving diagnostic precision and patient care.

P07.036.A Mainstream genomic testing is acceptable to cardiologists: the development and evaluation of a Genetic Counsellor led program in an Australian metropolitan hospital

***Heather Chalinor**[1], Simon Bodek[1], Ainsley Campbell[1], Linda Cicciarelli[1], Melissa Martyn[2], Rigan Tytherleigh[2], Elizabeth Jones[1], Geoff Wong[1], Han Lim[1], Nicole Brisbane[1], Jackie Gibcus[1], Terase Lancefield[1], Hamid Salehi[1], James Theuerle[1], Omar Farouque[1]*

[1]Austin Health, Melbourne, Australia, [2]Melbourne Genomics, Melbourne, Australia.

Background: Genetic Services have limited capacity to meet the growing demand for diagnostic genomic medicine. Mainstream

genomic testing is an alternative model of care, however, specialty-specific training in genetics is critical if precision medicine is to be embraced.

Material and methods: A mainstream genomic testing program for patients at risk of inherited cardiomyopathy, arrhythmia and familial hypercholesterolemia was developed. A Genetic Counsellor was embedded in select cardiology clinics for 9 months to train and support Cardiologists to provide genomic testing to patients. Cardiologists' experiences were assessed through completion of quantitative evaluation surveys pre- and post- the Genetic Counsellor embedment. The program, resources and evaluation survey were developed through an iterative process, informed by established mainstream programs and adapted from validated implementation measures.

Results: Twenty-three Cardiologists completed at least one evaluation survey. Cardiologists' familiarity with testing processes doubled ($p < 0.001$), they reported increased confidence with the practical requirements of testing ($p < 0.001$), their ability to interpret test reports ($p = 0.006$), and to discuss testing with patients ($p < 0.001$). By the second survey, all Cardiologists reported the use of mainstream testing was acceptable. The success of the program was further evidenced by an 11% pathogenic variant detection rate and Cardiologists' continued use of mainstream testing 8 months after the embedment period ended.

Conclusion: In under 12 months, the program successfully supported the adoption and ongoing use of genomic testing in a cardiology unit. This demonstrates how Genetic Counsellors can partner with specialty clinics to provide support, education and training, and establish a sustainable mainstream genomics program.

P07.037.B Spontaneous coronary artery dissection and a family history of aortic dissection: a genetic association study

Lucy McGrath-Cadell[1,2], *Stephanie Hesselson*[1,2], *Ingrid Tarr*[1,2], *Emma Rath*[1,2], *Michael Troup*[1,2], *Yunkai Gao*[1,2], *Keerat Junday*[1,2], *Monique Bax*[1,2], *Siiri E. Iismaa*[1,2], *Nicholas Collins*[3], *David WM Muller*[1,4], *Jason C. Kovacic*[1,2,4], *Eleni Giannoulatou*[5,2], *Robert M. Graham*[1,2,4]

[1]*Victor Chang Cardiac Research Institute, Sydney, Australia,* [2]*University of New South Wales, Sydney, Australia,* [3]*John Hunter Hospital, Newcastle, Australia,* [4]*St Vincent's Hospital, Sydney, Australia,* [5]*Victor Chang Cardiac Research Institute, Darlinghurst NSW, Australia.*

Background: Spontaneous coronary artery dissection (SCAD) is a cause of acute coronary syndrome, primarily affecting relatively young women (median age:51years) without typical cardiovascular risk factors. SCAD has a genetic component, with recent genome-wide association studies identifying multiple risk loci. Thoracic aortic dissection (type A), another vascular disorder, shares some genetic overlap with SCAD, suggesting potential common genetic predispositions.

Material and methods: We performed genetic screening or whole genome sequencing (WGS) of 17 SCAD cases (94% women) who had a family history of aortic dissection (AD) in a first- or second-degree relative (89% men). We assessed rare variants in candidate genes and genome-wide using the American College of Medical Genetics and Genomics criteria. Polygenic risk scores (PRS) were calculated to assess the cumulative genetic risk for SCAD, fibromuscular dysplasia, AD, and abdominal aortic aneurysm (AAA) in SCAD cases, relatives with AD, and controls.

Results: WGS identified pathogenic/likely pathogenic variants in *SMAD3*, *CBS* and *COL3A1* genes associated with aortopathies in three SCAD cases. Four variants of uncertain significance were found in candidate genes. PRS for SCAD were significantly associated with increased odds of SCAD in probands compared to controls (OR = 1.79, 95%CI = 1.08–2.99, p = 0.024).

Conclusion: Our study supports the complex genetics underlying SCAD, implicating rare pathogenic variants and polygenic risk. We identified pathogenic variants in SCAD cases with a family history of AD, highlighting potential genetic links between these vascular disorders. Findings underscore the importance of genetic screening in families of patients with SCAD and family history of AD to identify at risk individuals.

P07.038.C Long-Read RNA sequencing in cardiomyopathies : a new approach for genetic diagnostic with strong potential ?

L. RIALLAND[1,2], *E. Legrand De Milleville*[1], *H. Madry*[3], *B. Mohand Oumoussa*[3], *J.-F. Pruny*[4], *P. Charron*[4,1], *P. Richard*[2,1], *E. Villard*[1];

[1]*UMRS 1166, Paris, France,* [2]*APHP, UF Cardiogénétique et Myogénétique Moléculaire et Cellulaire, Paris, France,* [3]*UMS PASS P3S, Sorbonne-Université, Paris, France,* [4]*APHP, Centre de Référence des Maladies Cardiaques héréditaires ou rares, Paris, France*

Background: Dilated cardiomyopathies (DCM) are inherited diseases, for which genetic diagnostic conditions patient follow-up and family care (major gene *TTN*). However, current DNA Short Read (SR-DNA-Seq) based sequencing diagnostic yield is only 15–25% suggesting methodological limitations. This lack might be mitigated by RNA Long-Read (LR-RNA-Seq) which detects elusive DNA rearrangements and cryptic aberrant splicing causative mutations. We aim to evaluate LR-RNA-Seq for detection of Single Nucleotide Variants (SNVs) in coding exons and short/complex DNA Structural Variants (SV).

Material and methods: Cardiac RNA from 26 DCM cases were sequenced on a PromethION24 (ONT). SNVs and SV were called using a LR dedicated bioinformatic tool (Clair3). True variants calling thresholds were inferred from replication using DNA Sanger.

Results: Samples were covered with 11.6M reads (mean size:1094pb). Among 33 LR-RNA-seq variants, 11 were confirmed in DNA, allowing to define key parameters witnessing for high prior probability variants. All 3 causal SNV already diagnosed were detected. We detected 2 new causative truncating variants in the TTN gene in 2 other patients. Finally, we identified rare monoallelic variants overlapping with TTN locus, suggesting hemizygosity confirmed by Genomic DNA qPCR. Overall, the diagnostic yield of LR-RNA seq was 23% (6/26), at the upper limit of the reported yields for DCM.

Conclusion: LR-RNA-seq appears to be an efficient method to detect coding variants in expressed genes, as well as SV. Ongoing analysis of splicing and NMD-related variants in our LR-RNA-seq data might further increase diagnostic yield, potentially representing a key strategy to complement SR-DNA-Seq in genetic diagnostic.

P07.039.D RNA-sequencing unveils novel *FLT4* splice site variants in isolated CHD

Maxim Verlee[1], *Erika D'haenens*[2], *Laurenz De Cock*[3], *Laura Muino Mosquera*[4], *Katya De Groote*[4], *Kristof Vandekerckhove*[4], *Joseph Panzer*[4], *Ellen Roets*[4], *Björn Menten*[5], *Sofie Symoens*[4], *Paul Coucke*[1], *Tim Vandamme*[2], *Sarah Vergult*[6], *Bert Callewaert*[7]

[1]*Ghent University, Ghent, Belgium,* [2]*Center for Medical Genetics Ghent, Ghent, Belgium,* [3]*University of Ghent, Ghent, Belgium,* [4]*Ghent University Hospital, Ghent, Belgium,* [5]*Ghent University HospitalCenter for Medical Genetics, Ghent, Belgium,* [6]*Ghent University, Ghent University Hospital, Ghent, Belgium,* [7]*Ghent University HospitalCenter for Medical Gentics - 0K5, Ghent, Belgium.*

Background: Congenital heart disease (CHD) affects more than 8/1000 live-born babies and may occur isolated or as a syndromic constellation. The pathophysiology is complex, involving genetic and environmental contributions, with unknown etiology in most cases. Heterozygous loss-of-function (LOF) variants in *FLT4* have recently been linked to Tetralogy of Fallot (TOF). We report two families with LOF variants in *FLT4*, contributing to the molecular etiology of isolated CHD.

Material and methods: In 318 probands with isolated CHD and normal CNV analysis, we performed trio exome sequencing on genomic-DNA using a virtual CHD panel of 471 genes. *FLT4* (NM_182925.5) variants were classified using ACMG guidelines. We applied RNA-sequencing on lymphocytes to evaluate to evaluate splicing-effects.

Results: We identified novel PVs in *FLT4* in two families with non-syndromic CHD. In family one, two siblings diagnosed with TOF and MAPCAs harbored a heterozygous c.985+1G>A *FLT4* variant, inherited from their asymptomatic father. In family two, the proband presented with bicuspid aortic valve and aortic coarctation and harbored a heterozygous c.1657+6T>C variant in *FLT4*. The variant was inherited from her asymptomatic mother, but occurred de novo in the maternal grandmother diagnosed with TOF. For both variants RNA-sequencing revealed skipping of exon 7 and 12 in the c.985+1G>A and c.1657+6T>C variant respectively, resulting in a premature termination codon, reclassifying both variants as pathogenic. Previous targeted RT-PCR analysis for the c.1657+6T>C variant revealed normally.

Conclusion: Our report expands the clinical spectrum of heterozygous *FLT4* splice-site variants with reduced penetrance. RNA-sequencing is a powerful tool to uncover missing heritability in isolated CHD.

Background: The SECIS binding protein 2 (*SECISBP2*) gene is required for the synthesis of selenoproteins, potent antioxidants that regulate inflammatory signalling pathways and modulate levels of reactive oxygen species. Rare biallelic *SECISBP2* variants have been associated with pleiotropic phenotypes, including abnormal thyroid hormone metabolism, neurodevelopmental disorders and aortic aneurysm. Here, we report a consanguineous South Asian family with a history of three perinatal deaths due to progressive cardiomyopathy and arrhythmias with a rare homozygous splice site variant in the *SECISBP2* gene.

Material and methods: DNA from the parents and four offspring underwent whole-genome sequencing as part of the Elusive Hearts study of families with likely monogenic cardiac diseases. Genome-wide analysis on GATK joint-called VCFs was performed using seqr, and biallelic autosomal variants prioritised. RNA sequencing was performed on parental blood samples and stored fibroblasts from two cardiac-affected offspring.

Results: The rare NM_024077.5(*SECISBP2*):c.1303-2A>G variant (gnomADv4 AC = 2) was heterozygous in parental samples, and homozygous in three deceased offspring. A fourth baby without cardiac disease did not carry the *SECISBP2* variant. RNAseq confirmed this is a loss of function variant, with an in-frame event due to use of a cryptic splice site only seen in ~1% of transcripts. Keshan disease is a progressive cardiomyopathy resulting from nutritional selenium deficiency, and provides a precedent for associating disorders of selenoprotein biosynthesis with cardiac disease.

Conclusion: We report the first instance of perinatal lethal cardiomyopathy due to biallelic variants in *SECISBP2*, causing a more severe phenotype than previously reported cases linked to this gene.

P07.042.C Whole exome sequencing in pediatric cardiomyopathies

Luana Giovannangeli[1], *Elise Daire*[1], *Kahia Messaoudi*[1], *Walaa Darwiche*[1], *Sarah Sauval*[1], *Emilie Lacot-Leriche*[1], *Didier Herent*[1], *Nathalie Desjeux*[1], *Sabine Dirani*[1], *Jean-Benoit Baudelet*[2], *Luisa Marsili*[2], *Alexandre Delarue*[2], *Didier Klug*[2], *Olivia Domanski*[2], *Pascal De Groote*[2], *Pierre-Alexandre Fontanges*[2], *Jamal Ghoumid*[2], *Alexis Hermida*[1], *Florence Jobic*[1], *Guillaume Jedraszak*[1]

[1]*Amiens Picardie University Hospital, Amiens, France,* [2]*Lille University Hospital, Lille, France.*

Background: Pediatric cardiomyopathies are a group of rare diseases that include hypertrophic, dilated, restrictive, arrhythmogenic cardiomyopathies and left ventricular non-dilated cardiomyopathies. While their causes are well understood in adults, genetic causes in children are less known for both isolated and syndromic forms.

Material and ethods: We conducted a retrospective study (2018–2024), analyzing sequencing data from 59 patients aged <18 years old who underwent genetic testing for cardiomyopathy as index cases at the University Hospitals of Amiens and Lille. The main objective of this work was to explore the spectrum of genes involved in pediatric cardiomyopathies using solo Whole Exome Sequencing (WES).

Results: The detection rate of relevant variants identified through solo WES was 64.4% (38 out of 59 patients). Among these, pathogenic/likely pathogenic (P/LP) variants were identified in genes that are rarely described but known to cause isolated cardiomyopathies or to be involved in syndromic diseases. Moreover, two patients with severe disease had two P/LP variations in two different genes.

Conclusion: When compared with panels made on evidence-based assessment of genes, the results of our study show variations in genes that are missing from these panels. This confirms the need for extended genetic analysis in children with cardiomyopathy, even if it appears to be isolated, especially in cases of early presentation, to refine their genotypic spectrum. Furthermore, double mutations in sarcomeric genes are more severe than single mutation and we should systematically look for a second mutation in cases of paediatric presentation.

P07.043.D Beyond dilated cardiomyopathy: expanding the clinical spectrum of TTN truncating variants

Thaís Córdova[1], *Gui Rosa*[1], *Joaquim Sá*[1,2], *Marisa Teixeira*[1], *Rita Cerqueira*[1]

[1]*CGC Genetics, Unilabs, Porto, Portugal,* [2]*ULS Coimbra, Coimbra, Portugal.*

Background: TTN truncating variants (tvTTN) are known to cause dilated cardiomyopathy (DCM), but their role in other cardiomyopathies remains unclear. It is not uncommon to observe non-DCM phenotypes in patients with tvTTN, and accurate classification of these variants is crucial for diagnosis, especially regarding the PVS1 criterion. This study aims to expand the clinical spectrum of tvTTN non-DCM phenotypes.

Methods: We reviewed cases with non-DCM tvTTN from January 2017 to January 2025. Patients were studied using NGS-based cardiomyopathy panels or whole exome sequencing. Assuming the N2A transcript (NM_133378.4), all variants were matched to its exonic location, gene region, and PSI scores.

Results: We identified 11 cases, including eight with suspected hypertrophic cardiomyopathy (HCM), one with myofibrosis, one with left-ventricle non-compaction, and one neonatal death. Of the eight HCM cases, four variants were in the A-band, two in the M-band, and two in the I-band, with all but one [c.24248C>G p.(Ser8083*)] having a PSI of 100. The neonatal death case had an intronic variant (c.296-2A>T) in the Z-disc region. The myofibrosis case had a variant in the I-band with a PSI of 6.

Conclusion: Our findings confirm the wide spectrum of cardiomyopathy-related phenotypes that have been described in patients with tvTTN. These results alone do not establish genotype-phenotype associations, but provide further clues for building a more complete picture of the consequences of truncating variants in this gene, which have been particularly difficult to predict.

P07.044.A Clinical laboratory correlation improves the reporting strategy of variants of uncertain significance in hereditary cardiomyopathies and heart rhythm disorders

Carmela Fusco, Silvia Morlino, Mastroianno Sandra, Nardella Grazia, Ester Di Muro, Pietro Palumbo, Maria Pia Leone, Andrea Fontana, Massimiliano Copetti, Massimo Carella, Domenico Rosario Potenza, Antonio Petracca, Giuseppe Di Stolfo, ***Marco Castori***

Fondazione IRCCS-Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

Background: besides the ClinGen's efforts to standardize the ACMG/AMP criteria and European initiatives aimed at monitoring quality standards, molecular diagnostics of hereditary cardiomyopathies and heart rhythm disorders (HCHRDs) remains strongly influenced by the local strategies developed to overcome the variables in which genetic testing is requested. This is a monocentric study on the clinical and molecular findings of 363 pedigrees with various HCHRDs.

Material and methods: ACMG/AMP criteria were adapted according to the ClinGen's material and internal specifications, and the significance of selected variants was supported by RNA studies. Genotype-phenotype data were scrutinized by considering the concurrence of multiple variants in the same individual, disease-gene associations and the effect of selected clinical criteria.

Results: one or more (likely) pathogenic variants were found in 80 pedigrees (22.0%), while 96 (26.4%) displayed one or more variants of uncertain significance (VUS) only. The 132 identified VUS were subclassified according to the Bayesian score in three categories presenting distinguishable patterns of selected criteria. VUS_high showed profiles of key molecular criteria and resembled deleterious variants according to the combinations of assigned criteria, while the VUS_low category displayed a high chance of conflicting combinations of criteria and unsupported disease-gene associations. Reclassification to likely pathogenic by the application of applicable clinical criteria (PVS1_Strength, PP1 and PP4) was accessible to VUS_high and a few VUS_mid only.

Conclusion: this work represents a preliminary support to the clinical utility of VUS subclassification in HCHRDs.

P07.045.B Molecular autopsy in sudden cardiac death: conclusion of "cold-cases"

Francesca Dalla Zanna, *Maria Bueno Marinas, Marco Cason, Rudy Celeghin, Serena Pinci, Giulia Tosato, Monica De Gaspari, Cristina Basso, Kalliopi Pilichou*

University of Padua - Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy.

Background: Sudden cardiac death (SCD) occurs within an hour of symptom onset in apparently healthy individuals (1:100,000 in <35 years, annually), profoundly impacting families. Structural heart diseases and channelopathies, often genetically driven, contribute significantly. When medical history is unremarkable and autopsy findings are minimal, genetic testing aids diagnosis and risk assessment for the family care, though high-quality DNA from autopsy samples poses great challenges.

Material and methods: 114 SCD patients who underwent autopsy were subjected to Whole Exome Sequencing (WES). DNA was extracted from blood (n = 61) and from formalin-fixed paraffin-embedded (FFPE) tissue (n = 53) (average FFPE time = 8.8 years). Variant prioritization and classification followed American College of Medical Genetics and Genomics guidelines.

Results: FFPE tissue was a suitable starting material in 53% of samples (28/53). Interestingly, DNA quality showed no correlation with the year of tissue inclusion. Genetic variants in CMP-associated genes were detected in 45% of cases (40/89), with only 14 (16%) classified as pathogenic/likely pathogenic (P/LP). Notably, 50% of P/LP variants (n = 7) were found in the FFPE subcohort, resulting in a 25% positivity rate. Family co-segregation analysis identified two families where the SCD victim carried two distinct variants, each inherited from a parent.

Conclusion: Determining the genetic cause of SCD enables a more precise diagnosis, provides essential closure for families, and aids in assessing SCD risk in surviving relatives. Effective DNA isolation from FFPE SCD samples facilitates high-quality genetic analysis, playing a crucial role in resolving "cold cases" through molecular autopsy.

P07.046.C The role of compound heterozygous variants in cardiovascular disease: insights from a cohort of 345 CVD families

Roozbeh Manshaei[1], *Xin Chen*[1], *Marci L. B. Schwartz*[1], *Olivia M. Moran*[1], *Raymond H. Kim*[1], *Rebekah K. Jobling*[2]

[1]*Ted Rogers Centre for Heart Research Cardiac Genome Clinic, The Hospital for Sick Children, Toronto, ON, Canada,* [2]*The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Cardiovascular diseases (CVDs) are a leading cause of morbidity and mortality, with significant genetic contributions. While dominant inheritance models have been extensively studied, the role of autosomal recessive variants in CVD remains underexplored. This study analyzed genomic data from CVD-affected patients and their families to evaluate recessive compound heterozygous variants.

Material and methods: The trio genome sequencing data of 345 CVD-affected patients and their parents were retrospectively analyzed. A Recessive Potential Compound Heterozygous annotation framework identified candidate variants based on rarity (allele frequency≤0.0015 in 1000 Genomes and gnomAD) and quality. Inheritance configurations were determined using custom rules incorporating phasing and parental genotype matching. Fisher's exact test evaluated gene-level statistical significance to identify disproportionately impacted genes.

Results: Our analysis identified that compound heterozygous variants in TTN (FDR:0.0001) and OBSCN (FDR:0.0315) are significantly enriched in the CVD cohort. TTN, encoding titin, is essential for cardiac muscle integrity, and mutations in TTN are established causes of Dilated Cardiomyopathy (DCM), Hypertrophic Cardiomyopathy (HCM), and Left Ventricular Non-Compaction (LVNC)[1]. Similarly, OBSCN, encoding obscurin, plays a crucial role in muscle organization, with variants linked to HCM, DCM, and LVNC[2]. Our findings are consistent with previous studies and further validate their pathogenic relevance in CVD.

Conclusion: This study profiles the configuration of compound heterozygous variants in a CVD cohort. Validated by the identification of TTN and OBSCN as significant contributors, our results underscore the impact of compound heterozygosity in CVD. These findings provide insights into CVD genetics and offer potential implications for diagnostics and therapeutics.

P07.047.D *TTN*:c.12478del in proximal I-band of titin represents a common molecular cause of dilated cardiomyopathy in Slovenian patients

Nina Vodnjov[1], *Andraž Cerar*[2], *Aleš Maver*[1], *Borut Peterlin*[1], *Karin Writzl*[1]

[1]*University Medical Centre Ljubljana, Clinical Institute of Genomic Medicine, Ljubljana, Slovenia,* [2]*University Medical Centre Ljubljana, Department of Cardiology, Ljubljana, Slovenia.*

Background: Titin truncating variants (*TTN*tv-s) are the most common cause of dilated cardiomyopathy (DCM). Little is known about *TTN*-pathy in Slovenian patients with DCM. We aimed to investigate the relevance of *TTN*tv-s in Slovenian probands with DCM.

Material and methods: An internal database of exome sequencing results was used to identify probands with DCM. Their data were screened for (likely) pathogenic (LP/P) variants. Whole genome sequencing was used to investigate the founder effect of the most commonly identified variant. Patients' medical and family histories were collected retrospectively.

Results: 211 probands with DCM were identified, of whom 60 (27.1%) had a LP/P variant. Thirty-three *TTN*tv-s were classified as LP/P, 13 in I-band (19 probands) and 20 in A-band (25 probands). Thus, LP/P *TTN*tv-s explained 73.3% of the Slovenian molecular pathology of DCM. The most frequently identified variant was *TTN*:c.12478del, identified in 7 individuals (15.9%), affecting the I-band (cardiac-specific N2Bus region), suggesting its founder origin. These individuals had severely reduced left ventricular ejection fraction, three of whom also had tachyarrhythmia.

Conclusion: We observed a high yield of LP/P *TTN*tv-s in Slovenian probands with DCM. We found that a significant contribution to *TTN*-related DCM in the Slovenian population is due to a recurrent I-band variant. This highlights the importance of understanding population-specific genetic variability in the diagnosis of DCM.

P07.048.A Biallelic GNPTAB variants are a rare cause of arrhythmogenic cardiomyopathy and sudden cardiac death

Natasha Jane Henden[1], Natalie Stewart[2], Jennifer Rigby[3], Samantha Bryen[2], Alexandra Butters[2], Amy Baker[2], Laura Catto[2], Inuli Subasinghe[2], Laura Yeates[2], Cas Simons[2], Daniel MacArthur[2], Mary-Louise Freckmann[4], Andreas Zankl[2], Ebony Richardson[2], ***Jodie Ingles***[2]

[1]Garvan Institute of Medical Research, Sydney, Australia, [2]Garvan Institute of Medical Research, Darlinghurst, Australia, [3]ACT Genetic Service, Canberra, Australia, [4]Northern Sydney Local Health District, St Leonards, Australia.

Background: Pathogenic variants in the N-acetylglucosamine-1-phosphate transferase subunits alpha and beta (GNPTAB) are definitively associated with autosomal recessive mucolipidosis type II/III; a rare lysosomal storage disorder including skeletal dysplasia at birth (type II) or childhood (III). Cardiac features have been described, with shortened life expectancy due to cardiorespiratory failure. We report siblings with sudden cardiac death (SCD), arrhythmogenic cardiomyopathy (ACM) and skeletal dysplasia; with two heterozygous variants in GNPTAB.

Material and methods: DNA from the affected siblings underwent whole-genome sequencing as part of the Elusive Hearts study. Genome-wide analysis on GATK joint-called VCFs was performed for both siblings, with monoallelic/biallelic autosomal variants fitting known OMIM-inheritance associations prioritised in seqr.

Results: The NM_024312.5(GNPTAB):c.3503_3504del p.(Leu1168Glnfs*5) and c.1400A>G p.(Asp467Gly) variants were heterozygous in both affected siblings; and strongly inferred to be in trans based on variant co-occurrence data from gnomAD v2. The c.3503_3504del variant is pathogenic and a known Quebec founder; while c.1400A>G is present 6 times in gnomADv4 and classified as uncertain significance. While cardiorespiratory failure is reported, only two reports of dilated cardiomyopathy exist. Our sib pair includes a male with epiphyseal dysplasia in childhood and SCD aged 32years with cardiomegaly, abnormally shaped vacuolated myocytes, extensive fibrosis and fat infiltration of the RV. His sister had congenital hip dysplasia, ACM in her 30's, impaired RV, ventricular tachycardia on loop recorder.

Conclusion: We report an atypical presentation of GNPTAB-mucolipidosis type III, with ACM as the primary cardiac presentation, and mild skeletal dysplasia. GNPTAB should be considered in sudden cardiac death gene panels.

P07.049.B 'Impact of novel RAMBAs on cardiac development'

Maria Carolina Altomonte[1], *Anagha Maria Alex[2,3], Dilan Durmus[4], Catherine Roberts[4]*

[1]Imperial College London, London, United Kingdom, [2]King's College London, London, United Kingdom, [3]University College London, London, United Kingdom, [4]St George's, University of London, London, United Kingdom.

Background: Congenital Heart Diseases (CHDs) are the most common class of newborn defects and despite their high prevalence, the underlying mechanisms and genes involved are not yet clear. Retinoic acid (RA) is the most active metabolite of Vitamin A and has been identified as an important signalling molecule during vertebrate cardiac development. RA binds to nuclear receptors to regulate transcription. Bioavailability of RA is regulated by the balance between two enzyme classes which synthesise (Retinoic acid dehydrogenases-RALDHs) and metabolise (cytochrome p450 subfamily 26- CYP26s) RA. Both the excess and deficiency of RA produce similar heart defects in the embryo.

Material and methods: Two novel Retinoic acid metabolism blocking agents (RAMBAs), C2 and C17, and Talarozole (R115866) which inhibit CYP26 function were used to induce RA excess at 6hpf until 24 and 72hpf. RA signalling inhibition was induced with the similar treatment BMS195614 (Retinoic Acid Receptor α Antagonist (RAA)). Cardiac development was analysed by molecular makers for cardiomyocyte specification, with Fisher's exact Test used to determine statistical significance.

Results: All RAMBA-treated embryos show defective cardiac chamber formation and looping, indicating in vivo action of the novel RAMBAs and a role for CYP26 enzymes in zebrafish cardiac development. C17 displays higher potency in affecting cardiac specification than C2. Similar defects were seen in RAA-treated embryos, plus cardiac domain posteriorisation.

Conclusion: This research has demonstrated for the first time the in vivo effect on cardiac development of two novel RAMBAs, shedding light on RA signalling and metabolism during cardiac development.

P07.050.C Mutation burden for familial hypercholesterolemia in Bulgarian individuals

Ivanka Dimova[1], *Martin Georgiev[2], Darina Kachakova[1], Kunka Kamenarova[2], Kalina Mihova[3], Valentina Peycheva[1], Radka Kaneva[1]*

[1]Medical University Sofia, Sofia, Bulgaria, [2]Medical University of Sofia, Sofia, Bulgaria, [3]Medical University-Sofia, Sofia, Bulgaria.

Background: Familial hypercholesterolemia (FH) is a group of inherited genetic defects that result in severely elevated serum cholesterol concentrations due to delayed removal of low-density lipoprotein (LDL) from the blood in hepatocytes. The cause is autosomal dominant mutations in *LDLR* gene, gene for its ligand *APOB*, or *PCSK9*. Phenotypic expression of FH can also be caused by variants in the LDL-receptor adapter protein (*LDLRAP*) with recessive inheritance. The objective of our study was to analyze the type and frequency of mutations in these genes in Bulgarian cohort, using whole exome sequencing (WES).

Material and methods: We extracted data for these genes from sequencing files of 604 Bulgarians, analyzed by WES.

Results: We established pathogenic variants, as follows: 3 in *LDLR* (frequency 1:151) - c.1618G>A, c.1646G>A and c.2403_2406del; 2 in *APOB* (1:302) - c.904+2T>C and c.10580G>A; 1 in *PCSK9* - c.1522C>G and *LDLRAP* - c.89-1G>C (1:604). In addition, variants of unknown significance were also found: 8 in *LDLR* (1:75), 29 in *APOB* (1:21), 22 in *PCSK9* (1:28) and 4 in *LDLRAP* (1:151).

Conclusion: The incidence of FH in Bulgaria seems to be higher that the classical population data for 1:500. Currently, there are high-standard identification tests and several lipid-lowering treatments available, most at very low cost (statins), so FH screening should become a priority in health systems promoting public cardiovascular health. Genetic testing of FH provides a reliable molecular diagnosis of FH, prognostic information and the ability to perform precise risk stratification for coronary arterial disease in these patients.

P07.052.A Exome sequencing identifies pathogenic variants in patients with Atherosclerosis, regardless of risk groups

Zhanel Mirmanova[1], *Madina Zhalbinova*[1], *Ayaulym Chamoieva*[1], *Tomiris Shakhmarova*[1], *Nazerke Satvaldina*[1], *Saule Rakhimova*[1], *Ulykbek Kairov*[1], *Asset Daniyarov*[1], *Makhabbat Bekbossynova*[2], *Ainur Akilzhanova*[1]

[1]*Center for Life Sciences, National Laboratory Astana, Nazarbayev University, Astana, Kazakhstan,* [2]*Heart Center, University Medical Center, Nazarbayev University, Astana, Kazakhstan.*

Background: Genetic background significantly influences susceptibility to atherosclerosis (AS). We aimed to identify genetic variants in lipid and glucose metabolism genes in Kazakhstani patients with AS.

Material and methods: We performed whole exome sequencing in patients with AS (n = 297) with CHD, arterial hypertension and dyslipidemia. Phenotypic distribution into risk groups was based on the 2019 ESC/EAS Guidelines: very high risk (n = 166), high risk (n = 70), low risk (n = 61). Genetic variants in 17 genes related to lipid and glucose metabolism (*APOE, APOB, PNPLA/2/3, GCKR, TM6SF2, LYPLAL1, ABCB1, ABCG5/8, LDLRAP1, LIPA, LPA, PCSK9, SORT1*) were analyzed in risk groups of patients.

Results: Overall, 2 pathogenic (P), 3 likely pathogenic (LP) and 100 variants of uncertain significance (VUS) were identified in all groups. We found P variants *APOE* (C526T:p.R176C), *GCKR* (G1004A:p.W335X) and LP variants *LDLR* (C419T:p.P140L), *APOE* (T388C:p.C130R), *GCKR* (G307A:p.V103M) in low-risk group patients, P variant *APOE* (C526T:p.R176C) and LP variants *APOE* (T388C:p.C130R), *GCKR* (G307A:p.V103M) in high-risk group patients, P variants *APOE* (C526T:p.R176C) and LP variants *LDLR* (C419T:p.P140L), *APOE* (T388C:p.C130R), *GCKR* (G307A:p.V103M) in the very high risk group.

Conclusion: Pathogenic and likely pathogenic genetic variants were identified independently in all risk groups, mainly in 3 genes (*APOE, LDLR, GCKR*), which emphasizes the need for further studies to assess their clinical significance in pathogenesis of AS. Large number of VUS emphasizes the importance of functional studies to clarify their potential role. Further analysis including other genes involved in metabolic pathways of atherosclerosis development is crucial to deepen our understanding and improve prevention and treatment.

P07.053.B The impact of chromosomal microarray in congenital heart defects: a single center experience

Gulsum Kayhan[1], ***Ekin Alpaslan***[1], *Hacer Demet Ozcan*[1], *Semiha Terlemez*[2], *Fatma Canbeyli*[2], *Mehmet Ali Ergun*[1], *Meral Yirmibes Karaoguz*[1]

[1]*Gazi University Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [2]*Gazi University Faculty of Medicine, Department of Pediatric Cardiology, Ankara, Turkey.*

Background: Congenital heart disease (CHD) ranks among the most prevalent congenital anomalies and its mortality rate remains significantly high despite various treatment options. This study aims to investigate the diagnostic capabilities and clinical utility of chromosomal microarray (CMA) testing for patients diagnosed with CHD in our center.

Material and methods: A total of 113 patients with CHD were evaluated and divided into two groups: isolated CHD, which included 27 patients, and syndromic CHD, comprising 86 patients. The syndromic CHD group displayed at least one of the following traits: other congenital anomalies, dysmorphic features, intellectual disabilities, or developmental delays. The CMA test was performed on all patients.

Results: In the isolated CHD group, two patients had pathogenic CNVs, and three had variants of uncertain significance (VUS), resulting in a diagnostic rate of approximately 7%. In the syndromic CHD group, ten patients had pathogenic CNVs, and five had VUS, yielding a diagnostic rate of about 11.6%. Within this group, three pathogenic CNVs were classified as large chromosomal aberrations (3.4%). Overall, CMA clarified the molecular diagnosis for 10.6% of patients.

Conclusion: Our results indicated that CMA testing demonstrated a higher diagnostic rate for syndromic CHD compared to isolated CHD, aligning with existing literature. Recurrent microdeletion and duplication syndromes were identified in isolated CHD, whereas CNVs featuring unique breakpoints were also observed in syndromic CHD.

P07.054.C Increasing the diagnostic yield for Cardiomyopathy (CM) patients: investigating the role of rare Loss of Function (LoF) variants in CM genes for which LoF is not an established disease mechanism

Martine T. Meems-Veldhuis*, Karin Y. van Spaendonck-Zwarts, Imke Christiaans, Birgit Sikkema-Raddatz, Jan D.H. Jongbloed*

University of Groningen, University Medical Center Groningen, Department of Genetics, Groningen, Netherlands.

Background: Next Generation Sequencing (NGS) based gene-panel analysis in CM patients results in a diagnostic yield of ~30%. However, the potential yield is higher because Variants of Unknown Significance yet remain unsolved. The aim of this study is to investigate the role of LoF variants in CM related genes for which LoF is not an established disease mechanism, to potentially increase the diagnostic yield.

Material and methods: We selected the *ACTC1, ACTN2, DSC2, DSG2, MYH7, NEXN, RBM20, TNNI3* and *TNNT2* genes as potentially interesting candidates. We collected LoF variants identified in these genes after NGS-based CM gene panel analysis and (re) evaluated up-to-date molecular and clinical data from literature and (disease) databases, pathogenicity prediction tools and our local patient databases (*i.e.* co-segregation, multiple affected individuals with same variant).

Results: In our cohort of >6300 CM patients, we identified ~35 LoF variants (25 frame shift/nonsense and ~10 affecting RNA splicing (putatively) resulting in LoF) in the above mentioned genes in 120 patients. Clinical and molecular data indicate that

LoF variants in (a subset of) these genes are related to CM phenotype(s).

Conclusion: Our study shows that LoF variants in a subset of CM genes, for which this was not yet established, are involved in disease development, resulting in higher diagnostic yield. We are currently collecting data of other Dutch genome diagnostic laboratories to complement our study. That data and possibly data via other (inter)national collaborations is needed to definitely establish the role of LoF variant in these genes in CM phenotype(s).

P07.055.D Genetic analysis of sudden cardiac death cases

Tereza Kramářová[1], *Jana Zídková*[1], *Milan Sepši*[2], *Martin Zeman*[3], *Tomáš Novotný*[2], *Lenka Fajkusová*[1]

[1]*Centre of Molecular Biology and Genetics, University Hospital Brno, Brno, Czech Republic,* [2]*Department of Internal Medicine and Cardiology, University Hospital Brno, Brno, Czech Republic,* [3]*Department of Forensic Medicine, St. Anne's University Hospital, Brno, Czech Republic.*

Background: Sudden cardiac death (SCD) is a devastating event characterized by an unexpected natural death from cardiac causes. Genetic testing in SCD cases represents a crucial diagnostic tool for identifying inherited cardiac conditions and preventing future tragic events in families. Testing typically focuses on genes associated with cardiomyopathies and channelopathies, which are common causes of SCD, particularly in young individuals.

Material and methods: We utilized a custom capture panel sequencing approach for variant detection and copy number variant analysis in genes associated with inherited cardiac diseases.

Results: We present the genetic findings in a cohort of 395 Czech patients with suspected cardiomyopathies and arrhythmogenic syndromes. Pathogenic or likely pathogenic variants were identified in 104 unrelated patients. Within this cohort, we analysed a subgroup of 52 individuals who experienced sudden death before the age of 40. A pathogenic variant was identified in one case, while variants of uncertain significance were detected in seven cases. In one case, we identified a highly suspected causal variant in the *ACTN2* gene. Segregation analysis revealed that the proband's father carries this variant in a mosaic pattern, with the variant present in 24% of leukocytes, yet he remains asymptomatic and free of cardiac abnormalities.

Conclusion: In conclusion, our findings demonstrate the challenges and complexities of genetic testing in SCD cases. Although the detection rate of pathogenic variants was relatively low, the identification of a mosaic carrier parent highlights the difficulties in interpreting genetic findings and their clinical relevance.

P07.056.A Evaluation of a hereditary haemorrhagic telangiectasia specialist clinic in Scotland

Madeline C. Pearson[1], *Katie Douglas*[2], *Richard Green*[3], *Quentin Gardiner*[3], *Jonathan Berg*[1]

[1]*School of Medicine, University of Dundee, Dundee, United Kingdom,* [2]*Department of Clinical Genetics, NHS Tayside, Dundee, United Kingdom,* [3]*Department of Otolaryngology, Ninewells Hospital and Medical School, Dundee, United Kingdom.*

Background: Hereditary haemorrhagic telangiectasia(HHT) is a rare, multisystem genetic disorder that requires management of arteriovenous malformations(AVMs), epistaxis, and anaemia. We evaluated the HHT specialist clinic that was established in NHS Tayside in 2020.

Material and methods: HHT clinic data from 2020–2025 was reviewed. Linear mixed model regression was used to assess correlation between Quality of Life(QoL), haemoglobin(Hb), Epistaxis Severity Score(ESS) and time attending clinic.

Results: The 71 patients had a median age of 55.5years(IQR 31.3–70.5years), with a median of 6 appointments(IQR 3–11). Pathogenic Variants were identified in 66; 68%(45/66) ACVRL1; 24%(16/66) ENG; 8%(5/66) SMAD4. 32%(23/71) were screened for brain AVMs, with one detected(4%,1/23). 86%(61/71) were screened for pulmonary AVMs(PAVMs), with a prevalence of 30% (18/61). PAVM prevalence differed by genotype ($p < 0.01$); *ENG* carriers had higher PAVM prevalence than *ACVRL* carriers (58%(7/12) vs 15%(6/40), $p = 0.023$). 60%(3/5)*SMAD4* carriers had PAVMs.41%(29/71) received intranasal procedure(s), with 72% (21/29) requiring multiple procedures. 44%(31/71) are currently receiving iron replacement therapy, with 8%(6/71) requiring blood transfusions. 6%(4/71) have received bevacizumab treatment. QoL scores were positively correlated with Hb levels(beta0.22, $p < 0.01$) and negatively correlated with ESS(-2.98units, $p < 0.001$). After 6-months of clinic intervention ESS had decreased (-0.56,$p = 0.04$), but had returned to baseline by 2-years. There were no significant changes in QoL or Hb levels over 2-year follow-up.

Conclusion: The high intervention levels - for intranasal procedures, iron and/or blood transfusions and PAVM embolisation - support the need for a specialist service. The correlation between QoL and Hb/ESS suggests that a focus on more effective interventions to control epistaxis is required.

P07.057.B Genetic insights into pediatric cardiac disorders: results from a Cohort study of 102 patients

Maria Luca[1], *Angelo Corso Faini*[1], *Francesca Arruga*[2], *Fiorenza Mioli*[1], *Claudia Saglia*[1], *Giulia Margherita Brach Del Prever*[1], *Carmelo Maria Romeo*[1], *Caterina Scolari*[1], *Tullia Carradori*[1], *Fulvio Gabbarini*[3], *Chiara Riggi*[3], *Francesca Cairello*[4], *Tiziana Vaisitti*[1,2], *Alessandro Mussa*[5,6], *Diana Carli*[1,2], *Silvia Deaglio*[1,2]

[1]*Department of Medical Sciences, University of Torino, Torino, Italy,* [2]*Immunogenetics and Transplant Biology Unit, Città Della Salute e Della Scienza, Torino, Italy,* [3]*Cardiology Department, Regina Margherita Children's Hospital, Città Della Salute e Della Scienza, Torino, Italy,* [4]*Pediatric and Pediatric Emergency Unit, Pediatric Cardiology Service, The Children Hospital, AO SS Antonio e Biagio e C. Arrigo, Alessandria, Italy,* [5]*Department of Public Health and Pediatric Sciences, University of Torino, Torino, Italy,* [6]*Clinical Genetics Unit, Regina Margherita Children's Hospital, Città Della Salute e Della Scienza, Torino, Italy.*

Background: Next-generation sequencing (NGS) is routinely used for pediatric arrhythmias, cardiomyopathies, and collagenopathies and is increasingly applied to congenital heart defects. This study reports on 102 pediatric patients across these four categories.

Material and methods: Targeted in silico NGS and phenotype-driven clinical exome sequencing (CES) in negative cases were followed by parental segregation with Sanger sequencing.

Results: Overall, 37/102 (36%) patients tested positive with heterogenous diagnostic yields across subcategories: arrhythmic syndromes showed the highest rate (13/25,52%), followed by cardiomyopathies (7/21,33%), collagenopathies (3/9,33%) and congenital heart defects (14/47,30%). Right-sided obstructive lesions had the highest diagnostic rate (10/17,59%), with variants in RASopathy-genes, *GATA4*, *ELN*, and *JAG1*, followed by isolated septal defects (2/5,40%), including a familial *NKX2.5* case. Among cardiomyopathies, two myopericarditis cases harbored *DSP* variants, highlighting the importance of genetic testing in inflammatory presentations. Overall, variants of uncertain significance (VUS) were 14/102 (14%). Notably, a VUS in *MCTP2* segregated in a family with aortic coarctation, supporting its potential role in left-sided obstructive lesions. Unexpected findings included *MYBPC3* and *PKP2* pathogenic variants in two collagenopathies patients diagnosed respectively with 4q12q21 microdeletion syndrome and *CACNA1C*-related Timothy syndrome. Phenotype-driven CES analysis enabled additional diagnoses, including a pathogenic *WDFY3* variant in an autistic patient with aortic diameter at the upper limit.

Conclusion: Diagnostic yield in this study aligns with literature data, confirming the growing relevance of genetic testing in pediatric cardiology, both for isolated and syndromic presentations. Beyond confirming known associations, genetic testing refines clinical diagnoses, uncovers unexpected findings, guides risk stratification and personalized management.

P07.058.C A case report of a patient affected with facial CM-AVM caused by two somatic RASA1 mutations

Charlotte Kemper[1], *Magdalena Danyel*[1,2], *Sarina Schwartzmann*[1], *Dominik Brado*[3], *Barbara Klink*[3], *Daniel Stieber*[3], *Eric Blanc*[4], *Nicolai von Kügelgen*[4], *Dieter Beule*[4], *René Hägerling*[1,2]

[1]*Institute of medical genetics and human genetics, Charité Universitätsmedizin Berlin, Berlin, Germany,* [2]*Berlin Institute of Health (BIH), BIH Center for Regenerative Therapies, Berlin, Germany,* [3]*National Center of Genetics, Laboratoire national de santé, Dudelange, Luxembourg,* [4]*Berlin Institute of Health (BIH), Core Unit Bioinformatics, Berlin, Germany.*

Background: Vascular malformations are associated with a heterogeneous group of diseases including mosaic disorders caused by post-zygotic somatic mutations. Mosaic diseases require specialized diagnostic methods to detect the causative somatic variant. A patient with a large facial capillary-arteriovenous-malformation (CM-AVM) was referred for genetic testing. Previous testing of affected tissue in pathology had identified a single likely pathogenic somatic variant in *RASA1*, but no second hit. *RASA1* has previously been described in CM-AVM with a combination of heterozygous germline variants plus somatic second hit mutations.

Material and methods: We performed deep exome sequencing using unique molecular identifiers of DNA from both healthy and affected tissue. The data was processed and uploaded to a local version of the cBioPortal software, an open access platform originally designed for cancer genomics.

Results: We were able to identify two somatic variants in *RASA1*. The previously described variant c.1698+2T>C with a variant allele fraction (VAF) of 7% and the second variant c.2603+1G>A with a VAF of 4%. Both variants are predicted to affect splicing and have previously been classified as (likely) pathogenic in ClinVar. We therefore present the disease-causing combination of two somatic variants in RASA1 in a patient with a large facial CM-AVM.

Conclusion: Integrating diagnostic strategies from cancer diagnostics into the evaluation of mosaic vascular malformations can significantly improve the diagnostic yield.

Binaghi Hospital, Local Public Health and Social Care Unit (ASSL) of Cagliari, Cagliari, Italy,* [6]*Director of Medical Genetics Unit, University of CagliariDepartment of Medical Sciences and Public H, Cagliari, Italy,* [7]*Director of Centre for Research University Services (CeSAR, Centro Servizi di Ateneo per la Ricerca), University of Cagliari, Monserrato, Italy.*

Background: Brugada syndrome (BrS) is a cardiac arrhythmia disorder with an increased risk of sudden cardiac death, primarily linked to pathogenic variants in the *SCN5A* gene. Growing evidence suggests significant genetic heterogeneity, with variants in other genes potentially contributing to similar clinical manifestations. Furthermore, phenocopies represent a key challenge in differential diagnosis.

Material and Methods: WES on 87 individuals from 70 families with suspected BrS.

Results: Sixteen exhibited variants in genes not classically associated with BrS, suggesting a broader genetic spectrum underlying BrS-like phenotypes. Among them, five members of a family (including a mother with an implanted defibrillator and a sister with two episodes of cardiac arrest) harboured a 1q43 duplication, disrupting *RYR2*—an alteration undetectable by WES. Two patients (father and son) carried a variant in *DES*. Another patient had a variant in *LMNA* without signs of dilated cardiomyopathy and a *TRPM4* variant. Interestingly, *TRPM4* was also mutated in another family with a BrS diagnosis. In one family, BrS segregated with congenital heart defects, ranging from tetralogy of Fallot to transposition of the great arteries, with variants in *GDF1* and *SCN1B*, either together or separately. Surprisingly, one individual carried a hypomorphic homozygous variant in *CLN3*, the only form of neuronal ceroid lipofuscinosis known to involve cardiac manifestations. Deep phenotyping revealed early neurodegenerative symptoms at age 52.

Conclusion: These findings confirm that other known genes may contribute to BrS-like manifestations and phenocopies. Integrating comprehensive genomic analysis and deep phenotyping is essential for precise diagnosis and risk stratification,

ultimately guiding personalised therapeutic approaches in arrhythmia syndromes.

P07.060.A Blood DNA methylation signatures for more common forms of pulmonary hypertension

Zoe Khaw[1], *Anna Ulrich*[1], *Luke S. Howard*[2], *Martin R. Wilkins*[2], *UK PAH Cohort*[3], *Inga Prokopenko*[1], *Christopher J. Rhodes*[2]

[1]*University of Surrey, Guildford, United Kingdom,* [2]*National Heart and Lung Institute, Imperial College London, London, United Kingdom,* [3]

Background: Pulmonary hypertension (PH) describes conditions characterised by increased blood pressure in the pulmonary artery and right heart, leading to premature death by heart failure. Epigenetic variation in PH broaches the potential for pharmacological targets and a means by which to understand disease penetrance. Our recent pilot study (Ulrich, 2024, PMID: 38184627) from the UK PAH cohort established three significantly associated epigenomic loci hypermethylated in pulmonary arterial hypertension (PAH) (*CTSZ*, *COG6*, and *ZNF678*). Our study aims to validate and build upon these findings by conducting an epigenome-wide association study (EWAS) on blood DNA methylation data from individuals with PH of more common aetiologies alongside PAH, and performing a meta-analysis combined with pilot data.

Material and methods: We performed quality control (QC) on new IlluminaEPICv2.0 methylation data for 375 individuals (415 before QC): 116 disease-free controls, 195 patients under five PH diagnostic subgroups, and 64 PAH patients. We used the CPACOR pipeline (Lehne, 2015, PMID: 25853392) and the GLINT command-line tool to pre-process the raw methylation data, and EpiSmokEr to infer smoking status. Alongside the pilot study, total number of cases post-QC including all individuals with PH is 688, with 1,242 controls.

Results: We will conduct a case-control analysis combining the total sample data in a meta-analysis and investigate potentially discernible differences in methylation patterns between PH subtypes. We will present the results of our meta-analysis of these two studies.

Conclusion: By expanding the PH analysis, we will produce robust EWAS expanding the knowledge about molecular signatures of this rare condition.

P07.061.B Evaluation of genetic variants in Kazakhstani patients with atrial fibrillation: insights from targeted next-generation sequencing

Ayaulym Chamoieva[1], *Zhannur Abilova*[1], *Madina Zhalbinova*[1], *Zhanel Mirmanova*[1], *Saule Rakhimova*[1,2], *Ainur Akhmetova*[1], *Assel Chynybayeva*[3], *Ayan Abdrakhmanov*[3], *Ulykbek Kairov*[1,2], *Makhabbat Bekbossynova*[4], *Ainur Akilzhanova*[1,2,3]

[1]*Center for Life Sciences, National Laboratory Astana, Nazarbayev University, Astana, Kazakhstan,* [2]*Eurasian Society of Personalized Medicine, Astana, Kazakhstan,* [3]*Heart Rhythm Scientific Research Institute, Medical University Astana, Astana, Kazakhstan,* [4]*Heart Center, University Medical Center, Nazarbayev University, Astana, Kazakhstan.*

Background: Atrial fibrillation (AF) is the most common type of cardiac arrhythmia. AF affects over 33 million people globally, with a 25% lifetime risk. AF causes an irregular, often rapid heartbeat and raises the risk of heart failure, stroke and cardiac death. We aimed to evaluate the mutation spectrum of patients diagnosed with AF by targeted next-generation sequencing (NGS) in Kazakhstan.

Material and methods: We performed deep-coverage targeted NGS of gDNA isolated from whole blood samples of 47 AF patients on Illumina HiSeq 2000 platform. A designed custom HaloPlex panel of 96 genes associated with inherited cardiac arrhythmias and cardiomyopathies was used in our study. SureCall 2.0.7.0 software was applied for bioinformatics analysis. The clinical significance of obtained variants was interpreted according to ACMG guidelines.

Results: Genetic screening revealed 55 rare variants. We found 6 pathogenic (P) and 8 likely pathogenic (LP) variants in 14 (29.8%) individuals. Namely, disease-causing mutations are detected in *MYH7, CACNB2, LAMA2*, and *TTN* genes. In addition, 41 variants of unknown significance (VUS) with suggestive evidence of pathogenicity were identified in 28 (59.6%) patients. Moreover, pathogenic variants by functional characteristics were most frequently found in genes encoding sarcomeres (31%), ion channels (11%), and cell membranes (9%).

Conclusion: The study revealed clinically significant variants within 96 genes associated with cardiac diseases. We identified rare P/LP variants suspected to cause AF in 29.8% of patients showing a higher predisposition to severe phenotypes. Besides, a high occurrence of VUS has been observed, highlighting the need for functional studies.

P07.062.C Rare pathogenic variant *KCNH2*c.1825_1830del can lead to arrhythmia LQTS type 2 with consciousness loss episodes, multiple craniofacial and skeletal anomalies

Hayane Akopyan[1], *Khrystyna Bakum*[2], *Nadiya Helner*[1]

[1]*Institute of Hereditary Pathology of the National Academy of Medical Sciences of Ukraine, Lviv, Ukraine,* [2]*Danylo Halytsky Lviv National Medical University, Lviv, Ukraine.*

Background: Seizures like episodes activity is well-known reason for physical and intellectual delay leading to sudden death. Significant clinical and genetic heterogeneity of seizures poses a serious challenge for early diagnosis, and only molecular genetic testing helps to solve a problem in time. Aim of our study: Search for genetic cause of regular loss of consciousness in 19-year-old man with uncertain multiple craniofacial and skeletal anomalies.

Methods: Clinical genetic testing, sequence analysis and deletion/duplication testing of the 2095 genes ("Invitae").

Results: At the age of 13, a patient began to lose consciousness, sometimes with episodes of severe abdominal pain. He lost weight and began to lag of height and physical activity. Clinical examination revealed numerous craniofacial and skeletal anomalies: trigonocephaly, triangular flat face, disproportionately wide neck, microstomia, microretrognathia, deformation of distal phalanges I, III and V hand's fingers, keeled chest deformity, scoliosis. The patient had autistic behavior and was treated as an epileptic. Rare pathogenic variant *KCNH2* c.1825_1830del(p.Asp609_Lys610del) was identified. It's

important, that *KCNH2* gene is associated with autosomal dominant long QT syndrome (LQTS), type 2, which may result in syncope and seizure-like episodes activity (MedGen UID: 462293). After 4-day outpatient Holter recording the cardiologist's conclusion was coincident with molecular testing: Congenital long QTS syndrome type 2; paroxysmal form of pirouette ventricular tachycardia with hemodynamic disturbances and syncope. The patient was directed for implantation of a cardioverter-defibrillator.

Conclusion: Genetic testing confirmed the pathogenicity of the KCNH2c.1825_1830del variant as a cause of seizure-like episodes activity due to LQTS type 2 arrhythmia.

C.O.I. Disclosure:

H. Akopyan: None. **K. Bakum:** None. **N. Helner:** None.

P07.063.D A rare case of hypertrophic-restrictive cardiomyopathy with extensive myocardial and valvular calcifications: whole-exome sequencing (WES) analysis of an uncommon clinical phenomenon

Lodovico Bortot[1], *Beatrice Spedicati*[1,2], *Alessia Paldino*[3], *Stefania Lenarduzzi*[2], *Aurora Santin*[1,2], *Matteo Dal Ferro*[3], *Gianfranco Sinagra*[3], *Giorgia Girotto*[1,2]

[1]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy,* [2]*Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy,* [3]*Cardiovascular Department, Azienda Sanitaria Universitaria Giuliano Isontina (ASUGI), Trieste, Italy.*

Background: Myocardial calcifications are rare, typically resulting from acquired factors. A small proportion of cases are monogenic disorders, and genes such as *ABCC6* and *ENPP1*, which are an established cause of arterial calcifications, have recently been associated.

Material and methods: A 57-year-old woman underwent cardiological evaluation, echocardiography, cardiac-magnetic-resonance (cMR), myocardial biopsy, and WES.

Results: The patient, evaluated for exertional dyspnoea, underwent echocardiography that revealed mitral annular calcifications. cMR showed diffuse intra-myocardial calcifications, at midwall and subendocardial layers, associated with hypertrophy, suggesting hypertrophic-restrictive cardiomyopathy. Myocardial biopsy suggested a metabolic-driven cardiomyopathy. WES identified two compound heterozygous variants in the *ENPP1* gene (NM_006208.3), which encodes ectonucleotide pyrophosphatase/phosphodiesterase 1, regulating extracellular pyrophosphate and calcium phosphate homeostasis: a pathogenic splicing variant (ACMG) c.2311+1G>A and a missense variant c.2330A>G p.(H777R), classified as VUS (ACMG). Segregation analysis in the healthy siblings showed that two of them carried one variant each. *ENPP1* variants are a well-known cause of arterial calcifications, ranging from severe early-onset to milder, later-onset forms. In severe cases, variants cluster in functional regions, though no clear genotype-phenotype correlation is found. While primarily linked to arterial and valvular calcifications, myocardial calcifications may represent a rare, poorly characterized phenotypic expression.

Conclusion: The identification of biallelic *ENPP1* variants highlights the role of genetic testing in this condition, underlining its relevance for recurrence risk assessment and personalized treatment. Indeed, bisphosphonates might be a valuable option, though patients' outcome have been variable (PMID: 29921207). A functional proteomic study is assessing the variants' impact, considering innovative enzyme replacement therapies (PMID: 39342427).

P07.065.B Investigating sudden death in two sisters: the role of molecular autopsy

Fabrizia Pellanera[1], *Marta Romani*[2], *Martina Di Lullo*[2], *Valeria Cacciafesta*[2], *Roberta Tarallo*[2], *Pasquale Linarello*[3], *Rossella Falcone*[2], *Matteo Surdo*[2], *Ettore Cotroneo*[2], *Laura Gigante*[2]

[1]*Azienda Ospedaliera di Terni, Terni, Italy,* [2]*Eurofins Genoma, Rome, Italy,* [3]*Eurogins Genoma, Rome, Italy.*

Background: Sudden cardiac death (SCD) poses a significant risk in children and young adults, frequently linked to genetic predispositions. Molecular autopsy (MA) refers to DNA-based identification of the cause of death. This case study explores the genetic underpinnings of sudden death in two sisters.

Material and methods: The proband, a 14-year-old female who suddenly died at home, was the third child to a healthy couple. Her 16-years-old sister deceased 17 years prior while bathing in the sea. MA on the proband and parents DNA was performed by whole exome sequencing (WES). Sampling with forensic methods was done on objects belonging to the first sister and genomic DNA was obtained by swabbing a trouser. Both parents and the second child of the couple have normal cardiologic investigations.

Results: WES of the proband identified the paternally inherited pathogenic heterozygous c.7175A>G (p.Tyr2392Cys) variant in *RYR2* gene, cause of catecholaminergic polymorphic ventricular tachycardia (CPVT) characterized by arrhythmias during physical stress. Minisequencing confirmed the same RYR2 variant in the first sister suggesting this variant contributed to their sudden deaths. The presence of the same variant in the healthy father is an unexpected finding as mean penetrance of RYR2 pathogenic variants is high (>80%).

Conclusion: MA provided a crucial explanation for the family and allowed for accurate risk assessment and genetic counseling for the surviving sister. This case underscores the importance of MA in sudden cardiac death even in the absence of family history advocating its implementation as a standard practice in unexplained fatalities.

P07.066.C Mutational burden of genetic variants in cardiomyopathy-associated genes provides new insights for postmortem molecular diagnosis of SCD in Kazakhstan

Ainur Akilzhanova[1,2,3], *Ayaulym Chamoieva*[1], *Madina Zhalbinova*[1], *Zhanel Mirmanova*[1], *Tomiris Shakhmarova*[1], *Diana Samatkyzy*[1], *Saule Rakhimova*[1,3], *Ulan Kozhamkulov*[1,3], *Gulbanu Akilzhanova*[4], *Ulykbek Kairov*[1,3], *Akilzhanov Kenes*[5,4], *Tolkyn Zhakupova*[6,7], *Makhabbat Bekbossynova*[8], *Dos Sarbassov*[1,9]

[1]*National Laboratory Astana, Nazarbayev University, Astana, Kazakhstan,* [2]*Heart Rhythm Scientific Research Institute, Medical University Astana, Astana, Kazakhstan,* [3]*Eurasian Society of Personalized Medicine, Astana, Kazakhstan,* [4]*Pavlodar Branch, Semey Medical University, Pavlodar, Kazakhstan,* [5]*Pavlodar City Hospital #1, Pavlodar, Kazakhstan,* [6]*Medical University Astana, Astana, Kazakhstan,* [7]*Institute of Forensic Expertise, Astana, Kazakhstan,* [8]*Heart*

Center, University Medical Center, Nazarbayev University, Astana, Kazakhstan, [9]School of Sciences and Humanities, Nazarbayev University, Astana, Kazakhstan.

Background: The study aimed to evaluate the mutational burden in Kazakhstani Sudden cardiac death (SCD) young (<45 yo) victims revealed by next-generation sequencing.

Material and methods: Targeted sequencing of 174 candidate genes associated with heart diseases was conducted in 67 SCD victims. Based on forensic examination results, SCD cases were divided into three groups: coronary artery disease (CAD) postmortem SCD/CAD (n = 28), non-diagnostic cardiac changes and secondary cardiomyopathy postmortem SCD/SCM (n = 34), and SCD with other heart anomalies (n = 5).

Results: We identified 537 unique variants among all cases. According to ACMG, three variants were categorized as pathogenic (P), 8 as likely pathogenic (LP), and 179 as variants of uncertain significance (VUS). Rare pathogenic variants were identified in 11 out of 51 cases, including 3 (27%) individuals who died from CAD. The corresponding frequency among SCM group was 64%. Comparative analysis of data between groups of SCD/CAD, SCD/SCM, and the control group of 78 people without CVD has shown that 1) the number of homozygous variants was predominant in the SCD/CAD group ($p = 0.0514$); 2) the number of rare variants in both groups was relatively similar; however, the distribution of variants in the SCD/SCM group differs significantly ($p = 0.0023$); 3) unique variants predominates in those who died from SCD ($p = 0.0002$), particularly in the SCD/SCM group; 4) the mutational burden in the SCD/SCM group predominates compared to those who died from SCD with CAD ($p = 0.0182$).

Conclusions: Increased genetic variant burden (P and VUS) is associated with non-diagnostic cardiac changes but not CAD.

P07.067.D Influence of genetic factors on the severity of monogenic familial hypercholesterolemia

Anastasia Musonova, *Darya Sidorenko, Ekaterina Deviatkina, Polina Fedorova, Darya Banina, Vladimir Nazarov, Sergey Lapin*

First Pavlov State Medical University of St. Petersburg, Saint Petersburg, Russian Federation.

Background: Monogenic familial hypercholesterolemia (FH) is one the most common hereditary disease characterized by an increased level of low-density lipoprotein cholesterol (LDL-C) and risk of atherosclerotic cardiovascular disease (ACVD). FH has variable expressivity that can be influenced by other genetic factors. The aim of the study is to determine the prevalence of co-existence and influence of LDL-C polygenic score (PS) and high level of Lp(a) (Lp(a)>50 mg/dL) on the severity of FH.

Material and methods: The study included 27 genetically confirmed «definite» and «probable» FH patients. All patients underwent electrophoresis of lipoproteins, measurement of Lp(a) and PS.

Results: The frequency of pathogenic variants in *LDLR* and *APOB* genes was 72.1% and 25.9%, respectively. The most common variant in *LDLR* gene was p.Glu101Lys (n = 6), in *APOB* gene - p.Arg3527Gln (n = 6). Large deletions and duplications in *LDLR* gene were not identified. Electrophoresis showed type IIa and IIb pattern of WHO classification of hypercholesterolemia in 90.9% and 9.1% of cases, respectively. High levels of Lp(a) was detected in 42.9% of patients. High PS (PS ≥ 0,8) was detected in 26.1% of cases. Pathogenic variants in the *LDLR* and *APOB* genes, high PS and high level of Lp(a) were detected in 15.4% of patients. These patients were characterized by higher incidence of ACVD ($p = 0.036$) and higher level of LDL-C compared to FH (9.80 vs 6.97 mmol/L, $p = 0.039$).

Conclusion: Monogenetic FH, high PS and high level of Lp(a) can co-exist in patients with FM. High PS and high level of Lp(a) influence the severity of FM.

P07.068.A Novel *LRP1*variant in a patient with idiopathic pulmonary arterial hypertension

Mónica Mora-Gómez[1], *Lucía Miranda-Alcaraz*[1], *Natalia Gallego-Zazo*[1], *Alejandro Cruz-Utrilla*[2], *Nuria Ochoa-Parra*[2], *Alejandro Parra*[1], *Mario Cazalla*[1], *Valeria Vásquez*[1], *Cristina Silván*[1], *Juan A. Jiménez-Estrada*[1], *Manuel Rodríguez-Canó*[1], *Pedro Arias*[1], *Julián Nevado*[1], *Pablo Lapunzina*[3], *Pilar Escribano-Subías*[2], *Jair Tenorio-Castano*[3]

[1]Institute of Medical and Molecular Genetics (INGEMM), Madrid, Spain, [2]Hospital 12 de Octubre, Madrid, Spain, [3]Hospital Universitario La Paz, Madrid, Spain.

Background: Pulmonary arterial hypertension (PAH) is a rare and progressive disease characterized by the remodeling of the pulmonary arterial vasculature. It can cause heart failure and death if untreated. In 2000, the *BMPR2* gene was the first gene related to PAH. Since then, the development of next-generation sequencing has allowed us to identify 27 new genes associated with the disease.

Material and methods: Whole exome sequencing was performed in a patient with idiopathic PAH who had a negative result on the PAH gene panel.

Results: We detected a heterozygous missense variant (c.8185C>T) in the *LRP1* gene. This gene codifies a receptor involved in different pathways, like vascular homeostasis. LRP1 regulates the TGF-β signaling pathway, the most studied one in PAH, by interacting with TGF-β family receptors. According to some studies, LRP1 is overexpressed in lung and smooth muscle cell (SMC) samples from PAH patients. However, there are reports of *LRP1* knockout SMC in mice that spontaneously develop this pathology. It is believed that the elevated protein levels in PAH patients may be due to compensatory mechanisms in response to PAH conditions since this protein is involved in tissue homeostasis.

Conclusion: According to that, we hypothesize that this variant, which affects an interaction domain, could cause a loss of function of LRP1 and consequently upregulate the TGF-β pathway, which leads to typical PAH pathobiological changes. This study adds genetic evidence about the relationship between *LRP1* and PAH development.

P07.069.B A novel *ACTC1* gene mutation in a family with left ventricular noncompaction

Kinga Hadzsiev[1], *Peter Nagy*[2], *Reka Faludi*[3], *Gergely Buki*[1], *Kira Dorogi*[1], *Agnes Till*[1], *Renata Szalai*[1]

[1]University of Pecs Medical School Department of Medical Genetics, Pecs, Hungary, [2]University of Pecs Medical School Department of Paediatrics, Pecs, Hungary, [3]University of Pecs Heart Institute, Pecs, Hungary.

Background: Alpha cardiac actin (ACTC1) is the major protein of cardiac sarcomeric thin filaments and is essential for cardiac muscle contraction. Mutation in the *ACTC1* gene has been associated with left ventricular noncompaction, hypertrophic and dilated cardiomyopathy, and atrial septal defects. These overlapping allelic disorders show high variability in severity.

Material and methods: A four-month-old female patient phenotypically characterized by a not uneventful perinatal period, cardiomegaly, and echocardiography identified left ventricular non-compact cardiomyopathy. Due to severe heart failure, she underwent a heart transplantation at age of 10 months, as a result her condition and psychomotor development are improved. Based on clinical findings a multigene NGS cardiomyopathy panel test was performed.

Results: NGS panel analysis detected a heterozygous c.43G>C (p.Gly15Arg) variant in *ACTC1* gene. The variant was classified with uncertain significance followed by ACMG guideline, so parental carrier testing was carried out. The presence of the variant was confirmed in the DNA sample of the asymptomatic father. As the child's symptoms were consistent with the left ventricular noncompaction and dilated cardiomyopathy phenotypes, and the variant was inherited from the father, father was referred to cardiology examination, which detected marked left ventricular hypertrabeculation.

Conclusion: The implementation of intrafamilial carrier testing allows for the appropriate classification of variants of uncertain pathogenicity. Furthermore, in some cases, with the knowledge of the presence of a mutation detected in an asymptomatic state, which may later manifest as a severe disease, with an early prevention and follow-up can significantly improve the quality of life and lifespan.

P07.070.C A shield against Brugada: the p.His558Arg polymorphism in action

Tugba Afsin Erdogdu[1], *Omer Cagri Akcin*[1], *Kudret Aytemir*[2], *Cem Coteli*[2], *Ceren Damla Durmaz*[1]

[1]Department of Medical Genetics, Faculty of Medicine, Hacettepe University, Ankara, Turkey, [2]Department of Cardiology, Faculty of Medicine, Hacettepe University, Ankara, Turkey.

Background: Brugada syndrome, an autosomal dominant inherited channelopathy, predisposes individuals to arrhythmias and sudden cardiac death. Pathogenic *SCN5A* variants account for 20–30% of Brugada syndrome cases, with reduced penetrance and variable expressivity.

Clinical Report: A 55-year-old female initially referred for evaluation of pheochromocytoma, a malignancy with a 40% association with hereditary cancer syndromes. Clinical exome sequencing identified a pathogenic *SCN5A* variant (c.845G>A; p.Arg282His) along with a potentially protective polymorphism (c.1673A>G; p.His558Arg). While incidental *SCN5A* variant raised concerns about Brugada syndrome, the patient demonstrated no phenotypic or electrocardiographic signs, even under conditions that could provoke arrhythmias, such as electroconvulsive therapy for psychosis and adrenergic stress. Ajmaline provocation testing revealed no diagnostic features of Brugada syndrome. A detailed review of the literature revealed that p.His558Arg can partially compensate for sodium channel dysfunction caused by pathogenic *SCN5A* variants, potentially explaining the patient's asymptomatic presentation.

Discussion: This case highlights three critical considerations: (1) reduced penetrance in genetic channelopathies may be modulated by variant interactions, emphasizing the need to explore compensatory mechanisms; (2) filtering variants based solely on allele frequency may overlook clinically significant protective modifiers; (3) despite the patient's asymptomatic status, the co-inheritance of pathogenic *SCN5A* variants with protective polymorphisms warrants familial genetic screening due to a 50% risk of transmission and the potentially fatal nature of Brugada syndrome.

Conclusion: This case underscores the importance of integrating molecular findings with clinical evaluation and illustrates how personalized medicine approaches can guide risk assessment, therapeutic decisions, and familial screening in inherited cardiac syndromes. **Grants**: None.

P07.072.A *ABCA3* and *NOTCH1* mRNA expressions differ in chronic thromboembolic pulmonary hypertension patients with rare missense variants

Neslihan Coban[1], *Ecem Inci*[1,2], *Aybike Sena Ozuynuk Ertugrul*[1,2], *Berkay Ekici*[3], *Cagri Gulec*[4], *Pinar Koseoglu Buyukkaya*[1,2], *Ajar Kocak*[3]

[1]Department of Genetics, Aziz Sancar Institute for Experimental Medicine, Istanbul University, Istanbul, Turkey, [2]Graduate School of Health Sciences, Istanbul University, Istanbul, Turkey, [3]Department of Cardiology, Faculty of Medicine, Ufuk University, Ankara, Turkey, [4]Istanbul Faculty of Medicine, Department of Medical Genetics, Istanbul University, Istanbul, Turkey.

Background: Pulmonary hypertension (PH) is characterized by elevated blood pressure in the pulmonary arteries, eventually damaging the right heart. Chronic thromboembolic PH (CTEPH) is a rare subtype of PH due to persistent obstructive thrombi with undefined genetic origins. This study aims to analyze the expression levels of the genes in which CTEPH patients have genetic variants.

Material and methods: DNA and RNA samples were isolated from blood samples of 15 CTEPH patients. WES was conducted on the Illumina NovaSeqX instrument using Sureselect V6 kit. A total of 41 PH-related genes were examined. The mRNA expression levels were determined using qRT-PCR and statistically analyzed.

Results: Among 15 CTEPH patients, 4 unique VUS were found in *ABCA3* (1 missense) and *NOTCH1* genes (2 missense, 1 splice site) in 4 patients. A 45% decrease in *ABCA3* expression was observed in the patient with *ABCA3* (NM_001089.3:c.1304G>A) variant, while *NOTCH1* expression was increased by 43% in the patient with *NOTCH1* (NM_017617.5:c.4692T>G) variant compared to others. Moreover, the 6-minute walking distance was shorter for the patients with rare *NOTCH1* variants than other CTEPH patients ($p = 0.009$). Additionally, patients with *NOTCH1* variants had higher New York Heart Association functional classes, indicating more severe heart failure ($p = 0.014$).

Conclusion: The findings suggest that rare *ABCA3* and *NOTCH1* variants alter the mRNA expression levels of the genes. The pathophysiology of CTEPH is rooted in thromboembolic events; however, the genetic alterations governing proliferation within the pulmonary vasculature may predispose individuals to PH and correlate with more severe manifestations of the disease.

P07.073.B Noncompaction cardiomyopathy, sinus node dysfunction and aortic dilatation in family with HCN4 variant

Sivan Koka[1,2], *Ziv Dadon*[3,2,4], *Amiram Nir*[3,2,4], *Michael Glikson*[3,2,4], *Ephrat Levy-Lahad*[1,2,4]

[1]*The Fuld Family Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*The Eisenberg R&D Authority, Shaare Zedek Medical Center, Jerusalem, Israel,* [3]*Jesselson Integrated Heart Center, Shaare Zedek Medical Center, Jerusalem, Israel,* [4]*Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel.*

Background: HCN4 pathogenic variants cause bradycardia and sinus node dysfunction (SND). There is increasing reports of a more complex phenotype, including noncompaction-cardiomyopathy, aortic dilatation (AD), mitral valve defects, early-onset atrial fibrillation (AF), atrioventricular block and ventricular-tachycardia, caused by pathogenic variants in a specific domain of *HCN4*.

Material and methods: We evaluated a 47-year-old woman and her 18-year-old son, both with bradycardia and AD. The woman also has hypertrophic cardiomyopathy (HCM) and AF, suspected for Marfan-like-syndrome without eye/skeletal involvement. Her son also had mitral valve prolapse and left ventricular noncompaction (LVNC). Family history revealed cardiomyopathy, bradycardia, aortic dilatation and HCM.

Results: Multi-gene-exome-based-panel testing revealed a likely pathogenic variant in *HCN4* (c.1456C>T, p.Pro486Ser) in the mother, and excluded *FBN1* and other connective-tissue genes variations as a cause. Her son was found heterozygous for the same variant.

Conclusion: *HCN4* variant, usually associated with SND, was found in a family with a more complex phenotype of LVNC and AD, mitral valve defects and early-onset AF. The p.Pro486Ser is very rare and located just upstream to transmembrane-domain-6, a location characteristic of other variants previously reported to cause this phenotype. This further confirms the existence of a specific *HCN4* region associated with the combined phenotype of sinus bradycardia, LVNC, and thoracic aortic aneurysms. Another variant near this region, A485V, a known Moroccan-Jews founder, was originally reported in 2010 as causing SND. More recently it has been reported to cause AF and LVNC. Based on these reports, we believe that A845V heterozygotes should be screened for AD.

P07.074.A Identification of a clinically relevant *MYBPC3* copy number variation using whole-Gene NGS sequencing

Laura Cazon[1], *Noël Brögger*[1], *Marlene Pérez*[1], *Iria Gómez*[1], *Rosalía Debén*[2], *María Sánchez*[1], *Xusto Fernández*[1], *Diego Cabrera*[1], *Almudena Amor*[1], *María Valverde*[1], *Soledad García*[1,3], *Ivonne Cárdenas*[1], *Martín Ortíz*[1], *Juan Pablo Ochoa*[1,4]

[1]*Health in Code, A Coruña, Spain,* [2]*HEALTH IN CODE, A Coruna, Spain,* [3]*Hospital Universitario San Cecilio, Granada, Spain,* [4]*Centro Nacional de Invertigaciones Cardiovasculares Carlos III, Madrid, Spain.*

Background: Pathogenic variants in *MYBPC3* are a well-established cause of hypertrophic cardiomyopathy (HCM), with loss-of-function variants typically associated with this phenotype. Haploinsufficiency is considered the primary disease mechanism. However, copy number variations (CNVs) in *MYBPC3* are rare and not routinely screened for in clinical settings. Here, we report a novel *MYBPC3* CNV in a 53-year-old male proband with dilated cardiomyopathy (DCM), an atypical presentation for loss-of-function variants in this gene, and a family history of HCM and sudden cardiac death.

Material and methods: The patient's genomic DNA was analyzed using a next-generation sequencing (NGS) panel covering the entire *MYBPC3* gene. CNVs were detected via a read-depth approach and validated by orthogonal molecular techniques (Sanger sequencing).

Results: A novel 17 kb deletion encompassing exons 13–35 and the 3′ UTR of *MYBPC3*, as well as part of the 3′ UTR of *MADD*, was identified. This variant was classified as likely pathogenic (LP) according to ACMG guidelines and ClinGen CNV classification criteria.

Conclusion: This case presents an unexpected phenotype, as DCM is not the typical manifestation of *MYBPC3* loss-of-function variants. The finding highlights the need for further investigation into the phenotypic variability associated with *MYBPC3* CNVs. Additionally, it underscores the importance of comprehensive *MYBPC3* NGS sequencing, including CNV detection, to enhance molecular diagnosis in patients with cardiomyopathies.

P07.075.D Neonatal Marfan syndrome: a spontaneous mutation necessitating cardiac intervention

Elsa Harte[1], *Nitha Naqvi*[2], *Anne Child*[3], *Jose Antonio Aragon-Martin*[1,3,4]

[1]*William Harvey Research Institute, Queen Mary University of London, London, United Kingdom,* [2]*Department of Paediatric Cardiology, Royal Brompton Hospital, London, United Kingdom,* [3]*Department of Surgery & Cancer, Faculty of Medicine, Imperial College, London, United Kingdom,* [4]*Institute of Ophthalmology, University College London, London, United Kingdom.*

Background: Neonatal Marfan syndrome (nMFS) can arise from a spontaneous pathogenic variant in the FBN1 gene. Genotype-phenotype correlations have associated this rare MFS subclass with specific 24–34 exon region (NM_000138.5) pathogenic variants. nMFS is associated with a more severe phenotype than the classical autosomal dominantly inherited Marfan syndrome. Congestive cardiac failure within the first few years of life is the primary cause of mortality in nMFS, with limited research into treatment interventions.

Material and methods: We analysed the genetic phenotypes and efficacy of cardiac treatment interventions in three cases of nMFS

Results: All cases had an FBN1 pathogenic variant between the 25–26 exons (gene transcript ENST00000316623.10)(Table 1). Case 1: At age 12, they were cardiac symptom-free and intervention was limited to an attempted ASD closure. Case 2: underwent mitral and tricuspid valve repair within the first year of life. They subsequently underwent a PEARS procedure at nine years old. At age 14, they were attending school full-time on cardiac pharmacotherapy with recurrent supraventricular tachycardia. Case 3: underwent two major cardiac surgeries. The first was mitral and tricuspid valve repair at two months old, requiring a repeat tricuspid valve repair at 24 months. At age seven, they were attending school full-time with significant skeletal abnormalities and requiring CPAP and BiPAP.

Conclusion: These cases demonstrate that by proactively combining early high-risk cardiac procedures with ongoing cardiovascular pharmacotherapeutics, nMFS patients can be treated to surpass previously reported life expectancies.

Table 1

	Case 1 (exon 25)	Case 2 (exon 26)	Case 3 (exon 26)
FBN1 variant	**c.3032G>T [p.(G1011V)]**	**c.3115T>C [p.(C1039R)]**	**c.3143T>C [p.(I1048T)]**
Cardiovascular Intervention	**At 8 years old:** An unsuccessful attempt at device closure of an atrial septal defect (ASD).	**Within first year of life:** Mitral valve repair (ring annuloplasty) and tricuspid valve repair (de Vega annuloplasty), Patent Foramen Ovale (PFO) left open.**At 9 years old:** Redo sternotomy (second sternotomy), dissection of mediastinal adhesions, aorto bicaval cardiopulmonary bypass, complex mitral valve repair with CE Physio II annuloplasty size 28 mm, personalised external aortic root support (PEARS) procedure to the aortic root and ascending aorta.	**Within first year of life:** Secundum ASD closure, mitral valve repair (chordae shortening and partial annuloplasty), tricuspid valve repair (leaflet repair and partial annuloplasty). Re-do repair of mitral valve followed by mitral valve replacement.**22 months post initial operation:** Prosthesis & Tricuspid valve repair with 6 days of Extracorporeal Membrane Oxygenation post operatively.
Cardiovascular Pharmacotherapy	N/A	atenolol 40 mg twice daily, aspirin 75 mg once daily, digoxin 100 micrograms twice daily, irbesartan 75 mg once daily	bumetanide 0.9 mg three times per day, atenolol 10 mg twice daily, spironolactone 15 mg twice daily, digoxin 70mcg twice daily, irbesartan 90 mg once daily, warfarin, sildenafil 15 mg three times per day
Non-Cardiac Features	**At 12 years:**, hypermobile joints & spine, flat feet, height: >99.6th centile, visual problems, lens dislocation - wearing glasses.	**At 14 years:** severe scoliosis, multiple joint laxity, spinal surgery with extendable rods at 3 years and 8 years of age. lens subluxation, retinal detachment with 2 eye surgeries.	**At 7 years old:** uses a wheelchair, requires continuous positive airway pressure (CPAP) and bilevel positive airway pressure (BiPAP) therapy.

P07.076.A Diagnostic and prognostic value of whole-exome sequencing in heart transplant donors and recipients

Mirgul Bayanova[1], *Aida Zhenissova*[1], *Dias Malik*[1], *Aizhan Abdikadirova*[1], *Malika Sapargalieyva*[1], *Lyazzat Nazarova*[1], *Gulzhan Myrzakhmetova*[1], *Svetlana Novikova*[1], *Aidos Bolatov*[1,2], *Yuriy Pya*[1]

[1]*"University Medical Center" Corporate Fund, Astana, Kazakhstan,* [2]*Shenzhen University, Shenzhen, China.*

Background: Advancements in next-generation sequencing have significantly enhanced our understanding of donor-recipient compatibility, the genetic etiology of end-stage organ failure, the influence of genetic polymorphisms on transplant outcomes, and the pharmacogenetics of immunosuppressive therapies [1]. In Kazakhstan, where heart transplantation (HTx) remains rare, there is limited data on the genetic profiles of donors and recipients [2].

Material and methods: An observational study recruited 32 pairs of donors and recipients of HTx over the past 10 years at the "University Medical Center" Corporate Fund (Astana, Kazakhstan). Whole-exome sequencing (WES) was carried out on the NovaSeq 6000 platform.

Results: Pathogenic and likely pathogenic variants were identified in 9 recipients with dilated cardiomyopathy in the TTN, RBM20, LMNA, and MYH7 genes, and in 2 recipients with hypertrophic cardiomyopathy in the MYH7 and MYH7B genes. Variants of uncertain significance were detected in 17 heart recipients, affecting genes such as TTN, TTNI3, NOTCH1, FLNC, LAMA4, CACNA1C, SYNE2, RBM20, PKP2, MYH6, MYBPC3, ACTN2, and TNNC1. Genomic sequencing of donors revealed one pathogenic variant (KCNE1) and one likely pathogenic variant (RYR1) among two heart recipients. The study identified variations in genes associated with immunosuppressive drug metabolism and transport, including CYP3A4, ABCB1, ABCC2, CYP2C19, CYP2C8, CYP2J2, ABCC8, NOD2, NR1I2, POR, SUMO4, and UGT1A8, among heart recipients.

Conclusion: WES identified significant variants in recipients associated with cardiomyopathies and immunosuppressive drug metabolism, as well as in donors linked to sudden cardiac arrest. The demonstrated utility of sequencing in post-transplant management highlights the need for further validation through longitudinal studies.

P07.077.B Whole exome sequencing as molecular diagnostic tool for congenital heart defects

Valentina Peycheva[1,2], *Kristiyana Vitanova*[1], *Kunka Kamenarova*[1,2], *Kalina Mihova*[1,2], *Darina Kachakova*[1,2], *Martin Georgiev*[1,2], *Olga Slavcheva*[3], *Ivelina Ivanova*[3], *Maria Sredkova-Ruskova*[3], *Anelia Nankova*[4], *Maria Tarneva*[4], *Simeon Shishkov*[5], *Ivanka Dimova*[2,6], *Radka Kaneva*[1,2]

[1]*Medical University of Sofia, Medical Faculty, Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Sofia, Bulgaria,* [2]*Medical University of Sofia, Medical Faculty, Department of Medical Chemistry and Biochemistry, Laboratory of genomic diagnostics, Sofia, Bulgaria,* [3]*Medical University of Sofia, University Paediatrics Hospital, Department of Clinical Genetics, Sofia, Bulgaria,* [4]*Medical University of Sofia, University Endocrinology Hospital "Acad. Ivan Penchev", Sofia, Bulgaria,* [5]*National Cardiology Hospital, Sofia, Bulgaria,* [6]*Medical University of Sofia, Department of Medical Genetics, Sofia, Bulgaria.*

Background: Development of exome based molecular approaches has led to the identification of numerous genes involved in cardiac morphogenesis and have a role in the pathogenesis of congenital heart diseases (CHD). The aim of this study was to identify the genetic causes of either isolated CHD, or cardiovascular defect in the context of syndromic condition.

Material and Methods: Nine Bulgarian patients with non-syndromic or syndromic CHD were referred to our lab. Whole exome sequencing (WES) using NovaSeq 6000 sequencing platform (Illumina) was performed. In non-syndromic cases a CHD gene panel comprising 546 genes was used for the analysis. Confirmation Sanger sequencing of the discovered variants was performed.

Results: In seven patients an overall of 16 variants of interest were detected. Four pathogenic/likely pathogenic variants and 12 variants with unknown significance (VUS), but with potential role in the disease phenotype were found. Nine of them were identified in genes directly associated with the cardiovascular phenotype of the patients - *DTNA, LDB3, MYH6, MYH7, MYH11, NEBL, TBX1, TMEM43, TTN*. Among them, one likely pathogenic variant in *MYH6* gene and one VUS in *MYH11* gene were novel. Two of the detected variants in *MYH7* and *MYH11* genes confirmed the suspected diagnosis in two patients with family history of cardiovascular defect.

Conclusion: WES is powerful diagnostic tool for detection of disease-causing genes in both syndromic and non- syndromic CHD. This helps to improve the individual therapy and prophylactics to reduce the risk of sudden cardiac death in the affected individuals and to elucidate the recurrent family risk.

Background: Dystrophinopathies are a heterogeneous group of X-linked diseases, caused by pathogenic variants in the *DMD* gene, that mainly affect skeletal and cardiac muscle, but can also involve the brain. To date, there are nine reported cases of male affected patients with a pathogenic *DMD* variant's mosaicism. These patients presented with cardiac involvement and asymmetrical muscle weakness. A single case of isolated cardiac involvement, asymptomatic creatine kinase (CK) elevation and limited radiological signs of muscle wasting has been described.

Material and Methods: We here describe a male patient, who came to our attention at 30 years of age. Persistent troponin elevation and chest pain initially suggested myocarditis, however the cardiac MRI revealed heart hypokinesia, slight dilation and significant late enhancement with adipose replacement. Exome sequencing (ES) on a peripheral blood sample was requested due to suspicion of a cardiomyopathy.

Results: ES identified a mosaic pathogenic variant of the *DMD* gene: c.6283C>T, p.(Arg2095Ter), with an allelic fraction of 55%. Our patient did not present any symptoms related to skeletal muscle involvement and his CK levels were slightly above the normal range (204 mU/mL, n.v. 24–190 mU/mL). Neuropsychological evaluation was suggested, due to internalizing traits shown at clinical evaluation and excessive dependance upon his mother, despite his age.

Conclusion: Our case further expands the clinical spectrum associated with *DMD* mosaic variants in males, which can present with dilated cardiomyopathy and bizarre behaviors, hinting to an atypical neurodevelopment, without skeletal muscle involvement or severe hyperCKemia.

Houston Merritt Center for Neuromuscular and Mitochondrial Disorders, Department of Neurology, Columbia University Irving Medical Center, New York, NY, USA.*

Background: Thymidine kinase 2 deficiency (TK2d) is an ultra-rare, autosomal recessive, mitochondrial myopathy. Early age at symptom onset is associated with rapid disease progression. Pyrimidine nucleoside therapy with doxecitine and doxribtimine is in development. We assessed survival, functional outcomes and safety in patients with age of TK2d symptom onset ≤12 years who received pyrimidine nucleos(t)ides.

Material and Methods: Treated patients were pooled from retrospective (NCT03701568, NCT05017818) and prospective (NCT03845712) sources and company-supported expanded access programs (EAPs; functional outcomes not collected). Untreated patients were pooled from literature reviews (2019; updated 2021) and a retrospective chart review (NCT05017818). Survival in 50th-percentile treated and untreated patient

matched-pairs was assessed using proportional hazard and marginal Cox models, and restricted mean survival time analyses. Functional outcomes (developmental motor milestones; ventilatory/feeding support) were compared pre- and post-treatment.

Results: Analyses included 82 treated (median [Q1, Q3] treatment duration: 54.8 [15.2, 78.4] months) and 93 untreated patients with age of symptom onset ≤12 years. Survival and functional outcomes are summarized in tables 1 and 2, respectively. In the safety population (age of symptom onset ≤12 years, n = 50; EAPs excluded), two patients (4.0%) discontinued treatment due to TEAEs; among those with data, diarrhoea was the most common TEAE (33/39 [84.6%]).

Conclusion: In patients with age of TK2d symptom onset ≤12 years, pyrimidine nucleos(t)ide therapy substantially improved survival and was well tolerated; stabilization or improvement in functional outcomes was observed.

Table 1. Survival outcomes for patients with age of TK2d symptom onset ≤12 years

	Untreated patients	Treated patients
Patients who died, n/N (%)	53/93 (57.0)	3/82 (3.7)
Proportional hazard and marginal Cox model estimates of reduced risk of death (compared with untreated patients)		
In the time from symptom onset	-	92–94% (hazard ratio = 0.06–0.08; $p < 0.0001$)
In the time from treatment initiation	-	87–95% (hazard ratio = 0.05–0.13; $p < 0.0001$)
Restricted mean survival time (95% confidence interval), years		
Over 30 years from symptom onset	14.4 (11.1–17.6)	29.2 (28.2–30.3)
Over 6 years from treatment initiation	2.8 (2.2–3.5)	5.8 (5.5–6.0)

Table 2. Functional outcomes in treated patients with age of TK2d symptom onset ≤12 years

		Pre-treatment	Post-treatment
Loss and regain of motor milestones			
Motor milestone loss	At risk, n [n1]	49	46
	Not at risk, n	33	36
	Lost ≥1 milestone, n/n1 (%)	41/49 (83.7)	10/46 (21.7)
	Lost ≥4 milestones, n/n1 (%)	20/49 (40.8)	1/46 (2.2)
Regain of previously lost motor milestones	At risk, n [n2]	41	40
	Not at risk, n	41	42
	Regained ≥1 milestone, n/n2 (%)	2/41 (4.9)	30/40 (75.0)
	Regained ≥4 milestones, n/n2 (%)	0/41 (0)	9/40 (22.5)
Use of ventilatory and feeding support during treatment			
Ventilatory support	Using support at treatment initiation, n [n3]	31	-
	Missing data, n	29	-
	Reduced hours of use post-treatment, n/n3 (%)	-	5/31 (16.1)
	Discontinued support post-treatment, n/n3 (%)	-	5/31 (16.1)
Feeding support	Using support at treatment initiation, n [n4]	19	-
	Missing data, n	30	-
	Discontinued support post-treatment, n/n4 (%)	-	2/19 (10.5)

P08.002.A Integrative transcriptomics in primary mitochondrial myopathies: toward insights for diagnosis and stratification (Award Candidate)

Alessia Nasca[1], *Andrea Legati*[1], *Marco Barresi*[1], *Elisa Moresco*[1], *Rossella Izzo*[1], *Daniele Sala*[1], *Silvia Marchet*[1], *Franco Salerno*[2], *Lorenzo Maggi*[2], *Claudio Fiorini*[3], *Alberto Pietro Pasti*[3], *Santino Blando*[4], *Salvatore Loris Siragusa*[4], *Leonardo Caporali*[3], *Costanza Lamperti*[1], *Daniele Ghezzi*[1,5]

[1]*Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [2]*Neuroimmunology and Neuromuscular Diseases Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [3]*Laboratory of Neurogenetics, IRCCS Institute of Neurological Sciences, Bologna, Italy,* [4]*Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna, Bologna, Italy,* [5]*Department of Pathophysiology and Transplantation (DEPT), University of Milan, Milano, Italy.*

Background: Primary mitochondrial myopathies (PMM) are mitochondrial disorders mainly affecting skeletal muscle but with possible dysfunction of multiple organ systems resulting in highly variable clinical phenotypes and prognoses. PMM arises from genetic defects in mitochondrial DNA (mtDNA) including mtDNA point mutations and large-scale single deletions, or nuclear DNA (nDNA) genes causing multiple mtDNA deletions. This study investigates gene expression and transcriptomics pathways analysis in muscle biopsies from PMM patients to refine genotype-phenotype correlations and uncover molecular mechanisms and potential biomarkers for diagnosis and stratification.

Material and Methods: Muscle biopsies from a total of 100 PMM patients with large-scale mtDNA single deletions (MacroDel), multiple mtDNA deletions (MultiDel), or the m.3243A>G variant (m.3243) were analyzed versus disease-controls (muscles from subjects without any evidence of mtDNA alterations). RNA sequencing (RNA-seq) was performed to identify differentially expressed genes (DEGs) and pathway enrichment.

Results: Preliminary RNA-seq data analysis of the different subgroups with MacroDel, MultiDel, and m.3243A>G each versus controls revealed a significant number of DEGs and altered pathways (e.g. oxidative phosphorylation; cholesterol metabolism; translation; aerobic respiration; thermogenesis···). The study is currently ongoing to expand the analysis to the whole cohort.

Conclusion: Integrated analysis of RNA-seq data from muscle biopsies of well-defined cohorts of PMM patients with known mtDNA defects is expected to provide insights into the molecular mechanisms underlying these conditions. The integration of genetic, transcriptomic and clinical data can be useful to stratify patients, identify potential biomarkers, support personalised therapeutic approaches and contribute to the development of targeted therapeutic strategies.

P08.003.B Accurate quantification of mitochondrial DNA heteroplasmy and copy number at the single cell level with digital PCR (Award Candidate)

Noemi Castelluccio[1], *Andrei Rybouchkin*[1], *Sofie Symoens*[2], *Wim Trypsteen*[2,3], *Paul Coucke*[2], *Björn Menten*[2], *Ward De Spiegelaere*[4,3], *Dominic Stoop*[1], *Björn Heindryckx*[1]

[1]*Ghent-Fertility and Stem Cell Team (G-FaST), Department for Reproductive Medicine, Ghent University Hospital, Ghent, Belgium,* [2]*Center for Medical Genetics Ghent (CMGG), Department of Biomolecular Medicine, Ghent University Hospital, Ghent, Belgium,* [3]*Ghent University Digital PCR Core facility (DIGPCR), Ghent, Belgium,* [4]*Laboratory of Veterinary Morphology, Faculty of Veterinary Medicine, Ghent University, Merelbeke, Belgium.*

Background: Mitochondrial DNA (mtDNA) heteroplasmy and copy number are critical parameters influencing mitochondrial function and disease phenotypes. Current prevention strategies, such as preimplantation genetic testing (PGT) and nuclear transfer (NT), mainly rely on the analysis of single-cell biopsies. However, existing methods often lack the sensitivity for detecting small yet clinically relevant changes. Digital PCR (dPCR) offers a precise alternative with enhanced sensitivity, reproducibility, and reduced noise.

Materials and Methods: We developed a dPCR assay to quantify mtDNA copy number and heteroplasmy in single cells. Using a mouse model carrying the m.5024C>T mutation, we analysed unmanipulated mutant and pronuclear transfer (PNT) embryos across various stages, including oocytes, polar bodies, blastomeres, and trophectoderm (TE) and inner cell mass (ICM) of blastocysts. Validation was performed with synthetic templates of known mutation loads (0.01–50%). DPCR results were compared with next generation sequencing (NGS).

Results: dPCR reliably detected mutation loads as low as 0.1%. Single-cell analysis of cleavage stage embryos revealed no significant differences in heteroplasmy or mtDNA copy number between blastomeres. Strong correlations were found between oocytes and polar bodies; and between ICM and TE of blastocysts. At high mutation levels (50–80%), dPCR and NGS demonstrated strong concordance. However, in PNT embryos with low mutation loads (<4%), dPCR accurately quantified minor alleles (<1%), while NGS produced more false positives. In non-mutant samples, dPCR detected minimal mutant alleles (~0.07%), while NGS reported mutation loads of ~0.6%.

Conclusion: dPCR provides precise mtDNA quantification, outperforming NGS at low mutation levels with superior accuracy and fewer false positives.

P08.004.C Re-evaluation of children with undiagnosed intrahepatic cholestasis identifies novel genetic causes

Amita Moirangthem, *Moinak S. Sarma, Anshu Srivastava, Pooja Motwani*

Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background: Familial intrahepatic cholestasis(FIC) comprise a heterogeneous group of metabolic liver diseases which may be progressive leading to liver failure. More than 15 monogenic causes have been identified as causative. Genes like *PPM1F, WDR83OS, LSR, VPS50, UNC45A, SLC51B* have been reported in only a few patients and disease association is not definite. Despite using broad spectrum genomic test like exome sequencing(ES), approximately 50% remain without a molecular confirmation.

Material and Methods: We selected 11 patients with a clinical diagnosis of FIC without a molecular confirmation despite ES. A reanalysis of the ES data was performed in all followed by repeat ES in 3 of them.

Results: All patients except one had features suggestive of progressive FIC. All had normal GGT levels. Liver biopsy was performed in 5 and showed features consistent with FIC. Reanalysis of prior focussed ES data showed poor coverage of many recently identified genes. Pathogenic variants were detected in *USP53* and *LSR* by repeat ES in 2 patients. Variants in probable novel candidate genes - *PATJ, EPHX2* were also identified. 2 patients with compound heterozygous variants in *PATJ* share a common variant and showed mild cholestasis. A patient with recurrent cholestasis without progressive liver disease was found to harbor a monoallelic pathogenic variant in *SEMA7A*.

Conclusion: Molecular diagnosis still remains elusive in a significant proportion of FIC cases. On re-evaluation we could confirm genetic etiology in 2 of 11 patients and add *PATJ* and *EPHX2* to the expanding list of probable candidate genes.

P08.005.D Expanded newborn screening of phenylketonuria in Ukraine: genetic landscape

Olena Kutsyk[1], *Nataliia Olkhovych*[1,2], *Nataliia Samonenko*[1], *Oksana Barvinska*[1], *Nataliia Mytsyk*[1,2], *Bohdana Leshyk*[1], *Julia Zhyvytsia*[1], *Iryna Hrehul*[1], *Svitlana Kormoz*[1], *Maryna Patsora*[1], *Mariia Haidei*[1], *Tetiana Zhurenko*[1], *Mykola Veropotvelian*[3], *Olena Grechanina*[4], *Volodymyr Olkhovych*[2], *Halyna Makukh*[5], *Natalia Gorovenko*[6,2]

[1]*National Specialized Childrens' Hospital Okhmatdyt, Kyiv, Ukraine,* [2]*National Scientific Centre, Institute of Genetic and Regenerative Medicine, Kyiv, Ukraine,* [3]*Interregional Medical Center Genetics and Prenatal Diagnostics named after P.M. Veropotvelyana, Kryvyi Rih, Ukraine,* [4]*Interregional Specialized Medical and Genetic Center - Center for Rare (Orphan) Diseases, Kharkiv, Ukraine,* [5]*Lviv Perinatal Center, Lviv, Ukraine,* [6]*National University of Health named P.L.Shupika, Kyiv, Ukraine.*

Background: Phenylketonuria (PKU) is the inherited metabolic disease that causes the accumulation of phenylalanine and leads to intellectual disability. This disorder could be effectively diagnosed at an early stage within neonatal screening (NS). In Ukraine NS for PKU started in 2000 and confirmatory testing was presented by RFLP analysis of 9 pathogenic variants in the *PAH* gene. In October 2022, an expanded NS program was started followed by expanding genetic testing for diagnosis confirmation. It allowed the study of the *PAH* gene mutation spectrum in the Ukrainian population.

Material and Methods: DBS, LC-MS/MS, IFA, NGS, Sanger sequencing.

Results: From October 2022 to December 2024, 354 696 newborns from 4 regional screening centers were examined and 76 patients with PKU were confirmed. The incidence of PKU in Ukraine was determined to be 1:4 653 (excluding the occupied territories). A total of 45 distinct rearrangements were detected. In the study two novel variants were found - p.Thr186Lys and chr12:102854685-102877616del. The most common pathogenic variant was p.R408W (61/152, 40,1%). There were 11 patients with the p.R408W in both alleles. Other frequent pathogenic variants were p.A403V (16/152, 10,5%) and p.R158Q (7/152, 4,7%). Most of the rearrangements were found in exons 12 (55,9%), 7 (13,8%) and 11 (7,2%), therefore the analysis of these exons is proposed to be used as the first step of molecular genetic diagnosis of PKU in Ukraine.

Conclusion: Expanding of *PAH* molecular genetic testing allows studying the pathogenic variants spectrum in the Ukrainian population and improves the diagnosis algorithm of PKU.

P08.006.A Background splicing of the *GALNS* gene unveils the hotspots for pathogenic splice-altering variants

Igor Bychkov[1], *Alexandra Ilyushkina*[1], *Nataliya Vytnova*[1], *Aleksei Vasilenko*[1], *Dmitry Munov*[1], *Tatiana Markova, MD*[1], *Natalia Buchinskaia*[2]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Saint-Petersburg State Medical Diagnostic Center, Saint-Petersburg, Russian Federation.*

Background: For 10%–15% of patients with biochemical phenotype of Mucopolysaccharidosis Type IVA (MPS IVA), standard molecular-genetic testing fails to identify one or both causative variants in the GALNS gene. At least part of these variants is located deep in the GALNS introns and leads to pseudoexons (PEs) activation. Also, some of the reported exonic variants may alter GALNS splicing but are misclassified as, for example, missense variants. Information on the background or nonproductive splicing may indicate hotspots for such variants and serve as strong predictor of their outcome.

Material and Methods: The studied variants were collected after bioinformatic analysis of public repositories of the GALNS gene variants - ClinVar, Human Gene Mutation Database and gnomAD. The selected variants were subjected to in vitro splicing analysis using minigene assay in HEK293T cells. Information about background splicing (BS) was obtained with Snaptron analysis of SRA2 data.

Results: We identified eight PE-activating variants in the GALNS gene and demonstrated their clustering within wild-type PEs, which are present in mRNA as part of background splicing. Also, we demonstrate that "weak" canonical exons of the GALNS gene serve as hotspots for splicing variants that exert their deleterious effect by altering splicing regulatory elements, such as splicing enhancers and silencers.

Conclusion: We confirm that wild-type PEs and weak canonical exons of the GALNS gene are hotspots for splice-altering variants and these loci should be closely examined during molecular genetic diagnostics to improve detection of otherwise elusive variants and deepen the understanding of MPS IVA pathogenesis.

P08.008.C Whole-genome DNA methylation profiling and identification of differentially methylated regions in obese children (Award Candidate)

Barbara Slapnik[1,2], *Robert Šket*[1,2], *Klementina Črepinšek*[1,2], *Blaž Vrhovšek*[1,2], *Tine Tesovnik*[1,2], *Barbara Jenko Bizjan*[1,2], *Jernej Kovač*[1,2]

[1]*University Medical Centre Ljubljana, Ljubljana, Slovenia,* [2]*Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.*

Background: Hereditary factors account for 40–70% of BMI variance, underscoring a strong genetic predisposition to obesity. However, the rapid rise in obesity prevalence cannot be fully explained by genetics alone. DNA methylation, an epigenetic mechanism, has been increasingly linked to obesity. Altered methylation patterns have been observed in obesity-associated genes, as well as genes involved in hypoxia and inflammation. We hypothesize that children with obesity exhibit distinct DNA methylation patterns compared to controls without obesity.

Material and Methods: Whole-genome sequencing using Oxford Nanopore technology was performed on whole blood of 10 children with obesity (BMI SDS > 2.0) without known monogenic variants linked to obesity alongside 10 age- and sex-matched controls without obesity. All participants were screened for copy number variations in severe early-onset obesity genes before methylation analysis. Basecalling and methylation calling were conducted with Dorado and Modkit. Differential analysis identified differentially methylated positions and regions, which were subsequently subjected to functional enrichment analysis.

Results: A total of 226,073 significantly differentially methylated positions ($p < 0.01$) were identified, including sites within the promoters of key obesity-related genes such as *POMC*, *ADCY3*, *LDLR*, *LEPR*, and *PCSK9*. Consolidation of DMPs revealed 548 differentially methylated regions. Some of these DMRs were associated with genes involved in pancreatic secretion, protein digestion, and abnormal eating behavior.

Conclusion: Obese children exhibit distinct DNA methylation patterns in genes linked to obesity and related processes. These findings highlight the role of epigenetic modifications in obesity pathogenesis and its comorbidities.

Background: XRN1 has been well characterised as a 5′-3′ exoribonuclease involved in mRNA decay within cytosolic stress granules. Here we report an association of *XRN1* with human disease in a cohort of infants with genetically undiagnosed mitochondrial cardiomyopathy.

Material and Methods: Through Matchmaker Exchange, we collated a cohort of individuals with similar heterozygous de novo variants in *XRN1* identified independently through research and clinical genome sequencing (GS). Functional studies were performed on available patient-derived tissues.

Results: Six individuals from five unrelated families presented similarly with lethal perinatal cardiomyopathy and failure to thrive following an acute viral infection. GS of each individual identified a de novo *XRN1* variant in the poorly conserved C-terminal domain, resulting in near-identical frameshift mutations and premature truncation of the protein's C-terminal tail. Despite having no known role relating to mitochondrial function in mammals, quantitative proteomics conducted on patient skeletal muscle revealed a consistent mitochondrial disease phenotype characterised by a combined abundance defect in oxidative phosphorylation (OXPHOS) complexes. These findings were supported by impaired OXPHOS assembly, assessed by Blue Native PAGE, histochemistry, and reduced respiratory chain enzymatic activity in muscle, heart and liver of affected individuals. RNA-sequencing of patient skeletal muscle additionally measured an increase in mitochondrial genome transcription, indicating a response to mitochondrial stress.

Conclusion: We propose *XRN1* as a candidate gene associated with a novel form of autosomal dominant lethal perinatal mitochondrial cardiomyopathy. Functional studies on patient-derived cells are continuing to provide insights into the precise disease mechanism.

P08.010.A Novel molecular mechanisms and treatment option for *LIG3*-dependent Chronic Intestinal Pseudo-Obstruction

Chiara Diquigiovanni[1], *Nicola Rizzardi*[2], *Erica Cataldi Stagetti*[1], *Arianna Orsini*[1], *Alessandra Maresca*[3], *Anna Costanzini*[4], *Christian Bergamini*[2], *Roberto De Giorgio*[4], *Elena Bonora*[1,5]

[1]*Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy,* [2]*Department of Pharmacy and Biotechnology, University of Bologna, Bologna, Italy,* [3]*Istituto di Ricovero e Cura a Carattere Scientifico, Istituto delle Scienze Neurologiche di Bologna, Programma di Neurogenetica, Bologna, Italy,* [4]*Department of Translational Medicine, University of Ferrara, Ferrara, Italy,* [5]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: Chronic intestinal pseudo-obstruction (CIPO) is characterized by severe and recurrent sub-occlusive episodes mimicking a mechanical obstruction in the absence of any lumen-occluding lesion. We identified a novel recessive syndrome due to DNA ligase 3 (*LIG3*) mutations in patients with CIPO, leukoencephalopathy and neurogenic bladder. *LIG3* mutations affect mitochondrial DNA maintenance, leading to defective energy

production. We aimed at identifying altered molecular pathways and developing possible targeted treatments to revert/ameliorate the syndromic CIPO-related cellular energy impairment.

Material and Methods: Patients and control derived fibroblasts were used for RNA sequencing (RNAseq), immunofluorescence, western blot, live cell growth, ATP, and Ca^{2+} levels assays. Fibroblasts were exposed to L-Glutamine (L-Gln), which was also administered to *LIG3*-CIPO patients. Gastrointestinal (GI) symptoms were measured via Gastrointestinal Symptom Rating Scale.

Results: RNAseq revealed a profound dysregulation in mutant fibroblasts *vs*. controls, with overexpression of genes involved in extracellular matrix development and remodeling and mitochondrial functions. Histopathology of gut biopsies of *LIG3*-mutant patients showed collagen and elastic fiber accumulation. Mutant fibroblasts exhibited impaired mitochondrial bioenergetics and altered Ca^{2+} homeostasis. Supplementation with high concentrations of L-Gln (6 mM) restored growth and ATP levels in *LIG3*-mutant fibroblasts and improved significantly GI and extra-GI symptoms in *LIG3*-mutant patients after 8 months of treatment.

Conclusions: Mitochondrial dysfunction and symptom profile related to *LIG3* deficiency can be rescued by L-Gln supplementation. Our results provide a clinically relevant translational approach paving the way to effective, gene-based treatments for CIPO.

Background: Sengers-syndrome (S.S) is a genetic disorder characterized by congenital cataracts, hypertrophic cardiomyopathy, skeletal myopathy and lactic acidosis. All reported cases were genetically caused by biallelic mutations in the *AGK* gene. We herein report a pathogenic variant in TIMM29 gene, as a novel cause of S.S. Notably, AGK and Tim29 proteins are components of the TIM22 complex, which is responsible for importing carrier proteins into the inner mitochondrial membrane.

Material and Methods: Clinical data of 17 consanguineous patients featuring S.S was obtained. Linkage analysis, and sequencing were used to identify the disease-causing gene. Tissues derived from the study participants and a Drosophila melanogaster model were used to evaluate the effects of TIMM29 variant on S.S.

Results: The patients presented with a severe phenotype of S.S, markedly elevated serum creatine-phosphokinase, combined mitochondrial-respiratory-chain-complexes deficiency, reduced pyruvate-dehydrogenase complex activity, and reduced adenine nucleotide translocator 1 protein.Histopathological studies showed accumulation of abnormal mitochondria. Homozygosity mapping and gene sequencing revealed a biallelic variant in *TIMM29* NM_138358.4:c.514T>C NP_612367.1:p.(Trp172Arg). The knockdown of the *Drosophila TIMM29* orthologous gene (*CG14270*) recapitulated the phenotype and pathology observed in the studied cohort. We expand the clinical phenotype of S.S and provide substantial evidence supporting *TIMM29* as the second causal gene of a severe type of S.S, designated as S.S- *TIMM29*.

Conclusion: The present study uncovers several biochemical differences between the two S.S types, including the hyperCPKemia being almost unique for S.S-TIMM29 cohort, the different frequency of MMRCC and PDHc deficiencies among the two S.S types.

P08.012.C Biallelic Variants in Alkaline Ceramidase 3 Cause Infantile and Early Childhood Onset Neurodegeneration with Progressive Leukodystrophy

R. Kaiyrzhanov, *R. Maroofian, ACER3-related disease Study Consortium;*

Department of Neuromuscular diseases UCL Institute of Neurology Queen Square, London, United Kingdom

Background: Biallelic variants in Alkaline Ceramidase 3 (*ACER3*) have recently been linked to early-onset leukodystrophy in 3 case reports describing 5 families with 7 patents. We describe previously unreported 57 patients from 54 unrelated families with biallelic variants in ACER3 and cumulatively delineate the phenotypic spectrum of *ACER3*-related disease.

Material and Methods: Exome sequencing, extensive data sharing, and GeneMatcher were used to identify the patients reported here. ACER3 enzyme activity, lipidomics in patient fibroblasts, mutagenesis, functional assays, and protein modeling were performed.

Results: The cohort is composed of 64 patients from 59 families including 34 females and 30 males. 45 individuals are currently alive with a mean age of 6.6 ± 4.9 years (range 1.4–18). 19 patients (30%) died between the ages of 3 and 19 years due to the rapidly progressive disease. The disease presents with predominantly infantile-onset (86%), moderate (52%) and rapidly (39%) progressive neurological deficit manifesting with global developmental delay (71%) or developmental regression (98%)/stagnation (83%) commonly resulting in limbs spasticity (93%), limb dystonia (72%) and axial hypotonia (73%) with invariable posterior gradient white matter signal changes and diffuse cerebral volume loss (73%) on neuroimaging. Functional studies reveal significantly reduced ceramide hydrolysis. Mutant analysis identifies functional hot spots, with in vitro assays showing a 2–40% decrease in ceramidase activity. Lipidomic analysis confirms a 50% increase in ceramide and sphingomyelin levels, alongside reduced sphingosine.

Conclusion: Biallelic variants in ACER3 are associated with infantile and childhood-onset neurodegeneration with progressive leukodystrophy.

P08.013.D SGLT1 functional polymorphisms are associated with early postprandial glycemic variability

Gaia Chiara Mannino[1], *Angela Palummo*[1], *Carolina Averta*[1], *Elettra Mancuso*[1], *Giorgio Sesti*[2], *Francesco Andreozzi*[1]

[1]*University Magna Graecia of Catanzaro, Catanzaro, Italy,* [2]*University of Rome Sapienza, Rome, Italy.*

Background: The sodium/glucose co-transporter 1 (SGLT1) is encoded by *SLC5A1* and is primarily responsible for the intestinal uptake of glucose. Homozygous mutations of *SLC5A1* cause glucose/galactose malabsorption (GGM [MIM: 606824]). Subjects with normal glucose levels (normotolerant, NGT) at fasting and 2 hours after a glucose tolerance test (OGTT) but with 1h-OGTT ≥ 155 mg/dL (NGT-1h-high) have a worse cardio-metabolic risk profile compared to those with 1h-OGTT glucose < 155 mg/dl (NGT-1h-low). We investigated whether a haplotype with 3 missense mutations (p.N51S, p.A411T, and p.H615Q) of *SLC5A1* affected early postprandial glucose levels (1h-OGTT), and the functional significance of these variants.

Material and Methods: 800 metabolically well-characterized adult NGT volunteers were genotyped, subjected to a 75g-OGTT and stratified as NGT-1h-high or NGT-1h-low. Site specific mutagenesis was performed to introduce the three variants into a cellular model of human intestinal epithelium (CACO2).

Results: MAFs were higher ($P < 0.05$) in NGT-1h-low (1.515% N51S, 9.139% A411T, 3.926% H615Q) than in NGT-1h-high subjects (0.549%, 1.315%, 1.515%, respectively). Computation of a genetic risk score revealed that rare alleles conferred a dose-dependent lower risk of being classified as NGT-1h-high (OR 0.419, CI95% 0.217–0.810, $P < 0.01$). Glucose uptake was significantly reduced ($p < 0.0001$) in CACO2 expressing mutant SGLT1 (% reduction = ~29% N51S, ~30% A411T, ~33% H615Q). Cells carrying double or triple mutations showed even weaker glucose transport ability compared to wild-type (37–49%, $p < 0.0001$).

Conclusion: These data suggest that heterozygous *SLC5A1* missense variants may contribute to early post-prandial glycemic patterns, and that targeting intestinal glucose uptake might be a feasible strategy for preventing the formation of dysglycemia and long-term cardio-metabolic complications.

P08.015.B Nanopore long-read NGS for the study of structural variants in the mitochondrial genome

Elisa Moresco[1], *Marco Barresi*[1], *Rossella Izzo*[2], *Claudio Fiorini*[3], *Francesco Casadei*[3], *Luca Morandi*[3,4], *Alessia Nasca*[1], *Nadia Zanetti*[1], *Eleonora Lamantea*[1], *Costanza Lamperti*[1], *Leonardo Caporali*[3], *Daniele Ghezzi*[1,2], *Andrea Legati*[1]

[1]*Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [2]*Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy,* [3]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Program of Neurogenetics, Bologna, Italy,* [4]*Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna, Bologna, Italy.*

Background: Mitochondrial DNA (mtDNA) point mutations and large deletions or duplications are linked to neuromuscular and neurodegenerative diseases, cancer, and diabetes. While short-read next-generation sequencing (NGS) is the gold standard for mtDNA analysis, it is limited in detecting structural variants (i.e. large-scale deletions, duplications, and complex rearrangements). To overcome this limitation, we evaluated Nanopore long-read NGS.

Material and Methods: Whole DNA samples isolated from muscle biopsy of patients diagnosed for carrying single large (N = 30) and multiple mtDNA deletions (N = 30) were analyzed. DNA samples were processed according to Nanopore Rapid Sequencing Kit, a PCR free protocol, and sequenced on MinION/PromethION device. Reads were aligned to rCRS mtDNA sequence, using minimap2 and ngmlr; structural variants were called using Sniffle tool, combined with an in house pipeline.

Results: Nanopore long-read NGS analysis allowed us to easily detect single large deletion breakpoints and calculate deletion heteroplasmy. Long-read allowed to better characterize and quantify alterations of mtDNA molecules in samples affected by multiple deletions. Through an in house pipeline, we also identified long-reads with sequences compatible with complex mtDNA rearrangements, not detectable through the use of standard approaches or short-read NGS.

Conclusion: Since NGS has become the method of choice for genetic studies including the analysis of mtDNA, we think it is extremely important that geneticists and researchers are aware of the multiple NGS approaches available, including those based on long-reads, which can allow to overcome some limitations of standard short-read NGS.

P08.016.C Genetic correction of metabolic diseases in patient cellsand mouse models

Timo Keskinen[1], *Sami Jalil*[1], *Suvi Tikkakoski*[1], *Jonna Saarimäki*[1], *Diego Balboa*[1], *Mervi Hyvönen*[2], ***Kirmo Wartiovaara***[2]

[1]*University of Helsinki, Helsinki, Finland,* [2]*Helsinki University Hospital, Helsinki, Finland.*

Background: Inherited metabolic diseases can be treated by correcting the underlying genetic change in a target tissue. Many disease genes are active in the liver and editable with viruses, lipid nanoparticles or enveloped delivery vehicles. The argininosuccinatic aciduria (ASLD), methylmalonic acidemia (MMA), primary hyperoxalouria (HP1), and propionic acidduria (PA) are all potentially life-threatening recessive liver diseases which cause metabolic symptoms and can be envisioned to be treated with genetic correction.

Material and Methods: We created induced pluripotent cells (iPSCs) of patients with genetic metabolic diseases and CRISPR-Cas9 single nucleotide editing tools to target the specific genetic alterations, some of which represent founder mutations in the Finnish population. The corrections were made using different delivery vehicles, enabling the comparison of the efficacy, and the cellular phenotypes measured with biochemical methods and/or imaging. Lastly, we created a mouse model of the ASLD Finnish founder mutation and tested the different delivery strategies of in vivo correction.

Results: We describe the successful correction of four metabolic gene alterations with different genome editing tools and delivery systems in the patient iPSCs. We also show the improved cell phenotype as a result of the correction. The in vivo data shows high gene editing in the mouse liver tissue, and the phenotype analyses are ongoing.

Conclusion: Our results show that genetic alterations can be corrected in vitro in patient cells and in vivo in mouse liver. This

supports the development of disease correction therapeutic interventions in metabolic diseases of the liver.

P08.017.D Transcriptomics on yeast models to deepen the knowledge of mitochondrial disease-associated pathways

Rossella Izzo[1,2], *Martina Magistrati*[3], *Alexandru I. Gilea*[3], *Nicole Giandebiaggi*[3], *Marco Barresi*[1], *Elisa Moresco*[1], *Marta Lualdi*[4], *Tiziana Alberio*[4], *Dario Brunetti*[1,5], *Cristina Dallabona*[3], *Andrea Legati*[1], *Daniele Ghezzi*[1,2]

[1]*Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico "Carlo Besta", Milan, Italy,* [2]*Department of Pathophysiology and Transplantation (DEPT), University of Milan, Milan, Italy,* [3]*Department of Chemistry, Life Sciences and Environmental Sustainability, University of Parma, Parma, Italy,* [4]*Department of Science and high Technology, University of Insubria, Varese, Italy,* [5]*Department of Clinical Sciences and Community Health (DISSCO), University of Milan, Milan, Italy.*

Background: Primary mitochondrial disorders and different forms of neurodegeneration can be associated with mitochondrial dysfunction. Most mitochondrial proteins are encoded by nuclear genes, imported into the organelle thanks to the mitochondrial targeting sequence, cleaved by specific peptidases (e.g. PITRM1) and released into the mitochondrial matrix. Biallelic *PITRM1* variants have been identified in patients with complex mitochondrial disorders (MD) whereas single heterozygous variants with Alzheimer disease (AD). Yeast models show an easy-detectable phenotype in mitochondrial defects, so we apply a hypothesis-free approach based on whole transcriptomics to identify new impaired cellular or mitochondrial pathways to improve our knowledge on the pathomechanisms.

Material and Methods: We focused our studies on CYM1 and STE23, encoding mitochondrial peptidases (respectively PITRM1 and IDE human orthologues). We performed RNAseq on single and double knock-out yeast models and on strains harbouring the corresponding MD or AD human PITRM1 variants. Transcriptomics data were used to identify differentially expressed genes (by DESeq2) and to detect dysregulated pathways (using GSEA package). Mitochondrial metabolism assays, functional and proteomics analyses were also performed.

Results: The most up-regulated genes in the mutant strains were implicated in the regulation of proteolysis, while in the KO-strain in the metabolism of NADP. In AD-group, down-regulated genes were involved in membrane biosynthetic processes, while in MD-group in helicase activity. Some of these findings correlated with functional and proteomic data.

Conclusion: Transcriptomics on yeast models can increase knowledge about the molecular pathogenesis in mitochondrial diseases and identify impaired pathways, which can represent novel therapeutic targets.

P08.018.A Exploring heteroplasmic variants in mtDNA: insights from single-cell transcriptomics

Marco Barresi[1], *Ivano Di Meo*[1], *Alessia Nasca*[1], *Eleonora Lamantea*[1], *Andrea Legati*[1], *Daniele Ghezzi*[1,2]

[1]*Unit of Medical Genetics and Neurogenetics, Foundation IRCCS Neurological Institute Carlo Besta, Milan, Italy,* [2]*Department of Pathophysiology and Transplantation (DEPT), University of Milan, Milan, Italy.*

Background: The study of mitochondrial heteroplasmy, defined by the coexistence of wild-type and mutant variants of mitochondrial DNA (mtDNA), is crucial for understanding biological processes and pathologies associated with mtDNA. Bulk RNA sequencing has long been established as the primary method for profiling mtDNA mutations and assessing their effect on trascriptomics; however, this approach doesn't account for the considerable variability in heteroplasmy among individual cells, where thousands of different mtDNA molecules exist. Our aim was to study the distribution of mtDNA variants in scRNA-seq data and their link with global gene expression.

Material and Methods: Four fibroblast cell lines from patients with different heteroplasmic mtDNA variants (m.11777C>A, m.13513G>A, m.13514A>G, m.13063G>A) were analyzed. Based on a 10x Genomics protocol, a data analysis workflow was implemented utilizing integrated bioinformatics pipelines: Cell Ranger, Mitotrace, Seurat, and DEsingle within Linux-based and R environments. Input data included BAM files, rds files containing read count matrices, and reference genomic sequences in GRCh38.fasta format.

Results: The mean heteroplasmy at RNA level was comparable to that identified in DNA. All samples showed a bimodal distribution with most of the cells close to homoplasmic wild-type or homoplasmic mutant status. The comparison of these two extreme subpopulations showed some differences in gene expression, used for pathways enrichment analysis.

Conclusion: We evaluated a novel approach for identifying the distribution of mtDNA variants in scRNA-seq data. This has allowed a detailed examination of how mutant heteroplasmy status influences gene expression differences, giving exciting prospects for investigating mtDNA heteroplasmy across various clinical contexts.

P08.019.B Insights into the pathophysiology of *POLG2* mutations leading to early onset mtDNA deletion and depletion syndrome

Caterina Giovine[1], *Ilaria Cestonaro*[1], *Raquel Brañas Casas*[2], *Elisa Baschiera*[1], *Nicola Facchinello*[2], *Leonardo Salviati*[1], *Natascia Tiso*[2], *Mara Doimo*[1]

[1]*Istituto di Ricerca Pediatrica, Padova, Italy,* [2]*Università degli studi di Padova, Padova, Italy.*

Background: Several mitochondrial disorders are characterized by depletion of mitochondrial DNA (mtDNA) and accumulation of multiple mtDNA deletions due to mutations in genes involved in mtDNA maintenance (mtDNA maintenance defects -MDMDs). Mutations in POLγ, the mtDNA replicative polymerase, represent the major cause of mtDNA instability resulting into MDMDs. POLγ is a trimeric complex constituted by one major replicative subunit, POLG1, and two smaller accessory subunits, POLG2. One of the proposed roles of POLG2 is the preservation of the integrity of the POLγ holoenzyme. We recently identified a homozygous mutation in the POLG2 gene in a patient affected by early onset acute liver failure.

Material and Methods: We established a primary fibroblast culture from the patient's skin biopsy and characterized its biochemical and molecular profile using Seahorse analysis, real-

time PCR and western blot analysis. In parallel, we are generating a zebrafish knock-in (KI) polg2 mutant line harboring the patient's mutation to study its effect in vivo.

Results: Our preliminary results showed that the analysed mutation impairs mitochondrial respiration and cause mtDNA depletion and a change in the levels of different mitochondrial proteins involved in mitochondrial replication.

Conclusion: Our data show the impact of mutation on POLG2 gene on the process of mtDNA maintenance and replication. The developed models will be instrumental to test the effect of specific molecules targeting the stability of POLγ holoenzyme.

P08.023.B Severe neonatal hypotonia caused by *SLC30A5* variant affecting function of ZnT5 zinc transporter

*V. Dolgin[1,2], P. Chabosseau[3], J. Bistritzer[4], I. Noyman[4], O. Staretz-Chacham[5,6], O. Wormser[1], N. Hadar[1], M. Eskin-Schwartz[1,2], B. Kanengisser-Pines[2], G. Narkis[2], R. Abramsky[5,2], E. Shany[5], G. A. Rutter[3,7,8], K. Marks[5], **O. Birk**[1,2,9];*

[1]The Morris Kahn Laboratory of Human Genetics, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, [2]Soroka Medical Center, Genetics Institute, Beer Sheva, Israel, [3]CRCHUM and Department of Medicine, Université de Montréal, Montréal, QC, Canada, [4]Pediatric Neurology Unit, Division of Pediatrics, Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, [5]Department of Neonatology, Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, [6]Metabolic Clinic, Division of Pediatrics, Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, [7]LKC School of Medicine, Nanyang Technological College, Singapore, Singapore, [8]Department of Diabetes, Endocrinology and Medicine, Faculty of Medicine, Imperial College, London, United Kingdom, [9]The Danek Gertner Institute of Human Genetics, Sheba Medical Center, Tel-Hashomer, Israel

Background: The tightly-regulated spatial and temporal distribution of zinc ion concentrations within cellular compartments is controlled by two groups of Zn^{2+} transporters: the 14-member ZIP/SLC39 family, facilitating Zn^{2+} influx into the cytoplasm from the extracellular space or intracellular organelles; and the 10-member ZnT/SLC30 family, mobilizing Zn^{2+} in the opposite direction. Genetic aberrations in most zinc transporters cause human syndromes. Previous studies demonstrated osteopenia and male-specific cardiac death in mice lacking the ZnT5/*SLC30A5* zinc transporter, and suggested association of two homozygous frameshift *SLC30A5* variants with perinatal mortality in humans, due to hydrops fetalis and hypertrophic cardiomyopathy.

Material, Methods and Results: We studied the molecular basis of a novel severe hypotonia syndrome. Homozygosity mapping combined with exome sequencing studies of consanguineous Bedouin kindred, as well as transfection experiments and zinc monitoring in HEK293 cells, demonstrated that a bi-allelic in-frame 3 bp deletion variant in *SLC30A5*, deleting isoleucine within the highly conserved cation efflux domain of the encoded ZnT5, results in lower cytosolic zinc concentrations, causing a syndrome of severe non-progressive neonatal axial and limb hypotonia with high-arched palate and respiratory failure. There was no evidence of hydrops fetalis, cardiomyopathy or multi-organ involvement. Affected infants required nasogastric tube or gastrostomy feeding, suffered from various degrees of respiratory compromise and failure to thrive, and died in infancy.

Conclusion: A biallelic SLC30A5 (ZnT5) variant, affecting cytosolic zinc concentrations, causes a severe hypotonia syndrome with respiratory insufficiency and failure to thrive, lethal by 1 year of age.

P08.024.C Expanding the genetic and clinical spectrum of LBSL: characterization of a Russian cohort of 206 patients

***Ekaterina Zakharova**[1], Svetlana Mikhaylova[2], Elena Saifullina[3], Elena Larshina[1], Ilya Nagornov[1], Alexandra Ilyushkina[1], Maria Sumina[4], Fatima Bostanova[1], Igor Bychkov[1]*

[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Ministry of Health of the Russian Federation Research and Clinical Institute for Pediatrics of the Pirogov, Moscow, Russian Federation, [3]Bashkir State Medical University, Ufa, Russian Federation, [4]"Clinical and Diagnostic Center "Mother's and Child Health Protection", Ekaterinburg, Russian Federation.

Background: Leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL) is a rare inherited disorder caused by biallelic pathogenic variants in the DARS2 gene. The vast majority of patients harbor a common variant c.228-21_228-20delinsC in a compound heterozygous state, which reduces exome sequencing yield and obscures genotype-phenotype correlations for LBSL. Several large deletions have also been reported, further complicating the disease investigation.

Material and Methods: The diagnosis was confirmed by genealogical analysis, clinical presentation, brain MRI, and Sanger sequencing of DARS2 exons. Whole-genome sequencing was performed for one patient.

Results: We investigated 206 patients (aged 6 months-53 years) diagnosed over 15 years. Three forms were identified based on age of onset: early (0–4 years, 49%), childhood (5–14 years, 35%), and late (≥15 years, 16%). The most common symptoms were cerebellar ataxia and axonal neuropathy. The first symptoms included gait disturbances, leg weakness, and, rarely, seizures or tremors. In most cases (77% of 127 patients), the disease manifested in asymptomatic individuals, while in 10% cases it was associated with a traumatic brain injury and in 10% with viral infections, highlighting their potential role as triggers. Genetic analysis identified 27 unique DARS2 variants, including 13 novel. A large deletion spanning exons 16–17 in four patients, may represent a distinctive feature of the Russian population. Additionally, we describe a unique case of two patients with the common variant c.228-21_228-20delinsC in the homozygous state.

Conclusion: Our findings broaden the LBSL clinical and genetic landscape by reporting new pathogenic variants.

P08.025.D Spatial transcriptomics reveals altered *TMSB4X* expression in Fabry disease

***Árpád Ferenc Kovács**[1,2], Sándor Dávid Kovács[1], Luca Kamilla Li[1], Júlia Krisztina Erhardt[1], Karolina Schnabel[3], Lajos Hegyi[2], Nóra*

Fekete[4], Attila Fintha[2], László Kőhidai[4], Péter Reismann[3], Éva Pállinger[4], Hajnalka Vágó[1], Csaba Bödör[2]

[1]Heart and Vascular Center Semmelweis University, Budapest, Hungary, [2]Department of Pathology and Experimental Cancer Research Semmelweis University, Budapest, Hungary, [3]Department of Internal Medicine and Oncology Semmelweis University, Budapest, Hungary, [4]Department of Genetics, Cell- and Immunobiology Semmelweis University, Budapest, Hungary.

Background: Fabry disease is the most common lysosomal storage disorder, characterized by hypertrophic cardiomyopathy and subclinical chronic inflammation. In a subset of patients, significant organ damages accompanied by systemic inflammation can be observed. We hypothesized that the exacerbation of the chronic inflammatory condition may significantly contribute to the development of acute organ dysfunction. Our aim was to immunologically characterise the explanted heart of a Fabry disease patient with cardiomyopathy undergoing heart transplantation, and circulating T lymphocytes of Fabry patients using spatial and single cell transcriptomics.

Material and Methods: 10x-based spatial transcriptomics of explanted heart and further single cells transcriptomics analysis of negatively FACS sorted circulating T lymphocytes of Fabry patients (N = 7) and age-matched controls (N = 8) was performed using the 5' gene expression kit (10 000 cells/patient). Quality control, clustering and gene expression analysis was performed in Scanpy v.1.10.

Results: Spatial transcriptomics reveals an abundant NPPA expression within the inner endothelial lining could be observed. Within striking distance cardiac resident CD163+ macrophages in explanted heart tissue show a higher TMSB4X expression compared to cardiomyocytes or cardiac patrolling monocytes. We have also identified a modified TMSB4X expression pattern in circulating T cells of Fabry patients.

Conclusion: Our preliminary data suggests that NPPA together with TMSB4X may play a significant role in overturning equipoise towards organ dysfunction.

Background: Several genes involved in sphingolipid metabolism have been implicated in lipid storage disorders. Sphingolipids are critical for the composition of cell membranes, in particular facilitating vesicle trafficking. *SGMS1*, encoding sphingomyelin synthase 1 (SMS1), which catalyzes the reaction from ceramide to sphingomyelin, has not yet been linked to a Mendelian disease, except for our oral presentation at last year's ESHG conference.

Material and Methods: Using CRISPR-Cas9 and base editing, three different *SGMS1* missense variants were introduced into HeLa cells. Furthermore, we generated *SGMS1* knockout cells. We subsequently investigated the phenotype of the cell lines using quantitative RT-PCR, immunofluorescence and lipidomics.

Results: We present the clinical data of now five individuals from three unrelated families harboring biallelic *SGMS1* missense variants. All affected individuals presented with a neurodevelopmental delay phenotype. The three missense variants were confirmed to result in SMS1 deficiency. Additionally, abnormal morphology of the Golgi apparatus was detected in immunofluorescence staining for all variants. The most aberrant morphology was observed in the *SGMS1* knockout cell line indicating disrupted intracellular trafficking processes as a result of the loss-of-function of SMS1 protein.

Conclusion: We further delineate the clinical and molecular spectrum of affected individuals with SMS1 enzyme deficiency. Our data strengthen the assumption that biallelic SGMS1 variants are causative for a so far unpublished hereditary metabolic disorder.

P08.027.B Alteration of 3-D chromatin structure as a novel mechanism involved in inherited metabolic diseases

*Alejandro Soriano-Sexto[1], **Obdulia Sánchez-Lijarcio**[1], Leonardo Beccari[2], Natalia Castejón-Fernández[1], Juan Ramón Tejedor[3], Magdalena Ugarte[1], Pilar Rodríguez-Pombo[1], Mario F. Fraga[3], Belén Pérez[1]*

[1]Centro de Diagnóstico de Enfermedades Moleculares, Centro de Biología Molecular Severo Ochoa, CIBERER, IdiPAZ. Universidad Autónoma de Madrid, Madrid, Spain, [2]Centro de Biología Molecular Severo Ochoa, CIBERER, Madrid, Spain, [3]CINN, ISPA, FINBA, IUOPA, CIBERER, Oviedo, Spain.

Background: The application of different omics technologies beyond the exome can solve the most elusive cases with inherited metabolic diseases (IMD), reducing the diagnostic gap.

Material and Methods: Transcriptomic studies were performed in combination with targeted long-read sequencing (T-LRS) using nanopore technology (MinION sequencer), as well as Circular Chromosome Conformation Capture (4C) studies to determine the cause of two patients' pathology. These studies were performed in DNA and RNA extracted from patients' fibroblasts.

Results: We have selected two patients with clinical and biochemical diagnosis of two different IMD: maple syrup urine disease and GLUT1 deficiency syndrome. The transcriptomic analysis revealed reduced mRNA levels of *DBT* and *SLC2A1*, respectively. The T-LRS results allowed us to identify a hypermethylation defect in *DBT* promoter and the insertion of a transposable element (LINE_L1) of 2.5 Kb in the 3' UTR region of *SLC2A1*. Methylation analysis (850k arrays) showed a specific methylation defect in the *DBT* promoter, as well as a pathology-specific epigenetic signature. No genomic variants have been detected in this case yet. 4C analysis, performed using the promoter of each gene as a viewpoint, revealed a loss of interactions between *DBT* and transcriptionally active genes in the first patient. In the second case, a loss of interactions between the *SLC2A1* promoter and its enhancer was observed, likely caused by the LINE insertion.

Conclusion: These findings broaden the mutational spectrum to include new non-standard variants, highlighting the importance of using different technologies to resolve all cases and defining the molecular and epigenetic mechanisms underlying IMD.

P08.028.C Correlation of heteroplasmy variation between mother and child and maternal age at conception in two mitochondrial diseases

Andrea Pietra[1,2], *Alessandro Vaisfeld*[3,4], *Chiara La Morgia*[1,2], *Leonardo Caporali*[1], *Claudio Fiorini*[1], *Flavia Palombo*[1], *Eleonora Pizzi*[1,2], *Alberto Pietro Pasti*[1], *Martina Romagnoli*[1], *Valerio Carelli*[1,2]

[1]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Programma di Neurogenetica, Bologna, Italy,* [2]*Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy,* [3]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [4]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy.*

Background: MtDNA is present in many copies in cells and different variants may coexist leading to the condition of "heteroplasmy" or "polyplasmy". Deleterious mtDNA variants need to cross a threshold of heteroplasmic load before developing clinical symptoms. During oogenesis, mtDNA undergoes a reduction of copy number, named "genetic bottleneck", that can shift drastically the heteroplasmic loads of mtDNA variants from mother to child. It is still investigated how selection against certain mtDNA variants may occur, purifying from pathogenic variants the pool of mtDNAs along the germline. In this study, we analyzed the relationship between the age at conception and the change in heteroplasmy from mother to child in two mitochondrial diseases.

Materials and methods: We considered 117 heteroplasmic carriers of the variants m.3243A>G or m.3460G>A responsible for MELAS and LHON syndromes, respectively. Heteroplasmy degree was determined in blood cells with the SNaPshot approach. We correlated the difference of heteroplasmy between mother and child and the maternal age at conception.

Results: We observed a consistent trend towards the reduction of mutant mtDNA in child compared to mother's heteroplasmy as maternal age at conception increased, for both m.3243A>G and m.3460G>A variants. This selection was more evident after 30 years of maternal age at conception, whereas it was not apparently influenced by maternal heteroplasmy.

Conclusions: This study suggests that there is a correlation between variation of heteroplasmy between mother and child and maternal age at conception. At our knowledge, this is the first evidence in human of a phenomenon recently described in a mouse model.

P08.029.D Investigation of secondary lipids associated with inflammation in Neu1 deficient mice

Ebru Ada, *Volkan Seyrantepe*

Izmir Institute of Technology, Izmir, Turkey.

Background: Lysosomal Neuraminidase 1 (Neu1) is responsible for sialic acid removal from glycoproteins and sialoglycoconjugates. Neu1 mRNA was highly expressed in humans' pancreas, kidney, and liver but low in brain. Mutations in *NEU1* cause a rare lysosomal storage disorder, sialidosis. In previous studies, marked increase was shown in of GM3, GD3, GM4, and LM1 ganglioside levels in spleen, liver, and kidney of sialidosis patients. In mice, Neu1 expression is shown in highest levels in kidney and pancreas tissues, and less expression in brain, liver, and spleen. *Neu1-/-* mice model mimics Type II (severe form) of sialidosis with visceromegaly and severe kidney defects caused by vacuolization in glomeruli regions. In this study, we aimed to explore altered secondary lipid metabolism associated with inflammation in mice models of sialidosis.

Material and Methods: Shotgun lipidome and RT-PCR analysis were used to determine the levels of secondary lipids and inflammation-related gene expression in kidneys of 2- and 5-month-old *Neu1-/-* mice.

Results: We detected a remarkable decrease in secondary lipids of PA, PC, PE, and PI phospholipids, sphingomyelin, and cholesterol esters in both age groups. Besides our data showed significantly increased levels of pro-inflammatory cytokines, including Ccl2, Ccl3, Ccl4, and Ccl5, and anti-inflammatory cytokines Ccl1, Ccl7, Ccl19, Il-11, Il-4, Il-10, Il23a, and Il-12 in the 2- and 5-month-old kidneys of *Neu1-/-* mouse models.

Conclusion: Our results indicate that secondary lipid alteration is associated with inflammation in *Neu1-/-* mice, offering a novel, comprehensive insight into pathophysiological aspects that may guide preclinical researchers in future research.

P08.030.A Mutational spectrum of hypophosphatasia in Russian patients and investigation of ALPL gene splicing

Dmitrii Munov[1], *Polina Geletskaia*[1], *Tatiana Nagornova*[1], *Janna Belaya*[2], *Natalia Kalinchenko*[2], *Nato Vashakmadze*[3], *Alisa Vitebskaya*[4], *Sergey Moiseev*[4], *Oleg Glotov*[5], *Elena Merkuryeva*[1], *Ekaterina Zakharova*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Endocrinology Research Center, Moscow, Russian Federation,* [3]*Research Center for Children's Health, Moscow, Russian Federation,* [4]*First Moscow State Medical University, Moscow, Russian Federation,* [5]*Research Institute of Obstetrics, Gynecology and Reproductology, Saint-Petersburg, Russian Federation.*

Background: Hypophosphatasia (HPP) is a rare inherited disorder associated with pathogenic variants in the *ALPL* gene, leading to reduced activity of tissue-nonspecific alkaline phosphatase (TNSALP). Main symptoms include impaired mineralization of bones and teeth, respiratory issues, seizures, muscle weakness, and bone pain. According to public mutation databases, pathogenic splicing variants in *ALPL* comprise about 6% which is lower than commonly expected (15%), indicating the need for deeper investigation of *ALPL* splicing.

Material and Methods: We present molecular genetic data of 82 patients with confirmed HPP diagnosis referred to our Centre during 2014–2024. Genotyping was performed using Sanger sequencing. To assess the impact of variants on splicing, we used minigene assay and HEK293T cells.

Results: In our patient's cohort, we identified 58 variants: missense (44, 76%), nonsense (1, 2%), synonymous (1, 2%), frameshift (4, 7%), in-frame deletions (3, 5%), in-frame insertion (1, 2%), and splicing variants (4, 7%). This distribution correlates well with data from the global *ALPL* mutation database (alplmutationdatabase.jku.at). To improve the classification of *ALPL* variants, using bioinformatical approaches we analyzed patient's variants and additional variants from public mutation databases and selected 228 that were predicted to affect splicing. The minigene system comprising all exons of the *ALPL* gene, demonstrated good recognition of exons and was validated with previously characterized splicing variants.

Conclusion: The *ALPL* variant spectrum in Russian patients correlates with global data. The developed minigene system is a reliable tool for functional analysis of splicing-affecting variants, advancing understanding of *ALPL* splicing in HPP.

P08.031.B Genetic and Dietary Influences on Total Cholesterol Levels: APOE Gene-Diet Interactions in a Korean Population

Myeong Seog Woo, *Sang Hun Lee, Young Gwang Kim, Seo Gyun Jeong*

Dankook University, Yong in, Korea, Republic of.

Background: Dyslipidemia, a prevalent metabolic disorder affecting approximately 40% of the Korean population, is influenced by both genetic predisposition and dietary intake. This study focused on the apolipoprotein E (APOE) gene to examine its role in modulating total cholesterol levels under varying dietary conditions.

Material and Methods: We conducted a genome-wide association study (GWAS) using 2,426 individuals from the Korean Genome and Epidemiology Study (KoGES), excluding participants with missing or extreme values. Two significant single nucleotide polymorphisms (SNPs) in APOE, rs429358 ($P = 0.0058$) and rs7412 ($P = 5.9 \times 10^{-9}$), were associated with total cholesterol levels. To investigate gene-diet interactions, we analyzed caloric intake, minerals, and vitamins.

Results: Among six minerals and eight vitamins evaluated, most minerals demonstrated consistent effects on cholesterol. An "inverted U relationship" emerged for carbohydrates, proteins, and fats, prompting their exclusion from further interaction analyses. The most notable modification was observed for vitamin B1 in individuals carrying rs7412 ($\beta = -17.052$). Additionally, calcium ($\beta = -4.68285$, $P = 0.02$) and vitamin A1 (retinol) ($\beta = -4.04966$, $P = 0.03$) showed significant interactions with rs7412, suggesting that increased intake of these nutrients may lower total cholesterol among carriers of this APOE variant.

Conclusion: These findings emphasize the importance of APOE-diet interactions in cholesterol regulation and suggest potential benefits from personalized nutritional interventions. Further studies with larger, controlled dietary cohorts are warranted to confirm these associations, and future research should also address potential ethnic differences in gene-diet interactions.

P08.032.C Unravelling phenylalanine-induced neuronal dysfunction: transcriptome analysis of NT2-derived neurons highlights neurite impairment and synaptic connectivity

Sara Stankovic[1], *Andrijana Lazic*[1], *Marina Parezanovic*[1], *Marina Andjelkovic*[1], *Milena Ugrin*[1], *Milena Stevanovic*[1,2,3], *Sonja Pavlovic*[1], *Maja Stojiljkovic*[1], *Kristel Klaassen*[1]

[1]*Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia,* [2]*Institute of Physiology and Biochemistry "Ivan Djaja", Faculty of Biology, University of Belgrade, Belgrade, Serbia,* [3]*Serbian Academy of Sciences and Arts, Belgrade, Serbia.*

Background: Phenylketonuria (PKU) is the most common inherited disorder of amino acid metabolism, characterized by elevated phenylalanine (Phe) levels in the blood and brain, leading to cognitive impairment if untreated. However, Phe-mediated brain dysfunction is not fully understood. Here, we investigated gene expression alterations due to excessive Phe exposure in human neuronal model, providing additional molecular insights into PKU pathophysiology.

Material and Methods: NT2/D1 cells were differentiated in culture using retinoic acid for four weeks. Resulting NT2-derived neurons (NT2/N) were treated with varying concentrations of Phe (1.25, 2.5, 5, 10 and 30 mM) for seven days and subjected to whole-mRNA short-read sequencing. Differentially expressed genes (DEGs) were identified, followed by overrepresentation and enrichment analysis. To validate differential expression, qRT-PCR was performed.

Results: After treatment with three different Phe concentrations (2.5 mM, 5 mM, and 10 mM), DEGs highlighted *CDC42BPG*, *CDH6*, *GPR50, LRP4*, *PREX1*, *PCSK9*, *RASGRF2* (up-regulated) and *PRMT8* (down-regulated) genes, placing them in the context of PKU for the first time. qRT-PCR confirmed these findings. Overrepresented and enriched processes included neuron projection guidance, dendrite and axon impairment, synaptic transmission, and neurotransmitter uptake. In contrast, the 30 mM Phe treatment group clearly represented the neurotoxicity of Phe, exhibiting enrichment in apoptotic pathways, while 1.25 mM Phe treatment did not yield any DEGs.

Conclusion: We established NT2/N as a novel model for Phe-mediated neuronal dysfunction. Differential gene expression profiling and enrichment analysis revealed that exposure to applied Phe concentrations leads to neurite impairment and affects synaptic connectivity.

P08.033.D Molecular genetic analysis of patients with Fabry disease and their prevalence in Ukraine

Nataliia Olkhovych[1,2], *Nataliia Mytsyk*[1,2], *Mariana Mostovyak*[2], *Lina Moshkivska*[1], *Svetlana Kormoz*[1], *Iryna Hrehul*[1], *Anna Shylova*[1], *Nataliia Samonenko*[1], *Volodymyr Olkhovych*[2], *Nataliia Gorovenko*[3,2]

[1]*National Children's Hospital OKHMATDYT, Kyiv, Ukraine,* [2]*National Scientific Centre, Institute of Genetic and Regenerative Medicine, Kyiv, Ukraine,* [3]*National University of Health named P.L.Shupika, Kyiv, Ukraine.*

Background: Fabry disease is an X-linked lysosomal storage disorder caused by a *GLA*-related alpha-galactosidase A deficiency. The peculiarity of the GLA gene is its extremely high heterogeneity, which causes difficulties in interpreting the results of molecular genetic analysis of individuals with suspected Fabry disease, especially females.

Material and Methods: blood samples of patients with suspected Fabry disease were examined by NGS and Sanger sequencing.

Results: The variants in the *GLA* gene were found in 41 patients (29 families) with suspected Fabry disease, including 29 men and 12 women. All women were identified through cascade family analysis of the primary male patient. Therefore, the calculation of quantitative indicators of the frequency of *GLA* gene variants was performed exclusively for the first male patients identified in each family. In total, 20 variants of the *GLA* gene were detected - missense (14/20; 70%), nonsense (3/20; 15%), and point deletions (3/20; 15%). A little more than half of the variants were pathogenic (11/20), others were probably pathogenic except two (p.Asp313Tyr and p.Ser126Gly) had an uncertain value or contradictory pathogenicity classifications. The most frequent variants were p.Arg112Cys (4/29; 14%) and p.Asp313Tyr (3/29;10%), and the remaining variants were unique i.e. met in one or two families at most.

Conclusion: The study results are the basis for further study of the genetic heterogeneity of the Fabry disease and contribute to the optimization of early diagnosis and genetic counseling in Ukraine.

P08.034.A Mutational analysis of the *GCDH* gene in patients with glutaric aciduria type I in Ukraine

Lina Moshkivska[1], *Nataliia Olkhovych*[1,2], *Nataliia Mytsyk*[1,2], *Oksana Barvinska*[1], *Julia Zhyvytsia*[1], *Svitlana Kormoz*[1], *Iryna Hrehul*[1], *Olena Kutsyk*[1], *Anna Shylova*[1], *Maryna Shulha*[1], *Bohdana Leshyk*[1], *Nataliia Fruntsevich*[1], *Nataliia Samonenko*[1], *Maryna Patsora*[1], *Mariia Haidei*[1], *Volodymyr Olkhovych*[2], *Natalia Gorovenko*[2,3]

[1]*National Specialized Childrens' Hospital Okhmatdyt, Kyiv, Ukraine,* [2]*National Scientific Centre, Institute of Genetic and Regenerative Medicine, Kyiv, Ukraine,* [3]*National University of Health named P.L.Shupika, Kyiv, Ukraine.*

Background: Glutaric aciduria type I (GA1) is a hereditary disease caused by *GCDH*-related deficiency of the glutaryl-CoA dehydrogenase. The spectrum and frequency of pathological variants in the *GCDH* gene vary depending on the population, which is taken into account when developing the algorithm for effective diagnosis of GA1.

Material and Methods: Bio samples of patients with GA1 were analyzed by biochemical (LC/MSMS, GC/MS), and molecular genetic (NGS, Sanger sequencing) methods.

Results: Since 2014, 13 patients (5 of them by NBS) with GAI were identified in Ukraine by metabolic markers (elevated C5DC, glutaric, and 3-OH glutaric acids) and *GCDH* gene analysis. 12 pathogenic variants were identified: 9 missense, one deletion in the coding region, and two splicing variants. Most of the rearrangements were localized in exon 11 of the *GCDH* gene (16/26, 61.5%). The p.Arg402Trp variant has the highest frequency (12/26, 46%). This variant has been described as the most common among Caucasians in various populations, from 20% in Turkey to 52% in Poland (Pokora et al, 2019). All other variants were rare, i.e., they were found in one, two, or three families.

Conclusion: The most common variant in the *GCDH* gene among patients with GA1 in Ukraine is the p.Arg402Trp, which is similar to the European populations. The localization of 61.5% of the detected variants in exon 11 makes it advisable to analyze this exon first in patients with the GA1 metabolic profile. This approach will speed up and reduce the cost of GA1 diagnostics.

P08.035.B Beyond-Standard WES Data Analysis Reveals Mitochondrial Instability in a Patient with Chronic Muscle Pain and Fatigue

Agnieszka Pollak*, Grazyna Kostrzewa, Malgorzata Rydzanicz, Maria Franaszczyk, Karolina Rutkowska, Piotr Stawinski, Rafal Ploski*

Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.

Background: Mitochondrial DNA (mtDNA) is crucial for ATP synthesis, and its instability can lead to various diseases. Factors contributing to mtDNA instability include defects in replication, repair mechanisms, and accumulated mutations. Additionally, mitochondrial dysfunction has been linked to nuclear genome instability, suggesting a bidirectional relationship. Understanding mtDNA instability is essential for studying its role in disease and aging

Material and Methods: We performed exome sequencing and mtDNA sequencing in a young patient with chronic muscle pain and fatigue. Our analysis included detection and quantification of mtDNA rearrangements from paired-end sequencing data.

Results: Standard analyses did not reveal pathogenic SNVs or CNVs in nuclear DNA or mtDNA. While high-throughput sequencing has improved mtDNA variant detection, identifying mtDNA rearrangements, particularly multiple deletions, remains challenging. To address this, we applied **eKLIPse**, a specialized tool for detecting and quantifying mtDNA rearrangements. eKLIPse identified several low-level mtDNA deletions. Further analysis of DNA from uroepithelial and hair follicle cells confirmed mtDNA rearrangements in uroepithelial cells but not in hair follicle cells. The analysis of samples from mother was normal

Conclusion: Comprehensive WES-based mtDNA analysis revealed tissue-restricted mitochondrial instability, likely contributing to the patient's chronic muscle pain and fatigue. Further research is needed to elucidate the underlying mechanisms and clinical significance of this instability.

C.O.I. Disclosure:

P08.036.C Unraveling the spectrum of *RFX6* mutations associated with diabetes

Prapaporn Jungtrakoon Thamtarana[1], *Duangkamon Bunditvorapoom*[1], *Chutima Chanprasert*[1], *Thanarat Salahong*[1], *Nattachet Plengvidhya*[1], *Alessandro Doria*[2]

[1]*Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand,* [2]*Joslin Diabetes Center, Harvard Medical School, Boston, MA, USA.*

Background: Regulatory Factor X6 (RFX6) is a transcription factor essential for β-cell development and function. Biallelic *RFX6* mutations cause Mitchell-Riley syndrome, characterized by neonatal diabetes, pancreatic hypoplasia, and intestinal atresia. Heterozygous mutations are associated with diabetes onset in childhood or adulthood. This study examined the effects of a novel *RFX6* mutation (identified through exome sequencing in a family with autosomal dominant diabetes) and five previously reported mutations.

Material and Methods: Wild-type and mutant RFX6 proteins were expressed in HEK293 cells and analyzed for protein levels, nuclear localization, and transcriptional activity on the insulin promoter using Western blotting, immunofluorescence, and luciferase assays. Proteasomal degradation was assessed using the MG132 inhibitor.

Results: The novel p.Ile878Asnfs3 mutation significantly increased protein levels, abolished nuclear translocation, reduced transcriptional activity by 67%, and conferred resistance to proteasomal degradation. p.Arg181Gln significantly reduced nuclear localization and transcriptional activity by 55% and 67%, respectively. Truncating mutations (p.Leu292Ter and p.Lys351Ter) significantly reduced protein levels, nuclear localization (by 20% and 47%), and transcriptional activity (by 70% and 66%). p.Arg726Ter significantly reduced nuclear localization (by 12%), while p.Arg866Ter maintained high nuclear localization. p.Ile878Asnfs3 exhibited 100% penetrance, whereas p.Arg181Gln, p.Leu292Ter, and p.Lys351Ter had reduced penetrance (57%, 91%, and 50%, respectively) but remained a risk for diabetes in younger or prediabetic carriers. Notably, individuals with combined p.Arg726Ter/p.Arg866Ter developed Mitchell-Riley syndrome, despite neither mutation alone significantly impairing transcriptional activity.

Conclusion: These findings provide insights into RFX6-related diabetes mechanisms and variable penetrance, emphasizing the impact of specific mutations on disease presentation.

P08.037.D Elevated soluble ACE2 in Gaucher patients : An evolutionary advantage?

Tova Hershkovitz[1], *Ahmad Fokra*[2], *Hagit Baris Feldman*[3], *Alina Kurolap*[4], *Safa Kenany*[2], *Zaid A. Abassi*[2]

[1]*The Genetic Institute, Galilee Medical Center, Nahriya, Israel,* [2]*Technion-Israel Institute of Technology, Haifa, Israel,* [3]*Genetics Institute and Genomic Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel,* [4] *Genetics Institute and Genomic Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.*

Background: Gaucher disease (GD) has a high carrier rate among Ashkenazi Jews, although the most common disease-causing variant, N370S, is pan-ethnic. This has led to speculations of evolutionary advantage for carriers, particularly of this variant. During the recent COVID-19 pandemic, GD patients reportedly had a surprisingly low infection rate and mild symptoms considering their disease status. As SARS-CoV-2 gains entry into the cell via membrane-bound angiotensin-converting enzyme 2 (ACE2), we speculated that differences in levels of soluble ACE2 in GD patients could contribute to this protective state. While ACE is a biomarker of GD, ACE2 levels have not been explored in GD.

Material and Methods: We measured serum levels of ACE and ACE2 by ELISA in 33 GD patients and 17 age- and sex-matched controls as well as macrophage bound ACE2 by western blot, in 7 GD and 7 age- and sex-matched controls.

Results: Our results revealed a significant elevation of both serum and macrophage-bound ACE and ACE2 in GD patients compared to healthy controls. Moreover, the most robust ACE2 elevation was observed in N370S homozygotes (60 ng/ml in homozygotes versus 20 ng/ml in controls; $P \leq 0.001$.), regardless of treatment status.

Conclusion: We provide preliminary evidence for significant soluble ACE2 elevation in GD patients, particularly those with the N370S homozygous genotype. Since coronaviruses use the ACE2 receptor as a gateway for host cell entry, we speculate that elevated circulating ACE2 may serve as a decoy, giving advantage to GD patients during viral infections, of which SARS-Cov-2 serves as a contemporary example.

P08.038.A Mutational spectrum of X-ALD in Russian patients and investigation of the *ABCD1* gene splicing

Natalya Vytnova[1], *Svetlana Mikhaylova*[2], *Polina Baranova*[1], *Ramil Salakhov*[3], *Ildar Minniakhmetov*[3], *Ekaterina Zakharova*[1]

[1]*RCMG, Moscow, Russian Federation,* [2]*Ministry of Health of the Russian Federation Research and Clinical Institute for Pediatrics of the Pirogov Russian National Research Medical University Detached Structural Unit Russian Children's Clinical Hospital, Moscow, Russian Federation,* [3]*Endocrinology Research Centre, Moscow, Russian Federation.*

Background: X-linked adrenoleukodystrophy (X-ALD) is a recessive inherited neurodegenerative disease associated with biallelic variants in the *ABCD1* gene and leading to progressive demyelination of the nervous system and adrenal insufficiency. Although it is generally accepted that about 15% of all pathogenic variants alter splicing, the *ABCD1* splicing remains poorly understood.

Material and Methods: We present molecular genetic data of 198 patients with X-ALD who were referred to the Research Centre for Medical Genetics from 2004 to 2024 years. The diagnosis was confirmed by clinical and radiological examination followed by NGS and Sanger sequencing of *ABCD1*. HEK293T cells and pSpl3_Flu2_miniTK minigene vector were used to assay the impact of variants on splicing.

Results: In our patient's cohort, 140 unique variants were identified, including: indel variants - 17%, frameshift - 11%, nonsense - 23%, missense - 42%, splicing - 7%, which correlates well with literature data (https://adrenoleukodystrophy.info/). After bioinformatic analysis of patients' variants, we identified additional 17 that were predicted to affect splicing. We created a minigene system for all exons of the *ABCD1* gene and validated it on well-known *ABCD1* splicing variants. Further, to improve variant classification in public databases of X-ALD mutations we analyzed the Human Gene Mutation Database, ClinVar, and ALD.info database and selected another 102 variants that were predicted to affect splicing.

Conclusion: We demonstrated that our minigene system for *ABCD1* is suitable for functional analysis of variants that are predicted to affect splicing, which is what we are currently working on.

P08.039.B Pancreatic magnetic resonance imaging in carriers of m.3243A>G mitochondrial disease with and without diabetes

Simone Rask Nielsen[1,2], *Mimoza Gjela*[3], *Malene Pontoppidan Stoico*[4,2], *Asbjørn Mohr Drewes*[5,2], *Søren Schou Olesen*[5,2], *Inge*

Søkilde Pedersen[4,2], Christina Brock[5,2], Anja Lisbeth Frederiksen[1,2,6], Jens Brøndum Frøkjær[3,2]

[1]Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark, [2]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark, [3]Department of Radiology, Aalborg University Hospital, Aalborg, Denmark, [4]Department of Molecular Diagnostics, Aalborg University Hospital, Aalborg, Denmark, [5]Mech-Sense, Department of Gastroenterology and Hepatology, Aalborg University Hospital, Aalborg, Denmark, [6]Department of Clinical Genetics, Odense University Hospital, Odense, Denmark.

Background: The mitochondrial DNA variant m.3243A>G disrupts oxidative phosphorylation reducing mitochondrial adenosine triphosphate production, and is strongly associated with an elevated risk of diabetes mellitus (1). This pathophysiology likely arises from impaired beta-cell function and decreased insulin sensitivity (2); however, the precise mechanisms remain unclear. This study aimed to determine whether m.3243A>G carriers exhibit pancreatic morphological changes.

Material and Methods: Healthy controls, non-diabetic and diabetic m.3243A>G carriers were evaluated using a unique approach of magnetic resonance imaging (MRI) parameters of the pancreas. We measured gland volume to evaluate atrophy, T1 relaxation time and magnetic resonance elastography (MRE) stiffness for evaluation of fibrosis, and proton density fat-fraction (PDFF) for fat content (3).

Results: The study included 11 non-diabetic and 12 diabetic m.3243A>G carriers and 23 controls. T1 relaxation time ($p < 0.001$) and MRE-derived stiffness ($p = 0.03$) differed between groups. The diabetic carriers had a slightly higher median (interquartile range) T1 relaxation time [909ms (868–1085) vs. 823ms (785–852), $p = <0.001$] and MRE-derived stiffness [1.32kPa (1.24–1.43) vs. 1.23kPa (1.12–1.28), $p = 0.02$] than healthy controls, but non-diabetic carriers showed no differences from controls in these parameters. Pancreatic volume and PDFF did not differ among groups.

	Controls	m.3243A>G	Any m.3243A>G subdivided		p-value[a]

Age (years)	42.0 ± 14.2	41.7 ± 13.2	36.0 ± 13.0	46.8 ± 11.5	0.16 (overall)
Body mass index (kg/m^2)	23.9 ± 3.7	23.4 ± 5.1	24.5 ± 4.6	22.3 ± 5.5	0.45 (overall)
HbA1c (31–44 mmol/mol)	34 (32–36)	44 (36–45)	36 (32–42)	45 (44–55)	**<0.001*** (overall)
Pancreatic magnetic resonance imaging					
Gland volume (ml)	63.2 ± 17.0	63.2 ± 15.6	-	-	0.99
	-	-	67.2 ± 13.6	59.5 ± 17.0	0.53 (overall)
T1 relaxation time (ms)	823 (785–852)	868 (782–909)	-	-	0.07
	-	-	782 (769–867)	909 (868–1085)	**<0.001* (overall)**
MRE-derived stiffness (kPa)	1.23 (1.12–1.28)	1.31 (1.23–1.36)	-	-	**0.01***
	-	-	1.30 (1.22–1.33)	1.32 (1.24–1.43)	**0.03*** (overall)
P roton density fat fraction (%)	3.0 (1.9–4.8)	3.5 (2.2–6.9)	-	-	0.26
	-	-	2.5 (1.9–5.1)	4.5 (2.5–8.1)	0.16 (overall)

Data are expressed as mean±standard deviation or median and (range).
[a]p-value is results from t-test between healthy controls and carriers of m.3243A>G, unless "overall" is stated, which refers to analysis of variance between three groups (healthy controls, non-diabetic and diabetic carriers of m.3243A>G).
HbA1c - hemoglobin A1C; ml - milliliter; ms - milliseconds; MRE - magnetic resonance elastography; kPA - kilopascal.

Conclusion: While there was no pancreatic atrophy or increased fat content in m.3243A>G carriers on MRI, T1 relaxation time and MRE-derived stiffness were slightly higher in diabetic carriers. This may indicate mild fibrotic pancreatic changes secondary to diabetes, comparable to MRI findings in type 1 and type 2 diabetes (3).

P08.040.C Late-onset epi-CblC: Correlation of *MMACHC* promoter methylation and *PRDX1*expression in patient blood and fibroblasts

*Martina Skopkova[1], **Andrea Andresova**[1], Pavlina Kabelikova[2], Katarina Brennerova[3], Daniela Gasperikova[1]*

[1]Institute of Experimental Endocrinology, Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia, [2]Institute of Experimental Oncology, Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia, [3]Department of Paediatrics, National Institute of Children's Diseases, Bratislava, Slovakia.

Background: Mutations in the *MMACHC* gene leading to AR combined methylmalonic aciduria and homocystinuria (cblC). Additionally, specific mutations in the downstream inversely oriented *PRDX1* gene resulting in aberrant *PRDX1* transcripts overlapping *MMACHC* promoter lead to its methylation and expression downregulation (epi-CblC). We identified a patient with unusually late-onset epi-CblC type having compound heterozygous pathogenic *MMACHC*:c.271dup and novel *PRDX1*:c.599G>A variant causing aberrant splicing. We detected increased methylation of the *MMACHC* promoter in the patient blood compared to fibroblasts. We aimed to determine whether the observed difference in promoter methylation between the tissues is related to expression of the PRDX1 gene, which could contribute to explain the late-onset in the patient.

Material and Methods: Pyrosequencing and methyl-specific qPCR of bisulfite-treated DNA from blood and fibroblasts of the patient and two healthy controls were performed to evaluate the methylation level of the *MMACHC* promoter. The gene expression of *MMACHC* and *PRDX1* was assessed by qPCR.

Results: We confirmed that *MMACHC* promoter methylation was increased in the patient blood (35%) compared to fibroblasts (5%) by pyrosequencing and qPCR. The *MMACHC* expression was significantly decreased in the patient blood compared to blood of healthy controls, while the expression in fibroblasts was compar-

able with controls. The *PRDX1* gene expression was higher in the patient blood when compared to healthy controls, but was at the same level as expression in the patient fibroblasts.

Conclusion: We did not confirm the association between *PRDX1* expression and level of the *MMACHC* promoter methylation in the patient blood and fibroblasts.

P08.041.D *EARS2*-related mitochondrial encephalopathy: insight into the disease mechanism

Erika Santi[1], *Giorgia Babini*[1], *Sara Carli*[1], *Flavia Palombo*[2], *Benedetta Piccolo*[3], *Ilaria Pettenuzzo*[4], *Gaia Tioli*[5], *Luisa Iommarini*[5], *Joanna Rorbach*[6], *Caterina Garone, Professoressa associata*[1]

[1]*Department of Medical and Surgical Sciences, Alma Mater Studiorum University of Bologna, Bologna, Italy,* [2]*Programma di Neurogenetica, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy,* [3]*Child Neuropsychiatry Unit, Department of Gynaecology, Obstetrics and Neonatology, University Hospital of Parma, Parma, Italy,* [4]*UOC Neuropsichiatria dell'età pediatrica, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy,* [5]*Department of Pharmacy and Biotechnology, Alma Mater Studiorum University of Bologna, Bologna, Italy,* [6]*Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.*

Background: *EARS2* is a nuclear gene encoding for the mitochondrial glutamyl-tRNA synthetase, a mtDNA translation enzyme responsible for the esterification reaction of glutamate with its cognate tRNA. Autosomal recessive *EARS2* variants lead to mitochondrial encephalomyopathy. Our project aims to understand the disease mechanism of *EARS2* disease to explain the clinical variability of patients and identify targets for therapy.

Material and Methods: a family with one proband and one unaffected sibling, both carrying recessive pathogenetic variants in the *EARS2* gene (c.484C>T; c.600C>A), was identified by whole exome sequencing. Muscle biopsy and fibroblast cell lines of both siblings were analysed with molecular genetics, biochemical, and electron microscopy studies.

Results: mitochondrial respiratory chain activities in muscle homogenate revealed an abnormal increase of citrate synthase in the unaffected sibling demonstrating a compensatory mechanism preventing the manifestation of the disease, whereas a multiple OXPHOS deficiency was identified in the symptomatic patient. Complex IV and V subunit protein levels were decreased in patients' fibroblast cell lines compared to controls. In vitro S^{35} L-methionine labeling assay demonstrated a severe reduction of the de novo mitochondrial protein synthesis in both patients. Oxidative stress and reduction of the mitochondrial mass were also present as well as impairment of the mitochondrial bioenergetics, network, and dynamics. All the abnormalities were more pronounced in the symptomatic sibling. Preliminary data from RNA-bulk sequencing revealed deregulation of mitophagy and OXPHOS metabolism pathways.

Conclusion: our results suggest an interplay between mitochondrial dynamics, translation, and oxidative stress in the disease mechanism of EARS2 defect.

P08.042.A NGS detection of mtDNA multiple deletions uncovers gene-specific patterns

Leonardo Caporali[1], *Claudio Fiorini*[1], *Andrea Legati*[2], *Danara Ormanbekova*[1], *Marco Barresi*[2], *Alberto Pietro Pasti*[1], *Rossella Izzo*[2], *Michele Todisco*[1], *Santino Blando*[3], *Francesco Casadei*[1], *Nadia Zanetti*[2], *Eleonora Lamantea*[4], *Maria Lucia Valentino*[3], *Costanza Lamperti*[2], *Chiara La Morgia*[3], *Valerio Carelli*[3], *Daniele Ghezzi*[2]

[1]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy,* [2]*Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [3]*University of Bologna, Bologna, Italy,* [4]*Fondazione IRCCS Istituto Neurologico Carlo Besta, Bologna, Italy.*

Background: Mitochondrial DNA (mtDNA) is maintained, transcribed, and replicated by enzymes encoded by nuclear DNA. Pathogenic variants in genes forming the mtDNA replisome are linked to conditions ranging from ptosis and isolated myopathies to severe encephalomyopathies. These disorders are often linked to deleted mtDNA molecules accumulation in post-mitotic tissues (eg skeletal muscle) or, more rarely, to mtDNA copy number depletion.

Material and Methods: We examined the abundance and characteristics of multiple mtDNA deletions in skeletal muscle biopsies from patients with a myopathy/encephalomyopathy phenotype, carrying pathogenic variants in genes involved in mtDNA maintenance. Whole mtDNA was sequenced via next-generation sequencing (NGS) after target enrichment from total genomic DNA. Deletions and duplications were mapped by identifying reads with breakpoints using the MitoSAlt tool.

Results: The abundance of mtDNA deletions varied significantly across patients, with the highest levels in *POLG* cases and the lowest in *OPA1* cases. Most deletions were mapped to the major arc, but a significant number were identified in the minor arc, particularly in *POLG* cases. Although mtDNA duplications are less reported, significant levels were found in a subset of patients, including those with *DGUOK*, *MGME1*, *RNASEH1*, *TOP3A*, and some *POLG* and *TWNK* cases. These findings suggest novel mechanisms in mtDNA deletion formation.

Conclusion: This study offers the first NGS-based characterization of multiple mtDNA deletions in skeletal muscle from patients with mitochondrial replisome defects. Specific deletion patterns linked to some genetic defects were identified, highlighting the potential of deletion mapping for molecular diagnostics and for understanding replisome proteins' function.

P08.043.B CLINICAL AND BIOCHEMICAL ANALYSIS OF INFANTS WITH ABNORMAL NEWBORN SCREENING FOR KRABBE DISEASE WITH FOUR *GALC* VARIANTS

Dietrich Matern[1], *AMy L. White*[1], *Joseph J. Orsini*[2], *Deepa S. Rajan*[3], *Carlos A. Saavedra*[2]

[1]*Mayo Clinic, Rochester, MN, USA,* [2]*NY State Department of Health, Albany, NY, USA,* [3]*Children's Hospital of Pittsburgh, Pittsburg, PA, USA.*

Background: A challenge in using molecular genetic testing as part of newborn screening (NBS) for Krabbe disease (KD) is predicting disease risk given *GALC* variants of uncertain significance or conflicting reports about pathogenicity.

Material and Methods: We analyzed biochemical genetic results and clinical outcomes for infants identified by the New

York NBS Laboratory or Mayo Clinic's Biochemical Genetics Laboratory and found to have at least one of the following *GALC* variants: c.334A>G (p.T112A), c.956A>G (p.Y319C), c.1901T>C (p.L634S), or c.349A>G (p.M117V).

Results: All children homozygous for p.T112A or compound heterozygous for p.T112A and a pathogenic *GALC* variant were clinically asymptomatic (n = 73). Five children with the p.Y319C variant in the compound heterozygous or homozygous state developed late infantile KD and received a bone marrow transplant. 35 other children with the p.Y319C variant in the compound heterozygous or homozygous state were asymptomatic. One of 26 children who are compound heterozygous for p.L634S developed infantile KD. Of 12 children with a *GALC* genotype including p.M117V, two compound heterozygous patients developed infantile KD.

Conclusion: Evaluating the long-term clinical outcomes and biochemical findings of children with commonly identified *GALC* variants and an abnormal NBS for KD is useful to understand genotypes of uncertain significance. Here we provide an update on our understanding of the genotype/phenotype correlation of KD with the goal of reducing unnecessary anxiety and improving long-term follow up of children at risk to develop KD.

P08.044.C Altered mitochondrial transcripts in Primary Mitochondrial Myopathies characterized by mtDNA deletions: an RNA-seq approach

Andrea Legati[1], *Rossella Izzo*[2], *Marco Barresi*[1], *Elisa Moresco*[1], *Alessia Nasca*[1], *Eleonora Lamantea*[1], *Costanza Lamperti*[1], *Daniele Ghezzi*[1,2]

[1]*Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [2]*Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy.*

Background: Primary mitochondrial myopathies (PMM) are a group of heterogeneous disorders characterized by skeletal muscle involvement due to genetic defects in mitochondrial DNA (mtDNA) or nuclear DNA. Single large or multiple mtDNA deletions are common findings in PMM, however, the effects at transcriptional level of this type of alterations are not fully elucidated. This study aims to investigate gene expression alterations and gene fusion events in patients affected by single large-scale or multiple mtDNA deletions.

Material and Methods: we studied total RNA samples isolated from muscle biopsies of PMM patients affected by single (N = 30) and multiple (N = 15) mtDNA deletions, and of 10 controls. RNA sequencing (RNA-seq) was performed on Novaseq platform (Illumina), differential gene expression analysis and identification of fusion events were conducted on mt-mRNA transcripts.

Results: bulk RNA-seq revealed differentially expressed mtDNA-genes in patients with single or multiple mtDNA deletions compared to controls. In single deletions, expression levels of genes within the deletion decreased proportionally to deletion heteroplasmy. In multiple deletions, reduced gene expression showed a weaker association with cumulative heteroplasmy. Gene fusion events caused by deletions were also analyzed, identifying primarily involved genes.

Conclusion: this study provides novel insights into the mitochondrial transcriptome alterations associated with mtDNA deletions in PMM patients. Bulk RNA-seq allowed for the identification of mtDNA DEGs and gene fusion events in muscle tissue. These results may contribute to a better understanding of the molecular mechanisms underlying PMM and of their clinical heterogeneity.

Background: The genetic landscape of inherited optic neuropathies (ON) is continuously expanding to include several genes encoded in both nuclear and mitochondrial DNA, therefore encompassing a wide range of inheritance patterns. Occasionally, a few pathogenic variants in mitochondrial respiratory Complex I (CI) genes have been identified in optic neuropathy cases, besides the more typical severe presentation of CI deficiencies.

Material and Methods: We investigated CI genes through NGS screening to identify possibly causative variants in patients with optic atrophy. Those who were found to carry pathogenic possibly causative variants underwent additional clinical evaluations, including MRI and neurological examinations.

Results: We identified pathogenic or likely pathogenic variants in 31 patients from 23 families, with biallelic or hemizygous variants in 11 different CI-related genes. These variants span all major types of peptides involved in the structure of CI, including 3 core subunits (*NDUFS7*, *NDUFV1*, *NDUFV2*), 4 accessory subunits (*NDUFA1*, *NDUFA10*, *NDUFA12*, *NDUFB11*), and 4 assembly factors (*NDUFAF2*, *NDUFAF3*, *NDUFAF4*, *NDUFAF8*). Notably, defects in core CI subunits lead to isolated optic atrophy, while defects in accessory CI subunits and assembly factors lead to a spectrum ranging from isolated to syndromic optic atrophy. In some cases, the disease presentation with acute onset of vision loss allowed us to link novel genes to the recessive Leber hereditary optic neuropathy (LHONAR) phenotype.

Conclusion: Our case series broadens the genetic landscape of ON and LHONAR phenotypes, highlighting the pivotal role of

nuclear CI genes in ON pathogenesis and their so far underestimated prevalence in ON molecular diagnosis.

P08.046.A Transaldolase deficiency (Eyaid syndrome): Natural history of hepatic involvement

Nouf Salah Almutairi[1], *Aisha Al Shamsi*[2], *Wafaa Eyaid*[3]

[1]*Department of pediatrics, King AbdulAziz Medical City, Riyadh, Saudi Arabia,* [2]*Pediatrics Consultant, Genetic and Metabolic Division, Pediatrics Department, Tawam Hospital, Al Ain, United Arab Emirates, Al Ain, United Arab Emirates,* [3]*Department of genetics and precision medicine. King AbdulAziz Medical City, Riyadh, Saudi Arabia, Riyadh, Saudi Arabia.*

Background: Transaldolase deficiency is an autosomal recessive disorder that impacts the pentose phosphate pathway, a crucial pathway causing oxidative stress and multisystem failure, primarily affecting the liver, which is responsible for the mortality associated with this disorder. This study aims to clarify the clinical variability and hepatic manifestations of this uncommon condition through a comprehensive case series.

Material and Methods: We analyzed 21 patients diagnosed with transaldolase deficiency, focusing on their clinical presentations, familial patterns, and outcomes post-intervention. Data were collected via medical records, genetic testing, imaging, and liver biopsies. Patients were categorized based on familial occurrence and severity of liver disease.

Results: The study revealed a high incidence of familial clustering, with consanguinity noted in several families, highlighting the genetic predisposition. Hepatosplenomegaly was universal, with varying degrees of liver fibrosis and cirrhosis. Two patients underwent liver transplantation with successful outcomes, indicating its potential as a therapeutic option. Other manifestations included congenital heart defects, metabolic disorders, and in some cases, early mortality due to severe liver failure.

Conclusion: This case series underscores the phenotypic heterogeneity of transaldolase deficiency, emphasizing the need for early diagnosis, genetic counseling, and considering liver transplantation in severe cases. The findings advocate for a multidisciplinary approach in managing this condition, with a focus on long-term prognosis and post-transplant stability.

P08.047.B A case of neonatal lactic acidosis: investigating *SUCLG1*-related mitochondrial DNA depletion syndrome

Anke Schumann[1], *Annette Wohlleber*[2], *Sebastian Hurst*[2], *Jürgen Kohlhase*[2], *Eva Wohlleber*[3], ***Ulla Teresa Schultheiss***[4]

[1]*Center for Child and Woman Medicine, Children's Hospital, Department of Pediatric, Adolescent Medicine and Neonatology, Freiburg University Hospital, Freiburg, Germany, Freiburg, Germany,* [2]*SYNLAB MVZ Humangenetik Freiburg GmbH, Freiburg, Germany,* [3]*SYNLAB MVZ Humangenetik Freiburg GmbH, Freiburg im Breisgau, Germany,* [4]*SYNLAB MVZ Humangenetik Freiburg GmbH and Institute of Genetic Epidemilogy, Medical Center, University Freiburg, Freiburg, Germany.*

Background: Variants in *SUCLG1* disrupt succinyl-CoA ligase enzyme function, impairing mitochondrial DNA recycling and energy generation, resulting in mitochondrial DNA depletion. Symptoms range from severe hypotonia and developmental delay to fatal infantile lactic acidosis, depending on enzyme activity loss.

Material and Methods: Whole-exome-sequencing, tandem-mass-spectrometry and gas-chromatography-mass-spectrometry were used for diagnostic work-up.

Results: A neonate born to consanguineous parents underwent prenatal trio-exome diagnostics due to an SGA fetus with short femurs, suspected Fallot's tetralogy, and vermis hypoplasia. Initial analysis did not identify (likely) pathogenic variants. After birth, the infant developed severe lactic acidosis (30 mmol/L), metabolic decompensation, and liver failure, necessitating intensive care. Metabolic profiling revealed elevated propionylcarnitine levels and related ratios in acylcarnitine analysis, alongside markedly increased urinary concentrations of lactate, 3-hydroxypropionic acid, methylcitrate, and methylmalonic acid. The presence of methylglutaconic acid and 3-hydroxy acids suggested mitochondrial dysfunction or mitochondrial DNA depletion syndrome, particularly involving *SUCLG1* or *SUCLA2*. Reanalysis of the trio-exome identified a homozygous variant of uncertain significance (c.719T>G, p.(Leu240Arg), VUS, class 3) in *SUCLG1*, correlating with the clinical phenotype. Classification using ACMG criteria (PP4-moderate, PM2-supporting, PP3-moderate) yielded a VUS score of 5, indicating a "hot" VUS requiring additional evidence for definitive interpretation.

Conclusion: This case highlights the importance of interdisciplinary diagnostics and integrated omics in identifying disease mechanisms in critically ill patients. Planned steps include genetic testing of an affected aunt with neonatal losses and functional studies to validate the variant's pathogenicity. As the variant remains a VUS, further evidence is required to confirm its disease association.

P08.048.C Severe recurrent rhabdomyolysis with alpha-methylacyl-CoA racemase (AMACR) deficiency

Sharan Goobie, *Anthony Vandersteeen*

IWK Health, Dalhousie University, Halifax, NS, Canada.

Background: AMACR deficiency is a rare autosomal recessive peroxisomal disorder, resulting in impaired conversion of branch-chain fatty acid pristanic acid and C_{27}-bile acid intermediates, dihydroxycholestanoic acid (DHCA) and trihydroxycholestanoic acid (THCA), to their corresponding (S)-isomers. Clinical presentation can vary with age. Adult onset presentation is characterized by sensorimotor neuropathy, pigmentary retinopathy, seizures, ataxia, and cognitive decline. Children can present with transaminitis, and neonatal cholestasis. Rhabdomyolysis at any age is a rare presentation.

Case Report: We report a 46 year old male with severe recurrent episodes of rhabdomyolysis, beginning in adolescence. Rhabdomyolysis has become more frequent with age, and requires less exertion to precipitate an episode, with hospitalization roughly every 2–3 months over the past several years. Between episodes, he experiences chronic myalgia and muscle cramps. A novel homozygous variant in the AMACR gene, was predicted to be damaging by in silico analysis. Biochemical analysis identified markedly elevated pristanic acid, THCA and DHCA, consistent with a diagnosis of AMACR deficiency. Whole exome sequencing did not identify an alternate explanation for his episodes of rhabdomyolysis.

Conclusion: Rhabdomyolysis has only been reported in three previous published cases of AMACR deficiency. Two of the patients were on antipsychotic medications, which is not the case for our patient. Our patient follows a low phytanic acid/ pristanic acid diet, however, this has not altered his clinical course. Our case provides further evidence that rhabdomyolysis is a clinical presentation associated with AMACR deficiency, in the absence of the more well described neurologic features of this condition.

P08.049.D Novel FH gene variant with intrafamilial variability: expanding the phenotype spectrum of a rare disease

Monira Alshehri[1], *Azizah Mushiba*[2], *Nora Alsarhan*[2], *Abdullah S. Alshehri*[3], *Ashraf Dallol*[4], *Naif Almontashiri*[5], *Amal Alhashem*[6]

[1]*Applied Genomics Technologies Institute (AGTI), King Abdulaziz for Science and Technology, Riyadh, Saudi Arabia,* [2]*Department of Pediatric, Children's Specialized Hospital, King Fahad Medical City (KFMC), Riyadh, Saudi Arabia,* [3]*Biochemical Genetics and Toxicology, Pathology and Clinical Laboratory Medicine Administration, King Fahad Medical City, Riyadh, Saudi Arabia,* [4]*Noor Diagnostics and Discovery, Thuwal, Saudi Arabia,* [5]*College of Applied Medical Sciences and Center for Genetics and Inherited Diseases, Taibah University, Madinah, Saudi Arabia,* [6]*Seha Virtual Hospital, Ministry of Health (MoH), Riyadh, Saudi Arabia.*

Background: Fmarase Hydratase (FH) is a critical enzyme in the Krebs cycle, playing a pivotal role in cellular energy production. Biallelic pathogenic variants in the FH gene lead to fumarase deficiency (FMRD), also known as fumaric aciduria, a rare autosomal recessive metabolic disorder primarily affecting the nervous system. This study presents a consanguineous family with five affected individuals harboring a novel FH variant of uncertain significance (VUS), demonstrating biochemical confirmation and significant intrafamilial phenotypic variability.

Material and Methods: A retrospective analysis was conducted on 13 patients who underwent genetic testing and urine organic acid analysis. Clinical data were reviewed and compared with existing literature.

Results: Whole exome sequencing (WES) identified a novel homozygous FH variant (Chr1:241504102, NM_000143.4, c.1048C>G, p.(Arg350Gly)), initially classified as a VUS. Segregation analysis confirmed its presence in affected family members. Urine organic acid analysis via mass spectrometry revealed elevated fumaric acid levels in homozygous patients, corroborating the biochemical diagnosis of FMRD. Notably, affected individuals exhibited a delayed-onset phenotype, with symptoms such as psychomotor retardation, hypotonia, and seizures manifesting during puberty, contrasting with the typically severe early-onset presentation and high mortality associated with FMRD.

Conclusion: This report underscores the expanding phenotypic spectrum of FMRD, emphasizing intrafamilial variability and a delayed-onset clinical course. The findings highlight the necessity of integrating biochemical assays with genetic testing to establish variant pathogenicity in rare metabolic disorders. This case contributes to the growing understanding of FMRD and reinforces the importance of comprehensive diagnostic approaches in managing rare genetic diseases.

P08.051.B A novel*NADK2*frameshift variant in a patient with mitochondrial NAD kinase deficiency: Expanding the genotypic spectrum

D. Yildiz*, G. Ürel Demir, P. Simsek Kiper, G. Utine;*

Hacettepe University, Faculty of Medicine, Department of Pediatric Genetics, Ankara, Turkey

Background: Mitochondrial the nicotinamide adenine dinucleotide (NAD) kinase deficiency is a rare autosomal recessive disorder of the nicotinamide adenine dinucleotide phosphate (NADPH) biosynthesis that presents with variable severity and can cause dienoyl-CoA reductase deficiency (DECRD, OMIM #616034). This disorder is caused by variants in NAD kinase 2, mitochondrial (*NADK2*, OMIM *615787), located on chromosome 5p13.2. In this study, we present a currently 12-year-old patient who is under follow-up for growth retardation, global developmental delay, microcephaly, and thin corpus callosum. The patient's laboratory work-up including metabolic tests have been normal.

Material and Methods: The whole exome sequencing (WES) was performed.

Results: WES analysis identified a homozygous c.1124dup variant in the NADK2 gene. The detected variant was classified as "likely pathogenic" according to American College of Medical Genetics (ACMG) guidelines and was not reported in healthy population databases.

Conclusion: This case highlights the importance of WES analysis in elucidating the genetic etiology of patients with neurometabolic disorders. Our findings unveil that the molecular pathogenesis in this patient may be driven by NADPH-dependent processes rather than hyperlysinemia and DECRD.

P08.052.C Investigation of Fatty Acid β-Oxidation Defects in Rio Grande do Sul, a Southern State of Brazil

Marcela Rodrigues Nunes[1,2], *Bianca Fasolo Franceschetto*[3], *Lilia Farret Refosco*[3], *Carolina Fischinger Moura de Souza*[3,4], *Ida Vanessa Doederlein Schwartz*[3], *Paulo Ricardo Gazzola Zen*[1,2], *Bibiana Mello de Oliveira*[1,2]

[1]*Universidade Federal de Ciências da Saúde Porto Alegre (UFCSPA), Porto Alegre, Brazil,* [2]*Hospital Santa Casa de Porto Alegre, Porto*

Alegre, Brazil, [3]Hospital de Clínicas de Porto Alegre (HCPA), Porto Alegre, Brazil, [4]Casa dos Raros, Porto Alegre, Brazil.

Background: Fatty acid β-oxidation defects (FAODs) are a group of disorders affecting the fatty acid transport chain and mitochondrial β-oxidation. These conditions impact energy homeostasis, primarily in the liver, heart, and skeletal muscles, and often present with multi-system involvement and potentially life-threatening manifestations. FAODs are inherited as autosomal recessive disorders with variable presentation, manifesting either in the neonatal period or later.

Material and Methods: This study aimed to clinically characterize FAOD patients in Rio Grande do Sul, Brazil, focusing on clinical, biochemical, genetic, and therapeutic aspects. A retrospective study was conducted using data from medical records submitted by physicians through an electronic form. Ethical approval was obtained.

Results: Sixteen patients were included, 62.5% female, with a mean age of 19.2 years. The majority (75%) were born in Rio Grande do Sul. Common signs and symptoms included hypoketotic hypoglycemia (81.3%), liver dysfunction (68.8%), and both seizures and vomiting (56.3%). The most frequent diagnoses were Very long-chain acyl-CoA dehydrogenase deficiency (VLCADD, 31.3%) and Long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency (LCHADD, 18.8%). Average time to diagnosis was 5.14 years, predominantly made during a metabolic crisis (56.3%), with confirmation through genetic analysis (87.5%) and acylcarnitine profile (81.3%). Nutritional therapy was provided to 93.8% of patients, including carnitine supplementation (50%), triheptanoin (43.8%), and medium-chain triglycerides (25%). There were two recorded deaths (12.5%).

Conclusion: FAODs are multi-systemic and heterogeneous, with a prolonged diagnostic odyssey. Clinical management highlights the importance of nutritional and multidisciplinary therapy. Further research, professional training, and public policies for early diagnosis, including neonatal screening, are essential.

Background: Smith-Lemli-Opitz syndrome (SLOS) is a rare autosomal recessive polymalformative syndrome caused by 7-dehydrocholesterol reductase (*DHCR7*) deficiency. Its natural history remains poorly understood, with no international consensus on treatment or management. Alongside the creation of a French SLOS cohort in parallel to an European cohort, a national diagnosis and care protocol (PNDS) has been established to standardize disease management.

Material and Methods: A group of expert physicians (from national rare disease networks) was formed to review the literature on SLOS. The cohort, based on the French rare diseases database BaMaRa, was set up in collaboration with ERN MetabERN (UIMD) to monitor retrospectively and prospectively SLOS individuals across French centers.

Results: Collegial discussions led to consensus on key clinical signs of SLOS, aiding non-specialists in recognizing the syndrome, and establishes monitoring guidelines. Cholesterol supplementation has shown no adverse effects in normalizing blood cholesterol levels, despite the lack of clear evidence for survival improvement. In contrast, statins have an unfavorable benefit-risk ratio, offering no benefit and potential adverse effects. Beyond genetic counseling, extended family screening and the identification of *DHCR7* heterozygotes are important. Mouse studies suggest that some psychotropic drugs (aripiprazole, trazodone) which inhibit DHCR7 can cross the placental barrier and may induce pseudo-SLOS. The use of these drugs should be avoided a few weeks before and during pregnancy if either parent is a SLOS carrier. Ongoing cohort data collection will refine these recommendations.

Conclusion: The first recommendations for surveillance and management of SLOS have been developed and validated by French experts.

P08.054.A Association between variants of the LEP, LEPR, and FTO genes with obesity in adults from the Colombian Caribbean (Cartagena de Indias, Colombia)

Luisa Jimenez Rodríguez, *Sara Mestra Meriño, Gustavo Mora García, María Ruiz Diaz, Diana Mena-Yi, Eduer Pérez Castilla*

Universidad de Cartagena, Cartagena, Colombia.

Background: Obesity is a public health issue influenced by genetic and environmental factors. Genes such as LEP, LEPR, and FTO have been associated with an increased risk of obesity in various populations. Cartagena de Indias, with its mixed

population and unique ethnic characteristics, represents a relevant context for study.

Material and Methods: A case-control study was conducted with adults from the Colombian Caribbean who are part of the Cartagena Cohort Study (CaReS) in Cartagena de Indias, Colombia. Risk variables were analyzed. Polymorphic variants (Single Nucleotide Polymorphisms, SNPs) in the genes LEP (rs7799039), LEPR (rs1137101), and FTO (rs9939609) were genotyped. Allelic and genotypic frequencies were calculated by direct counting, and Hardy-Weinberg equilibrium was assessed. To compare case and control groups, null hypothesis tests were applied.

Results: A total of 150 cases and 150 controls (with and without obesity, respectively) were included. Variants in the FTO, LEP, and LEPR genes were found to be associated with the risk of developing obesity. The absence of the AA genotype in FTO, AA in LEP, and AG in LEPR increased the risk, whereas the presence of AA (LEP) was associated with a lower risk of developing obesity. Significant differences were found in the genotypic distribution of the SNP rs9939609 (FTO) between case and control groups ($p < 0.05$).

Conclusion: The polymorphic variants of the FTO (rs9939609), LEP (rs7799039), and LEPR (rs1137101) genes are suggested to be associated with the risk of developing obesity in this population. Further analyses are needed to confirm these findings.

P08.056.C Whole exome sequencing has identified genetic risk factors contributing to non-syndromic early-onset childhood obesity in consanguineous families

Hazal Banu Olgun Celebioglu[1,2], *Ayse Pinar Ozturk*[3], *Sukran Poyrazoglu*[3], *Feyza Nur Tuncer*[1]

[1]*Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey,* [2]*Istanbul University, Institute of Graduate Studies in Health Sciences, Istanbul, Turkey,* [3]*Istanbul University, Istanbul Faculty of Medicine, Department of Pediatrics, Pediatrics Endocrinology Unit, Istanbul, Turkey.*

Background: Obesity is defined as abnormal fat accumulation that leads to comorbidities presenting life-threatening risks. Childhood obesity has been acknowledged to elevate mortality risk due to type-2-diabetes mellitus (T2DM), cardiovascular diseases, and cancer. We aimed to identify candidate genes for obesity utilizing independent consanguineous families from Turkiye.

Materials and Methods: Three families having at least one obese child were recruited with body mass indexes (BMI) calculated in available members. Peripheral DNA obtained from all recruits was subjected to whole exome sequencing (WES), followed by bioinformatic analysis on the Genomize-SEQ Platform. Variant filtering for minor allele frequency (MAF)<0.01 in all normal populations was applied, and candidates were confirmed by Sanger sequencing of family members.

Results: A total of 16 individuals were recruited. WES identified a shared variant in the *ATXN3* gene across all affected family members. Among additional genetic variants detected in different families, two were in *SH2B1* and *ADIPOQ* genes; previously associated with obesity. Furthermore, five novel heterozygous variants in *ANKK1*, *NEGR1*, *OGDH, ABCB1*, and *GSK3B* genes were discovered and predicted to lead to excessive fat accumulation and dysregulation of energy metabolism in individuals.

Conclusion: Our results suggest the cumulative impact of variants in multiple genes leading to the early-onset obesity observed in individuals from disparate families. The shared variant in the *ATXN3* gene is a strong candidate for obesity, which will be screened in a sporadic cohort prior to functional analyses. Regular follow-up was recommended to the families, along with embracing a more active lifestyle and healthier eating habits.

P08.057.D Unusual case of MPS I diagnosed at the age of 28 years old

Larisa Barseghyan[1], *Satenik Muradyan*[1,2], *Tamara Sarkisian*[3,1], *Artyom Gasparyan*[3,1]

[1]*Yerevan State Medical University after Mkhitar Heratsi (YSMU), Yerevan, Armenia,* [2]*BIL Armenia Healthcare Students' Association of Armenia, Yerevan, Armenia,* [3]*Center of Medical Genetics and Primary Health Care, Yerevan, Armenia.*

Background: We present a case of a 28-year-old male, who was referred for genetic consultation by the cardiologist, due to aortic regurgitation III^0, bicuspid aortic valve, and mitral regurgitation II^0 with the suspicion of Loeys-Dietz's syndrome. Physical examination revealed a narrow forehead, synophrys, big nose, mouth, and ears, blurry vision at night, short neck, contracture and deformity[1] of upper and lower limbs, other bone deformities, and umbilical and inguinoscrotal hernias. The 32-year-old brother of the patient who was also present at the genetic consultation, has similar symptoms (similar facies, upper and lower limb contracture and deformity, umbilical hernia, and cardiac abnormalities) indicating a possibility of a familial case of MPS I[2].

Methods: The type of genetic testing was the "connective tissue" disease panel. Analysis was performed using Next-Generation Sequencing (NGS)[3].

Results: NGS identified two heterozygous mutations in the IDUA gene (chr4:987085A>C, chr4:987915C>T), consistent with MPS I (AR), and an additional heterozygous variant of uncertain significance (VUS) in the COL9A3 gene.

Conclusion: This case underscores the familial nature of Mucopolysaccharidosis (MPS) I, as evidenced by the similar clinical features observed in both the 28-year-old patient and his 32-year-old brother. The patient's heterozygous mutations in the IDUA gene support the MPS I diagnosis and emphasize the need for additional genetic testing on the brother to determine his risk of the condition. Such patients mainly die at an early age, especially in the absence of appropriate treatment. This case is unusual as both the phenotype and genetic findings are atypical for MPS I.

Turkey, [4]Department of Hematology, Istanbul Basaksehir Cam and Sakura City Hospital, Istanbul, Turkey.

Background: Metabolic syndrome (MetS) is defined as a metabolic dysfunction characterized by the co-occurrence of multiple risk factors. The aim of our study was to elucidate the effects of ADIPOQ rs266729, rs17300539, and rs2241766, AGT rs699 and rs4762, AGTR1 rs5186, AGTR2 rs11091046, ApoC-III rs2854116 and rs2854117, NR3C1 rs10052957 and rs41423247, and GNB3 rs5443 gene polymorphisms on MetS.

Material and Methods: The study included 200 patients who met the diagnostic criteria for MetS and 100 healthy controls. Variant analyses were performed using PCR-RFLP from genomic DNA samples.

Results: ADIPOQ rs17300539 GA, AGT rs699 TT, AGTR1 rs5186 AC, and AGTR2 rs11091046 CC genotypes were more frequently observed in patients diagnosed with MetS compared to healthy controls ($p < 0.05$, for all). MetS patients with AGT rs699 TT genotype had a higher incidence of hypertension compared to individuals with CC/CT genotype of the same polymorphism ($p = 0.047$). Individuals with ADIPOQ rs17300539 AA/AG and NR3C1 rs41423247 CC genotypes were found to have higher mean waist circumferences compared to others ($p < 0.05$, for all). Individuals with ADIPOQ rs17300539 AA/AG, NR3C1 rs10052957 GG, and AGT rs4762 GA/AA genotypes exhibited significantly higher incidence of nephropathy. Individuals with ADIPOQ rs17300539 AA/AG and NR3C1 rs10052957 GG genotypes had significantly higher incidence of retinopathy compared to others.

Conclusion: Our study, which has yielded numerous novel findings regarding MetS and gene polymorphisms, will illuminate future research.

P08.059.B Newborn novel monoallelic variants in *ACADVL* gene correspond to the enzymatic activity reduction: implication for pathogenetic definition

Clarissa Berardo*[1,2], *Alessandra Vasco**[1], *Alessia Mauri*[1,2], *Simona Lucchi*[1], *Andrea Meta*[1], *Laura Cappelletti*[1], *Laura Saielli*[1], *Francesca Fiumani*[1], *Diana Postorivo*[1], *Cristina Montrasio*[1], *Stephana Carelli*[1,2], *Cristina Cereda*[1,2]

[1]Functional Genomics, Rare Diseases and Newborn Screening Unit_Buzzi Children's Hospital, Milan, Italy, [2]Pediatric Research Center_Dept Biomedical and Clinical Sciences_University of Milan, Milan, Italy.

Background: Very long-chain acyl-coenzyme A dehydrogenase deficiency (VLCADD) is a rare autosomal recessive inborn error detected by newborn screening (NBS), which is caused by defects in *ACADVL* gene. This leads to the abnormal accumulation of long chain acylcarnitines and consequently to cardiac, muscle and liver disfunctions. Our aim was to investigate the correspondence between residual enzymatic activity (REA) and 3 novel missense variants in VLCADD heterozygous newborns.

Material and Methods: Dried blood spots collected from newborns were analyzed at the NBS Laboratory, Buzzi Children's Hospital, Milan, Italy. Three newborns with very slight increase in C14, C14:1, C14:2 acylcarnitines were referred for clinical evaluation and follow-up. Whole exome sequencing was performed on DNA from DBS. REA was detected in lymphocytes.

Results: One subject with a REA = 29% showed the c.1048G>A (p.Gly350Ser) classified as VUS by ClinVar and AlphaMissense and likely pathogenic by ACMG. The second neonate had the c.1291G>C (p.Asp431His) variant classified as VUS by ClinVar and ACMG and pathogenic by AlphaMissense and a REA = 25%. The third one had the c.757G>A (p.Gly253Arg) classified by ClinVar as VUS and likely pathogenic by ACMG and AlphaMissense with a REA = 28%. All variants were within the protein catalytic domain.

Conclusion: We report three novel heterozygous missense variants in the *ACADVL* gene corresponding to REA levels lower than 30%. This may be due to the variants that modify the aminoacids within the protein catalytic domain. It might be important to monitor these subjects since some heterozygous with severe reduced REA could develop disease-related symptoms overtime.

P08.060.C Unique Genetic Variants and Population Dynamics of Phenylketonuria and Wilson's Disease in Ecuador

Vanessa Isabel Romero Aguilar

Universidad San Francisco de Quito, Quito, Ecuador.

Background: Phenylketonuria (PKU) and Wilson's disease are rare metabolic disorders with profound public health implications in Ecuador. PKU results from pathogenic PAH variants causing phenylalanine accumulation, while Wilson's disease arises from ATP7B mutations affecting copper metabolism. This study explores the genetic landscape of these disorders, focusing on unique variants and clinical challenges in Ecuador's diverse population.

Methods: Next-generation sequencing identified PAH and ATP7B variants in Ecuadorian patients. Population dynamics, including founder effects and geographic clustering, were analyzed. Barriers to effective management were assessed through surveys and evaluations of dietary and treatment resources.

Results: Fifteen PAH variants were detected in PKU patients, with c.754C>T (p.Arg252Trp) being the most prevalent. The c.441+5G>T variant was concentrated in Papahurco, an isolated population, reflecting a founder effect. For Wilson's disease, rare variants such as p.M685* and p.M671* were common, while the globally frequent p.H1069Q was absent. Limited access to low-phenylalanine foods, supplements, and treatments, particularly in rural areas, highlights systemic disparities.

Conclusions: Ecuador's unique genetic variants necessitate population-specific diagnostic and treatment approaches. Accessible nutritional resources are essential for PKU management, while early genetic testing and improved access to Wilson's disease treatments can mitigate severe outcomes. These findings underscore the need to integrate genetic diversity into global frameworks for rare disease management.

P08.061.D Double the trouble: dual diagnosis in Fabry disease may contribute to atypical phenotypes

Charles Lourenco[1], *Amadeu Queiroz*[1], *JAQUELINE M. FONSECA*[2]

[1]FACULDADE DE MEDICINA DE SAO JOSE DO RIO PRETONEUROGENETICS, Ribeirao Preto, Brazil, [2]FLEURY DLE LABORATORY, RIO DE JANEIRO, Brazil.

Background: Dual (or multiple) molecular diagnoses involve more than one clinical diagnosis and more than one genetic locus, each segregating independently. The obvious significance of Dual Genetic Disorders (DGD) has direct practical implications. From a scientific point of view, case reports that claim "broadening" or "extension" of a particular phenotype for a single-gene disorder should be viewed with caution. In an extreme scenario, the clinical recognition of a "novel syndrome" may turn out to represent DGD for two previous known disorders Material and Methods: clinical and molecular features of a cohort of Brazilian patients with Fabry disease harboring a second pathogenic mutation for another disease.

Results: Among the 340 sequential DNA samples submitted to investigation of hypertrophic cardiomyopathy, small fiber pain with recurrent abdominal pain and progressive nephropathy of unknown cause, a molecular diagnosis involving a mendelian disease gene related to the clinical phenotype at the time of referral was reported for 60% of patients. Two or more molecular diagnoses were reported for 68 patients (20%), including 20 Fabry patients. Some of the atypical features in the Fabry cohort patients were prolonged attacks of abdominal pain even after enzyme replacement therapy (two Fabry patients with acute hepatic porphyrias), recurrent strokes in a patient with Fabry disease and COL4A1 mutation, complex cardiomyopathy in two patients with Fabry disease (one with PTPN11 mutation and the other with TTR-amyloidosis), among others.

Conclusion: Diagnostic next generation sequencing for multiple genes (massive parallel sequencing) affords opportunities for providing insights into relationships between multilocus genomic variation and disease.

Instituto Nacional de Rehabilitación, Ciudad de México, Mexico,* [4]*Instituto Nacional de Cancerología, Ciudad de México, Mexico*

Background: Eating disorders are complex mental health conditions characterized by abnormal eating habits that negatively impact a person's physical and mental health. Risky eating behaviors are closely related to risk factors such as BMI, sex, depression, and anxiety.

Aim: The objective of this study is to determine the association of gene methylation status RLEP, LEP, FTO, BDNF, and COMT with the risk factors for eating disorders in Mexican university students.

Material and Methods: An analytical cross-sectional study was carried out. Data on risky eating behaviors, anxiety, and depression were collected using self-applicable questionnaires EAT, BAI, and BECK, respectively. The methylation of the genes was determined by MSP-PCR.

Results: We included 83 individuals, 61.4% women, and 38.6% men. Interestingly, our results showed an association between the risk of eating disorder with anxiety and/or depression. When we determine the interaction between genes and risk factors, we find that the greater the number of risk variables, the greater the association of presenting risky eating behaviors in Mexican university students.

Conclusion: We found an association between risk factors, especially depression and anxiety, with risky eating behaviors in Mexican university students.

P08.063.B Case Report - Leber's Hereditary Optic Neuropathy

Katharina Goldin[1], *Nadja Ehmke*[1], *Tamara Grigoryan*[1], *Magdalena Danyel*[1], *Deniz Arman Atalay*[2], *Melanie Brugger*[3], *Christiane Neuhofer*[4], *Denise Horn*[1], *Henrike Lisa Sczakiel*[1]

[1]*Charité - Universitätsmedizin Berlin, Berlin, Germany,* [2]*Epilepsiezentrum Berlin-Brandenburg, Berlin, Germany,* [3]*Technical University of Munich, Munich, Germany,* [4]*University of Regensburg, Regensburg, Germany.*

Background: This report presents the case of a boy with early-onset optic atrophy and confirmed diagnosis of Leber's Hereditary Optic Neuropathy (LHON) at age eight through Whole Exome Sequencing (WES). The patient presented with visual impairment since age one, motor difficulties and mild cognitive development delay. Cranial MRI showed symmetrical supratentorial white matter changes. LHON is a rare mitochondrial disorder characterized by optic atrophy and progressive vision loss, typically manifesting in adulthood.

Material and Methods: Genetic investigations included an NGS leukodystrophy panel, followed by single WES and segregation analysis of candidate variants, ultimately followed by trio WES.

Results: After an initial NGS panel for leukodystrophy did not explain a clear cause of the patient's symptoms, single WES identified the mitochondrial homoplasmic variant m.11778G>A in the *MT-ND4* gene, confirmed as maternally inherited by segregation analysis. This variant accounts for over 50% of LHON cases worldwide and is a well-studied pathogenic variant, causing mitochondrial complex I dysfunction. Retinal ganglion cells, with high energy demand, are particularly vulnerable. Clinical findings align with LHON phenotypes. The identified *MT-ND4* variant, however, does not explain the patient's developmental delay. Two years later, trio WES identified a de novo *SPTBN1* variant, associated with developmental delay, intellectual disability, speech disorders and behavioral anomalies. The patient's mother, an asymptomatic carrier of the *MT-ND4* variant, demonstrates incomplete penetrance.

Conclusion: This case highlights the value of mtDNA analysis in pediatric optic neuropathies, where identifying the variant enabled a definitive diagnosis and multidisciplinary care. Emerging therapies, e.g. Idebenone, may improve LHON outcomes.

Background: Neonatal T cells form a unique developmental layer, characterized by the absence of memory T lymphocytes and a predominance of naïve T cells. Upon activation, neonatal naïve T cells exhibit a heightened readiness for activation, but the molecular mechanisms behind this rapid T cell mobilization in neonates remain unclear. Our previous study uncovered a novel transcriptional regulatory mechanism in adult naïve CD4+ T cells involving the splicing of LINE1 elements into new transcript variants, which control T cell quiescence and activation state.

Materials and methods: In this study, we isolated naïve CD4+ T cells from enrolled healthy donors across neonatal, adult, and elderly age groups. Using flow cytometry analysis, we evaluate the quiescent and activated states of naïve CD4+ T cells, assessing cell cycle, surface marker expression, and protein synthesis. We also conducted RNAseq to identify gene classes and biological processes affected by the absence of LINE1.

Results: We found that neonatal naïve T cells, upon activation, exhibit faster cell cycle entry, higher energy production, and increased protein synthesis compared to adults. Neonatal naïve T cells show reduced LINE1 levels due to tonic TCR activation by self-antigens, maintaining basal mTORC1 signalling and suppressing LINE1 via PTBP1-mediated splicing suppression. Modulating LINE1 through tonic TCR stimulation affects protein synthesis and cell cycle progression. Additionally, we observed that LINE1 levels increase with age, while protein synthesis rates decline.

Conclusions: Our study identified a novel role for LINE1 in T cell development, highlighting its critical function in human T cell activity during aging.

P09.002.D Unveiling X-Linked Primary Immunodeficiencies: The Impact of Genetic Testing on Early Diagnosis and Novel Variant Discovery

***Enrique Fernández-Tabanera[1]**, Irene Perea-Romero[1], Miriam León-Otegui[1], Elena Ordoñez[2], Bibiana Palao[1], Raquel Bernad[1], Naroa Martín[1], Germán Benito[1], Mireia Lechuga[2], Isabel Castilla[2], María Moreno[1], Vincenzo Cirigliano[2], Luis Izquierdo[1], Jessica Quinn[3], Vanessa Tenembaum[3], Fred Modell[3]*

[1]Veritas Genetics, Madrid, Spain, [2]Veritas Genetics, Barcelona, Spain, [3]Jeffrey Modell Foundation, New York, NY, USA.

Background: Primary immunodeficiencies (PI) are genetic disorders that involve the immune system. The Jeffrey Modell Foundation (JMF) is a global non-profit organization dedicated to improving the diagnosis and treatment of PI. X-linked genetic disorders are particularly significant among PIs, as they primarily affect males, which are often underdiagnosed.

Material and Methods: In this study, supported by JMF, samples from patients suspected of PI were analyzed using next-generation sequencing, targeting 575 immune-related genes.

Results: Among 1,591 individuals tested, 334 cases (21%) were genetically diagnosed. Of these, 65 cases (19.5%) involved X-linked genetic variants. The two most prevalent genes among the X-linked cases were *BTK* and *WAS*, associated with Agammaglobulinemia and Wiskott-Aldrich Syndrome, respectively. Both accounted for 41 genetic diagnoses, representing 12.3% of all positive cases and 63% of the X-linked cohort. Interestingly, among the 41 X-linked diagnostic variants in these genes, 25 had not been previously reported in the clinical literature. Of these, 16 were likely pathogenic truncating variants, while 8 were missense, categorized as strong variants of uncertain significance (SV). Finally, one of the diagnostic variants was a synonymous SV located in the last nucleotide of the exon, predicted to affect splicing.

Conclusion: This study highlights the critical role of early genetic testing in diagnosing PI, while emphasizing the need for greater clinical attention to X-linked PI due to their high prevalence. The significant proportion of novel SV variants highlights the key role of functional studies and segregation analyses to determine their pathogenicity, which would improve and complement diagnostic accuracy.

P09.003.A Single cell profiling of peripheral immune cells in Parkinson's disease

***Lovatiana Andriamboavonjy[1]**, Sebastien Audet[1], Gael Moquin-Beaudry[2], Laura Hamilton[1], Antoine Duquette[3], Sylvain Chouinard[3], Michel Panisset[3], Martine Tetreault[1]*

[1]CRCHUM, Montreal, QC, Canada, [2]Gustave Roussy Institute, Paris, France, [3]CHUM - Department of Neurology, Montreal, QC, Canada.

Background: Although Parkinson's disease research has unsurprisingly focused on the neurodegeneration happening in the brain multiple studies are pointing to peripheral immune dysregulation as a key contributor to PD progression. Therefore, we aimed to perform the first comprehensive analysis of the complete peripheral blood mononuclear cells compartment in PD patients utilizing the resolution of single-cell sequencing.

Material and Methods: PBMC were isolated from 14 blood samples from individuals with PD diagnosis, and 10 healthy age-matched control samples. Single-cell libraries were obtained with standard 10X Genomics protocols. Transcriptomic and T cell receptor (TCR) sequencing were run in parallel on the pools to enable the comparison of transcriptomic and immunologic

profiles from single cells. Standard bioinformatic tools were used for processing and annotations.

Results: Broad cluster analysis showed a general increase in activation signaling in PD samples, exhibiting a slight trend of increased monocytes and decreased lymphocytes. Further analysis of myeloid cells revealed an activated $CD14^{+}/CD83^{+}$ monocyte subpopulation, for which differentially expressed genes suggested a heightened inflammatory state in PD. Lymphoid cells analysis also showed increased pro-inflammatory NK56hi cells in PD samples. TCR clonotyping identified PD-specific sequences, with multiple motifs shared across multiple samples, but none were linked to known causative sequences in current annotation databases.

Conclusion: Overall, we present the first comprehensive single-cell atlas of the PBMC compartment, and provide insights into the peripheral immune mechanisms at play in PD pathogenesis. We believe these data could lead to the definition of prognosis gene signatures, and the identification of new therapeutic targets.

P09.005.C A novel in vitro platform for functional validation of germline variants in clonal haematopoiesis

Aurora Casiraghi[1], *Michela Colombo*[1], *Ilaria Gori*[1], *Manuel Tardaguila*[1], *Jacopo Zasso*[1], *Patricio Fuentes Bravo*[1], *Paola Benaglio*[1], *Chiara Chiereghin*[1], *Arianna Landini*[1], *Bruno Ariano*[1], *Edoardo Giacopuzzi*[1], *Nicola Pirastu*[1], *Cecilia Dominguez-Conde*[1], *Giovanni Fagà*[1], *Nicole Soranzo*[1,2,3]

[1]*Human Technopole, Milano, Italy,* [2]*Department of Haematology, University of Cambridge, Cambridge Biomedical Campus, Cambridge, United Kingdom,* [3]*Wellcome Sanger Institute, Wellcome Genome Campus, Hinxton, United Kingdom.*

Background: Clonal haematopoiesis of indeterminate potential (CHIP) is characterized by somatic mutations in genes associated with haematological malignancies, at >2% allele fraction in asymptomatic individuals. Recent GWAS have identified germline variants (GVs) linked to CHIP risk, but functional validation remains lacking.

Material and Methods: GVs coming from fine mapping of CHIP GWAS were introduced in H1 human embryonic stem cells using CRISPR/Cas9 alone or in combination with CHIP driver mutations. Cells were differentiated in a competitive setting towards haematopoietic lineages and key time points were assayed by 10x Multiome, tracking the edited genotypes by cell barcoding.

Results: Conditionally independent variants with high fine-mapping posterior probabilities were annotated using the Open-Targets V2G score and manually curated. The GV rs62237617 C>T, predicted to be associated with the expression of CHEK2 (a gene regulating the response to DNA damage and associated to CHIP risk), was selected to be tested in our in vitro platform alone or in combination with the common CHIP driver mutation DNMT3A-R882H.

Conclusion: We set up a functional validation platform to explore the possible interplay of GVs and CHIP mutations. This approach can be further expanded to include multiple GVs, enabling a deeper understanding of the role of germline variation in CHIP.

P09.006.D Defining genetic determinants of T-cell receptor repertoires at single-cell resolution

Hannah Kockelbergh[1], *Esther S. Ng*[1], *Luke Jostins-Dean*[1,2], *COMBAT consortium*[3], *Stephen N. Sansom*[1], *Julian C. Knight*[4,5,6], *Yang Luo, PI*[1]

[1]*Kennedy Institute of Rheumatology, Oxford, United Kingdom,* [2]*Nightingale Health, Helsinki, Finland,* [34]*Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [5]*Chinese Academy of Medical Science Oxford Institute, University of Oxford, Oxford, United Kingdom,* [6]*NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom.*

Background: Variation in the human leukocyte antigen (HLA) genes encoded by the major histocompatibility complex (MHC) locus is extensive and mediates risk of autoimmune disease and infection response. HLA presents peptides to the T-cell receptor (TCR), which is formed through somatic recombination of Variable (V), Diversity (D) and Joining (J) gene segments. While bulk sequencing has been used to study HLA-TCR associations, single-cell sequencing allows a more granular investigation of these relationships at the individual cell level.

Material and Methods: We analysed 228,588 single T cells from the COVID-19 Multi-omics Blood Atlas (COMBAT) Consortium, integrating TCR repertoire data with HLA genotypes from 100 donors. We used linear regression models to identify associations between genetic variations in the MHC locus and features of the TCR repertoire, including V-gene segment usage, while adjusting for age and sex.

Results: As expected, we observed cell type-specific associations between MHC variants and the TCR repertoire, particularly with TCR alpha chain V- gene segment usage. Notably, amino acid changes in position 13 in HLA-DRB1 are associated with increased usage of TRAV20 in naive CD4+ T cells (beta = 0.738, p = 1.16e-09) compared to central memory CD4+ T cells (beta = 0.268, p = 0.0533).

Conclusion: Our findings demonstrate that HLA genotype influences TCR repertoire in a cell type-specific manner, reinforcing the importance of single-cell resolution analyses to uncover dynamic HLA-TCR associations.

P09.007.A Early Genetic Diagnosis of ELANE-Related Neutropenia: Insights from a Global Primary Immunodeficiency Screening Program

Irene Perea-Romero[1], *Enrique Fernández-Tabanera*[1], *Miriam León-Otegui*[1], *Elena Ordoñez*[2], *Bibiana Palao*[1], *Raquel Bernad*[1], *Naroa Martín*[1], *Germán Benito*[1], *Mireia Lechuga*[2], *Isabel Castilla*[2], *María Moreno*[1], *Vincenzo Cirigliano*[2], *Luis Izquierdo*[1], *Jessica Quinn*[3], *Vanessa Tenembaum*[3], *Fred Modell*[3]

[1]*Veritas Genetics, Madrid, Spain,* [2]*Veritas Genetics, Barcelona, Spain,* [3]*Jeffrey Modell Foundation, New York, NY, USA.*

Background: Primary Immunodeficiencies (PI) are a group of more than 450 inherited conditions affecting the immune system. Early and accurate diagnosis of PI is crucial for accessing appropriate treatment and significantly improving patient outcomes.

Material and Methods: Prospective analysis and clinical assessment were accomplished for 1591 affected individuals with

PI through the Jeffrey Modell Foundation (JMF) program. Molecular diagnoses were performed using a next-generation sequencing approach by analyzing a 575 PI-related gene panel.

Results: Overall, 21% (334/1591) of the patients studied were genetically characterized. The genetic analysis revealed 5 cases with heterozygous variants in the ELANE gene (4 males and 1 female; median age 2.75 years), from Latin America (n = 3), Asia (n = 1), and Europe (n = 1). All diagnosed cases presented a similar clinical manifestation, starting in the first months of life and characterized mainly by neutropenia (in all 5 patients), abnormality of granulocytes (n = 3), recurrent infections (n = 2), fever (n = 2), and anemia (n = 2). All identified disease-causing variants, 4 missense and 1 nonsense variant in the last exon, were located in the Peptidase S1 domain and expected to have a dominant-negative effect.

Conclusion: JMF emphasizes the critical importance of early and accurate PI diagnosis for timely access to effective treatments and improvement of patient outcomes, as exemplified by the management of ELANE-related neutropenia through early identification of disease-causing variants and Granulocyte-Colony Stimulating Factor (G-CSF) therapy.

P09.008.B Combining next generation sequencing and cytogenetics for the diagnosis of ICF1 syndrome

Mar Xunclà[1,2], *Irene Valenzuela*[1,2], *Amaia Lasa-Aranzasti*[1,2], *Laura Batlle-Masó*[3], *Andrea Martín-Nalda*[4], *Elena García-Arumí*[1,2], *Eduardo F. Tizzano*[1,2], *Roger Colobran*[1,3,5]

[1]*Department of Clinical and Molecular Genetics. Hospital Universitari Vall d'Hebron, Barcelona, Spain,* [2]*Medicine Genetics Group. Vall d'Hebron Institut de Recerca (VHIR). Hospital Universitari Vall d'Hebron, Barcelona, Spain,* [3]*Translational Immunology Group. Vall d'Hebron Institut de Recerca (VHIR). Hospital Universitari Vall d'Hebron, Barcelona, Spain,* [4]*Pediatric Infectious Diseases and Immunodeficiencies Unit. Hospital Universitari Vall d'Hebron, Barcelona, Spain,* [5]*Immunology Division. Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: Immunodeficiency, centromeric instability, and facial dysmorphism (ICF) syndrome type 1 (ICF1, OMIM #242860) is a rare autosomal recessive disorder characterized by immunodeficiency of variable extent, mild facial anomalies and chromosomal instability. It is caused by variants in the *DNMT3B* gene.

Material and Methods: NGS, G-band cytogenetic analysis.

Results: The patient was a 1-year-old boy who presented with recurrent infections, hypogammaglobulinemia and low B cells, pointing to a primary immunodeficiency (PID). Genetic analysis using targeted NGS-PID panel (461 genes), identified two rare heterozygous variants in the *DNMT3B* gene. The first variant, c.1957G>A/p.Asp653Asn had been described in the literature in a patient with ICF1 syndrome in *trans* with another likely pathogenic variant and was therefore classified as likely pathogenic (LP). The second variant, c.2185G>A/p.(Ala729Thr), considered pathogenic by most computational predictors, had not been previously reported in the literature and was classified as a variant of uncertain significance (VUS). Parental testing confirmed that the variants were in *trans* in the patient. Given the presence of a LP and VUS in the patient, we performed cytogenetics analysis to confirm ICF1. Chromosomal analysis showed that 44% of metaphases displayed alterations in the juxtacentromeric heterochromatin of chromosomes 1 and 16, including multibranched configurations and heterochromatin decondensation, findings characteristic of ICF1 syndrome.

Conclusion: The cytogenetic findings allowed to reclassify the c.2185G>A/p.(Ala729Thr) variant as LP, confirming the diagnosis of ICF1 syndrome in the patient. This study illustrates the importance of integrating modern sequencing techniques (NGS) and classical cytogenetic methods to reach a definitive genetic diagnosis.

P09.009.C A novel mutation in proteasomal gene *PSMD7* results in dysregulated protein degradation, enhanced inflammasome activation, and interferon response

Eirini Kalogerakou[1], *Katariina Nurmi*[1], *Gonçalo Barreto*[1], *Kristiina Silventoinen*[1], *Mikko R. J. Seppänen*[2,3], *Kari K. Eklund*[1,4,5]

[1]*Faculty of Medicine, Clinicum, Translational Immunology Program, Helsinki, Finland,* [2]*Adult Immunodeficiency Unit, Infectious Diseases, Inflammation Center, University of Helsinki and Helsinki University Hospital, Helsinki, Helsinki, Finland,* [3]*Rare Disease Center, Children and Adolescents, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [4]*Department of Rheumatology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [5]*ORTON Orthopaedic Hospital, Helsinki, Finland.*

Background: Necrotizing fasciitis (NF), is a severe infectious disease affecting soft tissues. Recent findings suggest that germ line mutations of genes regulating the innate immune responses may predispose to NF and trigger an autoinflammatory form of NF. We describe a patient who presented with NF and carried heterozygous variants in *TRIM23*, *PSMD7* and *PSMA5*. PSMD7 is a proteasome 26S subunit, which is critical for degradation of ubiquitinated proteins in the proteasome. Increased *PSMD7* expression has been associated with cancer, but the impact of PSMD7 in inflammation is not well understood. The patient had persistent severe inflammation which was ameliorated with IL-1β receptor antagonist anakinra.

Material and Methods: To characterize the role of PSMD7 in immune cells, we utilized CRISPR-Cas9 to create THP-1 cell lines carrying heterozygous *PSMD7* knockout (KO). Patient-derived macrophages and *PSMD7 KO* cells were stimulated with lipopolysaccharide (LPS) and inflammasome activators. NLRP3 inflammasome activation, proteasome function and interferon response were studied.

Results: Patient derived macrophages and *PSMD7 KO* cells responded to NLRP3 inflammasome activation with increased IL-1β secretion, and expression of interferon beta 1, followed by enhanced interferon response. Loss of *PSDM7* affected proteasomal activity, with patients and KO cells exhibiting higher intracellular and extracellular ubiquitin levels.

Conclusion: Ubiquitination is essential for maintaining homeostasis under steady state and inflammatory conditions, especially in regulation and degradation of NLRP3 inflammasome. Loss of proteasomal lid subunit PSMD7, elevates ubiquitin levels, enhances NLRP3 inflammasome activation and increases interferon response. Proteasomal dysfunction may predispose to hyperinflammation and NF.

Background: Autoinflammatory disorders (AIDs) are genetically heterogeneous conditions characterized by episodic or persistent unprovoked inflammation caused by aberrations in various components of innate immunity. The clinical diagnosis of these disorders is challenging due to their highly diverse and overlapping phenotypes.

Material and Methods: We recruited 193 families (200 individuals) with clinical findings suggestive of AIDs from September 2021 till August 2023. Exome sequencing (ES) was carried out after detailed clinical evaluation.

Results: The predominant clinical findings at presentation in 200 affected individuals were recurrent fever (82%), arthritis (60%), urticaria (44%), abdominal pain (21%), oral ulcer (21%), uveitis (14%), and cutaneous polyarteritis nodosa (8%). Most of the patients exhibited elevated levels of inflammatory markers (70%). Molecular diagnosis was achieved in 58 out of 193 families (30%). Of these, twelve (20%) families had type I interferonopathies (*DNASE1L3, C1QA, C1QB, ACP5, DNASE2, ADA2*), seven (12%) families had defects affecting inflammasomes (*MVK, NLRP12, NLRP3*), and sixteen (28%) families had non-inflammasome related conditions (*NOD2, TNFRSF1A, LPIN2, SLC29A3, TNFAIP3, RIPK1, DOCK11, IL1RN*). Twenty-three (40%) families had variants in genes causing other monogenic conditions mimicking AIDs (*LEMD3, AP1G1, TBXAS1, LACC1, ELANE, TGFB1, PLG, GPNMB, KRAS, NCSTN, RETREG1, TBXAS1, STXBP2, IRAK4, NFKBIA, JAK3, PRG4*). We identified 50 disease-causing variants in 34 distinct genes in 58 families. Among these, twenty-one (42%) variants were novel.

Conclusion: We highlight the utility of ES as a diagnostic tool in identification of monogenic AIDs, which will aid in ending the diagnostic odyssey and facilitate in personalized therapy.

Background: The etiology of immunodeficiencies with suspected Mendelian inheritance is comparatively poorly understood. In an attempt to identify novel genes underlying these phenotypes, we systematically analyzed exome data for CNVs beyond established disease genes.

Material and Methods: Exome sequencing was performed for 112 cases with suspected immunodeficiency (46% singletons, 47% trios), rare CNVs determined using ExomeDepth. In a first tier, a diagnostic panel of 449 genes was analyzed (PMID: 35748970). In 90 patients, the analysis was extended to all genes and confirmed with customized MLPA assays in a subset of cases.

Results: We identified a pathogenic SNVs (LP/P) in seven established genes (20% diagnostic yield). Systematic analysis of exome data revealed 1.4 CNV per individual, in total 112 CNVs affecting 156 genes, including 69 immune-related genes. MLPA-based validation of the first 44 CNVs (22 duplications, 22 deletions) confirmed 29 CNVs (66%) including all inherited ones, although the size of seven differed. As expected, confirmed CNVs were significantly larger ($p = 0.0047$; median: 4 exons, range 1–23) than unconfirmed ones (2 exons (1–4)). Nevertheless, 52% of the smaller CNVs (1–4 exons) could be confirmed. These were good candidate genes, as they encode proteins of metabolite interconversion enzymes, RNA metabolism and protein modifying enzymes.

Conclusion: Genome-wide CNV-analysis from exome data allowed detecting novel candidate genes for primary immunodeficiencies, while whole genome sequencing is advantageous in molecular characterization. Heterogeneity is high, since mostly a single case each was identified, requiring multicentric cooperation for genetic validation. Further studies will allow a better understanding of primary immunodeficiencies.

P09.012.B Building an immune cell atlas from diverse Latin American (LATAM) populations

Tarran S. Rupall[1], *Bess Chau*[1], *Carla P. Jones*[1], *Anna Lorenc*[1], *Marina Fernandez*[2], *Danilo Ceschin*[2], *Pablo A. Romagnoli*[2], *Yesid Cuesta-Astroz*[3], *Maximiliano Berro*[4], *Marcela Sjoberg*[5], *Luis Tataje-Lavanda*[6], *Alejandra Medina-Rivera*[7], *Gosia Trynka*[1]

[1]*Wellcome Sanger Institute, Hinxton, United Kingdom,* [2]*Centro de Investigación en Medicina Traslacional "Severo R. Amuchástegui", Instituto Universitario de Ciencias Biomédicas de Córdoba, Córdoba, Argentina,* [3]*Instituto Colombiano de Medicina Tropical, Universidad CES, Medellín, Colombia,* [4]*Hospital De Clínicas,Universidad de la República, Montevideo, Uruguay,* [5]*Pontificia Universidad Católica De Chile, Santiago, Chile,* [6]*Universidad Privada San Juan Bautista, Lima, Peru,* [7]*Universidad Nacional Autónoma de México, Mexico City, Mexico.*

Latin American (LATAM) populations are under-represented in genetic and genomic studies, hampering the discovery and translation of such studies across populations. We aim to expand our understanding of these populations by mapping the impact ancestral genetic diversity has on cell composition and gene regulation in peripheral blood mononuclear cells (PBMC) in healthy individuals using single-cell technologies. Here, we describe a new experimental workflow to enrich common and rare immune cell types for single-cell (sc) multiomic assays.

PBMCs are collected and cryopreserved in Mexico, Argentina, Colombia, Peru, Chile and Uruguay. We applied spectral flow cytometry (FACS) to enrich 13 different immune cell types into six buckets: CD4 T, CD8 T, B, NK, myeloid (monocytes and dendritic cells) and rare (Treg, gdT, NKT, ILC, progenitor B, dnT and dpT cells). We generated scRNA-seq and CITE-seq (130 cell surface proteins) data.

We developed a 16-colour spectral FACS panel to identify key cell type markers for sorting. Post-sort purity checks reveal minimal cellular contamination in each sorted bucket. Our initial scRNA-seq and CITE-seq data set demonstrates the sorting strategy provides better cell capture; increasing detection of rare cell types, such as Treg, which increase in proportion by ~3-fold in scRNAseq data compared to FACS.

Here, we demonstrate our approach enables robust data generation and we will scale this up by generating scRNA-seq, CITE-seq and scATAC-seq data for 160 individuals, capturing ~2M cells. This comprehensive immune cell atlas will improve our understanding of genetic and environmental influences on the immune system from diverse LATAM populations.

Background: Mendelian Susceptibility to Mycobacterial Diseases (MSMD) is a rare immunodeficiency that increases susceptibility to infections from pathogens like BCG vaccine, Mycobacterium tuberculosis, non-tuberculous species, and Salmonella strains. The role of IFN-I in MSMD is not fully understood, and its effects on risk stratification and treatment options are not well understood. This study examines the regulation of interferon-stimulated genes in MSMD patients to understand their impact on disease progression and IFN signature test scores.

Material and Methods: The study involved 18 MSMD cases and 20 healthy controls, using RNA isolation, cDNA synthesis, and SYBR-Green real-time quantitative PCR methods to determine gene expression levels involved in the Type I IFN pathway including STAT1, PRKR, IFI27, IFI44, IFI44L, IFIT1, RSAD2, MX1, and LY6E. Statistical analyses were performed using SPSS 16.0 software, with a p-value of <0.05 considered significant.

Results: In 77% of MSMD patients, a high IFN signature score (>7) was observed, attributed to increased expression of the IFIT1, PRKR, and MX1 genes compared to controls ($p = 0.004$, $p = 0.03$, and $p = 0.02$). Conversely, the expression levels of the IFI27 and RSAD2 genes were found to be decreased ($p = 0.01$ and $p = 0.02$).

Conclusion: The study evaluated the activation of the Type I interferon (IFN-I) pathway in MSMD patients and explored the use of the IFN signature test as a biomarker. The results suggest that IFN-I inhibitors could be a potential treatment option for patients with pronounced IFN-I activation, in addition to standard treatments like antibiotics, IFN γ therapy, or hematopoietic stem cell transplantation.

P09.014.D Blended phenotypes in congenital neutropenia: Contribution of consanguinity

Dilsu Dicle Erkan[1], *Sule Unal Cangul*[2,3], *Arda Cetinkaya*[1,3,4]

[1]*Medical Genetics Department, Faculty of Medicine, Hacettepe University, Ankara, Turkey,* [2]*Pediatric Hematology Department, Faculty of Medicine, Hacettepe University, Ankara, Turkey,* [3]*Research Center for Fanconi Anemia and Other Inherited Bone Marrow Failure Syndromes, Hacettepe University, Ankara, Turkey,* [4]*Bioinformatics Department, Institute of Medical Sciences, Hacettepe University, Ankara, Turkey.*

Background: Congenital neutropenia (CN) is a rare disorder (1/10,000) characterized by reduced neutrophil counts and recurrent infections. CN can be isolated or syndromic, and is linked to >30 genes. Traditionally, CN with additional clinical features has been linked to monogenic causes. However, considering the emerging concept of blended phenotypes, we investigated whether multiple pathogenic variants in distinct genes could explain CN with extra-clinical findings.

Material and Methods: We evaluated 24 CN patients without pathogenic variants in *ELANE*, *HAX1*, *TAZ*, *SLC37A4*, or *SBDS*. Nine had additional unexplained clinical findings. Clinical and/or whole exome sequencing (Twist 2.0, KAPA HyperCap) was performed for all. Microarray was conducted in 19 individuals to assess CNVs and homozygosity regions.

Results: Eight (33.4%) of 24 individuals had at least one monogenic variant explaining CN. Six had multiple pathogenic variants in at least two genes, explaining their complex phenotype. Interestingly, an individual with blended phenotype diagnosed with benign ethnic neutropenia due to a nonrare variant in *ACKR1*, congenital hearing loss and abdominal pain attacks explained by variants in *GJB2* and *PPOX*. Notably, five of six individuals with reported parental consanguinity or extensive homozygosity regions had blended phenotypes. One consanguineous individual had a homozygous *RINT1* variant, explaining both liver failure and neutropenia.

Conclusion: This study highlights the complicated genetic landscape of CN in a consanguineous population. Additional phenotypic features in individuals with consanguineous parents is a good indicator of multiple disease-causing genes in our cohort. This emphasizes the need for comprehensive genetic testing to fully explain their clinical phenotype.

P09.015.A Thymus-regulating genetic variant rs2204985 associated with overall survival in stem cell but not in solid organ transplantation

Julia Nihtilä[1], *Albert Rosenberger*[2], *Silja Tammi*[1], *Maria Semenova*[1], *Urpu Salmenniemi*[3], *Maija Itälä-Remes*[4], *Rachel E. Crossland*[5], *David Gallardo*[6], *Katarzyna Bogunia-Kubik*[7], *Ilkka Helanterä*[8,9], *Fredrik Åberg*[8,9], *Kati Hyvärinen*[1], *Jukka Partanen*[1], *Jarmo Ritari*[1]

[1]*Finnish Red Cross Blood Service, Helsinki, Finland,* [2]*Department of Genetic Epidemiology, University Medical Center, Georg August University Göttingen, Göttingen, Germany,* [3]*Comprehensive Cancer Center, Stem Cell transplantation Unit, Helsinki University Hospital, Helsinki, Finland,* [4]*Turku University Hospital, Turku, Finland,* [5]*Translational and Clinical Research Institute, Faculty of Medical Science, Newcastle University, Newcastle, United Kingdom,* [6]*Department of Hematology, ICO Girona, Girona, Spain,* [7]*Laboratory of Clinical Immunogenetics and Pharmacogenetics, Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland,* [8]*Transplantation and Liver Surgery, Helsinki University Hospital, Helsinki, Finland,* [9]*University of Helsinki, Helsinki, Finland.*

Background: The thymus is crucial for educating T cells to achieve central immunological tolerance, a key feature in successful transplantation. Recently, variants in the T cell receptor (TCR) gene were linked to thymus function [1]. We and others have reported inferior overall survival (OS) with donor rs2204985 AA genotype in allogeneic stem cell transplantations (HSCT) [2-3].

Material and Methods: We investigated four TCR variants in (i) HSCT cohorts from Finland (n = 765 donors, n = 1305 recipients), UK (n = 334 donors, n = 403 recipients), and Poland (n = 102 donors, n = 168 recipients), (ii) an independent HSCT cohort from Germany (n = 703 donors, n = 1331 recipients); and (iii) two solid organ transplantation cohorts from Finland (n = 1025 kidney transplants [4]; n = 666 liver transplants [5]). Data were analyzed using meta-analysis of multivariate cox proportional hazard survival models against OS.

Results: In a meta-analysis of HSCT cohorts (i) and (ii), the rs2204985 G allele was additively associated with improved OS (HR = 0.880, 95% CI 0.777–0.996, p-value 0.043), supporting our previous meta-analysis results (AA genotype HR = 1.23, 95% CI 0.94–1.96) [3]. No significant associations were observed in solid organ transplantations.

Conclusion: The T cell receptor variant rs2204985, which regulates thymus function, is associated with HSCT outcome. This finding is functionally plausible, as the entire hematopoietic system is replaced in HSCT, requiring donor immune cells to undergo thymic education and selection. In solid organ transplantations, peripheral tolerance may be more important.

P09.016.B Transcripts containing retrotransposable elements play a regulatory role in modulating the functions of tumor infiltrating lymphocytes

Francesco Panariello[1,2], *Rebecca Vadalà*[1,2], *Valeria Ranzani*[1], *Alen Stambolliu*[1,3], *Benedetto Polimeni*[1,2], *Michele Panepuccia*[1,3], *Federica Marasca*[1], *Sergio Abrignani*[1,2], *Beatrice Bodega*[1,2]

[1]*National Institute of Molecular Genetics (INGM), Milan, Italy,* [2]*Department of Clinical Science and Community, University of Milan, Milan, Italy,* [3]*SEMM, European School of Molecular Medicine, Milan, Italy.*

Background: Unravelling Tumor Infiltrating Lymphocytes (TIL) heterogeneity is essential to develop more effective

immunotherapies. We have recently highlighted the role of LINE1, the predominant class of Retrotransposable Elements (RE), in regulating TIL exhaustion by integrating in transcripts related to T cell activation and downregulating their canonical isoforms. Nevertheless, the role of RE expression as a determinant of TIL diversity and function remains poorly explored.

Material and Methods: We have isolated CD3+ and CD45+ T cells from tumor resections of Non-Small Cell Lung Cancer (NSCLC) and Colorectal Cancer (CRC) patients. Due to the challenging task of studying transcripts containing RE with current single-cell technologies, we performed both long- and short-read scRNA-seq. We have developed a pipeline to analyze long-read data to generate a cancer-specific Atlas of RE-transcripts that we quantified at isoform level using full-length short-read data.

Results: We described approximately 40,000 novel transcripts that are specific to NSCLC and CRC, with some shared instances. Almost 46% of them included REs, resembling their genomic distribution. Trajectory inference analysis confirmed the positive correlation between LINE1 and exhausted TILs, but it also revealed an enrichment of Alu-containing transcripts in active T cells, while regulatory T cells (Treg) and follicular T helper cells (Tfh) mostly expressed transcripts containing the LTR class.

Conclusion: To elucidate the relevance of RE-transcripts in TIL identity, we will leverage CRISPR-Cas13 system to specifically modulate them and evaluate their impact, introducing the innovative concept that RE transcripts may serve as novel immunological checkpoints and a promising avenue for cancer therapy.

Introduction: Proteasome-associated autoinflammatory syndromes (PRAAS) are disorders caused by immunoproteasome dysfunction. The immunoproteasome is a large protein complex, its core consisting of the catalytic subunits β1i, β2i and β5i. We describe two cases with monoallelic de novo variants in *PSMB8*, encoding β5i, showing features distinct from the classical PRAAS phenotype associated with autosomal recessive mutations.

Materials: Two independent individuals were identified through genome sequencing. Subsequently, phenotypic data, immunophenotyping profiles and interferon scores were collected. Variant effects on proteasome assembly were assessed by complexome profiling—a mass spectrometry-based proteomics technique—on interferon-gamma-stimulated patient-derived fibroblasts.

Results: Individuals presented with early-onset autoinflammation with immunodeficiency. Features consistent with PRAAS included systemic inflammation, microcytic anemia, skin rash, myositis and liver dysfunction, although lipodystrophy nor joint contractures were present. Patients also presented recurrent infections, chronic inflammatory airway disease and pulmonary hypertension, and enteropathy. Immunological investigations in both patients revealed B and NK lymphopenia, reduced switched memory B cells with hypogammaglobulinemia, and an elevated interferon signature. Genome sequencing identified a de novo variant in *PSMB8* in each individual: NM_148919.4:c.704C>A;p.(Ala235Asp) and NM_148919.4:c.269C>T;p.(Ser90Phe). Complexome profiling of p.(Ala235Asp) revealed disrupted immunoproteasome assembly, resulting in reduced abundance while leaving the constitutive proteasome unaffected. Furthermore, there was an accumulation of assembly intermediates of the immunoproteasome complex that did not contain β5i.

Conclusion: We describe two individuals with early-onset systemic autoinflammation and immunodeficiency, caused by monoallelic de novo variants in *PSMB8* that disrupt immunoproteasome assembly, likely acting through negative dominance. This report expands the spectrum of PSMB8-associated disease and PRAAS in general.

P09.018.D Molecular features of Familial Mediterranean Fever and Pro-inflammatory Cytokines Levels in Patients with Various *MEFV* Pathogenic Variants

Ekaterina Deviatkina, *Sofia Burbygina, Anastasia Musonova, Vladimir Nazarov, Darya Sidorenko, Sergey Lapin, Polina Fedorova, Darya Banina, Salim Tarchokov*

First Pavlov State Medical University of St. Petersburg, Saint Petersburg, Russian Federation.

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease manifested by recurrent fever with signs of systemic inflammation caused by *MEFV* pathogenic variants that lead to inflammasome hyperactivation and hyperproduction of IL-1β and IL-18. FMF is a disorder with variable expressivity and penetrance: heterozygous variants carriers can develop FMF phenotypes.

Material and Methods: The study included 1271 samples positive for pathogenic variants in *MEFV*, identified by sequencing of 2, 3, 5, 10 exons. Concentrations of CRP, IL-6, IL-8 and IL-18 were measured by ELISA for 3 groups: 95 patients (FMF) with different MEFV genotypes (homozygous (n = 18), compound-heterozygous (n = 27), heterozygous (n = 34), heterozygous variants with

variant of unknown significance (VOUS) (n = 9) and only VOUS (n = 9)), patients with systemic lupus erythematosus (SLE, n = 49) and a group of healthy donors (HD, n = 16).

Results: From 1271 samples, homozygous for pathogenic variants was 11,49%, compound-heterozygous - 27,69%, heterozygous - 42,17%, heterozygous/VOUS - 5,90% and VOUS - 12,75%. 32 variants were detected, the most common were p.Met694Val (39,89%), p.Val726Ala (19,12%), p.Met680Ile (13,86%). Concentrations of CRP, IL-6 and IL-18 in FMF group was significantly higher than in HD and SLE groups (P < 0.0001). Concentration of IL-18 was significantly higher in all FMF subgroups than in HD. Comparing IL-18 levels between different pathogenic *MEFV* variants, samples with «aggressive» variants (p.Met694Val and p.Met680Ile) were characterized by increased concentration of IL-18 (P = 0.0411).

Conclusion: Patients with FMF in this study characterized by classic spectrum of *MEFV* variants with high prevalence of «aggressive» genotypes. Pro-inflammatory markers' levels depend on *MEFV* genotype and specific variants.

P09.019.A Clonal Hematopoiesis in People Living With HIV: Association With Aging and Inflammation

Valeriia Timonina[1], *Konstantin Popadin*[2], *Jacques Fellay*[1,3]

[1]*EPFL, Lausanne, Switzerland,* [2]*Immanuel Kant Baltic Federal Univercity, Kaliningrad, Russian Federation,* [3]*CHUV, Lausanne, Switzerland.*

Background: Clonal Hematopoiesis of Indeterminate Potential (CHIP) is the accumulation of leukemogenic somatic mutations, strongly linked to aging, increased mortality, and age-related diseases. One proposed mechanism is that CHIP marks chronic inflammation. If so, People Living With HIV (PLWH), who already experience heightened inflammation, should (i) exhibit accelerated aging, (ii) have increased CHIP prevalence, and (iii) show even greater inflammation and more severe age-related phenotypes when CHIP is present. Since (i) and (ii) are well established, we focus on (iii)—how CHIP and HIV are linked to inflammation and aging.

Material and Methods: We screened 1,636 participants (≥60 years) from the Swiss HIV Cohort Study (SHCS) for CHIP with a targeted panel covering 24 genes, with a median sequencing coverage of 737X. CHIP was detected in 414 individuals (25.3%).

Results: As expected, CHIP was associated with age, accelerated epigenetic aging, and increased all-cause mortality, with stronger associations for larger clone sizes and multiple CHIP variants. However, age-related diseases demonstrated either the absence of association with CHIP, or gene-specificity.Additionally, CHIP was associated with lower CD4-T-cell count, higher CD8-T-cell count, lower CD4:CD8 ratio, and higher HIV load, even after adjusting for ART initiation, potentially suggesting an increased inflammation level and immune dysregulation.

Conclusion: We demonstrated expected associations of CHIP with a proxy of inflammation and aging in PLWH, but not all age-related diseases showed consistent trends, which might mean a complex interaction of HIV and CHIP and different CHIP-related effects on health in the context of HIV.

P09.020.B Germline variants and somatic mosaic chromosomal alterations affect COVID-19 vaccine immunogenicity, infectious diseases, and autoimmune diseases

Yukinori Okada[1], *Kyuto Sonehara*[1], *Yoshifumi Uwamino*[2], *Ryunosuke Saiki*[3], *Koichi Matsuda*[1], *Seishi Ogawa*[4], *Ho Namkoong*[2]

[1]*The Unversity of Tokyo, Tokyo, Japan,* [2]*Keio University School of Medicine, Tokyo, Japan,* [3]*Kyoto University, Kyoto, Japan,* [4]*Kyoto Univrsity, Kyoto, Japan.*

Background: Vaccine immunogenicity is influenced by the vaccinee's genetic background.

Material and Methods: We performed GWAS of vaccine-induced SARS-CoV-2-specific IgG antibody titers and T-cell immune responses in Japanese cohorts (mRNA-1273 and BNT162b2, *N* = 2086).

Results: We identify associations with SARS-CoV-2-specific antibody titers at the immunoglobulin heavy chain (IGH) and MHC locus, and associations with the T-cell responses at MHC. The lead variants at IGH contain a missense variant (rs1043109-C; p.Leu192Val) in the Immunoglobulin Heavy Constant Gamma 1 gene (*IGHG1*), which strongly decreases the antibody titers ($\beta = -0.54$) and is rarely present in Europeans, highlighting the importance of genetic studies in various populations. SARS-CoV-2-specific antibody serostatus data from the UK Biobank (UKB; *N* = 152,906) independently reveal associations at the IGH, MHC, immunoglobulin kappa light chain and 16p11 locus. HLA imputation analyses in the Japanese cohorts pinpoint *HLA-DRB1* as the strongest determinant of the antibody titers, and *HLA-DRB1* and *HLA-DPB1* as that of the T-cell responses within MHC. Blood proteome profiles (2,932 Olink Explore proteins) from 4,236 individuals demonstrate that antibody titer-associated variants modulate circulating immune regulators, including LILRB4 and FCRL6. In addition to germline mutations, age-related somatically expanded mosaic chromosomal alterations (mCA) affecting MHC and IGH impair SARS-CoV-2-specific antibody production. Furthermore, MHC/IGH-affecting expanded mCAs confer risk of infectious and immune diseases, such as sepsis and Graves' disease, in Japanese and European biobanks ($N_{Total} = 663{,}133$). Expanded mosaic loss of sex chromosomes (X or Y) impact such phenotypes including rheumatoid arthritis.

Conclusion: Our results underscore the contribution of both germline and somatic mutations to adaptive immunity functions.

P09.021.C A genomic upgrade to 2139 genetic variants in the interactive coagulation factor IX database provides enhanced insights into hemophilia B

Taner Karagöl[1], *Alper Karagöl*[1], *Holly J. Spencer*[2], *Ziqian Xu*[2], *Stephen J. Perkins*[2]

[1]*Department of Medicine, Royal Free Hospital, University College London, London, United Kingdom,* [2]*Research Department of Structural and Molecular Biology, University College London, Darwin Building, London, United Kingdom.*

Background: *F9* gene variants are frequently associated with the rare bleeding disorder hemophilia B. These have been compiled in our widely-used coagulation factor IX (FIX) variant database (https://www.factorix.org) from 2013 and updated in 2022. Here,

we report the introduction of new variant analysis tools, along with corrections and a significant increase of new *F9* variants.

Material and Methods: A total of 513 new *F9* variants and 2358 new clinical cases were analyzed, resulting in an updated count of 2139 *F9* variants and 7710 related patient cases. *F9* variants were identified from peer-reviewed publications and genomic databases, and incorporated into our database. Given a recent increase in reported pre-mRNA alterations in *F9*, we implemented deep neural network-based tools and phenotypical predictions in our dataset.

Results: The *F9* variants cover 424 (92%) of the 461 FIX residues, including 20 newly reported ones. These total 1542 point mutations, 336 deletions, 97 polymorphisms, 69 duplications, and 95 other types. While point variants remain predominant (72%), non-coding sequence variants increased by 119%, with 361 point variants in UTRs or introns. According to patient cases, p.Arg43Trp and p.Ile443Thr showed severity changes. Inhibitor risk in severe hemophilia B cases was calculated as 6.4%.

Conclusion: New recent expansions to the FIX database and its biocuration process have been described. Most variants are associated with minor structural changes in the FIX protein, while others are associated with alterations in pre-mRNA processing of the gene. The updated database will assist clinicians and researchers in assessing treatments for hemophilia B patients.

P09.022.D Mainstreaming genomic testing for paediatric inborn errors of immunity

Emily DeBortoli[1], Tenielle Clinch[1], Aideen McInerney-Leo[1], Anna Sullivan[2], Alberto Pinzon-Charry[2], Mariana Melo[2], Jane Peake[2], Peter McNaughton[2], ***Tatiane Yanes***[1]

[1]University of Queensland, Brisbane, Australia, [2]Queensland Children's Hospital, Brisbane, Australia.

Background: A mainstreaming model-of-care (MoC) was established in Queensland, Australia to support genomic testing (GT) for paediatric inborn errors of immunity (IEI). The model's feasibility and acceptability among clinicians and families have previously been demonstrated. However, its long-term impact remains unknown, and this clinical cohort has not yet been characterised within an Australian context. This study aimed to i) evaluate the long-term impact of the MoC on GT practices and patient outcomes ii) describe the first Australian cohort of paediatric IEI

Methods: A retrospective audit and chart review were conducted to identify all instances of paediatric IEI GT in Queensland from 2017–2024. Data collected included demographics, indication for GT, GT instances, testing modality, results, and testing outcomes. GT ordering and interpretation behaviours were reviewed to evaluate the impact of the MoC.

Results: 261 patients were identified as meeting the inclusion criteria for the audit. The mean age of GT was seven years, and the most common indication for testing was inflammatory bowel disease (n = 25, 14%). There was a linear increase in the number of patients tested from 2017–2018 (n = 40) to 2021 (n = 50), which reduced post-MoC implementation (n = 36 2022; n = 37 2023; n = 26 2024). Diagnostic rates improved post-MoC implementation, at 18% and 23%, respectively. Improved documentation related to GT was noted, including recording informed consent, results, variant interpretation, and familial considerations.

Conclusion: A mainstreaming MoC improves paediatric IEI GT practices. Developing an IEI database will allow for ongoing tracking of GT, description of clinical cohort, and evaluation of future services.

P09.023.A Genome-wide aggregated *trans*-effects analysis detects key role of immune checkpoint signalling in Sjögren's disease

Athina Spiliopoulou[1], *Andrii Iakovliev*[2], *Buddhiprabha Erabadda*[1], *Paul M. McKeigue, Professor of Genetic Epidemiology and Statistical*[1]

[1]Usher Institute, University of Edinburgh, Edinburgh, United Kingdom, [2]Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom.

Background: Sjögren's disease (SjD) is an autoimmune condition that frequently co-occurs with rheumatoid arthritis. We have previously reported that genome-wide aggregated *trans*-effects (GATE) analysis identifies up to 15 core genes for rheumatoid arthritis, of which seven encode immune checkpoints. The objective of this new study was to determine whether these core genes are relevant to SjD also.

Material and Methods: Using publicly available summary statistics for genotype associations with transcript levels in whole blood (eQTLGen) and circulating proteins on the Somalogic or Olink platforms (DeCODE, UK Biobank), GATE scores were calculated in 950 cases of primary SjD (without rheumatoid arthritis when first diagnosed) and 459105 non-cases of European ancestry in UK Biobank.

Results: The top core gene for rheumatoid arthritis - *PDCD1*, encoding the immune checkpoint PD-1 - was also the top core gene for primary SjD (standardised GATE score log odds ratio 0.23, $p = 2 \times 10^{-7}$). Of the six other immune checkpoint genes identified as core genes for rheumatoid arthritis, three - *TIGIT*, *TNFRSF14*, *LILRA4* - were associated in the same direction with SjD at $p < 0.01$.

Conclusion: These results establish that genetic downregulation of immune checkpoint signalling increases risk of both SjD and rheumatoid arthritis. The causal role of *PDCD1* is supported by reports of SjD developing as a rare adverse effect of PD-1 inhibitors used to treat cancer. As no disease-modifying treatment for SjD is available, one implication is that PD-1 agonists, now at clinical stage, should be trialled for SjD.

P09.024.B Characterization of a novel *FLI1* mutation in a family with thrombocytopenia and other congenital malformations

Daniele Ammeti[1], *Serena Barozzi*[2], *Alessandro Pecci*[2], *Melania Eva Zanchetta*[1], *Edward Cesnik*[3], *Alessandra Ferlini*[4], *Mariabeatrice Sanchini*[4], *Laura Verga*[2], *Valeria Bozzi*[2], *Fabio Corsolini*[5], *Michela Faleschini*[1], *Anna Savoia*[6], *Stefania Bigoni*[4]

[1]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy, [2]IRCCS Policlinico San Matteo Foundation, Pavia, Italy, [3]Ferrara University Hospital, Ferrara, Italy, [4]Ferrara University Hospital and University of Ferrara, Ferrara, Italy, [5]IRCCS Istituto Giannina Gaslini, Genoa, Italy, [6]University of Verona, Verona, Italy.

Background: FLI1-related thrombocytopenia (FLI1-RT) is an extremely rare disease caused by mutations in *FLI1*, encoding a transcription factor which mutations cause a non-syndromic thrombocytopenia with enlarged platelets. In a family with

thrombocytopenia associated with congenital anomalies, we identified a novel, heterozygous single nucleotide deletion of *FLI1*, which has been characterized from a molecular point of view.

Material and Methods: Genetic analyses were performed by Whole Exome Sequencing and CGH array. Platelet morphology was assessed by light microscopy and transmission electron microscopy. In vitro studies were performed in HEK293T and HeLa cells after overexpression of wild-type or mutant *FLI1* and analysed by immunoblotting, immunofluorescence and dual luciferase assays. In vivo platelets were analysed by immunoblotting and flow cytometry.

Results: The mutant frameshift protein is unexpectedly highy overexpressed in patients' platelets and in vitro models due to its increased stability. Although localised in the nucleus, the mutant protein loses its transcriptional activity, supporting its pathogenic role. Consistently, patients' platelets show alterations of the expression of several biomarkers directly associated with FLI1-RT. The two affected individuals have haematological features consistent with FLI1-RT, such as moderate thrombocytopenia, large platelet size with giant alpha granules and reduced delta granules content.

Conclusion: For the first time, FLI1-RT is observed with other extra-haematological abnormalities, such as cardiac defects, upper limb anomalies and polymicrogyria. Despite extensive genetic analysis, we have not identified other co-segregating mutations associated with the extra-haematological phenotype, suggesting that specific mutations of FLI1 may be responsible for the aetiopathogenesis of a more complex phenotype.

P09.025.C Exploring ERVL-MaLR dynamics in tumor-infiltrating tregs to unveil novel immunotherapeutic candidates

Alen Stambolliu[1,2], *Francesco Panariello*[1], *Michele Panepuccia*[1,2], *Valeria Ranzani*[1], *Federica Marasca*[1], *Beatrice Bodega*[1,3]

[1]*National Institute of Molecular Genetics (INGM), Milan, Italy,* [2]*SEMM European School of Molecular Medicine, Milan, Italy,* [3]*Department of Clinical Science and Community, University of Milan, Milan, Italy.*

Background: The tumor microenvironment (TME) is characterized by heterogeneous immune infiltration, where the dynamic interaction between effector T cells and regulatory T cells (Tregs) plays a central role in driving cancer progression and influencing patient survival. Recently, Retrotransposable Elements (REs) have emerged as key regulators of tumor-infiltrating lymphocyte (TIL) function. We have demonstrated that LINE1-derived transcripts impair the activity of exhausted TILs, but also represent targets to restore T cell effector function. Despite this, the role of RE expression in shaping the function and behavior of pro-tumoral Tregs remains largely uninvestigated.

Material and Methods: REs expression in TILs from tumor and adjacent normal tissues across six independent datasets was quantified using IRescue, a tool developed in our lab for analyzing 10X single-cell RNA sequencing data. Chromatin accessibility of REs in TILs was further investigated using single-cell ATAC sequencing data. Binding motif analysis was performed to identify transcription factor regulatory networks associated with RE activity.

Results: Among all RE families, ERVL-MaLR expression was consistently associated with Tregs across all tumors analyzed. Specific ERVL-MaLR subfamilies were found to be upregulated in tumoral Tregs compared to their counterparts in adjacent normal tissues. Binding motif analysis of ERVL-MaLR-accessible regions identified BATF as a potential transcription factor involved in the regulation of their expression.

Conclusion: This analysis reveals a previously uncharacterized association between ERVL-MaLR expression and tumoral Tregs. Deciphering the regulatory mechanisms underlying ERVL-MaLR expression holds potential for advancing Treg-targeted immunotherapy approaches.

P09.026.D Demonstration of Microchimerism by Short Tandem Repeat Analysis in a Patient with Homozygous Exons 1–3 Deletion in *DCLRE1C* Gene

Lale Yilmaz Celik, *Tuna Eren Esen, Cigdem Aydogmus*

Department of Medical Genetics, Basaksehir Cam and Sakura City Hospital, Istanbul, Turkey.

Background: Severe combined immunodeficiency (SCID) is a group of inherited disorders characterised by severe dysfunctions of the immune system. Transplacental maternal engraftment (TME), the presence of maternal T cells in peripheral blood/bone marrow prior to transplantation, has been reported in patients with SCID. TME is mostly asymptomatic, rarely causing Graft-Versus-Host disease.

Material and Methods: A 6-month-old girl whose lymphocyte profile analysis was compatible with SCID was evaluated. Short tandem repeat (STR) analysis was performed in the skin biopsy of patient and peripheral blood of patient and maternal peripheral blood. Whole exome sequencing was performed from DNA obtained from the skin biopsy of patient.

Results: In STR analysis of patient's peripheral blood and skin biopsy, peaks belonging to maternal STR loci were observed. STR analysis data obtained from maternal and patient's peripheral blood were evaluated as compatible with TME. Short tandem repeat analysis of patient's skin biopsy showed low peak height peaks of maternal STR loci supporting Graft-Versus-Host disease. Whole exome sequencing analysis identified approximately 28 kb homozygous deletion encompassing exons 1–3 of *DCLRE1C* gene. *DCLRE1C* gene has been associated with 'SCID, Athabascan type' and 'Omen Syndrome' with autosomal recessive inheritance.

Conclusion: The ability to assess the rate of TME in patients with SCID will depend on the severity of Graft-Versus-Host disease. TME may pose difficulties in donor selection for haematopoietic stem cell transplantation. summary, this study demonstrates the molecular genetic challenges due to Graft-Versus-Host disease and microchimerism and importance of considering microchimerism in whole exome analysis in SCID patients.

P09.027.A Advancing diagnosis of inborn errors of immunity through exome reanalysis for novel gene-disease associations

Jorge Diogo Da Silva[1,2,3], *Ana Rita Soares*[1,2,4], *Isabel Alonso*[1]

[1]*Genetyca, Atrys, Porto, Portugal,* [2]*Centro de Genética Médica, ULS de Santo António, Porto, Portugal,* [3]*Life and Health Sciences Research Institute, University of Minho, Braga, Portugal,* [4]*Unit for Multidisciplinary Research in Biomedicine, Abel Salazar Biomedical Sciences Institute, Porto University, Porto, Portugal.*

Background: inborn errors of immunity (IEI) are a group of monogenic conditions presenting with immunodeficiency,

autoimmunity and/or autoinflammation. The International Union of Immunological Societies standardizes gene-disease associations, with the recently published 2024 update including over 60 novel entities comparing with the 2022 nosology. We analyzed the database from a genetic diagnostic laboratory with interest in IEIs for variants underlying these novel conditions.

Material and Methods: we reviewed 2082 exome-based NGS studies for variants in 63 novel IEI genes. We excluded frequent variants (MAF>1%), intronic variants with SpliceAI score <0.2, variants with coverage <10x, or with a VUS-low classification.

Results: we identified seven cases with eight candidate heterozygous variants for AD conditions. Two cases had a likely pathogenic variant: a missense *FOXI3* variant in a patient with Alagille syndrome and no immunodeficiency; and a compatible nonsense *OTULIN* variant in a patient with recurrent mild bacterial infections. Two cases had VUS-high variants: one case with a severe hyperthermia reaction and a *JAK1* (VAF 42%) and *ERN1* variant, associated with autoinflammation and immune dysregulation, respectively; one case with recurrent fever and a *JAK1* (VAF 12%) variant. Finally, three cases had one VUS-mid: one case with IgA glomerulonephritis and *ERN1* variant; one case with IgG3 deficiency and recurrent pneumonitis and an *ALPK1* variant, associated with autoinflammation; and one case with *NLRP12*-associated autoinflammation and a *PLCG1* variant, associated with immune dysregulation.

Conclusion: the rapid discovery of IEI genes should lead to reanalysis of exome-based tests, as underlying diagnoses can be detected, improving clinical care.

P09.028.B Genetic diagnosis of hereditary autoinflammatory syndromes in patients with fever of unknown origin

Darya Sidorenko, *Vladimir Nazarov, Sofia Burbygina, Sergey Lapin*

First Pavlov State Medical University of St. Petersburg, Saint-Petersburg, Russian Federation.

Background: Fever of unknown origin (FUO) is a challenging clinical entity, characterized by unexplained repetitive elevation of temperature ≥38.3. The etiological spectrum of FUO is wide. Hereditary autoinflammatory syndromes (HAS) may be one of the main cause of FUO. The aim of this work is to determine the diagnostic value of genetic testing of patients with FUO.

Material and Methods: 442 patients with FUO were selected. The coding sequences of the IL10, IL10RA, IL10RB, IL1RN, LPIN2, MEFV, MVK, NLRP3, NOD2, PLCG2, PSTPIP1, TNFRSF1A genes were tested with NGS panel (ParseqLab©, Russia).

Results: At least one variant in the studied genes was detected in 149 (33.7%) cases. In total 201 variants were found. 132 (65.7%) of them were variants with unknown significance (VUS). *NOD2* gene had the largest number of VUS (52 variants). Likely pathogenic (N = 40, 19.9%) and pathogenic variants N = 29, 14.4%) were found in *MEFV* (N = 64), *MVK* (N = 2) and *NLRP3* (N = 2) genes. Among all 442 patients, diagnosis was verified for 25 individuals (5.7%): 22 patients had Familial Mediterranean fever (*MEFV* gene) and 3 had Muckle-Wells syndrome (*NLRP3* gene). Also, 2 patients were carriers of *MVK* pathogenic variants. 103 patients (23.3%) had genotype with unknow significance (VUS for diseases with AD inheritance) and 21 (4.8%) had genotype with no clinical significance (VUS for diseases with AR inheritance). Negative results of genetic testing were obtained for 293 patients (66.3%).

Conclusion: Prevalence of genetically confirmed HAS in patients with FOU was 5.7%. Group of FOU patients characterized by high prevalence of VUS (65.7%).

P09.029.C Genetic susceptibility to idiopathic pulmonary fibrosis: insights from Sardinian patients

Stefano Mocci[1], *Silvia Deidda*[2], *Caterina Mereu*[1], *Michela Lorrai*[1], *Chiara Cocco*[1], *Gaia Tosone*[1], *Federica Cannas*[1], *Laura Serventi*[1], *Celeste Sanna*[1], *Michela Murgia*[1], *Alessia Mascia*[3], *Marina Serra*[3], *Sara Lai*[4], *Erika Giuressi*[5], *Andrea Perra*[3], *Roberto Littera*[4], *Sabrina Giglio*[1]

[1]*Medical Genetics, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy,* [2]*Pneumology Unit, R. Binaghi Hospital, Cagliari, Italy,* [3]*Oncology and Molecular Pathology Unit, Department of Biomedical Sciences, University of Cagliari, Cagliari, Italy,* [4]*Medical Genetics, R. Binaghi Hospital, Cagliari, Italy,* [5]*Medical Genetics,R. Binaghi Hospital, Cagliari, Italy.*

Background: Idiopathic pulmonary fibrosis (IPF) is a severe interstitial lung disease marked by progressive scarring, loss of lung function, and, ultimately, respiratory failure. Although environmental factors play a role, the growing recognition of genetic predisposition is reshaping our understanding of disease mechanisms. With its distinct genetic background, the Sardinian population provides a unique opportunity to unravel the interplay between common and rare genetic variants in IPF pathogenesis and progression.

Material and Methods: This study leveraged the Sardinian genetic landscape to investigate both the impact of *HLA* alleles and haplotypes and the contribution of rare genetic variants to IPF susceptibility and progression. Through genotyping and WES in a well-characterised cohort, we explored allele frequencies, haplotypes, and pathogenic variants, correlating these findings with clinical outcomes, including response to antifibrotic therapies.

Results: The *HLA-DRB1*04:05* allele and a extended Sardinian haplotype (*HLA-A*30:02, B*18:01, C*05:01, DQA1*05:01, DQB1*02:01, DRB1*03:01*) were strongly associated with slower disease progression, improved survival (Log Rank = 0.032 and 0.01), and better pulmonary function at 36 months ((DLCO%p; p = 0.005 and 0.02). Rare pathogenic variants in *TERT, RTEL1, PARN*, and *CTC1* were identified in 22% of patients, with 12% affecting genes beyond the telomerase pathway, hinting at novel disease mechanisms. Preliminary findings suggest that TERT variants may influence

Conclusion: These unique and original findings provide an unparalleled lens to decode IPF pathogenesis. The Sardinian genetic landscape unveils novel immunological and genetic mechanisms, offering a transformative framework for predictive biomarkers and personalised therapies that could redefine IPF management across diverse populations.

P09.030.D Catalogue of HBB variants: the significance of harmonising HBB nomenclature in variant classification

Dino Hasanagic[1], *Melida Mahinic*[1], *Ana Gutalj*[1], *Kathryn Curry*[2], *Ena Toman*[1], *Maida Ljubijankic*[1], *Betty Mattias*[2], *Jane Beckwell*[2], *Jeffrey Bissonnette*[2], *Denis Trivanovic*[1], ***Amina Kozaric***[1], *Mark J. Kiel*[2]

[1]*Genomenon, Sarajevo, Bosnia and Herzegovina,* [2]*Genomenon, Ann Arbor, MI, USA.*

Background: The HBB gene encodes the beta-globin subunit of haemoglobin and variants in this gene are associated with various haemoglobinopathies, including sickle cell disease and beta-thalassemia. The inconsistency in *HBB* variant nomenclature has contributed to challenges in accurate interpretation and classification.

Material and Methods: Mastermind Genomic Search Engine (Genomenon, Inc) was used to collect all *HBB* variants from the literature, followed by a semi-automated curation with manual expert review to classify variants according to the ACMG/AMP criteria. Each variant was initially linked to its published classification; however, reclassification was performed following adjustments to the nomenclature.

Results: Systematic literature review of 3,234 articles yielded 1,480 *HBB* variants. Out of those, 141 (9.5%) HBB variants required nomenclature revisions. After reclassification, 28 variants were upgraded to pathogenic (eight variants were previously classified as conflicting interpretations of pathogenicity in ClinVar and 20 were VUS), 6 variants were downgraded to likely benign from conflicting, while 69 variants remained VUS. Examples of upgraded variants are: p.Ala130Pro (Hb Crete), p.Glu102Gln (Hb Rush), and p.Glu122Lys (Hb O-Arab, also known as Hb Egypt and Hb O-Thrace).

Conclusion: The application of proper *HBB* variant nomenclature led to clinically significant changes for 34 variants. This effort underscores the importance of establishing standardised nomenclature and classification practices to improve the accuracy and consistency of genetic variant interpretation, which is crucial for clinical decision-making and patient care.

P09.031.A De Novo or Inherited: Gonosomal Mosaicism in Hereditary Angioedema due to C1 Inhibitor Deficiency

Laura Batlle-Maso, *Janire Perurena-Prieto, Laura Vinas-Gimenez, Aina Aguilo-Cucurull, Paula Fernandez-Alvarez, Johana Gil-Serrano, Mar Guilarte, Roger Colobran*

Vall Hebron Research Institute, Barcelona, Spain.

Background: Hereditary angioedema (HAE) is a rare genetic disease characterized by recurrent episodes of swelling due to dysregulated endothelial permeability. The most common form, HAE-C1-INH, results from pathogenic genetic variants in the SERPING1 gene, leading to deficient C1-Inhibitor function and transmitted in an autosomal dominant manner.

Materials and Methods: We investigated a patient with sporadic HAE-C1-INH presenting with typical clinical features and markedly reduced C1-INH function. Sanger sequencing was performed in the index patient and the asymptomatic parents with normal C1-INH function and C4 levels. cDNA sequencing evaluated the effect of the identified variant on splicing. Deep amplicon sequencing of maternal DNA was used to quantify mosaicism across tissues.

Results: We identified a novel splice site variant in SERPING1 (c.890-1G>C) and, by analyzing the cDNA, we demonstrated that the variant produces two aberrantly spliced transcripts, confirming its pathogenicity. Despite the normal function of C1-INH in the parents, we found that unexpectedly, the mother was a carrier of the genetic variant. Sanger sequencing profiles revealed the presence of gonosomal mosaicism in the mother. We confirmed and quantified the mosaicism in different tissues by high-depth NGS-based deep amplicon sequencing, showing a variant allele frequency ranging from 17 to 23%.

Conclusion: In this study, we present the first case of gonosomal mosaicism in a family with a single child affected by HAE-C1-INH and unaffected parents. Our results underscore the importance of parental genetic testing in all patients, even if asymptomatic, and highlight the implications of gonosomal mosaicism for genetic counseling.

P09.032.D Optimisation and validation of a droplet digital PCR assay for copy number variation of the alpha-tryptase coding region of *TPSAB1* to identify hereditary alpha-tryptasemia

Honor Gartland[1,2]

[1]*Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom,* [2]*University of Manchester, Manchester, United Kingdom.*

Background: Testing for hereditary alpha-tryptasemia (HαT) is now available to patients in England with persistently elevated basal serum tryptase. Identifying HαT informs patient management, limits unnecessary testing for more serious blood disorders and prevents excessive treatment, NHS cost and ongoing patient anxiety[1]. HαT is associated with an in *cis* copy number increase of the alpha-tryptase coding region of *TPSAB1* (*TPSAB1α*)[2].

Material and Methods: Clinical validity of a droplet digital polymerase chain reaction (ddPCR) protocol, provided by Manchester University NHS Foundation Trust, for *TPSAB1α* copy number to identify HαT was assessed. This included using digested DNA and undigested DNA, to facilitate alpha shift calculations (copy number in digested DNA - copy number in undigested DNA) and distinguish *TPSAB1α* copies in *cis* from copies in *trans* when *TPSAB1α* absolute copy number is two. Fifty-two samples of known *TPSAB1α* copy number were blind tested using an optimised protocol.

Results: The protocol was highly accurate for determining *TPSAB1α* copy numbers up to four (including zero) but less accurate at higher copy numbers. Ranges for defining *TPSAB1α* copy number based on the observed copy number values were set accordingly. Alpha shift thresholds were also set.

Conclusion: Following local adjustments and refinement, a protocol for *TPSAB1α* copy number detection by ddPCR has been validated for clinical use. Ongoing data monitoring will be carried out to show protocol efficacy on a larger data set. We discuss how this technique could have other clinical applications where phasing of duplicated regions informs clinical outcome or risk.

P09.033.C Genetic profiling of myeloid malignancies: A single-center study using myeloid panel testing

Umut Can Tekbas, *Haktan Bağış Erdem, Hanife Saat, Atakan Deniz*

Ankara Etlik City Hospital, Ankara, Turkey.

Background: Myeloid neoplasms are a genetically heterogeneous group and the detection of associated genetic alterations plays an important role in the differential diagnosis, prognosis and treatment of the disease. For this reason, myeloid panel studies using next-generation sequencing (NGS) are of great importance in this patient population. In this study, we aim to contribute to the literature by summarising the results of myeloid panel studies in our center.

Material and Methods: Between June 2024 and January 2025, 98 patients referred to our clinic were tested using a large customised myeloid panel containing 65 genes. Patients with acute myeloid leukaemia (AML) represented the largest group with a total of 46 (46.9%) patients. 26 (26.5%) patients with chronic myeloproliferative disorders (CMPD) and 16 (16.3%) patients with myelodysplastic syndrome (MDS) also made up the majority of the study group with AML patients (89.7% in total).

Results: A total of 161 oncogenic/likely oncogenic variants were detected in 82/98 (%83.6) patients according to the ClinGen/CGC/VICC criteria. The most common variants in AML patients were in *DNMT3A, NPM1, NRAS*, and *FLT3*; in CMPD patients in *NF1*, *ASXL1*, and *NRAS*; and in MDS patients in *RUNX1*, *ASXL1*, and *CBL*.

Conclusion: Due to the genetic heterogeneity of myeloid neoplasms, it is important to use large panels in this group and to clarify and manage conditions such as germline variants, mosaicism or clonal haematopoiesis of indeterminate potential (CHIP) by evaluating some features such as the fractions of detected variants, age and clinical findings of the patients.

P09.034.D Investigating diagnostic efficacy of whole exome sequencing in inborn errors of immunity

Máté Biró[1], *Eszter Kovács*[1], *Beáta Bessenyei*[1], *Katalin Koczok*[1], *László Madar*[1], *Zsuzsanna Szűcs*[1], *Orsolya Nagy*[1], *István Balogh*[1], *Gergely Kriván*[2], *Vera Goda*[3], *Rita Káposzta*[4]

[1]*Division of Clinical Genetics, Department of Laboratory Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary,* [2]*2Department for Pediatric Hematology and Hemopoietic Stem Cell Transplantation, National Institute of Hematology and Infectious Diseases, Central Hospital of Southern Pest, Budapest, Hungary,* [3]*Department for Pediatric Hematology and Hemopoietic Stem Cell Transplantation, National Institute of Hematology and Infectious Diseases, Central Hospital of Southern Pest, Budapest, Hungary,* [4]*Department of Pediatrics, Faculty of Medicine, University of Debrecen, Debrecen, Hungary.*

Background: Inborn errors of immunity (IEI) represent a highly heterogeneous group of disorders, encompassing over 400 potential causative genes, making genetic diagnosis a challenging process. The identification of genetic background underlying IEIs has significantly advanced with the widespread adoption of next-generation sequencing (NGS) technologies. However, diagnostic yield remains around 30%. This study aims to collect and analyze whole exome sequencing (WES) data from patients with a phenotype of IEI to assess diagnostic efficacy in our laboratory.

Material and Methods: WES was conducted using established standard protocols. Sequencing data were analyzed through our bioinformatics pipeline with a newly developed virtual gene panel, which included all genes associated with IEI as defined by the International Union of Immunological Societies (IUIS). Variant classification was performed according to the American College of Medical Genetics and Genomics (ACMG) guidelines.

Results: Of the 228 samples tested, clinically relevant genetic variants were identified in 46 cases, resulting in a diagnostic efficacy of 20%. Several novel genetic variants, classified as likely pathogenic, were detected. The 46 diagnosed patients were categorized into the disease groups of the IUIS classification, with representation from each major group, reflecting the broad spectrum of IEIs in the cohort.

Conclusion: Our study demonstrates that WES provides a valuable tool for the genetic diagnosis of IEIs, achieving a diagnostic efficacy of 20%. This yield correlates well with data from similar studies; however, it remains lower than that observed for other genetic diseases, highlighting the need for improvement and potential implemantation of complementary diagnostic methods.

Dimiccoli Hospital, Barletta, Italy,* [8]*IRCCS Bambino Gesù Children's Hospital, Rome, Italy,* [9]*Università degli Studi di Tor Vergata, Rome, Italy,* [10]*NextClinics International, Bologna, Italy,* [11]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: Many X-linked agammaglobulinemia (XLA) patients have reached adulthood, with female relatives in reproductive age possibly carrying a deleterious *BTK* variant. Studies on reproductive outcomes in XLA families are lacking. We sought to investigate the state of preconception/prenatal genetic counseling, carrier status screening, and reproductive decisions in XLA families.

Material and Methods: In this multicenter, retrospective cohort study, we collected a 3-generation pedigree and data on mothers/sisters of XLA index patiens, including carrier status and pregnancy outcomes.

Results: 53 adults with XLA, belonging to 52 families were gathered. 52 mothers, and 33 sisters were enrolled. All XLA sisters received genetic counseling, 40% opting for carrier status determination. The main reasons for declining genetic testing in XLA sisters were their young age and the perception of XLA as an affordable disease, followed by the willingness to postpone the decision at the time of pregnancy, and by the decision to not have children. Among the carriers in reproductive age 60% chose invasive prenatal diagnosis. Prenatal testing resulted in 5 XLA diagnoses, with 2 pregnancy terminations, 1 miscarriage, 2 live births. 3 carriers refused prenatal testing, with 6 live births, including 3 XLA-affected sons. One non-genotyped sister had an XLA affected son. In total, 9 XLA diagnoses were made, including 6 live births.

Conclusion: Attitutes towards preconception and prenatal testing in XLA families are varied. Preconception genetic counseling, and the perception of XLA as a manageable conditions with dedicated care are percieved as key factors for informed choices by XLA families.

P09.037.C Role of founder effect in forming a new endemic region of patients with thiamine-responsive megaloblastic anemia

Medina Gurzhikhanova[1], *Nikolay Chekanov*[2], *Tatyana Salimova*[1], *Olga Goronkova*[1], *Ruslan Abasov*[1], *Olga Musharova*[2], *Fizaliya Khisamieva*[3], *Aina Taxaeva*[4], *Oksana Malkova*[5], *Natalya Boyarchuk*[5], *Elena Raikina*[1], *Michael Maschan*[1]

[1]*Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation,* [2]*"Biotech campus" LLC, Moscow, Russian Federation,* [3]*Children's Republican Clinical Hospital of the Ministry of Health of the Republic of Tatarstan, Kazan, Russian Federation,* [4]*E.P. Glinka Republican Children's Clinical Hospital, Grozny, Russian Federation,* [5]*Russian Children's Clinical Hospital of the N.I. Pirogov Russian National Research Medical University of Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation.*

Background: Rogers syndrome, or thiamine-responsive megaloblastic anemia (TRMA), is a hereditary disorder caused by dysfunction of the high-affinity thiamine transporter 1. This syndrome is characterized by a clinical triad of symptoms: megaloblastic anemia, non-autoimmune diabetes mellitus, and sensorineural hearing loss. To date, approximately 100 families with genetically proven disease have been documented, primarily in endemic regions such as the Middle East, South Asia, and the northern Mediterranean. Notably, there have been no reported cases in Russia. This research aims to clinically characterize patients with genetically confirmed Rogers syndrome and investigate the founder effect's role in its increased incidence in Russia.

Material and Methods: A total of ten patients diagnosed with TRMA were analyzed, with a median age at diagnosis of 2 years (ranging from 1 to 16 years).

Results: Symptoms manifested from infancy to the first year of life; seven patients exhibited the classical triad, while others presented additional symptoms like cardiomyopathy. Genetic testing revealed a pathogenic homozygous c.1223+1G>A mutation in the *SLC19A2* gene in eight of the patients, all of whom reside in the North Caucasian federal district. This finding suggests a potential founder effect contributing to the higher frequency of TRMA in this region. Furthermore, it indicates that the North Caucasus may be a new endemic region for this disease.

Conclusion: Timely diagnosis and treatment are essential to prevent severe complications associated with this disorder. Identifying new endemic areas TRMA may facilitate earlier recognition and management of affected children.

P09.038.D GenIA, the Genetic Immunology Advisor database for genetically driven immune disorders

Andrés Caballero-Oteyza[1,2,3], *Xiao P. Peng*[4], *Laura Crisponi*[5], *Michele Proietti*[1,2,3]

[1]*University Hospital Freiburg, Freiburg, Germany,* [2]*Medical School of Medicine, Hanover, Germany,* [3]*RESiST cluster of Excellence, Hanover, Germany,* [4]*Montefiore Medical Center/ Albert Einstein College of Medicine, New York, NY, USA,* [5]*Institute for Genetic and Biomedical Research, National Research Council, Monserrato, Italy.*

Background: The landscape of genetically driven immune disorders has grown rapidly over the last decades thanks to the combination of hypothesis-generating -omics technologies and hypothesis-driven functional studies. However, with increasing knowledge comes the challenge of capturing, harmonizing and synthesizing all layers of genotypic, phenotypic and mechanistic information while making this easily accessible.

Objective: To create a comprehensive, expertly curated, multidimensional database that enables aggregation, standardization, and synthesis of knowledge in the scientific literature by and for researchers, geneticists and clinicians in the field.

Methods: The database was designed and written in SQL following a subject-centered model. The web application is written in PHP, HTML, CSS and JavaScript. Most of the data stored in GenIA was extracted by manual review of research articles, though unpublished functional data can also be stored.

Results: We developed a publicly accessible resource that provides curated, detailed and multilayered information, anchored around patients; but also includes diagnostic paradigms and pitfalls associated with individual genes and conditions, along with an international functional test registry. Literature curation was completed for 30 genes and is ongoing for others. These pilot curations show the many ways in which this database can be used by scientists and clinicians to answer specific and valuable questions.

Conclusion: GenIA encompasses more thorough and comprehensive genetic, mechanistic, and phenotypic immunogenetic knowledge than other currently existing databases. GenIA's architecture allows sophisticated data interrogation, the result of which may ultimately translate into reduced diagnostic odysseys, better preventing strategies and improved patient care. Our model could be adopted by other clinical areas.

P09.039.A HLA-DRB1 high-resolution allele frequencies in a cohort of Romanian stem cell donors

A. Caragea[1], *R.-I. Ursu*[2], *A. Constantinescu*[3], *L. Bohiltea*[2], *I. Constantinescu*[1];

[1]*Carol Davila University of Medicine and Pharmacy, Bucharest, Department of Immunology and Transplantation Immunology, Bucharest, Romania,* [2]*Carol Davila University of Medicine and Pharmacy, Bucharest, Department of Medical Genetics, Bucharest, Romania,* [3]*Carol Davila University of Medicine and Pharmacy, Bucharest, Bucharest, Romania*

Background: The HLA-DRB1 alleles are one of the primary molecular representatives of the HLA-class gene cluster. The aim of the current study is identifying the main HLA-DRB1 alleles in a Romanian cohort of healthy stem cell donors and their 6-digits high-resolution frequencies.

Material and Methods: The study, conducted at the Immunology and Transplantation Immunology Department of the Fundeni Clinical Institute, involved 420 voluntary donors from the Romanian National Registry of Voluntary Hematopoietic Stem Cell Donors (RNDVCSH). HLA genotyping was carried out using the Immucor Mia Fora NGS MFlex kit.

Results: The results revealed 41 different HLA-DRB1 alleles, the most common being DRB1*16:01:01 (allele frequency, AF, 12.6%), DRB1*11:04:01 (AF 12.1%), DRB1*03:01:01 (AF 12%), DRB1*07:01:01 (AF 9.3%), DRB1*01:01:01 (AF 7.3%) and DRB1*11:01:01 (AF 6.3%) and 13:01:01 (AF 6%). Out of all the detected HLA-DRB1 variants, only 3 showed frequencies higher than 10%, while 18 had frequencies lower than 1%, out of which 15 were rare variants, with AFs lower than 0.5% (identified in maximum 3 of the 420 individuals each).

Conclusion: The current research provides important data on the HLA-DRB1 alleles frequencies for the Romanian population. The study showed similarities as well as disparities for the more common and less frequent alleles between our analyzed cohort and the various European and non-European populations, proving the importance of this data for the specificity of organ transplantation among different populations and individuals, as well as for a better understanding of the population genetics of the region. Further studies are needed for confirming these findings.

P09.040.B Differential gene expression analysis of iNKTs cultured for 4 and 6 weeks

Robin Klieber[1,2,3], *Hana Gmucová*[2], *Tereza Dekojová*[1,2,3], *Tomáš Kříž*[1,2,3], *Pavel Ostašov*[1], *Daniel Lysák*[2], *Pavel Jindra*[2], *Monika Holubová*[1,2,3]

[1]*Laboratory of Tumor Biology and Immunotherapy, Biomedical Center, Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic,* [2]*Department of Hematology and Oncology, University Hospital in Pilsen, Pilsen, Czech Republic,* [3]*Consortium of iNKT Research and Therapy (CiRT), Pilsen, Czech Republic.*

Background: Invariant NKT cells (iNKTs) are rare regulatory cells that are increasingly used in cell therapy (e.g., to treat severe infections or prevent post-transplant complications). They can be used allogeneically, which allows us to make a batch of cells from one apheresis that can be used for multiple patients. To treat as many patients as possible, we need to expand them in vitro. However, long-term culture can lead to changes in the transcriptome that are associated with a reduction in the therapeutic potential of the cells. Our aim was to compare the transcriptome of iNKTs cultured for the minimum and maximum time periods used in clinical settings.

Material and Methods: iNKTs from 7 healthy donors were isolated using microbeads and activated with IL-15, CD1d positive feeder cells (C1R-CD1d) and α-galactosylceramide for 4 and 6 weeks. Total RNA was extracted and rRNA depleted. The final libraries were normalised, pooled and sequenced.

Results: PIAS4 and IL17D gene expression was significantly downregulated, whereas the key signaling receptors CD28, CD3G, IL2RA and IL6ST were significantly upregulated after six weeks of cultivation. Upregulation of IL41I, associated with lower T cell proliferation activity was also detected. GOE analysis revealed biological pathways such as T cell activation, immune response regulation and activation pathway and T cell receptor signaling pathway. Gene expression of key senescence genes remained statistically unchanged over the culture period.

Conclusion: Prolonged cultivation of iNKTs has no adverse effect on the transcriptional activity, allowing us to expand the cells in larger numbers.

C.O.I. Disclosure:

P09.041.C Fetal Down Syndrome: An Early Analysis of AIRE and GATA1-Related Immunologic and Hematologic Dysfunctions

Vincenza Ylenia Cusenza[1], *Beatrice Melli*[1,2], *Davide Nicoli*[1], *Sandra Martinelli*[1], *Maria Paola Bonasoni*[3]

[1]*Molecular Pathology, Azienda USL-IRCCS of Reggio Emilia, Italy, Reggio Emilia, Italy,* [2]*Unit of Obstetrics and Gynecology, Azienda USL-IRCCS of Reggio Emilia, Italy, Reggio Emilia, Italy,* [3]*Pathology Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, Reggio Emilia, Italy.*

Background: Down syndrome (DS), caused by trisomy of chromosome 21, is associated with immune and hematological dysfunctions, including thymic abnormalities. The latter contribute to the dysregulation of the immune system, increasing susceptibility to autoimmune diseases and infections. The *AIRE* (Autoimmune Regulator) gene expression can compromise immune tolerance, leading to abnormal autoimmune responses in DS. Similarly, the *GATA1* gene is mutated in DS, favouring hematological disorders such as anemia and megakaryocytic leukemia. *GATA1* is also expressed in thymic cells, influencing T cell development and function. *GATA1* expression modulation plays a critical role in the development of leukemia in DS. To the best of our knowledge, in DS fetuses, abnormalities in *GATA-1* and *AIRE* expression have never been analyzed in depth.

Material and Methods: Formalin fixed paraffin embedded (FFPE) tissues (thymus, liver, heart) from 3 DS fetuses of the second trimester obtained from legal termination of pregnancy and 3 age matched controls were used for gene expression analysis. RT-qPCR was performed to analyze *AIRE* and *GATA1* expression at a precocious stage. *GATA1* mutations analysis was performed on Sanger sequencing.

Results: RT-qPCR analysis identified the differential expression of *AIRE* e *GATA1* genes between DS fetuses and controls. These results substain the hypothesis of precocious immune and hematological dysfunctions that impair the fetuses health.

Conclusion: The findings of these early dysfunctions in DS immune system may pave the way for new diagnostic and

therapeutic strategies, allowing early intervention in pregnancy and better management of DS-associated issues in life.

P09.042.D Investigation of Genetic Regulation of Paroxysmal Nocturnal Hemoglobinuria Disease

Kutay BULUT[1,2], *Bahar Sevgili*[3], *Zuhal Demirci*[3], *Fatma Keklik Karadag*[3], *Fahri Sahin*[3], *Guray Saydam*[3], *Sunde Yilmaz Susluer*[1]

[1]*Ege University, Department of Medical Biology, Bornova, Turkey,* [2]*Rare and Undiagnosed Disease Platform, Izmir Biomedicine and Genome Center (IBG), Balcova, Turkey,* [3]*Ege University, Department of Hematology, Bornova, Turkey.*

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a ultra rare clonal stem cell disease that manifests itself with acquired non-immune intravascular hemolysis findings, bone marrow failure, and thrombosis clinic. Since PNH occurs as a result of somatic mutation of hematopoietic stem cells, it affects all three cell lines of the hematopoietic system at different rates.

This study aims to elucidate the molecular mechanisms underlying the rare disease PNH, to obtain more data on this patient group, and to investigate expression levels of some epigenetic regulator genes and disease-associated gene.

Material and Methods: Blood samples were collected from 21 PNH patients. RNA isolation and cDNA conversion were performed for further analyses. mRNA expression levels of DNMT3A, ASXL1, TET2, EZH2, RUNX1, IDH1, PIGA, PHF6, U2AF1, ATM genes were determined using qRT-PCR method. Quantitative evaluation of gene expressions was performed by ΔΔCT analysis using the housekeeping GAPDH gene ratio. $p < 0.05$ was considered significant.

Results: Overexpression was observed in DNMT3A, ASXL1, TET2, EZH2, RUNX1, PHF6, ATM and U2AF1 genes. Fold change values were detected as 1.04, 15.30, 1.57, 1.87, 3.58, 2.38, 3.43 and 3.94, respectively. Downregulation was observed in IDH1 and PIGA genes. Fold change values were detected as 0.86 and 0.15, respectively.

Conclusion: Overexpression was observed in most of the methylation-related genes and especially the overexpression in ASXL1 gene suggests that this gene may play an important role in the diagnosis and treatment of the disease. Further studies, such as WES and RNA-seq, will be performed for better understanding of pathogenesis of the disease.

P09.043.A Spontaneous hematological recovery in a patient with Fanconi Anemia

Carmelo Maria Romeo[1,2], *Francesca Arruga*[1,2], *Chiara Novara*[3], *Angelo Corso Faini*[1,2], *Maria Luca*[1,2], *Giulia Margherita Brach del Prever*[1,2], *Fiorenza Mioli*[1,2], *Claudia Saglia*[1,2], *Caterina Scolari*[1,2], *Tullia Carradori*[1,2], *Tiziana Vaisitti*[1,2], *Giovanni Del Borrello*[3], *Paola Quarello*[3,4], *Franca Fagioli*[3,4], *Silvia Deaglio*[1,2], *Diana Carli*[1,2]

[1]*Department of Medical Sciences, University of Turin, Turin, Italy,* [2]*Immunogenetics and Transplant Biology Unit, University Hospital "Città della Salute e della Scienza di Torino", Turin, Italy,* [3]*Pediatric Onco-hematology Division, Regina Margherita Children's Hospital, Città Della Salute e Della Scienza, Turin, Italy,* [4]*Department of Public Health and Pediatric Sciences, University of Turin, Turin, Italy.*

Background: Fanconi anemia (FA) is a rare autosomal recessive disorder caused by pathogenic variants in DNA-repair genes, leading to bone marrow failure, congenital abnormalities and cancer predisposition. Somatic genetic rescue via revertant mosaicism has been reported, particularly in hematopoietic tissues.

Material and Methods: We describe two siblings with FA who exhibit discordant phenotype severity and genotype.

Results: A 16-year-old boy presented short stature, ectopic kidney, thumb duplication, a positive DEB-test and abnormal cell cycle analysis. He underwent hematopoietic stem cell transplantation (HSCT) at the age of 5 years due to progressive pancytopenia. His 13-year-old sister had multiple café-au-lait spots, thumb duplication, a positive cell cycle test at 1.5 years, and thrombocytopenia at 2 years, for which HSCT evaluation was initiated. However, her thrombocytopenia resolved spontaneously, and she remains hematologically stable. Clinical exome analysis revealed that the boy carried the heterozygous *FANCA* c.3660del, p.(Asn1221fs*26) and c.50dup, p.(Arg18Profs*19) variants, while his sister carried the heterozygous c.3660delC; p.(Asn1221fs*26) and c.51C>G p.(Gly17=) variants. Notably, the synonymous c.51C>G variant occurred at the same codon where the brother had the frameshift variant c.50dup, suggesting a possible somatic genetic rescue in hematopoietic tissue potentially explaining her hematological recovery.

Conclusion: Revertant mosaicism has diagnostic and clinical implications, necessitating repeated genetic analyses across tissues and over time. Spontaneous hematological remission should not reduce follow-up for other FA manifestations, as it remains a systemic disease, with persistent risks of other complications.

P09.044.B Prevalence, molecular and laboratory features of beta-thalassemia carriers in Northern part of Russia

Vladimir Nazarov, *Dmitriy Slivinskiy, Sergey Lapin, Anastasia Musonova, Darya Sidorenko*

Pavlov First St. Petersburg State Medical University, St. Petersburg, Russian Federation.

Background: Most cases of beta-thalassemia are diagnosed in regions with high prevalence of malaria. Russia is not endemic for malaria, but since it is a multi-ethnic country, it is believed that the prevalence of beta-thalassemia may be high.

Material and Methods: For characterization of prevalence, molecular and laboratory features of beta-thalassemia, results of blood test (RBC, Hb, hematocrit, MCV, MCH, MVHC, RDW) of 58266 risk group patients from Northern part of Russia were analyzed. For cases with low Hb and/or MCV and/or MCH, Mentzer and Sirdah indices were calculated. For samples positive for both indices, sequencing of *HBB* gene was performed.

Results: In studied group 182 samples were positive for both indices. After genotyping 64 samples were positive for 20 different heterozygous pathogenic *HBB* variants. The most common variant was c.25_26del (25.81%), but prevalence of others did not exceed 10% (c.93–21G>A - 9,68%, c.92+1G>A - 8.06%, c.316-197–8.06%, c.27dup - 8.06% etc.). Distribution of variants was uniform in coding and non-coding regions of *HBB*. Prevalence of *HBB*-positivity was 0.11%. *HBB*-positive patients had lower level of RBC,

Hb, MCV, hematocrit, MCH, RDW, indices and higher level of MCHC than *HBB*-negative patients ($p < 0.0001$). Prevalence of anemia in *HBB*-positive samples was 64%, in *HBB*-negative - 37%.

Conclusion: A high prevalence of beta-thalassemia carriers has been identified. There was only one hotspot variant (c.25_26del) with low frequency (25.81%). Laboratory features highlight that not all cases of beta-thalassemia present with anemia, and HBB-positive cases are characterized by more profound changes in blood test results and indices.

P09.045.C Investigating the shared genetic architecture between Immunoglobulin A deficiency and autoimmune diseases

X. Dang, *Q. Wang, C. Zhang, W. Yang;*

Department of Paediatrics and Adolescent Medicine, The University of Hong Kong, Hong Kong, China

Background: Immunoglobulin A deficiency (IgAD) is the most prevalent primary immunodeficiency, characterized by low serum IgA levels. Autoimmune diseases (ADs) frequently co-exist with IgAD, suggesting a shared genetic basis. This study aims to explore the genetic architecture underlying IgAD and ADs, shedding light on potential shared mechanisms.

Material and Methods: We utilized summary statistics from large-scale genome-wide association studies (GWAS) of IgAD and multiple ADs. Employing multi-trait analysis, genetic correlation, and co-localization analysis, we identified pleiotropic loci shared between IgAD and ADs. Shared genes between IgAD and ADs were identified through TWAS and MAGMA analysis, followed by functional enrichment analysis to uncover shared biological pathways and potential drug targets. Heritability enrichment and single-cell RNA-seq analysis were used to identify the critical tissues and cell types involved in both conditions.

Results: Our analysis identified 54 pleiotropic loci and 89 pleiotropic sigals significantly associated with both IgAD and ADs ($p < 5 \times 10^{-8}$). Co-localization analysis highlighted shared loci, including IFIH1, AHI1, CLEC16A, and STAT4. Gene-level analysis revealed shared pathways related to T-cell differentiation, viral infection, immunological diseases, and the intestinal immune network for IgA production. Heritability enrichment analysis pinpointed whole blood and the intestine as critical tissues for both conditions and single-cell RNA-seq analysis identified B cells as the most affected cell types.

Conclusion: Our findings unveiled a shared genetic architecture between IgAD and ADs, highlighting common functional mechanisms and providing insights into the biological interplay between these conditions.

P09.047.A IGLL1 in Newborn Screening for Severe T and B Cell Lymphopenia Using TREC/KREC Detection

Maria Ampleeva[1], *Andre Marakhonov*[1], *Anastasia Bobreshova*[1], *Efimova Irina*[1], *Anna Mukhina*[2], *Anna Shcherbina*[2], *Dmitry Pershin*[2], *Sergey Voronin*[1], *Sergey Kutsev*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation.*

Background: Agammaglobulinemia due to variants in *IGLL1* thought to be extremely rare form of B-cell deficiency but recently newborn screening by T cell receptor excision circle (TREC) or kappa-deleting recombination excision circles (KREC) revealed it to be much more frequent.

Material and Methods: TREC/KREC detection was performed more than 2 millions newborns from all regions of Russian Federation in 24-month period. If TREC or KREC were low than flow cytometry for lymphocyte subsets was done. 86 infants pretended to have agammaglobulinemia due to low counts of B-cells and KREC levels. In these 86 infants WES was done to find genetic defect. All of the genetic findings were confirmed by Sanger sequencing.

Results: In 22 newborns were found pathogenic or likely pathogenic genetic variants in *IGLL1* in homozygous or compound heterozygous form. Mostly, in 16 cases c.425C>T p.(Pro142Leu) [NM_020070.4] was found in homozygous (in 9 cases) or compound heterozygous (with other mutations or deletion of 1–2 exon) form. We observed high prevalence of this mutation in infants with low counts of B-cells and low KREC levels.

Conclusion: Formely, IGLL1 is the most frequent cause of isolated low KREC in newborn screening, but it's not as severe as we expected. Patients and sometimes their homozygous parents or sibs have no clinic of agammaglobulinemia.

P09.049.C The importance of whole genome sequencing in rare immunodeficiencies - case report of a pair of twins with Cartilage hair hypoplasia with Omenn syndrome

László Madar[1], *Katalin Koczok*[1], *Orsolya Nagy*[1], *Péter Blazsó*[2], *István Balogh*[1,3]

[1]*Division of Clinical Genetics, Department of Laboratory Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary,* [2]*Albert Szent-Györgyi Health Centre, Department of Pediatrics and Pediatric Health Center, Szeged, Hungary,* [3]*Department of Human Genetics, Faculty of Medicine, University of Debrecen, Debrecen, Hungary.*

Background: Primary immunodeficiency diseases (PIDs) are clinically and genetically highly heterogeneous with ~500 causative genes. Genetic diagnosis is challenging, whole exome sequencing (WES) might not lead to correct molecular diagnosis even in monogenic forms.

Patients and Methods: The proband and her twin sister were suspected to have Omenn syndrome, based on immunological parameters and clinical symptoms (lymphadenopathy, eosinophilia, dysmorphic appearance, low nasal bridge, shortening of tubular bones, generalized erythrodermia). WES analysis and array CGH did not reveal any pathogenic variant. In order to establish the diagnosis, whole genome sequencing (WGS) was performed in the deceased twin pair and parents.

Results: WGS identified compound heterozygosity for two previously reported pathogenic variants (LRG_163(t1):n.1-22_1-3dup and LRG_163(t1):n.147G>A) in the non-protein coding *RMRP* gene. Based on the genetic findings and the clinical picture, the diagnosis of Cartilage-hair hypoplasia with Omenn syndrome was established in the siblings.

Conclusion: The diagnostic efficiency of WES in case of primary immunodeficiency is very low (~20%). In the case of negative WES result, whole genome sequencing can be a significant aid in making a genetic diagnosis as it covers mitochondrial genome,

non-coding regions, promoters, enhancers, introns, regulatory elements and can detect CNVs and other structural variants. If the genetic background is identified, prenatal or pre-implantation testing should be offered.

P09.050.D A novel homozygous deletion of exon 10 of *PKLR* gene as a cause of severe congenital transfusion dependent hemolytic anemia

Liliya Valeri Nikolova-Georgieva, *Lidiya Dimova, Petya Nikolova-Hristova, Elitza Betcheva-Krajcir, Nataliya Todorov, Todor Vasilev, Petya Petkova, Toni Vekov*

Heart and Brain Center of Clinical Excellence, Pleven, Bulgaria.

Background: Pyruvate kinase deficiency (PKD) is the most common chronic hereditary non-spherocytic hemolytic anemia. The disease is characterized by variable degree of severity of chronic hemolytic anemia, from mild asymptomatic anemia to life-threatening, transfusion-dependent anemia. Chronic complications resulting from hemolysis, include iron overload, decreased bone density, cardiopulmonary complications, and increased overall mortality. We present a case of 1-year-old boy affected by severe congenital hemolytic anemia that needs many successive haemotransfusions since its early neonatal age due to laboratory confirmed severe and life-threatening hemolysis. The proband is the fourth child of consanguineous parents whose firstborn baby girl died with symptoms of severe hemolytic anemia.

Material and Methods: The genetic background of the condition of the proband, confirming PKD in the family, was elucidated by NGS-based method combined with computational CNV analysis, subsequently confirmed by orthodoxal method.

Results: Whole exome sequencing (WES) analysis revealed a novel pathogenic homozygous deletion covering exon 10 of the *PKLR gene* (NM_000298.6) encoding the pyruvate kinase enzyme. While there are several well described single nucleotide variants in the region that cause loss of function and are related to disease, reported phenotypes contributed to CNVs affecting exon 10 of the gene are missing.

Conclusion: We provide a detailed overview of a proband with a rare genetic form of PKD, describing the phenotype, family history and challenges of diagnostics in order to the need for thorough molecular analysis in patients with undiagnosed hemolytic anemia. We discuss the available treatment options for the conditions and the outcomes for our patient.

P09.051.A Novel *TLR7* frame-shift mutation probably associated with multiple sclerosis: functional characterization and transcriptome analysis

Radoslava Vazharova[1], *Adelina Yosifova*[2], *Atanas Syarov*[3], *Eliana Dimova*[4], *Maya Atanasoska*[5], *Lubomir Balabanski*[5], *Slavyana Yanusheva Yaneva Staykova*[5], *Theodor Todorov*[6], *Angelina Trifonova*[7], *Velislava Terzieva*[7]

[1]*Sofia University St Kliment Ohridski, Department of Biology, Faculty of Medicine, Medical genetics and Microbiology, Sofia, Bulgaria,* [2]*University Hospital Lozenets, Laboratory of Medical genetics and molecular biology, Sofia, Bulgaria,* [3]*Sofia University St. Kliment Ohridski, Sofia, Bulgaria,* [4]*Sofia University St. Kliment Ohridski, Faculty of Medicine, Sofia, Bulgaria,* [5]*CellGenetics Laboratory, Sofia, Bulgaria,* [6]*Sofia University St Kliment Ohridski, Faculty of Medicine, Sofia, Bulgaria,* [7]*University Hospital Lozenets, Laboratory of Clinical microbiology and virology, Sofia, Bulgaria.*

Background: Toll-like receptor 7 (*TLR7*) plays a crucial role in the innate immune system by recognizing viral RNA and activating pathways that induce IRF7 and NF-κB. Variants in *TLR7* have been linked to autoimmune diseases like SLE and severe COVID-19 outcomes. In this study, we report a novel frame-shift mutation in *TLR7* in a female patient with multiple sclerosis (MS). We aimed to investigate the functional consequences of this mutation through transcriptome analysis and in-vitro PBMC stimulation experiments.

Material and Methods: Whole-genome sequencing revealed a heterozygous *TLR7* frame-shift variant (c.2441del, p.Cys814Leufs*12) in the patient and her father who was found to be hemizygous for the mutation after targeted sequencing. Whole transcriptome sequencing was performed on blood samples from the patient, her father, and 4 TLR7-wild-type controls. Differential expression analysis was conducted with DESeq2 (Q value ≤ 0.05). PBMCs of patient and controls were stimulated in vitro with Imiquimod and R848 to assess IRF7 and NF-κB gene expression using RT-qPCR, and the results were analyzed using GeneGlobe software (QIAGEN).

Results: Transcriptome analysis identified 65 differentially expressed genes: 34 up-regulated and 31 down-regulated. Enrichment analysis suggested a dysregulated immune response, with up-regulated genes such as *CD14*, *IL12RB2*, and *IL18RAP* involved in immune activation. Down-regulated genes like *TLR7*, *PAX5*, and *CD79A/B* are crucial for B-cell signalling.

Conclusion: This *TLR7* frame-shift mutation may contribute to immune dysregulation in mutation carriers. The altered expression of immune-related genes points to potential mechanisms linking *TLR7* variants and autoimmune diseases, warranting further study.

P10 Intellectual Disability

P10.001.B Biallelic variants in *RELCH*, encoding a Rab11-binding protein, cause a complex neurodevelopmental disorder

Ambrin Fatima[1], *Mariia Denichenko*[2], *Sohana Nadeem Hashmi*[1], *Ghazala Zafar*[1], *Farhan Bahadar Ali*[3], *Yasmin Tatour*[4], *Bilal Ahmed Mian*[1], *Nada Danial-Farran*[4], *Hagar Mor-Shaked*[5], *Elena Chervinsky*[4,6], *Tahir Naeem Khan*[2], *Mathias Toft*[7,8], *Zafar Iqbal*[8], *Erica Davis*[2]

[1]*The Aga Khan University, Karachi, Pakistan,* [2]*Lurie Children's Hospital of Chicago, Chicago, IL, USA,* [3]*Peshawar Medical college, Peshawar, Pakistan,* [4]*Genetics Institute, Ha'emek Medical Center, Afula, Israel,* [5]*Hadassah-Hebrew University Medical Center, Jerusalem, Israel,* [6]*Ruth and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel,* [7]*Institute of Clinical Medicine, University of Oslo, Oslo, Norway,* [8]*Department of Neurology, Oslo University Hospital, Oslo, Norway.*

Background: RELCH is a Rab11-GTP binding protein involved in nonvesicular cholesterol transport from recycling endosomes to the trans-Golgi network. To date, *RELCH* has not been implicated in human disease.

Material and Methods: We used a multidisciplinary approach that combined clinical information and exome sequencing data with in vitro and in vivo modeling to identify the underlying genetic cause and disease pathomechanism.

Results: We investigated five pediatric cases from two unrelated consanguineous families that were unified through GeneMatcher. Our cases presented with severe neurodevelopmental phenotypes, including global developmental delay, microcephaly, generalized spasticity, and profound neurological impairments. MRI scan revealed ventriculomegaly, abnormalities in the corpus callosum, and bilateral gyral dysmorphism in occipital lobes with encephalomalacia in left occipital lobe. Exome sequencing identified a biallelic frameshift variant in family 1 while family 2 harbors a splice donor site variant in *RELCH*; both variants segregate with the phenotype in each respective family. Patient-derived primary fibroblasts revealed no detectable protein in family 1, and exclusion of exon 4 with concomitant reduced immunoreactivity of RELCH in family 2. Furthermore, zebrafish models with *relch* ablation display neurodevelopmental deficits including reduced head size and a depletion of commissural neurons.

Conclusion: Genetic and functional data implicate *RELCH* loss-of-function with a clinically heterogeneous neurodevelopmental disorder characterized by microcephaly and profound neurological impairments. Thus, we add to the repertoire of genetic disorders underscored by deregulated intracellular cholesterol.

[1]*Department of Molecular Medicine and Surgery, Karolinska Institutet, stockholm, Sweden,* [2]*Department of Clinical Genetics and Genomics, Karolinska University Hospital, Stockholm, Sweden,* [3]*Institute of Medical Genetics, Med Campus IV, Johannes Kepler University Linz, Linz, Austria,* [4]*Department of Molecular Biology, Faculty of Natural Science, Comenius University, Bratislava, Slovakia,* [5]*Institute for Clinical and Translational Research, Biomedical Research Centre, Slovak Academy of Sciences, Bratislava, Slovakia,* [6]*Science for Life Laboratory, Karolinska Institutet Science Park, Solna, Sweden,* [7]*Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden,* [8]*Department of Pediatric Neurology, Faculty of Medicine, Comenius University and National Institute of Children´s Diseases, Bratislava, Slovakia,* [910]*Department of Clinical Genetics and Genomics, Sahlgrenska University Hospital, Gothenburg, Sweden,* [11]*Department of Neuroscience, Karolinska Institutet, stockholm, Sweden,* [12]*Lund Stem Cell Center, Department of Experimental Medical Science, Lund University, Lund, Sweden.*

Background: Heterozygous variants in *CTNND2* are associated with a broad spectrum of neurodevelopmental disorders, ranging from mild (dyslexia, ADHD) to severe (intellectual disability, autism). Despite its clinical significance, a comprehensive characterization of *CTNND2*-associated disorders is lacking. Furthermore, δ-catenin, encoded by *CTNND2*, is a brain-specific component of the cadherin-catenin cell adhesion complex, but it remains unclear how its loss affects neurodevelopment.

Material and Methods: We analyzed the clinical and genetic profiles of 54 patients carrying 40 *CTNND2* variants, identified via exome sequencing, SNP array, and karyotyping. Facial dysmorphism was evaluated using Face2Gene, and pathogenicity was assessed through in-silico modeling. Functional studies included in vitro neural modelling and transcriptome analysis of three patient-derived neural stem cell lines and organoids to investigate early neurogenesis. CRISPR-Cas9 was employed to generate three *CTNND2* knockout lines for comparative analysis.

Results: The *CTNND2* variants, missense ($n = 14$) and loss-of-function ($n = 26$), were linked to developmental delay (61%), intellectual disability (65%), and behavioral abnormalities (52%). In cases with family data, 11 had de novo mutations, and 4/16 transmitting parents showed a phenotype. Functional studies, though variable between lines, revealed disrupted neurogenesis in one patient, characterized by aberrant neural rosette formation. Transcriptome analysis showed dysregulated WNT signaling. Partial rescue of these phenotypes was achieved by excluding a WNT activator, highlighting δ-catenin's role in early neural development.

Conclusion: Our study highlights the phenotypic and genetic heterogeneity of *CTNND2*-related disorders, emphasizing δ-catenin's critical role in neurodevelopment. WNT signaling dysregulation suggests a potential mechanistic pathway, underscoring the need for personalized diagnostic and therapeutic approaches.

P10.003.D Non-coding structural variants disrupt regulatory elements steering FOXG1 transcription in early neurodevelopment (Award Candidate)

Lisa Hamerlinck[1], *Eva D'haene*[1], *Nore Van Loon*[1], *Michael B. Vaughan*[1], *María del Rocío Pérez Baca*[1], *Lara Colombo*[1], *Sebastian Leimbacher*[1], *Lies Vantomme*[1], *Esperanza Daal*[1], *Annelies Dheedene*[2], *Björn Menten*[2,1], *Bert Callewaert*[2,1], *Sarah Vergult*[1]

[1]*Department of Biomolecular Medicine, Ghent University, Ghent, Belgium,* [2]*Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Belgium.*

Background: The FOXG1 transcription factor is a crucial regulator of embryonic brain development. Pathogenic variants affecting FOXG1 cause FOXG1-syndrome. Although structural variants (SVs) downstream of FOXG1 have been reported in individuals with FOXG1-syndrome-like characteristics, the regulatory mechanisms leading to aberrant FOXG1 transcription remain unclear.

Methods & Results: We performed a thorough literature review and identified 37 individuals with FOXG1-syndrome-like characteristics and an SV affecting the noncoding sequence downstream of FOXG1. Furthermore, we identified a de novo noncoding deletion in an individual with FOXG1-syndrome features, allowing us to define a ~100 kb commonly affected regulatory region (CARR). By integrating publicly available and in-house epigenomics data, Hi-C, UMI-4C, and in vivo enhancer assays in zebrafish, we uncovered multiple regulatory elements within this CARR, including a neuronal enhancer cluster and the distal boundary of the FOXG1-containing topologically associating domain (TAD). Hi-C analysis on a lymphoblastoid cell line of our patient revealed increased interactions with the adjacent TAD. Moreover, sequential UMI-4C and CUT&RUN assays during induced pluripotent stem cell (iPSC) differentiation into neural progenitor cells (NPCs) demonstrated dynamic activation of the

enhancer cluster and increased interaction with the FOXG1 promoter. Finally, CRISPR-Cas9 deletion of the enhancer cluster and TAD boundary in iPSC-derived NPCs resulted in decreased FOXG1 transcription.

Conclusion: We identified and characterized a CARR downstream of FOXG1, containing enhancer and architectural elements essential for proper FOXG1 transcription. Our findings provide new insights into chromatin architecture and gene regulation at the FOXG1 locus, improving SV interpretation in individuals with FOXG1-syndrome-like characteristics.

P10.004.A Competition in blood of clones with both loss-of-function and hypomorphic or benign *NIPBL* variants in Cornelia de Lange patients: postzygotic mutations or rescue events? (Award Candidate)

Mathilde Quibeuf[1], *François Lecoquierre*[1], *Kévin Cassinari*[1], *Nathalie Drouot*[1], *Alice Goldenberg*[1], *Florence Petit*[2], *Juliette Coursimault*[1], *Sophie Coutant*[1], *Fatima-Zahra Abani*[1], *Pascale Saugier-Veber*[1], *Gael Nicolas*[1]

[1]*Inserm U1245 – Department of Genetics, Univ Rouen Normandie and CHU Rouen, Rouen, France,* [2]*Univ.Lille, CHU Lille, ULR7364 RADEME, F-59000 Lille, France.*

Background: Cornelia de Lange (CdLS) is a rare recognizable intellectual disability syndrome. Loss-of-function (LOF) *NIPBL* variants explain ~70% of solved cases. Most pathogenic variants occur de novo and 13% are mosaics with a somatic/blood allelic ratio (AR) bias that remains poorly understood and impedes blood-based tests.

Material and Methods: We report rates of *NIPBL* mosaic variants in a 10-year retrospective analysis of CdLS patients screening. In two cases with two mutant populations with a WT and two alternative exclusive mosaic alleles, we performed single-molecule deep (1000x-average) sequencing in blood ± saliva ± skin fibroblasts, RNAseq, and/or long-read HiFi PacBio sequencing.

Results: Of 97 pathogenic *NIPBL* variants carriers, 24 (24.7%) showed mosaicism. No nonsense/frameshift variant was detectable in blood (AR < 1%) while 3 missense, 1 structural variant (SV), 3 splice (including 1 deep-intronic) variants were detectable in blood (AR = [4–25%]), suggesting a hypomorphic effect.

In two cases, two mutant populations were identified. One showed one haplotype carrying either a deep intronic one-bp deletion resulting in a 53-bp frameshift inclusion in RNAseq from cultured fibroblasts or a nearby variant with no effect on splicing, enriched in blood. The second patient carried a 2-exon in-frame deletion in blood with corresponding exon skipping, and multiple low-level breakpoints. PacBio sequencing revealed that there were two clones from one haplotype, the second clone harbored a low-level complex frameshift SV, which was likely the causal event, both having likely occurred during the zygote division.

Conclusion: Postzygotic mutations and rescue of mutant alleles may explain somatic/blood biased AR, along with NIPBL functions in mitosis.

Background: Variants in Brain specific kinase-2 (BRSK2) have recently been associated with a neurodevelopmental disorder (NDD).

Material and Methods: Through international collaboration, we assembled thirty-five novel cases with *BRSK2* variants. We performed negative geotaxis and bang sensitivity assays in *Drosophila* upon knockdown of the fly orthologue *sff* or upon overexpression of human *BRSK2* wildtype and mutant constructs.

Results: Twenty-four individuals carried truncating variants, and eleven harbored missense variants in *BRSK2*, of which seven were located in the kinase domain, one in the UBA domain and two in the C-terminus. Ten variants occurred de novo, twelve were inherited and thirteen of unknown inheritance. Clinical features included variable degrees of developmental delay, normal IQ to moderate intellectual disability and variable neuropsychiatric aspects such as autistic features, ADHD, anxiety or depression.- Upon pan-neuronal knockdown of *sff* in *Drosophila*, we observed impaired locomotor behaviour and increased seizure susceptibility. Furthermore, we investigated the consequences of three missense variants, two of them from the kinase domain. Ubiquitous or pan-neuronal overexpression of human *BRSK2* in flies resulted in lethality or locomotor impairment for the wildtype, respectively, indicating toxicity. The two kinase domain variants had no effect, while the C-terminal missense variant behaved like the wildtype. This indicates a loss-of-function effect at least for the kinase domain missense variants.

Conclusion: Our findings further delineate the clinical and molecular spectrum of *BRSK2*-associated NDD and provide further insights into the role of BRSK2/sff in nervous system function and the specific consequences of missense variants depending on their location.

Background: NCOR2 plays a vital role in gene regulation by acting as a transcriptional repressor and modifying chromatin structure through the activation of histone deacetylase 3 (HDAC3). HDAC3 can associate with the related corepressor complex NCoR, and its interaction with these complexes suppresses the transcription of target genes. Recently, a case report described an individual with biallelic *NCOR2* variants presenting with autism and intellectual disability [Prasun, 2024].

Material and Methods: In this study, we report 11 individuals with either biallelic or monoallelic variants in NCOR2 gene. We used the online matching platform (GeneMatcher) to identify individuals with monoallelic and biallelic variants involving NCOR2. Additionally, we conducted functional studies using Drosophila to further investigate the role of Smr, the NCOR2 homolog, in neural development.

Results: Among those individuals, 8 have biallelic variants in NCOR2 and overlapping features, including global development delay, marked speech delay, intellectual disability, autism spectrum disorder, seizures, abnormal tonus, movement disorder, ventriculomegaly and distinctive physical features such as brachycephaly, midface hypoplasia, dysplastic ears, limb and digit anomalies. The remaining 3 individuals with monoallelic variants also present overlapping features including intellectual disability, autism spectrum disorder and movement disorder. We identified nonsense, missense and frameshift variants affecting highly conserved residues. Previous studies in mice highlighted NCOR2 as essential for brain development [Jepsen et al,2007]. Similarly, we observed in Drosophila that Smr (the NCOR2 homolog) is crucial for cell development.

Conclusion: We further define this condition as a multisystem neurodevelopmental disorder resulting from either monoallelic or biallelic variants in NCOR2.

Background: Loss-of-function variants in SETD5 gene cause the core phenotype of 3p25.3 microdeletion syndrome characterized by intellectual disability/autism, slow growth, dysmorphic features and malformations such as postaxial polydactyly, congenital heart condition and genitourinary anomalies. The prognosis seems milder in cases with intragenic SETD5 variants.

Material and Methods: Descriptive collaborative study of Spanish children with intragenic variants in *SETD5* gene.

Results:32 cases collected (17 male/15 female), 2 prenatally diagnosed, one inherited. Mean age: 7.5 years (0–38). Prenatal anomalies (14/21): 5 nuchal edema, 4 single umbilical artery, 4 growth retardation and 2 postaxial polydactyly. Postnatally: all exhibited neurodevelopmental disorder, though 3 had normal intelligence. 12/27 hypotonia, 1/31 seizures. Growth: 5/29 short stature, 5/30 microcephaly. Congenital malformations: 10/27 heart disease, 5/26 genitourinary anomalies, 9/26 deafness, 10/24 dental anomalies and 13/21 digital anomalies (6 polydactyly). Main facial features: long/smooth philtrum (81%), arched/thick eyebrows and anteverted/thick nares in 75%. Sequence variants: 5 previously described, 25 nonsense/frameshift, 2 missense and 4 affecting a splice-donor site.

Conclusion:32 new cases and 26 new variants are described expanding the SETD5 phenotype and genotype. 3 cases with normal intelligence support the milder phenotype in these patients. Prenatal anomalies are described in detail for the first time, and two cases were diagnosed prenatally. *SETD5* gene haploinsufficiency should be considered in the differential diagnosis of KBG and Cornelia de Lange syndrome

P10.008.A Whole exome vs whole genome sequencing in developmental disorders : a nationwide randomized trial

Mathilde Geysens[1], *Erika Souche*[2], *Hilde Van Esch*[2], *Kris Van Den Bogaert*[2], ***Joris Robert Vermeesch***[2], *on behalf of the BeSolveRD consortium*[3]

[1]*KULeuven, Leuven, Belgium,* [2]*University Hospitals of Leuven, Centre for Human Genetics, Leuven, Belgium,* [3]

Background: Whole exome (WES) or whole genome (WGS) sequencing are recommended as first- or second-tier molecular test for the diagnosis of patients with developmental disorders (DD). The clinical utility and cost-effectiveness of WGS however remain debated.

Material and Methods: 566 individuals with an unexplained DD were prospectively recruited across the 8 Belgian human genetics centres and randomized into either the standard of care (SoC) arm, in which WES and a microarray or shallow WGS were applied, or the WGS arm. SNV and CNV calling and interpretation was performed in the diagnostic laboratories with similar softwares and pipelines for both arms. In addition, harmonized reanalysis of the WGS data was performed using the Emedgene variant interpretation platform, integrating STR and SV calling.

Results: WGS had a diagnostic yield of 40.3%, a 10.6% increase compared to SoC (29.7%) ($p = 0083$). This added yield mainly results from a higher detection rate of SNV/indels (+9.1%) with only two pathogenic variants being non-coding. The diagnostic yield was higher in females (46.7%) compared to males (28.1%) ($p < 0.0001$). While de novo variants remain the main identified cause of DD (21.2%), the analysis of inherited variants in genes known to cause autosomal dominant phenotypes lead to more diagnoses (5.2%) than the recessive (2.1%) or X-linked (4.1%) analyses, in the Belgian population.

Conclusion: Our study shows the feasibility of implementing WGS in a clinical setting and demonstrates its growing added value for the diagnosis of patients with DD. Our results also highlight the importance of incorporating inherited variant analysis into routine genetic diagnostics.

P10.009.B A novel developmental disorder caused by de novo variants in potassium channel gene*KCNC4*

Diana Baralle[1], *Jenny Lord*[1], *Annie Godwin*[2], *Matt Guille*[3], *Katrin Deinhardt*[4], *Nicola Foulds*[5], *Cerys Roberts*[1], *Tia Fletcher*[3], *Callum Ives*[6], *Elisa Fadda*[1], *Meriel McEntegart*[7], *Mariana Vargas-Caballero*[8]

[1]*University of Southampton, Faculty of Medicine, Southampton, United Kingdom,* [2]*University of Portsmoouth, Portsmouth, United Kingdom,* [3]*University of Portsmouth, Portsmouth, United Kingdom,* [4]*University of Bremen, Bremen, Germany,* [5]*University Hospital Southampton, Southampton, United Kingdom,* [6]*Maynouth University, Ireland, Ireland,* [7]*St Georges Hospital, London, United Kingdom,* [8]*University of Southampton, Southampton, United Kingdom.*

Voltage-gated potassium (Kv) channels are critical for neuronal excitability, with mutations in KCNC1-3 linked to neurological disorders. KCNC4 encodes the Kv3.4 potassium subunit and has not been associated with disease. We describe a proband presenting with developmental delay, ataxia, microcephaly, cerebellar atrophy, and hypomyelination alongside a cohort of *KCNC4* variants. Patch clamp electrophysiology revealed three loss-of-function variants (p.Ser268Gly, p.Arg362Cys, p.Leu481Pro) and one gain-of-function variant (p.Arg404His). Computational

modelling of neuronal firing confirmed that these mutations significantly disrupt neuronal excitability. We generated a KCNC4 *Xenopus tropicalis* crispant model and recapitulated patients' phenotypes, including stunted growth, microcephaly and neurodevelopmental defects. Analysis of neuronal firing in the *Xenopus tropicalis* model showed impaired excitability, consistent with the role of Kv3.4 in enabling high-frequency neuronal firing in vivo. These findings establish KCNC4 as a novel disease gene, expanding the spectrum of potassium channelopathies. Our findings have important implications for clinical diagnostics and therapeutic development.

P10.010.C Biallelic variants in*ITSN1*are implicated in neurodevelopment disorders with severe intellectual disability

A. Srivastava[1], *S. Vaish*[1], *V. Srinivasan*[1], *P. Chandra*[1], *M. Kvarnung*[2], *L. Bird*[3], *V. Raju*[4];

[1]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India,* [2]*Karolinska university hospital, Stockholm, Sweden,* [3]*Rady Children's Hospital, San Diego, CA,* [4]*Indira Gandhi Institute of Child Health, Bangalore, India*

Background: ITSN1 (*Intersectin 1*) is a well-recognized member of the multidomain scaffold ITSN family involved in regulation of endocytosis and play important roles in cell signaling pathways including kinase regulation and Ras activation. Highly expressed in neurons, it is major binding partner for the neuronal GTPase dynamin1. De novo truncating variants in *ITSN1* are implicated in neurodevelopment disorders spectrum. The study summarizes the biallelic variants in *ITSN1* as the genetic basis of neurodevelopment disorders with severe intellectual disability.

Material and Methods: We performed whole exome sequencing of trio and two additional families were identified through GeneMatcher. Disease segregation was confirmed through Sanger sequencing. Molecular biology assays and RNA sequencing was used to investigate the functional impact of biallelic pathogenic variants.

Results: We identified inherited biallelic *ITSN1* truncating (p. Tyr965Ter) and missense variants in three individuals of diverse ancestry who present with microcephaly, global developmental delay, severe intellectual disability, and psychomotor disorder with cortical atrophy. Fibroblasts with truncating variant showed that ITSN1 mRNA transcript is prone to nonsense-mediated decay, and expression of ITSN1 is reduced leading to partial loss of function. RNA sequencing identified metabolic, neurodegeneration and splicing defects pathways implicated in the clinical features of severe intellectual disability and neurodevelopmental disorder.

Conclusion: Our results demonstrate that biallelic *ITSN1* variants are the basis of neurological symptoms through loss of function genetic mechanism mediated through disruption in RNA splicing and neurodegeneration. This is the first human genetics study that links severe ID with disruption in neurodegeneration.

P10.011.D Mitochondrial copy number is associated with cognitive function, cognitive decline, and dementia: a longitudinal study in UK Biobank

Charley Xia

University of Edinburgh, Edinburgh, United Kingdom.

Background: Mitochondria is the powerhouse of cell, playing a crucial role in brain health. Mitochondrial copy number (mtCN) is a proxy for mitochondrial function and has been linked to cognitive function and impairment. However, existing studies are often limited by cross-sectional designs, small sample sizes, or a focus on dementia patients.

Methods: Using data from 243,152 UK Biobank participants of European ancestry, we examined the longitudinal relationship between mtCN in blood and cognitive function, as well as its association with cognitive decline, including incident dementia, over a 16-year follow-up. Additionally, we leveraged publicly available genome-wide association study (GWAS) summary statistics to assess the genetic relationship between mtCN and fluid intelligence.

Results: We found that higher mtCN was positively associated with cognitive function. Moreover, higher baseline mtCN was protective against cognitive decline and all-cause dementia over the 16-year follow-up. However, the effects of mtCN observed at population-level differed from those observed in individuals experiencing cognitive decline, suggesting heterogeneous influences of mtCN. Genetic analyses revealed a moderate degree of shared genetic architecture between mtCN and cognitive function, with overlapping genes involved in pathways associated with known mitochondrial diseases. However, no casual effect of mtCN was observed on cognitive function.

Conclusions: Our findings support mtCN as a potential biomarker for cognitive health and cognitive aging. The observed heterogeneity suggests that mtCN may influence cognition through distinct pathways in normal and cognitively declining individuals. Further research is needed to establish the underlying mechanisms.

P10.012.A Do genomic risk scores contribute to neurodevelopmental and mental health characteristics in CNV-associated intellectual disability?

Zhaotian Chi[1], *IMAGINE-ID Consortium*[2], ***Kate D. Baker***[1]

[1]*University of Cambridge, Cambridge, United Kingdom,* [2]

Background: Copy number variant (CNV) risk scores are quantitative measures of CNV burden and gene content (loss-of-function intolerance, dosage sensitivity). Population studies have associated CNV risk scores with cognitive and psychiatric traits, however it is not known whether similar patterns exist within CNV-associated Intellectual Disability (ID).

Methods: This study analysed data from the UK-based IMAGINE-ID study. Participants were children and adolescents with neurodevelopmental difficulties and CNVs reported by diagnostic laboratories (N = 1,646, 4–19 years). Multivariate regression models examined the predictive value of CNV risk indices alongside CNV inheritance and socioeconomic status (SES). Outcome measures were developmental quotient, physical disabilities, ASD, ADHD and mental health symptoms from the Development and Well-Being Assessment (DAWBA).

Results: CNV-summated loss-of-function intolerance (pLI) emerged as the strongest predictor of mental health and neurodevelopmental traits, but with unexpected negative associations. Post-hoc analysis identified a threshold effect, whereby lower-range pLI scores (comparable to population samples) predicted higher psychiatric risks, while higher-range pLI scores predicted reduced psychiatric risks. Interpretation of pLI-outcome relationships was complicated by inheritance and SES.

Conclusion: These findings challenge the assumption that higher CNV risk scores universally increase psychiatric risks in children and young people. In the context of CNV-associated ID, genomic risk scores may predict neurodevelopmental and psychiatric outcomes in a complex, non-linear manner. Genomic risk factors interact with inheritance patterns and social deprivation to shape neurodevelopmental and mental health outcomes, highlighting the need for contextualised genetic counselling and support.

P10.014.C Switch I variants exhibit selective effects on RAC1

Hebah Althebaiti[1], *Siddharth Banka*[2], *Tom Millard*[1]

[1]*University of Manchester, Manchester, United Kingdom,* [2]*Manchester Centre for Genomic Medicine, 6th Floor St Mary's Hospital, Manchester, United Kingdom.*

Background: RAC1-related neurodevelopmental disorder (RAC1-NDD) is characterised by extraordinary phenotypic heterogeneity (e.g. extreme micro- or macrocephaly). RAC1 variants even in the same region of the protein can have opposite functional consequences. The switch I region of this highly conserved small GTPase is critical for effector-binding for activation of downstream pathways, but the functional effects of variants affecting this region have been less explored.

Material and Methods: Identification of switch I variants (via collaborations, variants databases, and literature search), clinical data collection, and fibroblast spreading (for WAVE pathway activity) and RAC1 Raichu biosensor (for PAK binding) assays.

Results: In 22 individuals, we identified 11 distinct pathogenic or likely pathogenic RAC1 switch I missense variants. All individuals showed developmental delay and intellectual disabilities, with the majority also showing microcephaly. Y32H, F37S, and N39D variants exhibited dominant negative (DN) effects on both WAVE and PAK signalling; P34S showed an activating effect on the WAVE pathway but a DN effect on PAK; N39S and S41F showed DN effects on WAVE without significant impact on PAK, while Y40H displayed a DN effect on PAK but had no effect on WAVE.

Conclusion: RAC1 switch I substitutions have variant-specific consequences on downstream signaling pathways. These findings will facilitate diagnosis and provide insights into disease mechanism which are critical for developing treatment strategies.

H. Althebaiti: None. **S. Banka:** None. **T. Millard:** None.

P10.015.D Identification of a novel recurrent pathogenic *TAF4* variant demonstrates the potential of genomic data sharing in a national healthcare system

Michael Spiller, *Renarta Crookes*

Sheffield Children's Hospital, Sheffield, United Kingdom.

Background: Exome and genome sequencing have greatly improved the diagnostic yield for neurodevelopmental disorders. However, many cases remain undiagnosed due to factors such as unidentified disease genes, and technical and analytical limitations.

Material and Methods: Diagnostic whole genome sequencing was performed by the NHS England Genomic Medicine Service (GMS), with sequencing data processed by the Genomics England bioinformatics pipeline. Variant analysis and interpretation conducted by NHS Genomic Laboratory Hubs, with confirmation by Sanger sequencing.

Results: We identified and confirmed a frameshift variant in a poorly-sequenced repetitive region of *TAF4*, an autosomal dominant intellectual disability gene. Using the Genomics England Clinical Variant Ark, we identified seven further probands (10 individuals in total) heterozygous for this variant, all presenting with a consistent phenotype. Both de novo occurrences and inheritance from affected parents were observed. This variant has not been previously reported, likely due to the repetitive nature of the region interfering with sequencing methods and diagnostic pipelines. However, our findings establish the *TAF4* frameshift variant as a recurrent cause of intellectual disability, and by far the most common pathogenic variant in this gene.

Conclusion: Our work demonstrates the importance of pursuing diagnoses in genomic regions often disregarded due to sequencing challenges; we expect that similar loci may harbour further diagnoses. Furthermore, our findings provide an excellent example of the potential of genomic data sharing within a national healthcare system - through this we were able both to verify our findings and to supply diagnoses to seven additional otherwise-undiagnosed patients.

P10.016.A Application of highthroughput approaches to investigate the impact of Variants of Uncertain Significance on splicing mechanism in Neurodevelopmental Disorder (NEUDIG project)

Giovanni Papagni[1], *Nicola Pomella*[1], *Fjorilda Caushi*[1], *Benedetta Bartilomo*[1], *Beatrice Piola*[1], *Maria Cerminara*[2], *Alessandra Bianchi*[2], *Marco Fontana*[3], *Iris Chen*[2], *Michele Iacomino*[2], *Paolo Uva*[4], *Silvia Boeri*[5], *Elisa Degrandis*[3,5], *Federico Zara*[2,3], *Aldamaria Puliti*[3,2], *Slavica Trajkova*[6], *Alfredo Brusco*[6], *Lucia Corrado*[1], *Sandra D'Alfonso*[1]

[1]*Università del Piemonte Orientale, Dipartimento Scienze della Salute, Novara, Italy,* [2]*IRCCS Istituto Giannina Gaslini, Medical Genetics Unit, Genoa, Italy, Genova, Italy,* [3]*University of Genoa, DiNOGMI Dipartimento di Neuroscienze, Riabilitazione, Oftalmologia, Genetica e Scienze Materno-Infantili, Genoa, Italy, Genova, Italy,* [4]*Clinical Bioinformatics Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy., Genova, Italy,* [5]*IRCCS Istituto Giannina Gaslini, Child Neuropsychiatry Unit, ERN EpiCARE Centre, Genoa, Italy, Genova, Italy,* [6]*Università of Torino; Department of Medical Sciences, Torino, Italy.*

Background: The Massively Parallel Splicing Assay (MaPSy) is employed to evaluate the splicing effects of multiple variants in a single assay. This method uses an amplicon-based library cloned into the pSPL3 plasmid, which is then transfected into HEK293T cells, followed by next-generation sequencing (NGS) analysis. The primary limitation is the lack of a barcode system limiting the total number of variants tested in a single assay. The objective of the study is to Develop high-throughput splicing assays capable of testing up to thousands of variants from Exome Sequencing (ES) data of 1,100-NDD (Neurodevelopmental-Disorder) families (NEUDIG-project). MaPSy as well as a barcode-based approach, named Variant Exon Sequencing (Vex-Seq) have been selected.

Material and Methods: We prioritized 782 ES-identified de novo variants with a SpliceAI score>0.5, MAF < 0.05. 350 had an allele count (AC)<10. Vex-Seq will be used to test wild-type and mutated alleles, in triplicate, totaling 2,100 assays in a unique experiment. Fourteen variants where in SFARI gene database and analysed also by MaPSy assay.

Results: We preliminary tested the SpliceAI prediction on splicing of 14 VUS with MaPSy. For all the fourteen variants (2

exonic, 9 intronic, 2 splicing) aberrant splicing isoforms were detected.The observed aberrant splicing was predicted to generate 11 out-of-frame transcripts, and 4 in-frame transcripts. The Vex-Seq library has been designed and the experiment is ongoing.

Conclusion: Our results confirm that VUS impact on splicing mechanism can be analyzed by a massive approach and SpliceAI is an effective predictor for prioritizing splicing-altering variants.

P10.017.B Cellular functional tests of *ARX* gene variants provide further insights into a better understanding of genotype-phenotype correlations in both male and female patients

Rasha Faraj[1,2], *Audrey Farrugia*[3,4], *Aline Dubos*[4], *Audrey Schalk*[5], *Cecile Voisset*[1,2], *Gaëlle Friocourt*[1,2,6]

[1]*Inserm UMR1078, Faculté de Médecine et des Sciences de la Santé, Université de Bretagne Occidentale, Brest, France,* [2]*Inserm UMR1101, Faculté de Médecine et des Sciences de la Santé, Université de Bretagne Occidentale, Brest, France,* [3]*Institut de Médecine Légale de Strasbourg, Fédération de Médecine Translationnelle de Strasbourg (FMTS), Université de Strasbourg, 11 Rue Humann, Strasbourg, France,* [4]*Institut de Génétique et de Biologie Moléculaire et Cellulaire (IGBMC), CNRS UMR7104, INSERM U1258, Université de Strasbourg, Illkirch, France,* [5]*Laboratoire de Diagnostic Génétique, Nouvel Hôpital Civil, Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [6]*Centre de Référence des Déficiences Intellectuelles et polyhandicaps de causes rares. CHRU de Brest - Bâtiment 5 - 2 Avenue Foch, 29609 Brest Cedex, France.*

Background: Intellectual disability (ID) is a major neurodevelopmental challenge, with mutations in the X-linked *ARX* gene being a frequent cause. *ARX*, a master regulator of brain development, encodes a transcription factor orchestrating the delicate symphony of key target genes' expression essential for proper GABAergic neuron development and function. Variants in *ARX* cause a broad clinical spectrum, from asymptomatic female cases to severe neurodevelopmental disorders (NDDs) in male and female patients. This study aims to investigate the functional consequences of 15 *ARX* variants, including likely pathogenic and some novel de novo variants with atypical clinical presentations, such as cases of sudden infant death.

Material and Methods: Missense and frameshift variants were transiently expressed in N2a cells. Functional assays, including Luciferase reporter, Western blot, Immunofluorescence, and RT-qPCR, assessed the level of expression of the produced proteins, their localization, their interaction with known corepressors TLE1 and CtBP1, and their transcriptional activity on a few *ARX*-known targets.

Results: All variants tested exhibited disrupted transcriptional regulation, often linked to altered expression or localization. Interestingly, our findings reveal that some variants exert dominant negative effects, potentially offering an additional explanation for skewed X-inactivation and the unexpectedly severe phenotypes observed in female patients.

Conclusion: Altogether, these findings shed valuable light on the molecular mechanisms driving *ARX*-related NDDs and their remarkable phenotypic diversity. Through a comprehensive review of published *ARX* variants, we aim to establish clear genotype-phenotype correlations based on the nature of the variant (frameshift or missense), its localization, as well as the sex of the patient.

P10.019.D Genotype-phenotype correlation and familial inheritance of ASXL3-related disorder

Nicola Holmes[1,2], *Emily Woods*[1], *Meena Balasubramanian*[1,3]

[1]*Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom,* [2]*University of Manchester, Manchester, United Kingdom,* [3]*University of Sheffield, Sheffield, United Kingdom.*

Background: *ASXL3*-related disorder is a neurodevelopmental disorder characterised by developmental delay, intellectual disability, microcephaly, and feeding difficulties. Patients typically harbour de novo heterozygous truncating *ASXL3* variants, which appear to cluster in the first half of exons 11 and 12. This study investigates the correlation between the location or type of variant and disease presentation. We present nine families with inherited *ASXL3*-related disorder and estimate the penetrance of the disorder.

Material and Methods: 204 affected individuals were collated from the literature and a concurrent natural history study. Variants were grouped based on their location and predicted consequence. Phenotypic information was standardised for statistical analysis by Fisher exact or Student t-test, where appropriate. Penetrance was estimated as the proportion of all individuals in published and unpublished families which harbour the familial *ASXL3* variant that present with features of the disorder.

Results: Significantly more individuals with a variant in exon 11 had microcephaly, sleep apnoea, hyperventilation, feeding tube requirement and reflux. Developmental delay and intellectual disability were also more severe in this cohort. Conversely, autism and behavioural problems were more common in the cohort with exon 12 variants. In our families, *ASXL3*-related disorder was inherited from both affected and unaffected parents, with an estimated penetrance of 89%.

Conclusion: These findings suggest a distinction in the disease mechanism of variants in exon 11 and 12, although it is not clear whether variants in exon 11 result in nonsense-mediated decay or truncation. Our pedigrees highlight the variable expressivity and incomplete penetrance of this disorder.

de Moulins, Moulins, France, [6]Service de génétique, Groupe hospitalier de La Rochelle-Ré-Aunis, La Rochelle, France.

Background: Purine rich element binding protein A (PURA) encoded by the *PURA* gene (5q31) is an important transcriptional regulator that binds DNA and RNA and has a key role in neuronal development and differentiation. Haploinsufficiency of this gene has been reported to cause a severe neurodevelopmental syndrome with a wide range of symptoms including intellectual disability, cerebral abnormalities and seizures. Only one large 5q31 duplication of 3.36 Mb involving this gene has been described by Rosenfeld et al. in 2011 in a patient who exhibits less severe symptoms with global developmental delay. However, the consequences of *PURA* overexpression on neurocognitive development have never been studied.

Material and Methods: Through a national collaboration, we collected seven 5q31 duplications involving *PURA* mainly de novo ranging from 571 kb to 3,5 Mb in patients with a neurodevelopmental disorder. To understand the impact of these duplications on neuronal development, we performed in vitro functional studies on mouse hippocampal neurons as well as human SH-SY5Y neuroblastoma cell line (which can be differentiated into neuron-like cells). *PURA* has been overexpressed in these cells by transfecting a PURA-MYC-DDK plasmid to mimic gene dosage effect.

Results: Overexpression of PURA protein induces a significant decrease in proximal dendritic arborization and in the number of dendrites compared to control condition.

Conclusion: Finally, these in vitro experiments aim to understand the neuropathological mechanisms associated with 5q31 duplications and to determine whether the duplication of *PURA* alters the neurodevelopmental trajectory and induces alterations at the dendritic and synaptic levels.

P10.021.B MECP2 mRNA profiling in Rett brain showed a mutated monoallelic transcript, while RNAscope analysis in wild type brain defined transcript and cell-specific localization

Silvia Montanari[1], *Martina Mietto*[1], *Miryam Rosa Stella Foti*[1], *Maria Sofia Falzarano*[1], *Francesca Gualandi*[1], *Marcella Neri*[1], *Paola Rimessi*[1], *Rita Selvatici*[1], *Silvia Torelli*[2,3], *Joussef Hayek*[4], *Stefania Bigoni*[1], *Alessandra Ferlini*[1,2]

Background: Rett syndrome is an X-linked dominant neurodevelopmental disorder mainly affecting girls, caused by MECP2 gene mutations. These include nonsense or frameshift mutations leading to premature protein truncation and mRNA decay, missense mutations in exons 3–4, reducing MeCP2 binding ability to methylated DNA, and deletions that mainly arise in the N-terminal and C-terminal domains. MeCP2 protein regulates gene expression and is highly expressed in the brain, where its dysfunction leads to the disorder neurological manifestations.

Material and Methods: X-chromosome inactivation (XCI), standard histology and MECP2 transcript profile were performed on a post-mortem Rett girl brain specimen carrying the R106W missense variation. This patient belongs to a 54 female subjects' cohort that we have clinically and genetically characterised. Due to specimen quality, further studies were limited. We also defined the MECP2 transcript spatial localization in a control human brain, cerebral cortex and cerebellum areas by RNAscope assay.

Results: The Rett brain specimen showed only the mutated MECP2 transcript, consistent with 95:5 skewed X-chromosome inactivation. RNAscope analysis revealed that MECP2 transcript is highly represented in human adult cerebral cortex and cerebellum, especially in Purkinje and granular cells.

Conclusion: This study confirmed the brain wide MECP2 transcript representation observed with protein analysis. RNAscope provided further insights about the cell-specific and spatial MECP2 transcript localization. XCI analysis in the Rett brain showed that only the mutated MECP2 messenger is transcribed. This finding supports the role of XCI in favouring the mutated MECP2 allele transcription, emphasizing loss-of-function mechanisms and impaired brain early-expressed key genes repression.

P10.022.C RNU4-2 monoallelic variants as a leading cause of syndromic neurodevelopmental disorder, including in patients with parental consanguinity

Aida Bertoli-Avella*, Christian A. Ganoza, Mariana Ferreira, Maryam Najafi, Daniel L. Polla, Krishna K. Kandaswamy, Kornelia Tripolszki, Peter Bauer, Jorge Pinto Basto*

Centogene GmbH, Rostock, Germany.

Background: We investigated the role of rare variants in the non-coding RNU4-2 gene as a newly identified cause of neurodevelopmental delay (NDD) and intellectual disability (ID) in a cohort of 4,918 patients with NDD/ID, enriched for parental consanguinity.

Material and Methods: Genome sequencing (GS) data from 22,928 individuals in our Biodatabank were queried for rare, monoallelic variants in RNU4-2. Human Phenotype Ontology (HPO)-encoded clinical information was extracted and analyzed using the ontologyX R package.

Results: Nearly 50% of the 4,918 patients with NDD/ID reported parental consanguinity. Eight relevant heterozygous RNU4-2 variants were identified in 28 patients. HPO-based analysis revealed a consistent syndromic phenotype characterized by NDD, abnormal brain morphology, hypotonia, global developmental delay, microcephaly, seizures, atypical behavior, and facial dysmorphism. RNU4-2 variants accounted for approximately 0.55% of NDD/ID cases in our full cohort, and 0.25% in the subset of consanguineous patients.

Conclusion: This study underscores the significance of *RNU4-2* as a major genetic cause of NDD/ID, extending its relevance to consanguineous patients, where recessive disorders are often suspected. We advocate for the re-evaluation of existing GS data to uncover potential diagnoses and emphasize the importance of GS as a first-tier diagnostic test.

Gemelli, IRCCS, Rome, Italy, [10]Molecular Medicine for Neurodegenerative and Neuromuscular Diseases Unit, IRCCS Fondazione Stella Maris, Rome, Italy, [11]IRCCS Azienda USL di Reggio Emilia, Reggio Emilia, Italy, [12]Operative Unit of Medical Genetics and Laboratory of Genetics, AORN A Cardarelli, Napoli, Italy, [13]University of Pavia, Dep. of Molecular Medicine, Pavia, Italy, [14]Department of Molecular Medicine, University of Pavia, Pavia, Italy.

Background: Recent studies have identified pathogenic heterozygous variants in the *RNU4-2* gene, which encodes the small nuclear RNA U4, as the molecular cause underlying ReNU syndrome, a syndromic neurodevelopmental disorder characterized by moderate to severe developmental delay (DD), intellectual disability (ID), a distinct facial gestalt, and multisystem involvement. Causative variants have predominantly been detected within an 18-nt critical region essential for the stability of the U4/U6 snRNA duplex and ensuring the proper spliceosome assembly.

Materials and methods: A cohort of 190 molecularly unexplained DD/ID cases that had previously been found negative via WES/WGS underwent WGS reanalysis or targeted sequencing to identify any pathogenic *RNU4-2* variant.

Results: We report on five affected individuals carrying pathogenic/putative pathogenic *RNU4-2* variants (2.6%). Three individuals harbored the recurrent pathogenic n.64_65insT variant, while two were heterozygous for private/rare maternally inherited variants (n.30A>T, n.43_44insT) within the 5' Stem-loop region. Deep clinical phenotyping reveled a consistent pattern of features, with global DD, ID, brain malformations, and a recognizable facial gestalt. Based on structural homology models and available cryo-EM data, we show that n.30A>T and n.43_44insT are predicted to impair crucial intra-/intermolecular interactions required for spliceosome function.

Conclusion: Our findings broaden the mutational spectrum of ReNU syndrome and confirm the 5' Stem-loop as a second mutational hotspot in *RNU4-2*. We suggest that a more complex genetics likely underlies the inheritance of a subset of *RNU4-2* variants from an apparently unaffected parent, and propose facial gestalt core features as a clinical screening tool to prioritize patients for *RNU4-2* mutation scan.

Genetics Group, Vall d'Hebron Research Institute, Barcelona, Barcelona, Spain.

Background: Intellectual disability (ID) is a common developmental disorder, either isolated (non-syndromic) or in combination with malformations and abnormalities (syndromic). Despite advances in next-generation sequencing (NGS) technologies like exome sequencing (ES), the molecular cause often remains unresolved, with germline-based diagnostics detecting only about 30% of cases. This highlights the molecular complexity of ID and the need for alternative diagnostic strategies.

Material and Methods: We analyzed blood and tissue samples from 14 patients with ID and associated cutaneous pigmentation disorders (PS). Using exome, genome, RNA sequencing and Nextera deep sequencing, we explored genetic causes, focusing on mosaicism and tissue-specific (fibroblast and melanocyte cultures) mutations in germline-negative cases.

Results: We identified low-grade mosaicism (up to 1.7%) in five patients, involving (likely) disease-causing variants in four known genes (*GNA11, HRAS, HUWE1*, and *OTUD5*) and a novel candidate gene (*SCARA3*). Furthermore, we detected three germline variants in three patients, affecting the genes *TFE3, BNIPL* and *NSD1*. The study achieved an overall detection rate of approximately 60%. These findings highlight the limitations of germline-based diagnostics and emphasize the importance of tissue-specific sampling for precise variant identification.

Conclusion: This study demonstrates that analyzing tissue samples and employing advanced NGS approaches is critical for improving diagnostic yields in ID patients, particularly when germline analysis fails to provide conclusive results. Our results suggest that novel diagnostic strategies, including the assessment of mosaicism and tissue-specific mutations, are essential for uncovering the molecular genetic causes of ID and may provide valuable insights into the pathogenesis of associated syndromic conditions.

[1]*Hunter Genetics, Newcastle, Australia,* [2]*University Of New South Wales, Sydney, Australia,* [3]*Liverpool Hospital Department of Genetics, Sydney, Australia,* [4]*Children's Hosptial of Philadelphia, Philadelphia, PA, USA,* [5]*Children's Hospital of Philadelphia, Philadelphia, PA, USA,* [6]*Hôpital Pitié-Salpêtrière, Paris, France,* [7]*Caen Normandy University Hospital, Normandy, France,* [8]*Quaid-i-Azam University, Islamabad, Pakistan,* [9]*Filadelfia, Dianalund, Denmark,* [10]*National Center of Genetics, Dudelange, Luxembourg,* [11]*Genetic Health Western Australia, Perth, Australia,* [12]*Universitat Autònoma de Barcelona, Barcelona, Spain,* [13]*Université de Brest, Brest, France,* [14]*Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands.*

Background: Intellectual developmental disorder with dysmorphic facies and behavioural abnormalities (IDDFBA; OMIM:618089) is a recently identified neurodevelopmental syndrome caused by pathogenic variants in *FBXO11*. While its genetic basis is established, the full phenotypic spectrum remains incompletely defined. This study aims to refine the clinical characterisation of FBXO11-related disorder by analysing 16 previously unreported cases.

Material and Methods: Through an international multicentre collaboration, we identified 16 individuals (8 males, 8 females; age range: 17 months to 20 years) with pathogenic or likely pathogenic variants in *FBXO11*. Phenotypic data were collected, and facial dysmorphisms analysed using GestaltMatcher, a machine learning-based tool. Variant classification followed ACMG/AMP guidelines, and genotype-phenotype correlations were explored.

Results: Our cohort exhibited a broad phenotypic spectrum, with mild intellectual disability and speech delay as the most consistent features. Behavioural abnormalities, particularly aggression, were common, while autism spectrum disorder was rare. A characteristic facial gestalt included a broad nasal tip, thin upper lip with a long, smooth philtrum, and large ears. Other features included sleep disturbances, brachydactyly, hyperhidrosis, and joint hyperlaxity. Genotype-phenotype analysis revealed that missense variants were associated with behavioural anomalies, nonsense variants with hypotonia, and large gene disruptions with brachydactyly. Otitis media, previously reported, was not seen in our cohort.

Conclusion: This study refines the phenotypic spectrum of FBXO11-related disorder, highlighting novel features such as hyperhidrosis and brachydactyly while de-emphasizing otitis media. These findings enhance diagnostic accuracy, particularly in mild intellectual disability and behavioural anomalies, where exome sequencing has historically had lower diagnostic yields.

P10.028.A Fine-scale characterization of the X-linked intellectual disability gene *HCFC1* reveals neuroanatomical phenotypes in female heterozygous mice

Binnaz Yalcin[1], *Emilia Skutunova*[1], *Ayushma Ayushma*[2], *Stephan C. Collins*[1], *Shilpi Minocha*[2]

[1]*Inserm 1231, Dijon, France,* [2]*Kusuma School of Biological Sciences, Indian Institute of Technology Delhi (IITD), New Delhi, India.*

Background: X-Linked Intellectual Disability (XLID) is a neurodevelopmental disorder with X-linked recessive inheritance, characterized by cognitive dysfunction and accounting for about 16% of all cases of ID in males worldwide. However, in most cases, the underlying molecular mechanisms are largely unknown. This project aims to decipher the role of HCFC1, a chromatin-binding transcriptional coregulator, implicated in X-linked cobalamin ID associated with microcephaly.

Material and Methods: Given the full mouse Knockout of HCFC1 is lethal, we utilized the Emx1 Cre line to delete *Hcfc1* specifically in the telencephalon. High-Resolution Episcopic Microscopy (HREM) was used for neuroanatomical studies and 3D Slicer for the segmentation of 24 brain regions, providing

volumetric and morphology data of the entire brain at near-cellular resolution.

Results: Our findings reveal that both male *Emx1Cre;Hcfc1* hemizygote and female *Emx1Cre;Hcfc1* homozygous mice die within hours after birth and present neuroanatomical defects, including complete agenesis of the hippocampus and absence of the corpus callosum. Unexpectedly, we also observed phenotypes in adult heterozygote females, notably a 20% reduction of the volume of both the cortex and the corpus callosum, and a 17% decrease of the hippocampus and the retrohippocampus. The anterior commissure, the fasciculus retroflexus and the fimbria of the hippocampus have smaller volume with 30%, 14% and 10% decrease respectively, in comparison to the matched WT controls.

Conclusion: Our project highlights sex-specific *HCFC1*-associated phenotypes across the mouse brain, suggesting that the medical community assess the contribution of X-inactivation in carrier mothers to help classify variants in probands.

P10.029.B ARID1B-related disorder in 87 adults: Natural history and self-sustainability

Pleuntje J. van der Sluijs[1], *Marjolein Gösgens*[1], *Alexander J.M. Dingemans*[2], *ARID1B consortium*[3], *Gijs Santen*[1]

[1]*Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [2]*Radboudumc, Nijmegen, Netherlands,* [3]

Background: ARID1B is one of the most frequently mutated genes in intellectual disability cohorts. Thus, far few adult-aged patients with ARID1B-related disorder have been described, which limits our understanding of the disease's natural history and our ability to counsel patients and their families.

Material and Methods: Data on patients aged 18+ years with ARID1B-related disorder were collected through an online questionnaire completed by clinicians and parents.

Results: Eighty-seven adult patients with ARID1B were included. Cognitive functioning ranged from borderline to severe intellectual disability. Patients identified through the genetic workup of their child were either mosaic or had a variant in exon 1. New clinical features identified in this population are loss of skill (16/64, 25%) and recurrent patella luxation (12/45, 32%). Self-sustainability data showed that 88% (45/51) could eat independently, and 16% (7/45) could travel alone by public transport. Facial photo analysis showed that patients' photographs taken at different ages clustered consistently, separate from matched controls.

Conclusion: The ARID1B spectrum is broad, and as patients age, there is a significant shift in the medical aspects requiring attention. To address the changing medical needs with increasing age, we have formulated recommendations to promote timely intervention in an attempt to mitigate disease progression.

P10.030.C Houge-Janssens syndrome types 1–4: Clinical overview and novel pathogenic mechanisms

Gunnar Douzgos Houge[1], *Sofia Douzgou Houge*[1], *Iris Verbinnen*[2], *Veerle Janssens*[2]

[1]*Haukeland University Hospital, Bergen, Norway,* [2]*KU Leuven Institute for Rare Diseases, Leuven, Belgium.*

Background: Houge-Janssens syndrome (HJS) is caused by protein phosphatase type 2A (PP2A) dysfunction. PP2A is a trimer of a catalytic (C), a scaffolding (A) and one of 15 regulatory (B) subunits. PP2A oppose the activity of numerous serine/threonine protein kinases, including growth promoting kinases of the PIK3CA/AKT/mTOR and RAS/MAPK pathways. This presentation gives an overview of both the clinical spectrum and known or potential pathogenic mechanisms in Houge-Janssens syndrome.

Material and Methods: All publications on individuals with dominant pathogenic variants in three B subunits (*PPP2R5D* in HJS type 1, *PPP2R5C* in HJS type 4, and *PPP2R5E*), the major scaffolding subunit (*PPP2R1A* in HJS type 2) and the major catalytic subunit (*PPP2RCA* in HJS type 3) were reviewed, clinical features were compared, and genotype-phenotype correlations were investigated and compared to biochemical results on subunit (B to A/C) and substrate (S to PP2A) binding.

Results: We provide a clarifying molecular and clinical comparison of the four types of Houge-Janssens syndrome (HJS) and delineates the molecular mechanisms. This explains why the phenotype can range from learning difficulties and autism to severe intellectual disability with intractable epilepsy. Our study strongly suggests that the regulatory subunits of PP2A are not only important for guiding the phosphatase to the right substrates, but also for protecting these substrates from unwarranted and spontaneous dephosphorylation.

Conclusion: Our work is a reference for understanding clinical and biochemical features of Houge-Janssens syndrome, and our combined results suggest that PP2A has an important role in dephosphorylation timing.

Background: *DYRK1A* haploinsufficiency syndrome (DHS; OMIM#614104; ORPHA:464311;268261) accounts for approximately 1% of cases of intellectual disability (ID) and/or autism spectrum disorder (ASD) and is included in the differential diagnosis of Angelman/Rett-like entities. It is characterized by ID, microcephaly, epilepsy, behavioural abnormalities, and distinctive dysmorphic features.

Material and Methods: We have conducted a retrospective and collaborative study, through the Spanish Society of Clinical Genetics and Dysmorphology, aimed to identify individuals affected by DHS and provide their clinical and molecular characterization, including the biochemical analysis of the associated-kinase activity in new *DYRK1A* variants.

Results and conclusion: A total of 33 cases of DHS were identified across 10 hospitals, involving 25 variants, 15 of which are novel, thereby contributing to an expanded understanding of the molecular basis of the condition. All variants are de novo; moreover, all the missense variants analyzed were catalytically dead supporting functional haploinsufficiency. The main clinical features in the Spanish cohort include ID, epilepsy, autism, microcephaly, and a recognizable craniofacial phenotype, consistent with previously described features, though with lower prevalence of ophthalmological, renal, and feeding anomalies. Unusual features include tibial osteochondroma, bifid uvula, and anteriorly placed anus. Additionally, a patient with macrocephaly and an atypical phenotype, carrying a truncating variant in the C-terminal region that preserves enzymatic activity, may represent a new syndrome associated with *DYRK1A*. The limited number of cases and their concentration in regions with access to medical geneticists suggests that this condition is underdiagnosed, highlighting the need for specialized assessment and comprehensive genomic sequencing studies.

P10.032.A Refining the Neurodevelopmental Phenotype of Snijders Blok-Campeau Syndrome

Théo Berger[1], *Alexandra Afenjar*[1], *Boris Keren*[2], *Emmanuelle Lacaze*[1,3], *Fanny Phelippeau*[2], *Jean-Madeleine De Sainte Agathe*[2], *Nathalie Dorison*[4,3], *Sarah Grotto*[1], *Solveig Heide Guihard*[2], *Delphine Héron*[2], *Daphné Lehalle*[1], *Caroline Nava*[2], *Marie-Christine Nougues*[3], *Florence Robin-Renaldo*[3], *Diana Rodriguez*[3], *Sandra Whalen*[1], *Cyril Mignot*[1], *Anna Gerasimenko*[1]

[1]*Département de Génétique, Centre de référence "déficiences intellectuelles de causes rares", APHP Sorbonne Université, GH Pitié Salpêtrière et Trousseau, Paris, France,* [2]*Département de génétique, Hôpital Pitié-Salpêtrière, Assistance Publique-Hôpitaux de Paris, Paris, France,* [3]*Département de Neurologie pédiatrique, Centre de référence Neurogénétique, Hôpital Armand Trousseau, Paris, France,* [4]*Unité Dyspa, Neurochirurgie Pédiatrique, Hôpital Fondation Rothschild, Paris, France.*

Background/Objectives: Snijders Blok-Campeau syndrome (SBCS) is caused by pathogenic variants (PV) in CHD3. To date, all reported patients have global developmental delay and the majority have mild to severe intellectual disability (ID). However, long-term neurodevelopmental trajectories of affected individuals has been poorly studied to date. This study aims to refine the expected neurodevelopmental prognosis of SBCS.

Methods: We conducted a retrospective analysis of 12 individuals from 10 families, carrying CHD3 PV, identified through WES/WGS, with a median age of 11.5 years [range: 6–42] at last evaluation. Standardized neuropsychological assessments were conducted in 4 patients.

Results: Patients exhibited global developmental delay, with motor delay related to axial hypotonia in all, and language delay in 9/12. Diagnoses of neurodevelopmental disorders could be established or suggested during follow-up: ID ($n = 6$), ADHD ($n = 10$), developmental coordination disorder ($n = 4$), ASD ($n = 3$). Half of our patients attended ordinary classes with human help or classes for children with special needs, the other half attended special schools for children with ID. All individuals of the former group started to speak sentences at or before 3 years of age, whereas those in the latter spoke sentences much later.

Conclusion: This study confirms the broad spectrum of neuropsychological profiles in SBCS. Unexpectedly, half of our patients had a favorable cognitive/schooling outcome, despite universal global developmental delay. Our data suggest that the cognitive performance of children with SBCS may be higher than previously reported, and that early developmental delay does not imply permanent cognitive impairment.

P10.033.B Expanding the phenotypic spectrum of Helsmorteel-van der Aa Syndrome: a multigenerational case report

Sara Calabrese[1,2], *Andreina Minicucci*[1,2], ***Maria Elisabetta Tortorino***[1,2], *Tommaso Pippucci*[1,3], *Cesare Rossi*[1,4], *Marco Seri*[5], *Francesca Montanari*[1]

[1]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Policlinico Sant'Orsola Malpighi, Medical Genetics Unit, Bologna, Italy,* [2]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy,* [3]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Policlinico Sant'Orsola Malpighi, Computational Genomics Unit, Bologna, Austria,* [4]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Policlinico Sant'Orsola Malpighi, Molecular biology and medicine Unit, Bologna, Italy,* [5]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Policlinico Sant'Orsola Malpighi, Bologna, Italy.*

Background: Helsmoortel-van der Aa syndrome (HVDAS) is a rare neurodevelopmental disorder caused by pathogenic variants in ADNP gene, leading to developmental delay, intellectual disability

and autism spectrum disorder. Patients often exhibit characteristic facial dysmorphisms and variable systemic manifestations, including hypotonia and gastrointestinal issues. HVDAS shows a wide range of phenotypic expression, from severe presentations in children to milder forms in adults, with autosomal dominant inheritance.

Material and Methods: An 11-year-old boy was assessed for intellectual disability with speech impairment, recurrent infections and mild dysmorphic features. We performed array-CGH, followed by NGS panel for RASopaties which proved negative. Lastly, whole exome trio sequencing (WES) was performed. Upon identification of a maternally inherited pathogenic variant, targeted segregation analysis in first degree relatives was carried out.

Results: We identified the maternally inherited heterozygous pathogenic variant c.2865_2868del (p.Ser955Argfs*36) in the ADNP gene. Subsequent targeted genetic testing found the variant also in the patient's maternal grandmother and in his sister. Mother (43) and grandmother (74) were both presenting with mild and variable phenotypic features consistent with HVDAS (learning difficulties, mild gastrointestinal symptoms, congenital cataract). His sister (15) was previously assessed for cognitive and language impairment.

Conclusion: This is the first report, to the best of our knowledge, documenting the presence of a pathogenic ADNP variant in elderly individuals, providing new data on the phenotypic spectrum and variability in expressivity. Our findings improve the understanding of HVDAS intrafamilial phenotypic heterogeneity, suggesting that attenuated presentations may occur in adulthood, potentially contributing to the underdiagnosis of this condition.

Background: Developmental language disorder (DLD) is characterized by impaired language development despite adequate linguistic input, and can majorly impact communication and social participation. The role of monogenic causes in DLD is largely unknown and routine genetic testing is rarely offered. This study assesses the diagnostic yield of genome sequencing in severe DLD, and investigates its underlying genetic foundations.

Material and Methods: We designed a prospective cohort study involving trio-based genome sequencing in 25 individuals (aged 3–25y) with severe DLD, normal intelligence (IQ >70) and no autism spectrum disorder. Only individuals with a negative first-degree family history were included, to enrich for de novo variants.

Results: (Likely) pathogenic variants were found in nine individuals, resulting in a molecular diagnostic yield of 36%. The identified genetic causes were diverse, encompassing single nucleotide variants (n = 5), copy number variants (n = 3), and one sex chromosome aneuploidy (n = 1). In seven individuals a de novo variant was found, whilst two had autosomal recessive disorders. The genetic findings provided actionable clinical insights in several cases.

Conclusion: This study shows the value of genome sequencing in individuals with severe language disorders, even in the context of normal intelligence. We observed a high prevalence of rare genetic variants in individuals with severe DLD and a negative family history. Our findings suggest that the molecular background of DLD strongly overlaps with that of other neurodevelopmental disorders. Thus, one should consider (at least a subgroup of) DLD as part of the spectrum of cognitive disorders, rather than a distinct aetiological entity.

P10.035.D Clinical and molecular characterization of Malan syndrome: new insights from a Spanish case series. Highlighting ophthalmologic manifestations and adulthood care

Irene Valenzuela Palafoll[1], *Laura Trujillano-Lidon*[1], *Lasa-Aranzasti Amaia*[1], *Barbara Masotto*[1], *Anna Cueto-Gonzalez*[1], *Emma Lorente*[1], *Paula Fernandez Alvarez*[2], *Ivon Cusco*[1]

[1]*Hospital Vall d'Hebron, Barcelona, Spain,* [2]*Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Universitari Vall d'He, Barcelona, Spain.*

Background: Malan syndrome (MALNS) is a neurodevelopmental disorder caused by pathogenic variants in the *NFIX* gene. Patients with MALNS exhibit overgrowth, typical craniofacial features, intellectual disability, and a range of psychobehavioral, musculoskeletal and ophthalmologic signs. The natural history of the disorder is poorly characterized due to the small number of adult individuals described so far.

Material and Methods: We identified 5 unpublished individuals with a neurodevelopmental disorder and overgrowth phenotype, all carrying likely pathogenic variants in the *NFIX* gene. Exome sequencing was used as a diagnostic tool.

Results: The mean age of the individuals is 25 years (range 15–33). Clinical presentation was predominantly characterized by psychobehavioral comorbidities (100%), musculoskeletal involvement (100%), vision impairment (100%), and seizures (50%). Ophthalmologic manifestations were present in all individuals, including strabismus (80%), optic atrophy (40%), and cataract (40%). We report a previously unreported ophthalmologic feature in one patient: unilateral spontaneous absorption of a cataractous lens. Regarding the molecular spectrum, 4 likely pathogenic variants in *NFIX* were identified, none of which have been previously reported. One of the families has two affected daughters, with the variant not identified in the parents, providing evidence of germline mosaicism.

Conclusion: The inclusion of new patients with MALNS increases the understanding of the molecular spectrum of *NFIX* and is essential for delineating the phenotype of this condition. The case series includes a set of sisters with the same novel pathogenic variant in *NFIX*, providing further evidence of germline mosaicism. Ophthalmologic manifestations are prominent and require special surveillance, even in adulthood.

Background: 1700 genes have been reported in genetic forms of intellectual disability or autism, often with limited information on clinical spectrum, comorbidities and natural history. These data are essential for medical care and genetic counseling. We initiated in 2016 an international participatory registry and database to gather such information.

Material and Methods: Clinical information is entered by a family caregiver of an affected individual in a structured questionnaire (41 multiple choice questions and 92 sub-questions, 5 open text qualitative questions) available online in 8 languages (https://genida.unistra.fr). Gene specific charts are generated and updated from the deidentified MCQ data.

Results: GenIDA counts 2095 well documented single patient files, the largest cohorts for KdVS (KANSL1/17q21.31del) 248, Kleefstra syndrome 211, DDX3X 70. The three most represented countries are France (918), USA (399) and UK (176). Comorbidities overlooked previously have been identified such as respiratory infections or childhood asthma in KdVS. The various manifestations of behavior problems or epilepsy and their perceived severity are reported, as well as the perceived efficiency of epilepsy medications. Nine gene specific papers have been published since 2022, reporting broad aspects or more focused studies (scoliosis or ocular manifestations in KdVS, speech and language for DDX3X, arrythmia in Kleefstra syndrome). We will report unpublished observations for MED13L (n = 52) and for the recently identified major ID gene RNU4-2 (n = 23).

Conclusion: GenIDA has proved its utility for investigating the various phenotypes relevant to health, quality of life, cognitive, behavioral and communication aspects in specific neurodevelopmental disorders.

P10.037.B Expanding the clinical and mutational spectrum of FBXO11-associated Neurodevelopmental Disorder: a monocentric study of 9 additional cases

Alessio Ludovico Del Popolo[1,2], *Maria Lisa Dentici*[1], *Lorenzo Sinibaldi*[1], *Francesca Romana Lepri*[3], *Monia Ginevrino*[3], *Maria Gnazzo*[3], *Rossella Capolino*[1], *Alessandra Mandarino*[4], *Federico Casciani*[1,2], *Federica Lo Bascio, MD*[1,2], *Miriam L. Carriero*[1,2], *Monia Magliozzi*[3], *Antonio Novelli*[3], *Maria Cristina Digilio*[1]

[1]*Medical Genetics Unit, Ospedale Pediatrico Bambino Gesù, Rome, Italy,* [2]*Department of Biomedicine and Prevention, University of Rome "Tor Vergata", Rome, Italy,* [3]*Translational Cytogenomics Research Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy,* [4]*Child and Adolescent Neuropsychiatry Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy.*

Background: FBOX11 encodes an F-box protein involved in the SCF ubiquitin ligase complex, regulating protein turnover. Pathogenic variants in this gene are linked to an autosomal dominant intellectual developmental disorder with dysmorphic facies and behavioral abnormalities (IDDFBA, OMIM:618089). To date,80 cases have been reported, but no germline mosaicism has been described.

Material and Methods: Data were collected from patients with a confirmed heterozygous FBXO11 variant. Genetic testing was performed on DNA extracted from peripheral blood of probands and parents using Clinical Exome Sequencing.

Results: We report 9 individuals from 6 families (age range of 3–48 years). Three were novel variants and one was reported at a low allele fraction of 23% in peripheral blood in a 19-year-old boy. In one family 3 siblings harbored a missense variant, likely inherited from the not tested mother who presented intellectual disability and suggestive facial features. Another family presented two siblings carrying the same variant (both parents tested negative, suggesting germline mosaicism). All patients displayed facial dysmorphism, intellectual disability and/or developmental delay. MRI anomalies (2/9) were described, including ventriculomegaly, hippocampal anomalies, white matter reduction.

Conclusion: This study further molecularly and clinically characterizes FBXO11-associated IDDFBA disorder. We present the first report of a likely germline mosaicism due to the recurrence of an apparent de novo heterozygous variant in two siblings and the first affected individual with allele fraction of 20% in peripheral blood with a full-blown FBXO11-related phenotype. Additionally, the oldest individuals of our cohort help delineate the management recommendations in adulthood.

P10.038.C Analysis of MeCP2 interaction with the splicing factor PRPF40B and potential implications for Rett Syndrome pathogenesis

Sara Pastore[1,2], *Silvia Gasparini*[3], *Susanna Croci*[4], *Alessandra Russo*[1,2], *Letizia Giordano*[5], *Alessandra Renieri*[1,2,4], *Ilaria Meloni*[1,2], *Cecilia Mannironi*[3]

[1]*Medical Genetics, University of Siena, Siena, Italy,* [2]*Med Biotech Hub and Competence Center, Department of Medical Biotechnologies, University of Siena, Siena, Italy,* [3]*Institute of Molecular Biology and Pathology, National Research Council, Roma, Italy,* [4]*Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy,* [5]*Sapienza University of Rome, Roma, Italy.*

Background: Rett syndrome (RTT, OMIM #312750) is a rare X-linked neurodevelopmental disorder caused by mutations in the *Methyl-CpG-binding protein 2* (*MECP2*) gene in over 95% of cases. MeCP2 is multifunctional protein which regulates gene transcription, chromatin organization, and RNA splicing. Its role in RNA maturation and alternative splicing dysregulation and their contribution to RTT neuropathology remain poorly understood. This study aims to validate and characterize in neuronal cells MeCP2 interaction with PRPF40B, a pre-mRNA processing factor involved in alternative splicing regulation.

Material and Methods: In order to identify differentially expressed and spliced genes associated with MeCP2 mutation, we will compare mutated and isogenic WT iPSC-derived neurons from two patients with the p.R168X mutation through a comprehensive transcriptomic analysis. In parallel, PRPF40B knockdown will be performed in both WT and p.R168X neurons to elucidate its role in MeCP2-mediated splicing regulation. Additionally, co-immunoprecipitation assays are ongoing to validate the interaction between MeCP2 and PRPF40B in human HEK-293 and SH-SY5Y neuroblastoma cell lines.

Results and conclusions: We have demonstrated the binding of MeCP2 to PRPF40B in human HEK-293 and SH-SY5Y neuroblastoma cell lines. By comparing WT and RTT-causing *MECP2* mutant constructs, we have shown that the large C-terminal truncating mutation (p.R168X) abolishes MeCP2 binding to PRPF40B. Validation in patient-derived neurons is ongoing. To further explore the functional significance of the MeCP2/PRPF40B interaction, ribonucleoprotein (RNP) complexes will be isolated, and bound RNA will be characterized. Bioinformatics analyses will identify key genes and pathways associated with the disease, highlighting potential therapeutic targets for RTT.

P10.039.D Visuospatial abilities predict general adaptive functioning in Williams syndrome

Charlotte Willfors[1,2], *Astrid Hallman*[3,1], *Johan Lundin Kleberg*[3,4], *Ann Nordgren*[1,2,5]

[1]*Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden,* [2]*Department of Clinical Genetics and Genomics, Karolinska University Laboratory, Karolinska University Hospital, Stockholm, Sweden,* [3]*Department of Psychology, Stockholm University, Stockholm, Sweden,* [4]*Centre for Psychiatry Research, Department of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden,* [5]*Department of Laboratory Medicine, Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden.*

Background: Williams syndrome (WS) is associated with mild to moderate intellectual disability and specific challenges in visuospatial abilities, characterized by an atypical processing style on tests of construction. To overcome difficulties with visuospatial construction, individuals with WS typically adopt a piecemeal approach resulting in relative success in reduplicating the local elements of an image, but failure to reduplicate global elements. This study ought to address how these specific difficulties with visuospatial construction translate into everyday life in individuals with WS.

Material and Methods: We collected standardized measures of visuospatial ability and adaptive functioning from 24 individuals with WS (50% female, age 9–53 years), and 24 typically developed controls matched on mental age. Regression analyses were used to analyze the data.

Results: The WS group showed severe difficulties with visuospatial construction in comparison to normative data, and applied a piecemeal approach to solve the task. The general adaptive functioning level was low, with a large variation, and characterized by a relative strength in social domains, and challenges with cognitive and practical domains. There was a positive association between visuospatial ability and adaptive functioning, whilst verbal IQ did not add significantly to the model. The final regression model showed that the visuospatial performance predicted 54% of the variation in adaptive functioning scores.

Conclusion: Our findings highlight the importance of clinical assessments and interventions targeting visuospatial difficulties to improve everyday functioning in WS.

P10.040.A Diagnostic yield in a paediatric cohort of patients with Intellectual Disability, Autism Spectrum Disorder and Epilepsy using a 1568 gene panel and *RNU4-2* sequencing

Simona Mellone[1], *Denise Vurchio*[1], *Giulia Borgonovi*[2], *Giulia Paglino*[1], *Tatiana Scagliotti*[2], *Avin Piroutiniya*[2], *Alessandro Ugonotti*[2], *Sara Ronzani*[1], *Caterina Lonati*[1], *Maurizio Sciancalepore*[1], *Giorgia Mandrile*[3], *Giovanni Battista Ferrero*[3], *Amanda Papa*[4], *Umberto Dianzani*[1,2], *Maurizio Viri*[4], *Mara Giordano*[1,2]

[1]*Laboratorio di Genetica, S.C.D.U. Biochimica Clinica, Azienda Ospedaliero Universitaria "Maggiore della Carità", Novara, Italy,* [2]*Dipartimento di Scienze della Salute, Università del Piemonte Orientale, Novara, Italy,* [3]*S.S.D. Microcitemie-Pediatria, Azienda Ospedaliero Universitaria San Luigi Gonzaga, Orbassano, Italy,* [4]*S.C.D.O. Neuropsichiatria Infantile, Azienda Ospedaliero Universitaria "Maggiore della Carità", Novara, Italy.*

Background: For neurodevelopmental disorders (NDDs), a molecular diagnosis is key for management, predicting outcome and counseling.

Material and Methods: Using a custom 1568-gene NGS panel, we analyzed 572 patients (401 males, 171 females) diagnosed with various NDDs, including intellectual disability (ID), autism spectrum disorder (ASD) and epilepsy. All patients had previously negative for array-CGH and FRAXA. A subset of 202 patients was sequenced by Sanger for *RNU4-2*, a spliceosoma RNA component recently implicated in NDDs but not yet included in the panel.

Results: Pathogenic (P) or Likely Pathogenic (LP) variants were identified in 133 cases, yielding an overall detection rate of 23.2%. Among available trios, 54.9% exhibited de novo mutations. Notably, the prevalence of P/LP variants was significantly higher in females than in males (33.9% vs. 18.7%; $p = 0.00008$). Among

patients with epilepsy, 25.6% carried causative variants spanning 23 genes. In those with isolated epilepsy, 20.0% harbored P/LP with *KCNQ2, NALCN, PAK3, PRRT2, SCN1A* and *SLC2A1* being involved in ≥ 2 patients. Among ASD patients, 18% carried P in 11 genes, including *KANSL1, SLC9A6, CDKL5, SYNGAP, SCN1A* and *FOXP1*. No variant was detected in the *RNU4-2* 18-bp critical region, although 2 rare variants were identified in three patients: n.29 A>T (in all the 3 patients vs 5/31388 in gnomAD) and n.96 A>T absent in gnomAD that warrant further investigation.

Conclusion: Our 1,568-gene NGS panel proves to be a powerful diagnostic tool for NDDs in clinical practice and it that will be improved by adding *RNU4-2* and other spliceosome genes.

P10.041.B Investigating the effect of missense variants in HNRNPU-related neurodevelopmental disorder

Louise Mary Baxandall[1], *Meena Balasubramanian*[1], *Ang Li*[2]

[1]*Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom,* [2]*Sheffield University, Sheffield, United Kingdom.*

Background: HNRNPU is abundantly expressed in the nucleus where the insoluble portion tethers caRNA to chromatin, and the soluble portion dissociates from chromatin enabling compaction before mitosis. Variants in *HNRNPU* cause HNRNPU-related neurodevelopmental disorder (HNRNPU-NDD). The phenotype of HNRNPU-NDD varies but most patients have intellectual disability, developmental delay, seizures, and craniofacial dysmorphisms. The primary disease mechanism of HNRNPU-NDD is loss of function (LOF), however there is an increasing number of pathogenic missense variants.

Material and Methods: Genotype-phenotype analysis comparing the phenotypes of LOF variant patients and missense variant patients was performed. Site directed mutagenesis was used to create hnRNP-U with the variants of interest and western blotting was done to characterise the impact of four missense variants in the ATP binding domain of the protein.

Results: No phenotype difference was seen between missense variant patients and LOF variant patients. Functional analysis showed that proteins carrying missense variants are still expressed and hence not targeted for degradation. It also showed that missense variants in the ATP binding domain of hnRNP-U reduce protein solubility. The result of this is the protein is only able to tether caRNA to chromatin, it is unable to evict the RNAs in time for mitosis.

Conclusion: A similar phenotype for both LOF and missense variants suggest there is a similar disease mechanism hence, missense variants must be causing a qualitative or quantitative LOF. Functional analysis shows that this is likely to be a qualitative LOF with the four variants studied decreasing the solubility of the protein.

P10.042.C Functional evidence supports expansion of the CEP104 disease spectrum beyond Joubert Syndrome

Nikoleta Argyrou[1], *Elise A. Ferreira*[2,3], *Harriet A.J. Saund*[4], *Ideke J.C. Lamers*[5], *Marc Engelen*[6], *Saskia N. Van Der Crabben*[7,3], *Anna Akhmanova*[8], *Clara D.M. van Karnebeek*[9,10,3], *Ronald Roepman*[1], ***Machteld M. Oud***[11,3]

[1]*Department of Human Genetics, Radboud Institute for Medical Innovation (RIMI), Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Department of Paediatrics, Emma Children's Hospital, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands,* [3]*United for Metabolic Diseases, Amsterdam, Netherlands,* [4]*Cell biology, Neurobiology and Biophysics, Department of Biology, Faculty of Science, Utrecht University, Utrecht, Netherlands,* [5]*Department of Human Genetics, Radboud Institute for Medical Innovation (RIMI), Radboud University Medical Center, Nijmegen, the Netherlands, Nijmegen, Netherlands,* [6]*Amsterdam Neuroscience Institute, Amsterdam, Netherlands,* [7]*Department of Human Genetics, Amsterdam University Medical Centers, University of Amsterdam, Amsterdam, Netherlands,* [8]*Cell Biology, Neurobiology and Biophysics, Department of Biology, Faculty of Science, Utrecht University, Utrecht, Netherlands,* [9]*Emma Center for Personalized Medicine, Departments of Pediatrics and Human Genetics, Amsterdam University Medical Center, Amsterdam, Netherlands,* [10]*Departments of Pediatrics and Laboratory Medicine, Laboratory Genetic Metabolic Diseases, Amsterdam University Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [11]*Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Ciliopathies are a group of congenital disorders caused by cilia dysfunction. Cilia are small signaling organelles present on many eukaryotic cells that play an important role during development. The ciliary protein CEP104 is required for cilium elongation and sonic hedgehog signaling (SHH). Biallelic pathogenic variants in *CEP104* cause Joubert syndrome (JBTS), characterized by psychomotor developmental delay, oculomotor apraxia and cerebellar hypoplasia visualized as a 'molar tooth sign' (MTS) on brain imaging. More recently, variants in *CEP104* were also associated with intellectual disability disorder 77, a non-syndromic neurodevelopmental disorder without the characteristic MTS. We describe a young girl with biallelic variants in *CEP104*, who presents with a neurodevelopmental disorder phenotype without MTS. To investigate the pathogenicity of the variants we studied ciliogenesis and SHH in proband-derived fibroblasts.

Methods: Skin-derived fibroblasts of the proband and three controls were evaluated by immunofluorescence for ciliogenesis, ciliary length, microtubule stability, and SHH properties. Cilium parameters were quantified using the automated FIJI-tool ALPACA. The effect of the missense variant on protein-protein interactions was assessed by co-immunoprecipitation.

Results: CEP104 proband-derived fibroblasts displayed slightly shorter cilia and a significant difference in SHH component levels in comparison to controls, while ciliogenesis and microtubule stability were not affected. The missense variant also disturbed CEP104 binding to CSPP1.

Conclusion: Our results suggest pathogenicity of the *CEP104* variants and thereby provide a clinical and molecular diagnosis for this family. Furthermore, it provides evidence to expand the *CEP104*-associated disease spectrum beyond JBTS and suggests to investigate *CEP104* in patients with intellectual deficit.

P10.043.D *SETD5*-related neurodevelopmental disorder: 50 novel individuals and review of the literature

Berardo Rinaldi[1], *Francesca Clementina Radio*[2], ***Beatrice Conti***[1], *Cecilia Mancini*[2], *Giulietta Scuvera*[1], *Camilla Cappelletti*[2], *SETD5 study group*[3], *Marco Tartaglia*[2], *Maria Francesca Bedeschi*[1]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [2]IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Italy, [3]ERN-ITHACA, Paris, France.

Background: Mendelian disorders of the epigenetic machinery are a broad group of neurodevelopmental disorders involving various components of the epigenetic machinery and other functionally related genes. *SETD5* gene (OMIM *615743) maps to chromosome 3 (3p25.3), and encodes for the lysine methyltransferase family member SET Domain Containing 5. The primary role of SETD5 is promoting gene expression through the trimethylation of lysine 36 of histone H3 (H3K36), a crucial event for chromatin partitioning. Pathogenic variants in *SETD5* are associated with a neurodevelopmental disorder known as "intellectual developmental disorder, autosomal dominant 23" (OMIM #615761, ORPHA: 404440) featuring intellectual disability of various degree, hypotonia, feeding difficulties, dysmorphic features, autism spectrum disorder, and behavioral disorders.Up to know about 35 patients have been described in literature in several reports.

Material and Methods: we launched an international call via the ERN ITHACA website to improve the current knowledge of this condition and collected 50 novel cases.

Results: we present our clinical data comparing them with what already known in literature.

Conclusion: our work has allowed us to broaden the phenotypic description of the *SETD5*-related neurodevelopmental disorder, also confirming the role of ERN-ITHACA as valuable platform for data exchange

P10.044.A Neurodevelopmental profile of Kleefstra syndrome: nature and trajectory of regressions

Adrien LEGRAND[1], Romain DUQUET[2], Cristina Alina BIRZU[3], Solveig HEIDE[2], Laurence PERRIN SABOURIN[4], Daphne LEHALLE[2], Anna GERASIMENKO[2], Boris CHAUMETTE[5], Delphine HERON[2], ***Perrine CHARLES***[2]

[1]Ste Anne Hospital, Psychiatric department, reference center for rare diseases with psychiatric manifestations, PARIS, France, [2]1-Salpêtriere Hospital, Genetic department, reference center for intellectual disabilities, PARIS, France, [3]Salpêtriere Hospital, Neurologic department, ICM Paris Brain Institute, PARIS, France, [4]Robert Debré Hospital, Genetic department, reference center for intellectual disabilities, PARIS, France, [5]INSERM U1266, Ste Anne Hospital, Psychiatric department, reference center for rare diseases with psychiatric manifestations, Paris, France.

Kleefstra syndrome is a rare genetic disorder caused by haploinsufficiency of the EHMT1 gene: microdeletion in chromosomal region 9q34.3 (in 85% of cases) or mutation in the EHMT1 gene coding for euchromatin histone methyltransferase 1, characterized by the core clinical phenotype of intellectual disability, hypotonia, severe speech delay, and distinct facial characteristics with additional clinical features including sleep disturbances with an erratic sleep pattern, overweight, psychiatric disorders, and autism spectrum disorders. Among psychiatric manifestations, anxiety, mood disorders, psychosis have been reported as an enduring severe apathy (Verhoeven et al, 2010). Regressive behavioral phenotype might appear at adolescent/adult age (Willemsen, 2012).We report five young adults including two twin sisters who develop psychiatric catatonia-like manifestations associated with regression. Therapeutic care has shown lack of response to traditional treatments for catatonia and strategy was based on anti-psychotic medications. For one case diagnosis of dysimmun encephalitis was evoked with improvement after encephalitis management and anti-psychotic medications.We also report five patients with late onset psycho-motor regression along with somatic manifestations as major weight loss, signal abnormalities on brain MRI and unfavorable evolution.As for some others neurodevelopmental disorders, poor evolution in adulthood tends to be described in Kleefstra syndrom as illustrated by cases presented, suggesting existence of a neurodevelopmental neurodegenerative continuum.

P10.045.B Wieacker-Wolff-Syndrom (WRWF): From a novel variant of uncertain significance to a likely pathogenic variant in *ZC4H2* using RNA sequencing

Melik Malek Khelifa[1], *Bernd Auber[1], Anke Katharina Bergmann[2], Sandra von Hardenberg[1], Nataliya Di Donato[1], Tim Ripperger[1]*

[1]Hannover Medical School, Hannover, Germany, [2]University Hospital Würzburg, Würzburg, Germany.

Background: WRWF is a severe X-linked neurodevelopmental delay disorder caused by deleterious variants in *ZC4H2*, encoding a zinc-finger protein involved in interneuron differentiation. Affected males show fetal muscle weakness, contractures, delayed motor development, facial and bulbar weakness, and dysmorphic facial features. We present a patient with a novel *ZC4H2* variant, which was reclassified as likely pathogenic (LP) following cDNA analyses.

Material and Methods: Trio whole-exome sequencing (WES); targeted cDNA analyses.

Results: An 8-months-old boy with severe congenital dystonia, severe developmental delay, hypotonia, and dysmorphic facial features was referred to our outpatient clinic. By trio exome sequencing, an intronic hemizygous variant of uncertain significance (VUS) was detected in the index patient: NM_001178032.3(ZC4H2):c.156+5G>T r.spl? p.? (PM2_SUP). His asymptomatic mother was a heterozygous carrier. After three years, reassessment of the variant revealed a patient carrying a G>A-substitution at the same position. This variant resulted in aberrant splicing using a cryptic donor splice site at c.156+5 (PMID 26056227) which led to the insertion of 45 bp into the mRNA. We conducted cDNA analyses, demonstrated a similar aberrant splicing event in the family presented herein and reclassified the variant as likely pathogenic (PM1, PM2_SUP, PM4, PP3).

Conclusion: By integrating cDNA sequencing, we demonstrated aberrant splicing and, in theory, in-frame insertion of 15 amino acids. Our report highlights the importance of comprehensive genetic and transcriptomic (re)analyses. This underscores the need for functional validation of VUS to improve the accuracy of variant interpretation, curation, and patient management.

P10.046.C Molecular diagnosis of neurodevelopmental disorders: insights from 300 cases

Mario Benvenuto, PhD*, Pietro Palumbo, Massimo Carella, Ada Piepoli, Silvia Morlino, Marco Castori, Orazio Palumbo*

Division of Medical Genetics, Fondazione IRCCS-Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

Background: Neurodevelopmental disorders (NDDs) are a group of heterogeneous conditions affecting 5−10% of people worldwide and the leading cause for referral genetic clinical services. Despite significant advances in genomic technologies, achieving a molecular diagnosis remains challenging due to their complex genetic architecture, requiring multiple testing approaches.

Patients and Methods: We investigated 300 patients affected by NDDs using a multi-tiered molecular analysis approach combining SNP−array and NGS. Initially, all patients underwent SNP-array analysis. Subsequently, negative cases underwent 338 genes panel sequencing involved in neurodevelopmental disorder.

Results: Our integrated approach achieved a molecular diagnosis in 30% of cases (91/300). In details, we found pathogenic or likely pathogenic CNVs in 15% (46/300) of cases involving critical chromosomal regions, including 1p36, 2p16.3, 7q11.23, 15q11-q13, 16p11.2, 22q11.21, and Xp22. TRS analysis allowed us to reveal a causal or likely causal SNVs in 18% (45/254) of cases. Among them, of particular interest a de novo microdeletion affecting *BICRA* a gene recently associated to Coffin−Siris syndrome type 12, a splice−altering synonymous variant in *KMT2E* validated through RNA analysis, a novel missense variant in *ADNP*'s DNA−binding domain for which bioinformatics analysis revealed its destabilizing effect on protein structure.

Conclusion: Our multi−modal approach achieved a diagnostic yield comparable to current literature and revealed multiple novel disease−causing variants. Future studies integrating multi−omics approaches and periodic reanalysis of negative cases may improve diagnostic yield and maybe uncover new NDD genes.

P10.047.D Modeling Schaaf-Yang Syndrome: Insights from iPSC-Derived Neurons

Mónica Centeno-Pla[1,2,3], *Clàudia Puigsasllosas-Pastor*[4], *Aina Prat-Planas*[1,2], *Juan Diego Gutiérrez-Ávila*[1,2], *Elena Rojano*[2,5,6], *Pedro Seoane*[2,5,6], *Daniel Tornero*[4], *Isaac Canals*[7], *Daniel Grinberg*[1,2], *Roser Urreizti*[2,3], *Raquel Rabionet*[1,2], *Susanna Balcells*[1,2]

[1]*Department of Genetics, Microbiology and Statistics, Faculty of Biology, University of Barcelona, IBUB, IRSJD, Barcelona, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER) - Instituto de Salud Carlos III, Madrid, Spain,* [3]*Clinical Biochemistry Department, Hospital Sant Joan de Déu, Institut de Recerca Sant Joan de Déu, Esplugues de Llobregat, Spain,* [4]*Department of Biomedical Sciences, Institute of Neuroscience, University of Barcelona, Barcelona, Spain,* [5]*Department of Molecular Biology and Biochemistry, University of Málaga, Málaga, Spain,* [6]*Instituto de Investigación Biomédica de Málaga (IBIMA-Plataforma BIONAND), Málaga, Spain,* [7]*Division of Metabolism and Children's Research Center, University Children's Hospital Zurich, Zurich, Switzerland.*

Background: Truncating mutations in *MAGEL2* are associated with Schaaf-Yang syndrome (#MIM 6615547; SYS), a severe ultra-rare neurodevelopmental disease. SYS patients present with intellectual disability, neonatal hypotonia, sleep disorders, and joint contractures, among other symptoms. MAGEL2 contributes to the regulation of protein recycling pathways, circadian rhythm, and mRNA metabolism.

Material and Methods: Using transcription factor-mediated differentiation, 4 SYS and 4 control iPSC lines were differentiated into iNeurons (iNs) and iAstrocytes (iAs), and co-cultured. Proteomic and transcriptomic analyses were carried out to identify expression alterations at the mRNA or protein levels. Additionally, calcium imaging was performed on forebrain neurons differentiated from SYS and control neural progenitor cells (NPCs) to assess neuronal activity over time and along differentiation.

Results: iNs and iAs were successfully generated from SYS and control iPSCs. Integrated proteomics and transcriptomics analyses revealed distinct molecular signatures, highlighting dysregulations in extracellular matrix organization and collagen degradation pathways. NPC-derived cultures changed upon development, exhibiting gradually more synchronous activity patterns. Calcium imaging in forebrain neurons uncovered functional traits of SYS physiopathology.

Conclusion: The obtained iNs and iAs establish a relevant in vitro model for SYS. The identified DEGs in SYS iNeurons suggest a potential novel role for MAGEL2 in extracellular matrix organization, and could serve as biomarkers for monitoring future therapeutic strategies. These findings lay the groundwork for further investigations into MAGEL2's role in neuronal activity and function.

P10.048.A Variants in *SNRPN* underlie a variable neurodevelopmental disorder

Purvi Majethia[1], *Arrate Aguirre*[2], *R Sai Prathap Yadav*[3], *Monalisa Ghosh*[3], *Aishwarya Kakade*[4], *Selinda Mascarenhas*[1], *Sanket Limaye*[1], *Manish Jaiswal*[5], *Guiomar Perez de Nanclares*[2], *Pavan Agrawal*[3], *Sonal Nagarkar-Jaiswal*[4], *Anju Shukla*[1]

[1]*Department of Medical Genetics, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India,* [2]*2Rare Diseases Research Group, Molecular (Epi) Genetics Laboratory, Bioaraba Health Research Institute, Araba University Hospital-Txagorritxu, Vitoria-Gasteiz, 01009, Araba, Spain,* [3]*Centre for Molecular Neurosciences, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India,* [4]*CSIR-Centre for Cellular and Molecular Biology, Hyderabad, India. Academy of Scientific and Innovative Research (AcSIR), Ghaziabad, India,* [5]*Tata Institute of Fundamental Research, Hyderabad, India.*

Background: Small nuclear ribonucleoprotein polypeptide N (*SNRPN*, MIM*182279), a bicistronic imprinted paternally expressed gene, is located in the Prader-Willi critical region (PWCR) on chromosome 15q11.2-q13. Till date, two single-nucleotide variants in *SNRPN* have been identified in two affected individuals from two unrelated families with Prader-Willi syndrome (PWS).

Material and Methods: Detailed clinical evaluation followed by exome sequencing was performed in the probands. Allele-specific RT-PCR was performed to determine the parental origin of the mutated allele. In vivo functional studies using *Drosophila melanogaster* was carried out to determine the developmental and behavioral phenotypes of the identified variants.

Results: Proband 1 presented with speech delay, mild intellectual disability (ID), seizures, and truncal obesity and harbored a de novo heterozygous missense variant, c.260C>A p.(Pro87His) in *SNRPN* (NM_003097.6) on his paternal allele. Proband 2, with clinical features overlapping with PWS was identified with a paternally expressed variant, c.280C>T p.(Arg94Trp) in *SNRPN* inherited from her asymptomatic father.

Functional studies show that knockdown of *SmB*, fly homologue of *SNRPN*, during early development leads to larval lethality with impaired locomotion and early developmental defects. We show that the variants identified in the study, c.260C>A and c.280C>T are evolutionary conserved and confirm them as loss-of-function alleles using rescue experiments in *Drosophila*. Additionally, knockdown of *SmB* in mature neurons led to increased inter-male aggression, increased food intake in males, and increased daytime sleep in isolated females.

Conclusion: We herein validate the association of variants in *SNRPN* with a neurodevelopmental disorder with clinical spectrum ranging from isolated ID to PWS.

P10.049.B A*de novo**KCNA3*and an inherited*KCNQ3*variants associated with reduced potassium channels expression in a patient with developmental and epileptic encephalopathy, intellectual disability, and behavioral anomalies

Enrica Marchionni[1], *Vito Luigi Colona*[2,3], *Emanuele Agolini*[4], *Michela Murdocca*[3], *Monia Russo*[3], *Maria Stellato*[3,5], *Valeria Latini*[3,5], *Anna Maria Nardone*[1], *Paola Spitalieri*[3], *Luigi Mazzone*[5], *Antonio Novelli*[4], *Federica Carla Sangiuolo*[1,3], *Giuseppe Novelli*[1,3]

[1]*Medical Genetics Unit, Tor Vergata University Hospital, Rome, Italy,* [2]*Unit of Neurorehabilitation, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy,* [3]*Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy,* [4]*Translational Cytogenomics Research Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy,* [5]*Child Neurology and Psychiatry Unit, Tor Vergata University Hospital, Rome, Italy.*

Background: In 2024, de novo missense *KCNA3* variants were linked to a developmental and epileptic encephalopathy characterized by marked speech delay, motor delay, intellectual disability (ID), and autism spectrum disorder (ASD)[1]. We report a 14-years-old boy presenting with drug-resistant epilepsy, marked hetero-aggressiveness, psychomotor agitation, hyperkinesis, CC -2SD, and ID (Leiter-3 QI:41). A de novo heterozygous NM_002232.5(KCNA3):c.1433T>A, p.Val478Glu variant and a heterozygous maternally inherited NM_004519.3(KCNQ3):c.1720C>T, p.Pro574Ser variant were detected through a targeted NGS panel and trio-exome sequencing. The aim of this study was to characterize the effect of these variants.

Material and Methods: Human dermal fibroblasts (HDFs) were isolated from the patient and an age-matched control' skin biopsy.*KCNQ3/KCNA3* mRNA expression was analyzed by quantitative RT-PCR, while KCNQ3/KCNA3 protein expression was analyzed by Western Blot (WB) and quantified by densitometric analysis.

Results: Compared to the control, transcript levels of *KCNQ*3 and *KCNA3* markers in patient-HDFs were reduced by 40% and 77% respectively (***$p = 0.0002$; ****$p < 0.0001$). WB confirmed a statistically significant reduction in KCNQ3 and KCNA3 protein levels (35% and 50%, respectively; *$P < 0.05$) in patient-HDFs.

Conclusion: The *KCNA3*-related phenotype aligns with the proband's clinical features. However, the same *KCNQ3* variant has been reported in three unrelated individuals with isolated ASD; in two cases, it was inherited from an asymptomatic parent[2]. To date, patients carrying both *KCNA3/KCNQ3* variants have not been reported. The reduced expression of both proteins in patient-HDFs suggests the contributing role of the rare de novo *KCNA3* variant with the inherited *KCNQ3* one, possibly acting as a modifier of the patient's complex phenotype.[1]PMID:37964487 [2]PMID:23596459

P10.050.C A study of six Turkish patients with Alazami syndrome: clinical and genetic insights

Ali Babazade[1], *Yusuf Bahap*[1], *Lale Yılmaz Çelik*[2], *Zeynep Esener*[3], *Naz Güleray Lafcı*[4,5], *Gulsum Kayhan*[1]

[1]*Gazi University Faculty of Medicine, Ankara, Turkey,* [2]*Basaksehir Cam and Sakura City Hospital, İstanbul, Turkey,* [3]*Balikesir University, Faculty of Medicine, Balikesir, Turkey,* [4]*Hacettepe University, Medical Faculty, Department of Medical Genetics, Ankara, Turkey,* [5]*Health Science University, Dr. Sami Ulus Obstetrics and Gynecology, Children Health and Disease Training and Research Hospital, Department of Medical Genetics, Ankara, Turkey.*

Background: Alazami syndrome (ALAZS) is a rare disorder caused by biallelic loss-of-function variants in the *LARP7* gene. It presents with developmental delays, intellectual disabilities, primordial dwarfism, and distinct facial dysmorphism. To date, the literature has documented approximately 55 cases.

Material and Methods: This study presents six patients from five families who were evaluated and molecularly diagnosed with ALAZS by various centers across Türkiye. Furthermore, we provide a comprehensive review of the existing literature on previously documented cases.

Results: A cohort of six patients, consisting of four males and two females, had an age range of 22 months to 15 years at the examination. All patients exhibited characteristic features of ALAZS, such as intellectual disability (ID), developmental delay, and reduced height. Antenatal manifestations, including IUGR, were noted in all of the patients ($n = 6$, 100%). Other findings included microcephaly ($n = 6$, 100%), gait imbalance ($n = 3$, 50%), genitourinary issues ($n = 4$, 66%), gastrointestinal manifestations($n = 3$, 50%) and cardiac abnormalities ($n = 3$, 50%). Molecular analysis revealed five distinct variants across five families, comprising five frameshift variants.Additionally, one out of the six patients had a dual diagnosis, having ichthyosis vulgaris.

Conclusion: This study provided more insights into ALAZS's phenotype and genotype, integrating our findings with a literature review to define and emphasize its characteristics more clearly.

P10.052.A Expansion of *MAD1L1*-associated phenotype: second case with chromosomal aneuploidy

Mirjana Gusic[1], *Moritz Hebebrand*[2], *André Weber*[2], *Miriam Kinzel*[2], *Markus Stumm*[2], *Oliver Wachter*[1], *Steffen Lott*[1], *Konstanze Hörtnagel*[1]

[1]*MVZ Martinsried GmbH, Martinsried, Germany,* [2]*MVZ Humangenetik Berlin-Lichtenberg, Berlin, Germany.*

Background: Loss-of-function (LoF) variants in *MAD1L1* have been recently described as the cause of autosomal recessive disorder characterized by chromosomal aneuploidy, systemic inflammation and increased tumor predisposition in a single case: an adult

woman with multiple benign and malignant neoplasms, dysmorphic features, short stature and microcephaly.

Material and Methods: A teenage boy with intellectual disability (ID), short stature, dysmorphic features, microcephaly and epilepsy was referred to our diagnostic center for whole exome sequencing (WES) and chromosome analysis.

Results: Duo-WES analysis identified two rare, heterozygous LoF variants: c.1396C>T p.(Gln466*), inherited from mother, and c.820_823delGAGA p.(Glu274Profs*52) in *MAD1L1*. In addition, WES identified a previously reported rare heterozygous LoF variant in *CACNA1A* c.4869+1G>T r.spl p.?, which provides a genetic cause of the ID and epilepsy, but also indicates incomplete penetrance as the variant was inherited from mother. The contribution of these three variants together to the patient`s phenotype currently remains unclear. In addition, chromosome analysis in boy´s lymphocytes revealed mosaic aneuploidy in 36% of analyzed metaphases.

Conclusion: We report the second case with two LoF variants in *MAD1L1*, providing further evidence that the loss of MAD1L1 causes an autosomal recessive syndrome with chromosomal aneuploidy. Both known cases present short stature, microcephaly and dysmorphic features. Despite comparable levels of aneuploidy, our case has not shown so far evidence of tumorigenesis or inflammation, indicating possible variability in phenotypic expression but also highlighting the need for surveillance. Additional cases and functional studies are needed to better define the clinical spectrum of *MAD1L1*-associated aneuploidy syndrome.

P10.053.B Somatic mosaicism of unmethylated FMR1 full mutation and heterogeneous premutation alleles in an asymptomatic older male

*Elisa Bettella[1,2], Marilena Cameran[1,2], Carlo Zanon[2], Valentina Liani[1], Elena Cavaliere[1], Fabiola Spolaor[3,2], Federica Beghetti[3], Giulia Bonato[4], Miryam Carecchio[4], Giovanna Mioni[5], Elisa Di Giorgio[6], Zimi Sawacha[7], Stefano Sartori[1], **Roberta Polli**[1,2]*

[1]Department of Women's and Children's Health, University of Padua, Padua, Italy, [2]Pediatric Research Institute "Città della Speranza", Padua, Italy, [3]Department of Information Engineering, University of Padova, Padua, Italy, [4]Department of Neuroscience, University of Padua, Padua, Italy, [5]Department of General Psychology, University of Padua, Padua, Italy, [6]Department of Developmental Psychology and Socialization, University of Padua, Padua, Italy, [7]Department of Information Engineering, University of Padua, Padua, Italy.

Background: Fragile X syndrome (FXS) is the most common inherited cause of intellectual disability and autism, caused by full mutations (FM) of the *FMR1* gene with expansions of over 200 CGG repeats in the 5'UTR region. These expansions lead to promoter methylation, resulting in transcriptional silencing and loss of the FMRP protein. Premutations (PM), with 55–200 CGG repeats, remain transcriptionally active but cause toxic overexpression, leading to premutation-associated conditions (FXPAC). Rare cases of FXS with little or no methylation show residual gene function, associated with better cognitive outcomes. Complex patterns of methylation and mosaicism increase the risk of FXPAC. Objective: A thorough clinical evaluation was performed on a 77-year-old asymptomatic male, who was found to have a complex and rare molecular mosaicism, with both FM and a wide range of premutation alleles, all unmethylated.

Methods: Clinical assessment included neurological exams, IQ tests (WAIS-IV, MMSE), cognitive evaluations, gait analysis, and sEMG. Brain MRI checked for degeneration. RNAseq analyzed FMR1 gene function.

Results: Neuropsychological evaluation revealed normal or higher-than-normal performance in several cognitive domains, with balance disturbances and abnormalities in posture, ground reaction forces, muscle activity, and joint angles. No other neurological signs were observed. Preliminary RNAseq data showed increased FMR1 mRNA levels and identified differentially expressed genes involved in neuronal function, synaptic plasticity, and cellular stress response.

Conclusion: Investigating these rare cases could reveal genetic and functional mechanisms that protect against clinical manifestations, providing important insights into factors that modulate the wide phenotypic variability in both FXS and FXPAC.

P10.054.C Genetic causative aberrations and diagnostic yield in children with Autism spectrum disorders

***Olivera MIljanovic**[1], Jelena Jovanovic[2], Sladjana Teofilova[3], Gordana Stojanovic[3], Ranka Rolovic-Neskovic[3], Alenka Hodzic[4], Borut Peterlin[4]*

[1]Clinical Centre of Montenegro, Center for Genomic Medicine and Immunology, Podgorica, Montenegro, [2]Clinical Centre of Montenegro, Center for genomic medicine and Immunology, Podgorica, Montenegro, [3]Clinical Centre of Montenegro, Center for genomic medicine and Immunolog, Podgorica, Montenegro, [4]Clinical Institute of Genomic Medicine, UMCL, Ljubljana, Slovenia.

Background: Autism spectrum disorders (ASD) are considered a complex disorder, with a high heritability of up to 80%. However, only 10–20% of ASD cases can be diagnosed as single-gene pathogenic variants or chromosomal aberrations. The male-to-female ratio is approximately 3–4:1, and comorbidity (seizures, mental retardation) occurs in approximatelyy 50% of ASD cases.

Material and Methods: To determine the presence of causative genetic variants in a cohort of 84 children with ASD, we performed the following analyses: G-band karyotyping, FMR1 gene (CGG expansion), MECP2 gene, whole-genome microarray, and whole-exome analyses, including trio-exome in some patients.

Results: The male-to-female ratio in study group was 5:1. The overall diagnostic yield of genetic causes in ASD patients was 12%. No chromosomal abnormalities were found by karyotype analyses. Genetic analyses on the *FMR1* and *MECP2* genes confirmed fragile X syndrome in five boys and Rett syndrome in one girl with ASD (8.7% of those tested). In three boys with ASD, a de novo single gene causative variant (*TBL1XR1, NAA15, PRKAR1B*) was found, and in one boy, a deletion of the 2q23.3q24.2 region (16% and7% of those tested, respectively). Seven pair of siblings were present in our cohort (17% of the study group), but no genetic causative variant was found among them.

Conclusion: Our study highlights the importance of genetic testing as an attempt to incorporate genetic causes into a comprehensive causal framework of ASD, which may help clinicians to provide tailored counseling and clinical action in children with ASD, given the 12% diagnostic yield.

P10.056.A Description of two patients with novel biallelic variants in *GTF3C3* and associated phenotype review

Lucía López-López[1], *Amjad Khan*[2], *Fiona Blanco-Kelly*[1], *Pablo Mínguez*[1], *Yolanda Benítez*[1], *Belén Benavides-Mori*[1], *Susana Hidalgo-Vico*[1], *Olga Zurita*[1], *Carmen Ayuso*[1], *Berta Almoguera*[1]

[1]*IIS–Fundación Jiménez Díaz University Hospital, Madrid, Spain,* [2]*University of Lakki Marwat, Khyber Pakhtunkhwa, Pakistan.*

Background: Biallelic variants in *GTF3C3* have recently been associated with an autosomal recessive form of syndromic intellectual disability. To date, only 12 affected individuals have been reported. We present two previously unreported patients carrying novel biallelic variants in *GTF3C3* and a review of the phenotype associated in the patients described to date.

Material and Methods: Two patients were selected for the study. Patient 1 is a 22 years-old Spanish female who was subjected to Whole-exome sequencing and further Sanger sequencing for segregation studies. Patient 2 is a Pakistani 22 years-old female who was studied by trio-whole exome sequencing. Variants were classified using the American College of Medical Genetics and Genomics (ACMG) guidelines. The clinical features of these patients were combined with data from previously reported cases to provide a comprehensive overview of the disorder.

Results: Genetic analysis identified compound heterozygous variants c.2498A>G and c.1708C>T in Patient 1, confirmed to be in trans, and a homozygous missense variant c.266T>A in Patient 2. Both patients presented with intellectual disability and generalized epilepsy as the core symptoms. By integrating these findings with data from previously reported cases, the frequency of all observed manifestations of the syndrome was quantified.

Conclusion: This study contributes to a more comprehensive understanding of *GTF3C3*-related syndromic intellectual disability by adding two newly identified patients with novel biallelic variants.

P10.057.B Expanding the Genotypic Landscape of TBL1XR1-Related Conditions: A Novel Variant in Pierpont Syndrome

Miriam Lucia Carriero[1,2], *Daniela Verrigni*[3], *Elisa Pisaneschi*[3], *Federica Lo Bascio*[1,2], *Alessio L. Del Popolo*[1,2], *Federico Casciani*[1,2], *Giuseppe Novelli*[2], *Antonio Novelli*[3], *Maria C. Digilio*[1], *Lorenzo Sinibaldi*[1]

[1]*Medical Genetics Unit, Translational Pediatrics and Clinical Genetics Research Area, Bambino Gesù Children's Hospital, Rome, Italy,* [2]*Department of Biomedicine and Prevention, University of Rome, Rome, Italy,* [3]*Translational Cytogenomics Research Unit, Bambino Gesù Children's Hospital, Rome, Italy.*

Background: Pathogenic variants in the TBL1XR1 gene are associated with Pierpont syndrome (PRPTS; MIM #602342), a rare autosomal dominant disorder characterized by global developmental delay, axial hypotonia, specific craniofacial dysmorphisms, and abnormal subcutaneous fat distribution. The condition is commonly associated with the c.1337A>G (p.Tyr446Cys) variant and, more rarely, other missense variants. These variants cluster in the WD40 repeat regions of the protein, crucial for protein-protein interactions. Recent studies implicate TBL1XR1 in a broader neurodevelopmental spectrum, including intellectual disability and autism spectrum disorder, with or without dysmorphic features.

Material and Methods: We report a 4-year-old male with global developmental delay, microcephaly, hypotonia, autistic-like behaviors, and distinctive facial features. Additional findings included brachydactyly and fetal pads. Neonatal neuroimaging revealed porencephaly and interhemispheric asymmetry. Genetic testing included karyotyping, FMR1 CGG repeat analysis, SNP-array, and exome sequencing.

Results: Exome sequencing identified a novel heterozygous NM_024665.7: c.959_961del, p.(Asn320del) in-frame deletion in TBL1XR1, absent in the maternal DNA. Paternal DNA was unavailable to confirm de novo status. This variant is absent in population databases. Functional predictions indicate a pathogenic effect, supported by the high conservation score of the affected residue across vertebrate species and its location within a mutational hotspot in the WD40 repeat regions. According to ACMG criteria, it was classified as likely pathogenic.

Conclusion: Our findings expand the genotypic landscape of TBL1XR1-related conditions, highlighting the role of in-frame deletions in Pierpont syndrome pathogenesis. They underscore the need for comprehensive genotype-phenotype correlation studies to refine diagnostic and therapeutic strategies for this rare yet heterogeneous disorder.

P10.058.C Biallelic variant, c.2511C>G p.(Ser837Arg) in *CNTROB* is associated with a neurodevelopmental disorder

Robert Patrick Selvam, *Vaishnavi Ashok Badiger, Shrikiran Hebbar, Vivekananda Bhat, Anju Shukla*

Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India.

Background: Centrobin, encoded by *CNTROB*, is a core component of the centrosome and is asymmetrically localised to daughter centrioles during mitosis. A biallelic canonical splice-site variant c.355+1G>A in *CNTROB* has been recently reported in a 14-year-old female with intellectual disability, short stature, microcephaly, cataract, abnormal teeth, obesity, hypertension, and insulin resistance. Centrobin-depleted zebrafish embryos have shown microcephaly, curved and shorter bodies, and morphological features indicating ciliary dysfunction.

Material and Methods: A detailed clinical evaluation followed by exome sequencing (ES) was performed on the proband after obtaining informed consent.

Results: A one-year and seven-month-old female presented with developmental delay and failure to thrive. Antenatally, oligohydramnios and intrauterine growth retardation were documented, and she was born with a low birth weight (−1.85SD). She has microcephaly (−3.6 SD), short stature (−3.1 SD), and is underweight (−3.3 SD). Examination revealed facial dysmorphism, generalised hypotonia and an ejection systolic murmur. Magnetic resonance imaging of the brain showed white matter volume loss and a thin corpus callosum. Echocardiogram showed ostium secundum-type atrial septal defect. ES revealed a biallelic missense variant c.2511C>G p.(Ser837Arg) in *CNTROB* (NM_053051.5). In silico tools [SpliceAI - 0.48 (donor loss); 0.26 (acceptor loss) and Human Splice Finder Pro] predict the variant to cause aberrant splicing. Splice-site analysis using reverse transcription PCR from RNA extracted from skin fibroblasts is being processed.

Conclusion: We herein report a family with a biallelic variant in *CNTROB* associated with a neurodevelopmental disorder. Further validation of this variant and collaborative efforts are necessary to validate the gene-disease association.

P10.059.D An iPSC model for the SRCAP-related neurodevelopmental disorder "Floating-Harbor Syndrome"

*Johannes Rhode[1], Stephanie Edwards[1], Ana Tzvetkova[1,2], Lars Riff Jensen[1], Faruq Mohammed Hossain[1], Björn Nowack[3], **Lisa Hagenau**[1], Andreas W. Kuss[1]*

[1]Human Molecular Genetics Group, Department of Functional Genomics, Interfaculty Institute for Genetics and Functional Genomics,University Medicine Greifswald, Greifswald, Germany, [2]Institute of Bioinformatics, University Medicine Greifswald, Greifswald, Germany, [3]SensID Gmbh, Rostock, Germany.

Background: Floating-Harbor-Syndrome (FLHS) is a rare disease, characterized by intellectual disability, short stature and facial dysmorphism. FLHS is caused by heterozygous nonsense mutations in the FLHS locus of the SRCAP gene. SRCAP plays a versatile role in different cellular functions including chromatin remodeling, gene regulation, DNA repair and cell division.

Material and Methods: Induced pluripotent stem cells (iPSCs) from a healthy donor were modified using CRISPR/Cas9 to introduce a mutation in the FLHS locus. Unspecific mutations in off-target regions were excluded by Sanger sequencing and chromosomal integrity was confirmed using low coverage whole genome sequencing. Expression of pluripotency factors and germ layer differentiation was examined with RT-qPCR and immunofluorescence microscopy.

Results: The modified cells showed a heterozygous deletion in the FLHS locus, resulting in a premature stop codon previously described in FLHS patients. No unspecific modifications or chromosomal abnormalities were detected in these cell lines. The cells tested positive for pluripotency markers OCT4, SOX2, NANOG, TRA1-60 and were able to differentiate into cells belonging to all three germ layers.

Conclusion: The cell lines presented here fulfill the criteria to be considered pluripotent and both carry the same pathogenic mutation in the FLHS locus. These two cell lines can therefore serve as iPSC models to investigate the function of SRCAP in the context of various cell types, including e.g. cortical neurons. This will allow further investigations into the pathogenic effects of SRCAP mutations on a molecular and cellular level and thus gain insights into the etiology of FLHS.

P10.060.A De novo missense variant in DNA-binding homeobox domain of ADNP causes Helsmoortel-van der Aa syndrome in a 24-year-old woman

*Mario Benvenuto, PhD[1], Ada Piepoli[1], Luigi Bisceglia[1], Paola D'Addetta[1], Massimo Carella[1], Marilena C. Di Giacomo[2], Orazio Palumbo[1], Marco Castori[1], **Pietro Palumbo**[1]*

[1]Division of Medical Genetics, Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [2]Medical Genetics Service and laboratory of Cytogenetics, SIC Anatomia Patologica, "San Carlo" Hospital, Potenza, Italy.

Background: Helsmoortel-van der Aa syndrome (HVDAS) is a rare neurodevelopmental disorder typically caused by truncating variants in ADNP, which encodes for a 1,102-amino-acid protein arranged into multiple functional domains. To date only 3 missense variants has been described in medical literature, and all carrier patients seems to show milder phenotypes compared to truncating variants.

Patient and Methods: We describe a 24-year-old Italian girl with intellectual disability (HP:0001256), speech and language delay (HP:0000750), microcephaly (HP:0000252), truncal obesity (HP:0001956), elevated serum testosterone levels (HP: 0030088), increased circulating dehydroepiandrosterone sulphate concentration (HP:0034589), aggression towards others (HP:5200125) and self-injurious behaviour (HP:0100716), amenorrhea (HP:0000141) and polyphagia (HP:0002591). DNA of the patient underwent a multistep molecular analysis. Structural modeling of wild-type and mutated DNA binding domain of ADNP was obtained using Alphafold 3, while protein-DNA binding affinity was conducted by using PDA-Pred tool.

Results: Targeted resequencing identified a novel heterozygous de novo ADNP missense variant c.2405C>T, p.(Ser802Phe) in the DNA-binding homeobox domain. MetaDome analysis revealed that this variant is located in a region that is highly intolerant to missense variants. Structural modeling showed that an introduction of an aromatic amino acid may alter intramolecular interactions and binding with DNA. Protein-DNA binding affinity showed that wild-type conformation is energetically favorited.

Conclusion: We describe the first missense mutation affecting the ADNP DNA-binding homeobox domain. Our findings suggest that this variant may impairs DNA interaction and gene expression regulation. Our adult patient, who is the oldest reported to date, sheds light on the long-term progression of HVDAS.

P10.062.C Expanding the phenotypic spectrum of *PAN2*-related neurodevelopmental disorder: two siblings with a novel homozygous frameshift variant

Violeta Rusu[1], *Dominique Braun[1], Christiane Zweier[1], Gabriela Oesch Nemeth[2], Maria Iciar Sanchez-Albisua[2], Claudia Böttcher[2], Harald Gaspar[1]*

[1]Universitatsklinik fur Humangenetik, Bern, Switzerland, [2]Universitatsklinik fur Paediatrics, Bern, Switzerland.

Background: Biallelic, truncating variants in *PAN2*, encoding a mRNA deadenylation complex subunit, have been reported in six affected individuals from four families with a syndromic neurodevelopmental disorder (NDD) including variable intellectual disability, hypotonia, sensorineural hearing loss, EEG abnormalities, multiple congenital anomalies, short stature, skeletal anomalies, and facial dysmorphism.

Methods: Diagnostic quattro-exome sequencing was performed in two siblings with NDD and their consanguineous, healthy parents.

Results: A novel homozygous frameshift variant (c.1661del p.(Phe554Serfs*42)) was identified in both siblings. Parents were heterozygous carriers. The 13 year old girl presented with severe intellectual disability, MRI anomalies (multiple, nonspecific white matter lesions subcortical and periventricular, hypoplasia of the vermis with slight rotation), febrile seizures, unilateral cataract,

combined moderate hearing loss, and short stature with reduced IGF-1 and normal IGFBP-3 levels. Due to elevated gonadotropins, ovarian insufficiency was suspected. Her 6 year old brother had severe intellectual disability, epilepsy, sensorineural hearing loss, and brain malformations such as polymicrogyria, malrotation of the hippocampus and focal cortical dysplasia. In both siblings, facial dysmorphism were noted including prominent supraorbital arches and eyebrows, short palpebral fissures, a long philtrum, a thin upper lip, and slightly low-set, backward-rotated ears. Furthermore, broad thumbs, clinodactyly fingers V, and hypoplastic fingernails were noted.

Conclusion: While the siblings showed overlapping clinical findings with the affected individuals reported in literature, severe brain malformations such as in the boy were not described before. Our findings therefore contribute to a further characterization of the phenotypic spectrum of the *PAN2*-related neurodevelopmental and multiple congenital anomalies disorder.

P10.063.D Unusual clinical presentation in a girl with a novel de novo loss-of-function (LoF) variant in *FRYL* identified through Whole Exome Sequencing (WES) reanalysis

Elisa Rubinato[1], *Federica Perino*[2], *Beatrice Spedicati*[1,2], *Stefania Zampieri*[1], *Giulia Gortani*[1], *Marco Carrozzi*[1], *Giorgia Girotto*[1,2], *Luciana Musante*[1]

[1]*Institute for Maternal and Child Health IRCCS Burlo Garofolo, Trieste, Italy,* [2]*Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy.*

Background: Reanalysis of WES data has proven an effective strategy for diagnosing neurodevelopmental disorders or malformations after inconclusive initial results. However, variant interpretation remains challenging, particularly for highly penetrant ones such as LoF variants, due to complex genotype-phenotype correlations. Recent studies identified de novo LoF and missense variants in *FRYL* in 14 patients with developmental delay, intellectual disability (ID), congenital anomalies and dysmorphic features.

Material and Methods: WES and data reanalysis; clinical follow-up.

Results: We report the case of a 7-year-old girl referred to our department with a syndromic condition. She was born at term by cesarean section, after a pregnancy complicated by polyhydramnios. At birth, she presented with severe respiratory distress and hypotonia. MRI revealed corpus callosum hypoplasia and tetraventricular hydrocephalus. Cognitive milestones were achieved (current IQ = 112), but she had lower limb hyposthenia and hyporeflexia and never gained the ability to walk. EMG/ENG studies and muscle biopsy were normal. She also has severe scoliosis, mild unilateral renal hypoplasia, and tricuspid regurgitation. Reanalysis of WES data identified a de novo c.3944delA, p.(Asn1315Thrfs*7) variant in *FRYL*. This frameshift variant is predicted to be pathogenic and is likely to result in a premature stop codon, with subsequent degradation of the transcript by nonsense-mediated decay (NMD). In vitro studies on patient-derived fibroblasts are underway to confirm this hypothesis.

Conclusion: Our patient is the first reported without ID but with peripheral neurological involvement and inability to walk, expanding the clinical spectrum of FRYL-associated disorders and underlying the importance of systematic data reanalysis.

E. Rubinato: None. **F. Perino:** None. **B. Spedicati:** None. **S. Zampieri:** None. **G. Gortani:** None. **M. Carrozzi:** None. **G. Girotto:** None. **L. Musante:** None.

P10.064.A Genetic diagnostics of neurodevelomental disorders using targeted gene panel sequencing

Lukáš Ryba, *Lenka Dvořáková, Petra Hedvičáková, Zuzana Mušová, Pavel Votýpka, Petra Peldová, Zdeněk Sedláček, Markéta Havlovicová, Markéta Vlčková*

Department of Biology and Medical Genetics, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague 5, Czech Republic.

Background: Neurodevelopmental disorders (NDDs) represent a diverse group of conditions that affect the development and function of the brain. Identifying their genetic causes is crucial for prognosis, reproductive counseling, and family support. This study assessed the diagnostic yield of gene panel sequencing in patients who underwent targeted gene panel sequencing due to diagnoses of intellectual disability, global developmental delay, or autism spectrum disorder.

Material and Methods: We retrospectively analysed 605 patients (417 males, 188 females) referred between 2019 and 2023. All had negative results from karyotyping, arrayCGH, and fragile X syndrome testing before gene panel sequencing. The number of sequenced genes, enrichment method and sequencing platform varied over the years. Initially, 270 samples were analysed using a targeted Custom Intellectual Disability panel from SOPHiA (286 genes) and sequenced using the MiSEQ platform (Illumina). The next 335 samples were enriched using a clinical exome solution from SOPHiA (539–602 genes) and sequenced on NovaSeq (Illumina). Variants were prioritised and interpreted using SOPHiA DDM software, based on frequency, predicted pathogenicity, and the ACMG guidelines. Where applicable, variants were validated using Sanger sequencing.

Results: The diagnostic yield was 15.2% (92/605), with most cases involving autosomal dominant de novo variants. Patients with severe ID, MRI abnormalities or hearth defects were more likely to have a positive genetic result.

Conclusion: This study highlights the effectiveness of targeted gene panels in diagnosing ID/GDD and aligns with previous findings[1,2,3], emphasizing its role in clinical practice.

Neuroscienze, Riabilitazione, Oftalmologia, Genetica e Scienze Materno-Infantili, Genova, Italy, [8]IRCCS Istituto Giannina Gaslini, Child Neuropsychiatry Unit, ERN EpiCARE Centre, Genova, Italy, [9]BioFolD Unit, Department of Pharmacy and Biotechnology, University of Bologna, Bologna, Italy.

Background: Despite advances in DNA-based diagnostic techniques, a portion of neurodevelopmental disorders (NDDs) remains undiagnosed. X-chromosome inactivation (XCI) can be leveraged to identify missing heritability. To explore this, we aim to integrate RNA sequencing (RNA-seq) and XCI profiling with DNA sequencing.

Material and Methods: We studied a preliminary cohort of 7 females: six exhibiting XCI-skewing (>80%) — comprising three mothers of NDD patients, three NDD cases — and one NDD case with a random XCI, by methylation-sensitive STR-profiling. All tested negative for CMA, FRAXA and exome (ES). We integrated RNA-seq with exome sequencing data to identify allelic imbalance.

Results: In the six females with skewed XCI, RNA-seq confirmed a chromosome-wide allelic imbalance, showing that the allelic expression of X-linked heterozygous variants deviated from the expected range for random inactivation (observed ratio: 0.01–0.26, which is lower than the expected 0.5 ± 0.15, previously reported [PMID: 30552425]). Conversely, in the female with random XCI, RNA-seq validated a balanced allelic ratio (observed ratio: 0.40). Further analyses are underway to identify which of the mono-allelically expressed genes could be causative for the NDD.

Conclusion: RNA-seq combined with XCI profiling presents a promising approach for investigating undiagnosed NDD cases. This method has the potentially to enhance diagnostic yield by identifying functional and epigenetic abnormalities that lead to XCI imbalance.

P10.066.C De novo missense variants in *FBXW11* associated with diverse neurodevelopmental phenotypes: insights from two new cases

Anna Magdalena Walczak[1], *Robert Śmigiel*[2], *Maria Franaszczyk*[1], *Karolina Rutkowska*[1], *Rafał Płoski*[1]

[1]Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland, [2]Medical University of Wroclaw, Wrocław, Poland.

Background: The *FBXW11* gene, encoding an F-box protein involved in ubiquitination, has been implicated in neurodevelopmental disorders. We present two new cases with *FBXW11* (NM_001378974.1) missense variants, highlighting phenotypic variability and its correlation with variant location.

Material and Methods: Patients: Case 1: A 2-year-old girl with a de novo variant: c.1399G>T (p.Val467Phe) in the F-box domain. Phenotype includes global developmental delay, microcephaly, hypotonia, and dysmorphic features. **Case 2:** A 6-year-old boy with a de novo variant: c.1319G>C (p.Gly440Ala) in the WD40 repeat domain. Phenotype includes autism spectrum disorder (ASD), ADHD, and social communication difficulties. Brain imaging was normal.

Methods: Whole-exome sequencing identified *FBXW11* variants. Both were classified as likely pathogenic (ACMG Class 4), absent in gnomAD (v4.1.0) and in-house databases. Variants are located in critical domains: F-box (Case 1, exon 5) and WD40 repeat (Case 2, exon 10).

Results: The girl's variant is associated with severe developmental delay and structural anomalies, consistent with prior reports linking the F-box domain to brain malformations. The boy's variant correlates with behavioral and cognitive impairments, such as ASD and ADHD, aligning with WD40 repeat domain involvement in autism-related phenotypes.

Conclusion: These cases suggest a genotype-phenotype correlation in *FBXW11*-related disorders: F-box domain variants are linked to severe developmental delay, while WD40 repeat domain variants are associated with behavioral and cognitive impairments. This highlights the importance of variant location in predicting clinical outcomes and expands understanding of *FBXW11*'s role in neurodevelopmental disorders.

P11 Neurogenetic and Psychiatric Disorders

P11.001.D Long range enhancer-promoter interaction maps contribute to understanding the impact of non-coding de novo variants on autism spectrum disorder risk

Elena Bacchelli[1], *Martina Casciaro*[1], *Marta Viggiano*[1], *Elvira Zakirova*[2], *Theresa Lahoud*[2], *Paola Visconti*[3], *Annio Posar*[3,4], *Scaduto Maria Cristina*[3], *Nicolis Silvia Kirsten*[2], *Elena Maestrini*[1]

[1]University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy, [2]University of Milano-Bicocca, Department of Biotechnology and Biosciences, Milano, Italy, [3]IRCCS Istituto delle Scienze Neurologiche di Bologna, UOSI Disturbi dello Spettro Autistico, Bologna, Italy, [4]University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy.

Background: Whole-genome sequencing (WGS) studies of autism spectrum disorder (ASD) have started to highlight the role of rare de novo variants (DNVs) within non-coding regulatory regions. However, it is still difficult to predict their functional consequences. We recently performed RNApolIII-ChIA-PET of mouse brain-derived neural stem cells (mNSC), which identified a list of thousands of human-mouse syntenic Long Range Interactions (hmsLRI), connecting gene promoters to (often very distant) enhancers. These regions are expected to be functionally relevant for neurodevelopment, representing a valuable resource for variant interpretation in ASD.

Material and Methods: We analyzed WGS data of our cohort of 105 ASD families and three large ASD collections, to identify DNVs overlapping with hmsLRI regions. We developed mNSC transgenic for defective Cas9-KRAB, to direct epigenetic repression to specific enhancers (or, as a control, the connected gene promoter transcription start site, TSS), via suitable guideRNAs, to monitor the effect on the expression of the connected gene via qRT-PCR.

Results: We showed that evolutionarily conserved DNVs in hmsLRI regions are enriched in ASD probands ($p = 0.0141$) and we identified the genes functionally connected to the enhancers carrying conserved DNVs. Focussing on recurrently mutated elements, we started the experimental validation of the effect of selected DNVs. We obtained 90% downregulation of the expression of *FOXG1* by guide-RNAs directed against the TSS, and are now testing the comparative effect of repressing connected enhancers.

Conclusion: These results highlight the significance of long-range interactions in the potential impact of conserved DNVs within regulatory regions on specific target genes.

Background: Parkinson's disease (PD) is heterogeneous both clinically and genetically with complex phenotypes and different progressive courses. In addition to recent advancements on the identification of both rare and common variants contributing to disease onset and risk, a comprehensive evaluation of the whole genome landscape in subjects with PD will improve our knowledge of the genomic basis of this disease. The study aims at deciphering the genetic impact of coding and non-coding regions of genomes of PD patients in Northern Italy and at integrating whole genome sequencing (WGS) in clinical practice.

Material and Methods: WGS is conducted on PD subjects with short-read (Illumina) technology. Additionally, for selected cases, long-read (Oxford Nanopore) sequencing is also performed. Bioinformatic analysis is carried out using the GPUs-accelerated NVIDIA Clara™ Parabricks® automatized pipeline. We also developed a consensus pipeline for Structural Variants (SVs) analyses.

Results: We have carried out WGS of approximatively 1500 PD patients on the Illumina platform and long-read sequencing on a selected group of subjects. In a subset of cases, we have identified pathogenic and risk variants in known causative genes. We have also identified Copy Number Variants that haven't been detected with standard clinical methods.

Conclusion: The integration of short- and long-read sequencing allows the identification of novel mutations and mechanisms/pathways in unsolved clinical cases with PD. Overall, this study demonstrates that incorporating WGS in clinical practice allows the detection of diagnostic variants that conventional methods failed to identify.

Background: CAPRIN1 is a ubiquitously expressed protein involved in essential cellular processes, including proliferation and cell migration. In brain, it is recruited to neuronal RNA granules and directly modulates transport and translation of mRNAs that are necessary for synaptic plasticity. Haploinsufficiency of CAPRIN1 has been implicated in neurodevelopmental disorders.

Material and Methods: Human induced pluripotent stem cell (hiPSC) of three *CAPRIN1*-patients and three healthy controls were used to generate forebrain cortical organoids (fBOs). Metabolic analysis was performed using Seahorse mitochondrial stress tests. Single-cell RNA sequencing is in progress.

Results: Morphological analysis of *CAPRIN1*-patients derived organoids show defects in growth and proliferation, suggesting an altered composition of the forebrain organoids. An overrepresentation of immature neurons and glial cells was observed using flow cytometry. Since these cells predominantly rely on glycolysis, β-oxidation, and redox signalling for their metabolic processes, we conducted metabolic analyses. Preliminary results suggest an increase in glycolysis and a rise in reactive oxygen species (ROS). Single cell-RNA sequencing has also been performed at different stages of fBO maturation, to dissect their cellular composition and analysis of the results is ongoing.

Conclusion: Following our previous work (PMID: 35979925), our results suggest that *CAPRIN1* haploinsufficiency impacts the cellular fate and composition of neuronal compartments, giving initial explanation to the neurodevelopmental defect observed in patients. The 3D cortical organoid model enables the

identification of cellular and metabolic mechanisms that could serve as therapeutic targets for this disorder.

Neurodevelopmental disorders exhibit an intriguing sex bias with females being less often and less severely affected than males. While neurodevelopmental disorders-associated genes are evenly distributed across all autosomes, they are overrepresented on the X-chromosome highlighting the particularly important role of the X-chromosome in the phenotype formation of Neurodevelopmental disorders. In males, most X-linked genes are hemizygous, i.e., males only carry the allele inherited from the mother. In contrast, random XCI in female cells results in a mosaic expression of X-linked genes in female tissue, substantially influencing phenotype development of X-linked gene defects. However, hemizygosity of X-linked genes in males and random XCI in females only partially explain the fact that females are disproportionally less affected by neurodevelopmental disorders. By leveraging the clonal status of human iPSCs with a skewed XCI, we established an in vitro system of neurodevelopment for the detection of facultative escape genes during neuronal differentiation trajectories. By analysing transcriptomic data at allele-specific resolution, we identified two novel categories of facultative escapees that change their expression from the inactive X-chromosome depending on the cell´s differentiation status and specific cell type. The dynamic reactivation of facultative escapees substantially influenced the phenotype of brain organoids generated from a patient with an X-linked neurodevelopmental disorder, revealing an unknown layer of female brain protection. Taken together, our data demonstrate the dynamic nature of a set of genes located on the inactive X-chromosome, able to change their expression profile in a temporal- and lineage-specific manner.

Background: Psychiatric disorders represent a significant global health burden with complex etiologies involving both genetic and environment. While the independent effects of these factors have been thoroughly investigated, their interactions in shaping psychiatric disorder risk remain poorly understood. This study aims to investigate the interaction between Polygenic scores (PGS) as proxies for genetic risk and environmental factors at both the individual and family levels for psychiatric disorder risk.

Material and Methods: This study utilized the iPSYCH case-cohort sample (n = 141,265). Environmental factors, including region, urbanicity, parental socioeconomic status and history of inflammatory and infectious diseases, were obtained from Danish nationwide registers. Generalized logistic regression was used to examine the effects of PGS, environmental factors and their interactions on psychiatric disorders. Analyses were adjusted for age, sex and (PCA). Inverse probability weighting was applied to account for selection bias.

Results: Both PGS and environmental factors were associated with psychiatric disorders, consistent with previous findings. We found evidence of gene-environmental interactions across several psychiatric disorders. For instance, individuals with a history of autoimmune disease showed a stronger association between PGS and bipolar disorder. Those with an early-life brain injury (≤10 years) showed a stronger PGS association for schizophrenia. The most consistent finding emerged in the analysis of parental education, which moderated the PGS-diagnosis association across all psychiatric diagnoses investigated.

Conclusion: We found evidence that some environmental factors may moderate genetic susceptibility to psychiatric disorders.

Additional studies in diverse populations are needed to validate these findings and enhance applicability across different settings.

P11.006.A Polygenic burden of neurotransmitter and ion channel pathways in generalzied and focal epilepsy (Award Candidate)

Emadeldin Hassanin[1], *Maryam Omidvar*[2], *Dheeraj Bobbili*[1], *Holger Lerche*[2], *Patrick May*[3]

[1]*LCSB - Luxembourg Centre for Systems Biomedicine, Esch-sur-Alzette, Luxembourg,* [2]*Department of Neurology and Epileptology, Hertie Institute for Clinical Brain Research, University of Tübingen, Tübingen, Germany,* [3]*Luxembourg Centre for Systems Biomedicine, Esch-sur-Alzette, Luxembourg.*

Background: Common genetic variants contribute to epilepsy risk. We investigated the polygenic burden and pathway-specific polygenic risk scores (PRS) in neurotransmitter (GABAergic, glutamatergic) and ion channels pathways across genetic generalized epilepsy (GGE), focal epilepsy (FE), and GGE subtypes. This study leveraged data from the ILAE and the Epi25 Consortiums.

Material and Methods: GWAS summary statistics were used to construct pathway-specific PRS for European-descent individuals with GGE (n = 3,305) and FE (n = 9,095), compared to 24,218 controls. GGE subtypes included juvenile myoclonic epilepsy (JME), juvenile absence epilepsy (JAE), generalized tonic-clonic seizures (GTCS), and childhood absence epilepsy (CAE). Associations were assessed using logistic regression.

Results: GABAergic PRS showed significant enrichment in GGE (OR = 1.15–1.20, $P < 0.05$) but modest enrichment in FE (OR = 1.00–1.05, $P > 0.05$) across multiple databases (GO, Reactome, KEGG). Within GGE subtypes, JME showed the strongest GABAergic associations. Glutamatergic pathway PRS demonstrated elevated significant burden in GGE (OR = 1.15–1.20, $P < 0.05$) and modest in FE (OR = 1.00–1.05, $P > 0.05$), with notable enrichment in JME. Ion channel analysis revealed divergent effects for calcium channels, showing significant positive association in GGE (OR = 1.08–1.12, $P < 0.05$) but negative association in FE (OR = 0.92–0.98, $P < 0.05$), while voltage-gated cation channels showed consistent positive associations across both epilepsy types.

Conclusion: This study highlights differential polygenic influences on neurotransmitter and ion channel pathways in GGE, FE, and GGE subtypes, particularly opposing calcium channel effects. Distinct GABAergic and glutamatergic patterns were observed in GGE, especially in JME and CAE, providing insights of polygenic burden in epilepsy.

P11.007.B Genome-wide analysis of tandem repeat expansions in Autism Spectrum Disorder

Marta Viggiano[1], *Fabiola Ceroni*[2], *Roan Spadazzi*[1], *Martina Casciaro*[1], *Paola Visconti*[3], *Annio Posar*[3,4], *Maria Cristina Scaduto*[3], *Elena Bacchelli*[1], *Elena Maestrini*[1]

[1]*University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy,* [2]*Oxford Brookes University, Faculty of Health and Life Sciences, Oxford, United Kingdom,* [3]*IRCCS Istituto delle Scienze Neurologiche di Bologna, UOSI Disturbi dello Spettro Autistico, Bologna, Italy,* [4]*University of Bologna, Department Of Biomedical And Neuromotor Sciences, Bologna, Italy.*

Background: Tandem repeat expansions (TREs) are associated with over 60 monogenic disorders. Recent whole genome sequencing (WGS) studies highlighted their involvement in autism spectrum disorder (ASD), but further studies are necessary to better elucidate the role of specific TREs in ASD risk.

Material and Methods: We analyzed WGS data of 105 ASD families using ExpansionHunter Denovo (EHdn), to identify TREs whose lengths were outliers compared with other members of the cohort. TREs were filtered according to Z-score>10 and TR length>150 bp (high-confidence, HC-TREs). Then we used ExpansionHunter to accurately genotype the most interesting TREs in our cohort and in 629 European individuals from the 1000 Genomes Project WGS data, and REViewer to generate read visualizations for all individuals at each locus. The frequency of specific TREs was assessed using TR-gnomAD data. Experimental validation was performed using fluorescent Long-Range PCR (LR-PCR) and Repeat-primed PCR.

Results: We identified 280 HC-TREs from 124 ASD individuals. We then prioritized 10 TRE in genes already implicated in ASD or other neurodevelopmental disorders (NDD). Among these, the most interesting one is a rare AAG expansion in the intron 11 of *CACNB1*, a gene recently highlighted among the top candidate ASD-relevant tandem repeat loci. Interestingly, LR-PCR confirmed that the tandem repeat, expanded in the unaffected mother, is further expanded in the ASD proband.

Conclusion: The identification of tandem repeat expansions in *CACNB1* and other ASD/NDD risk genes strengthens the role of rare TRE in the genetic aetiology and phenotypic complexity of ASD.

M. Viggiano: None. **F. Ceroni:** None. **R. Spadazzi:** None. **M. Casciaro:** None. **P. Visconti:** None. **A. Posar:** None. **M. Scaduto:** None. **E. Bacchelli:** None. **E. Maestrini:** None.

P11.009.D Severe recessive *ADCY5* related encephalopathy: a case report and literature review

Sarra Bouri[1], *Laurence Lohmann*[2], *Jean-Marc Costa*[3], *Claude Cances*[4], *Olivier Patat*[1]

[1]*Purpan Toulouse University Hospital, Toulouse, France,* [2]*Laboratoire Cerba, Saint Ouen L'Aumone, France,* [3]*Laboratoire Cerba, Saint Ouen l'Aumone, France,* [4]*Hopital des Enfants, Toulouse University Hospital, Toulouse, France.*

Background: *ADCY5*-related disorder (*ADCY5*-RD) is primarily an autosomal dominant movement disorder characterized by paroxysmal exacerbations during sleep or awakening, occasionally associated with neurodevelopmental delay, with or without intellectual development disorder. Most of the associated variants are missense, with a presumed gain-of-function mechanism.

Only four families with recessive *ADCY5*-RD have been reported to date, with a more frequent neurodevelopmental component, often severe and harboring missense, splicing, or frameshift variants. We present the 5th family with a recessive form of *ADCY5*-RD.

Material and Methods: Two cases from a consanguineous family were explored for a syndromic movement disorder by exome sequencing through standard care.

Results: Exome sequencing identified a novel splice site variant, NM_183357.3: c.2898_2900+22del p.(?) in the homozygous state, inherited from asymptomatic heterozygous parents. Their phenotype was reminiscent of the one described in previously reported

recessive ADCY5-RD cases with a severe neurodevelopmental outcome, abnormal movements, feeding difficulties, failure to thrive, and premature death for some cases.

Conclusion: We hypothesize a loss-of-function mechanism in recessive *ADCY5*-RD, with a presumed correlation between phenotype and residual ADCY5 activity. Additionally, we highlight rare dominant *ADCY5*-RD cases for which the gain-of-function mechanism was questioned.

P11.010.A Brain-restricted chromosome 1q gains underlie focal epilepsy with hyaline astrocytic inclusions

Sara Baldassari[1,2], *Ann-Sofie Demeulemeester*[2], *Melina Scopin*[2], *Lina Sami*[2], *Rayann Checri*[2], *Caroline Nava*[2], *Laila El-Khattabi*[2], *Marion Doladilhe*[2], *Sarah Ferrand Sorbets*[2,3], *Georg Dorfmuller*[2,3], *Homa Adle-Biassette*[4], *Mathilde Chipaux*[2,3], *Jean-Christophe Poncer*[2], *Stephanie Baulac*[2]

[1]*Paris Brain Institute, Paris, France,* [2]*Institut du Cerveau (ICM), Paris, France,* [3]*Rothschild Foundation Hospital, Paris, France,* [4]*service d'Anatomie Pathologique, AP-HP, Hôpital Lariboisière, Paris, France.*

Background: Brain somatic mosaicism is an emerging cause of neurological disorders, including cortical malformations and epilepsy. Here, we aimed to identify the genetic basis of focal epilepsy with hyaline astrocytic inclusions, a distinct neuropathological entity.

Methods: We analyzed matched blood and surgically-resected brain tissue from eight children with drug-resistant focal epilepsy and hyaline astrocytic inclusions using deep whole exome sequencing, genome-wide copy number analysis, and fluorescence in situ hybridization (FISH). We performed laser capture microdissection of astrocytes followed by targeted sequencing, and multi-electrode array (MEA) recordings to assess epileptiform activity.

Results: We identified brain-specific mosaic chromosome 1q gains in 6/8 patients that were absent from blood. Variant allele analysis revealed these gains originated from maternal meiosis, suggesting they were subsequently lost from non-neural lineages through postzygotic rescue. The 1q gain was significantly enriched in astrocytes with hyaline inclusions. Local epileptiform activity were investigated for correlation with the density of affected astrocytes in acute cortical slices.

Conclusion: We establish chromosome 1q gain as a genetic cause of focal epilepsy with hyaline astrocytic inclusions and show that brain-restricted mosaicism can arise through postzygotic rescue of meiotic errors. Our findings highlight tissue-specific mosaicism as a novel disease mechanism and suggest astrocyte-specific chr1q gains contribute to epileptogenesis in this distinct clinicopathological entity

P11.011.B Integration of proteomics enables the establishment of genetic diagnoses in a cohort of dystonia affected individuals (Award Candidate)

Ivana Džinović[1,2], *Robert Kopajtich*[1,2], *Matej Škorvánek*[3,4], *Ján Necpál*[5,6], *Robert Jech*[7], *Holger Prokisch*[1,2], *Juliane Winkelmann*[1,2,8], *Michael Zech*[1,2,9]

[1]*Institute of Human Genetics, School of Medicine and Health, Technical University of Munich, Munich, Germany,* [2]*Institute of Neurogenomics, Helmholtz Zentrum München, Munich, Germany,* [3]*Department of Neurology, P.J. Safarik University, Kosice, Slovakia,* [4]*Department of Neurology, University Hospital of L. Pasteur, Kosice, Slovakia,* [5]*Department of Neurology, Zvolen Hospital, Zvolen, Slovakia,* [6]*Parkinsonism and Movement Disorders Treatment Center, Zvolen Hospital, Zvolen, Slovakia,* [7]*Department of Neurology and Center of Clinical Neuroscience, First Faculty of Medicine Charles University and General University Hospital in Prague, Prague, Czech Republic,* [8]*DZPG, Deutsches Zentrum Für Psychische Gesundheit, Munich, Germany,* [9]*Institute for Advanced Study, Technical University of Munich, Garching, Germany.*

Background: Dystonia is a movement disorder characterized by vast genetic and phenotypic heterogeneity. Most patients are left without conclusive genetic diagnosis following whole exome (WES) and whole genome sequencing (WGS). However, the added benefit of proteomic analyses of patient-derived material in this disease category has not been systematically explored yet.

Material and Methods: Primary fibroblast cell lines derived from 76 dystonia index cases and four affected relatives were subjected to bulk proteomics and the expression profiles were analyzed using PROTRIDER tool (1). Complementary RNA sequencing was done for a subset of selected cases and the output was inspected with IGV. Short-read WGS data was available for all study participants.

Results: The analysis of proteomic expression changes enabled the verification of WGS-detected variants in genomic regions prone to sequencing and alignment errors (*IRF2BPL* and *MECP2*) and the re-classification of one variant of uncertain significance to likely pathogenic (*SLC16A2*). Furthermore, proteomic outlier detection highlighted pathogenic gene underexpression in three cases (*SPG11*, *UFC1*, *ATM*) caused by (deep) intronic variants. Transcriptomic analysis corroborated the deleterious effect of these intronic variants on splicing integrity.

Conclusion: Systematic implementation of proteomics in the dystonia cohort provided key information for 8.6% (6/70) WGS-inconclusive index patients. Adding omics layers such as proteomics further supports genomic variant interpretation and increases the diagnostic yield in dystonia patients with ambiguous WES and WGS findings.

n.a.=information not available.

heritability (>25%) and >400 dystonia-linked genes, the etiology remains unresolved in most patients, suggesting pathogenic variants in additional genes contribute to the disorder.

Methods: Exome sequencing data from 1,924 genetically unsolved dystonia patients, including five trios, was searched for variants in genes not yet linked to dystonia. Variants were filtered based on frequency in controls, in silico predictions, gene constraint, segregation, and literature on gene function. Genes with multiple hits were prioritized. An independent cohort of 1,825 patients from Munich, Germany, was analyzed to identify additional variant carriers.

Results: We identified *ADGRB2*, *ERF*, and *WDR5* as novel dystonia candidate genes. In *ADGRB2*, a G-protein coupled receptor critical for neurodevelopment, two truncating and one splice site variant were identified in our sample (Table); patients shared a late-onset cervical/cranial dystonia phenotype. For *WDR5*, involved in histone modification and an interactor of the dystonia gene *KMT2B*, three missense variants were associated with adult-onset cervical dystonia. In *ERF*, encoding a transcription factor, we identified a de novo frameshift variant, and an additional stop-gain variant was found in the Munich cohort; patients had predominantly upper body dystonia (Table).

Conclusion: Our findings suggest that variants in *ADGRB2*, *ERF*, and *WDR5* may contribute to dystonia, supported by high-impact variants, similar phenotypic patterns, and biological functions consistent with known dystonia genes.

P11.013.D CAG repeats in *HTT*, *ATXN1* and *ATXN2* genes as modifiers of the phenotype in mental disorders: schizophrenia and bipolar disorder. (Award Candidate)

Sergio Pérez Oliveira[1,2,3], *Mar González-Fernández*[1,3], *Paz García-Portilla*[4,5,6], *María Victoria Álvarez*[1,3]

[1]*Instituto de Investigación del Principado de Asturias (ISPA), Oviedo, Spain,* [2]*University of Oviedo, Oviedo, Spain,* [3]*Laboratorio de Genética. Hospital Universitario Central de Asturias (HUCA), Oviedo, Spain,* [4]*Department of Psychiatry, University of Oviedo, Oviedo, Spain,* [5]*Health Service of the Principality of Asturias (SESPA), Oviedo, Spain,* [6]*Centro de Investigación Biomédica en Red, Salud Mental (CIBERSAM), Oviedo, Spain.*

Background: Intermediate alleles (IAs) of short tandem repeats (STRs) in *HTT*, *ATXN1*, and *ATXN2* genes have been linked to neurodegenerative and psychiatric disorders. Moreover, *HTT* IAs have been associated with bipolar disorder (BD), suggesting a genetic influence on BD phenotype. Huntington's disease (HD) is characterised by motor, cognitive, and psychiatric manifestations, which may lead to clinical overlap with BD. Schizophrenia-like psychosis occurs in HD in 6–25% of cases, with the paranoid form being the most common. Additionally, early-onset HD has been associated with a greater risk of developing psychosis, further highlighting the shared genetic and clinical features between these conditions. These findings underscore the importance of genetic screening to improve the diagnosis and management of neuropsychiatric disorders.

Material and Methods: This study analysed *HTT*, *ATXN1*, and *ATXN2* CAG repeats in 334 BD, 234 SCH patients and 1070 controls. Statistical analyses included Chi-squared, Fisher's Exact, Kruskal-Wallis with Dunn's post hoc, and regression models.

Results: A higher *HTT* IAs frequency in BD (7.4%) compared to controls (4.1%) was found, but the adjusted p-value (0.067) suggests only a trend. *ATXN1* IAs frequency was higher in BD (12.5%) than in controls (7.2%) ($p = 0.0598$) and significantly higher compared to SCH (4.7%) ($p = 0.03$). *ATXN2* IAs showed no significant differences across groups. Additionally, two expanded alleles in BD for *HTT* (0.9%) and one in SCH for *ATXN2* (0.5%) were identified.

Conclusion: These results suggest that *HTT* and *ATXN1* IAs may contribute to BD susceptibility, reinforcing the genetic overlap between neuropsychiatric and neurodegenerative disorders.

Background: The 22q11.2 Deletion Syndrome (22q11.2DS) is the most common microdeletion syndrome in humans and it is associated with high rates of neurodevelopmental disorders (NDDs). Literature data revealed downregulation of miR-185 expression, located in the 22q11.2 region, in the whole blood of patients with 22q11.2DS. Here we analyze miR-185 expression during neural differentiation of induced pluripotent stem cells (iPSCs), derived from patients with 22q11.2DS, and search for miR-185 potential target genes associated with NDDs.

Material and Methods: The expression of miR-185 was assessed by Taqman qRT-PCR using specified Taqman assay for miR-185. miRNet platform was used to elucidate miR-185 function in NDDs. miR-185 target genes were predicted by using miRDB, mirWalk and TargetScan. The selection of miR-185 target genes related to NDDs was conducted using online available tools GeneTrack, miRNet and Metascape.

Results: Decreased expression of miR-185 was detected in iPSCs derived from patients with 22q11.2DS, compared to healthy control. In addition, the expression of miR-185 was significantly downregulated in neurons from patients with 22q11.2DS compared to expression detected in neurons of healthy control. Using online available tools, we selected three potential target genes of this miRNAs related to NDDs - *CSMD2*, *DLG2* and *HIC2*.

Conclusion: Obtained results indicate that miR-185 and it target genes *CSMD2*, *DLG2* and *HIC2* could serve as novel therapeutic targets. Future studies are needed to evaluate their relationship and involvement in neurodevelopmental outcome seen in patients with 22q11.2DS.

Background: Familial Adult Myoclonus Epilepsy (FAME) is a rare autosomal dominant disorder caused by the same intronic TTTTA/TTTCA repeat expansion in seven distinct genes. TTTTA-only expansions are benign, while those containing TTTCA insertions are pathogenic. We investigated the genetic basis of dominant cortical myoclonus without seizures in two unrelated families.

Material and Methods: Repeat-primed PCR, long-range PCR and nanopore sequencing were used to detect and characterize expansions at known FAME loci.

Results: We identified a novel repeat expansion in *MARCHF6*, comprising elongated TTTTA repeats (388–454) and 5–11 TTTCA repeats at the 3′ terminus, segregating with cortical myoclonus in eight affected individuals. This configuration shows meiotic stability but low-level somatic variability in blood. We observed an inverse correlation between the number of TTTCA repeats and the age at myoclonus onset.

Conclusion: These findings indicate that as little as five TTTCA repeats combined with expanded TTTTA repeats can cause cortical myoclonus without epilepsy, highlighting potential mechanisms underlying FAME pathophysiology.

P11.016.C Positive and negative affect, related mental health traits, and cognitive performance: shared genetic architecture and potential causality

Chloe Slaney[1], *Naoise Mac Giollabhui*[2], *Peter J. Van der Most*[3], *Ensor R. Palacios*[4], *Harold Snieder*[3], *Michel Nivard*[1], *Gibran Hemani*[1], *Catharina A. Hartman*[3], *Golam M. Khandaker*[1]

[1]*University of Bristol, Bristol, United Kingdom,* [2]*Massachusetts General Hospital, Boston, MA, USA,* [3]*University of Groningen, Groningen, Netherlands,* [4]*University of Bath, Bath, United Kingdom.*

Background: Altered affect and cognitive dysfunction are features of many neuropsychiatric conditions which are highly comorbid, remain poorly understood, and have few efficacious treatments. Exploring their genetic architecture and causal relationships may provide insights into aetiology and comorbidity.

Material and Methods: Using Lifelines Cohort data, we conducted the first genome-wide association studies (GWAS) on positive and negative affect using a validated measure ($N = 57{,}946$) and four cognitive domains (working memory, reaction time, learning and memory, executive function; $N \geq 35{,}729$). We used genetic correlation and bidirectional Mendelian randomization (MR) to assess genetic overlap and causality, incorporating large GWAS on related - albeit distinct - phenotypes (depression, anxiety, wellbeing, general cognitive ability [GCA]).

Results: We identified one GWAS hit for reaction time, and many loci with suggestive associations for other phenotypes ($N = 11$–20), including positive ($N = 20$) and negative ($N = 15$) affect. For most phenotypes, suggestive hits have higher gene expression in brain tissue compared to other tissues. Genetic correlations between negative and positive affect suggest they are dissociable constructs ($r_g = -0.18$). GCA has higher genetic

overlap with negative affect ($r_g = -0.19$ versus -0.06) which could indicate that negative affect and GCA have a higher shared neural basis and/or they exhibit causal relationships. Supporting the latter, MR analyses suggest higher GCA may reduce negative affect, depression and anxiety, and increase wellbeing, with little impact on positive affect. Conversely, depression and lower wellbeing may causally reduce GCA.

Conclusion: These results suggest GCA may be a valid target to prevent negative affect; and depression/wellbeing may be valid targets for GCA.

P11.017.D Cell-type and developmental specificities of rare variants underlying psychiatric co-occurrences in autism

Jade England[1,2,3], *Thomas Renne*[1,3], *Florian Bénitière*[1], *Cécile Poulain*[1,3], *Vincent-Raphaël Bourque*[1,4,3], *Martineau Jean-Louis*[1], *Guillaume Huguet*[1], *Sébastien Jacquemont*[1,2,3]

[1]*CHU Sainte-Justine research center, Montréal, QC, Canada,* [2]*CHU Sainte-Justine, Montreal, QC, Canada,* [3]*Université de Montréal, Montreal, QC, Canada,* [4]*McGill University, Montreal, QC, Canada.*

Background: Co-occurring psychiatric diagnoses are frequent in autism spectrum disorder (ASD) and significantly impact quality of life. Whether their genetic contributors and brain processes overlap or are distinct from those of autism remains unknown. To investigate this, we developed a cell-type[1] burden approach that enhances power to test associations between rare inherited variants and traits while providing a functional readout.

Material and Methods: Using exomes from 43,531 autistic individuals from the SPARK cohort[2], we analyzed rare (MAF <0.001), loss-of-function and missense variants in intolerant genes (LOEUF < 0.6). Associations with 11 psychiatric diagnoses were tested by functional burden ; aggregating variants across cell-types and developmental epochs. Psychiatric diagnoses included: ADHD (n = 14,342); anxiety (n = 9,013); sleep disorders (n = 7,295); depression (n = 4,769); obsessive-compulsive (n = 3,884); disruptive behavior disorder (DBD) (n = 3,539, including oppositional defiant (ODD, n = 2,872)); bipolar (n = 1,284); tics (n = 1,205); schizophrenia (n = 487) and eating disorders (n = 371).

Results: ADHD, ODD and DBD exhibited a significant missense variants burden, particularly in inhibitory interneuron subtypes. For ADHD, ODD and DBD, respectively 33%, 81% and 60% of the missense variants signals were distinct from autism liability. ODD also showed loss-of-function variant signals in inhibitory interneurons. No significant burden was observed for other diagnoses, which may be partially attributed to limited statistical power.

Conclusion: These findings highlight the cell-specific impact of rare SNVs on psychiatric co-occurrences in ASD, with interneurons playing a central role. This enhances our understanding of the genetic and cellular underpinnings of psychiatric diagnosis in autism and reveals that part of this liability is distinct from autism susceptibility.

P11.018.A Identification and rescue of circadian rhythm defects in Prader-Willi syndrome neuronal cultures

A. Kaitlyn Victor[1], *Tayler Hedgecock*[2], *Andrew Liu*[3], ***Lawrence T. Reiter***[2]

[1]*St. Jude Children's Research Hospital, Memphis, TN, USA,* [2]*Tulane University, New Orleans, LA, USA,* [3]*University of Florida, Gainsville, FL, USA.*

Background: Prader-Willi Syndrome (PWS) is a multigenic neurodevelopmental disorder characterized by loss of expression of maternally imprinted genes in the 15q11.2-q13.1 region. PWS individuals present with hypotonia, developmental delay, childhood obesity, and sleep disorders. Little is known about the molecular mechanism during development which leads to excessive daytime sleepiness in PWS. Since current mouse models do not accurately recapitulate PWS phenotypes, cellular models from PWS patient samples are crucial to understanding the molecular etiology of disease during neural development.

Materials: We use dental pulp stem cell (DPSC) derived neuronal cultures to investigate a variety of neurodevelopmental disorders including PWS. These neuronal cultures contain a collection of cell types including glia, excitatory and inhibitory neurons.

Results: We have shown that *Per2*:luc DPSC-derived neuronal lines from PWS individuals have a shortened Per2 cycling period lengths. This shorter period was rescued to neurotypical control using the CKI inhibitor called longdaysin. Alongside these patient cell lines, we are employing *CRY1*-fluorphore-tagged U2OS lines to study MAGEL2's role in circadian cycling through CRY1 regulation. We will treat these cells using different pharmacological agents to see how modulating components downstream from MAGEL2 affects cycling in live cells.

Conclusions: These studies provide insights on how loss of normal MAGEL2 regulation of circadian cycling in PWS leads to excessive daytime sleepiness. Understanding how components downstream from MAGEL2 are modulated pharmacologically will provide new knowledge for future PWS sleep-related treatments of both PWS and the related disorder Schaaf-Yang Syndrome.

P11.019.B Non-canonical BRD4 function rescues the molecular disease signature of X-linked dystonia parkinsonism

Simona Capponi[1], *Sandra Ehret*[2], *Marie Follo*[2], *Fabian Gather*[3], *Tanja Vogel*[4], *H. Th. Marc Timmers*[1]

[1]*DKFZ - Medical Center-University of Freiburg, Freiburg, Germany,* [2]*Medical Center-University of Freiburg, Freiburg, Germany,* [3]*Hannover Medical School, Hannover, Germany,* [4]*University of Freiburg, Freiburg, Germany.*

Background: X-linked Dystonia-Parkinsonism (XDP) is a rare, neurodegenerative disorder, which predominantly affects males with a Filipino ancestry. The disease-associated phenotype results from the insertion of an SVA retrotransposon within intron 32 of the *TAF1* gene, encoding the largest subunit of the basal transcription factor TFIID. This insertion determines aberrant processing of *TAF1* mRNA synthesis, including intron 32 retention and incorporation of intron 32 sequences into mature *TAF1* mRNAs, together with a reduction in full-length mRNAs.

Material and Methods: To understand the molecular mechanism of XDP-associated transcriptional dysregulation, we developed a fluorescence- and cell-based reporter assay, which recapitulates the XDP molecular signature, and employed this assay as a screening platform for chemical libraries focused on epigenetic pathways. To validate the identified hits, we applied patients-derived neural progenitor cells and established XDP cerebral organoids.

Results: The screening led to the identification of BRD4 as a critical regulator of XDP-SVA-dependent defects in *TAF1* mRNA processing. Interestingly, the acetyl-lysine binding function of BRD4 is not essential for rescue of the XDP molecular signature, which requires instead non-canonical BRD4 functions associated with mRNA processing and termination. Similarly, defective *TAF1* mRNA processing in XDP patient-derived cell lines and cerebral organoids is also countered by BRD4 depletion.

Conclusion: Here, we use an unbiased, comprehensive screening approach to uncover a novel disease mechanism that links XDP pathogenesis to defecting transcription termination, which uncovers a non-canonical function of the transcription regulator BRD4.

Background: Developmental and epileptic encephalopathy (DEE) associated with *CACNA2D2* variants is an ultra-rare autosomal recessive disorder with a strikingly homogeneous phenotype. *CACNA2D2*, predominantly expressed in the cerebellum, encodes the $\alpha_2\delta$-2 subunit of voltage-gated calcium channels (VGCC). It regulates channel membrane trafficking and current properties. We aim to expand the clinical description and to assess the functional impact of relevant *CACNA2D2* variants.

Methods: Through GeneMatcher, ERN-EPiCARE and international collaborations, we assembled clinical and genetic information of patients carrying biallelic *CACNA2D2* variants. Functional characterization, including minigene assays and protein expression analysis of relevant novel variants were performed.

Results: We report clinical and genetic data of a new larger case series of 22 new individuals harboring *CACNA2D2* variants along with 9 previously reported cases. The cardinal manifestations included early-onset drug-resistant epilepsy, severe cognitive and motor impairment, and cerebellar atrophy. Facial and limb dystonia was observed in two families, while ataxia was absent in the newly reported patients. Molecular analysis identified 17 *CACNA2D2* variants, comprising 7 missense and 10 truncating variants (6 splicing, 3 nonsense, and 1 frameshift deletion). Functional studies demonstrated distinct pathophysiological mechanisms: missense variants affect the functional expression of VGCC, alter synaptic functions while truncating variants are likely triggering nonsense-mediated RNA decay, and lead to a complete loss of protein. Our data predict that aberrant expression of α2δ-2 disrupts the excitatory-inhibitory synaptic balance, a key mechanism underlying neurodevelopmental disorders.

Conclusion: Our findings strengthen the role of *CACNA2D2* in DEE and highlight the dual pathogenic mechanisms underlying this disorder, encompassing both channelopathy and synaptopathy.

P11.022.A Enhancing Parkinson's Disease Risk Prediction: Combining Polygenic Risk Scores with Transcranial Sonography

Andres Metspalu[1], *Mart Kals*[1], *Anu Reigo*[1], *Maris Teder-Laving*[1], *Mariliis Vaht*[1], *Tiit Nikopensius*[1], *Toomas Toomsoo*[2,3]

[1]*Institute of Genomics, University of Tartu, Tartu, Estonia,* [2]*Confido Medical Centre, Tallinn, Estonia,* [3]*School of Natural Sciences and Health, Tallinn University, Tallinn, Estonia.*

Background: Parkinson's Disease (PD) affects approximately 3% of individuals aged 65 and older. Currently, PD is diagnosed only when symptoms manifest. The polygenic risk score (PRS) can identify individuals with a very high genetic risk for PD, but its lack of specificity limits its clinical usefulness. Therefore, additional tests are needed for individuals with extremely high PRS. In this study, we combine PRS with transcranial sonography (TCS), utilizing signals from the substantia nigra (SN) to enhance PD risk prediction and potentially justify earlier intervention.

Material and Methods: PD-PRSs were calculated for over 41,000 participants aged 55 years and older from the Estonian Biobank, all without a prior PD diagnosis. Participants in the highest and lowest PD-PRS percentiles (n = 222) underwent TCS measurements. After identifying the butterfly-shaped mesencephalic brainstem, we located the maximal ipsilateral SN area in the axial plane. Images were captured, manually labeled, and planimetry was conducted.

Results: Out of 222 participants in the high-risk group, 9 (8.4%) were diagnosed with PD during the initial visit. In contrast, 3 (3.1%) individuals in the low PD-PRS group received new PD diagnoses. The most significant difference between the high- and low-risk groups was observed in SN hyperechogenicity (SN+) area, with mean values of 0.21 cm^2 for the high-risk group and 0.15 cm^2 for the low-risk group ($p < 0.001$).

Conclusion: Our multivariate analysis indicated that individuals with the highest PD-PRS had nearly six times higher odds of exhibiting SN+ compared to those with the lowest PD-PRS.

Background: Polymorphic DNA minisatellites have been largely overlooked in genome-wide association studies (GWAS), despite their potential significance in shaping genetic traits and contributing to disease susceptibility. Among these, MNS16A is a functional minisatellite located within the *TERT* locus, which previous studies have linked to longevity, Alzheimer's disease (AD), and cancer. The objective of our study was to examine the association between MNS16A, AD, and its related endophenotypes.

Material and Methods: MNS16A was genotyped by PCR in two independent Italian cohorts of European ancestry, comprising 828 individuals (434 cases and 394 controls). The association between MNS16A and AD risk was assessed using logistic regression, adjusting for *APOE* genotype, sex, and age, with results fixed-effects meta-analysed across the cohorts. Additionally, the relationship between MNS16A and AD-related endophenotypes, including leukocyte telomeric length (LTL), Tau-cerebrospinal fluid (CSF), and Tau-PET, was investigated in the Alzheimer's Disease Neuroimaging Initiative (ADNI) cohort using linear mixed models.

Results: MNS16A*S allele is associated with a reduced risk of AD (OR = 0.793, P = 0.029, I^2 =0.00%), longer LTL (beta = 0.030, P = 0.032) and reduced levels of Tau in both CSF (beta = −0.066, P = 0.032) and PET (Braak 5-6 SUVR, beta = −0.028, P = 0.049)

Conclusion: Our findings confirmed the association of the MNS16A*S allele with a reduced risk of AD. Furthermore, we were the first to associate the MNS16A*S allele with LTL and Tau levels in both CSF and PET imaging, reinforcing the protective role of the *S allele in AD-related endophenotypes. Further research with larger cohorts is needed to validate and extend these findings.

P11.024.C A Comprehensive Genotype-first Analysis of Potassium Channel Variants: Insights into Kv Channelopathies in a Multi-ethnic Cohort of 40,000 Exomes

Reagan Lee*, Reza Maroofian*

University College London, London, United Kingdom.

Background: Potassium ion channels, particularly voltage-gated (Kv) channels, are essential for repolarizing cell membrane potentials and propagating electrical signals. Defects in Kv channels, known as Kv channelopathies, are associated with a broad spectrum of neurological and cardiac disorders. Despite their clinical significance, these conditions remain poorly understood, especially in underrepresented populations.

Materials and Methods: We analysed 15 Kv genes with established neurological gene-phenotype associations using a multi-ethnic database of 40,000 exomes, including patients with neurological disorders and controls. Variants were filtered and classified using ACMG guidelines into Benign, Likely Benign, low/medium/high Variants-of-Uncertain-Significance (VUS), and Likely Pathogenic to Pathogenic (LP/P) categories. Gene constraint metrics were applied to assess gene variation intolerance and normalize variant loads across genes by size. Patients with high VUS or LP/P variants underwent phenotype correlation, full exome re-analysis, and segregation testing via Sanger sequencing or trio WES, when available.

Results: A total of 1,609 variants were classified across 15 Kv genes, with significant clustering of high VUS to LP/P variants in genes and regions with high constraint scores, particularly in voltage-sensing and intramembrane helices. LP/P variants were identified in controls or individuals with irrelevant phenotypes, suggesting incomplete penetrance. Out of 25 variants selected for segregation analysis, 15 were confirmed pathogenic, including one indicating a novel mode of autosomal recessive inheritance.

Conclusion: This genotype-first study of Kv channelopathies integrates gene constraint metrics and segregation data, advancing our understanding of variant pathogenicity and genotype-phenotype correlations. These findings provide crucial insights into Kv channelopathies, particularly in diverse and underrepresented populations.

P11.025.D SLC6A4 genotype predicts telomere shortening in depression more persistently than psychological factors

Hana Shimizu-Furusawa[1], *Handayani Halik*[2], *Andi Agus Mumang*[2], *Kristian Liaury*[2], *Yusuf Irawan*[2], *Andi Jayalangkara Tanra*[2], *Kei Asayama*[1], *Takayoshi Ohkubo*[1], *Izumi Naka*[3], *Jun Ohashi*[3], *Takafumi Ishida*[3], *Takuro Furusawa*[4]

[1]Teikyo University, Tokyo, Japan, [2]Hasanuddin University, Makassar, Indonesia, [3]The University of Tokyo, Tokyo, Japan, [4]Kyoto University, Kyoto, Japan.

Background: Environmental and psychological stress accelerates telomere shortening. Psychiatric disorders, especially those triggered by stress, can alter telomere length. Genetic factors associated with depression vary across cultures and environments. The serotonin transporter gene *SLC6A4* VNTR polymorphism affects susceptibility to psychiatric disorders differently in different regional populations. This study aimed to investigate the correlation between telomere length and depression in Indonesia, focusing on socioeconomic, cultural, and genetic factors amidst rapid social changes.

Material and Methods: We recruited 99 psychiatric outpatients and 101 participants without depressive symptoms of 16 to 76 years of age. Psychological assessments were conducted using the Self-Construal Scale (SCS) and Behavioral Inhibition System/Behavioral Activation System (BIS/BAS) via interviews. DNA extracted from the peripheral blood was used to identify the *SLC6A4* genotype by PCR, and telomere length was measured by quantitative PCR.

Results: The comparison of patients with depression and controls revealed significant telomere shortening in the patient group ($p < 0.0001$, Mann-Whitney U-test). Logistic regression showed that psychological scales were stronger predictors of depression than telomere length or *SLC6A4* polymorphisms ($p < 0.01$). A multiple regression analysis indicated that the LL genotype of *SLC6A4*, but not socioeconomic or psychological factors, was strongly associated with telomere length ($p < 0.005$).

Conclusion: Psychological factors were stronger predictors of depression than telomere length or SLC6A4 polymorphisms. However, the LL genotype of SLC6A4 was significantly associated with telomere length, independent of socioeconomic or psychological factors.

P11.026.A Comprehensive genetic analysis of an Italian Amyotrophic Lateral Sclerosis cohort

Alessia Fiorentino[1], *Danara Ormanbekova*[1], *Claudio Fiorini*[1], *Veria Vacchiano*[1], *Edoardo Ruggeri*[1], *Rocco Liguori*[1,2], *Sabina Capellari*[1,2], *Leonardo Caporali*[1], *Valerio Carelli*[1,2]

[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, Bolgona, Italy, [2]University of Bologna, Bologna, Italy.

Background: Amyotrophic Lateral Sclerosis (ALS) is the most prevalent motor neuron disease in adults, affecting approximately 1 in 350 individuals. It is caused by progressive degeneration of upper and lower motor neurons, leading to muscle atrophy, weakness, stiffness, and progressive paralysis, resulting in respiratory failure within 3–5 years of onset. ALS has a complex genetic architecture, involving monogenic, oligogenic, and polygenic inheritance. About 10% of ALS cases have a family history, with pathogenic mutations identified in over half of these cases. Sporadic ALS accounts for the remaining cases, with heritability estimated at 40–50%. Over 23 genes have been linked to ALS, with *C9orf72*, *SOD1*, *FUS*, and *TARDBP* collectively responsible for 60–70% of familiar cases.

Material and Methods: A combination of repeat-sizing of C9orf72 and whole-exome sequencing (in silico panel including genes) was used to comprehensively assess genetic variations in 439 Italian patients with ALS. Clinical and genetic data have been compared to assess the genetic contribution to the pathogenesis of familial and sporadic ALS.

Results: Pathogenic, likely pathogenic, and uncertain significance variants were identified in 15 genes, with *C9orf72* (7%), *SOD1* (3%), *FUS* (2%), and *TARDBP* (2%) being the most common. Overall, 23.7% of patients had a detectable genetic variant. Phenotype-genotype correlation revealed that patients with *C9orf72* expansions had poorer survival compared to those with other mutations or no mutations in the ALS panel genes.

Conclusion: These findings align with other high-throughput studies on the Italian ALS population, highlighting the genetic complexity of ALS and its role in clinical outcomes.

P11.027.B Genomic analysis of the overlap between internalizing and externalizing behaviors

Carolina Muniz Carvalho, *Vanessa K. Ota, Sintia I. Belangero*

Universidade Federal de São Paulo, São Paulo, Brazil.

Background: Internalizing problems, such as anxiety and depression, and externalizing behaviors, such as aggression and rule-breaking, often emerge early in life and are associated with adverse adult outcomes. A notable comorbidity exists between externalizing and internalizing psychopathology. Understanding the shared genetic factors is essential for comprehending their biological mechanisms.

Material and Methods: This study investigates the polygenic overlap between internalizing and externalizing behaviors using large-scale genome-wide association studies (GWAS) of internalizing behaviors (N = 64,641 children/adolescents) and externalizing behaviors (N = 1.5 million adults). We employed linkage disequilibrium score regression (LDSC), to explore SNP-heritability, genetic correlations, and FUMA to explore gene expression based on single nucleotide variants (SNVs).

Results: LDSC analyses revealed that a small proportion of SNVs explain these phenotypes (SNP-heritability: internalizing = 1.7%; externalizing = 6%). The genetic correlation between these traits was not significant (rg = 0.065, p = 0.27). FUMA identified 757 genes expressed in externalizing behaviors and 29 with internalizing behaviors, being that expression of these genes is downregulated (considering differentially expressed genes in both sides) and were enriched for cerebellar tissue and the cerebellum (GTEx data). Eight overlapping genes (e.g., *ARL17B, CRHR1, KANSL1, LRRC37A, MAPT, PLEKHM1, SPPL2C, STH)* were involved in neural processes, including the tubulin complex pathway (GO:0045298, adjusted-p-value = 0.049).

Conclusion: Our preliminary findings suggest that internalizing and externalizing phenotypes are partially explained by SNVs, although these SNVs are not genetically correlated. Shared genes may underlie these behaviors, warranting further causal studies to clarify their genetic relationship.

P11.028.C Further evidence of biallelic variants in *HACE1* as a cause of Spastic Paraplegia and Psychomotor Retardation

Ahad Yousuf Moulvi[1], *Hammad Yousaf*[2], *Cindy Colson*[3], *Lubaba Bintee Khalid*[2], *Rafia Zafar Ghumman*[4], *Iram Javed*[5], *Shahnaz Ibrahim*[6], *Salma Zia*[2], *Muhammad Musawer Khan*[7], *Perrine Brunelle*[3],

Anna Ruiz[8], Juan Pablo Trujillo Quintero[8], Henry Houlden[9], Mathias Toft[10,11], Ambrin Fatima[2], Zafar Iqbal[11]

[1]Ziauddin University, Karachi, Pakistan, [2]Department of Biological and Biomedical Sciences, The Aga Khan University, Karachi, Pakistan, [3]Clinique de Génétique Médicale Guy Fontaine Hôpital Jeanne de Flandre CHRU Lille, 59037 Lille, Cedex, Lille, France, [4]Islam Medical College, Sialkot, Pakistan, [5]Department of Paediatric Neurology, Children Hospital and Institute of Child Health, Faisalabad, Pakistan, [6]Department of Paediatrics and Child Health, The Aga Khan University, Karachi, Pakistan, [7]Bolan Medical College, Quetta, Pakistan, [8]Laboratori de Genètica, Centre de Medicina Genòmica, Corporació Sanitària Parc Taulí,Parc Taulí 1, 08208 Sabadell, Barcelona, Spain, [9]Department of Neuromuscular Diseases, University College London, Queen Square, Institute of Neurology, London, United Kingdom, [10]Institute of Clinical Medicine, University of Oslo, Oslo, Norway, [11]Department of Neurology, Oslo University Hospital, Oslo, Norway.

HACE1 encodes a HECT domain and ankyrin repeat containing E3 ubiquitin protein ligase, regulating several small GTPases. This protein is involved in several important functions, such as cell division, protein ubiquitination, and localization. Biallelic defects in *HACE1* have been implicated in spastic paraplegia and psychomotor retardation with or without seizures (OMIM 616756). Previously, 24 patients of various ethnicities have been reported with a range of variant types; pathogenic, likely-pathogenic, and variants of uncertain significance. Here, we studied five unrelated families of diverse ethnicities with eight patients of 10 months-to-30 years of age. Our patients presented global developmental delay, motor delay, dysarthria, dysphagia, and late-onset seizures. Exome Sequencing identified biallelic variants in the gene *HACE1*. Four out of the five families harbour biallelic loss-of-function variants (Family 1: *HACE1* (NM_020771.4): c.1396C>T p.(Gln466*); Family 2: c.2628-1G>C p.(?); Family 3: c.355G>T p.(Glu119*)); Family 4 carries a compound heterozygous nonsense variants (c.2242C>T p.(Arg748*)/c.152C>G p.(Ser51*)) while a missense variant (c.2711A>G p.(Tyr904Cys)) was identified in the Family 5. All variants segregated with the phenotype in respective families and are classified as pathogenic/likely pathogenic by ACMG criteria except the missense variant p.(Tyr904Cys) which is a VUS. This study strengthens and expands the genotype spectrum of *HACE1*-related rare neurodevelopmental disorder. The addition of our cohort will be helpful in understanding the genotype-to-phenotype correlation. Further, we provided genetic diagnosis to the participating families which will aid in genetic counseling and parental decision-making in the future.

P11.029.D *Up-regulation of a tRNA-derived small non coding RNA in tears of Parkinson's disease patients*

***Erika Salvi[1,2]**, Ilaria Vannetiello[3], Federico Cazzaniga[4], Arianna Ciullini[4], Nico Golfre' Andreasi[5], Simone Tomè[2,6], Antonio Emanuele Elia[5], Valentina Leta[5], Roberto Eleopra[5], Marcella Catania[3], Grazia Devigili[5], Fabio Moda[4,7]*

[1]Data Science Center, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy, [2]Computational multi-Omics of Neurological Disorders (MIND) Lab, Joint Research Platform, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy, [3]Neurology 8 Unit, Dementias and Degenerative Diseases of the Central Nervous System. Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy, [4]Unit of Laboratory Medicine, Laboratory of Clinical Pathology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy, [5]Department of Clinical Neurosciences, Parkinson and Movement Disorders Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy, [6]Department of Electronics, Information and Bioengineering, Politecnico Di Milano, Milano, Italy, [7]Department of Medical Biotechnology and Translational Medicine, Università degli Studi Milano, Milano, Italy.

Background: Parkinson's disease (PD) is a neurodegenerative disorder with motor and non-motor symptoms. Diagnosis remains challenging, requiring post-mortem confirmation. Tear fluid (TF) reflects ocular and central nervous system states, making it a promising non-invasive biomarker source. This study analysed TF miRNA profiles in PD patients compared to healthy controls (HC) to assess their potential for improving early diagnosis and disease monitoring.

Material and Methods: The study included a discovery (8 PD, 7 HC) and a validation cohort (9 PD, 9 HC). We assessed miRNA expression using TaqMan Human MicroRNA arrays, and their associations with clinical variables. Due to small sample size, a fold change threshold (95th percentile in HC) was set, classifying patients as above or below threshold. Composite scores of clinical variables were compared. Target gene prediction, pathway enrichment, and functional interaction analyses were conducted.

Results: We identified a miRNA upregulated in PD tears across two cohorts, reported as tRNA-derived with gene-regulation function. Its expression was higher in a PD subgroup with combined non-motor autonomic symptoms. Target genes are linked to neurodegeneration and cellular dysfunction. Over-representation analysis highlighted its role in the negative regulation of synaptic transmission, while network analysis revealed interactions among key PD-related genes and miRNA targets, suggesting its involvement in disease mechanisms.

Conclusion: Our findings suggest that TF miRNA profiling can identify PD-specific molecular signatures, highlighting its potential as a non-invasive source for early diagnosis. Further studies with larger cohorts and other neurodegenerative diseases are needed to validate these results and explore their clinical applicability.

P11.030.A Characterization of an SPG9 cell model to investigate hereditary spastic paraplegia: cell phenotyping and potential treatment

***Sherin Ramadan[1]**, Cecilia Evangelisti[2], Francesca Valenti[3], Nicola Rizzardi[3], Alessandra Cappellini[4], Valentina Papa[4], Giovanna Cenacchi[1], Camilla Evangelisti[4], Christian Bergamini[3], Marco Seri[2], Emanuele Panza[1,2]*

[1]Dipartimento di Scienze Mediche e Chirurgiche (DIMEC), Università degli studi di Bologna, Bologna (BO), Italy, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna (BO), Italy, [3]Dipartimento di Farmacia e Biotecnologie (FABIT), Università degli studi di Bologna, Bologna (BO), Italy, [4]Dipartimento di Scienze Biomediche e Neuromotorie (DIBINEM), Università degli studi di Bologna, Bologna (BO), Italy.

Background: Spastic Paraplegia type 9 (SPG9) is a rare genetic neurodegenerative disorder caused by mutations in the ALDH18A1 gene. In this study we've derived a cellular model based on a patient-derived fibroblast cell line carrying an

ALDH18A1 pathogenic variant (NM_002860.4:c.727G>C, p.Val243-Leu). Our investigation focuses on elucidating fundamental cellular properties, including cell dimensions, growth dynamics, and mitochondrial features, with the aim of gaining insights into the pathological mechanisms underlying SPG9. Furthermore, our in vitro model offers a unique scorable phenotype that can be used for rescues experiments and to identify novel therapies.

Material and Methods: Initial analyses of the SPG9 cell model revealed distinct phenotypes that are the results of alterations in cell dimensions, growth pattern, and mitochondrial features such as ROS production, ATP synthesis, by phalloidin staining, MTT analysis, galactose growth compared to WT cells. Furthermore, we explored a therapeutic approach by investigating the effects of amino acid supplementation on our in vitro model.

Results: Preliminary results suggest that it is possible to identify specific cell phenotypes, and that specific amino acid supplementation may hold promise as a potential treatment strategy for SPG9, offering a targeted approach to mitigate cellular dysfunction associated with *ALDH18A1* gene mutations.

Conclusion: Our study provides a comprehensive understanding of the cellular characteristics of SPG9, emphasizing the potential utility of amino acid supplementation as a therapeutic intervention. Moreover, our findings contribute to unravel the molecular mechanisms underlying SPG9 and pave the way for the development of targeted therapies for this rare debilitating neurodegenerative disorder.

P11.031.B The missing heritability of SPG7: a part of the answer in the detection of copy number variant

Charlotte Mouraux[1,2,3], *Jean-Loup Méreaux*[2], *Lena Guillot Noel*[2], *Claire-Sophie Davoine*[2], *Claire Ewenczyk*[2], *Marie Coutelier*[2], *Giulia Coarelli*[2], *Alexandra Durr*[2]

[1]*CHU Liège, Liège, Belgium,* [2]*Sorbonne Université, Paris Brain Institute – ICM, Inserm, CNRS, APHP, Pitié-Salpêtrière University Hospital, Paris, France,* [3]*GIGA – CRC – Rare Movement Disorders Research Group, University of Liège, Liège, Belgium.*

Background: Spastic paraplegia 7 (SPG7) represents the most frequent autosomal recessive spastic paraplegia. The phenotype picture is either pure or complex encompassing ataxia, optic atrophy, and parkinsonian features. Dominant inheritance has been reported in the literature, associated with specific variants, but it remains a subject of debate.

Material and Methods: We analysed genomic data from 74 patients from SPATAX/BIOMOV cohorts at the Paris Brain Institute (ICM) with a monoallelic variants in SPG7 and a phenotype compatible with SPG7. Copy number variant (CNV) analyses were performed on exome data using the Illumina Dragen software CNV pipeline.

Results: We identified seven patients (9.4%) carrying a deletion and the Ala510Val variant. A recessive transmission was described for two cases, the other five were sporadic. The age at onset was 43 ± 6.3 years, with unsteadiness and/or stiffness as the first signs. The pure form of SPG7 accounted for 30% and complex form for 70% associating with neuropathy, cerebellar ataxia, and oculomotor signs. No patients exhibited cognitive impairment or parkinsonism. MRI revealed cerebellar atrophy in four patients.

Conclusion: The detection of a CNV enabled the diagnosis of SPG7 in 9.4% of our cohort of heterozygous SPG7 carriers. The apparent heterozygous state of affected patients could be due to an insufficient variant coverage in SPG7 with previous techniques (e.g., NGS panel or WES), which hides a second pathogenic variant such as a CNV, an intronic variant, etc. Additionally, another explanation could be the presence of a second causative gene, specifically impacting the mitochondrial respiratory complex.

P11.032.C Genetic mosaicism in diffuse Malformations of Cortical Development: Insights and Implications in the diagnostic workflow

Flavia Fineschi[1], *Barbora Straka*[2,3], *Claudia Mandorlini*[1], *Valentina Cetica*[1], *Elena Cellini*[1], *Pavel Krsek*[2], *Aurelia Iuliana Timis*[1,4], *Domenico Rutigliano*[1], *Dalila De Vita*[1], *Daniela Pucatti*[1], *Simona Virdò*[1], *Massimo Delledonne*[4], *Renzo Guerrini*[1,5], *Elena Parrini*[1], ***Davide Mei***[1]

[1]*Neuroscience and Medical Genetics Department, Meyer Children's Hospital- IRCCS, Firenze, Italy,* [2]*Department of Paediatric Neurology, Motol Epilepsy Center, 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic,* [3]*Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic,* [4]*Functional Genomics Lab, Department of Biotechnology, University of Verona, Verona, Italy,* [5]*University of Florence, Florence, Italy.*

Background: Malformations of cortical development (MCDs), whether autosomal or X-linked-dominant, are often caused by de novo pathogenic variants, with somatic mosaicism also playing a contributory role. We aimed to assess the prevalence of somatic mosaicism in MCDs and to optimize the diagnostic protocol to identify mosaic pathogenic variants in both probands and parents of MCD patients carrying alleged de novo variants.

Material and Methods: We performed deep amplicon sequencing (DAS) with a read depth above >2,500 (mean depth: 87,071) on blood-derived DNA from 93 patient-parent trios (279 individuals) harbouring presumed de novo pathogenic variants in 31 MCD-associated genes, previously identified by targeted gene panel or exome sequencing. Amplicon libraries were prepared and sequenced using a 2×150 bp paired-end protocol on Illumina platforms. To detect mosaic variants, we developed MosDetection, a customized script that reprocessed bam-read-count output with adjustable parameters for SNVs and indels, providing sequencing depth and alternative/reference read counts for each trio.

Results: Mosaicism was identified in six unrelated individuals: four probands with variant allele frequencies (VAFs) ranging from 18% to 35% and two parents with VAFs of 3% and 8%, respectively. Notably, parents carrying these somatic pathogenic variants were asymptomatic.

Conclusion: Somatic mosaicism was identified in 6.4% of the cohort (6/93 trios), including 4.3% in probands (4/93 trios) and 2.1% in parents (2/93 trios). Our findings demonstrate that DAS combined with the MosDetection tool effectively detects low allele frequency variants. This approach enhances segregation analysis, mosaic variant identification, and VAF quantification, thus improving genetic counseling and diagnostic workflow.

P11.033.D Genetic and transcriptomic insights into major depressive disorder heterogeneity

Elisa Benetti[1,2,3], *Francesca Genova, PhD*[1], *Lidia Fortaner-Uyà*[3,4], *Federica Colombo*[3,4], *Sara Poletti*[3,4], *Francesco Benedetti*[3,4], *Alessandro Serretti*[5], *Chiara Fabbri*[6], *Luca Colnaghi*[3,7], *Paolo Provero*[1,8], *Benedetta Vai*[3,4]

[1]*Center for Omics Sciences, IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS San Raffaele Scientific Institute, Milan, Italy,* [3]*Vita-Salute San Raffaele University, Milan, Italy,* [4]*Psychiatry and Clinical Psychobiology Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy,* [5]*Università degli Studi di Enna "Kore", Enna, Italy,* [6]*Department of biomedical and neuromotor sciences, University of Bologna, Bologna, Italy,* [7]*Protein Signaling in Brain Physiology and Pathology, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy,* [8]*Department of Neurosciences, University of Turin, Turin, Italy.*

Background: Major depressive disorder (MDD) affects 5% of the population, impairing psychosocial functioning and quality of life. Its phenotypic heterogeneity complicates identifying genetic determinants, requiring advanced patient stratification and interpretable methods.

Material and Methods: Phenotypic stratification was conducted using a consensus clustering approach on MDD individuals from the UK Biobank (UKB). Two stratification models were applied: (i) multimodal neuroimaging (n = 7948); (ii) clinical information on depressive symptomatology (n = 35033). A Transcriptome-Wide Association Study (TWAS) was performed using PrediXcan. Clusters were characterized through Mann-Whitney-U and chi-squared tests for clinical variables, and logistic regression models for genes and pathways. RNA sequencing (RNAseq) was conducted using DESEQ2 on an independent MDD cohort (n = 83), stratified with a stability-based clustering on structural neuroimaging.

Results: Two distinct clusters were identified in both UKB datasets, differing in cardiovascular comorbidities, diabetes, and depression severity. Clinical clusters varied in treatment resistance and the predicted expression of NDUFAF3, GPX1, and DPPA4, while neuroimaging clusters differed in PABPC1 and FYN. Enriched pathways indicated roles in chemical stress response and chromatin remodeling. Two clusters were also found in the independent cohort, with RNAseq identifying 39 differentially expressed genes, including SOCS3, a trait marker for depressive symptoms, and MMP8, associated with stress.

Conclusion: This study demonstrates the existence of two homogeneous MDD groups linked with specific gene expression patterns, found in independent samples and using different strategies, providing insights on the molecular mechanisms for tailored therapeutic approaches. This research used the UKB (Application 56514) and was supported by the Italian Ministry of Health (GR-19 0616).

Background: Biallelic *TANGO2* loss-of-function variants cause a multisystemic disorder with metabolic-encephalomyopathic crises, rhabdomyolysis, and neurodegeneration. We generated induced-Pluripotent-Stem-Cells(iPSCs) from two siblings with the same genotype (c.262C>T(p.Arg88*);c.338delG(p.Gly113Alafs*10)) but exhibiting different clinical symptoms. Symptomatic patient-derived neurons showed increased oxidative stress, whereas asymptomatic sibling's cells remained comparable to controls. To further investigate, we examined TANGO2's role in mitochondrial redox-imbalance and synaptic connectivity in induced-glutamatergic-Neurons(iGluNeurons).

Material and Methods: iPSCs from TANGO2-patients and controls were differentiated into iGluNeurons via neurogenin-2-inducible overexpression. Mitochondrial membrane potential and elongation were evaluated with tetramethylrhodamine-ethyl-ester(TMRE) dye, while electrophysiological activity was recorded using High-Density Multi-Electrode-Array(HD-MEA). Neurotransmission changes were performed with glutamate assay.

Results: At 22 days in-vitro(DIV), no significant differences in mitochondrial membrane potential were observed, likely because this early maturation stage is too premature to reveal TANGO2-deficiency effects. Further analyses will exhibit energy maintenance at later stages. However, mitochondrial length increased in both patient-iGluNeurons, with slight elongation in the asymptomatic ones, highlighting enhanced fusion processes, potentially as a cellular stress response. Electrophysiological analysis (30DIV) showed that symptomatic patient-iGluNeurons exhibited a significant reduction in firing rate, burst rate, and duration compared to controls, suggesting impaired neuronal activity, and signaling. Additionally, glutamate release was reduced at 21DIV, further confirming synaptic dysfunction. Asymptomatic patient analysis is ongoing.

Conclusion: Increased mitochondrial fusion suggests an initial compensatory mechanism, more effectively sustained in the asymptomatic patient. Subsequent studies will explore whether asymptomatic patient's compensation involves enhanced ATP production and mitophagy. Electrophysiological impairment and reduced glutamate release observed underscore TANGO2's role in synaptic transmission and neuronal signaling.

P11.035.B No association between *FMR1* premutation and either ADHD or anxiety in 53,707 women undergoing genetic testing for family planning purposes

Liraz Klausner[1], *shai Carmi*[1], *Noa Lev-El Halabi*[2], *Shay Ben shachar*[3], ***Lina Basel-Salmon***[4], *Dana Brabbing Goldstein*[2]

[1]*Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel,* [2]*The Raphael Recanati Genetic Institute - Beilinson, Rabin Medical Center, Petach-Tikva, Israel,* [3]*CLALIT HEALTH CARE, Ramat Gan, Israel,* [4]*The Raphael Recanati Genetic Institute - Beilinson, Rabin Medical Center, Petah Tikva, Israel.*

Background: *FMR1* premutation has been inconsistently associated with neuropsychiatric phenotypes, possibly due to

ascertainment bias. We investigated the association between *FMR1* premutation and attention deficit hyperactivity disorder (ADHD), anxiety, and other psychiatric disorders in large-scale population-based genetic carrier screening data.

Material and Methods: We defined premutation as having 58–200 CGG repeats. Phenotypes were identified in linked electronic medical records via formal diagnoses or relevant medication purchases. As a positive control, we assessed premature ovarian insufficiency (POI) and elevated follicle-stimulating hormone (FSH) levels before the age of 40.

Results: Our study included 53,707 women, among them 464 premutation heterozygotes. The premutation status was associated with POI (hazard ratio [HR]: 4.08, 95% confidence interval [CI]: 2.16–7.72) and high FSH (HR: 3.43, 95% CI: 2.65–4.43) but not with ADHD (HR: 1.08; 95% CI: 0.75–1.56), anxiety (HR: 0.74; 95% CI: 0.53–1.04), anxiety and depression (HR: 0.86; 95% CI: 0.69–1.07), and other psychiatric disorders (HR: 1.22; 95% CI: 0.73–2.03). Our study was sufficiently powered to detect HR in the range approximately 1.5–2.

Conclusion: No association was found between FMR1 premutation status and either ADHD or anxiety. While our study design avoided bias towards affected families, participants may be healthier than average, and small effects cannot be excluded.

P11.037.D Importance of stereotypical migration routes for precise cortical interneuron positioning and circuit formation

*Sathish Venkataramanappa[1], Dagmar Schütz[1], Ralf Stumm[1], **Philipp Abe**[2]*

[1]Institute of Pharmacology and Toxicology, Jena University Hospital, Jena, Germany, [2]Institute for Clinical Genetics, University Hospital Carl Gustav Carus at TUD Dresden University of Technology, Dresden, Germany.

Background: Cortical GABAergic interneurons (cIN) are crucial for the proper function of cortical circuits. Incorrect numbers and defects in synaptic integration are linked to disorders such as epilepsy, schizophrenia, and anxiety. These interneurons originate in the ventral telencephalon and migrate into the developing cortex in two streams that are hypothesized to be key for their proper positioning and subsequent integration into the developing cortex.

Material and Methods: We utilized a Cxcr4 conditional knockout (cKO) mouse model to investigate the impact of disrupted stereotypic migration on cortical development. We analyzed cIN distribution, gene expression by single cell RNA-seq, and synaptic connectivity throughout embryonic and postnatal development.

Results: Despite reaching most cortical regions, Cxcr4-deficiency disrupts cIN migration within the sub-meningeal compartment, resulting in a permanent deficit of cINs in superficial layers. Aberrant positioning shifts cIN identity towards a somatostatin subtype and reduces expression of synaptic genes. Furthermore, GABAergic synapses preferentially target deep layers, mirroring altered cIN distribution.

Conclusion: Cxcr4-regulation of layer-specific cIN migration is essential for proper cIN allocation, maturation, and ultimately, formation of cortical circuits. Disruptions in this process may contribute to the pathophysiology of neurological and mental disorders.

P11.038.A A single-cell eQTL atlas of the human cerebellum reveals vulnerability of oligodendrocytes in essential tremor

*Charles-Etienne Castonguay[1,2,3], **Farah Aboasali**[1,2], Miranda Medeiros[1,2], Theodore Becret[2], Zoe Schmilovich[1,2], Anouar Khayachi[1,2], Alex Rajput[4], Patrick Dion[5,2], Guy Rouleau[1,2]*

[1]McGill University, Montreal, QC, Canada, [2]Montreal Neurological Institute-Hospital, Montreal, QC, Canada, [3]Université de Montréal, Montreal, QC, Canada, [4]University of Saskatchewan, Saskatoon, SK, Canada, [5]McGill University, montreal, QC, Canada.

Background: Essential Tremor (ET) is the most common movement disorder, affecting approximately 1% of the worldwide population. It is characterized by an active, postural, or kinetic tremor, primarily affecting the upper limbs, which can be very severely debilitating to quality of life. The pathophysiological mechanisms of ET are largely unknown, and despite strong evidence of heritability, studies of ET genetics have yielded mixed results.

Material and Methods: We sought to understand the effects of genetic risk factors in ET on the cerebellum by building a population-scale single-cell atlas of the human cerebellar cortex comprised of over 1 million cells from 109 individuals. We utilized single-cell expression quantitative trait loci (eQTLs) and Mendelian randomization (MR).

Results: We found evidence of downregulation of BACE2 in cerebellar oligodendrocytes caused by ET-associated variants in its locus. We also highlight a genetically vulnerable population of BACE2-expressing immature oligodendrocytes, which suggests demyelination. Additionally, we find dysfunctional interactions between Golgi cells, Purkinje layer interneurons, and oligodendrocytes in ET.

Conclusion: Our study suggests a putative disease model where oligodendrocytes play a crucial role in the pathogenesis of ET.

P11.039.B Integration of long-read nanopore sequencing for precision resolution of genomic variants in dystonia

***Ugo Sorrentino**[1], Martin Pavlov[1,2,3], Eugenia Tsoma[4], Petra Havrankova[5], Jan Necpal[6,7], Matej Skorvanek[8,9], Robert Jech[10,11], Holger Prokisch[1,3], Juliane Winkelmann[1,3,2], Michael Zech[1,3,12]*

[1]Institute of Human Genetics, School of Medicine and Health, Technical University of Munich, Munich, Germany, [2]Bavarian Genomes Network for Rare Disorders, Munich, Germany, [3]Institute of Neurogenomics, Helmholtz Zentrum München, Munich, Germany, [4]Regional Clinical Center of Neurosurgery and Neurology, Department of Family Medicine and Outpatient Care, Uzhhorod National University, Uzhhorod, Ukraine, [5]Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine and General University Hospital in Prague, Charles University, Prague, Czech Republic, [6]Department of Neurology, Zvolen Hospital, Zvolen, Slovakia, [7]Second Department of Neurology, Faculty of Medicine, Comenius University, University Hospital Bratislava, Bratislava, Slovakia, [8]Department of Neurology, P.J. Safarik University, Kosice, Slovakia, [9]Department of Neurology, University Hospital of L. Pasteur, Kosice, Slovakia, [10]Department of Neurology and Center of Clinical

Neuroscience, First Faculty of Medicine Charles University and General University Hospital in Prague, Prague, Czech Republic, [11]Department of Neurology, General University Hospital in Prague, Prague, Czech Republic, [12]Institute for Advanced Study, Technical University of Munich, Garching, Germany.

Background: Dystonia is a movement disorder characterized by monogenic aetiology in a relevant proportion of cases, with more than 400 disease-associated genes described to date. Because of well-known limitations regarding allele phasing, structural variant detection, short-tandem repeat analysis, and scrutiny of high-homology sequences, short-read sequencing (SRS) technologies are incapable of comprehensively characterising the full spectrum of genome variation. It is therefore crucial to investigate the feasibility of alternative diagnostic approaches, such as long-read DNA sequencing (LRS), which promise to overcome several unsolved challenges of SRS.

Material and Methods: We selected seven unrelated dystonia patients in which candidate variants could not be conclusively interpreted by SRS methods. LRS was performed on patients' native DNA fragments using an Oxford Nanopore Technology (ONT) platform according to the manufacturer's protocols. Bioinformatic analysis was performed using a pipeline supporting the calling of single-nucleotide variants, structural variants, short-tandem repeats, and modified bases.

Results: LRS analysis offered precise molecular characterization of each patient, resolving previous indeterminate findings. In two cases, phasing analysis proved compound heterozygosity of pathogenic variants (*HIBCH*, *OTUD7A*). In two other patients, previously unresolved complex structural variants were thoroughly characterized (*MECP2*, *SCGE)*. Accurate estimation of repeat-expansion length was critical for diagnosis in two additional subjects (*TBP*, *FMR1*). Finally, we re-evaluated one case with a suspicious variant call in a gene for which a pseudogene with high sequence similarity exists (*PI4KA*).

Conclusion: ONT-based LRS represents a promising tool for complementing SRS and resolving inconclusive results in the diagnosis of genetic forms of dystonia.

P11.040.C Memory disorders in Neurofibromatosis type I

Michela Lopardo[1], *Manuel Ruocco*[1], *Katrin Caiazza*[1], *Maria Anna Siano*[1], *Annalisa Masuccio*[2], *Alessandra D'Amico*[3], *Roberta Russo*[1], *Annibale Botto*[2], *Martina Di Stasi*[2], *Simona Sestito*[4], *Mariateresa Falco*[1], *Daniela Concolino*[4], *Renato Cuocolo*[1], *Francesco Di Salle*[1], *Daniela Melis*[1]

[1]*Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Section of Pediatrics, University of Salerno, Via Salvador Allende, 43 84081 Baronissi (Salerno), Italy., Salerno, Italy,* [2]*Radiology Unit, San Giovanni di Dio e Ruggi D'Aragona Hospital, Salerno, Italy, Salerno, Italy,* [3]*Tortorella Private Hospital Salerno Italy, Salerno, Italy,* [4]*Pediatric Unit AOU Mater Domini Catanzaro (Italy), Catanzaro, Italy.*

Background: Neurofibromatosis type I (NF1) is a neurocutaneous syndrome commonly associated with cognitive deficits, including memory disorders and learning disabilities. Among the neurobiological mechanisms involved are alterations in long-term potentiation (LTP) and volumetric changes in the hippocampus, a structure crucial for both long-term and short-term memory processes.

Material and Methods: The retrospective study involved 111 patients with NF1, mean age 22.76 years (range 5–63 years). A subgroup of 7 patients aged 5–16 years along with 10 healthy controls, underwent neuropsychological testing using the NEPSY battery (Developmental Neuropsychological Assessment), a standardised instrument that assesses specific aspects of verbal and non-verbal memory. In parallel, T1-weighted three-dimensional MRI images were used to calculate hippocampal volumes using validated neuroimaging software.

Results: 71% of the patients demonstrated difficulties with verbal and non-verbal memory tasks. Specifically, increased left hippocampal volume was associated with poorer performance on certain memory tests ($p < 0.05$). This correlation highlights a direct link between structural alterations and cognitive deficits in NF1 patients.

Conclusion: The results suggest that volumetric changes in the hippocampus negatively affect memory abilities in NF1 patients, with clear implications for the neurocognitive profile of this population. The use of the NEPSY battery provided a deeper understanding of the specific difficulties, underscoring the need for further studies aimed at developing interventions to improve patients' quality of life.

P11.042.A Exome sequencing in the diagnosis of pediatric neurogenetic disorders: An Indian perspective

Varun Venkat Raghavan Mandikal srinivasan[1], *Vykuntaraju K. Gowda*[2], *Dipali Rai*[3], *Himani Pandey*[4], *Devi Lal*[5], *Nagaraja M. Phani*[3]

[1]*Postgraduate Institute of Child Health, Noida, India,* [2]*Indira Gandhi Institute of Child Health, Bangalore, India,* [3]*Department of Molecular Genetics, Lifecell International, Chennai, India., Chennai, India,* [4]*Department of Molecular Genetics, Redcliffe Labs, Noida, India., Noida, India,* [5]*Department of Zoology, Ramjas College, University of Delhi, New Delhi, India.*

Background: Neurogenetic disorders are a large group of heterogeneous conditions with wide variability in age of onset, clinical presentation, and severity. Diagnosing these disorders is challenging due to a multitude of factors. Exome and genome sequencing have helped us overcome some of these to make a diagnosis.

Material and Methods: This is an ambispective study conducted over five years at a tertiary care center in India. We included patients with suspected monogenic disorders and recruited 3,914 families after excluding non-Mendelian disorders, subjecting them to exome sequencing. 3,856 underwent proband-only, while the rest opted for a trio exome.

Results: Males constituted 55.9%. Consanguinity was noted in 31.5% (1,232 cases). Positive family history of similarly affected siblings was seen in 5.6% (216 families). The overall diagnostic yield comprising matching pathogenic/likely pathogenic variants was 47.7% (1,867 cases). Novel mutations were seen in 54.6%. Multiple genetic diagnoses were obtained in 256 (6.54%): dual diagnosis was more commonly seen in 230 families, triple diagnosis in 22, four disorders in 2, and five disorders in 2 each, respectively. Autosomal dominant and recessive disorders comprised the majority; founder mutations were found in 15 genes, and one novel gene, *LARP1B*, was found to cause neurodevelopmental disorder phenotype. A novel phenotype in 12 genes was

noted. Expansion of phenotype was reported across 88 OMIM-related diseases. Secondary findings were seen in 5.4% of cases.

Conclusion: We present the data of a large cohort of pediatric patients from India diagnosed with neurogenetic disorders who displayed diversity in phenotypes and genotypes.

P11.043.A CHAMP1 directs the maturation of synaptic function and firing activity in iPSC-derived excitatory neurons

Dailey Nettles, Christina Stanton, Zach Hunter, Meris Privette, Lori McMahon, ***Stefano Berto***

MUSC, Charleston, SC, USA.

Background: Mutations in CHAMP1 are a major genetic risk factor for neurodevelopmental disorders (NDDs), with affected individuals exhibiting intellectual disability, autism spectrum disorder (ASD)-like behaviors, microcephaly, hypotonia, and distinctive dysmorphic features. CHAMP1 encodes for a zinc-finger protein involved in the chromosomal segregation during mitosis and in DNA repair mechanisms. However, the function of CHAMP1 in neurodevelopment remains relatively unexplored. We hypothesize that CHAMP1 orchestrates neuronal proliferation by modulating mitosis during prenatal development, ultimately promoting the maturation of synaptic and firing properties of excitatory neurons and synchronicity of local cortical circuits. CHAMP1 loss of function (LoF) could delay the maturation of both individual neurons and complex circuits.

Material and Methods: To test our hypothesis, we induced neural progenitor cells (NPCs) and mature neurons using a dual-SMAD inhibition approach with one neurotypical iPSC line (Ctrl1), two patient donor lines (CHAMP1(c.1489c>T), CHAMP1(c.2094-delT)), and one isogenic knockout line (iCHAMP1-/-).

Results: To quantify the development of functional properties in maturing neurons, we used whole-cell patch-clamp electrophysiology at one and two months in vitro. CHAMP1(c.1489c>T), CHAMP1(c.2094delT), and iCHAMP1-/- neurons exhibited altered membrane properties and reduced action potential amplitude and frequency compared to Ctrl1 neurons. Additionally, CHAMP1 LoF reduced the amplitude and frequency of spontaneous excitatory postsynaptic currents at 1 month in vitro.

Conclusion: More deficits were observed in CHAMP1(c.1489c>T) neurons compared to CHAMP1(c.2094delT), which correlates with the severity of CHAMP1 syndrome present in these patients. Together these results suggest that CHAMP1 directs the maturation of excitatory synaptic and firing activity.

P11.044.C Characterising Epilepsy Phenotype Heterogeneity in Biobank-Derived Disease Cases

Janne Auning Hansen[1,2]*, Julie Werenberg Dreier*[1,3]*, Jakob Christensen*[2,4]*, Bjarni Jóhann Vilhjálmsson*[1,5,6]

[1]*National Centre for Register-Based Research, Aarhus University, Aarhus, Denmark,* [2]*Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,* [3]*Centre for Integrated Register-based Research (CIRRAU), Aarhus University, Aarhus, Denmark,* [4]*Department of Neurology, Aarhus University Hospital, Aarhus, Denmark,* [5]*Bioinformatics Research Centre, Aarhus University, Aarhus, Denmark,* [6]*Novo Nordisk Foundation Center for Genomics Mechanisms of Disease, Broad Institute of MIT and Harvard, Cambridge, MA, USA.*

Background: Epilepsy is a heterogeneous disorder with diverse genetic and clinical characteristics. This complicates genome-wide association studies (GWAS) on biobank data, where diagnoses rely on the International Classification of Diseases system rather than detailed clinical characterisation. We both explore the scope of this problem by estimating genetic correlations between biobank-derived and clinically validated samples, and whether family history can improve diagnostic accuracy.

Methods: We conducted a GWAS within the Lundbeck Foundation Initiative for Integrative Psychiatric Research (iPSYCH) cohort (n = 4,409) using family history with LT-FH++. Genetic correlations between the biobank summary statistics - iPSYCH, FinnGen (n = 15,645), and UK Biobank (n = 3,500) - and the most recent International League Against Epilepsy (ILAE) GWAS of clinically validated samples (n = 29,944) were calculated using linkage disequilibrium score regression (LDSC).

Results: The biobanks were highly genetically correlated with the broadest ILAE GWAS phenotype (iPSYCH rg = 0.96, 95%CI 0.53–1.39, FinnGen rg = 0.78, 95%CI 0.59–0.97, UK Biobank rg = 0.84, 95%CI 0.49–1.19), suggesting consistent overall genetic architectures. Especially the UK Biobank summary statistics were highly genetically correlated with the genetic generalized subtype from the ILAE GWAS (rg = 0.92, 95%CI 0.56–1.27). Conversely, the focal ILAE GWAS subtypes resulted in higher estimates for iPSYCH (rg = 0.99, 95%CI 0.43–1.45) and FinnGen (rg = 0.74, 95%CI 0.45–1.03). Combing family history with the phenotype improved the iPSYCH-ILAE genetic correlations.

Conclusion: Non-validated biobank-derived epilepsy cases are highly genetically correlated with clinical cohorts, and combining family history with the phenotype can improve diagnostic accuracy. This improves the outlook of their inclusion in genetic meta-analyses.

P11.045.D Transcriptomic signature of sporadic frontotemporal lobar degeneration with TDP-43 subtype C

Ana Rajicic*, Merel Mol, Shamiram Melhem, Helena Kisic, John van Swieten, Harro Seelaar, Jeroen van Rooij*

Erasmus University Medical Center, Rotterdam, Netherlands.

Background: Frontotemporal lobar degeneration (FTLD) with underlying TDP-43 subtype C pathology (FTLD-TDP-C) is a sporadic type of early-onset dementia with a homogeneous clinical presentation. The aim of this study was to discover dysregulated pathways in FTLD-TDP-C through transcriptomics of its most affected region: the left temporal cortex.

Methods and methods: Bulk RNA sequencing was conducted on temporal cortices of a post-mortem cohort of 18 FTLD-TDP-C and 23 controls. Differential expression and overrepresentation analyses were run to detect differentially expressed genes (DEG) and functionally annotate them. To identify DEG specific to FTLD-TDP-C, we removed genes also dysregulated in temporal cortices of other neurodegenerative diseases: Alzheimer's dementia, progressive supranuclear palsy and FTLD with *MAPT* 10 + 16 deletion. Using cell deconvolution, differences in cell type composition between cases and controls were corrected. Furthermore, we performed weighted gene co-expression network analysis (WGCNA).

Results: We found 6324 DEG with FDR < 0.05, of which 3073 were upregulated and enriched for immune response and cell structures, and 3251 were downregulated and enriched for neuronal structures and synapse activity. In 3352 DEG considered

specific to FTLD-TDP-C, RNA splicing was upregulated, whilst postsynaptic specialisation was downregulated. WGCNA identified 18 modules, of which five were significantly correlated to FTLD-TDP-C, and enriched for RNA splicing, postsynaptic function, non-neuronal damage response, and transmembrane transport over the blood-brain barrier.

Conclusion: In FTLD-TDP-C, one fourth of all genes were differentially expressed, and half of these were specific to FTLD-TDP. Differential expression analysis and WGCNA indicated that RNA splicing and postsynaptic processes are significantly dysregulated in FTLD-TDP-C.

P11.046.A SPARK: a recontactable cohort of >150,000 people with autism engaged in research

*Jessica R. Wright, Amy Daniels, L. Casey White, J. Kiely Law, Pamela Feliciano, **Wendy K. Chung***

Boston Children's Hospital, Boston, MA, USA.

Background: SPARK is a cohort of autistic individuals and their family members that seeks to accelerate autism research.

Material and Methods: Participants are US residents who join online or through clinical sites and can choose to provide a saliva sample for exome- or whole-genome sequencing. SPARK collects medical history, family information and standardized questionnaires on the core symptoms of autism. SPARK returns genetic results to participants for autism/neurodevelopmental conditions with variants that meet American College of Medicine (ACMG) criteria for likely pathogenic (LP) or pathogenic (P).

Results: Exomes or genomes are available to approved researchers from nearly 58,000 participants (Table 1) with autism and 94,000 first-degree family members. Of sequenced participants with autism, 41% are from trios, 25% self-reported as people of color, 26% are primarily of non-European genetic ancestry (HapMap3), and 84% completed a medical history questionnaire. SPARK has returned 2,855 autism-related findings to participants and identified a LP/P variant in roughly 8.5 percent of autistic participants. The top 3 CNVs are 16p11.2 deletion, 16p11.2 duplication, and 22q11.2 duplication. The top 3 single nucleotide variants/indels are in *SCN2A*, *SHANK3* and *NF1*. Researchers can apply to recruit SPARK participants to their studies through SPARK's Research Match platform (base.sfari.org). Researchers have launched 304 studies using Research Match and engaged more than 50,000 SPARK participants.

Conclusion: SPARK provides a unique resource of recontactable autistic individuals and their families along with comprehensive genetic and phenotypic data that are freely available to approved researchers.

Characteristic (at enrollment)	Minors (N = 47,504)	Independent & Dependent Adults (N = 10,443)

P11.048.C Biallelic loss of function variant in *SORL1* causes complex hereditary spastic paraplegia - from genomics to functional analysis

Gautham Arunachal Udupi, *Yogananda Shamamandri Markandeya, Ananthapadmanabha Kotambail, Pooja Mailankody, Ramya Sukrutha, Chetan Ghati Kasturirangan, Chandrajit Prasad, Madhura Milind Nimonkar, Suravi Sasmita Dash*

National Institute of Mental Health and Neurosciences (NIMHANS), Bengaluru, India.

Background: Genes regulating the endolysosome and autophagy pathway are the major aetiological contributors to hereditary spastic paraplegia (HSP). *SORL1*, an endosomal trafficking protein, is essential for maintaining the homeostasis of glutamatergic neurons and white matter tract integrity. It has so far only been associated with a dominant form of Alzheimer disease (AD) and amyloid angiopathy and its relationship with HSP through shared macroautophagy mechanisms remains unexplored.

Material and Methods: Whole exome sequencing using the KAPA HyperCap workflow (Roche Sequencing Solutions, USA) on DNBSEQ-G400 (MGI Tech, Latvia) platform with 100 bp paired-end reads was performed. Long-read whole genome sequencing (LR-WGS) library was prepared using the ligation sequencing kit (Oxford Nanopore Technologies, UK) and were sequenced on Promethion 2i. Functional validation included transcriptomic analysis and cellular studies using patient-derived fibroblasts.

Results: We identified a novel biallelic NM_003105.6:c.1211+1G>A consensus splice donor variant (ClinVar Accession: VCV003238954.1) in *SORL1*. Transcriptomics confirmed significant nonsense-mediated decay and aberrant splicing. The evidence of reduced levels of *SORLA* and, consequently, a significant enlargement of endosomes and lysosomes in patient-derived fibroblasts, substantiates the pathogenicity of the variant.

Conclusion: The constraint score metrics (pRec-1.0), meiotic recombination studies, *SORL1-/-*mice models displaying HSP-like phenotypes with cerebroretinal vasculopathy (CRV), and in vitro studies showing endolysosomal enlargement in *SORL1-/-* glutamatergic neurones all support the likelihood that *SORL1* is recessive and aetiologically related. Collating all the evidence from phenotype analysis, functional studies, and literature suggests, *SORL1* is probably a new candidate for a recessive form of complicated HSP, expanding its known role beyond AD-related pathologies.
