Material and Methods: We categorize existing methods into two strategies (Table 1). We establish a benchmark for systematic evaluation with 12 scRNA-seq datasets and 35 GWAS datasets. We validate results with an independent brain data with the same individuals based scRNA-seq and scATAC-seq data spanning six human brain developmental stages.

Results and Conclusion: 1) "Cepo" is the superior method for defining cell-type specificity genes in genetic inference of cell type-trait/disease associations, though differential expression tests best rank gold-standard marker genes. 2) Performance is comparable with mouse- or human-derived transcriptomic data. 3) Method power increases with GWAS sample size and cell count per type. 4) We introduce a Cauchy p-value combination method integrating both strategies maximizes power while avoiding false positives. 5) Single-cell atlases or diverse single-organ datasets yield greater power than those with limited cell-type representation. 6) scRNA-seq data covering various brain developmental stages and stage-specific cell types enhance identification of cellular contributors to brain disorders and cognitive traits. 7) The superior performance of the Cauchy combination was validated with independent scATAC-seq data from the same individuals. 8) Leveraging schizophrenia-associated cell types significantly identified via GWAS and scRNA/ATAC-seq annotations improves polygenic risk prediction for schizophrenia.

Analytic strategies of different methods

Strategy	Method	Framework
From single cell to GWAS	e.g. sLDSC, MAGMA-gene set, sc-linker, CELLECT etc.	Takes cell-type-specific annotations in heritability enrichment analyses
From GWAS to single cell	e.g. scDRS, scPagwas	Uses GWAS-derived gene lists to make single cell disease risk scores based on cumulative scRNA-seq expression of the genes

P18.115.B Genetic associations with endometriosis and its sub-phenotypes: Insights from a multicenter Italian GWAS

Daria Marzanati[1,2], *Erika Carbone[1], Luca Pagliardini[2], Lisett Solano Narduche[2], Ludovica Bartiromo[3], Matteo Schimberni[3], Errico Zupi[4], Massimo Candiani[3], Paola Viganò[5], Davide Gentilini[1,6]*

[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, [2]Reproductive Sciences Laboratory, Obstetrics and Gynaecology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy, [3]Obstetrics and Gynaecology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy, [4]Department of Molecular and Developmental Medicine, Obstetrics and Gynecological Clinic, University of Siena, Siena, Italy, [5]Infertility Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [6]Bioinformatics and Statistical Genomics Unit, IRCCS Istituto Auxologico Italiano, Milan, Italy.

Background: Endometriosis is a complex disease characterized by different symptomatic manifestations and influenced by various genetic and environmental factors. The largest meta-analysis to date (Rahmioglu et al., 2023), identified 42 risk loci associated with endometriosis and its sub-phenotypes. Our study aims to investigate genetic factors associated with endometriosis and its sub-phenotypes within the Italian population; therefore, we conducted a Genome-wide association study (GWAS).

Material and Methods: This multicenter study involved specialized Italian centers that collaborated in collecting DNA samples from patients with surgically diagnosed and histologically confirmed endometriosis. We analyzed genotyping data from 862 cases and 1843 controls. SNP associations with endometriosis were evaluated, including analyses of 10 distinct phenotypic manifestations of the disease. Association analysis was conducted on the post-imputation SNPs dataset using a logistic regression model adjusted for covariates.

Results: Several polymorphisms were associated with endometriosis and its sub-phenotypes (raw p-value $<10^{-5}$). Notably, two SNPs reached genome-wide significance after correction for multiple testing (FDR < 0.05) in the gastrointestinal pain sub-phenotype analysis: rs185338542, located upstream of the ACOT7 gene, and rs138188726, an intronic variant in PCDH7. Additionally, 13 SNPs nominally significant in our Italian cohort overlapped with findings from the latest meta-analysis, supporting their role in endometriosis susceptibility.

Conclusion: Analyzing sub-phenotypes improves the genetic characterization of endometriosis. These results suggest that common variants may contribute to symptom heterogeneity, indicating that polymorphisms can have differentiated effects across the sub-phenotypes of the disease. Finally, our results were found to be consistent with those of the latest published meta-analysis.

P18.116.C Exploring the molecular basis of the genetic correlation between body mass index and brain morphological traits

Daniela Fusco[1], *Camilla Marinelli, PhD Student*[1], *Mathilde André*[1], *Lucia Troiani*[1], *Martina Noè*[1], *Fabrizio Pizzagalli*[1], *Davide Marnetto*[1], *Paolo Provero*[1,2]

[1]*Department of Neurosciences, University of Turin, Turin, Italy,* [2]*Center for Omics Sciences, IRCCS Ospedale San Raffaele, Milan, Italy.*

Background: Several studies have demonstrated significant phenotypic and genetic correlations between body mass index (BMI) and brain morphological traits derived from structural magnetic resonance imaging (sMRI). While there is evidence that increased BMI is associated with reduced gray matter volume, the related neurobiological mechanisms have yet to be characterized.

Material and Methods: Using LD score regression we estimated the genetic correlation between BMI and 435 brain morphology traits using genome wide association studies summary data from the UK BioBank. We then used summary-based Mendelian randomization (SMR) to identify genes whose genetically regulated expression (GReX) in 13 brain tissues from GTEx pleiotropically affects BMI and brain morphology. Finally, we used fine-mapping and colocalization (coloc-SuSie) to identify cases in which a single variant is associated with both BMI and brain morphology through gene expression.

Results: In agreement with previous literature, we find many sMRI traits to have negative genetic correlation with BMI, including in particular cortical areas, cortical and subcortical volumes. SMR analysis found 21 genes whose GReX pleiotropically affects brain morphology and BMI. Fine-mapping followed by colocalization analysis allowed, in several cases, the identification of credible sets of variants likely to be causal for both the macroscopic phenotypes and for gene expression. This happens for protein-coding genes VPS11 and TUFM, and antisense transcripts RP11-624M8.1 and RP11-552F3.9.

Conclusion: We have shown how the integration of data allows the molecular dissection of the genetic correlation between complex traits and the formulation of data-driven hypotheses on the relevant regulatory mechanisms.

P18.117.D A genetic atlas of protein complexes in 200 adults from the Shetland Isles

Jiantao Chen[1], *Xia Shen*[2]

[1]*Sun Yat-sen University, Guangzhou, China,* [2]*Fudan University, Shanghai, China.*

Protein complexes play critical roles in cellular processes, yet their genetic basis remains poorly understood. Here, we inferred 2,175 protein complex phenotypes based on a deconvolution technology and conducted GWAS in 200 individuals from the Shetland Isles. We identified 321 genome-wide significant independent protein complex quantitative trait loci (pcQTL), including 196 *cis*-pcQTL ($P < 5 \times 10^{-8}$) and 125 *trans*-pcQTL ($P < 2.3 \times 10^{-11}$). Among these, 17 *cis*-pcQTL were novel, while 85 *cis*-pcQTL had stronger effects compared to the conventional pQTL from GWAS of single proteins. We discovered 970 colocalized associations between protein complexes and human complex traits, where 959 showed significant potential causal effects between 143 protein complexes and 156 traits (FDR < 5%). We systematically investigated the protein complex markers identified for their therapeutic potential. Among the 190 protein complexes (covering 37 protein subunits) with *cis*-pcQTL, 51 protein complexes (covering 11 protein subunits) showed potential causal effects for at least one disease or health-related phenotype (FDR < 5%). Based on the DrugBank and Drugs.com databases, we found 37 drugs targeting 5 of the 11 protein subunits, resulting in 226 drug-complex-disease combinations. In summary, we provided valuable insights into the genetic architecture of protein complexes and identified new therapeutic possibilities between protein complexes and disease risk hidden in traditional analyses.

P18.118.A Investigating the shared genetic aetiology of hypertension and type 2 diabetes

Bethany Voller[1], *Ruby M. Woodward*[2], *Frank Dudbridge*[2], *Jack Bowden*[1,3], *Jane Masoli*[1,4], *Timothy M. Frayling*[1,5], *Luke C. Pilling*[1], *the GEMINI Collaborative*[6]

[1]*University of Exeter, Exeter, United Kingdom,* [2]*University of Leicester, Leicester, United Kingdom,* [3]*Department of Genetics, Novo Nordisk Research Centre, Oxford, United Kingdom,* [4]*Royal Devon University Healthcare NHS Foundation Trust, Exeter, United Kingdom,* [5]*University of Geneva, Geneva, Switzerland,* [6]

Background: Hypertension and type 2 diabetes (T2D) are common long-term conditions (LTCs) that frequently co-exist. We aimed to utilise statistical genetic approaches to uncover shared genetic mechanisms acting through pathways distinct to those of known risk factors.

Material and Methods: We estimated the genetic correlation between hypertension and T2D using LD-score regression and investigated the bidirectional causal relationship using Mendelian randomisation (MR). We quantified the contribution of 10 common risk factors in explaining the genetic correlation between hypertension and T2D and re-estimated the SNP-disease effects after 'removing' the causal effects of identified risk factors. We used colocalisation to identify shared causal genetic variants and investigated the genes and pathways implicated.

Results: Hypertension and T2D had strong genetic correlation ($rG = 0.48$, $p = 2*10^{-196}$), with evidence of a bidirectional causal relationship. BMI, waist-hip ratio, and triglycerides had the largest individual contributions to the genetic correlation. After removing the combined causal effects of these, substantial genetic correlation persisted ($rG = 0.31$, $p = 2*10^{-36}$), indicating remaining shared mechanisms. Sixteen regions showed evidence of a shared causal variant, including an intronic variant in *PCSK7*, previously associated with iron homeostasis, and pQTLs for NCF1, linked to oxidative stress; evidence from DrugBank supports this protein as a potential drug target.

Conclusion: We identified shared genetic causes between hypertension and T2D independent of well-known factors such as BMI; this increased understanding may be useful in future treatment and prevention of this key LTC pair.

P18.120.C Understanding the common genetic architecture of spontaneous coronary artery dissection using genetically-related phenotypes

Ingrid Tarr[1,2], *Stephanie Hesselson*[1,3], *Michael Troup*[1], *Paul Young*[1], *Yunkai Gao*[1,2], *Monique Bax*[1,3], *Keerat Junday*[1,2], *David WM Muller*[1,4], *Siiri Iismaa*[1,3], *Diane Fatkin*[1,3,5], *Jason Kovacic*[1,3,5], *Robert Graham*[1,3,5], *Eleni Giannoulatou*[1,3]

[1]*Victor Chang Cardiac Research Institute, Sydney, Australia,* [2]*School of Clinical Medicine, St Vincent's Healthcare Clinical Campus, Faculty of Medicine and Health, UNSW, Sydney, Australia,* [3]*UNSW, Sydney, Australia,* [4]*Cardiology Department, St Vincent's Hospital, Sydney, Australia,* [5]*Cardiology Department, St Vincent's Hospital, Sydney, Australia.*

Background: Spontaneous coronary artery dissection (SCAD) is significant cause of heart attacks and disproportionately affects women, but remains poorly understood. Genetic variants have been implicated in SCAD, and a recent genome-wide association study (GWAS) highlighted genetic overlap with other traits and high heritability - most of which is unidentified. Here, we aim to leverage the known genetic architecture of traits associated with SCAD to better understand its genetic risk via a multi-trait GWAS, followed by polygenic risk score (PRS)-based validation.

Material and Methods: A multi-trait analysis of GWAS (MTAG) was performed using published GWASs of SCAD and three genetically correlated traits: fibromuscular dysplasia, migraine, and blood pressure. Independent SCAD-MTAG variants of genome-wide significance were applied as a PRS on a cohort of $N = 105$ SCAD patients and $N = 67$ controls. The association of the SCAD-PRS and SCAD status was assessed via logistic regression, while controlling for sex and genetically determined principal components.

Results: Multi-trait GWAS analysis of SCAD and related traits reinforces the shared genetic aetiology of these traits, particularly between blood pressure and SCAD. This approach identified 19 loci, of which two were novel, and which may contribute to the extreme sex bias observed in this condition. PRS analysis of these results showed a significant relationship between these results and SCAD status (OR = 1.99, 95% CI = 1.28–3.08, p-value = 0.002).

Conclusion: Using related traits, we have identified additional common variants associated with SCAD and demonstrated the usefulness of this method via the production of a PRS with a strong relationship to disease.

P18.121.D Germline structural variants as risk alleles for high grade serous ovarian cancer

N. Mazumdar[1], *M. Diaz*[1], *R. Scott*[2], *N. Gull*[1], *P.-C. Peng*[1], *G. Contino*[2], *P. Pharaoh*[1], *M. Jones*[1];

[1]*Cedars Sinai Medical Center, West Hollywood, CA,* [2]*University of Birmingham, Birmingham, United Kingdom*

Background: Majority of women suffering from epithelial ovarian cancer (EOC) are diagnosed at stages III-IV with an aggressive histotype, high-grade serous ovarian cancer (HGSOC), and <30% of women survive past 5-years. Women inheriting high-moderately penetrant rare variants in genes of the homologous recombination repair pathway account for ~15–20% of cases. The rest harbor a combination of common risk variants identified from genome-wide association studies (GWAS) that individually confer small amounts of risk but collectively contribute to a complex polygenic architecture. Disease risk conferred through single nucleotide polymorphisms (SNPs) accounts for ~40% of the total sum of risk variants, with the majority of variants awaiting identification. Increasing the compendium of risk variants will aid women who can leverage the improved outcomes at earlier stages of diagnosis but are presently unidentifiable.

Material and Methods: We hypothesized that structural variants (SVs), which encompass a greater proportion of DNA than sequence variation via SNPs, confer risk for EOC and HGSOC. We performed a preliminary analysis in Genomics England where SVs were identified from whole-genome sequencing (WGS) data using the Manta-Canvas pipeline.

Results: We identified 3 variants impacting copy number (CNVs) that are presently at a significantly different frequency in 586 EOC cases compared to 2000 age, sex and ethnicity matched control participants ($p < 0.05$). We are expanding the set of cases to include those in the UK Biobank, All of Us and newly generated internal datasets.

Conclusion: The results of this analysis indicate germline regions associated with EOC heritability due to structural variation.

P18.122.A Genome wide association study meta analysis of detoxification and oxidative stress related genetic variants in prostate cancer

Beatriz Alvarez Gonzalez[1,2], *Carmen Maria Morales Alvarez*[3,2], *Alicia Torres Garcia*[3,2], *Luis Javier Martinez Gonzalez*[3,2], *Marisa Cañadas Garre*[4,5], *Maria Jesus Alvarez Cubero*[3,2,6], *Antonio Francisco Hernandez*[1,6,7]

[1]University of Granada, Legal Medicine and Toxicology Department, Faculty of Medicine, Health Sciences Technology Park (PTS), Granada, Spain, [2]GENYO, Centre for Genomics and Oncological Research: Pfizer, University of Granada, Andalusian Regional Government, Health Sciences Technology Park (PTS), Granada, Spain, [3]University of Granada, Department of Biochemistry and Molecular Biology III and Immunology, Faculty of Medicine, Health Sciences Technology Park (PTS), Granada, Spain, [4]Population Health Science, Bristol Medical School, University of Bristol, Bristol, United Kingdom, [5]MRC Integrative Epidemiology Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom, [6]Biosanitary Research Institute, ibs.GRANADA, Granada, Spain, [7]Consortium for Biomedical Research in Epidemiology & Public Health (CIBERESP), Granada, Spain.

Background: Prostate cancer (PCa) is a multifactorial disease influenced by genetic and environmental factors. While genome-wide association studies (GWAS) have identified multiple variants associated with PCa risk, the role of genes involved in detoxification, oxidative stress, and DNA repair remains incompletely understood. This study conducted a GWAS meta-analysis to identify genetic variants in these biological processes and evaluate their impact on PCa susceptibility.

Material and Methods: A comprehensive search of the literature and genomic databases, including GeneCards and PubMed, identified 279 genes involved in detoxification, oxidative stress, and DNA repair. Summary data from the PRACTICAL Consortium meta-analysis (79,148 PCa cases, 61,106 controls) were used to detect potential risk variants. A meta-analysis was performed using GWAS data from the FinnGen and UK Biobank cohorts (19,209 PCa cases, 288,847 controls). Variants were selected based on meta-analysis p-value < 0.01, minor allele frequency > 10%, and relevance to detoxification, oxidative stress, and DNA repair pathways.

Results: Summary data from the PRACTICAL Consortium meta-analysis identified 1,287 significant variants in 167 genes. Following the meta-analysis, 258 SNPs in 30 genes were significantly associated with PCa. These variants were prioritized based on linkage disequilibrium ($r^2 \geq 0.8$, $D' \geq 0.9$), p-value < 0.01, and involvement in pathways related to detoxification, oxidative stress, and DNA repair.

Conclusion: This study highlights the role of detoxification and oxidative stress related genes in PCa susceptibility and suggests that the identified variants could serve as biomarkers for risk and aggressiveness assessment. Further validation studies are needed to confirm these findings.

P18.123.B Association Analysis of Small Vessel Disease Variants Identifies a Novel *CTC1* Variant Linked to Migraine Susceptibility

Zizi Molaee

Centre for Genomics and Personalised Health-QUT, Brisbane, Australia.

Background: Migraine is a common neurological disorder affecting 15% of the global population. While vascular factors and genetic components are implicated in its pathogenesis, the relationship between migraine and cerebral small vessel disease (SVD) remains unclear. This study investigated the association between SVD-related genetic variants and migraine susceptibility.

Material and Methods: We conducted an association analysis of 37 single nucleotide polymorphisms (SNPs) in a cohort of 548 Caucasian individuals (267 migraine cases, 281 controls). SNPs were genotyped using a custom Sequenom MassARRAY assay and High Resolution Melt analysis. After quality control including Hardy-Weinberg equilibrium testing and linkage disequilibrium analysis, multiple testing corrections were applied using various methods including Bonferroni, Holm-Bonferroni, SIDAK, and Benjamini-Hochberg procedures.

Results: The missense variant rs62624978 (p.Gly414Val) in the CTC1 gene showed significant association with migraine across all correction methods ($p < 0.05$). Additionally, rs6478241 in ASTN2 demonstrated marginal association, though only remaining significant under false discovery rate correction. The CTC1 variant represents a novel finding in migraine genetics, potentially linking telomere maintenance and vascular integrity to migraine susceptibility.

Conclusion: Our findings identify CTC1 as a novel genetic factor in migraine susceptibility, suggesting a potential role for vascular integrity and telomere maintenance in migraine pathophysiology. This discovery provides new insights into the vascular contributions to migraine and highlights the genetic overlap between migraine and small vessel disease. Further research in larger, diverse populations is needed to validate these findings and explore their functional implications.

C.O.I. Disclosure:

Z. Molaee: None.

P18.124.C Genetic variant in*HMCN2*alters ETS-binding and impacts periodontitis risk

muqing niu[1], *Arne Schaefer*[2]

[1]*charite-university, Berlin, Germany,* [2]*Charite - Universitatsmedizin Berlin, Berlin, Germany.*

Background: Single nucleotide variants (SNVs) in the Hemicentin-2 (HMCN2) gene are associated with increased risk for stage III-IV Grade C periodontitis in young adults ≤35 years of age ($p = 6.1 \times 10^{-8}$). HMCN2, a key component of the collagen-containing extracellular matrix, maintains tissue structural integrity. This study aimed to identify the causal SNV and its biological consequences.

Material and Methods: SNVs were analyzed for transcription factor (TF) binding site alterations using the TF Affinity Prediction Tool (TRAP). Functional effects were assessed via Electrophoretic Mobility Shift Assay(EMSA) and allele-specific reporter gene assays. HMCN2 expression in gingival cells and biopsies was evaluated by qRT-PCR, immunohistochemistry, and immunofluorescence.

Results: SNV rs115281761 resided in a predicted binding site of the TF ETS Proto-Oncogene 2 (ETS2), and its rare G-allele ($MAF = 0.01$) altered the GGAA/T core motif ($P < 0.0001$). ETS2 is specifically expressed in basal epithelial cells and monocytes. EMSA confirmed ETS2 binding at rs115281761 and showed that the G-allele significantly reduced binding affinity. Reporter assays revealed that the region acts as an enhancer (3x induction, $p < 0.001$), with the G-allele reducing activity by 47% compared to the non-effect C-allele. HMCN2 expression was higher in gingival epithelial cells (9.5 fold) than in fibroblasts, with protein mainly localized to the epithelial basal membrane.

Conclusion: SNV rs115281761 in HMCN2 likely contributes to stage III-IV grade C periodontitis by altering ETS2 binding and HMCN2 enhancer activity, compromising gingival tissue integrity. These findings provide mechanistic insights into the genetic basis of severe periodontitis.

P18.126.A Omic study of intermediate phenotypes in colorectal cancer

Carmen Macias Real[1], *Silvia Carlés González*[2], *Ian Tomlinson*[3], *Ceres Fernández Rozadilla*[2]

[1]*Universidad de Santiago de Compostela, Santiago de Compostela, Spain,* [2]*Fundación Pública Galega Instituto de Investigación Sanitaria de Santiago (IDIS), Santiago de Compostela, Spain,* [3]*Department of Oncology, University of Oxford, Oxford, United Kingdom.*

Background: Colorectal cancer (CRC) is a major global health challenge with complex genetic underpinnings. While Genome-Wide Association Studies (GWAS) have identified over 200 loci linked to CRC risk, limited sample sizes leave hereditary factors incompletely understood. Telomere length (TL) provides a framework for exploring molecular phenotypes and disease complexity.

Material and Methods: We conducted a telomere length association study (TL-WAS), using TL as an intermediate molecular phenotype. Blood ($n = 51$) and colonic mucosa ($n = 76$) samples were used to model genetically predicted TL and assess its association with CRC risk. For TL-QTL mapping, telomeres were randomly assigned chromosomal positions, and the genome was divided into 1 Mb bins. TL-QTLs were identified by correlating TL with genetic variants. Using Nested Cross-Validated Elastic-Net, SNPs were assigned weights for TL prediction, and significant models were retained. MetaXcan integrated GWAS data with prediction models to evaluate gene-level associations between predicted gene expression and CRC risk.

Results: Using Nested Cross-Validated Elastic-Net, we identified 4,850 TL-QTLs in colonic mucosa and 4,195 in blood, with each variant assigned a weight reflecting its association with TL. These TL-QTLs were subsequently used in the CRC association study. Our analysis revealed a significant association between TL and CRC risk in both colonic mucosa ($p = 0.0051$) and blood ($p = 0.0181$).

Conclusion: Our study suggests that TL may be a useful biomarker for CRC. We also developed a model adaptable to other omics data. This approach may help identify new risk pathways and biological insights, improving resource allocation in population screening for individuals at higher CRC risk.

P18.127.B Exploring the association between genetic variants and the risk of developing type 2 diabetes in Uzbekistan

Alisher Abdullaev, *Anastasiya Punko, Abdushukur Rakhmatullayev, Zumrad Reyimbergenova, Elena Tsay, Vladimir Tsoy, Dilbar Dalimova, Shahlo Turdikulova*

Center for Advanced Technologies, Tashkent, Uzbekistan.

Background: Type 2 Diabetes (T2D) affects nearly half a billion people worldwide, yet genetic studies largely exclude Central Asian populations. This study investigates T2D-associated genetic variants in Uzbeks, aiming to enhance the understanding of T2D genetics and underscore the importance of including diverse populations in research to improve global disease models and precision medicine.

Material and Methods: This study encompassed 96 patients diagnosed with T2D and 96 healthy individuals of Uzbek ethnicity. Genetic screening was performed using the Global Screening Array v3.0, and statistical analyses were conducted using SNPassoc to examine genotype-disease associations under common genetic models.

Results: Under the additive model, several variants showed significant associations with T2D. Protective effects were found for rs4660329 (*MAST2*, $p = 1.91 \times 10^{-5}$, $OR = 0.40$), rs5909292 (*MAP3K15*, $p = 1 \times 10^{-4}$, $OR = 0.24$), and rs5909301 (*MAP3K15*, $p = 1.6 \times 10^{-4}$, $OR = 0.36$). Conversely, increased T2D risk was associated with rs16872304 (*ZFPM2*, $p = 3.30 \times 10^{-5}$, $OR = 3.56$), rs3859563 (*FUT6*, $p = 2.25 \times 10^{-4}$, $OR = 2.08$), and rs11002834 (*ZMIZ1*, $p = 5.43 \times 10^{-4}$, $OR = 3.43$).

Conclusion: Variants in *MAST2*, *ZFPM2*, *MAP3K15*, and *ZMIZ1* have been associated with T2D in previous studies, as documented in the GWAS catalog, highlighting their potential role in disease susceptibility and warrant further investigation to understand their biological significance.

P18.129.D A generic polygenic score for preeclampsia and tailored models exhibit similarly low discriminatory power

Ariel L. Zimerman[1], *Tzila Reich*[2], *Orit Reish*[1], *Ron Unger*[2]

[1]*Genetic Institute - Shamir Medical Center, Tzriffin, Israel,* [2]*The Mina Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat-Gan, Israel.*

Background: This work developed a new "generic" Polygenic Risk Score for the prediction of preeclampsia based on maternal UK-Biobank (UKB) data following established protocols and compared it to a systematic review of the literature

Material and Methods: Using UKB raw data and following published protocols and public tools (PLINK 1.9, PRSice-2) we produced a Genomic Wide Association Studies (GWAS) and Polygenic Risk Score (PRS) model for PET vs. healthy controls using UKB target and validation cohorts. Following PRISMA 2020 guidelines a literature search was conducted (March 2024). Quality assessment and comparison were conducted using modified Polygenic Risk Score Report Standards 2021 (PRS-RS).

Results: Our model achieved a ROC $AUC = 0.57$, increased OR from 1.2 to 4 for the top 1% compared to 25% quartile. The systematic review included 7 PET-PRS reports using LDpred2, ORS-CS, and machine learning methods. Four of the studies generated GWAS summary data; while the remaining three used published GWAS summaries from hypertension datasets without PET population. Reported PET-PRS ROC-AUC and C-statistics $AUC = 0.62$, 0.64, and 0.649.

Conclusion: Reported PRS methods and endpoints differ significantly precluding meaningful metanalysis. The ROC-AUC reported, including ours, were in the low discriminatory zone. The limited success of all the models regardless PRS methodology, suggests that the maternal genetic component of PET is limited. Future modes may benefit from integrating paternal and fetal genomic data and additional non-genetic factors.

P18.130.A Exploring female analogs of male-pattern hair loss

Sabrina K. Henne[1], *Sheetal Kumar*[2], *Yasmina Gossmann*[2], *Regina C. Betz*[3], ***Stefanie Heilmann-Heimbach***[2]

[1]*Institute of Human Genetics, Bonn, Germany,* [2]*University Hospital Bonn, Bonn, Germany,* [3]*Institute of Human Genetics, University Hospital of Bonn, Bonn, Germany.*

Background: Male-pattern hair loss (MPHL) is a prevalent and male-specific phenotype with a strong genetic basis. Whether an analog exists in females has been debated, with traits such as female-pattern hair loss (FPHL) or polycystic ovary syndrome (PCOS) being theorized. Here, we explore female analogs to MPHL, leveraging a polygenic risk score (PRS) approach and LD score regression (LDSC) to test for associations between MPHL-related genetic risk factors and female-specific traits or medical conditions.

Methods: Using data from the UK Biobank, we constructed MPHL-PRS from 169,105 men and calculated MPHL-PRS for 197,495 women, which we regressed on medical conditions and female-specific traits. LDSC was performed between MPHL and 2,148 phenotypes using public summary statistics from the male and female UK Biobank populations, respectively. Additionally, we conducted LDSC between MPHL and FPHL (based on an unpublished in-house GWAS in Europeans).

Results: The analyses showed no significant associations or genetic correlations after correction for multiple testing. However, some trends were observed ($P < 0.01$), including positive associations with malignant skin neoplasms, hypopituitarism, hypothyroidism, and fewer live births. MPHL further showed genetic correlations with earlier puberty and higher bone mineral density in females, mirroring previous findings in males. No association or genetic correlation with PCOS or FPHL was identified.

Conclusion: Overall, the data suggest no clear female analog to MPHL, though the phenotype may be less pronounced, potentially encompassing both positive and negative health outcomes. Further research is needed to elucidate the relationship between genetic risk factors for MPHL and female-specific health outcomes.

P18.131.B The genetic basis of the immune response to Sars-CoV-2 infection in the Italian municipality of Vo'

Ettore Zapparoli[1], *Enrico Lavezzo*[2], *Hélène Tonnelé*[3], *Fabio Simeoni*[1], *Jing Guo*[4], *Klaudia Walter*[4], *Anna S. Tascini*[5], *Sodbo Sharapov, PHD*[6], *Rebecca Elyanow*[7], *Martina Bado*[2], *Giorgia Mazzotti*[2], *Marco J. Morelli*[1], *Dejan Lazarevic*[5], *Nicola Pirastu*[6], *Nicole Soranzo*[6], *Ilan R. Kirsch*[7], *Andrea Crisanti*[2], *Stefano Toppo*[2], *Paolo Provero*[1], *Giovanni Tonon*[1]

[1]*Center for Omics Sciences, IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*Department of Molecular Medicine, University of Padova, Padova, Italy,* [3]*Department of Neurosciences "Rita Levi Montalcini", University of Turin, Turin, Italy,* [4]*Wellcome Sanger Institute, Wellcome Genome Campus, Hinxton, United Kingdom,* [5]*Università Vita-Salute San Raffaele, Milan, Italy,* [6]*Human Technopole, Milan, Italy,* [7]*Adaptive Biotechnologies, Seattle, WA, USA.*

Background: It is becoming increasingly evident that SARS-CoV-2 infection is here to stay. Therefore, understanding whether genetic variants may impact the response to the virus or vaccination is crucial. Studies on the genetics of the immune response to SARS-CoV-2 have been hampered by the lack of genetically homogenous populations and longitudinal studies, assessing the response to infection and vaccination through the lens of the individual genetic makeup.

Material and Methods: Here we conducted genotyping and whole-genome sequencing of a well-annotated and closely followed population, the municipality of Vo', that has provided crucial insights on SARS-CoV-2 infection and COVID-19 clinical manifestations.

Results: We identified MHC variants associated with altered dynamics of the T cell response to infection. Additionally, when examining the response to vaccination, we identified MHC genetic variants that correlated with either increased or decreased TCR responses. We generated a polygenic risk score able to comprehensively capture these variations. Finally, we modelled some of these variants altering HLA proteins and identified the aminoacids most likely impacting their interactions with SARS-CoV-2 epitopes.

Conclusion: In all, we provide robust indications of genetic profiles modulating the immune response in a longitudinal study that may provide important clues and directions in designing appropriate public health interventions.

P18.132.C Genetic variants in surfactant-related genes and their role in severe COVID-19: insights from an Italian cohort

Alessia Artusi[1,2], *Valeria Rimoldi*[2,3], *Alessio Gerussi*[4,5], *Pietro Invernizzi*[4,5], *Antonio Inforzato*[1,2], *Rosanna Asselta*[1,2]

[1]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy,* [2]*Humanitas Clinical and Research Centre - IRCCS, Rozzano, Italy,* [3]*Department of Biomedial Sciences, Humanitas University, Pieve Emanuele, Italy,* [4]*Division of Gastroenterology and Center for Autoimmune Liver Diseases, Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy,* [5]*Division European Reference Network on Hepatological Diseases (ERN RARE-LIVER), San Gerardo Hospital, Monza, Italy.*

Background: COVID-19 presents variable clinical manifestations, ranging from asymptomatic to life-threatening conditions. The virus binds angiotensin-converting enzyme receptors on alveolar epithelial type-II cells, impairing the production/secretion of pulmonary surfactant. This impairment increases alveolar surface tension, causing collapse, interstitial pneumonia, and acute respiratory distress syndrome. This study investigates the genetic predispositions within surfactant-related genes that could contribute to severe COVID-19.

Material and Methods: We analysed the genetic contribution of 26 surfactant-related genes in 527 Italian patients with severe COVID-19 with respiratory failure and 3,215 controls from the general Italian population. After QC, 8,2 million single-nucleotide polymorphisms (SNPs) were retained for common and rare variant association studies using PLINK v1.9.

Results: A total of 42,869 SNPs spanning 250 kb up- and downstream of the 26 surfactant-related genes were tested for association with COVID-19 severity, adjusting for age/sex/age^2/age*sex and the first 10 principal components of ancestry. We identified 42 suggestive signals ($P < 1e-03$), the top one being at chr17:36955694:T:A in the ACACA gene ($P = 5.1e-05$). We evidenced additional 75 suggestive hits ($P < 1e-03$) using recessive, genotype, and dominant models, with the top hits for each being chr16:2037451:T:TG ($P = 1.02e-05$), chr16:2037451:T:TG ($P = 1.8e-05$), and chr11:73189476:G:A ($P = 1.06e-04$), in ABCA3 (two signals) and P2RY2 genes, respectively. Haplotype analysis of these top three genes confirmed ACACA association, identifying two significant haplotypes ($P = 2.7e-03$), located within the gene

and 15-kb downstream, in a region enriched in distal enhancer-like elements.

Conclusion: The implicated genes regulate cholesterol homeostasis and phosphatidylcholine metabolism, essential for surfactant function. Meta-analysis and RNA/exome sequencing will further clarify their role in severe COVID-19.

P18.133.D New candidate genes for sweet and spicy food liking

Maria Pina Concas[1], *Silvia Camarda*[2], *Francesco Piluso*[2,3], *Harry Stevens*[2,3], *Alessandro Pecori*[1], *Romina Ruberto*[1], *Catherine Anna-Marie Graham*[3,4], *Paolo Gasparini*[1,2,3]

[1]*Institute for Maternal and Child Health, IRCCS "Burlo Garofolo", Trieste, Italy,* [2]*Department of Medicine, Surgery and health Sciences, University of Trieste, Trieste, Italy,* [3]*Lake Lucerne Institute, Vitznau, Switzerland,* [4]*Cereneo Foundation-Center for Interdisciplinary Research, Vitznau, Switzerland.*

Background: Food liking (FL) are one of the main determinants of our diet, and are key to health status. Previous studies have highlighted their moderate/high heritability, but little is known about the genes involved. This study aimed to identify new genes/variants associated with FL and test their association with parameters related to behaviour and health status.

Material and Methods: Approximately 2500 Italian individuals, for whom FL, genetic/genomic data, and health information were available, were included in the study. GWAS were performed on sweet and spicy FL. Regression models were applied to verify the relationship between the most associated SNPs and health parameters.

Results: As regards sweet foods, we found two interesting associations:1) for the liking of milk chocolate, a region in which the most associated SNP ($p < 5 \times 10^{-8}$) is an eQTL for the *LARP1* gene in Nucleus Accumbens, a central driver of reward response controlling the pleasantness and gratification given by food. This SNP was interestingly associated also with impulsivity ($p < 0.05$).2) For the liking of a group of sweet foods, the *RGS9* gene, that we also found associated with reward dependence and BMI ($p < 0.05$). Regarding spicy foods, we identified an association ($p < 1 \times 10^{-7}$) near the *DOCK3* gene that is expressed in the central nervous system. The most associated SNP is an eQTL for *CACNA2D2*, a gene already associated with FL and caffeine/coffee consumption.

Conclusion: These findings represent an important starting point for identify the genes involved in FL. Further research is needed to better elucidate their role on FL and health status.

P19 Genetic Epidemiology and Mendelian Randomisation

P19.001.B Mosaic loss of chromosome Y is a risk factor for coronary atherosclerosis in men: data from the SCAPIS study

Josefin Bjurling[1], *Jonatan Halvardson*[1], *Lars Forsberg*[1,2]

[1]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,* [2]*The Beijer Laboratory, Uppsala University, Uppsala, Sweden.*

Background: Atherosclerosis is the most common form of cardiovascular disease and the primary cause of myocardial infarction and stroke. Men have an increased risk of atherosclerosis, which can only partly be explained by cardiovascular and environmental risk factors. We hypothesize that mosaic loss of chromosome Y (mLOY), a male-specific chromosomal aberration, contributes to the male predominance. mLOY has previously been associated with adverse cardiovascular events, but no association with atherosclerosis is reported.

Material and Methods: The Swedish CArdioPulmonary bioImage Study (SCAPIS) is a population-based cohort studying cardiovascular and pulmonary disease. Atherosclerosis imaging information and genotyping data are available for the 30,000 participants aged between 50–64 years. Genotyping data was used to estimate mLOY in the male participants using the MoChA pipeline. Multivariable logistic regression analyses were performed to assess if mLOY in blood is associated with atherosclerosis, measured by coronary computed tomography (CCTA) and carotid ultrasound.

Results: We observed an association between having >10% mLOY in blood and presence of any coronary atherosclerosis (OR = 1.42, 95% CI = 1.04–1.97, p-value = 0.0318) and substantial coronary stenosis (OR = 1.53, 95% CI = 1.03–2.21, p-value = 0.0288), measured by CCTA. No association was detected with occurrence of carotid plaques. We further show that men with >10% mLOY exhibit an increased accumulation of calcified plaques (coronary artery calcium score >= 100, OR = 1.43, 95% CI = 1.05–1.93, p-value = 0.0195), indicating a higher risk of future cardiovascular events in this group.

Conclusion: This novel correlation between mLOY and coronary atherosclerosis could explain the overrepresentation of atherosclerosis in men, plausibly driving the known association between mLOY and major cardiovascular events.

P19.002.C Integrative polygenic score and single cell transcriptomic analysis reveals differed features among healthy individuals

Q. Wang, *X. Dang, W. Yang;*

University of Hong Kong, Hong Kong, Hong Kong

Background: Polygenic scores (PGS) have been widely used for estimating individual risk to a complex trait by assessing the combined effects of multiple genetic variants identified through GWAS. We hypothesize that healthy individuals with a high PGS for a complex disease are likely to display distinct molecular signatures indicative of their predisposition to disease risk.

Material and Methods: We utilized data from the OneK1K cohort, which includes genotype and single-cell RNA-seq data of peripheral blood mononuclear cells (PBMC) from nearly 1000 individuals. Polygenic risk scores (PGS) were computed for each individual across 10 complex traits including monocyte count, leukemia, and autoimmune conditions. Individuals in the top and bottom 5th percentile of PGS for each trait were selected for comparison at the single-cell level, focusing on the cellular composition, differential gene expression, and functional pathways.

Results: Our results reveal that B cells in healthy individuals at high risk of lymphoid leukemia display heightened activity influenced by BAFF activity, whereas individuals predisposed to autoimmune diseases exhibit dysregulated genes associated with immune regulation. The presence of overlapping dysregulated

genes in individuals at high risk of systemic lupus erythematosus (SLE) and those diagnosed with SLE lends support to the notion that susceptible individuals exhibit traits related to the disease.

Conclusion: Our study integrates PGS analysis with scRNA-seq to identify characteristics in healthy individuals with high polygenic scores. Exploring the functions of these dysregulated genes in high-risk individuals may reveal key factors influencing disease susceptibility, enhancing our understanding of disease initiation and development

P19.003.D Unravelling Diabetic Cardiomyopathy through genetic and epigenetic profiling

*Cecilia Di Primio[1], Khadija Sana Hafeez[1], Rebecca Filomena[1], Miriam Rosselli[1], Elisabetta Casalone[1], Carla Debernardi, phd Student[2], Alessia Russo[1], Alessandra Allione[1], Étienne Audureau[3,4], Flora Sam[5,6], Geneviève Derumeaux[3,7], **Giuseppe Matullo**[1,8], the CARDIATEAM Consortium[9]*

[1]University of Turin, Unit of Genomic Variability and Complex Diseases, Department of Medical Sciences, Turin, Italy, [2]University of Turin, Unit of Genomic Variability and Complex Diseases, Department of Medical Sciences, Torino, Italy, [3]Université Paris-Est Créteil, INSERM, IMRB, FHU Senec, Créteil, France, [4]Henri Mondor Hospital, Assistance Publique Hôpitaux de Paris, Biostatistics Department, Créteil, France, [5]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN, USA, [6]Boston University Chobanian & Avedisian School of Medicine, Whitaker Cardiovascular Institute, Boston, MA, USA, [7]Henri Mondor Hospital, Assistance Publique Hôpitaux de Paris, Département de Physiologie-Explorations Fonctionnelles, Créteil, France, [8]AOU Città della Salute e della Scienza, Medical Genetics Unit, Turin, Italy, [9]

Background: Diabetic Cardiomyopathy (DC) develops in a subset of Type-2-Diabetes (T2DM) patients characterized by cardiac dysfunction independent of ischemic diseases or hypertension. The underlying causes of DC remain unknown. This study, as part of the CARDIATEAM Consortium, aims to dissect the genetic and epigenetic landscape of DC, employing Polygenic Risk Scores (PRS) and Methylation Risk Scores (MRS) for enhanced risk stratification.

Material and Methods: We analyzed 173 deeply clinically phenotyped participants from a discovery cohort, grouped into two subsets defined by the severity of T2DM related cardiac dysfunction, with a prevalence of T2D among more severe individuals. PRS was calculated after genotype imputation with effect sizes from a T2DM Polygenic Score (PGS) [PGS001357]; MRS employed effect sizes from 145 CpGs identified in the Generation Scotland Study as strongly associated with T2DM. We evaluated four logistic regression models incorporating PRS, MRS, their combination and interaction.

Results: Both T2DM-based PRS and MRS had significantly different distribution between the groups (p-value 0.02 and 1.29e-05, respectively) with significant ORs at percentiles ≥80th and ≥90th (2.23 and 2.82 for PRS, 4.52 and 3.49 for MRS, respectively). Selecting the individuals with the highest PRS and MRS values, we obtained a significantly higher OR (6.48) for ≥80th. The combined model demonstrated the best discriminative ability (AUC = 0.753).

Conclusion: This study highlights the interplay between genetic and epigenetic factors in DC, being able to identify individuals at high risk to develop severe T2DM related cardiac dysfunctions and paving the way for improved screening and personalized management strategies.

P19.004.A Discovery of new loci associated with albuminuria using a multi-ancestry GWAS meta-analysis

*Sahar Ghasemi[1], Eva König[2], Iris M. Heid[3], Cristian Pattaro[2], Anna Köttgen[1], Matthias Wuttke[1], **Alexander Teumer**[4,5], on behalf of the CKDGen Consortium[6]*

[1]Institute of Genetic Epidemiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg im Breisgau, Germany, [2]Institute for Biomedicine, Eurac Research, Bolzano, Italy, [3]Department of Genetic Epidemiology, University of Regensburg, Regensburg, Germany, [4]University Medicine Greifswald, Department of Psychiatry and Psychotherapy, Greifswald, Germany, [5]DZHK (German Centre for Cardiovascular Research), Partner Site Greifswald, Greifswald, Germany, [6]

Background: Understanding albuminuria, a key marker of chronic kidney disease, requires identifying genetic variants and genes affecting urinary albumin-to-creatinine ratio (UACR) through genome-wide association studies (GWAS). Multi-lateral collaborations and rigorous, centralized data quality control (QC) are essential for reliable results.

Material and Methods: We utilized our newly developed "metaGWASmanager" package for streamlined QC workflow. Studies performed genotype imputation using state-of-the-art reference panels such as TOPMed, including low-frequency variants. Standardized scripts were distributed to all studies for conducting phenotype harmonization and GWAS. Ancestries were validated by principal component analysis on allele frequencies. A newly developed hierarchical fixed-effects meta-analysis workflow was performed with METAL to identify global and ancestry-specific loci.

Results: We aggregated 75 GWAS on UACR encompassing 816,577 individuals across six ancestries: 61% European (EUR), 15% East Asian (EAS), 14% African (AFR), 5% Admixed American (AMR), 4% South Asian (SAS), and 1% Middle Eastern (MID). Overall, we identified 108 associated loci of which 49 are novel compared to our previous CKDGen Consortium meta-analysis. Additional MR-MEGA analysis confirmed the homogeneity of the known locus at *CUBN* (rs45551835, p_assoc = 1.9e-170, p_ancestryhet = 0.53). Ancestry-specific meta-analyses identified 91 loci in EUR, 13 in EAS, and 3 in AFR, with 10, 1, and 1 being unique to these ancestries, respectively.

Conclusion: By incorporating participants from diverse ancestries, we address the limitations of prior studies focused primarily on European ancestry. Results expand the understanding of the genetic underpinnings of albuminuria. The identified loci represent promising targets for further functional follow-up studies and potential therapeutic targets for kidney disease.

P19.005.B Reducing Selection Bias in Biobanks: Improve Generalizability of Inverse Probability Weights by Accounting for Population Prevalences of Diseases

Ciarrah-Jane Shannon Barry[1,2], *Gibran Hemani[2], Bjarni J. Vilhjálmsson[1]*

[1]Aarhus University, Aarhus, Denmark, [2]University of Bristol, Bristol, United Kingdom.

Background: A recognised limitation within epidemiological studies is the non-representative nature of the sample due to selective participation. However, collecting detailed population phenotypic and genetic data is often impractical. To ensure validity in downstream analyses, it is important to employ methods that adjust for selection bias, ensuring the sample accurately reflects the broader population. Within recent literature Schoeler et al.(Nat Hum Behav 2023), use inverse probability weights (IPW) to correct for this participation bias, however their approach may not be suitable for health outcomes affecting probability of participation, e.g., psychiatric disorders and severe health outcomes.

Methods: Extending the least absolute shrinkage and selection operator (LASSO) model used by Scholer et al., we propose an additional regularization term that accounts for nationally reported population disease prevalence. We will perform downstream analyses, such as genome-wide association studies and Mendelian randomization, after correcting for selection bias through this adjusted reweighting in the Danish iPSYCH sample and UK Biobank to demonstrate differences in estimates.

Results: In simulations the IPW with an additional LASSO regularization term demonstrated a marked reduction in population-sample differences of disease prevalence, relative to the unadjusted LASSO approach. Applied analyses to demonstrate the impact of this sample correction in downstream analyses, such as genome-wide association studies and Mendelian randomization, are ongoing.

Conclusion: Our simulated results demonstrate that it is possible to reduce selection bias within large scale biobanks for both common and rare traits. Mitigation of discrepancy between sample and population distributions will improve the validity and generalisability of estimates in health and disease research.

P19.006.C Causal relationships between gut microbiome and age-related traits

Federica Grosso, *Daniela Zanetti, PhD, Serena Sanna*

Consiglio Nazionale delle Ricerche, Cagliari, Italy.

Background: In the past 20 years, the involvement of gut microbiome in human health has received particular attention, but its contribution to age-related diseases remains unclear.

Material and Methods: We performed a comprehensive investigation of 4,033 potential causal relationships between 37 traits representing gut microbiome composition and function and 109 age-related phenotypes, through the causal inference method two-sample Mendelian randomization (MR). We used inverse variance weighted (IVW), as main method to assess significance and weighted median and MR-PRESSO methods as sensitivity analyses. For IVW we employed a false discovery rate (FDR) correction to control for multiple testing within each outcome. Pleiotropy (egger intercept), heterogeneity (Cochran's Q statistics), leave-one-out and reverse MR were considered as sensitivity analyses. Finally, we performed replication with independent datasets to ensure strength of results, along with a post-hoc power analysis.

Results: Five causal relationships remained significant after multiple testing correction and sensitivity analysis, specifically between two taxa of *Coriobacteriales* and the risk of developing age-related macular degeneration ($p_{FDR} = 0.047$), species *Bifidobacterium adolescentis* and levels of TNFSF12 protein in plasma ($p_{FDR} = 0.0003$), and the lactose-galactose degradation microbial I pathway and levels of IL-15Rα ($p_{FDR} = 0.03$) and TRAIL ($p_{FDR} = 0.006$) proteins in plasma. The causal relationship between the microbial pathway and TRAIL protein levels was further confirmed using independent data ($p = 0.01$).

Conclusion: These results support the role of gut microbiome in regulating the inflammatory circuit and the importance of rigorous methodologies and replication to establish causality in MR studies. However, future studies are needed to investigate the underlying biological mechanisms.

P19.007.D Exploring causal mechanisms of sex dimorphism in lipid metabolism using the UK Biobank Pharma proteomics data

Daniela Zanetti[1], *Mine Koprulu*[2], *Daria V. Zhernakova*[1,3], *Federica Grosso*[1], *Fabio Busonero*[1], *Andrea Maschio*[1], *Francesca Crobu*[1], *Claudia Langenberg*[2,4,5], *Serena Sanna*[1,3]

[1]*Institute of Genetic and Biomedical Research (IRGB), National Research Council (CNR), Cagliari, Italy,* [2]*MRC Epidemiology Unit, University of Cambridge School of Clinical Medicine, Institute of Metabolic Science, Cambridge, United Kingdom,* [3]*University of Groningen, University Medical Center Groningen, Department of Genetics, Groningen, Netherlands,* [4]*Computational Medicine, Berlin Institute of Health at Charité-Universitätsmedizin Berlin, Berlin, Germany,* [5]*Precision Healthcare University Research Institute, Queen Mary University of London, London, United Kingdom.*

Background: Lipid traits are known to be sex-dimorphic, but the underlying sex-specific molecular players are largely unknown. Since protein levels are downstream products of gene expression, proteomics data can be crucial to understand sex-differences in lipids metabolism.

Material and Methods: We used sex-specific pQTL summary statistics for 1,462 circulating proteins measured in the UK Biobank Pharma Proteomics Project (UKB-PPP), and sex-specific summary statistics of high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C) and triglycerides (TG) from the Global Lipids Genetics Consortium. We performed additional analyses in the Lifelines cohort. A total of 1,366 and 1,389 proteins in men and women respectively had genome-wide significant hits and thus were selected as exposures for two-sample Mendelian Randomization (MR) analyses. MR was carried using two strategies: both cis- and trans-acting variants, and cis- only variants.

Results: A total of 51 and 28 proteins showed significant causal effects exclusively in women and men, respectively (p value after false discovery rate correction). The Cochran's Q test based on betas detected a total of 20 proteins showing significant sex-different causal effects, specifically 12 in the cis-trans analysis and 15 in the cis-only analysis. Out of these, 8 showed significant effect in the reverse MR and thus were considered inconclusive. Finally, using the Lifelines cohort we rule out the possibility that those results were driven by individuals under lipid-lowering drug therapy.

Conclusions: These results highlight the need to perform sex-stratified pQTL mapping and provide insight into potential genetic drivers of sex dimorphism in lipid metabolism.

P19.008.A Genome-wide association study meta-analysis reveals novel loci associated with polyps of the female genital tract

Nathan Ingold[1], *Stephanie Frankcome*[2], *Emily Moro*[3], *Jelisaveta Džigurski*[4], *Triin Laisk*[4], *Tracy O'Mara*[1]

[1]QIMR Berghofer, Brisbane, Australia, [2]Australian Catholic University, North Sydney, Australia, [3]Queensland University of Technology, Brisbane, Australia, [4]Institute of Genomics, University of Tartu, Tartu, Estonia.

Background: Female genital tract (FGT) polyps are benign overgrowths affecting women of all ages. While often linked to abnormal uterine bleeding, up to 82% are asymptomatic, leading to underdiagnosis. Estimated to be present in up to 50% of women, about 2.7% become malignant. Genetic drivers of FGT polyps and their genetic links to reproductive cancers remain understudied.

Material and Methods: We meta-analysed genome-wide association studies (GWAS) of FGT polyps from the UK Biobank, FinnGen, Estonian Biobank, and the Michigan Genomics Initiative (44,227 cases, 473,321 controls) and performed a transcriptome-wide association analysis (TWAS) to identify genes at significant GWAS loci. Mendelian randomisation (MR), and both global (LDSC) and local (LAVA) genetic correlation analyses were used to assess the genetic interplay between FGT polyps and a range of gynecological disorders.

Results: GWAS meta-analysis identified 25 FGT polyp risk loci, including a strong signal near *EEFSEC* (3q21.3), a region implicated in endometrial cancer and endometriosis risk. TWAS results highlighted 104 genes across multiple tissues, including *EEFSEC*. LDSC and LAVA revealed strong significant genetic correlations between all gynecological disorders, while MR revealed causal pathways between FGT polyps, endometrial cancer and uterine fibroids.

Conclusion: We reveal shared genetic relationships between FGT polyps and gynaecological diseases, and highlight *EEFSEC*'s potential role in conditions affecting the endometrium. Future aims include replicating findings and investigating the identified gene roles in polyp formation within endometrial cell lines.

P19.009.B Optimization of Multi-Ancestry Polygenic Risk Score Disease Prediction Models

Jon Lerga-Jaso[1], Andrew Terpolovsky[1], Biljana Novković[1], Alex Osama[1], Charlie Manson[1], Sandra Bohn[1], Adriano De Marino[1], Mark Kunitomi[2], ***Puya G. Yazdi***[1]

[1]Omics Edge, Miami, FL, USA, [2]Almaden Genomics, San Francisco, CA, USA.

Polygenic risk scores (PRS) have ushered in a new era in genetic epidemiology. However, PRS-based models still need to overcome several hurdles before they can be broadly applied in the clinic. Chiefly, they need to achieve sufficient accuracy, easy interpretability and portability across diverse populations. Leveraging trans-ancestry genome-wide association study (GWAS) meta-analysis, we generated novel, diverse summary statistics for 30 medically-related traits. We benchmarked the performance of six existing PRS algorithms using UK Biobank and built an ensemble model using logistic regression, which was validated on the diverse eMERGE and PAGE MEC cohorts. Our ensemble model surpassed current state-of-the-art PRS models, with minimal performance drops in external cohorts, indicating good calibration. Our PRS model for coronary artery disease identified 55–80 times more true coronary events than rare pathogenic variant models, reinforcing its clinical potential. Notably, the polygenic component modulated the effect of high-risk rare variants, stressing the need to consider all genetic components in clinical settings. To enhance predictive accuracy, we incorporated easily-accessible clinical characteristics creating disease prediction models intended as prospective diagnostic tests, with easily interpretable positive or negative outcomes. After adding clinical characteristics, 12 out of 30 models surpassed 80% AUC. Further, 25 traits exceeded the diagnostic odds ratio (DOR) of 5 and 19 traits exceeded DOR of 10 for all ancestry groups, indicating high predictive value. These findings show that newly developed PRS-based disease prediction models have sufficient accuracy and portability to warrant consideration of being used in the clinic.

P19.011.D Investigating maternal and perinatal causes of breastfeeding outcomes through Mendelian randomization

Maeregu Woldeyes Arisido[1], *Carolina Borges[2], Nancy McBride[2], Maria Christine Magnus[3], Luisa Zuccolo[1,2]*

[1]Health Data Science Centre, Human Technopole, Milan, Italy, [2]MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom, [3]Norwegian research institute, Oslo, Norway.

Background: Breastfeeding is a critical biological function providing essential health benefits to both mothers and offspring. Yet, in high-income countries many women stop breastfeeding shortly after birth and 44% never breastfeed exclusively. Genetic and modifiable risk factors likely contribute to this complex trait. We aimed to provide robust evidence about the causal role of maternal (socio-demographic, psychological, cardiometabolic) and perinatal factors on breastfeeding.

Material and Methods: We used individual-level data from 3 European cohorts (MoBa N = 60000, ALSPAC N = 7000, UKBB N = 4000) to conduct novel GWAS of breastfeeding traits including exclusive/initiation/establishment/duration, and meta-analyzed association results using fixed-effect inverse variance weighted approach. We performed two-sample Mendelian randomization (MR) to determine the causal effects of maternal and perinatal factors on breastfeeding outcomes. Genetic instrumental variables were extracted from publicly available GWAS. We compared MR results with those from confounder-adjusted multivariable regression (MVA) and ran extensive sensitivity analyses.

Results: MR results showed that higher maternal education causally increased the odds of initiating and sustaining breastfeeding, while smoking, obesity, high cholesterol and sleep disorder were detrimental. Specifically, a 1 kg/m^2 BMI increase corresponded to 20% lower odds of initiating breastfeeding and reduced the duration of exclusive breastfeeding by 0.5 weeks. Smoking and the diagnosis of sleep disorders reduced the odds of breastfeeding initiation by 57% and 43%, respectively. These causal associations were robust in sensitivity analyses including bias due to genetic pleiotropy and replication in MVA.

Conclusion: We provide causal evidence on maternal cardiometabolic liabilities and psychological stressors for suboptimal breastfeeding, identifying intervention targets to improve mother-offspring well-being.

P19.012.A Integrating single-cell and population-scale data to explore immune cell type variation and disease associations

Daniela Zanotti[1,2], *Alessandro Raveane*[1], *Arianna Landini*[1], *Matiss Ozols*[3], *Stephen Watt*[3], *Shuang Li*[3,4], *Olli Dufva*[3], *Cardinal Project Working Group*[5], *Francesca Ieva*[1,2], *Sarah A. Teichmann*[3,6], *Oliver Stegle*[7,8], *Nicola Pirastu*[1], *Nicole Soranzo*[1,3,4]

[1]*Human Technopole, Milano, Italy,* [2]*Politecnico di Milano, Milano, Italy,* [3]*Wellcome Sanger Institute, Hinxton, United Kingdom,* [4]*University of Cambridge, Cambridge, United Kingdom,* [56]*Cambridge Stem Cell Institute, Cambridge, United Kingdom,* [7]*German Cancer Research Centre (DKFZ), Heidelberg, Germany,* [8]*European Molecular Biology Laboratory (EMBL), Heidelberg, Germany.*

The immune system is dynamic, shaped by genetic and environmental factors. Variability in immune cell composition measured from clinical full blood counts has been linked to disease predisposition. Single-cell RNA sequencing (scRNA-seq) enhances resolution by identifying cell states. Integrating genomic data, scRNA-seq, and electronic health records informs how genetic variation and environmental factors influence cell abundance and disease risk.

We examined relationships between genetic variation, cell compositional traits, and 339 diseases using data from the CARDINAL study: 3,597 individuals from UKBiobank, 895 of Pakistani and Bangladeshi origin from Genes & Health. To overcome scRNA-seq compositional constraints, we derived absolute cell counts by interpolating proportions of 26 cell types with Sysmex full blood counts. We fitted linear models testing associations between absolute counts and disease diagnoses accrued over a 30+ year follow-up period. Then, we performed a Genome-Wide Association Study (GWAS) to identify genetic variants driving cell count differences.

Age and smoking were significantly associated with defined monocyte, T, and B cell populations. We identified 39 disease-cell-type associations, including CD14+ monocytes and naive B cells linked to obesity and type 2 diabetes. GWAS revealed 19 significant loci, some previously associated with cell type ratios, like rs3826007, linked to CD14+/CD16+ monocyte ratio. Our analysis showed that CD16+ counts drive the signal, while decreased CD14+ reflects compositional effects.

We show that population-scale single-cell studies reveal how age, lifestyle, disease, and genetics shape the immune system. The identified variants will help uncover potential causal roles of cell type abundance in disease, informing therapeutic development.

P19.013.B Modifiable Risk Factors for Alzheimer's Disease: a Mendelian Randomization perspective

Leona Knüsel[1], *Isabelle Francesca Foote*[2,3,4], *Zoltán Kutalik*[1,5]

[1]*University of Lausanne, Lausanne, Switzerland,* [2]*University of Colorado Boulder, Boulder, CO, USA,* [3]*Queen Mary University of London, London, United Kingdom,* [4]*Barts Health NHS Trust, London, United Kingdom,* [5]*University Center for Primary Care and Public Health, Unisante, Lausanne, Switzerland.*

Background: Despite extensive efforts, modifiable risk factors for Alzheimer's disease (AD) are still poorly understood. The long prodromal phase of AD, the presence of confounders, competing risk factors, and the risk of reverse causation make the detection of causal risk factors particularly challenging. To address these challenges, we used Mendelian Randomization to investigate the role of modifiable risk factors in AD.

Methods: We considered 30 genetically instrumentable risk factors as exposures. We used the AD GWAS from the IGAP consortium as the primary outcome, which ensured thorough classification and age-matching of cases and controls. Using this data, we performed extensive bidirectional univariable and multivariable Mendelian Randomization (MR) analyses.

Results: Whilst we could validate the well-known protective effect of intelligence and the risk-increasing role of LDL cholesterol, the effect of other risk factors did not align with the previous literature. Namely, we found evidence that a higher BMI reduces the risk for AD, mediated by lean mass. Furthermore, higher systolic blood pressure (SBP) robustly reduced the risk for AD. This effect was neither driven by competing risk factors nor by reverse causation, but we could replicate the risk-increasing effect of higher SBP on traits related to vascular dementia (VaD).

Conclusion: Beyond well-established risk factors for AD (such as intelligence and LDL cholesterol), we also found that higher SBP and higher lean mass had a robust protective effect on AD. Our findings demonstrate the importance of carefully assessing distinct components of exposures to understand how they relate to different forms of dementia.

P19.014.C Proteomic insights into the impact of exogenous hormones on breast cancer: A two-stage observational and Mendelian randomization study

Tayebeh Azimi, *Fatemeh Hadizadeh, Pascal Mutie, Torgny Karlsson, Åsa Johansson*

Uppsala University, Uppsala, Sweden.

Background: Breast cancer is the most common cancer among women worldwide. While exogenous hormones are known to increase the breast cancer risk, the underlying mechanisms remain unclear. This study aimed to identify proteins that mediate the effect of exogenous hormones on the risk of developing breast cancer.

Material and Methods: In a two-stage study, we first estimated the association with the current users of hormonal contraceptives (HC) in 5,242 premenopausal women and menopausal hormone therapy (MHT) in 16,500 postmenopausal women on the level of 2,923 plasma proteins in the UK Biobank. HCs and MHTs were categorized by hormonal content and route of administration. Second, we performed two-sample Mendelian randomization analyses to identify proteins causally associated with breast cancer.

Results: After multiple test correction, we identified seven proteins that were significantly associated both with use of any of the medications and causally linked to breast cancer development. These proteins, including ENG, EphA4, ICAM5, PTPRM, OMgp, PTPRK, and CST6, were considered potential mediators of the effect of exogenous hormones on breast cancer, with all of them having functions highly relevant to breast cancer development.

Conclusion: Our results suggest that the effect of exogenous hormones on breast cancer is partly mediated through different proteins. The results agree with that the estrogen component and predominantly oral medications have the greatest effect on protein levels. Identifying these proteins and their effects could potentially reveal new intervention targets for mitigating the effects of HC and MHT on breast cancer risk.

P19.015.D Blood pressure as a mediator of the potential causal effect of circulating plasma proteins on coronary artery disease and stroke: A Mendelian randomisation and observational study

*Devendra Meena[1], **Jingxian Huang**[1], Alexander G Smith[1], James Costantini and Mr James Yarmolinsky[1], Siwei Wu[1], Fotios Koskeridis[1], Marie-Joe Dib[2], Charalabos Antonatos[3], Xinzhu Yu[1], Georg W Otto[1], Yianni Vasilopoulos[4], Dipender Gill[1], Manuel Mayr[5], Paul Elliott[1], Abbas Dehghan[1], Ioanna Tzoulaki[1]*

[1]Department of Epidemiology and Biostatistics, Imperial College London, London, United Kingdom, [2]University of Pennsylvania, Philadelphia, PA, USA, [3]University of Patras, Rion, Greece, [4]University of Patras, Patras, Greece, [5]National Heart and Lung Institute, Imperial College London, London, United Kingdom.

Background: The biological pathways leading to elevated blood pressure (BP) and subsequent cardiovascular diseases (CVDs) remain incompletely understood. This study employed comprehensive proteome-wide Mendelian randomisation (PWMR) and observational analyses to investigate the shared proteomic landscape between BP, coronary artery disease (CAD), and stroke.

Material and Methods: A two-sample PWMR (cis-MR) study was conducted to assess the potential causal associations of 2,007 plasma proteins on BP and CVD, leveraging the largest available genome-wide association studies. The inverse-variance weighted method, or Wald ratio, was used as the primary method, complemented by robust MR approaches and Bayesian colocalization to mitigate confounding due to linkage disequilibrium. Network MR evaluated BP's mediating role in the effects of plasma proteins on CVD. Findings were further validated using the UK Biobank through comparative analysis and Cox proportional hazards models.

Results: PWMR and Bayesian colocalization analysis prioritized 13 plasma proteins potentially causally linked with BP (false discovery rate < 0.05; colocalization probability > 70%), with five proteins (ACOX1, BRAP, FGF5, FURIN, MST1) also associated with CAD and/or stroke risk. These associations were successfully replicated in the International Consortium for Blood Pressure (p-value < 0.05). Network MR revealed that BP mediated 30.4%–77.2% of the proteins' effects on CVD. These findings were supported by observational analyses, and downstream analyses showed no evidence of adverse effects from perturbing these proteins on other outcomes evaluated.

Conclusion: This study highlighted key proteomic features common to BP, CAD, and stroke, with BP potentially playing a major mediating role in their effects on CVD outcomes.

P19.016.A Implementation of precision genomics in healthcare - NGS analysis workflow streamline

***Sanja Mehandziska**, Marija Gjorgjievska, Djansel Bukovec, Ivan Kungulovski, Zan Mitrev, Goran Kungulovski*

Zan Mitrev Clinic, Skopje, North Macedonia, The Republic of.

Background: Personalized medicine tailors medical care using genetic, lifestyle, and environmental data. Advances in next-generation sequencing (NGS), including whole genome sequencing (WGS) and clinical/whole exome sequencing (CES/WES), enable genomics to transform healthcare by improving disease prevention. However, its adoption in clinical practice is hindered by the need for standardized, practical workflows.

Material and Methods: This study introduces a pipeline for variant filtering and interpretation using CES, WES, or WGS in 109 patients. The study categorized high-confidence variants into groups such as carrier status, cardiovascular disorders, hereditary cancer, and pharmacogenetics. Variants were prioritized using ACMG pathogenicity criteria and computational tools. Additional approach targeted variants of uncertain significance (VUS), prioritizing non-sense and frameshift variants in critical regions for future evaluation, ensuring clinically actionable insights. Polygenic scores for coronary heart disease, type 2 diabetes were also calculated and reported.

Results: The vast majority of patients >95% carried pathogenic variants for rare diseases, with a median of four variants. Pharmacogenetic analysis revealed poor and intermediate metabolizers in relevant pharmacogenes in 1/3 of patients, influencing drug efficacy. Actionable variants linked to arrhythmias, hereditary cancer, thrombotic risks, as well as high polygenic risk scores were identified, prompting specialist evaluations. VUS findings in genes associated with conditions such as thoracic aortic aneurysm and Lynch syndrome, required ongoing monitoring.

Conclusion: This workflow demonstrates the value of genomic profiling in clinical practice by providing actionable insights while addressing challenges like standardization and cost-effectiveness. This pipeline establishes a foundation for precision genomics in mainstream medicine.

P19.018.C Financial stress and sleep duration in immune and neuroendocrine patterning. An analytical triangulation in ELSA

***O. S. Hamilton**, A. Steptoe;*

University College London, London, United Kingdom

Background. Proinflammatory and neuroendocrine mediators are implicated in disease aetiopathogenesis. Stress increases concentrations of immune-neuroendocrine biomarkers through a complex network of brain-body pathways. Suboptimal sleep further modulates these processes by altering major effector systems that sensitise the brain to stress. Given the ubiquitous, impactful nature

of material deprivation, we tested for a synergistic association of financial stress and suboptimal sleep with these molecular processes.

Material and Methods: With data drawn from the English Longitudinal Study of Ageing (ELSA), associations were tested on 4,940 participants (~66 ± 9.4 years) across four-years (2008–2012). Through analytical triangulation, we tested whether financial stress (>60% insufficient resources) and suboptimal sleep durations (≤5/≥9 hours) were independently and interactively associated with immune-neuroendocrine profiles, derived from a latent profile analysis (LPA) of C-reactive protein, fibrinogen, leukocytes, cortisol, and insulin-like growth factor-1.

Results: A three-class LPA model offered the greatest parsimony. After adjustment for genetic predisposition, sociodemographics, lifestyle, and health, financial stress was associated with short-sleep cross-sectionally (RRR = 1.45; 95%CI = 1.18–1.79; $p < 0.001$) and longitudinally (RRR = 1.31; 95%CI = 1.02–1.68; $p = 0.035$), and it increased risk of belonging to the *high-risk* inflammatory profile by 42% (95%CI = 1.12–1.80; $p = 0.004$). Suboptimal sleep was not related to future risk of *high-risk* profile membership, nor did it moderate stress-biomarker profile associations.

Conclusion: Results advance knowledge by revealing how inflammation and neuroendocrine markers cluster in older cohorts and respond to financial stress over time. Financial stress associations with short-sleep are supported. The null role of suboptimal sleep, as exposure and mediator, in profile membership, provides valuable insight into the dynamic role of sleep in immune-neuroendocrine processes.

P19.019.D Evaluating the effects of genetically proxied metformin`s HbA1c lowering effects on aortic stenosis and coronary artery disease: A Mendelian randomisation study

Yamam Sbeih, *Christopher P. Nelson, Lana Stoma*

University of Leicester, Leicester, United Kingdom.

Background: Aortic stenosis (AS) and coronary artery disease (CAD) frequently co-occur, contributing to a significant cardiovascular burden. While metformin, a widely prescribed oral antihyperglycaemic agent, has demonstrated potential protective effects on CAD, its impact on AS remains unexplored. In this work we aimed to investigate the causal effects of metformin on AS and CAD incidence in the general population.

Material and Methods: We conducted a two-sample Mendelian randomisation (MR) study using genetic instruments associated with gene expression of known metformin targets (including AMPK, MC-1, MG-3, GDF-15, GLP-1/GCC, FBP-1, and ADCY1) and decreased HbA1c. Effect sizes were obtained from UK Biobank for HbA1c, a GWAS for AS (14,819 cases and 927,044 controls), and a CAD GWAS (34,541 cases and 261,984 controls) all from European ancestry. The random-effects inverse variance weighted (IVW) method was used for the primary analysis and each of MR-Egger, simple-median, simple-mode, weighted-median and weighted-mode were applied for the sensitivity analysis. An observational analysis was also performed within UK Biobank.

Results: Our MR analysis showed a protective effect of genetically proxied HbA1c lowering effects of metformin targets against CAD (OR = 0.60, 95% CI: 0.42–0.85) but not AS (OR = 0.92, 95% CI: 0.48–1.76). These findings were consistent across various sensitivity analyses, confirming the robustness of the results. The observational analysis yielded consistent results for AS but not for CAD.

Conclusion: While metformin demonstrates a protective role in CAD warranting further investigation, its efficacy for AS appears to be limited and hence can be deprioritised for AS treatment.

P19.020.A PolyGenie: Deciphering Genetic Liability Across Diseases in the GCAT Cohort

Xavier Farré Ramon, *Mireia Gasco, Susana Iraola-Guzmán, Francisco Fernández, Natàlia Blay, Rafael de Cid*

Germans Trias I Pujol Research Institute (IGTP), Badalona, Spain.

Background: Pleiotropy, where a single genetic variant influences multiple traits, is pervasive in the human genome. The finite number of segregating sites and the increasing number of Genome-Wide Association Studies (GWAS) underscores the significance of pleiotropy in understanding non-communicable diseases and the interplay between genetic and environmental factors affecting disease risk. Leveraging the GCAT cohort, we developed PolyGenie, a web-based tool for exploring polygenic risk score (PRS) associations across diseases and traits.

Material and Methods: We calculated approximately 100 PRSs for a deeply phenotyped cohort of 20,000 volunteers from Catalonia, leveraging real-world data such as Electronic Health Records, metabolite levels, detailed questionnaires, and environmental exposures. Our pipeline integrates GWAS summary statistics to estimate individual genetic liability and associate it with diseases, metabolite levels, and self-reported traits. PolyGenie is a dynamic resource, with plans to continuously expand by incorporating additional PRSs to cover a broader range of diseases and traits.

Results: PolyGenie facilitates PRS phenome scans, providing visual and quantitative insights into the associations between specific PRSs and a wide range of traits and diseases. For instance, we identified associations between the genetic liability for frailty and late-onset conditions such as obesity and gastroesophageal reflux disease. Additionally, the tool allows users to explore these associations by visualizing disease prevalence across PRS percentiles, stratified by sex or analyzed collectively, offering a more nuanced understanding of disease patterns and their genetic underpinnings.

Conclusion: By uncovering shared genetic bases across diseases and phenotypes, PolyGenie enhances our understanding of genetic influences on health and disease.

P19.021.B Joint impact of reproductive success and monogenic and polygenic risk on breast cancer

Erja Nynäs[1,2], *Jaakko Leinonen*[1,3], *Elias Lehto*[1], *Aino Kenttämies*[1], *FinnGen*[4], *Nina Mars*[1], *Heli Nevanlinna*[2], *Taru Tukiainen*[1,5]

[1]*Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland,* [2]*Department of Obstetrics and Gynecology, University of Helsinki, Helsinki, Finland,* [3]*Center for Child, Adolescent, and Maternal Health Research, Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland,* [45]*Department of Psychology and Logopedics, Faculty of Medicine, University of Helsinki, Helsinki, Finland.*

Background: Reproductive success and timing are strongly associated with breast cancer (BC), with earlier age at first birth (AFB) and higher parity offering protective effects. Whether

reproduction modulates hereditary BC risk, conferred by single-gene pathogenic variants (PV) and polygenic risk score (PRS), remains unestablished.

Materials and methods: We addressed this question in 200,000 genotyped Finnish women (>45 years) with over 20,000 confirmed BC diagnoses and comprehensive health-registry data on reproductive history available.

Results: BC incidence increased with higher AFB (HR = 1.028/year), lower lifetime parity (HR = 0.891/delivery), and higher PRS (HR = 1.685/SD). When analyzed jointly, AFB and parity stratified BC risk across PRS categories. For example, nulliparous women in the top PRS decile were at 8.7X greater lifetime BC risk compared to women with ≥3 deliveries in the lowest decile. We additionally noted positive additive interaction between AFB>35 and high genetic risk (RERI = 3.6).

GWAS performed for AFB, parity, and BC pointed to largely independent effects of reproduction and BC genetic predisposition. Only ER-positive BC and AFB displayed genetic correlation (rg = 0.1119, P = 0.0002), with no shared BC associations identified within the 36 AFB and parity loci. E.g., the signals at the ESR1-locus were distinct between BC and AFB.

AFB and parity stratified risk also among rare BC PV carriers. For instance, in CHEK2 c.1100delC carriers (N = 3161), higher AFB increased BC risk (HR = 1.021, p = 0.0152), while parity had no detectable effect, potentially reflecting shared biologic mechanisms.

Conclusion: These findings underscore the importance of considering reproductive behavior in BC risk management particularly in individuals at elevated genetic risk.

P19.022.C Sex-specific predictive performance of polygenic scores for type 2 diabetes

Valentina Rukins, *Kristi Läll, Triin Laisk, Reedik Mägi*

Estonian Genome Center, Institute of Genomics, University of Tartu, Tartu, Estonia.

Background: Genetic contribution to type 2 diabetes (T2D) susceptibility can be summarised in a polygenic score (PGS), offering the potential to enhance prevention strategies for individuals at high risk. However, current disease-predictive models overlook the sex-dependent effects of genetic risk factors, instead focusing on the different baseline risks for men and women. Although T2D prevalence in men and women is comparable, a prominent difference in prediabetes frequency may reflect distinct underlying biology. This study aims to systematically evaluate the sex-specific predictive performance of polygenic scores for T2D available in the Polygenic Score Catalog (PGSC).

Material and Methods: Using electronic health records of Estonian Biobank (EstBB) participants, we identified 13,818 T2D cases (63% women) and 189,634 controls (66% women). The analysis was restricted to T2D scores developed without EstBB data and published from 2019 to 2023 in the PGSC. A total of 55 PGSs were calculated for EstBB genotype data with pgsc_calc. The effects of PGSs on T2D risk were estimated using Cox proportional hazard models.

Results: We found that 50 scores had a statistically significant (FDR P-value < 0.05) hazard ratio per standard deviation of genetic risk, ranging from 1.06 to 1.56. No difference in the distribution of effect sizes in men and women was observed (P-value = 0.702, Wilcoxon test). Lastly, the analysis showed that 8 out of 10 best predictive scores for men and women are the same.

Conclusion: Taken together, these findings reveal no support for the substantial sex-specific predictive performance of publicly available T2D polygenic scores.

V. Rukins: None. **K. Läll:** None. **T. Laisk:** None. **R. Mägi:** None.

P19.023.D Robust within family Mendelian randomisation analyses of dairy consumption using the LCT variant

Emily Ruth Daubney[1], *David M. Evans*[1,2,3]

[1]*Institute for Molecular Bioscience, The University of Queensland, Brisbane, Australia,* [2]*The Frazer Institute, The University of Queensland, Woolloongabba, Australia,* [3]*MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom.*

Background: The long-term effects of dairy consumption on human health are unclear as long running randomised controlled trials are impractical and traditional observational epidemiological studies are subject to latent confounding. Population based Mendelian randomisation (MR) studies have utilised a variant in the lactase persistence gene (rs4988235) to proxy dairy consumption. However, this variant is subject to strong geographical variation, and consequently such MR studies are potentially confounded by uncorrected population stratification, dynastic effects and/or assortative mating. These processes may produce spurious findings and/or conceal genuine causal relationships.

Material and Methods: We performed within family tests of association using the rs4988235 variant in 19,074 sibships from the UK Biobank study and compared our results to those from an independent population-based subset of 349,779 unrelated individuals. We investigated 38 continuous and 52 binary medically relevant outcomes.

Results: Within family tests of association were largely consistent with population-based results including significant associations between the allele for lactase persistence and decreased levels of apolipoprotein-A/HDL-cholesterol. Interestingly a subset of traits showed association with lactase persistence in the within families analysis, but not the population based analysis including decreased risk of "fractured bones in the last five years".

Conclusion: We are in the process of replicating our findings in independent sibships. Our results highlight potential problems with relying on population-based MR studies alone for causal inference and the advantages that can be obtained by leveraging within family MR.

C.O.I. Disclosure:

P19.024.A Longitudinal genomic prediction of chronic diseases in Southern Europe

Federica Santonastaso[1], *Simona Costanzo*[2], *Edoardo Giacopuzzi*[1], *Chiara Chiereghin*[1], *Davide Bolognini*[1], *Arianna Landini*[1], *Soumick Chatterjee*[1], *Alessandro Gialluisi*[2,3], *Amalia De Curtis*[2], *Emanuele Di Angelantonio*[1,4], *Giovanni de Gaetano*[2], *Maria Benedetta Donati*[2], *Nicola Pirastu*[1], *Licia Iacoviello*[2,3], *Nicole Soranzo*[1,4,5]

[1]*Human Technopole, Milan, Italy,* [2]*IRCCS Neuromed, Pozzilli, Italy,* [3]*LUM University, Bari, Italy,* [4]*University of Cambridge, Cambridge, United Kingdom,* [5]*Wellcome Sanger Institute, Hinxton, United Kingdom.*

Background: Non-comunicable diseases pose significant challenges to global health. Polygenic risk scores (PRSs) have emerged as powerful tools for identifying genetic susceptibility, improving risk prediction, and informing prevention strategies. This study leveraged data from the Moli-sani study, a prospective cohort of 24,325 adults (≥35 years, 49.3% men) recruited in the Molise region of Italy, to evaluate the utility of PRS in predicting disease risk in Southern Europe.

Material and Methods: PRS weights were derived from genome-wide association studies (GWAS) in European populations. Cox proportional-hazards models were used to examine the association between PRS and the risk of major diseases—including breast, prostate and colorectal cancer, and coronary heart disease (CHD)—over 15 years.

Results: PRSs were significantly associated with the 15-year risk for breast cancer (HR[95%CI] = 1.70[1.51–1.90], $p = 8.05 \times 10^{-20}$), prostate cancer (HR[95%CI] = 1.99[1.79–2.21], $p = 1.24 \times 10^{-38}$), colorectal cancer (HR[95%CI] = 1.32[1.18–1.46], $p = 3.52 \times 10^{-7}$), and CHD (HR[95%CI] = 1.40[1.31–1.49], $p = 1.07 \times 10^{-25}$). Multivariable analysis showed that PRS added predictive value beyond baseline risk factors and family history. For example, CHD-specific PRS enhanced predictive accuracy, independently of family history and Framingham score (HR[95%CI] = 1.40[1.31–1.50], $p = 2.17 \times 10^{-21}$). Furthermore, PRS showed that individuals with a greater genetic predisposition were diagnosed earlier, as expected due to lifelong higher exposure to risk. For example, women with high breast cancer PRS reached equivalent cumulative risks 10 years earlier than their low-risk counterparts.

Conclusion: PRSs effectively stratify people with different disease risk and predict long-term health outcomes in the Italian population. These findings underscore the potential of PRS in precision medicine, particularly for early detection and personalised prevention of diseases.

Instituto de Salud Carlos III, Madrid, Spain.*

Background: The cGAS-STING pathway plays an important role in the innate immune response against pathogens. There are many studies that indicate that this pathway is involved in the pathogenesis of COVID-19. We investigated the association between common variants in the STING/TMEM173 gene and the risk of developing severe COVID-19.

Material and Methods: We genotyped two STING1 gene variants (rs78233829 and rs1131769) in 906 patients that require hospitalization due to COVID-19, including 400 patients attended in the Intensive Care Unit (ICU). We obtained the main clinical and analytical values, including the vaccination status (RNA vaccine). Early onset was a <65 years. The different groups were statistically compared with R.

Results: Allele and genotype frequencies for the two *STING1* variants did not differ between severe (ICU) vs less severe cases. However, there were significant differences between vaccinated (N = 105) vs non-vaccinated (N = 801) (p = 0.003, OR = 2.13, 95%, CI = 1.29–3.50). The *LZTFL1* variant that was associated with the risk of severe COVID-19 did not differ between the two vaccination groups.

Conclusion: *STING1/TMEM173* gene variants were associated with the risk of developing severe COVID-19 among vaccinated. Our results indicate that these common variants could serve to identify individuals with a reduced vaccination response, that would be at increased risk for developing severe COVID-19

P19.026.C ApoE Polymorphism Analysis in Health and Disease of South Asian Populations

P. Paudel[1], *A. Sah*[1], *P. Paudel*[2];

[1]*Maharajgunj Medical Campus, Tribhuvan University Teaching Hospital, Institute of Medicine, Kathmandu, Nepal,* [2]*Pokhara University School of Health and Allied Sciences, Pokhara, Nepal*

Background: This systematic review and meta-analysis assesses the distribution and health implications of apolipoprotein E (ApoE), which play crucial roles in lipoprotein metabolism, in South Asian populations, with a focus on neurodegenerative, movement-related, mental health, cardiovascular,metabolic and trauma-related disorders.

Material and Methods: A total of 53 studies identified through comprehensive searches in PubMed, Embase, and Google Scholar up to July 31, 2024, were included on the basis of predefined eligibility criteria after Risk Of Bias Assessment via the New York Ottawa Scale. Meta-analysis was performed using random-effects model, pooling allele frequency and genotype proportions with 95% confidence intervals. Subgroup analyses were conducted by disease type, reporting pooled logarithm of odds ratios and p-values for associations. The study was registered in PROSPERO (registration number CRD42024575197).

Results: The most prevalent APOE genotype was ε3/ε3 (73.7%), followed by ε3/ε4 (14%), ε2/ε3 (7.5%), ε2/ε4 (0.785%), ε4/ε4 (0.764%), and ε2/ε2 (0.35%).ε4-containing genotypes were found to be strongly associated with susceptibility to Alzheimer's disease, coronary artery disease, vascular dementia, and obesity, whereas the ε2/ε3 showed significant protective effects in Alzheimer's Disease.

Conclusion: This review reflects South Asian specificity of ApoE polymorphism–disease associations, highlighting the need for targeted genetic research and tailored public health strategies to advance personalized medicine and healthcare policies in this region. The review had several limitations, including data gaps for specific health conditions, underrepresentation of some South Asian countries, and heterogeneity in outcomes.

P19.027.D Shared Genetic Architecture and Novel Loci in Alzheimer's Disease, Amyotrophic Lateral Sclerosis, Lewy Body Dementia, and Parkinson's Disease: A Multi-Trait Genome-Wide Association Study

Fotios Koskeridis, *Charlie McKechnie, Paul Elliott, Paul Matthews, Abbas Dehghan, Ioanna Tzoulaki*

Imperial College London, London, United Kingdom.

Background: Neurodegenerative disorders such as Alzheimer's disease (AD), amyotrophic lateral sclerosis (ALS), Lewy body dementia (LBD), and Parkinson's disease (PD) exhibit distinct clinical features but often show overlapping pathophysiological processes suggesting potential shared molecular mechanisms. We aimed to study the genetic architecture of these diseases and identify novel as well as pleiotropic genetic loci.

Material and Methods: We applied Multi-Trait Analysis of GWAS (MTAG) on AD, ALS, LBD, and PD and leveraged their genetic correlations to detect novel loci. A subsequent multi-trait colocalisation analysis using brain single-cell expression quantitative trait loci (eQTL) was performed on the MTAG signals to prioritise candidate causal variants (Posterior probability > 0.7, percentage explained by variant > 75%), shared genes and their cells of expression.

Results: The MTAG analysis identified 4 novel loci for AD, 3 for ALS, 4 for LBD, and 1 for PD (Table). The colocalisation analysis highlighted 3 candidate causal variants. Specifically, rs6733839 (colocalised with AD and LBD) was an eQTL for *BIN1* in microglia; rs199529 (colocalised with ALS and PD) was an eQTL for *LRRC37A2* in microglia; and rs2526378 (colocalised with AD and ALS) was an eQTL for *RNF43* in oligodendrocyte progenitor cells.

Conclusion: Our study provides novel insights into the shared genetic basis and mechanisms of neurodegenerative diseases highlighting candidate genes that may play a pivotal role in disease pathogenesis, and potentially guiding the development of therapeutic strategies.

P19.028.A Nature vs nurture: unraveling social and genetic architecture of nine complex traits using All of Us

M. Hysong[1], *S. J. Cromer*[2,3], *I. R. Konigsberg*[4], *J. Sharma*[5], *M. M. Shuey*[6], *L. M. Glover*[7], *L. M. Raffield*[1];

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC,* [2]*Diabetes Unit, Massachusetts General Hospital, Boston, MA,* [3]*Harvard Medical School, Boston, MA,* [4]*University of Colorado – Anschutz Medical Campus, Denver, CO,* [5]*Johns Hopkins University, Baltimore, Baltimore, MD,* [6]*Vanderbilt University Med Center, Nashville, TN,* [7]*Duke University, Durham, NC*

Background: Social Determinants of Health (SDoH) significantly increase chronic disease risk and disproportionately affect marginalized communities. Integrating SDoH with Polygenic Risk Scores (PRS) could improve disease prediction; however, SDoH collection is nonuniform. Therefore, we explored various methods for defining and integrating SDoH into clinical risk prediction models with PRS across nine diseases including diabetes, heart disease, and asthma.

Material and Methods: We leveraged the All of Us Program to develop five domain-specific SDoH scores (economic stability, education, neighborhood environment, social and community context, and healthcare access) and a composite score encompassing all domains via measurement models. Baseline clinical regression models, adjusted for age, sex, and EHR-specific covariates, were incrementally expanded to four different models including: PRS or SDoH alone, both (joint model), and an interaction model (PRS*SDoH). We used area under the curve (AUC) to compare the predictive performance of models using composite scores and those incorporating simpler individual-level and area-level SDoH metrics.

Results: No single SDoH domain consistently outperformed the others, with individual-level income achieving AUCs comparable to composite scores. Individual-level SDoH measures generally outperformed area-level measures. Models incorporating SDoH improved predictive accuracy for certain diseases more than others, with the most predictive SDoH measure varying by disease. Some traits and domains had significant interactions between PRS and SDoH.

Conclusion: Simple SDoH measures performed comparably to complex composite scores in health outcome models. Disease-specific variations in SDoH associations suggest distinct "social architectures," highlighting the need for tailored, disease-specific approaches in integrating SDoH and PRS to improve prediction accuracy.

P19.029.B Investigating epigenetic changes in body mass index trajectories across childhood

Kym-Mai Nguyen[1], *Christopher Flatley*[1], *Alesha Hatton*[1], *Li Ying Thong*[1], *David Evans*[1,2,3], *Nicole Warrington*[1,2], *Allan McRae*[1], *Jacob Gratten*[4]

[1]*Institute for Molecular Bioscience, The University of Queensland, Brisbane, Australia,* [2]*The Frazer Institute, The University of Queensland, Brisbane, Australia,* [3]*MRC Integrative Epidemiology Unit, University of Bristol, Bristol, Australia,* [4]*Mater Research Institute, University of Queensland, Brisbane, Australia.*

Background: Body mass index (BMI) exhibits a non-linear trajectory across childhood. The genetics and epigenetics of cross-sectional BMI have been well studied, yet little is known about the epigenetic contribution to childhood BMI trajectories. Using the Avon Longitudinal Study of Parents and Children (ALSPAC) cohort we modelled BMI trajectories across childhood and assessed their association with DNA methylation (DNAm) at birth.

Methods: We derived 12 phenotypes that capture distinct features of non-linear BMI trajectories (age and BMI at adiposity peak and rebound; slope and area under the BMI curve (AUC) across infancy, early childhood, late childhood, and adolescence) by fitting 260,870 repeated BMI measurements (birth-18 years) in a mixed linear model. We estimated the proportion of phenotypic variance captured by all DNAm probes in our dataset (OREML analysis) and then performed epigenome-wide association studies (EWAS) of these phenotypes and three birth traits (birthweight, birth length, ponderal index) using cord blood DNAm ($n = 835$).

Results: OREML analyses suggested that cord blood DNAm in this dataset accounts for little phenotypic variance of the BMI trajectory traits. Consistent with this, there was no evidence of association with any probes in the EWAS ($P < 1.14 \times 10^{-7}$). Probes significantly associated with birth outcomes had weak associations with all BMI trajectory traits.

Conclusion: Neonatal blood DNAm profiles have strong associations with birth outcomes but are not predictive of BMI trajectory traits. Our study illustrates the unique opportunity that longitudinal cohorts provide to better understanding the epigenetic underpinnings of BMI trajectories across childhood, which can help identify critical development periods.

P19.030.C Lifetime estimation of time-varying BMI effects on diabetes using Mendelian Randomization and Functional Data Analysis

Nicole Fontana[1,2], *Piercesare Secchi*[1], *Claudia Giambartolomei*[2], *Emanuele Di Angelantonio*[2], *Francesca Ieva*[1,2]

[1]*Politecnico di Milano, Department of Mathematics, Milan, Italy,* [2]*Human Technopole, Health Data Science Center, Milan, Italy.*

Background: The causal effects of some exposures can vary throughout an individual's lifetime, with specific periods playing a more significant influence on health outcomes or revealing the long-term effects of risk factors.

Material and Methods: Using data from the UK Biobank, we examined the impact of time-varying genetically predicted BMI on T2D risk through various methodologies since their relationship across different life stages remains uncertain. First, we applied Factorial Multivariable Mendelian randomization (FM-MR) to estimate the effects of childhood and adulthood BMI, while exploring potential genetic interactions between them. Second, we focused on adulthood BMI (ages 50–70), treating it as a time-varying exposure. Initially, we assumed a cumulative effect of the time-varying trajectories of BMI on T2D risk. Then, low-dimensional factors extracted from functional principal component analysis were integrated into a Multivariable MR model to assess the time-varying causal effect.

Results: MF-MR analysis revealed that early-life BMI was non-significant, while high adulthood BMI showed a significant causal effect on T2D risk. Interaction terms were not significant, leading us to focus on adulthood BMI. Analysis of cumulative effects demonstrated a strong causal relationship between time-varying BMI during adulthood and T2D risk. Notably, functional MR analysis indicated that high BMI between ages 50 to 60 had the strongest association with T2D risk.

Conclusion: This study highlights the importance of understanding how risk factors evolve over a lifetime and their varying impacts on disease risk. Identifying critical exposure periods provides insights into clinical pathways and supports targeted prevention strategies.

P19.031.D Multi-Omics Integration for Identifying Early Molecular Signatures of Pleural Mesothelioma in a Prospective Cohort

Khadija Sana Hafeez[1], *Elisabetta Casalone*[1], *Alessandra Allione*[1], *Elton Jalis Herman*[1], *Clara Viberti*[1], *Simonetta Guarrera*[2,1], *Daniela Ferrante*[3,4], *Dario Mirabelli*[4,1], *Corrado Magniani*[3,4], *Irma Dianzani*[5], *Rosario Tumino*[6], *EPIC-Europe Study*[7], *Paolo Vineis*[8], *Giuseppe Matullo*[9,10]

[1]*Dept. Medical Sciences, University Of Turin, Torino, Italy,* [2]*Italian Institute for Genomic Medicine, IIGM, Torino, Italy,* [3]*Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy,* [4]*CPO Piemonte, Torino, Italy,* [5]*Department of Health Sciences, University of Eastern Piedmont, Novara, Italy,* [6]*Hyblean Association for Epidemiology Research AIRE ONLUS, Ragusa, Italy,* [78]*MRC Centre for Environment and Health, School of Public Health, Imperial College, London, United Kingdom,* [9]*Dept. Medical Sciences, University of Turin, Torino, Italy,* [10]*Medical Genetic Service, Città della Salute e della Scienza, Torino, Italy.*

Background: Pleural mesothelioma (PM) is a rare, aggressive malignancy primarily caused by asbestos exposure, with poor prognosis and limited treatment options. The molecular mechanisms underlying PM remain unclear, limiting opportunities for early detection and targeted therapies. Multi-omics integration offers a powerful approach to uncovering disease-associated pathways, improving risk assessment, and advancing biomarker discovery.

Materials and Methods: Multi-Omics Factor Analysis (MOFA) was applied to integrate genomic, DNA-methylation, miRNA, proteomic, and exome data from a nested case-control study within the EPIC cohort (142 preclinical PM cases and matched controls). Variance-capturing factors across omic layers were identified. Logistic regression models, adjusted for age, sex, and asbestos-exposure, assessed associations with PM risk. Model performance was evaluated using the AUC.

Results: High-variance factors, including Factor 5, showed a significant association with PM risk (OR = 17.09, 95%CI: 8.77–38.32, $p < 3.15e\text{-}14$) and correlated with genomics data. Adding Factor 5 to a null model increased the AUC to 0.87, improving risk stratification. Functional annotation highlighted immune regulation pathways and estrogen signaling. Methylation changes implicated XBP1_01 and HOXB4 target genes, which are associated with overall survival in mesothelioma. Dysregulated miRNAs (hsa-miR-4516, hsa-miR-486-5p) highlighted pathways associated with aging, immunity, and inflammation. Proteomic and exome analyses confirmed enrichment in pathways shaping the tumor microenvironment and supporting PM progression.

Conclusion: This study identifies key molecular signatures in preclinical PM, highlighting pathways involved in immune regulation, transcriptional control, and cellular stress. These findings enhance biomarker discovery and risk assessment and provide potential targets for early detection and therapeutic intervention.

Background: Type 2 diabetes (T2D) is a prevalent disease that arises from complex molecular mechanisms. Recent large-scale efforts by the T2D Global Genomics Initiative (T2DGGI) have generated novel insights into the genetic architecture of T2D. These findings can be subsequently used to pinpoint molecular mechanisms leading to T2D.

Material and Methods: In this work, we leverage the latest T2DGGI multi-ancestry genetic associations to identify causal molecular mechanisms in an ancestry- and tissue-aware manner. Using two-sample Mendelian randomization corroborated by colocalization evidence across four global ancestries, we analyse causal effects of 20,307 genetically-predicted gene expression and 1,630 protein levels on T2D risk using blood-derived cis-quantitative trait loci (QTL).

Results: We detect causal effects of 335 genes and 46 proteins on T2D risk, with 16.4% and 50% replication in independent cohorts, respectively. Increasing diversity enables identification of more causal molecular mechanisms due to the availability of additional instrumental variables. In our study, the causal effects of five and nine genes are detected only in the African and admixed American ancestry groups, respectively, and the causal effects of six proteins are detected only in the East-Asian ancestry group. Additionally, using gene expression cis-QTL derived from seven T2D-relevant tissues, we identify causal links between 676 genetically-predicted gene expression levels and T2D risk, including novel associations such as *CPXM1*, *FAM20B* or *PTGES2*. The identified causal effects are mostly shared across ancestries, but highly heterogeneous across tissues.

Conclusion: Our findings underscore the power of tissue-informed multi-omics causal inference analyses in uncovering molecular traits driving T2D.

P19.033.B Cell-free DNA methylation analysis reveals tissue of origin dynamics in health

Mio Aerden[1], *Huiwen Che*[2], *Kobe De Ridder*[2], *Kaat Leroy*[2], *Tatjana Jatsenko*[2], *Joris Vermeesch*[1], *Bernard Thienpont*[2]

[1]KU Leuven / UZ Leuven, Leuven, Belgium, [2]KU Leuven, Leuven, Belgium.

Background: Cell-free DNA (cfDNA), fragmented DNA circulating in blood plasma and other bodily fluids, serves as a minimally invasive liquid biopsy for monitoring tissue dynamics in pregnancy, transplantation, and cancer. However, knowledge gaps regarding biological variation in cfDNA—particularly related to sex, age, and intra-individual variability—impede clinical implementation. Addressing these gaps is essential to improve the accuracy and reliability of cfDNA-based diagnostics.

Material and Methods: To investigate cfDNA dynamics in health, two cohorts of healthy individuals were studied. A longitudinal cohort (n = 150; 20–88 years) was sampled at baseline and one year later, with balanced age and sex distribution. A diurnal cohort (n = 16; 20–30 years) was sampled over three days at morning, afternoon, and evening intervals. cfDNA libraries were prepared using enzymatic methyl-seq, targeting 4,989 tissue- and age-specific methylation markers, and sequenced on Illumina platforms. Cell-type deconvolution was performed using a custom algorithm.

Results: Deconvolution analysis revealed that cfDNA in healthy individuals predominantly originates from hematopoietic cells, with granulocytes, monocytes, and megakaryocytes as major contributors. cfDNA concentration and cell-type-specific turnover were significantly influenced by age, sex, BMI, and time of day. Additionally, a cfDNA methylation-based epigenetic clock demonstrated accurate chronological age prediction.

Conclusion: This study highlights the critical role of accounting for biological variables to improve the sensitivity and specificity of cfDNA-based tests. By establishing a healthy baseline, this research advances the potential of liquid biopsies for clinical applications.

P19.035.D Transcriptomic sepsis signatures successfully stratify patients in a Thai cohort

Katie L. Burnham[1], *Phumrapee Boonklang*[1], *Emma E. Davenport*[1], *Claire Chewapreecha*[2,1]

[1]Wellcome Sanger Institute, Cambridge, United Kingdom, [2]Mahidol Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand.

Background: Critical care syndromes, such as sepsis, are defined using clinical criteria that capture highly heterogeneous groups of patients. Identifying subgroups with shared biology could identify treatable traits and novel drug targets. We have previously identified transcriptomic Sepsis Response Signatures (SRS) in UK adults admitted to intensive care with sepsis (GAinS study), associated with distinct immune responses and mortality rates, but it is unknown whether these endotypes are consistent across syndromes, populations, and hospital settings. We therefore investigated SRS in the context of melioidosis, a neglected tropical disease caused by *Burkholderia pseudomallei*.

Methods: We recruited a cohort of adult patients with melioidosis (n = 371) together with matched infected (n = 158) and non-infected (n = 492) comparators from Ubon Ratchathani, Thailand, through the BurkHostGen study. We performed RNA-sequencing on whole blood samples and used our SepstratifieR algorithm to assign samples to SRS endotypes. We performed differential gene expression analysis (limma) and inferred immune cell proportions (CIBERSORTx).

Results: Melioidosis patients assigned to SRS1 had more severe infection (Kruskall-Wallis test: SOFA p = 1.1e-11; NEWS2 p = 2.5e-14) and a higher mortality rate than non-SRS1 patients (log-rank test p = 6.58e-06). We identified 4,502 genes differentially expressed between SRS1 and non-SRS1, replicating gene expression differences from the UK sepsis cohort (r = 0.73). We similarly replicated associations with inferred cell proportions, including expansion of immature neutrophils in the SRS1 endotype.

Conclusion: The SRS transcriptomic signature successfully stratified patients in a non-European bacterial infection cohort, demonstrating its portability and broader utility to identify higher risk patients with a distinct response to infection.

P19.036.A An integrated multi-omics analysis identifies novel protein biomarkers and potential drug targets for psoriatic arthritis

X.-F. Huang;

Wenzhou Medical University, Wenzhou, China

Background: Psoriatic arthritis (PsA) is a complex, chronic immune-mediated inflammatory arthropathy that currently lacks definitive biomarkers and treatment targets. Identifying novel biomarkers and treatment targets is urgently needed for effectively managing Psoriatic arthritis (PsA).

Material and Methods: We performed a comprehensive proteome-wide Mendelian randomization (MR) analysis, integrating the human plasma proteome with genome data. Candidate proteins' reliability was assessed through Protein-Protein Interaction (PPI) network analysis and validation with external datasets. Furthermore, single-cell RNA-seq analysis and functional experiments were also conducted.

Results: Proteome-wide MR analysis revealed seven plasma protein biomarkers significantly associated with PsA. Specifically, genetically predicted lower levels of NEO1 were linked to an increased PsA risk, whereas the remaining six proteins (IL23R, ERAP2, IFNLR1, KIR2DL3, CLSTN3, and POLR2F) exhibited a positive association with PsA risk. PPI analysis further supported these findings. Notably, druggability assessment revealed that scopoletin and esculetin were the two most significant drugs associated with ERAP2. Single-cell RNA-seq analysis revealed expression of IL23R, ERAP2, CLSTN3, and POLR2F in distinct T-cell subgroups of PBMCs derived from PsA patients. Furthermore, phenome-wide association studies (PheWAS) analysis assessed the potential side effects and safety as potential drug targets. Interestingly, experimental evidence showed that IFNLR1 expression is significantly upregulated under simulated inflammatory conditions.

Conclusion: This study employed proteome-wide mendelian randomization to identify seven plasma proteins associated with PsA, including IL23R, ERAP2 and IFNLR1, providing a foundation for personalized PsA treatment strategies and contributes significantly towards understanding the pathogenesis of PsA.

P19.037.B Evaluation of healthy lifestyle practices for obesity risk reduction in individuals with a high polygenic score

Yoichi Sutoh, *Tsuyoshi Hachiya, Yayoi Otsuka-Yamasaki, Shohei Komaki, Shiori Minabe, Hideki Ohmomo, Makoto Sasaki, Atsushi Shimizu*

Iwate Medical University, Yahaba, Japan.

Background: Polygenic scores (PGS) are promising tools in precision medicine; however, their application in preventive approaches remains under explored. We aimed to evaluate the impact of healthy lifestyle practices on obesity prevention in individuals with a high PGS for body mass index (BMI).

Material and Methods: The genetic risk of obesity was estimated using the BMI-PGS in four datasets from the Tohoku Medical Megabank Community-Based Cohort. One dataset (n = 9,958) was used for model development, whereas the others (n = 69,341) were used for validation. The validation datasets results were combined in a meta-analysis. Lifestyle factors were evaluated using self-administered questionnaires.

Results: Compared with the low PGS group (1st-10th percentiles), the odds ratios (OR) for obesity were 2.27 [95% CI: 2.12–2.44] in the intermediate group (11th-90th) and 4.83 [4.45–5.25] in the high PGS group (91st-100th). Obesity prevalence increased progressively, reaching approximately 48% upregulation at the highest percentile. Increased leisure-time exercise (LTE) was associated with reduced obesity risk in all groups, with an OR of 0.90 [0.87–0.94] in the high PGS group. However, high PGS and LTE individuals (top 20% of METs in the dataset) had a 3.2-fold increased risk of obesity than low PGS and minimal LTE. Similar trends were observed for other lifestyle factors, such as sodium intake.

Conclusion: Healthy lifestyle practices can reduce the risk of obesity, even in individuals with a high BMI-PGS. However, under the given study conditions, lifestyle modification alone may not fully offset for the genetic predisposition.

P19.038.C Increasing biological understanding of causal relationships through MR extension - Investigating telomere length and aneurysm

Charlotte Fawcett, *Christopher P. Nelson, Veryan Codd*

University of Leicester, Leicester, United Kingdom.

Background: Mendelian randomisation (MR) suggests evidence for a causal relationship between telomere length (TL) (Codd et al., 2021) and abdominal aortic aneurysm (AAA) (Roychowdhury et al., 2023). Although multiple pathways and risk factors have been implicated in AAA development, the mechanism of the TL-AAA relationship remains unknown. Blood pressure traits have particularly been highlighted as significant risk factors for AAA development.

Material and Methods: Extensions to MR such as multivariable MR (MVMR) can be used to investigate the role of multiple exposures, whilst combining univariate MR analyses in two-step MR can infer relationships. Using an instrument generated from Keaton et al., (2024), systolic blood pressure (SBP) is investigated for its potential role in the TL-AAA relationship.

Results: Early MVMR results examining the TL-AAA relationship suggest that both TL (0.528, p-value = 5.7 × 10-18) and SBP (0.007, p-value = 3.0 × 10-3) are statistically significantly associated with AAA. Consequently, two-step MR was then conducted to identify whether SBP could potentially be considered a mediator of this relationship. Separate MR analyses suggested a statistically significant relationship for the TL to SBP MR, whilst the SBP to AAA MR was inconclusive.

Conclusion: The results suggest that although TL has a causal relationship with AAA, further investigation of SBP is required to determine whether it is a mediator of this relationship, conducted

by extending two-step MR to calculate direct and indirect effects. Additionally, using network MR methods can further investigate the role of SBP, alongside other traits such as DBP, in understanding the TL-AAA relationship and its biological mechanisms.

Background: Pheochromocytoma and paraganglioma (PPGLs) have a strong genetic background, with approximately 30% of the cases caused by a germline pathogenic variant (PV).

Aim: To study the prevalence and characteristics of hereditary PPGLs in a large multicenter cohort.

Methods: A retrospective study of patients with a personal history of PPGL. All patients underwent germline DNA sequencing (whole exome or panel sequencing). Demographic, clinical, biochemical, and genetic data were gathered.

Results: Ninety patients underwent genetic evaluation (median age at diagnosis 47 [7-73]), and 29 (33.7%) had a family history of PPGL. 41 patients had pheochromocytoma, 45 had paraganglioma, and four had both. 34 patients (37.8%) carried a PV in a PPGL-related gene; *SHDB* (14 patients, 41.1%), *SDHD* ($n = 9$, 25.7%), *VHL* ($n = 6$, 17.6%), *NF1* ($n = 2$, 5.9%), *SDHC*, *SDHAF2*, and *RET* (one patient each, 2.9%). Age at diagnosis was significantly younger in the PV-carrier group vs. non-carriers (31.63 ± 2.71 vs. 50.48 ± 2.41, $p < 0.00001$). Seventeen patients with a PV had elevated levels of catecholamines, and all had purely elevated normetanephrine (NMN) levels. NMN-only secretion was associated with younger age at diagnosis vs. other secretion profiles (36.12 ± 3.69 vs. 48.85 ± 3.13 years, $p = 0.0006$). Twelve patients (13.3%) had aggressive tumor behavior, with a significantly higher rate of PV compared with patients with the non-aggressive disease ($n = 8$ [66.67%] vs. $n = 10$ [27.03%], respectively, $p = 0.013$).

Conclusion: Patients with PV in a PPGL-related gene were younger at diagnosis and had a higher rate of aggressive disease. These results underscore the importance of genetic evaluation in patients with PPGL.

Background: Idiopathic pulmonary fibrosis (IPF) is a chronic lung disease characterised by progressive scarring, respiratory decline and high mortality. Genetic studies have predominantly focused on European populations, limiting insights into the genetic landscape in diverse ancestries.

Material and Methods: We evaluated 35 previously reported IPF risk variants in clinically curated non-European IPF cases from United States and United Kingdom, alongside ancestry- and sex-matched controls (1:10 ratio) from UK Biobank. Ancestry was inferred using a random forest classifier trained on 1000 Genomes Project reference data. Association testing, adjusted for ancestry-specific principal components, was conducted separately for each population. Polygenic risk scores (PRS) based on the 35 IPF variants with weights from European studies were constructed to assess generalisability of previous IPF genetic studies across populations.

Results: We analysed 41 African, 60 South-Asian, 20 East-Asian, and 90 American ancestry IPF cases. Of the 35 variants studied, five were monomorphic in East-Asians. The *MUC5B* promoter variant - strongest IPF risk factor in Europeans, showed similar variant effects across all the ancestry groups despite differing allele frequencies and rarity in Africans and East Asians. While PRS based on these variants were significantly associated to IPF risk in non-European populations, removing *MUC5B* negated this

association in Africans and South Asians but had minimal impact in East Asians.

Conclusion: These findings highlight the need for more powered studies to understand the genetics of IPF in non-European populations. Population ancestry differences may have an impact on the generalisability and utility of reported IPF genetic risk variants.

P19.041.B Liver fat accumulation contributes to discordant genetic risk between type 2 diabetes and coronary artery disease

X. Jiang[1], *N. Hirschmüller*[1], *H. Taylor*[1,2], *E. Needham*[1], *M. Kelemen*[1], *T. Jiang*[1], *S. Ritchie*[1,3,4], *A. Butterworth*[1], *S. Lambert*[1];

[1]*Cardiovascular Epidemiology Unit, Victor Phillip Dahdaleh Heart & Lung Research Institute, Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom,* [2]*Center for Precision Health Research, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA, Bethesda, MD,* [3]*Cambridge Baker Systems Genomics Initiative, Department of Public Health and Primary Care, University of Cambridge, Cambridge, UK, Cambridge, United Kingdom,* [4]*National Institute for Health Research Cambridge Biomedical Research Centre at the Cambridge University Hospitals NHS Foundation Trust, Cambridg, Cambridge, United Kingdom*

Background: Type 2 diabetes (T2D) and coronary artery disease (CAD) are complex diseases that frequently co-occur. Recent clustering analyses of T2D genetic variants identified molecular pathways associated with disease. Here, we extend to a multi-disease approach and present a comprehensive analysis of the shared genetic and molecular determinants between T2D and CAD.

Methods: Shared genetic loci for T2D and CAD were identified using PLACO on data from multi-ancestry GWAS and confirmed using colocalisation. To understand common pathways of shared variants, we clustered variants using bNMF and assessed the associations of biomarkers and disease outcomes with clusters in 378,772 UK Biobank individuals. Finally, we examined the effect of liver fat on the risk of T2D and CAD using Mendelian randomisation (MR).

Results: We identified 154 genetic loci (90 novel) shared between T2D and CAD. There were 73 with concordant effects on T2D and CAD risk, 57 with discordant effects and 24 with mixed effects. Clustering shared loci using intermediate traits identified 7 clusters with distinct circulating metabolites and associations with different biomarkers and diseases. Some of which (e.g. beta cell and lipodystrophy) were similar to previous T2D clusters. Interestingly, clusters with high proportion of discordant variants were primarily related to liver fat, impacting circulating lipids. MR analysis further suggested that liver fat and the discordant effect on T2D and CAD may be causal.

Conclusion: Discordant risk loci in T2D and CAD centre on pathways regulating liver fat and circulating lipids, providing further insights into the complex relationship between T2D and CAD.

P19.043.D Utilising offspring genotype by proxy Mendelian randomization to investigate potential causal effects of offspring traits on their parents' health

Alesha Hatton, *Caroline Brito Nunes, David Evans*

University of Queensland, Brisbane, Australia.

Background: Offspring traits can have profound effects on parental health. This is especially evident during the perinatal period, when the fetus influences maternal physiology. The causal effect of such offspring traits on their parents' health outcomes can be investigated using Mendelian randomisation (MR), using offspring genetic variants to proxy offspring phenotypes. However, as maternal and offspring genotypes are correlated, analyses should be adjusted for maternal genotype to avoid pleiotropy through the maternal genome. This is difficult to perform at scale due to the paucity of genotyped mother-offspring pairs.

Material and Methods: We introduce offspring genotype by proxy MR, that can be performed in the absence of offspring genotype by utilising spousal information (i.e., father's genotype). Because fathers transmit half of their alleles to their offspring, it follows that paternal genotype will proxy offspring genotype, which in turn will proxy offspring phenotype. As an example, we applied this method to investigate the causal effect of fetal growth (using offspring birthweight) on maternal cardiovascular health in 45,546 spousal pairs in the UK Biobank. Complementary gene-by-environment interaction (GxE) MR analyses using maternal genotype were also performed.

Results: The offspring genotype by proxy MR design found no strong evidence for a causal effect, although confidence intervals were wide. Complementary GxE MR analyses suggested offspring birthweight was unlikely to causally affect maternal cardiometabolic risk factors.

Conclusion: Our study serves as a blueprint for future investigations into the putative causal effects of offspring on their parents using MR in the absence of offspring genotype information.

P19.044.A Polygenic prediction of estimated glomerular filtration rate in Africans

Christopher Kintu[1], *Ruth Nanjala*[2], *Kamiza Abram*[3], *Allan Kalungi*[3], *Machipisa Tafadzwa*[4], *Richard Mayanja*[5], *Tinashe Chikowore*[6], *Segun Fatumo*[1]

[1]*Queen Mary University, London, United Kingdom,* [2]*University of Oxford, Oxford, United Kingdom,* [3]*MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, Entebbe, Uganda,* [4]*Department of*

Medicine, University of Cape Town & Groote Schuur Hospital, Cape Town, South Africa, [5]The African Computational Genomics (TACG) Research Group, MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, Entebbe, Uganda, [6]Harvard Medical School, Boston, MA, United States of America., Boston, MA, USA.

Background: Polygenic risk score (PRS) prediction for African populations is hindered by the limited availability of genome-wide association study (GWAS) data. Although PRS derived from African American GWAS data have shown utility in other traits, their applicability in kidney function in Africans remains largely unexplored. Machine learning (ML) methods, such as PRSmix, have shown promise in improving PRS prediction in other ancestries.

Methods: We evaluated different PRS approaches for eGFR prediction in East Africans using data from the Uganda Genome Resource (UGR). Three PRS computation methods were compared: ML-based PRS integration (PRSmix), clumping and thresholding (PRSice-2), and Bayesian approaches (PRScs). PRSmix integrated 96 eGFR-specific scores using Elastic Net, applying them to the UGR dataset (n = 6,407). PRSice-2 and PRScs used the Million Veteran Program (MVP) dataset (n = 57,336) as the discovery set and UGR as the target set, with further partitioning into training (20%) and validation (80%) subsets.

Results: The results demonstrated a marked improvement in eGFR prediction with the PRSmix approach. PRSice-2 explained 0.22% of the variance in eGFR ($R^2 = 0.22\%$, $p = 0.0001634$), while PRScs explained 0.42% ($R^2 = 0.42\%$, $p = 0.000251$). PRSmix achieved a 5-fold increase in predictive power, explaining 1.16% of the variance ($R^2 = 1.16\%$). Additionally, PRSmix improved prediction for blood urea nitrogen (BUN) and cystatin-C, explaining 1.04% and 0.17% of the variance, respectively.

Conclusion: The PRSmix approach significantly enhanced eGFR prediction. Hence, further refinements are necessary to increase the proportion of variance explained and optimize clinical applications.

P19.045.B Partitioning of the polygenic risk score for body mass index reveals eight biological mechanisms

***Priscilla Vlaming**, Jeroen G.J. van Rooij, Joyce B.J. van Meurs, Jenny A. Visser*

Erasmus MC, Rotterdam, Netherlands.

Background: Obesity is a major global health issue arising from a combination of environmental factors and genetic predisposition. The latest genome-wide association study (GWAS) has identified 941 susceptibility variants for body mass index (BMI). However, translating variants to genes and biological pathways remains a major challenge. Here, we clustered BMI GWAS variants based on variant-trait associations and determined their potential biological relevance to obesity.

Methods: We applied hierarchical clustering of 941 BMI variants (GIANT meta-analysis) and variant-trait associations using the GWAS catalog. To evaluate biological relevance, we constructed weighted, partitioned polygenic risk scores (PRS) per cluster and associated each z-scaled PRS with body composition, body fat, energy intake and components of metabolic syndrome in the Rotterdam Study (N = 3941). All associations were adjusted for age and sex.

Results: We identified eight clusters containing variant-trait associations indicative of body fat, inflammation, blood pressure, lean mass, metabolic syndrome, childhood BMI, insomnia and educational attainment. The body fat and inflammation partitions were associated to all body composition and body fat measurements, with the highest effect sizes for BMI (body fat: $\beta = 0.565$, $p = 1.6e\text{-}17$, inflammation: $\beta = 0.414$, $p = 3.0e\text{-}10$) and body fat percentage (body fat: $\beta = 0.689$, $p = 8.3e\text{-}12$, inflammation: $\beta = 0.466$, $p = 3.1e\text{-}6$). Furthermore, the blood pressure partition was the only partition significantly associated with systolic ($\beta = 1.145$, $p = 5.0e\text{-}4$) and diastolic ($\beta = 0.714$, $p = 7.5e\text{-}5$) blood pressure.

Conclusion: Our study suggests that variant-trait associations can partition the BMI PRS into biologically relevant mechanisms. Greater understanding of these mechanisms could help to identity novel molecular pathways regulating metabolism, thereby improving prevention and treatment of obesity.

P19.046.C Plasma protein biomarkers of type 1 diabetes (T1D) and genetic evidence for their causality

***Xuan Zhou**[1], Andrii Iakovliev[2], Helen M. Colhoun[2], Paul M. McKeigue, Professor of Genetic Epidemiology and Statistical[1], Athina Spiliopoulou[1]*

[1]Usher Institute, University of Edinburgh, Edinburgh, United Kingdom, [2]Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom.

Background: Using plasma proteomic data in UK Biobank, we aimed to identify proteins cross-sectionally associated with type 1 diabetes (T1D) and then assess genetic evidence for a causal role in T1D.

Material and Methods: T1D was defined as prescription of insulin at recruitment to UK Biobank with a record of T1D diagnosis before age 50, or self-reported diabetes before age 50 with insulin therapy within one year of diagnosis. Logistic regression was used to test associations between measured plasma protein levels and T1D in 54219 participants. To assess causality of proteins, we (i)constructed genome-wide aggregated *trans*-effects (GATE) scores and tested their associations with T1D among the remaining 366663 participants, and (ii)examined if the protein-coding genes harbour rare variants causing autoimmune diabetes or are near known T1D GWAS hits.

Results: Association with T1D in 190 cases and 36870 non-diabetic controls identified 465 proteins (Bonferroni-corrected p-value<0.001/2919). Top hits included B7 family proteins (*CD276, NCR3LG1, PDCD1LG2*) and 12 exocrine pancreatic proteins. Genetic evidence for causality was available for 61 of these 465 proteins. Thirty-seven proteins, including *CD276, NCR3LG1*, and *PDCD1LG2*, were supported by associations of T1D with the GATE score for the protein or its receptor (p-value < 0.001). Twenty-eight proteins had been reported as T1D GWAS hits, and 3 (*CD55, IL2RA, PDCD1*) are known to cause monogenic autoimmune diabetes.

Conclusion: These findings highlight the B7 family of immune checkpoint regulators in T1D pathogenesis and emphasize the importance of genetic evidence in assessment of causality of protein associations.

P19.047.D Menopause changes the game: differential breast cancer risk in women living with obesity

***Torgny Karlsson**, Fatemeh Hadizadeh, Mathias Rask-Andersen, Åsa Johansson*

Uppsala University, Uppsala, Sweden.

Background: Previous research suggest that obesity is associated with no or lower risk of breast cancer in young women, while older women living with obesity show an increased risk, at some point after menopause. To what extent there is a differential effect and at what age obesity becomes a lifetime risk factor, remains inconclusive. We used genetics of body mass index (BMI) to determine the effect of obesity on breast cancer across the life-course.

Material and Methods: Aalen's additive hazard model was deployed to estimate the effect of a polygenic score of BMI on incident breast cancer during life-course, at unprecedented temporal resolution. The corresponding effect of BMI was estimated using the Mendelian randomization framework, where variations in effect of the score on BMI across age was properly accounted for. Data on age, BMI and incident breast cancer were taken from UK Biobank.

Results: We identified an increasingly protective effect of obesity in young women, up to age 50 years, after which the effect begins to diminish in strength. Around 65 years of age, obesity becomes a lifetime risk factor for breast cancer. Stratification by age-at-menopause revealed a time shift in the effect on breast cancer risk of 8 ± 4 years between women with late and early menopause, which closely matched the difference in mean age-at-menopause between the two groups.

Conclusion: Our results demonstrate the existence of a differential effect of obesity on breast cancer risk throughout life linked to menopause, which likely is due to menopausal changes in hormonal metabolism.

P19.048.A Brain-wide pleiotropy investigation of alcohol drinking and tobacco smoking behaviors

Giovanni Deiana[1,2], *Jun He*[2], *Brenda Cabrera-Mendoza*[2], *Roberto Ciccocioppo*[1], *Valerio Napolioni*[1], *Renato Polimanti*[2]

[1]*University of Camerino, Camerino, Italy,* [2]*Yale University, New Haven, CT, USA.*

Background: Previous studies advanced our understanding of brain mechanisms underlying alcohol drinking and tobacco smoking identifying pleiotropic links with brain structure and function

Material and Methods: To explore these pleiotropic mechanisms, we integrated data generated by the GWAS and Sequencing Consortium of Alcohol and Nicotine use (GSCAN; up to 805,431 participants) with information related to 3,935 brain imaging-derived phenotypes (IDPs) available from UK Biobank (N = 33,224)

Results: We observed global genetic correlations between smoking behaviors and white matter hyperintensities, the morphology of the superior longitudinal fasciculus, and the mean thickness of the pole-occipital region. The latter IDP showed a local genetic correlation with the age of regular smoking initiation (hg38 chr2:35,895,678-36,640,246: rho = 1, $p = 1.01 \times 10^{-5}$). Pole-occipital region had been previously linked to smoking initiation, educational attainment, chronotype, and cortical thickness. Our genetically informed causal inference analysis using both latent causal variable approach and Mendelian randomization, linked prefrontal and premotor cortex activity and that of superior and inferior precentral sulci and cingulate sulci to drinks per week (genetic causality proportion, gcp = 0.38, $p = 8.9 \times 10\text{-}4$, rho = -0.18 ± 0.07; inverse variance weighting, IVW beta = -0.04, 95%CI = -0.07 - -0.01). This relationship could be related to the role of these brain regions in the modulation of reward-seeking motivation and the processing of social cues

Conclusion: Overall, our brain-wide investigation highlighted that different pleiotropic mechanisms likely contribute to the relationship of brain structure and function with alcohol drinking and tobacco smoking, suggesting decision-making activities and chemosensory processing as modulators of propensity towards alcohol and tobacco consumption

P19.049.B Characterising effects of autoimmune condition liability on adverse pregnancy outcomes using Mendelian Randomization

Elisabeth Aiton, *Nancy McBride, Carolina Borges, Deborah A. Lawlor*

University of Bristol, Bristol, United Kingdom.

Background: Autoimmune conditions are often more common in women than men, diagnosed in early adulthood, and associated with adverse pregnancy outcomes. However, whether these conditions or medications used to manage them cause adverse pregnancy outcomes is unknown.

Material and Methods: We used two-sample Mendelian randomization to explore the effect of liability to ten autoimmune conditions on 15 pre-selected adverse pregnancy outcomes. Genetic instruments were selected from published GWAS and outcome genetic association data included up to 700,000 women within the MR-PREG collaboration. Main analyses used the inverse variance weighted (IVW) method. Sensitivity analyses included MR-Egger, weighted-median, excluding the HLA region, and accounting for fetal effects.

Results: We found strong evidence that liability to type 1 diabetes (T1D) increased risks of several adverse pregnancy outcomes, such as neonatal intensive care unit admission (OR = 1.03, 95% CI:1.01–1.04 per doubling in liability) and hypertensive disorders of pregnancy (OR = 1.02, 95% CI:1.01–1.02). Liability to rheumatoid arthritis also caused increased risks across outcomes, for instance on preterm birth (OR = 1.02, 95% CI:1.01–1.04). Multiple sclerosis liability had several protective effects, for example on hypertensive disorders of pregnancy OR = 0.98, 95% CI:0.97–0.99).

We also identified potential adverse effects of Hashimoto's thyroiditis, ankylosing spondylitis, systemic lupus erythymatosus, and systemic sclerosis. For coeliac disease, inflammatory bowel disease and psoriasis, there was limited evidence supporting any effects, though several estimates were imprecise. Sensitivity analyses largely supported main IVW results and suggested that the HLA region drove some effects.

Conclusion: Our preliminary findings suggest effects vary between autoimmune conditions.

P19.050.D Leveraging plasma proteomics and genomics to prioritise determinants of*MYBPC3*-related hypertrophic cardiomyopathy severity and potential pleiotropic effects on related cardiac diseases

Marion van Vugt[1,2,3], *Fahima Hassanzada*[2,4], *Mark Jansen*[2,4], *Annette Baas*[2,4], *Anneline te Riele*[4,2], *Dennis Dooijes*[2,4], *Saskia Van Der Crabben*[1,4,4], *Jan DH Jongbloed*[5], *Moniek GPJ Cox*[5], *Ahmad S. Amin*[1,4], *Ronald H. Lekanne Deprez*[1,4], *Diederik WD Kuster*[1], *Jolanda van der Velden*[1], *Connie R. Bezzina*[1,4], *Folkert W. Asselbergs*[1,3], *J. Peter*

van Tintelen[2,4], Karin Y. van Spaendonck-Zwarts[2,4,5], A. Floriaan Schmidt[1,3,6]

[1]Amsterdam UMC, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]University College London, London, United Kingdom, [4]European Reference Network for Rare, Low Prevalence and Complex Diseases of the Heart, Amsterdam, Netherlands, [5]University Medical Centre Groningen, Groningen, Netherlands, [6]UCL British Heart Foundation Research Accelerator, London, United Kingdom.

Background: Hypertrophic cardiomyopathy (HCM) is a highly variable disorder often caused by pathogenic *MYBPC3* variants. It may present with asymmetric left ventricular (LV) hypertrophy, LV outflow tract obstruction (LVOTO), or heart failure (HF).

Material and Methods: We studied 268 Olink-assayed plasma proteins in 144 *MYBPC3* carriers classified as unaffected, mildly, or severely affected (LV maximum wall thickness (LVMWT) ≥20 mm, LVOTO necessitating septal reduction therapy, HF, or malignant ventricular arrhythmia). Using a multi-tiered approach, we applied random forests and Firth regression to identify proteins associated with HCM severity, followed by replication and annotation based on tissue expression, druggability, and pathway analysis. Independent replication was obtained in 50,000 UK Biobank participants, including 100 HCM patients, and through Mendelian randomisation of HCM, HF, LVOTO, and LVMWT.

Results: Twenty-seven proteins associated with HCM severity in 52 unaffected (75% female; LVMWT 10±1 mm), 17 mildly affected (59% female; LVMWT 15 ± 2 mm), and 75 severely affected (31% female; LVMWT 19 ± 5 mm) *MYBPC3* carriers, of which 17 were independently replicated. NT-proBNP, MB, FGF-23, C1QTNF1, and NCAM1 are mainly cardiac proteins, while ADM, CXCL16, and CCL16 are highly expressed in secretory tissues, such as the liver. ADM is targeted by enibarcimab, a drug in development for HF. Five other proteins are targeted by drugs in development, and 11 by approved drugs. CXCL16 and CCL16 play a role in Gαi signalling, contributing to hypertrophy and contractile dysfunction.

Conclusion: This study identified and prioritised 8 proteins associated with HCM severity in *MYBPC3* carriers, providing biomarkers and therapeutic targets for HCM.

Sanitas Hospitales., Madrid, Spain, [10]Fundación de investigación e innovación. Sanitas Hospitales., Madrid, Spain, [11]Departamento Médico. Sanitas Hospitales., Barcelona, Spain.

Background: Recent technological highlights such as whole genome sequencing (WGS) and bioinformatics make it feasible to plan prospective genetic screenings in healthy population. In the last years, some studies have suggested advantages in disclosing actionable information regarding genetic risk of several diseases, reducing mortality and morbidity after close surveillance.

Material and Methods: A 10,000 individual prospective project using WGS was designed in our hospital group. Age of inclusion ranged from 30 to 65 years. DNA was extracted using Qiasymphony and Illumina DNA PCR-Free WGS was performed using Illumina Xplus machines (~30x depth genomes were accepted). GRCh37 reference assembly was used. A 293 actionable gene panel was designed (CLINVAR, NCCN, ESMO, AHA, ACMG, others). Pathogenic and likely pathogenic variants were disclosed only. Genetic counseling was provided to all patients. In case of high-risk result, clinical health plans were prepared for surveillance.

Results: 2648 patients were sequenced till end of January 2025 (1712 women). 454 patients (17%) disclosed actionable variants, being HFE the main detected variants (282 patients). Approximately ~5% of our patients (140) showed linkage to a more severe condition, including, cancer risk (72 patients), heart disease risks (31 patients) or pancreatitis susceptibility (23 patients). This project is still going, and further clinical data will be disclosed at the end of it.

Conclusion: Sequencing actionable gene panels in general population discloses presymptomatic patients at risk of disease (17%, 5% of them linked to severe conditions). This approach would help healthcare systems in prioritizing and surveilling such patients from general population.

P19.052.A Summary Statistic-Derived Metabolite Ratio QTL Analysis Identifies 427 Otherwise Missed Loci and Reveals Catalyzing Enzymes

*Sadegh Rizi[1], Zoltan Kutalik[2], **Adriaan van der Graaf**[2]*

[1]University of Tehran, Teheran, Iran, Islamic Republic of, [2]University of Lausanne, Lausanne, Switzerland.

Background: Metabolic pathways are dysregulated in diseases like type 2 diabetes. Yet, quantitative trait locus (QTL) studies focus on one biomarker at a time. Metabolite ratios are established proxies for pathway activity, however, their use in QTL studies has been limited due to the quadratic computational burden of pairwise combinations.

Materials and Methods / Results: We developed a statistical framework to compute ratio QTL (rQTL) from existing single metabolite QTLs (mQTL) summary statistics. Validating on 299 classically derived ratios (from individual-level data), we find strong concordance (β: $R^2 = 0.87$). After application to all (261,003) pairwise ratios of 723 metabolites we identified 17,454 rQTL with stronger significance than either constituent metabolite at Bonferroni

significance ($P < 2 \times 10^{-13}$), of which 437 rQTLs were not study-wide significant ($P < 5 \times 10^{-11}$) in the original mQTL study. The closest genes to the novel rQTLs were enriched for lipid metabolism (Reactome: $P = 4 \times 10^{-14}$). *Cis* Mendelian randomization and colocalization analysis identifies 9 proteins significantly influencing 521 metabolite ratios (MR-link-2 $P < 1 \times 10^{-6}$, coloc PP4 > 0.9). All proteins were enzymes, including sulfotransferase 2A1 (SULT2A1) protein abundance as a causal regulator of the ratio between dehydroepiandrosterone sulfate and etiocholanolone glucuronide (novel rQTL $P = 2 \times 10^{-15}$): two testosterone metabolites.

Conclusion: Our framework enables scalable and resource-efficient rQTL mapping from summary statistics, bypassing the need for individual-level data. We identify previously unknown metabolite pathway regulation, efficiently resolving rQTLs, otherwise understudied as phenotypes for QTL mapping.

Gemelli IRCCS, Rome, Italy.*

Background: Fluoropyrimidines are widely used in colorectal cancer (CRC) treatment, but 10–30% of patients experience severe toxicity (Grade 3–4), partly due to deficient dihydropyrimidine dehydrogenase (DPD) enzyme activity. Pre-treatment *DPYD* genotyping mitigates this risk by enabling personalized dosing. Using the World Health Organization's (WHO) Health Impact Assessment (HIA) guidance, we evaluated the feasibility, equity, and impact of systematically implementing *DPYD* genotyping in Finland through policy-driven integration.

Material and Methods: A structured HIA framework was applied, incorporating stakeholder engagement, oncologist and laboratory surveys, patient interviews, and Markov modeling. Quantitative analysis assessed health outcomes, while qualitative inputs captured operational challenges and patient acceptability.

Results: *DPYD* genotyping is widely adopted in Finnish oncology practice, with a reported prescription rate of 94.7%. Markov modeling showed that expanding from current adoption (94.7%) to full implementation (100%) led to marginal reductions in severe toxicity (23.9% to 23.6%) and toxicity-related mortality (0.12% to 0.11%). Challenges include test result delays (≥10 days in some regions), infrastructure disparities, and laboratory inefficiencies. Patient interviews revealed low awareness of *DPYD* testing but strong willingness to accept it, provided delays are minimized. Stakeholders assumed equity in access to be high, consistent with Finland's universal healthcare system.

Conclusion: Integrating DPYD genotyping systematically enhances patient safety and optimizes resource use. Addressing laboratory capacity and enhancing patient and provider education are critical for equitable and sustainable implementation. These findings provide actionable insights for scaling personalized medicine policies in other healthcare settings.

P19.054.C Identification of HIV restriction factors through mRNA expression variation in HIV-infected individuals

Sergey Oreshkov[1,2,3], *Christian Thorball*[1,4], *Jenny Meylan Merlini*[1], *Maude Muriset*[1], *Jacques Fellay*[1,4], *Federico Santoni*[1]

[1]*CHUV - Centre hospitalier universitaire vaudoise, Lausanne, Switzerland,* [2]*University of Lausanne, Lausanne, Switzerland,* [3]*Jules Gonin Eye Hospital, Fondation Asile Des Aveugles, Lausanne, Switzerland,* [4]*EPFL, Lausanne, Switzerland.*

Background/Objectives: The interaction between HIV-1 and the host immune system plays a crucial role in the natural control and progression of the infection. Previous studies have identified HIV-1 restriction factors, which are counteracted by viral "helper" proteins. The blood expression levels of these proteins vary among individuals, suggesting interindividual differences in the spontaneous control of HIV infection might lead to the identification of novel HIV restriction factors.

Methods: Study enrolled 150 participants from the Swiss HIV Cohort Study, with provided genotypes, pre-antiretroviral treatment PBMC aliquots, and viral load measurements. Using BRB sequencing, we derived gene expression profiles and assessed their associations with viral load. Mendelian randomization studies were performed on correlated genes to infer causal relationships within these associations.

Results: We employed a generalized linear model to assess the association between 792 genes and HIV viral load. Pathway analysis revealed upregulation in innate immune response and proteasome complex with increased viral load, alongside heightened mitochondrial activity and cell-cycle. Conversely, reductions were observed in ribosomal transcripts and downregulation of genes involved in cytokine-cytokine receptor interaction, including IL4R, IL7R, and TCF. Utilizing Transcriptome-Wide Mendelian Randomization, we rediscovered TRABD2A and identified new candidates as restriction factors.

Conclusion: We performed a large transcriptomic analysis of PBMCs from PLWH without antiretroviral treatment at the time of sample collection. Comparing gene expression levels and HIV-1 VL, we identified anticorrelated genes with potential anti-HIV activity non or partially counteracted by viral proteins.

P19.055.D Application of Mendelian randomization to appraise causality of the relationship between the gut microbiome and cancer

Amy Charlotte Dawes

MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom.

Background: The gut microbiome has been implicated in cancer aetiology; however, its causal relevance is not clear. Mendelian

randomization (MR) is increasingly being applied to assess the causal role of the gut microbiome on several health outcomes; however, the complexities and limitations of the method are not fully addressed in much of the current literature. Here, we aimed to appropriately apply MR to understand the role of the gut microbiome in cancer aetiology, whilst demonstrating the range of sensitivity analyses required to provide clarity in causal estimates.

Methods: Two-sample MR was used to examine the causal relationship between microbial traits from two large microbiome genome-wide association studies (mGWASs) and risk for cancers of the lung, breast, colorectum, pancreas, prostate, ovary, endometrium and oesophagus from the largest cancer GWASs, with replication sought in UK Biobank and FinnGen. A range of sensitivity analyses were performed to appraise the robustness of findings to violations of MR assumptions.

Results: Whilst our MR analyses suggested a putative causal role of 16 microbial traits across the eight cancers, few results were replicated in both UK Biobank and FinnGen and sensitivity analyses implied violations of MR assumptions, suggesting that these findings were unlikely to reflect causality.

Conclusion: Through testing for violations of core MR assumptions, our work demonstrates the importance of performing sensitivity analyses when assessing the robustness of MR findings, especially in the context of understanding the causal relevance of the gut microbiome on health outcomes.

P19.056.A Inflammatory Signatures in Hashimoto's Thyroiditis: A Proteomic Approach to Disease Progression and Treatment Effects

Vanna Znidar[1], *Dean Kalicanin*[1], *Ana Baric*[2], *Marko Vuletic*[2], *Sanda Sladic*[2], *Vesela Torlak-Lovric*[2], *Maja Cvek*[2], *Ante Punda*[2], *Vesna Boraska Perica*[1]

[1]*University of Split School of Medicine, Split, Croatia,* [2]*University Hospital of Split, Split, Croatia.*

Background: Hashimoto's thyroiditis (HT) is a chronic autoimmune disorder that leads to thyroid destruction and hypothyroidism. We aimed to investigate changes in inflammatory proteins in HT patients stratified into those that are in euthyroid state (EUTHY) and those in hypothyroid state (HYPO). Additionally, we explored the impact of levothyroxine (LT4) therapy on inflammatory markers.

Material and Methods: We measured 92 inflammatory proteins using Olink Target 96 Inflammation Panel in 440 individuals (168 EUTHY patients, 99 HYPO and 173 controls). Olink_anova analysis, adjusted for age, gender, and BMI, was performed to detect proteins differentially expressed in two groups of HT cases compared to controls. P-values per assay were adjusted using the Benjamini-Hochberg method, and post hoc comparisons were performed using Olink_anova_posthoc. Comparison between euthyroid patients on LT4 therapy and euthyroid patients without therapy was also performed.

Results: The most significant results came from post hoc analyses between HYPO and control group which showed upregulation of 18 and downregulation of 4 proteins. The most significantly upregulated proteins in HYPO were IL-17C, CCL19, and CCL20 whereas the most significantly downregulated proteins were ST1A1 and CASP-8. Notably, HT patients treated with LT4 showed no significant differences in inflammatory profiles compared to euthyroid patients without treatment.

Conclusion: This is the first systematic analysis of inflammatory proteins to explore changes of immune response in HT, especially during the transition from euthyroidism to hypothyroidism. We identified several markers potentially linked to disease progression. Additionally, our findings suggest that LT4 therapy has beneficial effects on inflammation in HT.

P19.057.B Clinical variability of the *CFTR* variant p.Arg117Cys uncovered by newborn screening for cystic fibrosis. Does the genetic background matter?

Emma S. Lundman[1], *Janne M. Strand*[1], *Silje Hogner*[1], *Mari Eknes Ytre-Arne*[1], *William Nicholas Tourniaire*[1], *Anita Christine Senstad Wathne*[2], *Mette Engan*[3], *Egil Bakkeheim*[4], ***Asbjorg Stray-Pedersen***[1]

[1]*Norwegian National Newborn Screening, Division of Pediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway,* [2]*Norwegian Resource Centre for Cystic Fibrosis, Division of Pediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway, Oslo, Norway,* [3]*Department of Paediatrics and Adolescent Medicine, Haukeland University Hospital, Oslo, Norway,* [4]*Norwegian Resource Centre for Cystic Fibrosis, Division of Pediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway.*

Background: The second most common CF-causing variant identified in the Norwegian newborn screening (NBS) is the p.Arg117Cys, prior to NBS only observed in 5% of clinically diagnosed CF-patients.

Material and Methods: From 2012 to 2015, 500 samples/year were tested using Luminex-CFTR-71-variant-assay. After lowering the IRT cut-off value, 2500 samples/year were sequenced using MiSeq139-variant-assay-v1 (2015-Feb2021) and CFTR-Clinical Sequencing-v2 (Mar2021-1Feb2025). All samples with at least one allele p.Arg117Cys detected during the 13 years of screening were selected. Samples carrying p.Arg117Cys from 2012–2015 were retrieved from the NBS biobank and re-tested with MiSeqDx-CF-Clinical-Sequencing. Clinical follow-up data of the infants with screening positive results were available.

Results: Among ~30.000 samples sequenced, 47 were NBS positive carrying at least one p.Arg117Cys allele, 11 of them homozygous. There were 411 heterozygous carriers, defined as NBS negative. The frequency of p.Arg117Cys compared to other pathogenic *CFTR* variants was 18–28%: a high allele prevalence in the Norwegian population. A variable clinical spectrum was uncovered among the NBS positives, even with identical pathogenic variant on the other allele. Co-occurring previously unevaluated *CFTR* variants were observed in the whole-gene sequenced samples.

Conclusion: The knowledge of the landscape of *CFTR* variants increased with more comprehensive sequencing. Extended allele background can be of importance and include disease-modifying variants in *CFTR*. Future studies may explore how to predict the clinical variability of *CFTR* variants by combining whole *CFTR* sequencing and filtered WGS and using long-reads technologies looking for cis- and trans-regulatory factors in *CFTR* and modifying variants in *MBL2, SFTPD*, and other genes.

P19.058.C Two-sample Mendelian randomization analyses on GWAS summary data: comparisons of instruments selection and causal effect estimation strategies

Giulia Pontali[1], *Solène Cadiou*[1], *Alessia Mapelli*[1,2], *Dariush Ghasemi-Semeskandeh*[1], *Brian Ferolito*[3], *Michele Filosi*[4], *Michela Massi*[1], *Eva*

König[4], Gianmauro Cuccuru[1], Xiyun Jiang[5], Johannes Rainer[4], Cristian Pattaro[4], Peter Pramstaller[1], Emanuele Di Angelantonio[1,5], Christian Fuchsberger[4], Adam Butterworth[5], Alexandre Pereira[6], Claudia Giambartolomei[1]

[1]Fondazione Human Technopole, Milano, Italy, [2]Politecnico di Milano, Milano, Italy, [3]3Veterans Affairs Healthcare System, Boston, MA, USA, [4]Eurac Research, Bolzano, Italy, [5]University of Cambridge, Cambridge, United Kingdom, [6]Veterans Affairs Healthcare System, Boston, MA, USA.

Background: Mendelian randomization (MR) estimates causal effects using genetic variants as instrumental variables (IVs). Single-SNP MR may overlook important genetic effects when an exposure has multiple independent IVs, potentially reducing power. Multi-SNP MR addresses this limitation, but its advantages remain unclear. This study systematically compares the performance of single-SNP and multi-SNP MR strategies using protein quantitative trait loci (pQTL) summary statistics and confirmed protein-trait causal associations.

Material and Methods: We analyzed cis-pQTL associations for 7143 proteins, from a meta-analysis of INTERVAL[1] (n = 9657) and Cooperative Health Research in South Tyrol (CHRIS)[2] studies (n = 4225). The IV selection followed three distinct strategies: (1) selecting the most significant SNP per locus, (2) identifying conditionally independent SNPs with unconditional effect sizes and errors (Unconditional), and (3) using conditionally independent SNPs with conditioned effect sizes and errors (Conditional). MR analyses were performed on 2011 phenotypes using meta-analysis data from the Million Veteran Program, UK Biobank, and FinnGen. Performance was assessed against known causal protein-trait associations (approved drug target and indication pairs) and compared using Fisher's exact tests and odds ratios.

Results: No significant difference was observed in true positives and false negative rates across the three approaches. The Unconditional multi-SNP approach identified more associations than the Conditional approach, but all methods detected a similar number of true causal associations.

Conclusion: Multi-SNP MR may capture additional signals but does not significantly improve MR accuracy. Further analyses are needed to refine instrument selection strategies and enhance causal inference.

P19.059.D Exploring modifying genes in NF1: unraveling the genetic basis of plexiform neurofibromas and optic pathway gliomas for personalized medicine

Qin Hao[1], Martin J. Larsen[1], Niels Illum[2], Lilian B. Ousager[1]

[1]Department of Clinical Genetics, Odense University Hosptial, Odense, Denmark, [2]H.C. Andersen Children's and Youth Hospital, Odense University Hosptial, Odense, Denmark.

Background: Neurofibromatosis type 1 (NF1) is a common autosomal disorder affecting ~1 in 3,000 individuals, caused by loss-of-function mutations in the NF1 gene on chromosome 17q11.2. NF1 exhibits near-complete penetrance and involves diverse clinical manifestations, including café-au-lait macules, neurofibromas, gliomas, skeletal abnormalities, and learning difficulties. Clinical variability is significant, with age-dependent onset and unpredictable progression. While genotype-phenotype correlations are limited, modifying genes, somatic mutations, and epigenetic factors likely contribute to this variability. Modifying genes, though not causative, can alter target genes and influence phenotypic expression, making their identification crucial for understanding NF1 pathogenesis and improving personalized care.

Material and Methods: This study focuses on two frequent and clinically significant NF1 manifestations: plexiform neurofibromas (PNFs) and optic pathway gliomas (OPGs). We compare the genetic backgrounds of NF1 patients with and without these manifestations using high-resolution genomic analyses. Family-based association tests are conducted to identify potential modifying genes and recurrent genetic changes.

Results: The preliminary results are promising. The completed analysis of the first batch of data will be presented.

Conclusion: This study highlights the role of modifying genes in NF1 phenotypic variability, particularly for PNFs and OPGs. Identifying these genetic influences could improve prognostic accuracy, guide targeted therapies, and advance personalized medicine for NF1 patients. This study seeks to unravel the molecular mechanisms underlying NF1's clinical variability, offering new insights into this complex disorder.

P19.060.A Identifying predictors of weight loss from a diverse set of biological, behavioural, and psychological factors

Birgit Malken[1], Kadri Arumäe[2], Ivan Kuznetsov[1], Uku Vainik[1,2,3]

[1]Institute of Genomics, University of Tartu, Tartu, Estonia, [2]Institute of Psychology, University of Tartu, Tartu, Estonia, [3]Montreal Neurological Institute, McGill University, Montreal, QC, Canada.

Background: Identifying predictors of successful weight loss could guide intervention selection and resource allocation. Our purpose was to explore predictors of weight loss from 172 polygenic scores (PGS) proxying a diverse set of variables including physiological markers, medical issues and procedures, health behaviours (including dietary intake and physical activity), and personality traits.

Material and Methods: We predicted the percent of weight lost, calculated as the person's minimum weight following their highest recorded weight, in an Estonian Biobank subsample (N = 47,217) of non-weight-stable people with BMI ≥ 25 kg/m2 at baseline (i.e., at their maximum weight), with at least one follow-up weight measurement available between one month and four years from baseline. A PGS was calculated for 172 variables using SBayesR, based on summary statistics from Genome-wide association studies in the UK Biobank cohort. All predictors and the outcome were first residualized for sex, baseline BMI, 20 principal components of ancestry, and the linear and quadratic terms of age and time from baseline and minimum recorded BMI, and standardized.

Results: Greater weight loss was most strongly predicted by the PGSs for apolipoprotein B, lymphocyte percentage, neutrophil percentage, HDL cholesterol, higher education, and number of non-cancer illnesses (β = .01 ⋯ .04). Lower weight loss was predicted by the PGSs for current and past smoking, higher age at first sexual intercourse, LDL cholesterol, and pain experienced in the last month (β = .01 ⋯ .03).

Conclusion: Biological and lifestyle variables emerged as the strongest predictors of weight loss.

P19.061.B CNV landscape of Hong Kong Chinese population and detection of rare CNV aggregation in twin pairs with specific learning disorders

Cheuk Yan Chung[1], *Wenxuan Jiang*[1], *Matthew Hoi Kin Chau*[1,2], *Dora Jue Pan*[3], *Mo Zheng*[4], *Silvia Paracchini*[5], *Zirui Dong*[1,2], *Catherine Alexandra McBride*[6], *Urs Maurer*[7,8,9], *Richard Kwong Wai Choy*[1,2]

[1]*Department of Obstetrics and Gynaecology, Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, Hong Kong,* [2]*Joint BCM-CUHK Center of Medical Genetics, Hong Kong, Hong Kong,* [3]*School of Humanities and Social Science, The Chinese University of Hong Kong (Shenzhen), Shenzhen, China,* [4]*Division of Science & Technology, Beijing Normal University-Hong Kong Baptist University United International College, Zhuhai, China,* [5]*University of St Andrews, School of Medicine, St Andrews, United Kingdom,* [6]*College of Health and Human Sciences, Purdue University, Indiana, IN, USA,* [7]*Department of Psychology, The Chinese University of Hong Kong, Shatin, Hong Kong,* [8]*Centre for Developmental Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong,* [9]*Brain and Mind Institute, The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Background: Additive genetic factors of genome-wide single nucleotide polymorphisms cannot fully explain the heritability of reading and mathematical ability estimated by the twin ACE model. We investigated the characteristics of copy number variants (CNV) and rare CNVs in twin pairs with specific learning disorders to understand their role and to address the missing heritability.

Material and Methods: Low-pass whole genome sequencing was performed on 844 Hong Kong Chinese twins for CNV calling at 10-kb resolution. Rare CNVs with allele frequency <1% in 15 twin pairs with dyslexia or dyscalculia were investigated.

Results: Overall, 4099 deletions and 1872 duplications were detected in 844 twins. The minimum, median, and maximum CNV sizes were 10 kb, 48 kb, and 5.26 Mb, respectively. Over 50% of CNVs were between 10–50 kb in size, which have previously been unappreciated. 45.9% and 44.5% of deletions and duplications overlapped with at least 1 gene. Rare CNVs previously reported in patients with neurodevelopmental diseases were detected in 4/15 twin pairs with specific learning disorders, including: intronic duplications of *NEGR1* (chr1:72592570_72630203dup), partial deletions of *NDUFAF2* (chr5:60244295_60277541del), intronic deletions of *FGF12* (chr1:151332079_151406433dup), and partial duplications of *POGZ* (chr3:g.191935518_191990864dup). These genes were related to dyslexia, attention deficit/hyperactivity disorder, developmental and epileptic encephalopathy, and White-Sutton syndrome, respectively.

Conclusion: We showed the first CNV map of the Chinese general population. Aggregation of rare CNVs was observed in 4/15 twin pairs with specific learning disorders and patients with neurodevelopmental diseases. This provides preliminary evidence that CNVs account for missing heritability of academic ability.

P19.062.C Saliva as a diagnostic medium: DNA methylation biomarkers for disorders beyond the oral cavity

Alba Hernangomez-Laderas[1], *Ariadna Cilleros-Portet*[1], *Sergi Marí*[1], *Bárbara P González-García*[1], *Ane Arregi*[2], *Alba Jimeno-Romero*[3], *Amaia Irizar*[3], *Iraia García-Santisteban*[1], *Itziar Gonzalez-Moro*[4], *Corina Lesseur*[5], *Nora Fernandez-Jimenez*[1], *Jose Ramon Bilbao*[1]

[1]*University of the Basque Country (UPV/EHU), Leioa, Spain,* [2]*University of the Basque Country (UPV/EHU), Donostia-San Sebastian, Spain,* [3]*Biogipuzkoa Health Research Institute, Donostia-San Sebastian, Spain,* [4]*Biobizkaia Health Research Institute, Barakaldo, Spain,* [5]*Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, NY, USA.*

Background: Saliva is an accessible biological fluid that could potentially contain diagnostic markers for complex diseases. Methylation and expression quantitative trait loci (mQTL and eQTL) can reveal the link between GWAS SNPs and complex traits. This study explores whether genetic predisposition to common diseases is reflected on DNA methylation (DNAm) and gene expression profiles in saliva.

Material and Methods: In saliva samples from the general population, we constructed a cis-mQTL database (n = 345) to capture the impact of 5,052,978 genetic variants on DNAm levels (736,680 CpGs) and a cis-eQTL database (n = 277) with 38,040 genes. Results were integrated with the largest available GWAS on several cancers, cardiometabolic traits, and neurodegenerative disorders using Summary-based Mendelian Randomization (SMR). Additionally, we analyzed the influence of the CpG sites associated with those disorders on gene expression (eQTMs) in 271 individuals of the cohort.

Results: We created the largest public saliva-based cis-mQTL and cis-eQTL databases, identifying 123,451 mSites and 1,717 eGenes, respectively. Integration with GWAS revealed 436 CpG sites and 22 genes as potential biomarkers. Five eQTMs were identified from those CpG sites and genes pleiotropically associated with diseases, including breast and prostate cancers, squamous cell carcinoma, and coronary artery disease.

Conclusion: Our study offers a valuable resource with the largest saliva-based mQTL and eQTL databases, to facilitate biomarker discovery for systemic diseases. These findings emphasize the potential of saliva in the diagnosis of complex traits beyond the oral cavity.

P19.063.D Charting the landscape of therapeutic and potential adverse events associated with JAK inhibition using Mendelian randomization

Juan Antonio Miguel González[1], *Milagros Sanchez-Mayor*[1,2], *Polychronis Pavlidis*[3], *Urko M Marigorta*[1,4]

[1]*Integrative Genomics Lab, CIC bioGUNE, Basque Research and Technology Alliance (BRTA), Bilbao, Spain,* [2]*Department of Population Health Science and Policy, Center for Biostatistics, Icahn School of Medicine at Mount Sinai, New York, NY, USA,* [3]*School of Immunology and Microbial Sciences, King's College London, London, United Kingdom,* [4]*Ikerbasque, Basque Foundation for Science, Bilbao, Spain.*

Background: The JAK-STAT pathway has emerged as an effective therapeutic target for immune-mediated diseases (IMIDs). However, concerns about its positioning and potential safety risks remain. Mendelian randomization, which leverages genetic data to assess causal relationships, can be geared to characterize the safety and efficacy profiles of JAK inhibitors (JAKi).

Material and Methods: We selected 78 genes from the JAK-STAT pathway and used eQTL and pQTL variants as instrumental variables to investigate the effects of altering these genes on

IMIDs, cardiovascular risk, cancer-related malignancies, and opportunistic infections as potential adverse events.

Results: We performed a comprehensive MR analysis to evaluate the therapeutic potential and unintended effects of JAKi. Our findings confirm known associations with IMIDs, such as inflammatory bowel disease and psoriasis, supporting the relevance of the approach. The analyses also suggest potential benefits, such as JAK2 targeting associated with a reduced risk of myeloproliferative neoplasms. However, our results highlight the need for caution in specific cases where JAKi use is linked to an increased risk of adverse effects, such as herpes zoster infection.

Conclusion: Our pathway-wide analysis provides a comprehensive map of the therapeutic potential and adverse effects, while proposing novel associations that need to be pursued through epidemiological analyses and devoted trials. This approach offers a valuable framework to provide a preliminary guide to evaluate drug targets.

P19.064.A Sex-Specific HLA Alleles Contribute to the Modulation of COVID-19 Severity

*Serena Spartano[1], Maria Vittoria Faggiano[1], Giovanna Guidi[1], **Pino D'Ambrosio**[1], Alessandro Vaisfeld[1], Agnese Novelli[1], Salvatore Falqui[1], Antonella Cingolani[1], Lorenza Lambertenghi[2], Alessandro Visentin[2], Annamaria Azzini[2], Elda Righi[2], Enrico Maria Trecarichi[3], Maria Mazzitelli[3], Silvano Coletti[4], Ian Mous[4], Thomas Rademacher[5], Carlo Torti[1], Evelina Tacconelli[2], Massimo Fantoni[1], Roberto Cauda[1], Francesco D. Tiziano[1]*

[1]Università Cattolica del Sacro Cuore, Rome, Italy, [2]Università di Verona, Verona, Italy, [3]Università Magna Grecia Renato Dulbecco, Catanzaro, Italy, [4]Chelonia SA, Lugano, Switzerland, [5]University College London, London, United Kingdom.

Background: Coronavirus Disease 2019 (COVID-19) exhibits a spectrum of clinical manifestations, from asymptomatic to severe pulmonary dysfunction or death. The variability in COVID-19 severity has largely been attributed to the host's genetic characteristics, suggesting a polygenic genetic architecture, without significant evidence of sex-related genetic differences.

Material and Methods: In this Italian retrospective case-control study, we investigated the association between COVID-19 severity (severe vs. asymptomatic/oligosymptomatic healed individuals) and HLA gene variants, analyzed by next-generation sequencing (NGS).

Results: We identified significant HLA alleles (according to conventional nomenclature), SNPs and haplotypes in the HLA-B, -C, -F, -DQA1, -DRB1, and -DRB5 genes associated with COVID-19 severity. Interestingly, these variants showed biological sex-related effects. Also, we identified specific haplotypes associated with COVID-19 severity shared by different conventional HLA alleles, indicated here as "super-haplotypes". These haplotypes had a biological sex-specific impact on disease severity and markedly increased the risk of severe COVID-19 compared to conventional HLA alleles (odds ratio up to 15).

Conclusion: Our data suggest that the revision of the current HLA nomenclature may help identify variants with a stronger effect on disease susceptibility and that association studies could benefit from the stratification of patients by biological sex. If replicated in other disease models, these findings could help define the functional diversity in immune response between sexes, also based on the HLA system. Finally, due to the pandemic's mortality rate, we hypothesize here that COVID-19 may have acted as a natural selection trigger, leading to a drift in HLA allelic frequencies in the general population.

P19.066.C Gene-environment interaction in human traits and diseases: a story of misconception

***Hugues Aschard**[1], Zachary R. McCaw[2], Linon Denis[1]*

[1]Institut Pasteur, Paris, France, [2]The Voleon Group, Mountain View, CA, USA.

Gene-environment interaction typically refers to generative models where the effect of a genetic variation on an outcome depends on the value of a non-genetic risk factor. In a statistical model, an interaction is defined as the product of two variables (here $G \times E$). By construction, this interaction term is correlated with the original variables, producing collinearity. For example, if E is a binary exposure with a frequency of 0.8 and G is a SNP with a minor allele frequency of 0.2, the expected correlation $cor(G, G \times E) = 0.85$. Such high collinearity can severely impact the interpretability of linear models. In the context of GxE, this has two consequences. First, estimates from interaction models are expected to have larger variance than estimates from marginal models, which explains the low statistical power of existing $G \times E$ interaction tests. Second, collinearity makes the assessment of each term's contribution to the outcome's variance challenging. The current standard, built for mathematically convenient, consists in comparing the R-squared between the marginal ($Y \sim G+E$) and interaction models ($Y \sim G+E+G \times E$), attributing most of the variance explained to the simpler model (marginal effects) and assigning what remains to more-complex terms (the interaction effect). We show that this approach systematically underestimates the contribution of GxE and poorly qualifies the expected change in genetic effect across the exposure spectrum. We propose an alternative metric, named the Pratt Index, that resolves this bias. When applied in real UK Biobank data, we measured variance explained by GxE up to five fold larger than suggested by the standard approach.

P19.068.A The etiologic role of trimethylamine N-oxide (TMAO) in cardiometabolic diseases in East Asians: A Mendelian randomization study

***Chenxi Li**[1], Shan Luo[2,1], Baoting He[1], Hugh Simon Lam[3], Yangbo Sun[4], Cherry Y Leung[5], Gabriel M Leung[1], C Mary Schooling[1,6], Shiu Lun Au Yeung[1]*

[1]School of Public Health, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong, [2]Department of Family Medicine and Primary Care, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong, [3]Department of Paediatrics, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [4]Department of Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN, USA, [5]Department of Community Health Systems, School of Nursing,

University of California San Francisco, San Francisco, CA, USA, [6]School of Public Health and Health Policy, City University of New York, New York, NY, USA.

Background: Trimethylamine N-oxide (TMAO) is a novel risk factor of cardiometabolic diseases although its etiologic role remains unclear. Previous Mendelian randomization (MR) studies, a design less vulnerable to confounding, showed no association with cardiometabolic diseases albeit the instruments used were not very strongly related to TMAO. Furthermore, these studies were conducted in Europeans and hence limits generalizability to other populations, such as East Asians.

Material and Methods: We conducted a genome wide association study (GWAS) (N = 2458) to identify genetic predictors of urinary TMAO (SD of log) in a Chinese birth cohort ("Children of 1997"). Information from these instruments were applied to summary statistics from East Asian GWAS of 12 cardiometabolic diseases (N≤433540) and 11 risk factors (N≤216058) using a 2 sample MR design. Association of genetically predicted TMAO with outcomes was estimated using inverse variance weighting, followed by several sensitivity analyses.

Results: At the significance level of 5×10^{-6}, the GWAS identified 28 instruments related to TMAO. The F statistics ranged from 20.98 to 35.51, indicating low level of weak instrument bias. Genetically predicted TMAO was not associated with all cardiometabolic outcomes (FDR adjusted p value>0.571). We also observed no strong evidence for an association with cardiometabolic risk factors. Sensitivity analyses, and the use of different instrument selection criteria based on p values gave similar conclusion.

Conclusion: This study showed TMAO unlikely relate to cardiometabolic disease and its risk factors in East Asians. These null findings require further replications when larger TMAO GWAS in East Asians become available.

P19.069.B *HLA* genotype combinations impact allele association with Multiple Sclerosis risk

Anna Serova-Erard[1,2], Igor Faddeenkov[1], Stanislas Demuth[1], Sonia Bourguiba-Hachemi[1], Pierre-Antoine Gourraud[1,3], Nicolas Vince[1], ***Francois Cornelis***[2,1,4]

[1]Nantes Université, INSERM, CR2TI - Center for Research in Transplantation and Translational Immunology UMR1064, Nantes, France, [2]CHU Clermont-Ferrand, Génétique – Oncogénétique Adulte – Prévention (GENOAP), Université Clermont-Auvergne, Clermont-Ferrand, France, [3]Nantes Université, CHU Nantes, Pôle Hospitalo-Universitaire 11: Santé Publique, Clinique des données, INSERM CIC 1413, Nantes, France, [4]Université Clermont Auvergne, UFR de Médecine et des professions paramédicales, Clermont-Ferrand, France.

Associations between Multiple sclerosis (MS) and *HLA* involve 7 predisposing and 6 protective alleles (*HLA-DRB1*03:01/*08:01/*13:03/*15:01, HLA-DQB1*03:02, HLA-DPB1*03:01, LTA-H51P* and *HLA-A*02:01, HLA-B*38:01/*44:02/*55:01, HLA-DQA1*01:01, HLA-DQB1*03:01*, respectively). Here, we explore the effects of *HLA*-wide genotype combinations on MS associations.

We analysed WTCCC *HLA* data for 11,376 MS-cases (2005 diagnosis criteria) and 18,872 controls. We performed principal component analysis for European ancestry selection. *HLA* alleles were imputed using the *HIBAG R* package or inferred with proxy SNPs (*rs2229092, rs9273912* and *rs9277565*), and then recoded to consider only the 13 MS-associated alleles. We divided the dataset, using 20% to search for MS-associated genotype combinations and 80% to test them for replication. Replicated combinations were assessed on the whole dataset.

We retained 9,024 MS and 13,923 controls from European Ancestry. In the 20% sub-sample, we observed 776 genotype-combinations, 41 of which were nominally MS-associated ($P < 0.05$). In the 80% sub-sample, 22 of those were replicated (*P corrected* <0.05/41). In the full dataset the 14 predisposing combinations (OR 1.83–6.75) accounted for 23.61% of MS-cases and the 8 protective combinations (OR 0.30–0.57) for 4.29%. Surprisingly, some predisposing combinations carried "protective" alleles and vice versa: the MS-association of a given *HLA*-allele depends on the combination of *HLA*-wide-genotypes involving that allele. Strikingly, 4.29% of patients, diagnosed with MS prior to 2005, carried protective combinations: it will be interesting to investigate those combinations in patients who would now be diagnosed with Neuromyelitis optica spectrum disorder or Myelin oligodendrocyte glycoprotein antibody-associated disease. Those combinations could help clarifying disease heterogeneity and improve diagnosis.

P19.070.C Investigating the repurposing potential of cardiometabolic and hormonal drugs for cancer treatment using Mendelian randomization

Tessa Bate[1,2]*, Karl Smith-Byrne[3], Richard M. Martin[1,2,4], Philip C. Haycock[1,2], James Yarmolinsky[1,2,5]*

[1]Medical Research Council Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom, [2]Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom, [3]Cancer Epidemiology Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom, [4]University Hospitals Bristol and Weston NHS Foundation Trust and the University of Bristol, NIHR Bristol Biomedical Research Centre, Bristol, United Kingdom, [5]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, United Kingdom.

Background: Approved cardiometabolic and hormonal medications targeting hallmarks of cancer represent potential repurposing opportunities for cancer treatment. We aimed to investigate the repurposing potential of approved anti-hypertensive, lipid-lowering, anti-adiposity and anti-oestrogenic drugs for breast and ovarian cancer treatment.

Material and Methods: We obtained or constructed genetic instruments to proxy cardiometabolic traits (body mass index (BMI), low-density lipoprotein cholesterol (LDL-c), systolic blood pressure (SBP)), and anti-hypertensive (angiotensin-converting enzyme (ACE), beta-1 adrenergic receptor (ADRB1), sodium-chloride symporter (NCC)), lipid-lowering (3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR), Niemann-Pick C1-Like 1 (NPC1L1), proprotein convertase subtilisin/kexin type 9 (PCSK9)), anti-adiposity (gastric inhibitory polypeptide receptor (GIPR)) or hormonal (cytochrome P450 Family 19 Subfamily A Member 1 (CYP19A1)) medication targets. The genetically proxied effects of these traits or targets on breast and ovarian cancer mortality was investigated using drug-target Mendelian randomization (MR). Current indications for these medications were employed as positive control outcomes. Assessment of potential collider bias is ongoing.

Results: Evidence was observed for genetically proxied HMGCR inhibition (HR per SD decrease LDL-c: 1.81 [1.15–2.83]) and BMI lowering (HR per SD decrease BMI: 0.89 [0.82–0.97]) on risk of breast cancer mortality, and for genetically proxied PCSK9 inhibition on risk of ovarian cancer mortality (HR per SD decrease LDL-c: 1.52 [1.06–2.18]).

Conclusion: Aside from a protective effect of lower BMI on breast cancer survival, no strong evidence was observed to support repurposing of anti-hypertensive, lipid-lowering, anti-adiposity or anti-oestrogenic drugs for breast or ovarian cancer treatment. General limitations of applying MR to cancer prognosis outcomes and collider bias may have affected analyses.

P19.071.D Polygenic Risk scores in prediction of overall COVID-19 non-recovery

Anne Florentine Goemans[1], *Olivia C. Leavy*[1,2], *Beatriz Guillen-Guio*[1], *Erola Pairo-Castineira*[3], *Konrad Rawlik*[3], *J. Kenneth Baillie*[3], *Amisha Singapuri*[2], *Rachael A. Evans*[2], *Christopher E. Brightling*[2], *Louise V. Wain*[1,2], *Tim CD Lucas*[1], *PHOSP-COVID Collaborative Group*[4]

[1]*University of Leicester, Leicester, United Kingdom,* [2]*The Institute for Lung Health, NIHR Leicester Biomedical Research Centre-Respiratory, University of Leicester, Leicester, United Kingdom,* [3]*Roslin Institute, University of Edinburgh, Easter Bush, United Kingdom,* [4]

Background: Predicting those at highest risk of ongoing symptoms after COVID-19 remains challenging. We hypothesised that incorporating genetic risk for organ impairment might improve prediction of those at risk of non-recovery, and be informative about the relationship between pre-existing conditions and longer-term recovery.

Material and Methods: Using 450 cases and 389 controls from the post-hospitalisation COVID-19 study (PHOSP-COVID) and summary statistics from large scale GWAS, we use PRSice-2 to calculate genome wide genetic risk for traits related to COVID-19 - through shared pathophysiology, similar clinical features, and previously published associations - and determine their association with non-recovery post COVID-19. We then test the hypothesis that using these genetic scores improves performance when added to a clinical prediction model of non-recovery at 12 months.

Results: Genetic risk of several traits - including BMI ($p = 0.0002$), chest pain ($p = 0.0035$), hypertension ($p = 0.0054$), T2DM ($p = 0.0057$), atrial fibrillation ($p = 0.006$), CFS ($p = 0.0111$), T1DM (0.0114), bronchitis ($p = 0.014$), IBD ($p = 0.0352$), FVC ($p = 0.0374$), anxiety/depression ($p = 0.0452$) - were nominally associated with non-recovery at 12 months. The model with clinical predictors only (AUC: 0.696, CI: 0.661–0.731) was improved by the inclusion of genetic risk of anxiety/depression alongside the first 10 genetic principal components (AUC: 0.714, CI: 0.680–0.749, $p = 0.018$), increasing total prediction accuracy from 65% to 66.5%. Other traits conferred smaller performance increases.

Conclusion: This work suggests that whilst there is some genetic overlap between COVID non-recovery and a number of traits, inclusion of genetic risk into a clinical prediction model does not meaningfully add to clinical prediction

P19.072.A Carrier screening in the Old Order Amish and Mennonite populations in Ontario, Canada

Victoria M. Siu[1,2,3], *Wendy McCaul*[2], *C. Anthony Rupar*[1,2,3]

[1]*Schulich School of Medicine and Dentistry, Western University, London, ON, Canada,* [2]*London Health Sciences Centre, London, ON, Canada,* [3]*Children's Health Research Institute, London, ON, Canada.*

Background: Old Order Mennonite (OOA) and Old Order Amish (OOA) communities in Canada immigrated from Europe in the 18th and 19th centuries. They maintain a separate lifestyle with minimal influx of new genes. Founder effect has led to an extremely high prevalence of autosomal recessive disorders. Families decline Canadian universal healthcare, pay directly for medical care, and decline prenatal diagnosis. Children with treatable genetic disorders were being diagnosed late, with increased morbidity and mortality. We have sought to provide carrier screening to enhance healthcare delivery.

Material and Methods: Since 2011, targeted variant carrier screening for genetic disorders has been offered by midwives to OOA/OOM couples at their prenatal visit or when characteristic antenatal ultrasound anomalies are found. The current screen consists of 26 disorders, 12 of which have specific treatments and only 4 of which are on the provincial newborn screening panel. Babies at 25% risk have cord blood tested with 48 hour turnaround time.

Results: Carrier frequencies range from 1:4 to 1: 40, with 1:17 OOM couples and 1:7 Amish couples at risk to have an affected baby. About 6% of OOA newborns have been diagnosed at birth with one of the disorders. Rapid diagnosis of treatable disorders has resulted in timely, effective treatment for disorders such as maple syrup urine disease (BCKDHA) or biotinidase (BTD) deficiency. Families have avoided the high cost and delays of the diagnostic odyssey, especially for dual diagnoses.

Conclusion: We have demonstrated the benefits of culturally acceptable carrier screening in these genetically isolated populations.

P19.073.B The landscape of autosomal recessive pathogenic variants identified by the Carrier test in the population of Western Romania

Miruna Gug[1,2,3], *Tudor Popoiu*[4], *Nicoleta Andreescu*[2,5], *Dorina Stoicanescu*[2], *Simona Farcas*[2], *Alexandra Mihailescu*[2], *Ioana Mozos*[1,6], *Paula Roman*[7], *Cristina Gug*[2,3]

[1]*Doctoral School, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Department of Microscopic*

Morphology, Discipline of Genetics, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [3]Medical Genetics Office Dr. Gug, Timisoara, Romania, [4]Department of Functional Sciences, Discipline of Medical Information and Biostatistics 3, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [5]Genomic Medicine Centre, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [6]Center for Translational Research and Systems Medicine, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [7]Student, Department of Microscopic Morphology, Discipline of Genetics, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania.

Background: Carrier screening is used to identify individuals or couples at risk of having a child with an autozomal-recesive (AR) genetic disorder.

Material and Methods: A cross-sectional study was conducted from January 1, 2020 to December 30, 2024. The study group included 604 unaffected, unrelated individuals, of European origin, who underwent NGS using 2 multi-gene panels (164 and 302). In all cases with positive test results, a genetic consultation was performed to discuss the risk of recessive diseases in their descendants.

Results: The carrier frequency was 1.45. 469 (77.64%) individuals carried at least one AR gene mutation (range 1–7). Hemochromatosis was identified as the most common chronic condition (approx. 1 in 5). The second most common AR disorder was cystic fibrosis (1 in 9), followed by biotinidase deficiency (1:17), primary deafness related GJB2 (1:18), congenital adrenal hyperplasia caused by 21-hydroxylase deficiency (1:19), galactosemia (1:20) and Wilson disease (1:38). Our data suggest a higher risk for some AR diseases in this Romanian population, notably those associated with HFE (2 variants), CFTR (22 variants), BTD (2 variants), GJB2 (7 variants), CYP21A2 (12 variants), GALT (7 variants), PAH (12 variants), SERPINA1 (5 variants), SMN1 (3 variants) and ATP7B (8 variants) gene.

Conclusion: This is the first study in Romania that investigated the number and distribution of recessive alleles in the population of western Romania to assess the risk for various single-gene diseases. Identification of carriers of these variants must be followed by genetic counseling to inform them about reproductive risks and reproductive options.

P19.074.C Association of genetic susceptibility to influenza infection in type 2 diabetes risk and glycemic traits: A Mendelian randomization study

Shiu Lun Au Yeung[1], *Kin On Kwok*[2]

[1]The University of Hong Kong, Hong Kong, Hong Kong, [2]Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: Previous studies suggested influenza infection associated with increased type 2 diabetes (T2D) risk although these findings may be vulnerable to confounding. We conducted a Mendelian randomization (MR) study to explore the association of genetic susceptibility to influenza in T2D risk and glycemic traits.

Materials and Methods: We identified two single nucleotide polymorphisms (SNPs), rs16861415 (*ST6GAL1*) and rs2837112 (*B3GALT5*), strongly (p value $< 5 \times 10^{-8}$) and independently (r^2<0.001) associated with influenza infection (defined based on self reports and electronic medical records) based on a genome wide association study (GWAS) of influenza infection (Cases: 40,356; Controls: 1,407,560). These SNPs were applied to analyze the genetic susceptibility to influenza in relation to T2D and glycemic traits using corresponding GWAS (Cases: 242,283, controls: 1,569,734 for T2D, and N< = 209,605 for glycemic traits). Given the limited number of instruments, we only used inverse variance weighted method and explored pleiotropy through single SNP analyses and literature review.

Results: Weak instrument bias was unlikely based on F statistics (> 10). Genetic susceptibility to influenza infection did not increase T2D risk (OR: 1.12 per log odds, 95%CI: 0.84 to 1.49) and glycemic traits. Single SNP analyses showed a strong association of rs16861415 with T2D risk (p-value: 1.85×10^{-7}). Literature review indicated *ST6GAL1* was implicated in immune and inflammatory pathway and may be a source of horizontal pleiotropy.

Conclusion: Genetic susceptibility to influenza infection was unrelated to T2D. However, larger studies are necessary to replicate these findings, which help inform whether influenza control reduces T2D burden.

P19.076.A The contribution of the proteome to respiratory and rheumatic co-morbidities

Ruby Mae Woodward, *Frank Dudbridge*

University of Leicester, Leicester, United Kingdom.

Background: Diseases often cluster together, but the underlying causes are not always clear. Shared risk factors, such as high BMI or smoking, may contribute, but biological mechanisms remain underexplored. Proteins play a key role in disease processes, and genetic variation can influence protein levels. This study aims to identify proteins contributing to disease co-occurrence, potentially informing drug discovery.

Material and Methods: We analysed genetic data on ~5,000 circulating proteins, assessing their role in disease pairs. This study prioritises co-morbidities between respiratory and rheumatic diseases, evaluating genome-wide genetic correlations and applying partial genetic correlation to isolate protein-driven effects.

Results: Our genome-wide analysis identified several proteins with genetic correlations across disease pairs. Notably, COPD and gout shared 106 genetically correlated proteins ($P < 0.001$), with 14 maintaining significance at $P < 0.00001$. Similarly, asthma and gout shared 47 proteins at $P < 0.001$, with 6 at $P < 0.00001$, highlighting potential biological connections. Furthermore, partial genetic correlation analysis revealed proteins with significant contributions to disease relationships. For example, *NCAN* attenuated the genetic correlation between COPD and gout from 0.185 (SE = 0.028) to 0.128 (SE = 0.030), with a t-test result of 4.36 ($P = 1.3 \times 10^{-5}$). Similarly, *SLITRK3* attenuated the genetic correlation between asthma and gout from 0.128 (SE = 0.024) to 0.079 (SE = 0.026), with a t-test result of 4.00 ($P = 6.2 \times 10^{-5}$).

Conclusion: These findings highlight proteins with potential roles in multimorbidity, offering candidates for biomarker research and drug repurposing. Future work will assess protein levels in individuals with and without disease pairs.

P19.077.B Romania: Remarkable Progress in Genomics Research and Personalised Medicine

Maria Puiu[1], *Octavian Bucur*[1], *Simona Olimpia Dima*[2], *Adrian Nicolae Buzatu*[1], *Simona Ruță*[3], *Stefan Busnatu*[4], *Viorel Jinga*[5]

[1]The Institute for Research and Development in Genomics, Bucuresti, Romania, [2]Carol Davila University of Medicine and Pharmacy, Clinical Institute Fundeni, Bucuresti, Romania, [3]Carol Davila University of Medicine and Pharmacy; Stefan S. Nicolau Institute of Virology, Bucuresti, Romania, [4]Carol Davila University of Medicine and Pharmacy; Department of Cardio-Thoracic Pathology, Bucuresti, Romania, [5]Carol Davila University of Medicine and Pharmacy; Department of Urology, "Prof. Dr. Th. Burghele" Clinical Hospital, Bucuresti, Romania.

Background: The Institute for Research and Development in Genomics (ICDG), established by the Romanian Government and coordinated by the Carol Davila University of Medicine and Pharmacy of Bucharest (UMFCD), entered the European genomic landscape in 2023, the same year that Romania joined the "1 + Million Genomes" (1+MG) Initiative. The ICDG oversees research in genomics, bioinformatics and other Omics sciences, participates in the development of pilot projects and collaborates with 20 institutions from the National Genomics Research Network, led by UMFCD.

Materials and Methods: A key project is the Development of Genomic Research in Romania (ROGEN) and the establishment of the national reference genome, an essential resource for exploring local genetic diversity and for improving personalized diagnosis and treatment. By collecting and analysing genetic data representative of the Romanian population, this project supports precision medicine and innovation in healthcare. The ICDG also collaborates with European consortia, including the Genome Data Infrastructure, the Genome of Europe, Beyond 1 Million Genomes Plus, to foster the sustainable advancement of genomic research across Europe.

Results: Although results are pending, ICDG is already contributing to the European genomic research ecosystem by promoting the creation of the Genome EDIC and promoting the objectives of the GDI and GoE.

Conclusion: By creating a modern infrastructure, developing the National Genomic Medicine Strategy and training the workforce through European funds, ICDG, with the support of UMFCD, aim to incorporate genomics into the Romanian medical system and integrate Romanian genomics into the European context, supporting medical research and personalised medicine.

P19.078.C Genetic Variation Underpins the Role of Hyperuricemia in Mesoamerican Nephropathy

Iván Landires[1], *Karen Courville*[1], *Gumercindo Pimentel-Peralta*[1], *Raúl Cumbrera*[1], *Norman Bustamante*[1], *Mauricio Arcos-Burgos*[2], *Virginia Núñez-Samudio*[1]

[1]*Instituto de Ciencias Médicas, Las Tablas, Panama,* [2]*Universidad de Antioquia, Medellín, Colombia.*

Background: The present study aims to characterize the genetic predisposition for the development of Mesoamerican Nephropathy (MeN) in patients from Panama.

Material and Methods: We followed a cohort of 61 MeN patients, 30 exposed healthy donors to heat stress and agricultural work and 30 non-exposed healthy donors from Central Panama for more than six years diagnosed with a comprehensive clinical, laboratory, and genetics protocol. A Whole Exome Sequencing approach was performed in patients diagnosed with MeN using the criteria of the Pan American Health Organisation (PAHO).

Results: We found a variant harbored in the APOE gene (rs429358 c.388T>C p.(Cys130Arg) belonging to the APOE4 haplotype, identified in 26% (16/61) of the patients, that exhibits an extraordinary and significant distortion of segregation (Hardy Weinberg Equilibrium of $P = 0.001$) when compared to unaffected populations from disparate regions around the world that was not found in the control groups. Blood uric acid levels in MeN patients carrying the APOE4 haplotype had a significantly higher concentration than non-carriers individuals.

Conclusion: These results may be key findings, as previous studies by our group and others suggested that uric acid metabolic dysfunction after exercise and heat stress associated with dehydration-induced hyperuricemia is frequently observed in MeN patients. We hypothesize that agricultural work at high temperatures elevates uric acid, even in healthy individuals, and that those with genetic predisposition, carriers of the APOE variant reported in this study, would be at increased risk of developing MeN.

P19.079.D Epigenetic clocks predict cardiovascular events in a cohort of Pacific Peoples living in NZ but genetic variation may lead to spurious risk estimates

Samuel FP Gibbs[1], *Gregory T. Jones*[2], *Vicky A. Cameron*[1], *Tony Fakahau*[3], *Chris M. Frampton*[1], *Nikki J. Earle*[4], *Katrina K. Poppe*[4], *Richard W. Troughton*[1], *Allamanda F. Faatoese*[1], *Anna P. Pilbrow*[1]

[1]*Christchurch Heart Institute, Department of Medicine, University of Otago, Christchurch, New Zealand,* [2]*Department of Surgical Sciences, University of Otago, Dunedin, New Zealand,* [3]*Analytical Intel Limited, Auckland, New Zealand,* [4]*Department of Medicine, Faculty of Medical and Health Sciences, University of Auckland, Auckland, New Zealand.*

Background: Epigenetic clocks show associations with cardiovascular disease (CVD) in non-Pacific populations. We hypothesised that epigenetic clocks may predict CVD in Pacific Peoples living in New Zealand (NZ), but clocks trained in predominantly European populations may be confounded by single nucleotide polymorphisms (SNPs) more frequent in Pacific populations.

Materials and methods: Whole-blood DNA methylation was measured with Illumina MethylationEPIC arrays in the Pasifika Heart Study community cohort ($n = 183$, Table 1). We calculated five epigenetic clocks: Horvath, Hannum, PhenoAge, Dunedin Pace of Ageing measured from the Epigenome (DunedinPACE) and Dunedin Pace of Ageing Methylation (DunedinPoAm). We tested if epigenetic clocks improve CVD risk prediction using Cox models adjusted for the linear predictor of the NZ 5-year CVD risk score (which includes 13 risk factors). Loci from each clock were screened for trimodal distributions indicative of underlying SNPs. Genotyping was confirmed with Taqman assays.

Results: The DunedinPACE, Hannum age-adjusted and PhenoAge age-adjusted clocks predicted incident CVD independently of baseline CVD risk (Table 2). The clocks constituent loci appeared free from overlapping SNPs, except for cg05513157 in DunedinPoAM, where each rs76801084 minor allele (C>T, cohort minor allele frequency = 0.18) was associated with a 0.93-fold decrease in DunedinPoAm ($p = 5.6 \times 10^{-11}$).

Conclusion: Epigenetic clocks can potentially improve CVD risk prediction for Pacific Peoples living in NZ. However, confounding SNPs present a major issue for their clinical application as they may lead to spurious risk estimates in some individuals.

P19.080.A Pleiotropic effects of genetics variants on Substance Use Disorder and Sleep Patterns

Bruna P. Marquezini[1], *Mariana Moyses-Oliveira*[2], *Malú Zamariolli*[2], *Laís F. Berro*[3], *Vinícius Dokkedal-Silva*[1], *Dalva Poyares*[1], *Jose Carlos F. Galduroz*[1], *Monica L. Andersen*[1], *Sergio Tufik*[1]

[1]*Departamento de Psicobiologia, Universidade Federal de São Paulo, São Paulo, Brazil,* [2]*Sleep Institute, Associação Fundo de Incentivo à Pesquisa, São Paulo, Brazil,* [3]*Department of Psychiatry and Human Behavior, University of Mississippi Medical Center, Jackson, MS, USA.*

Background: The neurobiology of substance use disorder (SUD) and sleep disorders are connected; however; little is known about the genetic mechanisms underlying their relationship.

Material and Methods: We have conducted a phenome-wide association study (PheWAS) in the São Paulo Epidemiologic Sleep Study (EPISONO, N = 1,042). The single nucleotide variants (SNV) rs4238213 and rs4727799 were selected from previous SUD genome-wide association studies. We tested the association between SNV genotypes and 460 EPISONO phenotypes, using age, squared-age, sex, a socioeconomical index and principal components (PCs 1–10) as covariates. Non-parametric tests were applied to validate nominally significant associations. To correct for multiple testing, we applied Bonferroni correction, treating each trait as a test, independently for each SNV ($p = 0.05/460$). OpenGWAS R package was applied to search for the potential associations of SNVs with traits available in other cohorts.

Results: We found SNVs' nominally significant associations for 36 phenotypes, including traits related to substance use and sleep patterns. SNV rs4238213 was nominally associated with lower odds of tobacco use (OR = 0.78) and increased REM sleep latency ($\beta = 0.10$). rs4727799 associations included higher odds of tobacco use (OR = 1.61) and decreased chance of drowsiness while reading (OR = 1.37). Traits related to sleep-disordered breathing were implicated with both SNVs. In the OpenGWAS database search, rs4727799 showed potential associations with sleep duration and chronotype in UK Biobank.

Conclusion: Our results suggest a pleiotropic effect of both SNVs on SUD and sleep-related traits, highlighting the possibility of an overlap between the genetic factors involved in the risk for SUD and sleep phenotypes.

P19.081.B Secondary Findings in 81 ACMG Recommended Genes: Insights and Healthcare Implications in 1,000 Greek Exomes

Nikolaos Marinakis[1,2], *Stefania-Niki Minakaki*[1], *Faidon-Nikolaos Tilemis*[1,2], *Danai Veltra*[1,2], *Maria Svingou*[1,2], *Petros Barbarigos*[1], *Afroditi Kampouraki*[1], *Konstantina Kosma*[1], *Kyriaki Kekou*[1], *Joanne Traeger-Synodinos*[1], *Christalena Sofocleous*[1], *Periklis Makrythanasis*[1,3,4]

[1]*Laboratory of Medical Genetics, Medical School, St. Sophia's Children's Hospital, National and Kapodistrian University of Athens, Athens, Greece,* [2]*Research University Institute for the Study and Prevention of Genetic and Malignant Disease of Childhood, St. Sophia's Children's Hospital, National and Kapodistrian University of Athens, Athens, Greece,* [3]*Biomedical Research Foundation of the Academy of Athens, Athens, Greece,* [4]*Department of Genetic Medicine and Development, Medical School, University of Geneva, Geneva, Switzerland.*

Background: Exome/Genome Sequencing (ES/GS) often uncovers additional clinically actionable genetic variations, termed Secondary Findings (SF). The American College of Medical Genetics and Genomics (ACMG) recommends analyzing 81 (v3.2) specific genes linked to conditions where early intervention significantly improves outcomes, including hereditary cancers, cardiomyopathies, and metabolic disorders. In this Greek cohort of 1000 exomes, secondary findings in the recommended genes are addressed in the context of both frequency of pathogenic or likely pathogenic variants and healthcare management.

Material and Methods: Pathogenic Single Nucleotide (SNVs) and Copy Number Variants (CNVs) were assessed using the 5% minor allele frequency threshold, ClinVar submissions, and ACMG classification criteria. Variants contributing to phenotype-causing

genotypes, in corresponding patients of the cohort, were not included.

Results: A total of 86 variants in 29/81 genes were detected in 118 samples (12%). Of these findings, 61% were associated with autosomal dominant phenotypes and 39% with autosomal recessivephenotypes. Variants in cardiovascular phenotypes were 37%, following from variants related with hereditary cancers in 23% of which 40% were associated with breast and ovarian cancer. In addition, 25 samples were carriers for the Wilson syndrome. Genes with the highest variant rates include *BTD, ATP7B, TTN, MUTYH* and *RYR1*.

Conclusion: Our results highlight the value of ES/GS not only in the diagnosis of rare diseases, but also in identifying clinically actionable SF. Providing insights into the burden of actionable genetic variants in the Greek population, can help informed clinical practices and guide the implementation of precision medicine initiatives.

P19.082.C Geographic and Molecular Characterization of Duchenne Muscular Dystrophy in Ecuador: Insights from the National Registry

Juan C. Pozo-Palacios[1,2], *Bigoni Gabriele*[1], *Juan E. Galarza*[2], *Borys Abrigo*[2], *Carlos A. Reyes*[2], *Byron Sancan*[2]

[1]*Universidad de Cuenca, Cuenca, Ecuador,* [2]*HEREDITY SA, Quito, Ecuador.*

Background: Duchenne Muscular Dystrophy (DMD) is a progressive, degenerative, and disabling genetic disorder affecting primarily pediatric populations. In Ecuador, the National DMD Registry offers valuable data for analyzing the geographic distribution, genetic, and clinical characteristics of patients, allowing for meaningful comparisons with international populations. The registry also assists in identifying inequalities in access to diagnostic and treatment services.

Material and Methods: A secondary data analysis was performed using the Ecuadorian Registry of Muscular Dystrophy, focusing on 90 confirmed DMD cases. The analysis identified the most frequent pathogenic polymorphisms and assessed geographic clusters using Geographic Information Systems (GIS) tools. The molecular findings were compared with global studies on the prevalence of deletions, duplications, and point mutations.

Results: Point mutations were identified in 49.35% of cases, with c.9091G>T, c.6982A>T, c.9100C>T, and c.9802C>T being the most frequent, each with a 2.63% relative frequency. Deletions accounted for 42.86%, primarily in exons 44 and 45, consistent with global patterns. Duplications were found in 7.79% of cases. Furthermore, 22% of patients were receiving combined treatments, including corticosteroids and ataluren. However, access to specialized care was limited to certain regions, indicating significant geographic disparities in healthcare availability.

Conclusion: This study highlights recurrent molecular patterns in Ecuadorian DMD patients, with a notably higher prevalence of point mutations compared to international data. The geographic disparities in diagnostic and treatment access underscore the urgent need to strengthen genetic health services, ensuring equitable and effective care for DMD patients in Ecuador.

P19.084.A Epigenetic profiling of severe asthma patients treated with biological therapies

Giada Moresco[1], *Laura Fontana*[1,2], *Elena Maria Parazzini*[3], *Stefano Quaranta*[1], *Ornella Rondinone*[1], *Marzia Gianò*[1], *Enrico Zoroddu*[4], *Beatrice Re*[3], *Cristina Albrici*[3], *Cecilia Rosso*[5], *Francesco Ferella*[5], *Matteo Floris*[4], *Carlotta Pipolo*[5], *Giovanni Felisati*[5], *Michele Mondoni*[3], *Stefano Centanni*[3], *Monica R. Miozzo*[1,2]

[1]*Medical Genetics, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy,* [2]*Medical Genetics Unit, ASST Santi Paolo e Carlo Hospital, Milano, Italy,* [3]*Respiratory Unit, ASST Santi Paolo e Carlo Hospital, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy,* [4]*Department of Biomedical Sciences, Università degli Studi di Sassari, Sassari, Italy,* [5]*Otorhinolaryngology Unit, ASST Santi Paolo e Carlo Hospital, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy.*

Background: About 30 million people worldwide are affected by severe asthma, a chronic respiratory disease with persistent symptoms despite glucocorticoid therapy. Approved biological treatments, including Mepolizumab, Benralizumab, and Dupilumab, inhibit type-2 cytokines (IL-5, IL-4, IL-13) binding to respective receptors and are highly effective in reducing symptoms. However, their precise mechanism of action is not yet well known, and there are no molecular biomarkers for predicting/monitoring treatment efficacy to assist clinicians in choosing the best therapy. We focused on methylation signatures related to asthma pathogenesis and biological treatments, to identify molecular biomarkers for personalized therapy.

Material and Methods: We analyzed the genome-wide methylation profiles of the nasal epithelium collected from 4 controls and 11 severe asthma patients, before therapy initiation (T0) and after 6 (T1) and 12 months (T2) of therapy. Libraries were prepared using the Diagenode Premium RRBS V2 kit and sequenced on the Illumina Nextseq2000 instrument. Data analyses were performed using homemade pipelines to identify DMRs and enriched pathways.

Results: Significant hypermethylation was evident in the nasal epithelium of severe asthma patients, and therapy-induced methylation changes correlated with improved clinical outcomes (mainly with Dupilumab at T1). Genes belonging to immune (*GATA3*, *ALOX5*), neuronal (*DLGAP1*, *CNTNAP2*), and chromatin remodeling (*WDR5*, *ARID3A*) pathways emerged as differentially methylated, suggesting their relevance in asthma pathogenesis and treatment response. Further sequencing and expression analyses of candidate genes are ongoing.

Conclusion: Methylation signatures could represent novel biomarkers for patient stratification, personalized therapy, and to monitor treatment efficacy.

P19.085.B Clinical exome sequencing in 25 Moroccan pediatric cases: Impact, challenges, and lessons from a low- and middle-income country

Yasser Ali El-Asri[1], *Laila Bouguenouch*[1], *Badreddine Elmakhzen*[1], *Omar Askander*[2]

[1]*Medical Genetics & Oncogenetics Laboratory, Hassan II University Hospital, Fez, Morocco,* [2]*Mohammed VI Center for Research and Innovation, Casablanca, Morocco.*

Background: Clinical Exome Sequencing (CES) has emerged as a groundbreaking tool for investigating rare genetic disorders and alleviating the associated "diagnostic odyssey" that has historically burdened patients and healthcare systems. However, the global adoption of CES remains uneven, particularly in Low- and Middle-Income Countries (LMICs) where genetic testing still faces numerous challenges.

Material and Methods: In order to assess the impact of CES, as well as the challenges and unique aspects of its application in a resource-limited environment, We studied a cohort of 25 Moroccan children suspected of having genetic disorders who underwent exome sequencing.

Results: CES yielded a diagnosis in 68% (n = 16) of the cases, significantly higher than the 30–50% diagnostic yield typically reported in the literature. The identified variants covered a broad spectrum of genetic conditions. Key challenges included a lack of awareness and understanding of CES among both patients and their primary healthcare providers, which was observed in 100% of the cases. Additionally, 40% (n = 10) of the cases presented incomplete or difficult-to-trace medical histories and prior diagnostic investigations, while 20% (n = 5) faced challenges in follow-up care.

Conclusion: Despite limited resources and infrastructure in the Moroccan healthcare system, CES provided critical diagnostic insights that were previously unattainable, demonstrating its capacity to overcome barriers and emphasizing the importance of efforts to democratize genetic testing technologies globally.

Parhon University Hospital, Iasi, Romania,* [5]*Faculty of Medicine, University of Medicine and Pharmacy Grigore T Popa, Iasi, Romania.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disorder and the 4th leading cause of renal replacement therapy. Its prevalence is estimated at 1 per 1,000 in population-based studies and 2–4 per 10,000 in large healthcare databases, indicating that its true burden remains uncertain. The PoliGeNReg project is a two-year cross-border study in Romania and the Republic of Moldova, aiming to establish an ADPKD patient registry that integrates epidemiological, clinical, and genetic data to improve disease outcomes.

Materials and Methods: The PoliGeNReg project is developed in collaboration with Renal Disease Expertise Centers in North-Eeastern Romania and the Republic of Moldova. As a preliminary phase, data from ADPKD patient databases in both regions were retrospectively collected and analyzed.

Results: A total of 522 patients with ADPKD accessed medical care in the past five years, with 42.13% from the Republic of Moldova and 57.87% from Romania. The preliminary epidemiological analysis includes parameters such as sex distribution, age range, number of medical services accessed annually, and the most common complications. Further data analysis, including chronic kidney disease (CKD) staging, extrarenal manifestations and genetic findings is currently ongoing.

Conclusions: The PoliGeNReg project provides a structured framework for the epidemiological assessment of ADPKD in a bicentric cross-border setting. Preliminary results highlight the clinical heterogeneity of the disease and the need for standardized monitoring of CKD progression, extrarenal manifestations, and genetic profiles. Future efforts will focus on genetic testing, refined CKD staging, and improved long-term follow-up, contributing to better risk stratification and personalized treatment.

P19.087.D Frequency of polymorphic variants associated with impaired estrogen metabolism in the Bulgarian population

Olga Antonova[1], *Boryana Gerasimova*[2], *Viktoria Spasova*[3], *Blaga Rukova*[4], *Savina Hadjidekova*[1], *Vesela Karamisheva*[5,6]

[1]*DEPARTMENT OF MEDICAL GENETICS, MEDICAL UNIVERSITY OF SOFIA, Sofia, Bulgaria,* [2]*Re:Gena, LTD, Sofia, Bulgaria,* [3]*Medical University of Sofia, Sofia, Bulgaria,* [4]*Department of Medical genetics, Medical Faculty, Medical University of Sofia, Sofia, Bulgaria,* [5]*Second Gynecology clinic, SBALAG "Maichin dom", Sofia, Bulgaria,* [6]*Department of Obstetrician and gynecology, Medical University, Sofia, Bulgaria.*

Background: The metabolism of estrogens leads to formation of 3,4-quinones which are major carcinogenic metabolites of estrogens. These compounds react with DNA, generating mutations that can accumulate and contribute to the development of neoplasia. The aim of this study is to determine the frequency of polymorphic variants associated with impaired estrogen metabolism in Bulgarian population.

Methods: Eighty volunteers were tested for twelve common genetic variants: *CYP1A1* (Msp1 T>C), *CYP1A1* (Ile462Val), *CYP1B1* (Val432Leu), *CYP17A* (34T>C), *MnSOD* (Ala16Val), *GSTM1* (Ins/Del), *GSTT1* (Ins/Del), *COMT* (Val158Met), *MTHFR* (677C>T), *SULT1A1* (Arg213His), *NQ01* (609C>T), *FACTOR V* (G1691A). All participants completed a questionnaire to assess dietary, epidemiological, and occupational risk factors that interact with the genome to predispose to disease development and progression.

Results: Preliminarily results of the 31 patients demonstrate that:-16 % are carriers of *CYP17A*, *COMT* and *GSTT1* risk variants;-58 % have deletion of *GSTM1* gene and 10% are double carriers of GSTM1/GSTT1 deletion;-16 % are carriers of three out of twelve high-risk polymorphisms;-9,6 % carry three high-risk and four moderate-risk variants;-25,8 % carry five to seven intermediate-risk polymorphisms, cumulatively affecting estrogen detoxification.

Conclusion: Specific combinations of high- and intermediate-risk genetic variants are common in the studied population. Genetic screening that considers the cumulative effect of multiple polymorphisms may provide a more comprehensive assessment of an individual's risk for impaired estrogen detoxification and the development of estrogen-dependent disorders.

P19.088.A Causality between longitudinal adiposity changes and lung dysfunction

Yelyzaveta Poliakova[1,2], *Yevheniya Sharhorodska*[3,4], *Halyna Makukh*[5,6], *Marika Kaakinen*[7], *Marjo-Riitta Jarvelin*[8,7,9], *Inga Prokopenko*[4,10]

[1]Ivan Franko National University of Lviv, Lviv, Ukraine, [2]School of Public Health, Imperial College London, London, United Kingdom, [3]Institute of Hereditary Pathology of National Academy of Medical Sciences of Ukraine, Lviv, Ukraine, Lviv, Ukraine, [4]University of Surrey, Guildford, United Kingdom, [5]Lviv Regional Clinical Perinatal Centre, Lviv, Ukraine, [6]Scientific Medical Genetic Center "LeoGENE", Lviv, Ukraine, [7]University of Oulu, Oulu, Finland, [8]Imperial College London, London, United Kingdom, [9]Brunel University London, London, United Kingdom, [10]People-Centred Artificial Intelligence Institute, University of Surrey, Guildford, United Kingdom.

Background: Lung function (LF) is a critical indicator of respiratory health and overall well-being. Obesity-induced LF changes involve mechanical alterations and inflammation driven by adipokines, with timing of obesity onset being crucial. However, the causal impact of longitudinal changes in body mass index (BMI) remains unclear. Previous research has not fully explored whether changes in body size over time influence LF parameters, including forced expiratory volume in one second (FEV1), forced vital capacity (FVC), and their ratio (FEV1/FVC). This study aims to investigate the potential causal relationship between longitudinal body-size changes and LF.

Material and Methods: We conducted a two-sample Mendelian randomization (MR) analysis to assess the causality between longitudinal body-size change (LBC) and LF. LBC, as exposure, was derived from UK Biobank-based genome-wide association study (GWAS, n = 400,429, European ancestry), with association analyses performed using BOLT-LMMv2.4. LF outcomes (FEV1, FVC, and FEV1/FVC) were obtained from SpiroMeta consortium (Shrine et al.,2019;PMID:30804560).

Results: The Weighted Median method indicated a modest negative relationship between LBC and the FEV1/FVC ratio (beta[SE] = −0.19[0.095], p = 0.04). Potential causal relationship was observed between LBC and FVC using Weighted median method (beta[SE] = 0.19 [0.095], p = 0.04), both were nonsignificant after Bonferroni correction. We detected no causal effect of LBC on FEV1, and there was no evidence of pleiotropy.

Conclusion: Our findings suggest that LBC may have a modest impact on LF, particularly affecting FEV1/FVC and FVC. The overall relationship remains complex, highlighting the need for further research on the long-term effects of adiposity changes on respiratory health.

P19.090.C Differentially expressed genes of human lens epithelial cells in different stages of diabetic retinopathy

Muhaiyo Bartolo Khodjayeva[1], *Franco Mercieca*[2], *Rosienne Farrugia*[1], *Jean Paul Ebejer*[1]

[1]University of Malta, Msida, Malta, [2]Mater Dei Hospital, Msida, Malta.

Background: Diabetic retinopathy (DR) and cataract are leading causes of blindness. This study aims to identify differentially expressed genes (DEGs) in human lens epithelial cells across various stages of DR to elucidate disease mechanisms, identify biomarkers, and discover potential drug targets.

Material and Methods: A cross-sectional comparative transcriptomics study was conducted with 250 participants recruited from a cataract waiting list at a public hospital in Malta. Participants underwent physical examinations, ophthalmic assessments, and blood tests (e.g., full blood count, renal/liver function, glucose levels). Lens capsule samples were collected during cataract surgery from non-diabetic controls (G1) and patients with no DR (G2), non-proliferative DR (G3), diabetic macular oedema (G4), and proliferative DR (G5). RNA sequencing of 50 samples (10 per group) was performed using the DNBSEQ platform, and GO and KEGG pathway analyses were conducted using the Dr. Tom bioinformatics system.

Results: A total of 173 DEGs were identified. Significant DEGs were determined using a log2 fold change threshold of ≥1.5 for upregulation and ≤−1.5 for downregulation, with a Q-value <0.05. Compared with controls, one downregulated DEG was identified between G1 and G2, 68 DEGs (32 upregulated, 36 downregulated) between G1 and G3, 43 DEGs (29 upregulated, 14 downregulated) between G1 and G4, and 61 DEGs (35 upregulated, 26 downregulated) between G1 and G5. Bioinformatics analyses revealed key DEGs and their associated pathways.

Conclusion: This study provides insights into molecular mechanisms underlying DR, age-related cataract and diabetic cataract, identifying potential biomarkers and therapeutic targets.

Background: Allan-Herndon-Dudley Syndrome (AHDS) is a rare X-linked syndrome caused by pathogenic variants in the *SLC16A2* gene. The syndrome disrupts the transport of thyroid hormones into the brain, resulting in severe intellectual and motor disabilities in affected males. While over 300 affected males from 100 families have been reported, the exact prevalence remains unknown. Triiodothyroacetic acid (tiratricol) is currently under clinical trials. Limited knowledge of the natural history, the potential benefits of early intervention, and the absence of long-term follow-up data represent significant barriers to comprehensive care.

Material and Methods: This study leverages data from the French National Rare Disease Database to enhance epidemiological understanding of AHDS. Key parameters include patient prevalence, age distribution, follow-up status, and mortality rates. A dedicated electronic case report form (eCRF) was developed collaboratively with physicians and reference laboratories to capture longitudinal clinical and biological data, differentiating outcomes between treated and untreated patients.

Results: 56 individuals (52M/3F) with pathogenic *SLC16A2* variants have been identified with an estimated prevalence of <1 per million in France. The median age is 13 years (IQR 9–20). Ten patients have died, with a median age at death of 13 years. 13 individuals currently receive compassionate tiratricol therapy. The eCRF is scheduled for launch in 2025.

Conclusion: This study, grounded in a national epidemiological effort, addresses critical gaps in AHDS knowledge by collecting and comparing real-world data from treated and untreated patients. It aims to inform long-term follow-up, optimize patient care, and guide future therapeutic strategies for this disorder.

P19.092.A Advancing genomic analysis to resolve the diagnostic odyssey of rare diseases in a developing country

. ***Gunadi***[1], *Kristy Iskandar*[2], *Dewiyani Widasari*[1], *Wulan Anggrahini*[1], *Syallom Gita Maharani*[1], *Pramana Adhityo*[1], *Nabila Ardia Pramono*[1], *Ali Zainal Abidin*[1], *Auliya Suluk Brilliant Sumpono*[1], *Yunika Puspa Dewi*[3], *Tyas Ikhsan Hikmawan*[4]

[1]*Universitas Gadjah Mada/Dr Sardjito Hospital, Yogyakarta, Indonesia,* [2]*Universitas Gadjah Mada Academic Hospital, Yogyakarta, Indonesia,* [3]*Dr Sardjito Hospital, Yogyakarta, Indonesia,* [4]*Universitas Gadjah Mada, Yogyakarta, Indonesia.*

Background: The underrepresentation of Asian genomes hinders the progress of genomic medicine, particularly in developing countries. Indonesia, with its diverse population and approximately 13 million individuals affected by rare diseases, faces significant challenges in diagnosing these conditions. Many patients experience lengthy diagnostic journeys, which prolong treatment. The Biomedical & Genome Science Initiative (BGSi), launched by Indonesia's Ministry of Health, seeks to tackle these challenges by establishing a genomic research infrastructure that includes Dr. Sardjito Hospital as the genomic hub for rare diseases. The initiative follows a comprehensive genomic analysis framework encompassing biobanks, patient registries, genomic analysis, bioinformatics, molecular diagnostics, and personalized therapy development.

Material and Methods: Patients with rare diseases were enrolled through outpatient clinics and hospital wards. After obtaining informed consent, patient data were registered, and blood samples were collected, stored in our institution's and national biobank, and processed for DNA extraction. Exome sequencing was performed using the NextSeq 550 platform, while adaptive sampling was utilized for 200 targeted panel genes using PromethION technology.

Results: In 2024, 642 patients with a rare disease were recruited. We analyzed the exome sequencing of the DNA from 9 patients using the NextSeq 550 and conducted adaptive sampling of the DNA from 6 patients using the Promethion. After receiving the results, some diagnoses were changed, and the treatments were updated accordingly.

Conclusion: By employing a genomic approach, we revolutionize the diagnosis of rare diseases, establishing a foundation for precision medicine through improved genomic research infrastructure and national collaboration.

P19.093.B Ethnic differences in the frequency of *CFTR* gene variants in the Russian Federation

Rena A. Zinchenko, *Nika V. Petrova, Elena I. Kondratyeva, Nataliya Y. Kashirskaya*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Russia is a home to more than 190 ethnic groups, including small indigenous and autochthonous nations of the country. Cystic fibrosis (CF) is a genetically inherited disorder characterized by a wide range of clinical manifestations and genetic variations.

Material and Methods: Genetic testing of healthy population and people with CF (pwCF) of different parts of Russia.

Results: The most common *CFTR* variants among pwCF in Russia: F508del (51.44%), CFTRdele2,3 (6.10%), E92K (3.71%), 1677delTA (2.51%), 3849 + 10 kbC-T (2.24%), 2143delT (1.995), 2184insA (1.93%0, W1282X (1.73%), L138ins (1.71), N1303K (1.62%), G542X (1.47%). High population frequency of **E92K** was found in the Turkic-speaking groups of the Volga region (VR) and North Caucasus (NC): Chuvash (53.12%), Chechens (12.5%), Udmurts (6.8%), Tatars (2.4%); **W1282X** - in Turkic-speaking groups: Karachais (90%), Nogais (100%), Abazins (50%) and Ossetians (37.5%); **1677delTA** - in autochthonous peoples as the Abkhaz-Adygean (Abazins and Circassians over 30%) and Nakh groups: Chechens (81.3%) and Ingush (100%). It has also been detected in other ethnic groups from the NC region, such as Armenians (25%) and Georgians (25%). Since 2007 the National Neonatal Screening programme (NSP) for CF has been introduced. Interestingly, even considering the NSP, no pwCF have been identified so far in the Yakut and Kalmyk populations.

Conclusion: Interethnic differences in the spectra of *CFTR* gene variants were shown both in pwCF and in healthy population of different parts of Russia. The most significant variation was identified in variants E92K, 1677delTA, and W1282X. Further studies are necessary in different populations.

P19.094.C No evidence for a causal effect of thyroid function and disease on risk for attention- deficit/hyperactivity disorder: A two-sample Mendelian randomization study

Triinu Peters[1], *Lars Dinkelbach*[2], *Luisa Rajcsanyi*[1], *Anke Hinney*[1], *Raphael Hirtz*[3]

[1]*University Hospital Essen, Section of Molecular Genetics in Mental Disorders, Essen, Germany,* [2]*University Hospital Essen, Department of Pediatrics III, Essen, Germany,* [3]*Helios University Medical Centre Wuppertal - Children's Hospital, Witten/Herdecke University, Witten, Germany.*

Background: Attention-deficit/hyperactivity disorder (ADHD) is the most prevalent neurodevelopmental disorder among children, characterized by symptoms of inattention, hyperactivity, and impulsivity. These symptoms can overlap with those observed in

individuals with thyroid disorders, especially hyperthyroidism. Previous epidemiological and clinical studies have indicated an association between thyroid function and dysfunction and ADHD. However, these studies may be subjected to different sources of confounding.

Material and Methods: Mendelian randomization (MR) was employed to overcome the limitations of previous association studies, particularly reverse causation and residual confounding. The instrumental variables for thyroid stimulating hormone (TSH), circulating free T3 (FT3), and circulating free T4 (FT4) were derived from a genome-wide association study (GWAS) of 271,040 individuals of European ancestry. For hypo- and hyperthyroidism, Hashimoto's thyroiditis, and Graves' disease, a cross-population GWAS was used (1.216 to 15.434 cases, up to 630.000 controls). For ADHD, we used the most recent GWAS with 38,691 cases and 186,843 controls. To account for possible violations of MR assumptions, we performed two-sample MR using eight different methods.

Results: We found no causal effect of any thyroid function phenotype on the risk of ADHD.

Conclusion: Although ADHD and thyroid dysfunction have overlapping symptoms, there was no evidence of a causal relationship. However, the power to draw definitive conclusions regarding hyperthyroidism and Grave's disease was limited. Nevertheless, these data do not encourage routine testing of thyroid function in cases with ADHD in the absence of additional symptoms suggestive of thyroid dysfunction.

P19.095.D Identifying Potential Drug Targets for Brain Tumors through Mendelian Randomization Analysis

D. Han, *X. Jin, J. Li, Y. Gao;*

BGI research, Shenzhen, China

Background: Brain tumors are a major health threat with poor prognosis, and identifying effective drug targets for treatment is crucial. Mendelian randomization (MR) analysis has emerged as a powerful tool for discovering causal relationships between genetic variations and diseases. This study aimed to use MR methods to identify potential drug targets for brain tumors.

Material and Methods: We performed summary data-based Mendelian randomization (SMR) analysis, colocalization analysis, and two-sample Mendelian randomization analysis using data from genome-wide association studies (GWAS) and cis-expressed quantitative trait loci (cis-eQTL) databases. Sensitivity analyses were carried out to ensure the reliability of the findings.

Results: The analysis identified four potential drug targets for brain tumors: *FAM160B1*, *GMEB2*, *RP11-617D20.1*, and *TBC1D7*. *FAM160B1* was found to be a risk factor for brain tumors (odds ratio [OR] > 1), while *GMEB2*, *RP11-617D20.1*, and *TBC1D7* were identified as protective factors (OR < 1). These genes may serve as novel targets for therapeutic intervention.

Conclusion: This study identified four potential drug targets for brain tumors through Mendelian randomization analysis. These findings provide valuable insights for drug development and treatment strategies, with potential clinical applications for brain tumor therapy.

P19.096.A Plasma proteome-based prediction for COVID-19 vaccination response

Yue Yao[1,2], *Jingxin Li*[3], *Xia Shen*[2,4,5]

[1]*Fudan University, Shanghai, China,* [2]*Greater Bay Area Institute of Precision Medicine, Guangzhou, China,* [3]*Jiangsu Provincial Center for Disease Control and Prevention (Jiangsu Provincial Academy of Preventive Medicine), Nanjing, China,* [4]*Karolinska Institute, Stockholm, Sweden,* [5]*University of Edinburgh, Edinburgh, United Kingdom.*

The COVID-19 pandemic has posed a significant global health crisis, and although vaccines have been developed, the variability in individual immune responses remains poorly understood. Predicting vaccination outcomes before administration could help to optimize vaccine strategies for individuals. This study involved follow-up blood sample collection from 208 Chinese participants who received three doses of the inactivated COVID-19 vaccine. Using association studies and Mendelian randomisation (MR) analysis of proteins with changes in COVID-19 antibody levels, we identified 14 biomarkers significantly associated with the responses post-vaccination. Before vaccination, a protein-level predictive model could forecast vaccine effectiveness for the primary series ($r^2 = 0.174$), booster shot ($r^2 = 0.131$), and complete vaccination series ($r^2 = 0.114$). Notably, polygenic scores (PRS) derived from these proteins and COVID-19 infection traits also provided predictive ability. In particular, COVID-19 infection traits outperformed protein scores in predicting responses after the primary series and booster shot, while protein scores were more effective in predicting antibody changes following the complete vaccination series. This study highlights the potential of plasma proteome-based models and polygenic scores to predict COVID-19 vaccination outcomes, offering insights into the mechanisms of immune response variability and aiding in the development of personalized vaccination strategies.

Background: The 3rd French National Plan for Rare Diseases focuses on reducing diagnostic. The AnDDI-Rares network implemented a project to assess diagnostic evolution in France over a decade (2012–2022) with the integration of high-throughput sequencing technologies.

Material and Methods: This study analyzed diagnostic rates in French centers for "Developmental Anomalies and Malformative Syndromes," comparing randomly selected weeks in 2012 and 2022. Secondary outcomes included diagnostic delays, patient expectations, technologies used and genome sequencing efficiency.

Results: The number of patients included was 303 in 2012 and 350 in 2022, representing an 15.5% increase in clinical genetic activity in France over ten years. The diagnostic rate for patients coming for a first advice increased from 18.6% to 23.9%. Overall genome diagnostic yield was 28.8%. Among 57 undiagnosed patients from 2012 who expressed a desire to continue investigations, genome sequencing yielded an additional 33.3% diagnostic rate. The average waiting time for positive results decreased from a median of 3 years in 2012 to 1.0 years in 2022. In total, 164 parents completed questionnaires on diagnostic expectations, revealing evolving patient needs and attitudes over time. Significant heterogeneity in diagnostic strategies was observed across centers, highlighting the impact of genome sequencing.

Conclusion: These results highlight advancements in diagnostic practices and the pivotal role of high-throughput sequencing, supported by the France Genomic Medicine 2025 Plan. The challenges of recontacting patients after 10 years are evident. Persistent diagnostic requests and insights from long-term follow-up underscore the need for continuous patient engagement and tailored support strategies.

P19.098.C Mendelian Randomization approach to unraveling the genetic link between eating behavior and metabolic traits

Yanina Timasheva[1], *Zhanna Balkhiiarova*[2], *Gulnaz Korytina*[1], *Inga Prokopenko*[3], *Olga Kochetova*[1]

[1]*Institute of Biochemistry and Genetics Ufa Federal Research Centre Russian Academy of Sciences, Ufa, Russian Federation,* [2]*UNIVERSITY OF SURREY, Guilford, United Kingdom,* [3]*University of Surrey, Guildford, United Kingdom.*

Background: Disordered eating contributes to weight gain, obesity, and type 2 diabetes (T2D), yet the mechanisms linking eating behaviors to specific metabolic phenotypes remain unclear.

This study aims to identify genetic variants associated with eating behaviors and examine their causal relationships with metabolic traits using Mendelian randomization (MR).

Material and Methods: We investigated the association between genetic variants in 30 genes and eating patterns in 200 individuals with T2D f and 397 healthy controls from the Volga-Ural region. Eating behaviors were assessed using the Dutch Eating Behaviour Questionnaire (DEBQ), categorizing eating patterns into emotional, external, and restrained eating. Two-sample MR analyses were performed to assess causality between eating behaviors and metabolic traits, utilizing summary statistics from large international consortia, including the UK Biobank, MAGIC, and the Global Lipids Genetics Consortium.

Results: We identified significant genetic associations between specific polymorphisms and eating behaviors. Notably, *HTR2A* rs6313 was associated with emotional eating, and *HTR1D* rs623988 and *CDKAL1* rs9295474 with external eating. MR analysis showed that external eating was inversely associated with glycated hemoglobin (HbA1c) in people with metabolic syndrome (MetS) and was linked to various anthropometric traits in the GWAS cohorts, such as BMI, waist circumference, and hip circumference.

Conclusion: Our findings suggest a genetic basis for different eating behaviors and their influence on metabolic traits. External eating, in particular, was found to have a causal relationship with glycemic and anthropometric traits. These results highlight the importance of genetic factors in shaping eating behaviors and their potential impact on metabolic health.

P20 Pharmacogenomics and Drug Repurposing

P20.002.A A Transcriptome-Wide Association Study to uncover the genetic factors driving toxic responses after chemotherapy with fluoropyrimidines in colorectal cancer

Ceres Fernández Rozadilla[1], *Carmen Macías Real, Predoctoral*[1], *Ana Rita Simões*[1], *Claire Palles*[2], *David Kerr*[3], *Ian Tomlinson*[3], *Ángel Carracedo*[4]

[1]*Fundación Pública Galega Instituto de Investigación Sanitaria de Santiago (IDIS), Santiago de Compostela, Spain,* [2]*Institute of Cancer and Genomic Sciences, University of Birmingham, Birmingham, United Kingdom,* [3]*Department of Oncology, University of Oxford, Oxford, United Kingdom,* [4]*Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain.*

Background: Colorectal cancer (CRC) is a deadly malignancy often requiring surgery and chemotherapy. Standard treatments, including fluoropyrimidines (5-fluorouracil or capecitabine) with oxaliplatin or irinotecan, improve survival but often cause adverse drug reactions (ADRs), affecting outcomes. Pharmacogenomics optimizes therapy by identifying genetic variations influencing drug efficacy and toxicity. While genome-wide association studies (GWAS) have had limited success, transcriptome-wide association studies (TWAS) integrate transcriptomic data with GWAS to discover new risk loci.

Material and Methods: Using summary statistics from the QUASAR2 pharmacogenomics GWAS (one of the largest toxicity GWAS reported), we conducted TWAS with PrediXcan to identify genomic loci associated with chemotherapy-induced toxicity across 50 tissue types. We performed colocalization with fastENLOC and fine-mapping through FOCUS to explore gene causality. Overlapping genes from TWAS and fine-mapping were prioritized for functional analysis. Additionally, we developed a Polygenic Transcriptome Risk Score (PTRS) to categorize patients based on their individual toxicity risk.

Results: We discovered 157 genomic loci significantly associated with toxicity risk through regulation of the expression of 187 candidate genes. Our fine-mapping analyses identified 11 of these genes as causal to ADR development. The derived PTRS weights demonstrated potential for stratifying populations based on their genetic predisposition to chemotherapy toxicity.

Conclusion: Integrating transcriptomic data into pharmacogenomic has allowed us to significantly enhance the identification of genetic risk loci associated with chemotherapy-induced toxicity in CRC. Moreover, our transcriptome-based analyses can contribute to gaining a deeper understanding of the molecular mechanisms underlying ADRs and support the development of personalized therapeutic strategies for CRC patients.

P20.003.B Pharmacogenetic analysis from exome sequencing data, combined with pharmaco-clinico-biological co-interpretation facilitates personalized management in nephrology and kidney transplantation

Ilias Bensouna[1], *Virginie Deroche*[2], *Fanny Ponce*[3], *Karl-Dietrich Hatz*[4], *Nicolas Jauniaux*[4], *Amina Benomar*[2], *Isabelle Debrix*[2], *Florence Federspiel*[2], *Laure Raymond*[3], ***Laurent Mesnard***[1]

[1]*Nephrology department, Tenon Hospital, Paris, France,* [2]*Pharmacy department, Tenon Hospital, Paris, France,* [3]*Genetics department, Eurofins Biomnis, Lyon, France,* [4]*Sonogen INTLAB AG, Kehl, Germany.*

Background: Preemptive pharmacogenetic panel testing has been shown to reduce the incidence of clinically detectable side effects by 30%. At Sorbonne University, exome sequencing is routinely performed for adults with genetically-suspected Chronic Kidney Disease (CKD), offering not only molecular diagnosis but also underutilized pharmacogenetic insights. CKD patients, who are frequently polymedicated, could greatly benefit from pharmacogenetic data as treatment efficacy and safety are influenced by genetic factors.

Material and Methods: We analyzed pharmacogenetic profiles for 456 adult patients who underwent exome sequencing (Twist capture, Illumina NovaSeq6000, 2×150 bp) for unknown nephropathy. The analysis targeted 217 variants in 23 pharmacogenes following CPIC and DPWG guidelines. HLA-A and HLA-B loci were characterized using a dedicated pipeline. Star alleles translation and dosing guidelines were conducted using SONOGEN-XP (INTLAB AG). 68 patients received medication reconciliation and counseling to assess potential dosage adjustments or treatment modifications. 19 cases were reviewed in multidisciplinary consultation meetings (MCM).

Results: In-house pharmacogenetic analysis demonstrated complete concordance with reference samples from Get-RM and orthogonal methods (PCR amplification and LC-MS detection, Immucor for HLA profile study). 100% of patients had at least one actionable pharmacogene variant. Following MCM, all 19 patients received recommendations regarding drug dosing or contra-indications, totaling 60 individualized recommendations. Relevant drugs impacted by altered metabolism included tacrolimus (9/19), azathioprine (1/19), tramadol (6/19), clopidogrel (7/19), allopurinol (3/19), atorvastatin (5/19).

Conclusion: Pharmacogenetic analysis based on exome is a valuable tool in CKD management, helping prevent adverse drug effects. It is particularly beneficial for patients with forthcoming immunosuppressive therapy for kidney transplantation.

Background: Corticosteroids (CS) improve survival in severe infections, but variable responses have been reported. We aimed to identify genetic variants that could be associated with the differential CS response.

Material and Methods: We performed a genome-wide association study (GWAS) of 90-day mortality in a cohort of hospitalized COVID-19 patients treated with CS from the SCOURGE consortium (Ncases = 375, Ncontrols = 1,850). Logistic regression models were conducted in ~9.5M TOPMed-imputed variants (significance set at $p = 5 \times 10^{-8}$). Then, we tested the polygenic overlap of the CS response between COVID-19 and all-cause sepsis using PRSice-2 to perform polygenic risk scores (PRS). The PRS were tested on the independent CS-treated all-cause sepsis patients (Ncases = 21, Ncontrols = 69) from the GEN-SEP cohort. The best PRS model was subject to pathway-specific PRS studies using PRSet to evaluate which pathways were related to the differential CS response.

Results: Three *PLCG2* variants, two intronic and one in the 3'-UTR region, were associated with CS response in COVID-19 ($p_{lowest} = 2.79 \times 10^{-8}$). A PRS model including 31,374 variants reaching a $p_{threshold} = 0.0298$ in the GWAS was nominally associated with CS response among all-cause sepsis patients ($p = 0.044$). Pathway-specific PRS analyses revealed the regulation of the cholesterol biosynthesis pathway as the most significantly associated with CS response in all-cause sepsis ($p = 0.001$).

Conclusion: Overlapping polygenic effects of the CS response between COVID-19 and all-cause sepsis were observed. Genetic variants affecting the regulation of cholesterol biosynthesis pathway could underlie the CS response differences during critical illness.

P20.006.A OncoAID: an open access targeted anti-cancer database

O. Landau[1], *S. Magidi*[2], *K. Thangathurai*[1], *E. Rubin*[1];

[1]*Ben-Gurion University of the Negev, The Shraga Segal Department of Microbiology, Immunology and Genetics, Beer-Sheva, Israel;, Beer Sheva, Israel,* [2]*Worldwide Innovative Network (WIN) Association - WIN Consortium, Chevilly-Larue, France, Chevilly-Larue, France*

Background: The rapid expansion of targeted therapies, from the first FDA-approved agent to over 150 by 2024, underscores the growing need for comprehensive and accessible oncology resources. Existing databases often lack global regulatory perspectives and integrated clinical data, limiting the scope of precision oncology. To this end, we developed OncoAID, an open-access database of FDA-approved anti-cancer therapies, enriched with external datasets, global approvals and AI-driven summaries.

Material and Methods: OncoAID was curated by manually compiling a table of FDA-approved targeted therapies (single agents and combinations) from NIH and DRUGS.com with a few of their properties. Additional references to external databases (PHARMGKB, DrugBank, and TTD) were added to provide supplementary data. Global regulatory statuses (EMA, PMDA, NMPA, WHO) were verified through documented approvals and AI-assisted translations. Progression-free survival (PFS) and overall survival (OS) were extracted from the FDA and DRUGS.com, while cell line IC50 values were sourced from GDSC. Concise AI-generated (Chat GPT and Perplexity) summaries were also added.

Results: As of November 2024, OncoAID includes 576 regimens (303 unique treatments across 345 indications). Among 407 entries with PFS data, combination therapies significantly prolonged median PFS versus single agents (p = 0.0059). Approvals increased markedly, especially for combinations, and a Venn analysis revealed regulatory discrepancies among agencies.

Conclusion: By integrating global approvals, clinical outcomes, and experimental efficacy data, OncoAID offers a robust platform for precision oncology. Its open-access interface and AI-generated summaries support data-driven decisions. Ongoing expansions aim to refine AI validation, broaden coverage, and maintain continuous updates. Access at https://fohs.bgu.ac.il/rubinlab/oncoaid/.

P20.007.B Defining the genetic determinants of CD8+ T cell receptor repertoire in immune checkpoint blockade

Yang Luo[1], *Esther S. Ng*[1], *Gusztav Milotay*[2], *Orion Tong*[2], *Chelsea Taylor*[2], *Shawn Sun*[2], *Guangyi Niu*[2], *Robert Watson*[2], *Bo Sun*[2], *Sophie MacKay*[2], *James J. Gilchrist*[2], *Martin Little*[2], *Benjamin P. Fairfax*[2]

[1]*Kennedy Institute of Rheumatology, Oxford, United Kingdom,* [2]*MRC Weatherall Institute of Molecular Medicine, Oxford, United Kingdom.*

Background: CD8+ T cells are central to cancer response during immune checkpoint blockade (ICB) therapy, with their activity driven by antigen recognition via the T cell receptor (TCR) repertoire. However, the role of genetic variation in shaping this repertoire and influencing treatment outcomes remains underexplored.

Material and Methods: Here, we genotyped 250 cancer patients and profiled their CD8+ T cell TCR repertoire before and after ICB treatment to explore the dynamic relationship between genetic variants and TCR repertoire. We conducted a genome-wide and human leukocyte antigen (HLA)-focused analysis of CD8+ T cell TCR repertoire using a linear regression model correcting for genetic principal components (PCs), TCR PCs, age, gender and cancer type.

Results: In total, we identified 11 genome-wide significant cis associations and 10 trans associations, primarily to the HLA, with V-gene usage meeting permuted P-value thresholds. Notably, TCR clones containing V-genes associated with HLA were less likely to be persistent across treatment. In a single-cell experiment, we find cells with HLA-matched TCR clones have increased tumor reactivity expression profiles and patients with HLA-matched TCR clones have improved overall survival.

Conclusion: Our work indicates a complex interplay between genotype and TCR repertoire in the context of ICB treatment, which has novel implications for understanding determinants of treatment response and patient outcomes.

P20.008.C From biobanks to bedside: Utilizing genetic data of population biobanks to prevent life-threatening adverse drug reactions

Mette Bentsen[1], *Joseph Dowsett*[1], *Michael Schwinn*[1], *Johan Bundgaard, MD*[1], *Michael Asger Andersen*[2], *Christoffer Egeberg Hother*[1], *Frederikke Byron Pedersen*[1], *Mette Nordahl Svendsen*[3], *Sædis Sævarsdottir*[4], *Kari Stefansson*[4], *Erik Sørensen*[1], *Ole Birger Vesterager Pedersen*[5,6], *Christian Erikstrup*[7], *Sisse Rye Ostrowski*[1,6]

[1]*Department of Clinical Immunology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark,* [2]*Department of Clinical Pharmacology, Bispebjerg hospital, Copenhagen, Denmark,* [3]*Department of Public Health, University of Copenhagen, Copenhagen, Denmark,* [4]*deCODE Genetics, Reykjavik, Iceland,* [5]*Department of Clinical Immunology, Zealand University Hospital, Køge, Denmark,* [6]*Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [7]*Department of Clinical Immunology, Aarhus University Hospital Skejby, Aarhus, Denmark.*

Background: Adverse drug reactions (ADRs) constitute a major issue in health care settings, as exemplified by life-threatening reactions such as malignant hyperthermia (MH) in response to anesthetic drugs. While improvements in pharmacogenetics (PGx) research have revealed genetic risk factors for ADRs, the application of preventative PGx testing is currently limited. For this project, we aimed to use existing resources of population biobanks to identify individuals at risk of severe ADRs.

Material and Methods: We linked genotypes from individuals in the Danish Blood Donor Study (DBDS) (n = ~130.000) and Copenhagen Hospital Biobank (CHB) chronic inflammatory disease cohort (n = ~300.000) with Danish health care registries to integrate genotypes with diagnoses, hospitalizations and prescriptions.

Results: We confirmed a previously known association between rare variants in the RYR1 gene and the occurrence of MH (p = 6e-06). Importantly, we identified 23 individuals with RYR1 variants who did not have an MH diagnosis, potentially because DBDS participants, as healthy blood donors, have limited exposure to drugs triggering MH. Uniquely for DBDS participants, we have permission and a plan to contact individuals that we expect are unaware of their high genetic risk of MH.

Conclusion: This study proves that biobank-driven PGx testing could be an important tool for informing individuals about their genetic risk for ADRs. However, widespread application of PGx testing in biobanks is currently limited by legislation and ethical concerns. Legislators and researchers alike should move forward with discussions on whether using existing biobank data for PGx testing is not only a possibility, but also our ethical responsibility.

P20.009.D miRNAs target of MEG3 lncRNA could modulate the response to biological treatments in Psoriatic Arthritis patients

Giada De Benedittis[1], ***Chiara Morgante***[1], *Andrea Latini*[2], *Arianna D'Antonio*[1], *Maria Sole Chimenti*[1], *Giuseppe Novelli*[1], *Cinzia Ciccacci*[2], *Paola Borgiani*[1]

[1]*University of Rome "Tor Vergata", Rome, Italy,* [2]*UniCamillus–Saint Camillus International University of Health Sciences, Rome, Italy.*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory rheumatic disease. Although the identification of the correct therapy remains a critical issue, the introduction of biological drugs seems promising. Treatment response could also be affected by epigenetic factors, including long non-coding RNAs (lncRNAs). In fact, our recent paper on PsA patients suggested a possible involvement of the lncRNA MEG3 in the treatment response to two biological drugs, TNF- and IL17-inhibitors.

Material and Methods: To further investigate the possible role of MEG3 in treated PsA patients, we performed a bioinformatic analysis using different web-based miRNAs target prediction tools. Then, we analysed the expression levels of the identified miRNAs in a cohort of 54 PsA patients at the beginning of therapy (T0) and after 12 months (T12), in patients who responded to treatment. We also evaluated a possible association between *MEG3* genetic variants and the levels of its predicted miRNAs target.

Results: The prediction analysis identified four miRNA targets: miR-21-5p, miR-19b-3p, miR-19a-3p and miR-17-5p. Preliminary results showed that miRNA target expression levels do not differ between Responder and non-Responder patients at T0. However, in the group of Responder patients, we observed a significant decrease of miR-17 (P = 0.03) and miR-19b (P = 0.04) levels at T12 follow-up compared to T0. Moreover, we observed that rs941576 variant in *MEG3* gene seems to influence the expression levels of miR-19a (P = 0.04) and miR-19b (P = 0.005).

Conclusion: Our results suggest that MEG3 could modulate the efficacy of biological therapies in PsA patients acting on its miRNA targets.

G. De Benedittis: None. **C. Morgante:** None. **A. Latini:** None. **A. D'Antonio:** None. **M. Chimenti:** None. **G. Novelli:** None. **C. Ciccacci:** None. **P. Borgiani:** None.

P20.010.A Investigating the genetic factors of medication dosing using biobank-linked drug purchase data

*Laura B. Luitva[1], Silva Kasela[1], Kristi Krebs[1], Estonian Biobank Research Team[1], Märt Möls[2], Lili Milani[1], **Maris Alver**[1]*

[1]Institute of Genomics, University of Tartu, Tartu, Estonia, [2]Institute of Mathematics and Statistics, University of Tartu, Tartu, Estonia.

Background: Despite significant pharmacogenomics (PGx) insights into key biological pathways influencing drug response, the polygenic contribution to dose variability and the potential of electronic health records (EHRs) for maintenance dose estimation remain largely unexplored. To address this gap, we leveraged longitudinal drug purchase data (median follow-up 7.3 years) from Estonian Biobank to derive medication dose metrics and investigate genome-wide associations.

Methods: We analyzed statins, warfarin, metoprolol, antidepressants, and antipsychotics, deriving daily doses per purchase, and median and maximum doses as consolidated metrics across purchases. Associations with polygenic scores (PGSs) for 16 traits were assessed using linear mixed models and multivariable regression with forward stepwise approach and Bonferroni correction. Genome-wide scans (GWAS) were followed by gene set enrichment analyses for PGx genes.

Results: Sample sizes ranged from 684 (antipsychotics) to 20,642 (statins), with median doses reflecting typical maintenance doses. PGS for indicator trait was significant for statins (coronary heart disease PGS; beta = 0.02, $P = 5.9 \times 10^{-10}$) and metoprolol (systolic blood pressure PGS, beta = 0.03, $P = 7.5 \times 10^{-13}$). Body mass index PGS was linked to daily doses of statins (beta = 0.02, $P = 6.4 \times 10^{-7}$), metoprolol (beta = 0.03, $P = 1.4 \times 10^{-14}$), and warfarin (beta = 0.03, P = 0.001), whereas educational attainment PGS showed opposing associations with statins (beta = −0.03, $P = 5.8 \times 10^{-4}$) and antidepressants (beta = 0.01, P = 0.002). Median and maximum doses showed similar but weaker associations. GWAS confirmed signals for metoprolol (*CYP2D6*, $P = 6.3 \times 10^{-21}$) and warfarin (*CYP2C9*, $P = 8.9 \times 10^{-60}$; *VKORC1*, $P = 4.2 \times 10^{-148}$), and gene enrichment revealed PGx relevance for statins (P = 0.006).

Conclusion: This study illustrates feasibility of deriving medication doses from EHRs and highlights independent contributions of polygenic liability and PGx factors to dose variability.

P20.011.B *PCSK9* Variants and Their Impact on Glucose Metabolism and Type 2 Diabetes Susceptibility

*Zhanna Balkhiyarova[1,2,3], Yinglai Qi[3], Vincent Pascat[3], Yevheniya Sharhorodska[1], Alessia David[3,4], Ben Jones[3,4], Chioma N. Izzi-Engbeaya[3,4], **Inga Prokopenko**[1,2]*

[1]University of Surrey, Guilford, United Kingdom, [2]People-centered AI Institute, University of Surrey, Guilford, United Kingdom, [3]Imperial College London, London, United Kingdom, [4]Imperial College Healthcare NHS Trust, London, United Kingdom.

Background: Lipid-lowering medications, particularly statins (HMG-CoA reductase inhibitors), have significantly reduced cardiovascular events and mortality but are linked to an increased risk of type 2 diabetes (T2D). Similarly, inactivating mutations in *HMGCR* are associated with T2D. Proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors, which effectively lower cholesterol, have yielded conflicting data on their role in glucose metabolism and T2D risk. Exploring genetic factors may provide valuable insights to inform clinical practice.

Material and Methods: This study examined the relationship between 226 *PCSK9* missense variants and metabolic traits, including LDL cholesterol, random glucose, and T2D, in 469,835 individuals from UK Biobank with whole-exome sequencing data. Statistical methods included single-variant analysis (PLINK), SKAT-O test, and unsupervised hierarchical clustering to identify potential variant groups of missense variant phenotypic effects.

Results: Single-variant analysis revealed significant associations between rs374014696 (Ala242Val, OR[95%CI] = 0.51[0.40–0.65], *p-value* $= 1.022 \times 10^{-7}$) and rs773660398 (Ala44Thr, OR: 1.50 [1.26–1.78], *p-value* $= 6.735 \times 10^{-6}$) with higher random glucose levels. Clustering analyses identified distinct variant groups. Cluster 1 variants were linked to lower LDL cholesterol and higher glucose. Cluster 2 variants were associated with lower T2D risk, while Cluster 3 showed a combination of lower LDL, higher glucose and T2D risk. Cluster 4 was associated with higher LDL cholesterol and likely elevated cardiovascular risk.

Conclusion: These findings suggest that certain *PCSK9* missense variants are associated with cholesterol reduction, higher glucose levels, and higher T2D risk. Genetic profiling may optimise lipid and glucose management strategies, emphasising the need for further studies in diverse populations.

P20.012.C The genetics of treatment resistant depression in the Pakistani DIVERGE cohort

*Muhammad Umar[1], Arsalan Hassan[2,3], Igor Pupko[1], Marius Cotic[1,4], Fahad Hussain[3], Bakht Khizar[3], Inzemam Khan[3], Elvira Bramon[1], Glyn Lewis[1], Muhammad Ayub[1], **Karoline Kuchenbaecker**[1,5]*

[1]Division of Psychiatry, University College London, London, United Kingdom, [2]BROAD Institute, Boston, MA, USA, [3]Institute of Omics and Health Research, Peshawar, Pakistan, [4]Department of Genetics and Genomic Medicine, Great Ormond Street Institute of Child Health, University College London, London, United Kingdom, [5]Genetics Institute, University College London, London, United Kingdom.

Background: Treatment resistant depression (TRD) is responsible for half of the disease burden. Research on TRD from low-and-middle income countries is scarce. We take advantage of the deep phenotyping in DIVERGE, the first large genetic epidemiological study of depression in Pakistan (N = 13,000), to investigate risk factors for TRD.

Material and Methods: TRD was defined as minimal to no symptom relief after antidepressant treatment lasting at least 12 weeks and with evidence of good/moderate medication adherence. Illumina's Global Diversity Array was used for genotyping and the DRAGEN array caller to derive CYP2D6 and CYP2C19 metabolizer groups. Factors were tested for association with TRD using multilevel logistic regression.

Results: Using data from 3,677 eligible patients (34 % with TRD), we found that social support and parents being first cousin were associated with lower risk (OR = 0.56, p = 0.001, OR = 0.81, p = 0.016, respectively) whilst psychotic symptoms and suicidal behaviour were linked to higher risk of TRD (OR = 1.35, p = 0.04, OR = 1.02, p = 0.029). In 1,085 patients with CYP enzyme phenotype data, poor (OR = 1.7, p = 0.02) and ultra-rapid (OR = 3.27 p = 0.001) metabolizers for *CYP2C19* were associated with TRD. A pilot GWAS of TRD in 1,500 patients yielded three loci associations at suggestive threshold p < 5 × 10-5 including

rs2392034 with nearby ST6GALNAC3 relevant to neuronal biology and cell integrity.

Conclusion: Studying diverse populations is important to identify population specific risk factors for TRD. This study was successful in identifying preventable risk factors and supports the importance of pharmacogenetic biomarkers in predicting TRD.

P20.013.D Exogenous hormones and cardiovascular disease risk: Decoding the molecular mechanisms of menopausal therapy

Pascal Mutie, Tayebeh Azimi, Fatemeh Hadizadeh, Torgny Karlsson, Åsa Johansson

Uppsala university, Uppsala, Sweden.

Background: Menopausal hormone therapy (MHT) and its association with cardiovascular disease (CVD) is a concern for many women. Recently, we published the most comprehensive study on contemporary MHT use and CVD risk utilizing Swedish national registers. We identified that various MHT formulations, including combined estrogen-progestin therapies, estrogen-only, and tibolone and different routes of administration, such as oral and transdermal, exhibit variable effects on CVD risk[1]. However, the underlying molecular mechanisms remain unclear.

Methods: To identify molecular mediators responsible for the increased risk of stroke and myocardial infarction during MHT use, we conducted a two-stage study. First, we identified proteomic changes associated with MHT use among 16,000 post-menopausal women in the UK Biobank. Second, we established the causal link between proteins and disease risk using a two-sample Mendelian randomization approach.

Results: Out of 2,924 proteins measured, 821 were associated with at least one type of MHT, with the highest number for orally administered products containing estrogen. For stroke, we identified seven proteins (FDR $q < 0.05$) that mediate the effect of MHT, including F11, a key protein in the coagulation system. For myocardial infarction, we identified six proteins, including CD34 previously linked to atherosclerosis and myocardial infarction.

Conclusion: The strong association between orally administered MHT products and both protein expression and CVD risk[1] is likely mediated through first-pass metabolism of these products. Identifying the proteins that mediate the effect of MHT on CVD could reveal new potential targets for intervention to mitigate the CVD risk associated with MHT use.

P20.014.A Regulatory polymorphisms of *MSH6*, *MSH2* and *PPP1R21* genes affect survival of immunotherapy-treated lung cancer patients

Martina Esposito[1], *Sara Noci*[2], *Francesca Minnai*[1], *Tania Camboni*[1], *Eleonora Mangano*[1], *Manuela Gariboldi*[2], *Elisa Frullanti*[3], *Claudia Bareggi*[4], *Elena Collovà*[5], *Serena Girelli*[6], *Sheila Piva*[6], *Gabriella Farina*[6], *Arianna Pagliaro*[7], *Luca Toschi*[7], *Luca Sala*[8], *Diego Cortinovis*[8], *Francesca Colombo*[1]

[1]*Consiglio Nazionale delle Ricerche - Istituto di Tecnologie Biomediche, Segrate, Italy,* [2]*Istituto Nazionale dei Tumori, Milano, Italy,* [3]*University of Siena, Siena, Italy,* [4]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [5]*ASST Ovest Milanese Legnano, Legnano, Italy,* [6]*ASST Fatebenefratelli-Sacco, Milano, Italy,* [7]*IRCCS Humanitas Research Hospital, Rozzano, Italy,* [8]*Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy.*

Background: Immune checkpoint inhibitors (ICIs) have improved survival in non-small cell lung cancer (NSCLC) patients, however many patients do not respond to treatment. Identifying markers of ICI response remains an unmet clinical need. This study hypothesizes that host genetics influence the response to ICIs, contributing to variability in efficacy among individuals

Material and Methods: We conducted a genome-wide association study (GWAS) in patients with NSCLC receiving ICI monotherapy with nivolumab, pembrolizumab, or atezolizumab, to identify germline variants associated with objective response rate (ORR), progression-free survival (PFS) and overall survival (OS) at 24 months after initiation of ICI therapy. Association analyses were performed for ORR (logistic regression using PLINK2 software) and survival (Cox proportional hazards model, using GenAbel package in R environment), with appropriate covariates

Results: We identified a locus on chromosome 2 (comprising more than 250 variants) associated with OS, with the top ten variants having a hazard ratio >1 and $P\text{-value} = 6.3 \times 10^{-8}$. The most significant polymorphisms were regulatory variants of genes at the locus, such as *MSH2*, *MSH6*, and *PPP1R21*, which play a role in the mismatch repair and endosomal trafficking, and may influence response to immunotherapy

Conclusion: This study identifies an association between a genomic locus on chromosome 2 and OS in NSCLC patients treated with ICI. Although these results require validation in larger cohorts and functional studies to elucidate the underlying mechanisms, they highlight the potential of germline variants as predictive biomarkers of response to ICI.

Hospital Universitario 12 de Octubre, Madrid, Spain. ERN-LUNG, European Reference Network on rare lung diseases (pulmonary hypertension)., Madrid, Spain.

Pulmonary arterial hypertension (PAH) is an infrequent and progressive disease characterized by sustained increased pressure in the pulmonary arteries, leading to high morbidity and mortality. Pharmacogenetics (PGx) enables personalized treatments through the analysis of genetic variants that affect the pharmacokinetics and pharmacodynamics of medications, thus optimizing the efficacy and safety of therapies.The aim of this study is to evaluate the impact of actionable genetic variants on the therapeutic response of PAH patients through a comprehensive pharmacogenetic analysis in a cohort of 100 patients from whole genome sequencing (WGS).Phased VCF files from PAH patients were analyzed using bioinformatics tools such as PharmCAT, StellarPGx, and xHLA. The analysis focused on key genes involved in the metabolism of level 1 medications, including warfarin and statins. Personalized PGx reports were generated, and the frequency of relevant variants in the cohort was evaluated.All patients presented between 7 and 60 PGx recommendations, with a mean of 28 recommendations per patient. For warfarin and statins, recommendations were obtained for 26.42% of the cohort. For statins, 31.74% of the recommendations were associated with ABCG2, CYP2C9, and SLCO1B1. For warfarin, 26.19% were linked to CYP2C9, CYP4F2, and VKORC1. The cis or trans configuration of haplotypes reinforced the accuracy of the recommendations.

This study demonstrates the high prevalence of actionable pharmacogenetic variants in patients with PAH, showing that integrating PGx into clinical practice can significantly improve therapeutic outcomes, consolidating its role in personalized medicine.

P20.016.C Comparison of star-allele caller performances on genotyping and sequencing data at different geographic scales

Marc B. Gros-La-Faige[1], *the POPGEN study group*[2], *FranceGenRef consortium*[2], *Emmanuelle Genin*[1,3], *Anthony F. Herzig*[1]

[1]*Inserm, Univ Brest, EFS, UMR 1078, GGB, Brest, France,* [23]*CHRU Brest, Brest, France.*

Pharmacogenetics is the study of genetic variants responsible for variable response to medication. These variants can explain alternate drug responses, and understanding their effects thus represents a key public health issue. To standardize pharmacogenetics studies, a specific nomenclature is used: the star-alleles, which associates haplotypes with the activity of a given pharmacogene. Such haplotype calling can be influenced by population origin, the complexity of the genomic region in question and choice of reference data; many star-allele callers have been developed with little insight on their performance in different scenarios.

The objective of this study is to determine the performances of the different tools available. To do this, we used sequencing data from the 1000 Genomes and FranceGenRef projects.

To this end, we have benchmarked different pipelines of star-allele annotation. We have observed some discrepancies between the output of star-allele annotation pipelines, coming from differences in the reference database used, the method employed and the range of each pipeline in terms of gene coverage and variant detection. We have also evaluated the impact of imputation on star-allele calling, examining its influence on calling accuracy and downstream phenotype prediction to assess the reliability of imputed data. We provide recommendations on which tools to use regarding the data available, the population observed and the gene studied.

This study provides insights into the strengths and limitations of different star-allele callers used for inferring unobserved data. These findings contribute to the assessment of the potential benefits of personalized care informed by pharmacogenetic variant information.

P20.017.D Genetic Clustering of *GLP1R* Variants Reveals Diverse Impacts on Metabolism and Mental Health

Zhanna Balkhiyarova[1,2,3], *Giuseppe Deganutti*[4], *Yinglai Qi*[3], *Christopher A. Reynolds*[4], *Ben Jones*[3,5], *Inga Prokopenko*[1,2]

[1]*University of Surrey, Guilford, United Kingdom,* [2]*People-centered AI Institute, University of Surrey, Guilford, United Kingdom,* [3]*Imperial College London, London, United Kingdom,* [4]*Coventry University, Coventry, United Kingdom,* [5]*Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Glucagon-like peptide-1 receptor (GLP-1R) plays crucial role in glucose metabolism and insulin secretion. GLP-1R agonists target GLP-1R while simultaneously bring changes to body weight and mental health, including depression. Missense variants in *GLP1R* gene change response to GLP-1R agonists by affecting the receptor structure and function, potentially leading to side effects. We investigated *GLP1R* gene variant's role in glucose metabolism, body mass index (BMI), and depression.

Methods: We analysed 72 coding missense variants in *GLP1R* gene from UK Biobank whole-exome sequencing data, determining their effect on structure via simulations, function via experimental evaluation of MiniGs-coupling/endocytosis, and associations with blood glucose, HbA1c, type 2 diabetes (T2D), BMI, and depressive phenotypes via association analysis with SAIGE, followed by unsupervised hierarchical clustering.

Results: We identified five distinct clusters of *GLP1R* variant structural/functional/phenotypic effects across six metabolic/mental phenotypes, determining their respective pathophysiological effects. Specifically, ClusterA 22 variants associated with improvement in metabolic/mental health. ClusterB 16 variants had positive effects on mental health, but no improvement in metabolic health. ClusterC 15 variants showed no improvement in metabolic health, potential issues with mental health. ClusterD 12 variants had positive metabolic health effects, but associated with mental health issues. Finally, ClusterF 7 variants lowered adiposity alongside glycaemic/mental health issues.

Conclusion: We report mechanistic heterogeneity of *GLP1R* variant effects on glucose metabolism, adiposity and psychological health. These mechanistic clusters suggest that individuals treated with GLP-1R mimetics respond differently to treatment, depending on their genetic composition. These insights should inform development of stratified treatment strategies.Funding: Diabetes UK 20/0006307

P20.018.A Pharmacogenomic insights into stroke: genetic variants influencing drug metabolism, anticoagulation, and risk in Asian populations

Shin-Yi Tsai[1,2,3], *Frans R. Tamara*[2], *Sheng Hsieh*[2], *Jan-Gowth Chang*[4]

[1]*Department of Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, USA,* [2]*Department of Medicine, Mackay Medical College, New Taipei City, Taiwan,* [3]*Department of Laboratory Medicine, Mackay Memorial Hospital, Taipei, Taiwan,* [4]*Show Chwan Healthcare System, Changhua City, Taiwan.*

Background: Stroke remains a leading cause of mortality worldwide, with mitochondrial dysfunction playing a critical role in its pathogenesis. Recent findings have elucidated the relationship between pharmacogenetic variants and the increased risk of stroke, particularly in certain conditions. However, using pharmacogenetics in clinical practice to mitigate the risk of adverse drug reactions and to contribute to more efficient healthcare delivery remains underexplored. This study aims to integrate genomic data to enhance precision medicine strategies in high-risk populations and adverse-effect prevention in susceptible populations.

Material and Methods: We conducted a retrospective cohort study involving 605 stroke patients and 1493 controls from Taiwan Biobank. Participants underwent whole-genome sequencing using the Next-Generation Sequencing Analysis Acceleration Platform v20230823 and Illumina DRAGEN v3.7.5.

Results: Our analysis identified significant associations between specific pharmacogenetic variants and stroke risk, shown in Table 1. Variants include CYP3A5 (3/3), poor metabolism of statins, and anticoagulants, suggesting a strong predictive value for stroke risk in the general population; ABCG2 rs2231142 (T), increasing uric acid levels, linked to stroke risk; CYP4F2 (3), affecting vitamin K metabolism, altering warfarin response.

Conclusion: Our findings underscore the critical role of pharmacogenetic testing in the personalization of medication therapy, especially in the context of managing stroke risk. Integrating individual genetic profiles into clinical decision-making makes it possible to tailor pharmacological interventions more precisely, optimizing therapeutic efficacy. This approach ensures that drug types and dosages are specifically adapted to individual genetic dispositions, significantly enhancing treatment outcomes.

The top 15 alleles with frequencies exceeding 2% within the stroke cohort

P20.019.B Development of a novel, highly inclusive qPCR genotyping assay to detect DPYD decreased and no function variants directly from EDTA whole blood

Anna Gasior[1], *Daria Law*[1], *John McDermott*[2,3], *William Newman*[2,3], *Amy Coles*[1]

[1]*APIS Assay Technologies, Manchester, United Kingdom,* [2]*Manchester Centre for Genomic Medicine, St Mary's Hospital, Manchester, United Kingdom,* [3]*Division of Evolution, Infection and Genomics, School of Biological Sciences, The University of Manchester, Manchester, United Kingdom.*

Background: The *DPYD* gene encodes dihydropyrimidine dehydrogenase (DPD) which metabolises fluoropyrimidines to their inactive form. Individuals with decreased or no function *DPYD* alleles have an increased risk of severe adverse reactions when treated with fluoropyrimidines. The majority of available genotyping assays do not detect all Tier 1 *DPYD* variants recommended in Association of Molecular Pathology (AMP) guidelines (2024), limiting their ability to avoid drug toxicity in individuals regardless of genetic ancestry. Additionally, these assays typically require gDNA extraction prior to genotyping adding cost and time to the workflow. Herein we describe the design and development of a novel qPCR assay able to detect all Tier 1 variants in the AMP guidelines either from extracted DNA or direct from EDTA whole blood samples

Material and Methods: For each AMP Tier 1 variant two differentially labelled, allele-specific probes and a PCR primer pair were designed to uniquely amplify and provide unmatched specificity for the alleles of interest. Assay optimisation was performed with respect to sample input, mastermix formulation and cycling conditions to ensure robust performance of the assay. Performance evaluation was performed on the optimised assay workflow to establish Limit of Detection, working range, precision, and accuracy using DNA fragments, characterised *DPYD* cell line samples from Coriell, and EDTA whole blood samples.

Results: Table 1:Performance Evaluation Results

Study	Result
Limit of Detection	0.107 ng/reaction
Working Range	0.107 ng–163.84 ng/reaction
Precision	No significant impact of day, kit lot, operator or run on genotype results
Accuracy	gDNA 30/30 (100%) EDTA Whole Blood 10/10 (100%)

Conclusion: The novel DPYD qPCR genotyping assay developed demonstrates 100% accuracy and addresses current available assay limitations by providing improved inclusivity and a simplified workflow.

P20.020.C Optimising CYP2D6 genotyping: An inclusive digital PCR approach for star (*) allele Copy Number Variation detection

Anam Rafaqat[1], *Anna Gasior*[1], *Jack Paveley*[1], *Agustin Guardiola*[1], *Leanne Fullen*[1], *Daria Law*[1], *John McDermott*[2,3], *William Newman*[2,3], *Amy Coles*[1]

[1]*APIS Assay Technologies, Manchester, United Kingdom,* [2]*Manchester Centre for Genomic Medicine, St Mary's Hospital, Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [3]*Division of Evolution, Infection and Genomics, School of Biological Sciences, The University of Manchester, Manchester, United Kingdom.*

Background: CYP2D6 metabolizes about 25% of commonly prescribed drugs, including opioids and tamoxifen. The gene encoding CYP2D6 is complex, with 163 identified star (*) alleles and frequent copy number variations (CNVs). Current clinical guidelines for CYP2D6-metabolized drugs may be biased by genetic diversity. Accurate genotyping at the *allele level is limited by the availability of CNV-quantifying assays. Existing methods often have complex workflows and lack the precision of digital PCR (dPCR). A dPCR assay to accurately determine CYP2D6 * allele CNVs could reduce health disparities by enabling pharmacogenetic testing tailored to individual genotypes. For example, oestrogen receptor-positive breast cancer patients with a poor metabolizer phenotype face higher recurrence risks with tamoxifen and may benefit from genotype-informed alternative therapies.

Material and Methods: The assay was designed to include the most relevant *CYP2D6* * alleles. Alleles with unknown or uncertain function were excluded. Alleles with an average frequency of ≥ 1.5% across biogeographical groups were prioritized, and those with ≥ 1% frequency in at least one group were considered to avoid genetic diversity bias.

Results: The assay covers 93% variants reported across diverse ethic groups, excluding alleles with uncertain functions. Despite 4% of alleles not being specifically differentiable, functional phenotypes were accurately assigned, resulting in 97% effective coverage. Proof-of-concept experiments confirmed the assay's high specificity in detecting CYP2D6 * allele CNVs.

Conclusion: This dPCR assay improves CYP2D6 * allele CNV determination, enhancing phenotypic accuracy and potentially supporting personalized treatment decisions across diverse populations.

P20.021.D Genetics helps determine differences in response to statin treatment: analysis on short and long-term low-density lipoprotein cholesterol trajectories

Andrea Corbetta[1,2,3], *FinnGen*[4], *Francesca Ieva*[3], *Emanuele Di Angelantonio*[1], *Andrea Ganna*[2]

[1]*Human Technopole, Milan, Italy,* [2]*Institute for Molecular Medicine Finland, Helsinki, Finland,* [3]*Politecnico di Milano, Milan, Italy,* [4]

Background: understanding the genetic basis of lipid-lowering responses to statin therapy may provide valuable insights into personalized cardiovascular therapies. This study examines how genetic predisposition, as captured by polygenic scores (PGS) for low-density lipoprotein cholesterol (LDL-C), influences short and long-term changes in LDL-C levels after statin initiation.

Material and Methods: from the FinnGen cohort, we extracted 11,343 individuals with LDL-C measurements within one year before and after statin treatment initiation (short-term) and 15,864 individuals with at least five years of statin treatment and LDL-C measurements (long-term), from which we defined trajectories and disentangled independent patterns using functional principal components. We tested the effect of polygenic scores (PGS) for LDL on absolute and relative reduction of LDL (short-term) and the constant and reduction pattern (long-term) and performed genome-wide association studies.

Results: we find that individuals in the top tertile of PGS have a greater absolute reduction (8.12[6.93–9.57] mg/dl) of LDL-C in the first year but a smaller relative reduction (1.81[0.06–2.99] %) compared with the bottom tertile. While individuals with high PGS are associated with higher five-year LDL-C measurements, PGS is not associated with long-term changes in LDL-C. The GWAS detects significant genome-wide signals for relative reduction and longitudinal mean LDL-C, previously reported for LDL-C levels.

Conclusion: short-term LDL-C reduction after statin initiation appears to have a genetic basis closely linked to LDL-C regulation. Long-term changes in LDL-C levels do not appear to be regulated by genetic factors, yet individuals with high PGS for LDL have higher LDL-C in the long term.

P20.023.B Whole Genome Sequencing (WGS): a powerful tool to gain novel insight into the *CYP2D6* gene

Stefania Zampieri[1], *Paola Tesolin*[1,2], *Giuseppe Giovanni Nardone*[2], *Alessandro Pecori*[3], *Maria Pina Concas*[1], *Mabel Troian*[1], *Aurora Santin*[1,2], *Lara Emily Rosso*[2], *Giulia Pianigiani*[1,2], *Beatrice Spedicati*[1,2], *Giorgia Girotto*[1,2]

[1]*Institute for Maternal and Child Health – IRCCS, Burlo Garofolo, Trieste, Italy,* [2]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy,* [3]*Institute for Maternal and Child Health – IRCCS, Burlo Garofolo, Trieste, Italy, Trieste, Italy.*

Background: The *CYP2D6* gene is a highly polymorphic pharmacogene involved in the metabolism of 25% of commonly used drugs. We aim to assess the feasibility of extracting relevant pharmacogenomic information from WGS data and to highlight any difference in *CYP2D6* allele frequencies between the north-eastern Italian isolated communities and the European populations.

Material and Methods: WGS was performed on 656 individuals from six different northeastern Italian genetic isolates. Cyrius software tool was used to perform *CYP2D6* genotyping and the cohort-specific allele frequencies were compared to those of a publicly available control cohort (PMID:33462347).

Results: We identified 43 haplotypes, 56% of which (24/43) were already present in the control cohort showing no significant difference in allele frequency. In contrast, 44% of haplotypes (19/43) were rare and were uniquely present in our cohort. Interestingly, 13 individuals (3 unrelated, 10 distant relatives) carried the extremely rare CYP2D6*28 × 2 allele, whose activity has not been characterized yet. Moreover, we identified a carrier of the CYP2D6*34 × 2 allele, which, to our knowledge, has never been described before.

Conclusion: The CYP2D6*28 × 2 is a rare allele which may be more frequent in the northeastern part of Italy than in the European population. However, it is not included among the most commonly tested alleles. Thus, it might explain a percentage of unsolved individual pharmacogenomic profiles. We will expand the screening to the general population to define the prevalence of the haplotypes enriched in our cohort. The findings will be relevant to tailor the pharmacological treatments in the Italian population.

P20.024.C Precision Medicine in Action: Implementation and utility of pharmacogenomic testing in aclinical setting

Marwan Shinawi, *Hunter Slosser, Leia Peterman-Prather, Julie Neidich, Dickson Patricia, Rebecca Brand*

WUSM, Saint Louis, MO, USA.

Background: Pharmacogenomics (PGx) is a rapidly developing field that utilizes an individual's genetic profile to reactively or preemptively guide drug selection, dosing adjustment, and prevent adverse drug reactions (ADRs).

Material and Methods: We conducted an IRB approved retrospective chart review study of the first 100 patients evaluated at our PGC between January 2021-November 2024.

Results: 2/3 of the patients presented to the clinic were female and 94% were referred from outpatient setting. The mean age of patients was 26.2 years old and 90% identified as White. The patients were mostly referred from genetics (48%), pediatrics (21%), and family medicine (19%). The most frequent current diagnoses were anxiety (36%), depression (30%), migraine (20%), and constipation (20%). The most common currently used medications were albuterol (27%), melatonin (23%), cetirizine (19%) and clonidine (17%), none of which have CPIC guidelines. Sertraline was the most often reported medication with ADRs (18%), followed by gabapentin, bupropion, guanfacine, and methylphenidate. The mean turnaround time was 27.6 days. All patients harbored at least one potentially actionable pharmacogenomic variant (mean: 5.6; range:1–9 per patient). The most frequently observed pharmacogenes with potentially actionable variants were: CYP2C19, CYP2D6 and CYP2C9. Preliminary analysis showed that PGx results led to patient management changes.

Conclusions: we demonstrate the feasibility and utility of PGx in a dedicated PGC. However, there are a number of challenges that need to be addressed including long turnaround times, high out-of-pocket costs, integrating PGx data into electronic health records, inclusion of underrepresented minorities, and lack of awareness of PGx testing availability.

P20.025.D Evidence of a protective effect of Metformin on abdominal aortic aneurysm risk: Insights from an observational study and Mendelian randomisation analysis using putative Metformin targets

Katie L. Saxby[1], *Svetlana Stoma*[1,2], *Frank Dudbridge*[3,2], *Nilesh Samani*[1,2], *Matthew J. Bown*[1,2], *Christopher P. Nelson*[1,2]

[1]*University of Leicester, Department of Cardiovascular Sciences, Leicester, United Kingdom,* [2]*NIHR Biomedical Research Centre, University of Leicester, Leicester, United Kingdom,* [3]*University of Leicester, Department of Population Health Sciences, Leicester, United Kingdom.*

Background: There is no proven treatment to prevent the growth of abdominal aortic aneurysm (AAA). Rupture of AAA is often fatal and surgical intervention may be offered if the risk of rupture is high. We have previously reported evidence of a potential causal association between Metformin, a drug usually prescribed to treat type 2 diabetes, and reduced AAA risk using Mendelian randomisation analysis, however the reliability of the instrument to represent Metformin treatment is uncertain. Our aim here was to assess for evidence of this association in observational data, and compare these findings with estimated causal effects.

Material and Methods: Logistic regression was used to test for evidence of association between AAA and self-reported Metformin use in 2,972 AAA cases and 89,160 propensity matched controls from UK Biobank.

Results: We found statistically significant evidence of a protective effect between Metformin treatment and AAA risk, OR 0.49 (95% CI: 0.41–0.59, $p = 3.15 \times 10^{-14}$). These findings are entirely consistent with the results of our MR analysis that found an estimated decrease in risk of 43%, OR = 0.57 (95% CI: 0.38–0.88 $p = 0.010$) per standard deviation decrease in HbA1c via Metformin gene targets, equivalent to the effect of a prescribed dosage of Metformin.

Conclusion: Our observational study found strong evidence that Metformin use reduces the risk of developing AAA, supporting our earlier findings that there is evidence of a potential causal association. Clinical trials are warranted to assess the efficacy of Metformin to reduce the risk of aneurysm growth and rupture in people with AAA.

P20.026.A *HSD3B1* as a prognostic biomarker in androgen deprivation therapy response for prostate cancer

Alicia Torres-García[1], *Beatriz Álvarez-González*[2], *Verónica Arenas-Rodríguez*[2], *Francisco Gutiérrez-Tejero*[3], *Xando García-Villamarín*[3], *Rocío Morón-Romero*[3], *Maria Jesús Alvarez Cubero*[1], *José Cabeza-Barrera*[3]

[1]*Instituto de Investigación Biosanitaria de Granada (Ibs.Granada), Granada, Spain,* [2]*Pfizer - Universidad de Granada - Junta de Andalucía Centre for Genomics and Oncological Research (GENYO), Granada, Spain,* [3]*Hospital Universitario Clínico San Cecilio, Granada, Spain.*

Background: Prostate cancer (PC) is the most prevalent neoplasm among men in Spain. Androgen deprivation therapy (ADT) is a key treatment that aims to maintain testosterone levels at castration

levels to inhibit tumor growth. However, in many patients, this treatment fails, leading to castration-resistant prostate cancer (CRPC). The objective of this study is to analyze the influence of genetic variants in the genes *HSD3B1* (rs1047303), *SRD5A2* (rs523349), *CYP17A1* (rs2486758), and *CYP19A1* (rs4775936) on the response to ADT.

Material and Methods: The rs1047303, rs523349, rs2486758, and rs4775936 variants were genotyped in 151 patients using TaqMan Genotyping technology on the QuantStudio™ 12K-Flex platform (Applied Biosystems). Clinical variables were extracted from the medical records of patients in the Andalusian Health System. The integration of experimental and clinical data was performed using SPSS Statistics software.

Results: A recessive model was established for *HSD3B1* (rs1047303), revealing that patients carrying two recessive alleles (C/C) exhibited a higher rate of therapeutic failure ($\chi^2 = 0.022$, $p = 0.027$, OR = 2.932, 95% CI = 1.132–7.593) and greater risk to developing CRPC ($\chi^2 = 0.004$, $p = 0.008$, OR = 4.349, 95% CI = 1.470–12.865). Furthermore, patients who developed CRPC were compared with those who experienced treatment efficacy. Among these groups, patients with a recessive genotype showed a higher risk of rapid progression ($\chi^2 = 0.013$, $p = 0.019$, OR = 4.219, 95% CI = 1.271–13.975). Therefore, patients carrying two alleles of rs1047303 exhibit poorer prognosis due to higher therapeutic failure rates.

Conclusion: The rs1047303 polymorphism in the *HSD3B1* gene could serve as a reliable predictive biomarker for the response to ADT and disease progression in PC patients.

P20.028.C Middle Eastern and Asian individuals possess distinct pharmacogeneticprofiles compared to Europeans

Ruslan Alali, Efstathios Papachristos, Najim Ameziane

Arcensus GMBH, Rostock, Germany.

Background: Pharmacogenetic information can be addressed during routine whole genome sequence (WGS)-based clinical genetics testing to provide personalized insights into an individual's drug metabolism, enabling more precise medication selection and dosing to minimize adverse reactions and optimize treatment efficacy.

Material and Methods: We used PharmCAT on 760 unrelated individuals (308 female) who have been enrolled in WGS clinical genetic testing and addressed tier 1 and tier 2 pharmacogenomics, which includes 17 genes and 66 drugs. The ethnic background of the individuals is from the Middle East (ME), Pakistan, Korea, and Europe. We investigated the distribution of the STAR alleles.

Results: Our results show that understudied ethnic groups (ME and Pakistan) differ significantly from Caucasian and East Asian populations in their pharmacogenetic constellation. Pakistani and Korean individuals had a significantly higher prevalence of non-functional CYP2C19 allele compared to European and ME. Importantly, about 5% of Middle Eastern and Pakistani have a deficient CYP2C9 allele, expected to result in poor metabolism of Ibuprofen. Additionally, 5.5% of ME and CE female carry a deficient G6PD allele, of whom 2 are homozygotes (associated with favism).

Conclusion: Our study, demonstrated that individuals from the Middle East and Asia have different pharmacogenomics profiles compared to Europeans. Pharmacogenetic knowledge can be impactful for certain individuals, potentially averting severe adverse reactions or guiding critical treatment decisions.

P20.029.D *CYP2B6* Variants: the key to a multidrug-resistant patient with paradoxical clinical response

Isabel Serra Nunes[1,2,3], *Jorge Diogo Da Silva*[1,4,5], *Ana Rita Soares*[1,4,2]

[1]*Serviço de Genética Médica, Centro de Genética Médica Dr. Jacinto Magalhães, Centro Hospitalar Universitário de Santo António, Unidade Local de Saúde de Santo António, Porto, Portugal,* [2]*Unit for Multidisciplinary Research in Biomedicine, Instituto de Ciências Biomédicas de Abel Salazar, Universidade do Porto, Porto, Portugal,* [3]*ITR-Laboratory for Integrative and Translational Research in Population Health, Porto, Portugal,* [4]*Genetyca-ICM by Atrys, Porto, Portugal,* [5]*Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal.*

Background: Pharmacogenetics analyses genes encoding enzymes that regulate the metabolism of endogenous and exogenous molecules, such as the cytochrome P450 enzyme family. These enzymes are key determinants in the metabolism of many drugs, including psychotropics. Identification of inadequate metabolic activity can guide dose and drug adjustments, thereby improving treatment outcomes.

Material and Methods: A pharmacogenetic analysis was conducted in a patient with syndromic intellectual disability (ID), refractory epilepsy, and multiple adverse reactions to psychotropic medications.

Results: Thirty-year-old male patient with severe ID, disruptive behavior with severe auto and heteroagression and refratory epilepsy. Comprehensive genetic testing for an underlying etiology of the syndrome was negative. The patient presented poor therapeutic response despite being treated with multiple medications for epilepsy and aggressiveness. He also manifested severe side effects, including paradoxical reactions to antipsychotic drugs, such as haloperidol, levomepromazine, ciamemazine and aripiprazole. Pharmacogenetic analysis revealed an altered *CYP2B6* *1/*2 × 2 diplotype, categorizing the patient as an ultra-rapid metabolizer for various drug classes, including opioids, antidopaminergics, monoamine depletors, and amphetaminergic stimulants. Therapeutic adjustment with *CYP2B6*-independent drugs (such as olanzapine and quetiapine) allowed significant improvement of behavior and seizure control.

Conclusion: Pharmacogenomics insights enabled precise therapeutic adjustments, highlighting the value of these genetic tests in clinical practice to optimize treatment outcomes and improve patient quality of life.

P20.030.A Large-scale pharmacogenetics of antidepressants using the UK Biobank drug prescription data

Paula Bogumiła Konowalska, *Jacek Hajto, Marcin Piechota, Michał Korostyński, Malgorzata Borczyk*

Maj Institute of Pharmacology Polish Academy of Sciences, Cracow, Poland.

Background: Epidemiological analyses show that more than 15% of the population has taken antidepressants. Despite their

common usage, choosing an effective and safe drug for a patient usually requires several attempts. Studies suggest that ~40% of the variability in response to antidepressants can be explained by genetic factors. This study aims to determine the level of association between the occurrence of pharmacogenetic variants and correlates of treatment efficacy in depression. We used whole-exome sequencing (WES) and Electronic Health Records (EHRs) available in the UK Biobank which include 75,000 individuals with a history of antidepressant medication use.

Material and Methods: We used a custom software to identify genetic variants and call star alleles from WES. Based on prescription data, we created a personalized therapy profile for each patient, detailing their individual treatment information. The occurrence of events related to the effectiveness of pharmacotherapy (change of dose, change of drug, adverse effect) were associated with pharmacogenetics variants using linear regression and Fisher's Exact Test.

Results: We show that *SLCO1B1* variants are associated with the number of changes in dose or drug in antidepressant treatment. Moreover, the increased function of *SLCO1B1* was associated with not having SSRI as the final drug in the patient's treatment regimen.

Conclusion: The results suggest that specific pharmacogenetic variants may affect the efficacy of antidepressant therapy. Understanding these relationships could help develop more personalized treatments for depression. However, further research is essential to investigate additional factors and phenotypes that may influence the effectiveness of treatment.

P20.031.B Effects of HLA-DRA, HLA-DQA1 and IL-6 gene variations to glatiramer acetate resistance in multiple sclerosis patients

Aysegul Sahbaz[1], *Busranur Oguz Selcuk*[2], *Fusun Mayda Domac*[2], *Serkan Demir*[3], *Mesrure Koseoglu*[4], *Ebru Hatun Uludasdemir*[3], *Gulsah Koc*[5], *Bayram Yilmaz*[6], *Deniz Kirac*[1]

[1]*Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey,* [2]*Erenkoy Mental and Nervous Diseases Training and Research Hospital, Department of Neurology, Istanbul, Turkey,* [3]*Sancaktepe Sehit Prof. Dr. Ilhan Varank Training and Research Hospital, Department of Neurology, Istanbul, Turkey,* [4]*Kanuni Sultan Suleyman Training and Research Hospital, Department of Neurology, Istanbul, Turkey,* [5]*Istanbul Aydın University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey,* [6]*Yeditepe University, Faculty of Medicine, Department of Physiology, Istanbul, Turkey.*

Background: Multiple sclerosis (MS) is among the most common autoimmune disorder characterized by inflammation and degeneration affecting central nervous system (CNS). Glatiramer acetate (GA) is an immunomodulatory drugutilized for treating relapsing-remitting MS. However, considerable number of patients do not present an appropriate response to this drug. This condition is known as GA resistance. In this study, it was aimed to investigate the relationship between nucleotide variations in HLA-DRA, HLA-DQA1 and IL-6 genes with GA resistance. Additionally, the relationship of environmental factors with MS were investigated.

Material and Methods: One hundred thirty-nine MS patients were enrolled in this study. Patients were divided into two groups as non-responders (n = 58) and responders (n = 81). After DNA was isolated from peripheral blood, rs3135388 and rs3135391 variations in HLA-DRA, rs9272346 variation in HLA-DQA1, and rs1800795 and rs1900796 variations in IL-6 were analyzed by Real-Time Polymerase Chain Reaction(RT-PCR).

Results: At the end of the study, it was found that the number of females was approximately 3 times higher in responders and 4 times higher in non-responders, compared to males. When nucleotide variations and allele distributions were compared between the groups, no significant relationship was found. Similarly, no significant relationship was found between risk factors and nucleotide variations. However, in non-responders, expanded disability status scale and lesion load were found to be statistically high.

Conclusion: In conclusion by increasing the number of patients, more meaningful results can be achieved in future studies. It is believed that elucidating pharmacogenetic characteristics (the drug response-generelationship) in MS patients using GA will contribute personalized treatment strategies.

P20.032.C Reusing sequencing data for a pharmacogenetic passport- Stakeholder interviews on implementation barriers and facilitators

Anja Roelofsen[1], ***Loes Lindiwe L. Kreeftenberg***[1,2], *Carla van El*[1,2], *Lidewij Henneman*[1,2], *Tessel Rigter*[1,2], *Daoud Sie*[3], *Pierre Bet*[4,2], *Martina Cornel*[1,2]

[1]*Amsterdam UMC, Vrije Universiteit Amsterdam, Dept Human Genetics, Community Genetics, Amsterdam, Netherlands,* [2]*Amsterdam Public Health Research Institute, Amsterdam, Netherlands,* [3]*Amsterdam UMC, Vrije Universiteit Amsterdam, Dept Human Genetics, Amsterdam, Netherlands,* [4]*Amsterdam UMC, Dept: Clinical Pharmacology and Pharmacy, Vrije Universiteit Amsterdam, Amsterdam, Netherlands.*

Background: Pharmacogenetics uses individuals' genetic profiles to optimize drug treatment and prevent adverse reactions. One strategy to obtain information on pharmacogenes is to reuse sequencing data to produce a pharmacogenetic passport, providing information preemptively to healthcare professionals for utilization throughout a patient's lifetime.

Aim: To explore stakeholders' perceived barriers and facilitators of implementing a pharmacogenetic passport by reusing sequencing data to extract data on pharmacogenes, in a Dutch University Medical Center.

Methods: Semi-structured interviews were conducted among 21 stakeholders. Interviews were analyzed using thematic analysis and themes were grouped under the Constellation Perspective constructs.

Results: Perceived implementation barriers included inadequate data infrastructure, limited knowledge of pharmacogenetics, lack of (visible) guidelines or protocols, unequal access, unclear division of tasks and unclear procedures, and other hospital priorities. Perceived facilitators included the ease, efficiency and affordability to obtain pharmacogenetic test results from reused sequencing data, stakeholders' positive attitudes about patient impacts of a pharmacogenetic passport, and that patient control of their own health data is provided.

Conclusion: When considering the implementation of a pharmacogenetic passport, strategies can be developed to diminish barriers and strengthen facilitators. It is important to focus on data infrastructure, (visibility of) guidelines, clear division of tasks, and pharmacogenetic education.

A. Roelofsen: None. **L.L. Kreeftenberg:** None. **C. van El:** None. **L. Henneman:** None. **T. Rigter:** None. **D. Sie:** None. **P. Bet:** None. **M. Cornel:** None.

P20.033.D Leptin gene polymorphism *(LEP* 2548 G>A) as pharmacogenomics factor in Ukrainian population

Ihor O. Marakhovskyi, *Olha O. Plokhotnichenko, Anastasiia Yu. Morozyuk, Svitlana V. Berkovska, Roman S. Nikolaiev, Tetiana V. Tyzhnenko, Artem K. Pochernyaev, Kateryna V. Misiura*

SI "V. Danilevsky Institute for Endocrine Pathology Problems of the National Academy of Medical Sciences of Ukraine", Kharkiv, Ukraine.

Background: Pharmacogenomics studies the influence of genetic factors on the effectiveness of drugs. Leptin gene polymorphism is potential pharmacogenetic marker associated with type 2 diabetes (T2DM). The project aim is to define the impact of 2548 G>A *LEP* polymorphism on the effectiveness of pharmacological therapy for T2DM.

Material and Methods: Genotyping of 61 T2DM patients (M/F: 35/26, age 53.93 ± 1.20 yrs, BMI 32.68 ± 0.77 kg/m2, HbA1c 7.54 ± 0.14%) was carried out by the RFLP method. Plasma total leptine concentration, lipid profile and FFA, AST, ALT, FRAP and others parameters were determined. Patients received various hypoglycemic therapy.

Results: Comparative analysis of biochemical parameters in groups who take/did not take metformin indicates the presence of antioxidant properties in the drug (in the group receiving metformin in carriers of the GG genotype FRAP 7622.22 ± 117.23 vs 4660.41 ± 643.24 $p = 0.023$ is significantly lower), and for carriers of the A allele: hepatoprotective effect (reduction of AST U/IL 0.68 ± 0.25 vs 1.01 ± 0.32 $p = 0.02$), and the ability of the drug to improve the lipid profile (cholesterol mmol/l 5.43 ± 1.01 vs 8.17 ± 1.25 $p = 0.000024$). Metformin has certain anti-inflammatory properties in carriers of the A allele in the group receiving the drug, as there was a significant decrease in inflammatory markers such as C-reactive protein (3.32 ± 2.91 vs 10.25 ± 1.34 $p = 0,02$) and interleukin-6 (6,47 ± 4,11 vs 16,31 ± 1,16 $p = 0,04$).

Conclusion: The effectiveness of metformin therapy depends on the presence of certain leptin's gene alleles. Understanding how genetic variants affect biomarkers allows for personalization of metformin therapy for patients with T2DM in Ukrainian population.

P20.034.A Validation of an Integrated SNP and CNV Pharmacogenomics Panel on Buccal and Blood Specimens

Jelena Feenstra[1], *Grace Wong*[2], *Cui Wen Chua*[2], *Xiaohan Xu*[3], *Shamala Letchmanan*[3], *Sing Yi Chia*[3], *Kathleen Hayashibara, Senior Scientist, Molecular Bioiogy*[1], *Say Li Kong*[3]

[1]*Thermo Fisher Scientific, South San Francisco, CA, USA,* [2]*Thermo Fisher Scientific, Marsiling, Singapore,* [3]*Thermo Fisher Scientific, Marsiling, CA, USA.*

Background: Pharmacogenomics (PGx) testing aims to identify genetic variations in drug metabolism enzymes and transporter genes. It is thought to be a future enabler of individualized patient care. We developed a PGx panel with integrated single nucleotide polymorphism (SNP) and copy number variation (CNV) data analytics workflow.

Material and Methods: We designed the TrueMark™ PGx SNP + CNV 64 Panel, 384-well plate (RUO) consisting of assays targeting 56 SNPs and 2 CNVs in CYP2B6, CYP2D6, CYP2C19, CYP2C9, CYP3A4, CYP3A5, CYP4F2, DPYD, NUDT15, SLCO1B1, TPMT, and VKORC1. DNA was extracted from 40 buccal swabs and 40 blood specimens collected from various ethnic groups using the MagMAX™ DNA Multi-Sample Ultra 2.0 Kit and KingFisher™ Flex system. Extracted DNA was loaded into a 384-well qPCR plate and processed on a QuantStudio™ 12K Flex Real-Time PCR system. Genotype and CNV calls were determined using Diomni™ Design and Analysis Software 3.0. All samples were tested in parallel on the Axiom™ PangenomiX Plus Array and results were compared.

Results: Results from both buccal swabs and blood samples yielded 100% concordance for CNVs and ≥99.9% concordance for SNPs between the 2 tests. The call rate for CNVs on the TrueMark™ PGx Panel 384-well plate was ≥97.8% for buccal swabs and 100% for blood samples; while for SNPs it was ≥99.8% for buccal swabs and ≥99.9% for blood samples.

Conclusion: TrueMark™ PGx SNP + CNV 64 Panel, 384-well plate supported excellent performance with high accuracy in SNPs and CNVs detection across different sample types from various ethnic groups.

P20.035.B Performance of a Combined SNP and Copy Number Pharmacogenomic Research Panel to Determine Phenotypes of Drug Metabolism Genes

Tibor Fule[1], *Kathleen Hayashibara, Senior Scientist, Molecular Bioiogy*[2], *Pius Brzoska*[2]

[1]*Thermo Fisher Scientific, Darmstadt, CA, USA,* [2]*Thermo Fisher Scientific, South San Francisco, CA, USA.*

Background: Variations in sequence or copy number of drug metabolizing enzymes may result in altered activity towards substrates. We created the TrueMark™ PGx SNP + CNV 64 Panel, 384-well plate (RUO) containing TaqMan SNP Genotyping and Copy Number assays targeting CYP2B6, CYP2C9, CYP2C19, CYP2D6, CYP3A4, CYP3A5, CYP4F2, DPYD, NUDT15, SLCO1B1, TPMT, and VKORC1. Accuracy of phenotypes is presented using 167 Genetic Testing Reference Material (GeT-RM) DNAs containing targeted variants.

Material and Methods: DNAs were mixed with TaqPath™ ProAmp™ Master Mix, loaded onto pre-spotted assay plates, and run on a QuantStudio™ 7 Real-Time PCR System. Copy number and genotype results were determined by the Diomni™ Design and Analysis v3.0 software. Diplotype calls were made using AlleleTyper™ Software v1.0 with translations based on PharmGKB.

Results: CYP2D6 5'UTR and Exon 9 assays produced 100% call rate, and 100% accuracy based on consensus results from several platforms. The 64-assay panel produced calls from 99.6% of wells and produced phenotype calls consistent with consensus star alleles in 99.3 % of sample-target combinations where discrepancies were caused by alleles not covered by the panel. Diplotypes with alleles covered by the panel were identified in 100% of cases.

Conclusion: A 384-well qPCR research panel incorporating both TaqMan SNP and Copy Number assays in a single workflow suggests possibilities for development of a robust and accurate tool for determining phenotypes of key pharmacogenetic markers. The panel demonstrated high accuracy and reliability. These results underscore the potential of this panel to facilitate accurate phenotypic predictions in a streamlined workflow.

P21 Population Genetics and Evolutionary Genetics

P21.001.C Imputing transcriptional patterns in ancient genomes to reveal drivers of selection

Davide Marnetto[1], *Mathilde André*[1], *Francesco Montinaro*[2], *Ettore Zapparoli*[1], *Paolo Provero*[1]

[1]*University of Turin, Torino, Italy,* [2]*University of Bari, Bari, Italy.*

Background: Learning methodologies that leverage large-scale training data potentially allow to predict past molecular datapoints that would otherwise be lost to time. Although gene expression has been previously inferred in ancient genomes, the relatively low genotyping quality of aDNA interferes with the application of full expression predictive models. In addition, genetic drift challenges the interpretation of spatio-temporal changes in genetically-determined trait components across wide-ranging datasets.

Material and Methods: We developed gene expression and alternative splicing prediction models for 14 GTEx tissues and applied them to over a thousand high-quality, imputed ancient genomes spanning 10,000 years of Western Eurasian history. We then fitted the predicted transcriptional profiles onto multivariate models including time, space and genomic ancestry, in order to reveal gene regulatory patterns matching chronological, spatial and genetic axes of variation. Finally we explored known loci under selection in Western Eurasians and fine-mapped these selection signals onto the predicted transcriptional traits.

Results: We show improved prediction models for gene expression over those designed for non-imputed ancient genomes and introduce predicted alternative splicing in ancient samples. Among other loci, we replicated divergent predicted gene expression over time for MCM6 and SLC22A5, even when correcting for PCs and geographic coordinates, and demonstrated similar divergence in predicted alternative splicing from SLC22A5 locus.

Conclusion: Applying predictive models of genetically-determined molecular traits, like gene expression and alternative splicing patterns, to samples across a space-time transect can precisely map the molecular functions associated with selection at specific loci.

P21.002.D Near-complete Middle Eastern genomes refine autozygosity and enhance discovery of disease-causing and population-specific variation

Younes Mokrab[1,2,3], *Mohammadmersad Ghorbani*[1], *Shabir Moosa*[1], *Zenab Siddig*[1], *Radi Farhad*[1], *Haroon Naeem*[1], *William Harvey*[4], *Francesco Kumara Mastrorosa*[4], *Katherine M. Munson*[4], *Arang Rhie*[5], *Evan E. Eichler*[4,6]

[1]*Sidra Medicine, Doha, Qatar,* [2]*Department of Genetic Medicine, Weill Cornell Medicine, Doha, Qatar,* [3]*Department of Biomedical Science, College of Health Sciences, Qatar University, Doha, Qatar,* [4]*Department of Genome Sciences University of Washington School of Medicine, Seattle, WA, USA,* [5]*National Human Genome Research Institute, Bethesda, MD, USA,* [6]*Howard Hughes Medical Institute, Seattle, WA, USA.*

Background: De novo genome assembly enabled by advances in long-read sequencing helped uncover previously inaccessible variation and novel sequence in the human genome. However, its impact on disease gene discovery remains largely unexplored, especially for underrepresented Middle Eastern (ME) populations, known for high consanguinity and founder mutations. Also, ME populations lack high-quality assemblies, crucial for studying genome structure, inbreeding effects, and disease risk.

Methods: We assembled near-complete phased genomes for six ME family trios($n = 18$), including healthy parents and children with unresolved neurodevelopmental conditions from Sudan, Jordan, Syria, Qatar, and Afghanistan. We analyzed structural features, local ancestry, immune receptor gene polymorphisms (*HLA/KIR*), runs of homozygosity (ROH), structural variation and novel sequences. Also, we did family trio analysis comparing assembly vs. read-based variant calling to identify deleterious variants in unresolved phenotypes. Finally, we assessed the value of population-specific references.

Results: We assembled highly accurate (Max QV = 59.3) near-complete (>99%, 14 telomere-to-telomere chromosomes; Max contig N50 = 98.2 Mb), well-phased genomes, identifying 75 novel *HLA/KIR* alleles and 42.2 Mb of novel sequence, 13.8% affecting known genes. ROH analysis revealed strong inbreeding signatures, covering one-third of Chr 6 and 12. We identified 23 de novo and recessive variants, as strong disease-causing candidates. Aligning short reads from ME samples to our assemblies improved mappability and variant calling, underscoring the importance of population-specific references.

Conclusions: Our findings underscore the significance of de novo assembly in disease variant discovery and the need for sampled ME references to detect population-relevant variation. Our study has been accepted for publication in Nature Genetics.

P21.003.A A genetic risk variant associated with the risk of primary biliary cholangitis is inherited from Neanderthals

Chiara Caime[1], *Harold Wang*[2], *Manuela Sironi*[1], *Rosanna Asselta*[3], *Pietro Invernizzi*[1], *Sriram Sankararaman*[2], *Alessio Gerussi*[1]

[1]*University of Milano-Bicocca, Monza, Italy,* [2]*University of California, Los Angeles, CA, USA,* [3]*Humanitas University - Department of Biomedical Sciences, Pieve Emanuele, Italy.*

Background: Primary Biliary Cholangitis (PBC) is a rare autoimmune cholangiopathy with polygenic influences and unknown etiology. While Neanderthal-derived genetic variants have been broadly linked to autoimmune conditions, their role in PBC remains unexplored. This study investigated the potential contribution of Neanderthal-derived alleles to PBC susceptibility.

Material and Methods: We employed genetic data from four European PBC case-control cohorts (CANUK, OLD_IT, NEW_IT,

MAYO). To analyze the association between Neanderthal-derived alleles and PBC risk, we used a set of 235,592 Neanderthal Informative Markers (NIMs), incorporating genotypic and NIM principal components to adjust for population stratification. Heritability analysis focused on the CANUK cohort, estimating the contribution of NIMs to genetic variance using the RHE-mE method. Temporal dynamics of a Neanderthal-derived TNPO3 haplotype were assessed using ancient DNA data from Europe and Asia to explore allele frequency changes over time.

Results: A Neanderthal-derived variant in the TNPO3 gene (rs12531711) was significantly associated with PBC in the CANUK cohort ($p = 2.04 \times 10^{-26}$) and validated across three additional cohorts. This SNP, linked to autoimmune diseases, affects the expression of IRF5 (upregulated) and TNPO3 (downregulated) in blood. It is nearly absent in African populations but prevalent in European and Asian populations. Temporal analysis of the Neanderthal-derived haplotype revealed that its frequency increased significantly during the Bronze Age (5,000-3,000 years BP) before stabilizing. NIM analysis showed no significant contribution of these variants to PBC heritability.

Conclusion: We show that a Neanderthal-derived haplotype is associated with PBC, supporting the role of archaic variants in the susceptibility to human autoimmune diseases.

P21.004.B The impact of selection on genotype imputation accuracy in ancient DNA studies

Jose Rodrigo Flores Espinosa[1], *Liisa Loog*[1], *Anders Eriksson*[2]

[1]*Genomics Institute, University of Tartu, Tartu, Estonia,* [2]*University of Tartu, Tartu, Estonia.*

Background: Ancient DNA (aDNA) provides unique insights into human evolutionary history by enabling the observation of allele frequency changes over time. However, aDNA studies face challenges due to DNA degradation and high levels of missing data. Genotype imputation using modern reference panels is a common strategy, but its accuracy declines with increasing evolutionary separation between the imputation panel and the target population, particularly in regions affected by natural selection. Selective sweeps create unique haplotype structures often poorly represented in modern panels, potentially leading to imputation artifacts. For example, imputation of Bronze Age individuals from the Pontic-Caspian Steppe inaccurately suggested high lactose tolerance frequencies at the LCT locus, later refuted by direct genotyping.

Material and Methods: We investigate biases introduced by aDNA genotype imputation in selection inference using forward-in-time simulations of human populations under various selection scenarios. We analyze imputation concordance over time and across loci experiencing selection, modeling different strengths and durations of selection.

Results: Strong selection significantly distorts imputation accuracy, particularly in regions surrounding selected loci and in samples predating the onset of selection. Strong selection leads to rapid haplotype homogenization, enhancing imputation accuracy relatively soon after selection begins. Weaker selection results in a more gradual accuracy drop, with effects persisting longer after selection starts.

Conclusion: These findings highlight the importance of considering loci selection history in aDNA imputation to avoid misleading inferences about allele frequency trajectories and the timing of adaptive events. Accounting for selection biases is crucial for accurate reconstructions of human evolutionary history.

P21.005.C Pangenome-based inference of structurally-complex haplotypes from short-read data

Davide Bolognini[1], *Alessandro Raveane*[1], *Andrea Guarracino*[2], *Erik Garrison*[2], *Peter H. Sudmant*[3], *Nicole Soranzo*[1]

[1]*Human Technopole, Milan, Italy,* [2]*UTHSC, Memphis, TN, USA,* [3]*UC Berkeley, Berkeley, CA, USA.*

Background: Pangenome graphs model genomic variation of multiple individuals. Genotyping is inferring the alleles of a DNA sample from sequenced reads, which can be enhanced by using a pangenome graph instead of a single genome as reference.

Material and Methods: We summarise and extend cosigt, a computational workflow for genotyping structurally complex haplotypes from short-read sequencing data using a pangenome graph. For a given short-read sample and region of interest, cosigt aligns short reads to the nodes in the graph and compares the coverage of the short reads over nodes with the coverage of each diploid combination of haplotypes from the reference graph through cosine similarity, picking the combination with the highest similarity score.

Results: We benchmarked cosigt on a selection of complex loci (e.g. AMY1 and C4) using short-read individuals from the 1000G project having matching haplotypes in the HPRC(y1) pangenome graph. Comparison of the expected haplotype structure with that predicted by cosigt revealed that our method could precisely genotype ~90% of the evaluated samples, achieving ~100% at matching structurally similar haplotype clusters (~93% in a leave-one-out setting). We also applied our workflow on a diverse dataset with > 3000 individuals from 1000G, HGDP and SGDP and we found that AMY1 gene copies in the haplotypes predicted by cosigt precisely matched the copy numbers predicted by the sequenced reads with 95–99% concordance across different amylase genes.

Conclusion: Cosigt improves on prior read-based genotyping approaches by leveraging pangenome graphs to reconstruct the haplotype structure of sequenced individuals in complex loci.

P21.006.D Curating the Portuguese variome from over 12,000 exomes: enhancing diagnostics and unlocking new research opportunities

Mariana Ribeiro[1], *Mafalda Melo*[2], *Susana Valente*[1,3], *Filipe Alves*[1], *Jorge Sequeiros*[1,3], *Margarida Venâncio*[2], *Diana Antunes*[2], *João Parente Freixo*[1], *Jorge Oliveira*[1,3], ***Paulo Silva***[1]

[1]*Centro de Genética Preditiva e Preventiva (CGPP), Instituto de Biologia Molecular e Celular (IBMC), Instituto de Investigação e Inovação em Saúde (i3S), Universidade do Porto, Porto, Portugal,* [2]*Unidade de Genética Médica, Hospital Dona Estefânia, Unidade Local de Saúde de São José, Lisboa, Portugal,* [3]*ICBAS – Instituto de*

Ciências Biomédicas Abel Salazar, Universidade do Porto, Porto, Portugal.

Background: Molecular genetic testing progressed from single-gene and small multigene panels to WES and WGS, increasing variants found per case and complicating interpretation of results. Initiatives like the 1000 Genomes Project, ExAC, and gnomAD have been crucial by releasing public information on variant frequency; however, none captures specificities of the Portuguese population.

Methods: Leveraging a dataset of 12,167 patients' WES at our diagnostics laboratory, we created an anonymous reference-set, a putatively representative Portuguese cohort of 3,972 persons, iteratively resampling our dataset by municipality, and ensuring uniqueness and representativity by correcting for population biases and for geographic distribution using Census 2021 data. We focused on variants in the 81 genes in the ACMG list (v.3.2, 2023) of medically actionable secondary-findings. The ExAC open-source codebase was adapted to run locally and display that dataset.

Results: The ExAC-based browser displays allele counts and frequency of variants, by municipality, with interactive maps displaying the geographic distribution of each variant. We identified 262 PAT/L-PAT variants across 50/81 ACMG genes, among 249 individuals with actionable findings (~6.3% of our population), distributed across cardiovascular (3.1%), cancer (2.0%), miscellaneous (1.1%), and metabolic (0.1%) disorders. When displayed on the interactive map, the hemochromatosis-causing NM_000410.4(*HFE*):c.845G>A p.(Cys282Tyr) variant showed a north-south frequency-gradient corroborating previous reports.

Conclusion: We established a reference-set of common, rare, and ultra-rare genetic variants, seemingly representative of the Portuguese population. It provides a complete overview of genetic variation in the 81 actionable ACMG genes, offering valuable information for patients, practitioners, and stakeholders, aiming towards improving healthcare in Portugal.

P21.007.A UK Biobank data shows local adaptation of immune-system genes in response to solar radiation

Chaw H. Thwe, Nicholas M. Fountain-Jones, Phillip E. Melton, Bennet J. McComish

University of Tasmania, Hobart, Australia.

Background: It is increasingly recognized that local adaption to environmental factors underlies differences in autoimmune disease prevalence across the globe. The prevalence of many autoimmune diseases increases with latitude, possibly because of vitamin D insufficiency. We hypothesise that availability of vitamin D exerts selective pressure on immune-system genes whose effects are modulated by the vitamin D receptor.

Material and Methods: We conducted a genotype-environment analysis using data from the UK Biobank on a genome-wide scale, focusing on the association with solar radiation levels to detect genomic regions that show signals of selection influenced by UV exposure. Genotyping and associated metadata, including latitude, longitude, and blood serum vitamin D levels were obtained from UK Biobank. Solar radiation levels were obtained from WorldClim. Logistic regression models were run genome-wide using Samβada for 20,000 individuals to identify variants undergoing positive selection.

Results: Genome-wide significant signals of local adaptation in response to solar radiation levels were detected at 71 loci. These loci are strongly enriched for genes involved in immune response to antigens. The strongest signal of selection, with $p = 1.35 \times 10^{-48}$, is at rs5743618, a missense SNP in *TLR1* that has previously been shown to be under selection in European populations.

Conclusion: The UK population shows strong signals of local adaptation in response to varying solar radiation levels, with immune system genes strongly enriched. Of particular interest are several genes that are involved in regulatory interactions with the vitamin D receptor, where selection may be driven by vitamin D levels.

P21.008.B Ape genomes reveal natural protection mechanisms against human diseases

Nachshon Egyes[1], *Simon Fishilevich*[1], *Katharina Lange*[1], *Nitzan Haim*[1], *Mimi Shwartz*[1], *Ron Moran*[1], *Georgii Bazykin*[2], *Martin Kuhlwilm*[3], *Tomas Marques-Bonet*[4], *David Gokhman*[1]

[1]*Molecular Genetics, Weizmann Institute of Science, Rehovot, Israel,* [2]*Department of Biology, Emory University, Atlanta, GA, USA,* [3]*Department of Evolutionary Anthropology, University of Vienna, Vienna, Austria,* [4]*Institut de Biologia Evolutiva, Consejo Superior de Investigaciones Científicas, Universitat Pompeu Fabra, Barcelona, Spain.*

Background: Human evolution has led to extraordinary adaptations, including a three-fold increase in brain size, the transition to upright walking, and an extended maturation and learning phase. However, these adaptations have also driven the emergence of severe disorders, such as Alzheimer's disease, bronchial asthma, and carcinomas. Here, we studied the evolutionary dynamics of disease emergence and disappearance by comparing the pathogenicity of variants in humans and other apes.

Methods: Specifically, we intersected human disease-causing variants from the ClinVar archive with high-coverage genomes of 139 great ape individuals from diverse genetic backgrounds. We next tested whether certain types of disease are more likely to undergo protection and quantified the rates at which different modes of protection evolved.

Results: We identified 342 human disease-causing variants that appear neutral in great apes. Our study revealed that the mechanisms protecting most of these variants are not restricted to a specific pathogenic variant, but are rather the result of the entire gene becoming protected in apes against pathogenic mutations. Interestingly, genes underlying diseases that affect fertility or hearing are particularly likely to evolve protection mechanisms in evolution. We further illustrated this by uncovering the compensatory mechanism in chimpanzees against a pathogenic allele in *BMP15*, which causes complete ovarian dysgenesis in humans, but is the wildtype allele in chimpanzees.

Conclusions: Overall, our targeted approach not only sheds light on the evolutionary dynamics of disease resistance but also provides a framework for leveraging these natural protection mechanisms to inform therapeutic development.

P21.009.C Natural selection on human lipid metabolism associated with cultural and dietary shifts in eastern Holocene Europe

Anders Eriksson, *Kaur Kivirüüt*

Institute of Genomics, University of Tartu, Tartu, Estonia.

Background: During the European Holocene, human populations underwent major transitions in lifestyle with important consequences for human metabolic processes. Indeed, genetic loci linked to digestion of lactase, fatty acid synthesis and antioxidant uptake have among the strongest signals of natural selection in the human genome. However, a comprehensive picture of how metabolic traits have evolved in response to dietary shifts is lacking.

Material and Methods: We combined ancient DNA data with eQTLs for blood metabolite concentrations to reconstruct metabolite profiles of Holocene Europe populations. We used cluster analyses to identify groupings of metabolites and lipid particle combinations with similar temporal trajectories, a robust statistical method to test for natural selection, and pathway analyses and isotope data from archaeological studies to interpret the results.

Results: We found strong shifts in predicted levels of VLDL, triglycerides, apolipoprotein B and glycoprotein acetyls during late Mesolithic and early Neolithic in Eastern Europe, consistent with natural selection and a shift of intake in dietary lipids from terrestrial to marine resources. A strong shift in the opposite direction was observed with the arrival of the Comb ceramic culture that brought farming and domesticated animals to the region. These predicted changes in dietary proteins are consistent with isotope data from lipid residues on ceramics from these populations.

Conclusion: We find evidence for natural selection acting to compensate for shifts in dietary intake of lipids associated with the cultural transformations of Holocene Europe. Our results support cultural and environmental factors as drivers of natural selection in human populations.

P21.011.A The Genome of Europe: A Reference Dataset of Genomes

Jeroen van Rooij[1], *Helen Ray-Jones*[1], *Erwin Bovenkamp*[1], *the Genome of Europe Consortium*[2], *André Uitterlinden*[3]

[1]*Erasmus MC, Rotterdam, Netherlands,* [23]*Erasmus Medical Center-Dept Internal Medicine, Laboratory of Population Genomics, Rotterdam, Netherlands.*

The 1 million genomes (1+MG) initiative aims to make at least 1 million whole genome sequences (WGS) accessible for use in research, health care, and prevention. Working Group 12, named Genome of Europe (GoE), aims to establish a European Reference of >500k WGS (@30x coverage) to better capture European genetic diversity. A digital Europe program (DEP)-funded initiative (also called GoE) will collect 100k samples in line with the 1+MG framework, and via the Genomics Data Infrastructure (GDI). In 2024, we introduced GoE at ESHG. We here outline the initiated GoE activities involving 51 institutes from 29 European countries. We have generated a sampling scheme for the 40 most common ancestral populations across the participating countries. We have further mapped the sequencing technologies used for this data collection and identify eligible legacy data. Three work packages establish prerequisites for GoE data collection: WP2 (Data quality & standards), WP3 (Ethical & legal) and WP4 (Data Infrastructure). WP5 will perform the data collection. WP6 will demonstrate scientific value through six use cases. WP7 handles communication, and WP1 coordinates. The GoE project has been well received, and is looking to expand, both by enabling additional countries to join, and by collaboration with other genome datasets. GoE will contribute to setting up national genome programs across Europe and assist in the implementation of genetic information in health care and prevention in a broad sense.

P21.012.B Investigating the distribution and frequency of *CFTR* alleles in Wales using linked data

Robert T. Maddison[1], *Thomas Stoneman*[2], *Rebecca Cannings-John*[1], *Fiona Lugg-Widger*[1], *Karen R. Reed*[1], *Andrew E. Fry*[1,2]

[1]*Cardiff University, Cardiff, United Kingdom,* [2]*All-Wales Medical Genomics Service, Cardiff, United Kingdom.*

Background: Routine clinical genetic test records represent an underutilised resource for research. Allele frequencies for cystic fibrosis (CF) in Wales were previously studied in in 1993. We aimed to study the spatial distribution and change in *CFTR* allele frequencies in Wales over the last 30 years by linking routine genetic test results to data held by the Secure Anonymised Information Linkage (SAIL) Databank. SAIL is a Trusted Research Environment that provides access to anonymised health and demographic data from the population of Wales.

Methods: We imported 16,181 *CFTR* gene test reports from the All-Wales Medical Genomics Service to SAIL. The relationships between allele frequency, geographic region, deprivation, and Welsh language were studied. To avoid bias from sampling related individuals, we used linked demographic data to detect relatives. *CFTR* allele frequencies were then compared with frequencies observed in 1993.

Results: Regions in South Wales exhibited higher rates of CF births, CF carrier status, CF testing, and *CFTR* allelic diversity compared with North, Mid, and West Wales. Thirty-six different *CFTR* variants were observed, 15 of which were counted in 1993. No significant difference in allele frequencies was observed between 1993 and 2023. We estimate that around 40% of related individuals in the sample were detected.

Conclusion: Routine genetic test results can be linked to anonymised health and demographic data and used for research. *CFTR* allele frequencies in Wales have been stable over the past 30 years but exhibit regional differences. Related individuals are challenging to detect using linked anonymised demographic data.

P21.013.C An initial version of the Korean pan-genome and structural variants using long-read sequencing

Jae-Yoon Kim, ***Sun-Yeop Kim****, Youngbeom Cho, Seung-Jin Park, Hyojin Heo, Jeong Hwan Kim, Jong-Lyul Park, Seon-Young Kim*

Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of.

Background: Recent genomic research has shown that a single reference genome cannot fully represent the genetic diversity of the human population, leading to reference bias and hindering the discovery of true genetic variants. This has spurred efforts to construct human pan-genomes, including the release of draft versions of the human and Chinese pan-genomes in 2023. Despite

notable genetic diversity among East Asian populations, pan-genome studies beyond China remain limited. To address this gap, we constructed the initial Korean pan-genome and identified Korean-specific structural variations.

Material and Methods: Twenty-one Koreans were sequenced using PacBio and Nanopore long-read platforms, complemented by Hi-C sequencing. High-quality telomere-to-telomere genome assemblies and annotations were generated after quality control. These assemblies were utilized to construct the Korean pan-genome using tools like Minigraph-Cactus and PanGenome-Graph Builder. The resulting pan-genome was analyzed to identify Korean-specific structural variations.

Results: We generated 28 high-quality assemblies with an average size of 3.01 Gb, an N50 of 50.34 Mb, and at least 97.5% of annotated protein-coding genes. The Korean pan-genome exceeded 3.2 Gb, revealing ~6 Mb of core genome regions absent from the current human reference genome. Structural variations specific to East Asians and Koreans were identified in the ALDH2 and APOD genes, both associated with alcohol metabolism.

Conclusion: Our Korean pan-genome is expected to uncover valuable genetic variations missing from the current reference genome, and contributes to the global effort of constructing a comprehensive human pan-genome.

Background: Pangenomes have recently been introduced as a transformative resource for genomics, providing a more accurate understanding of genetic diversity across populations. Here we present JaSaPaGe, a pangenome graph reference for the Japanese and Saudi Arabian populations.

Material and Methods: We utilized 39.69X PacBio high-fidelity long reads, 43.68X Hi-C short reads, 44.89X Nanopore long reads, and 19.87X ultralong reads of 9 Saudi and 10 Japanese individuals to construct the diploid genome assemblies, and consequently the JaSaPaGe pangenome graph, as well as separate pangenome graphs for the Japanese and Saudi Arabian populations. To validate our pangenome graphs, we conducted short-read variant-calling for 3 Saudi samples, 3 Japanese samples, and HG001, using our graphs alongside the HPRC pangenome graph, GRCh38, and T2T-CHM13 as reference genomes.

Results: Our contiguous haplotype-phased de novo assemblies had an average N50 of 70.6 Mb and an average QV score of 64.7. Variant calling of short-read sequencing data demonstrated that using a pangenome graph resulted in detecting more variants compared to a linear reference. The performance of variant calling was comparable between our pangenome graphs and the HPRC pangenome graph. Notably, more variants were identified in Japanese and Saudi Arabian samples when their population-specific pangenomes were used as references.

Conclusion: This study shows the necessity of population-specific pangenomes. Our pangenome graphs will serve as valuable genomic resources in both Japan and Saudi Arabia.

P21.015.A Genetic basis of human cold adaptation

Anna Kolesnikova[1], *Anders Eriksson*[2,3], *Toomas Kivisild*[1,4]

[1]*Department of Human Genetics, KU Leuven, Leuven, Belgium,* [2]*Center for Genomics, Evolution and Medicine (cGEM), Institute of Genomics, University of Tartu, Tartu, Estonia,* [3]*Health Data Unit, Applied Research Centre, Tallinn, Estonia,* [4]*Estonian Biocentre, Institute of Genomics, University of Tartu, Tartu, Estonia.*

Background: Human populations at high latitudes exhibit diverse cultural and physiological adaptations, yet the role of natural selection in shaping their genetic and molecular mechanisms remains incompletely understood. While lipid metabolism and thermogenesis are known to play key roles, other biological pathways may also contribute to cold adaptation. To explore this broader genetic landscape, we conducted a genome-wide analysis to identify functional variants and pathways involved in cold stress responses in Siberian populations.

Material and Methods: We analyzed WGS data from public databases (HGDP, EGDP, SDGP) of Western, Central, and Northeast Siberian populations. We identified variants with the highest F_{ST} between Siberian and other Eurasian populations and applied a linkage disequilibrium pruning approach to refine the variant list. Each variant was annotated for empirical significance across three tests previously applied to Siberian groups in *Pagani et al*., 2016 (nSL, iHS, Tajima's D) and assessed for functional and regulatory annotations.

Results: We identified 936 independent variants uniquely common in Siberian populations, including those in pathways related to lipid metabolism, thermogenesis, and adipogenesis. Enrichment in vascular function suggests possible adaptations in vasoconstriction. Cellular signaling pathways linked to stress responses and metabolic regulation were also highlighted.

Conclusion: Our findings support the hypothesis that recent and strong natural selection acted to adapt human physiology to cold climates both directly, through thermogenesis, regulation of adipose tissue and vasoconstriction, but also indirectly as metabolic shifts in response to dietary adaptations. These results provide a foundation for future studies on human adaptation to extreme cold environments.

P21.016.B Mothers on the move - thousands of complete mitochondrial sequences reveal the time-layered formation of the shared maternal gene pool in Estonia and Finland

*Hovhannes Sahakyan[1], Maere Reidla[1], Ene Metspalu[1], Monika Karmin[1], Rodrigo Flores[1], Raimonds Reščenko[2], Vita Rovīte[2], Jānis Kloviņš[2], Adam Ameur[3], Ulf Gyllensten[3], **Anne-Mai Ilumäe**[1]*

[1]University of Tartu, Tartu, Estonia, [2]Latvian Biomedical Research and Study Centre, Riga, Latvia, [3]Uppsala University, Science for Life Laboratory,Department of Immunology, Genetics and Pathology, Uppsala, Sweden.

Background: Phylogeographic reconstructions of European maternal history have mostly highlighted the expansions from glacial refugia. Here we have focused on a large-scale population-based examination of the maternal genepool of northeastern Europe, utilising complete mitochondrial sequences.

Material and Methods: We collected over 6000 full mtDNA sequences from Estonia, Finland, Sweden, Latvia and Poland with additional modern and ancient haploid genomes from published sources. We reconstructed dated phylogenetic trees for all of these sequences, established monophyletic lineages found in single populations or shared between several populations and estimated the dynamics of their effective population size.

Results: Almost 40% of Finnish individuals belong to monophyletic clusters common with linguistically related Estonians, whereas below 8% are shared with geographically close Swedish population. In Estonia, roughly 15% of individuals belong to shared Finnish-Estonian monophyletic clusters and less than 2% of Estonian individuals form haplogroups with Swedes. For the shared proportion of maternal gene pool, effective population size increases in the Bronze and Iron Age.

Conclusion: The phylogeny informed approach allows us to detect a geographic pattern previously associated primarily with male lineages. We demonstrate and discuss the importance of Bronze and Iron Age migrations on the formation of the eastern Baltic maternal gene pool by combining multiple line of evidence from modern and ancient mtDNA as well as archaeology.

P21.017.C Genetic contribution of ancient humans in Japanese populations

Kenichi Yamamoto[1], *Shinich Namba[1,2,3], Kyuto Sonehara[1,2,3], Ken Suzuki[2], Saori Sakaue[4], Niall P. Cooke[5,6], Shinich Higashiue[7], Shuzo Kobayashi[7,8], Hisaaki Afuso[7], Kosho Matsuura[7], Yojiro Mitsumoto[7], Yasuhiko Fujita[7], Torao Tokuda[7], the Biobank Japan Project[9], Koichi Matsuda[2], Takashi Gakuhari[10], Toshimasa Yamauchi[2], Takashi Kadowaki[11], Shigeki Nakagome[6,10], Yukinori Okada[1,2,3]*

[1]The University of Osaka, Suita, Japan, [2]The University of Tokyo, Tokyo, Japan, [3]RIKEN Center, Yokohama, Japan, [4]Harvard Medical School, Boston, MA, USA, [5]Max Planck Institute, Leipzig, Germany, [6]Trinity College Dublin, Dublin, Ireland, [7]Tokushukai group, Tokyo, Japan, [8]Shonan Kamakura General Hospital, Kamakura, Japan, [9][10]Kanazawa University, Kanazawa, Japan, [11]Toranomon hospital, Tokyo, Japan.

Background: Advancements in ancient genomics have revealed the ancestral admixture of modern humans. In Japan, a recent study has proposed a tripartite ancestral structure for the genetic origin of modern Japanese, involving indigenous Jomon hunter-gatherers and continental ancestors from Northeast Asia and East Asia. However, the broader implications of this ancestral structure for the genetic and phenotypic diversity of the Japanese population remain unclear.

Material and Methods: In this study, we conducted biobank-scale analyses to assess the applicability of the tripartite ancestral model and its phenotypic impact across the Japanese archipelago by integrating Biobank Japan with ancient Japanese and Eurasian genomes.

Results: We showed the suitability of the tripartite ancestral model throughout the Japanese archipelago, with significant variation in the Jomon ancestry at individual levels. This variation explained much of the genetic diversity observed in principal component analysis. Regarding phenotypic impacts, we identified a positive association between Jomon ancestry and body mass index (BMI). A genome-wide association analysis of Jomon ancestry, adjusted for geographical and ancestral substructures, identified 132 genetic markers predictive of individual Jomon ancestry. These variants are associated with significantly longer haplotypes than those from other variants, suggesting their origin from Jomon ancestry. The prediction model identified individuals who exhibit Jomon ancestry in an independent cohort of East Asian individuals from the UK Biobank and successfully replicated the positive association between Jomon ancestry and BMI.

Conclusion: Our comprehensive analysis of ancient and modern genomes provides valuable insights into the genetic contributions of ancient hunter-gatherers to contemporary populations.

P21.018.D Expanding HLA Imputation Capabilities for the Arab Population: A 25K Reference Panel and XGBoost Based Model

Hamdi Mbarek[1], *Christophe Demay[1], Guillaume Butler-laporte[2], Chadi Saad[1], Dinesh Velayutham[1], Mohamed Kohailan[1], Zainab Jan[3], Puthen Jithesh[3], Zohreh Calderone[4], Said Ismail[1], Qatar Genome Program Research Consortium[5]*

[1]Qatar Precision Health Institute, Doha, Qatar, [2]Division of Infectious Diseases, McGill University, Montréal, QC, Canada, [3]College of Health & Life Science, Hamad Bin Khalifa University, Doha, Qatar, [4]4American Red Cross, Holland Lab. for BioMedical Science, Baltimore, MD, USA, [5]

Background: The HLA region plays a critical role in disease susceptibility, immune surveillance, and allogenic transplantation compatibility. However, existing HLA imputation panels are predominantly trained on individuals of European ancestry, limiting their accuracy for underrepresented populations.

Material and Methods: To overcome this limitation, we developed the Arab HLA reference panel of 24,838 whole-genome sequenced individuals processed using Illumina DRAGEN 4.3.2, ensuring superior alignment and variant calling accuracy.

Results: We profile the HLA genetic diversity in Middle-Eastern biobank cohort, generating statistics on allele frequencies, linkage disequilibrium patterns, and population-specific haplotypes across classical HLA genes. We developed a Nextflow-based algorithm integrating three commonly used HLA genotyping tools (HISAT-genotype, HLA-HD, and T1K). All tools were standardized to use IMGT/HLA v3.49, guaranteeing uniform allele definitions and minimizing discrepancies between algorithms. This approach enabled us to derive reliable HLA alleles at both 3-field and 2-field resolution across all classical and non-classical HLA genes. We implemented an XGBoost-based model to predict HLA genotypes at 2-field resolution. The model was trained using on 80% subset of our dataset and validated on the remaining 20%. Additionally, external benchmarking was conducted using the 2,504-individual HLA reference panel from the 1000 Genomes Project. We explored HLA-disease associations for 169 traits, identifying novel and known associations with immune-mediated diseases prevalent in the Arab population.

Conclusion: Our 25K HLA reference panel and XGBoost-based imputation framework constitute the most comprehensive HLA resource for the Arab population to date, improving the accuracy of genetic analyses and advancing research in transplantation, infectious diseases, and autoimmune disorders at global scale.

P21.019.A Effects of natural selection on the genetic architecture of core genes for type 2 diabetes identified through *trans*-effects of common variants

Svitlana Braichenko, *Andrii Iakovliev, Athina Spiliopoulou, Helen Colhoun, Paul M. McKeigue*

University of Edinburgh, Edinburgh, United Kingdom.

Background: Waist-to-hip ratio linked to a higher risk of type 2 diabetes (T2D) and cardiovascular disease in South Asians (SA) compared to Europeans (EUR), is hypothesized to be driven by inter-population genetic differences. The "omnigenic" or sparse effector hypothesis postulates that core genes for a disease can be identified through the *trans*-effects of common SNPs. This study investigates differential selection pressure on *trans*-regulators of core genes for T2D, identified via Genome-wide Aggregated *Trans*-effects (GATE) analysis, to explain inter-population differences in T2D risk.

Material and Methods: We computed GATE scores for circulating proteins in 44,097/445,055 cases/controls (total 459105 EUR/7625 SA) of T2D in the UK Biobank using pQTLs from UKB-PPP and deCODE. We identified putative core genes through GATE scores associated with T2D ($P < 10^{-6}$). We sought evidence for differential selection in *trans*-pQTLs for these genes by calculating the fixation index (F_{st}) between EUR and SA. Deviation from neutrality in *trans*-pQTLs for core genes were ascertained via F_{st} enrichment test.

Results: *ADIPOQ*, encoding adiponectin, is the strongest of 18 discovered putative core genes for T2D ($LogOR = -0.091$, $P = 4 \times 10^{-55}$). Of these, three had large inter-ancestry differences in GATE scores: *ADIPOQ* (0.5SD), *TIMP4* (0.3SD), and *CTRB1* (0.3SD). F_{st} values were enriched in *trans*-pQTLs for *ADIPOQ* compared to neutral SNPs ($P < 10^{-10}$).

Conclusion: We provide genetic evidence that inter-population differences in *trans*-regulated *ADIPOQ* expression, inversely related to central adiposity, may mediate inter-population differences in T2D. These may occur due to differential selection on *trans*-pQTLs hinting at "thrifty genes" hypothesis.

P21.020.B Analysis of protein-coding genetic variation in 1,043 unrelated Sardinians

Matteo Floris[1], *Stefano Mocci*[2,3], *Federica Cannas*[2,3], *Michela Lorrai*[2], *Giulia Nutile*[2], *Federico Marongiu*[2], *Chiara Cocco*[2], *Enrico Zoroddu*[1], *Maximilian Frick*[2], *Caterina Mereu*[2], *Michela Murgia*[2], *Celeste Sanna*[2], *Laura Serventi*[2], *Gaia Maria Tosone*[2], *Andrea Perra*[4], *Sabrina Giglio*[2,3]

[1]*Department of Biomedical Sciences, University of Sassari, Sassari, Italy,* [2]*Medical Genetics, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy,* [3]*Center for Research University Services (CeSAR), (Centro Servizi di Ateneo per la Ricerca), University of Cagliari, Cagliari, Italy,* [4]*Oncology and Molecular Pathology Unit, Department of Biomedical Sciences, University of Cagliari, Cagliari, Italy.*

Background: Studying a population with unique genetic characteristics, such as Sardinians, offers the opportunity to discover novel functionally relevant genetic variants that have not been observed in large-scale sequencing studies and to open new avenues for understanding the impact of known disease-related variants.

Material and methods: To date, we performed the most comprehensive analysis of coding region variability in the Sardinian population. Using high-quality exome data from 1,043 unrelated individuals from a clinical genetics center in South Sardinia, we explored implications for personalized medicine. Allele frequencies were compared with those in the GnomAD v4.1 database.

Results: We identified 1,723,665 variants in canonical transcripts, with about one-third unique to Sardinians. Our analysis predicted 12,833 high-confidence and 8,855 low-confidence loss-of-function (LoF) variants, along with 2,294 splice-disrupting variants. Notably, 81.7% of LoF variants were singletons. We examined pathogenic and likely pathogenic variants enriched in Sardinians, including two known GJB2 pathogenic ones associated with genetic hearing loss, showing 61-fold and 7-fold frequency enrichment compared to Europeans; remarkably, no individuals exhibited deafness, even in a homozygous state. We also estimated the prevalence of pharmacogenetic and clinically actionable variants from the ACMG SF 3.2 gene list.

Conclusion: Our findings provide the first detailed landscape of genetic diversity in coding regions in Sardinians and offer new insights into the genetic epidemiology of monogenic diseases and pharmacogenetic traits.

P21.021.C The first settlers of the Faroe Islands - impacts on modern heterozygosity and personalized medicine

Hannes Gislason

University of the Faroe Islands, Faculty of Science and Technology, Tórshavn, Faroe Islands.

Background: The Faroe Islands, an isolated population of ~50,000 people, exhibit a high incidence of rare diseases, such as Primary Carnitine Deficiency (1:300). For diagnostic purposes, whole genomes from cases not affected by known mutations were sequenced at high coverage (x37). We explore the genomic variation and study the arrival and ancestry of the founding population.

Methods: We examined the relationship between the number (NROH) and sum (SROH) of ROHs to discover a bottleneck effect for ROHs larger than a minimum length. From this length and theory for the length distribution of ROHs, we estimate the timing of the initial settlement. Whole-genome SNPs and multidimensional scaling (MDS) were used to assess ancestry. SNPs within ROHs of different length intervals provided further insights into settlement timing and origins.

Results: Heterozygosity was 0.60, 0.29 and 0.93 for all, shared and unique SNPs, respectively. A population bottleneck is estimated to have begun between 50 and 300 AD, peaking around 600 AD. A distinct clustering near the central European and British populations of the 1000 Genome Project is likely the result of the population isolation and genetic drift. Further analysis using reference data including more populations from the British Isles and Scandinavia suggests the founders were Orcadians, or settlers of both Scandinavian and British ancestry.

Conclusion: The Faroese population is of European origin, possibly Orcadian or mixed central European/British/Scandinavian ancestry. This study suggests the population was founded in the 1st-4th century, potentially 2–3 centuries earlier than previously believed based on archaeological findings.

P21.022.D Unraveling the impact of Neanderthal introgression on brain morphology

Roberta Zeloni[1], *Adeline Morez*[1], *Daniela Fusco*[2], *Alessandro Amaolo*[2], *Francesca Carollo*[1], *Mahan Shafie*[2], *Fabrizio Pizzagalli*[2], *Paolo Provero*[2], *Luca Pagani*[1], *Davide Marnetto*[2]

[1]*University of Padua, Padua, Italy,* [2]*University of Turin, Turin, Italy.*

Background: Present-day non-African human populations still carry about 2% of variants inherited from an ancient admixture with Neanderthal individuals. Although the biological impact of Neanderthal introgression on human complex traits has been extensively explored, a thorough analysis of its influence on traits extracted from brain structural magnetic resonance imaging (sMRI) is still lacking. Exploiting genetic associations discovered in large biobanks combining genetic and brain MRI data, we aimed to determine not only the relative impact but also the directionality of the effects of introgressed SNPs in changing brain morphology.

Material and Methods: We identified the variants tagging archaic haplotypes in UK Biobank sMRI donors, and we considered the rest of the variants as modern. We first applied RHEmc, to partition SNP heritability between archaic and modern variants. We then implemented SLDP (Signed LD Profile) regression to unravel directional effects of variants on sMRI traits, by assigning in case of Neanderthal-inherited variants a positive score to the introgressed allele and a negative score to the other allele.

Results: Our results provide evidence for the contribution of Neanderthal alleles to the genetics underlying particular areas of cerebellum, parietal and temporal lobes. We evaluate the consistency of this completely independent line of evidence with findings based on Neanderthal braincase morphological analyses.

Conclusion: Our analyses suggest that indeed the genetics underlying the morphology of these areas diverged since the Neanderthal-modern human split and that introgression-derived variants still play a role in shaping our brain morphology.

P21.023.A Indigenous and african ancestry in the Uruguayan population

Lucia Spangenberg, *Camila Simoes, Hugo Naya*

Institut Pasteur de Montevideo, Montevideo, Uruguay.

Background: The Charrúas, an Amerindian group inhabiting Uruguay at the time of European contact, were largely eradicated as an ethnic group due to genocide. However, their cultural and genetic heritage persists in the Uruguayan population. While previous mitochondrial DNA studies confirmed Amerindian ancestry in living Uruguayans, genome-wide analyses remain scarce.

Material and Methods: We performed high-coverage whole-genome sequencing on ten Uruguayan individuals with self-declared Charrúan ancestry. Chromosomal segments of Amerindian origin were identified using ancestry deconvolution methods. Additionally, we analyzed haplotypes and compared genomic similarities between Charrúas and other indigenous groups. To better characterize Uruguay's genetic structure, we conducted low-pass whole-genome sequencing (LPS) on 850 individuals representing diverse geographic regions.

Results: We detected Amerindian ancestry in living Uruguayans, with haplotypes enriched in self-identified Charrúas but rare in other Amerindians. The genomic similarity between Charrúas and Guaraní aligns with historical records of contact. Surprisingly, we also found high similarity between Charrúas and the Diaguita from Argentina and Chile, potentially explained by Diaguita expansion and Charrúan nomadism. Preliminary results from 30 high-coverage genomes confirm Uruguay's complex admixed genetic structure.

Conclusion: This study provides the first genome-wide insights into Charrúan heritage and Uruguay's genetic diversity. While our findings confirm indigenous ancestry, larger sample sizes are needed for a complete characterization. The inclusion of 850 individuals in our LPS study will allow a more detailed understanding of Uruguay's population structure.

P21.024.B Introducing the Y chromosome ancestral reference sequence - Improving the capture of human evolutionary information

Annina Preussner[1], *Zehra Köksal*[2], *Leonor Gusmão*[3], *Vania Pereira*[4], *Jaakko Leinonen*[5], *Taru Tukiainen*[1,6]

[1]*Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland,* [2]*Department of Biomedical and Clinical Sciences, Linköping University, Linköping, Sweden,* [3]*DNA Diagnostic Laboratory (LDD), State University of Rio de Janeiro (UERJ), Rio de Janiero, Brazil,* [4]*Section of Forensic Genetics, Department of Forensic Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [5]*Center for Child, Adolescent, and Maternal Health Research, Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland,* [6]*Department of Psychology, Faculty of Medicine, University of Helsinki, Helsinki, Finland.*

Background: The human Y chromosome (chrY) is widely used in evolutionary studies, but its current references represent

evolutionarily young sequences. This can lead to misleading variant calling by disregarding certain sites or calling evolutionary uninformative sites. To overcome the issue of losing evolutionary informative sites in variant calling, we created an ancestral-like reference sequence for the chrY (Y-ARS).

Material and Methods: To generate the Y-ARS, we applied maximum parsimony to determine ancestral alleles in chrY sequences of seven humans and four great ape species. We then converted all sites in the T2T-CHM13 reference to their ancestral state. To evaluate this new reference, we aligned 50 short-read sequencing samples (representing all major haplogroups) to the Y-ARS and existing references (GRCh37, GRCh38, T2T-CHM13).

Results: The alignment to the Y-ARS yielded on average the highest number of SNPs per sample (N = 691) compared to existing references (N = 498–571). Notably, when the sample and the reference were phylogenetically close (e.g., haplogroup R1b and GRCh38), the number of SNPs decreased 13-fold compared to the Y-ARS alignment. Additionally, the Y-ARS resulted in calling only evolutionary derived SNPs, while alignments to other references resulted in calling 44% ancestral SNPs due to the sites being evolutionarily derived in the reference.

Conclusion: This study demonstrates how current references fail to capture the full range of evolutionary information on the chrY. The new Y-ARS improves the capture of evolutionary derived sites, making it a valuable resource for various evolutionary genetics applications, such as TMRCA estimation, phylogenetic analyses, and demographic modeling.

P21.025.C Following the genes - Diving deep into the genetics of Odisha's tribal populations

Sudeshna Datta[1,2], *Deepak Jena*[1], *Arup Ghosh*[1], *Viplov Kumar Biswas*[1], *Sudarshana Jena*[1], *Analabha Basu*[3], *Sunil Kumar Raghav*[1]

[1]*Institute of Life Sciences, Bhubaneswar, India,* [2]*Kalinga Institute of Industrial Technology, Bhubaneswar, India,* [3]*National Institute of Biomedical Genomics, Kalyani, India.*

Background: Endogamous indigenous populations hold key insights into the migration and evolution of modern ethnic groups. Here, we present a whole-exome sequencing of 621 self-declared healthy individuals collected from 4 districts of Odisha, a region with the highest tribal diversity in India. These individuals, collectively termed the OdiTribe belong to 13 major tribal groups representing 3 different linguistic families.

Material and Methods: We followed the GATK best practices for variant calling and ANNOVAR for annotating the variants. Quality control and statistical tests were performed using BCFtools and PLINK.

Results: We report a total of ~620k variants in our dataset. We uncovered 101,489 novel variants in our cohort, ~88% of which are OdiTribe specific (mostly singletons), ~10% are shared by other populations of India, and ~1% are shared by populations in different Asian countries. We found 220 pathogenic and likely pathogenic variants and identified pathogenic variants in the HBB (rs33915217; $p < 2.2 \times 10\text{-}16$) and HBD (rs549964658) genes with a high allele frequency for OdiTribe compared to the ExAC allele frequency. Population structure analysis by combining our exomes and GenomeAsia100k cohort captured continental and population-specific patterns of genetic variation. We found OdiTribe genetically closer to South-Asian populations, specifically the Indian tribal groups. Further, we observed 7 subclusters within the OdiTribe.

Conclusion: Overall, we reported the tribal groups of Odisha to be heterogeneous with varying degrees of homogeneity within a few groups, possibly attributed to either founder effect or population bottleneck.

P21.026.D Unraveling the role of loss of function variants in autozygous segments: insights into gene expression and disease mechanisms

Andrei Cristea[1], *Alessandro Raveane*[1], *Arianna Landini*[1], *Matiss Ozols*[2], *Stephen B. Watt*[2], *Cardinal Project Working Group*[3], *Oliver Stegle*[4,5], *David van Heel*[6], *Nicola Pirastu*[1], *Nicole Soranzo*[1,2,7]

[1]*Human Technopole, Milan, Italy,* [2]*Wellcome Sanger Institute, Hinxton, Saffron Walden, United Kingdom,* [34]*German Cancer Research Centre (DKFZ), Heidelberg, Germany,* [5]*European Molecular Biology Laboratory (EMBL), Heidelberg, Germany,* [6]*Queen Mary University of London, London, United Kingdom,* [7]*University of Cambridge, British Heart Foundation Centre of Research Excellence, Cambridge, United Kingdom.*

Background: The genetic architecture of the Genes & Health UK study cohorts of Pakistani and Bangladeshi donors offers up to 100 times greater statistical power for autozygosity analyses compared to cosmopolitan populations. Long runs of homozygosity (ROH) are genomic footprints of recessive inheritance and large deleterious effects, linked to an increased prevalence of specific diseases. Loss of function (LoF) variants within autozygous segments may disrupt gene expression, potentially driving disease development.

Material and Methods: Using genetic and single-cell RNA sequencing data, we examine the effects of high autozygosity on gene expression and phenotype association. We analyse the density, localisation, and gene overlap of ROH and identified LoF SNPs within these regions. We explore the impact of LoF SNPs within ROHs on autozygosity-specific phenotypes, specifically how these contribute to genomic architecture and disease development mechanisms.

Results: Across our cohort, we identified 674,244 ROHs with a median FROH coefficient of 0.172 per donor, reflecting the high prevalence of consanguineous unions. Additionally, 9,585 LoF variants within ROH segments were found. *SKA3*, *ZAN* and *ACOT* genes are enriched for LoF variants in more than 2 cell types, being involved in mitosis, gamete recognition, and cholesterol metabolism. We aim to further explore transcriptomic effects of LoF variants in ROH using single-cell RNA sequencing data.

Conclusion: Investigating LoF variants within ROH provides a framework for understanding the genetic mechanisms underlying disease development in populations with high autozygosity rates. These findings contribute to a deeper understanding of the local genomic effects of autozygosity and its phenotypic consequences.

P21.027.A A high-frequency Neandertal haplotype increases expression of the thermogenin Irisin in modern humans

Volker Soltys[1], *Hugo Zeberg*[2]

[1]*Max Planck Institute for Evolutionary Anthropology, Department of Evolutionary Genetics, Leipzig, Germany,* [2]*Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden.*

Background: About 47,000 years ago, modern humans encountered Neandertals while expanding into new environments,

leading to approximately 2% archaic DNA in present-day people outside Africa. Several archaic haplotypes show signs of selection that may have aided adaptation. Here, we report a Neandertal haplotype at unusually high frequency (~15% in Europe, ~24% in Southeast Asia) overlapping FNDC5, which encodes the peptide hormone Irisin. Irisin is released by skeletal muscle fibers and is key to thermogenesis.

Materials and Methods: We are currently studying this haplotype with several aims. First, we are scanning for signatures of selection which could explain its unusual high frequency. Second, we aim to identify the genetic variant causing increased FNDC5 expression by introducing the archaic variants into the modern human genome ('ancestralizing') via genome editing. Lastly, we aim to characterize the phenotypes associated with carrying this archaic haplotype.

Results: We find that variants on the Neandertal haplotype form the strongest eQTLs for FNDC5 in GTEx ($p = 6e\text{-}58$), with carriers exhibiting over double the expression compared to non-carriers. Moreover, present-day carriers show lower risk of metabolic syndrome (beta = 0.013, $p = 2e\text{-}15$) and reduced body fat (beta = 0.020, $p = 2e\text{-}9$). We also observed associations with certain cognitive phenotypes; specifically higher educational attainment and less daytime napping ($p = 5e\text{-}10$ and $2 \times e\text{-}14$, respectively), though these cognitive findings warrant caution.

Conclusion: Overall, this study illuminates how archaic gene flow helped modern humans adapt to new environments and colder climates.

C.O.I. Disclosure:

V. Soltys: None. **H. Zeberg:** None.

P21.028.B Joint effects of balancing selection and population bottlenecks on the evolution of a regulatory region of human anti-viral*APOBEC3*

Naoko T. Fujito[1,2], *Sundaramoorthy Revathidevi*[3,2], *Yoko Satta*[4], *Ituro Inoue*[2]

[1]*Brain Research Institute, Niigata University, Niigata, Japan,* [2]*National Institute of Genetics, Mishima, Japan,* [3]*College of Engineering and Technology, SRM Institute of Science and Technology, Tamil Nadu, India,* [4]*SOKENDAI (The Graduate University for Advanced Studies), Hayama, Japan.*

Background: Human anti-viral APOBEC3s are crucial components of the innate immune response, playing a key role in inhibiting viral replication and proliferation by inducing mutations in viral genomes. We analyzed a regulatory region of approximately 16 kb in the *APOBEC3* gene cluster, identifying three distinct haplogroups maintained at high frequencies in both African and non-African populations. Despite the long persistence of these haplogroups, one of which is shared by archaic hominins, the nucleotide diversity within each haplogroup was unusually low in non-Africans.

Material and Methods: We examined the frequency of this observation of low intra-haplogroup diversity and high inter-haplogroup divergence by coalescence simulation under neutrality and in the empirical distribution obtained through a genome scan. To explain these features and investigate the underlying evolutionary mechanisms, we performed forward simulations to model the joint effects of balancing selection and population bottlenecks.

Results: The simultaneous observations of low intra-haplogroup diversity and high inter-haplogroup divergence were incompatible with neutrality. We demonstrated the operation of balancing selection and a hitherto unexplored reduction in intra-haplogroup diversity by the forward simulations.

Conclusion: Our findings indicate that balancing selection has acted on the three haplogroups over the past ~1 million years since their emergence from the ancestral group, along with a more-than-expected reduction in intra-haplogroup diversity accompanied by the Out-of-Africa bottleneck. Most likely, the genealogy has been shaped by the combined effects of negative frequency-dependent selection and a severe reduction in effective population sizes, accompanied by the Out-of-Africa dispersal of modern humans.

P21.031.A Understanding the DNA methylation landscape within Variable Number of Tandem Repeats (VNTRs)

Delnaz Roshandel[1], *Shalvi Chirmade*[1], *Scott Mastromatteo*[1], *Bhooma Thiruv*[1], *Sana Allana*[1], *Zhuozhi Wang*[1], *Amirhossein Hajianpour*[1], *Katherine Keenan*[1], *Fan Lin*[1], ***Lisa J. Strug***[2]

[1]*The Hospital for Sick Children, Toronto, ON, Canada,* [2]*University of Toronto, Toronto, ON, Canada.*

Background: Variable number of tandem repeats (VNTRs) are a significant source of genetic variation. They have been understudied as their investigation is challenging with short-read sequencing. Pacific Biosciences (PacBio) HiFi long-read sequencing technology can simultaneously sequence ~20 kb reads and estimate DNA methylation levels. We aimed to use this technology to investigate VNTRs across autosomal chromosomes, their DNA methylation levels, and the factors that may affect their methylation.

Material and Methods: PacBio HiFi sequencing (30X) was performed on blood-derived DNA from 206 individuals of European origin. Tandem Repeat Genotyping Tool (TRGT) and its repeat catalog were used to genotype VNTRs and estimate their methylation levels.

Results: There were 218,881 VNTRs on Chr1-22 in the TRGT catalog. Of these, 87,480 (40%) had variable lengths across the population, and 68,894 (31%) had at least two CpGs within their sequence in all 412 haplotypes. VNTRs tend to be methylated across the genome except for VNTRs located within 5′ upstream of the genes, 5′UTRs, and first exons overlapping CpG islands and promoter regions where the average methylation levels were typically low. The length of 2,150 (5.7%) VNTRs were associated with their methylation levels. VNTRs overlapping CTCF binding sites, open chromatin regions, TF binding sites and enhancers were more likely to be associated with their methylation levels.

Conclusion: We have been generating a comprehensive resource on VNTRs including their alleles, allele frequencies and DNA methylation levels. We have demonstrated that VNTRs are frequent genetic variations in the genome and can affect methylation contributing to human diseases.

P21.032.B Accuracy of genetic ancestry profiles estimated by an efficient k-nearest neighbor algorithm in biobank-scale data sets

Juha Riikonen[1], *Sini Kerminen*[1], *Aki Havulinna*[1,2,3], *Matti Pirinen*[1,4,5]

[1]*Institute for Molecular Medicine Finland, Helsinki, Finland,* [2]*Finnish Institute for Health and Welfare, Helsinki, Finland,* [3]*Department of*

Computing, University of Turku, Turku, Finland, [4]Department of Public Health, University of Helsinki, Helsinki, Finland, [5]Department of Mathematics and Statistics, University of Helsinki, Helsinki, Finland.

Background: We present KANN, an efficient k-nearest neighbor regression method for individual-level genetic ancestry estimation that uses principal components (PCs). We use 18,125 samples from the Finnish Institute for Health and Welfare (THL) biobank with known reference ancestry profiles with respect to 10 Finnish source populations[1] estimated using a more computationally expensive, state-of-the-art method SOURCEFIND[2].

Material and Methods: We applied KANN with 10 PCs and compared the results to SOURCEFIND using total variation distance (TVD). We studied the marginal differences between the two methods in each ancestry source, and their distribution among samples where the methods differed highly (>0.05) for at least one source.

Results: In the test set, the mean TVD is 0.112 and, for all source populations, the lower and upper quartiles of the absolute marginal differences remain under 0.04. Among samples showing a high difference between the two methods, the difference is unevenly and asymmetrically distributed within pairs of populations, providing important information for interpretation of the estimates. For example, in samples for which KANN estimates a particularly high West Lapland (WL) component, a majority (85%) of the difference to SOURCEFIND occurs in East Lapland (EL) component, but when KANN's estimate for WL is particularly low, then only 32% of the difference occurs in EL.

Conclusion: With KANN, we can efficiently estimate ancestry profiles for biobank-scale data sets with high consistency to SOURCEFIND results. For situations where a detailed interpretation of KANN results is needed, we provide a framework for characterising uncertainty in ancestry profiles.

P21.033.C UMI-nanopore sequencing reveals population-specific haplotype diversity in the complex lipoprotein(a) KIV-2 VNTR in a multi-ancestry sample set

***Stephan Amstler**, Lara Escherich, Gertraud Streiter, Silvia Di Maio, Cathrin Pfurtscheller, Lukas Forer, Hansi Weissensteiner, Florian Kronenberg, Sebastian Schoenherr, Stefan Coassin*

Medical University of Innsbruck, Innsbruck, Austria.

Background: Lipoprotein(a) [Lp(a)] concentrations are a major, independent risk factor for cardiovascular diseases. Concentrations are highly ancestry-specific and nearly exclusively explained by a haplotype-dependent interplay of SNPs and a coding VNTR in lipoprotein(a) *(LPA* KIV-2 repeat; up to 40 5.6 kb repeats per allele). NGS has identified several SNPs within KIV-2 but fails to resolve the complex haplotypes across VNTR units. We combined unique molecular identifiers with nanopore sequencing (UMI-ONT-Seq) to sequence the KIV-2 VNTR of 328 individuals from eleven 1000-Genomes populations.

Material and Methods: Amplicon-based UMI-ONT-Seq data was analyzed using a custom Nextflow analysis pipeline (github.com/genepi/umi-pipeline-nf) to call KIV-2 SNPs and haplotypes, infer KIV-2 copy numbers via coverage-corrected haplotypes, and describe KIV-2 haplotype diversity. Validation included plasmid mixtures and trio concordance analysis.

Results: We identified 755 SNPs across 12,453 KIV-2 repeat units, with strong agreement between UMI-ONT-Seq and NGS for variant calling ($r = 0.97$) and KIV-2 copy number estimation ($r = 0.89$). Of 10,924 observed KIV-2 haplotypes, 2,308 were unique across all populations, including common (≥200 occurrences) and ancestry-specific patterns. PCA of the haplotypes revealed ancestry-specific clusters, with African individuals showing distinct clustering and European and Asian populations displaying widespread clusters. The frequent strongly Lp(a)-lowering KIV-2 SNPs 4733G>A and 4925G>A were detected only in non-African individuals ($n = 44$). Notably, 23 of 24 unrelated 4733G>A carriers shared an identical haplotype, possibly implying recent founder effects.

Conclusion: UMI-ONT-Seq enables precise haplotyping in a highly homologous (>97%), complex VNTR. This reveals novel ancestry-specific patterns and provides insights into genetic population diversity in this dark genome region.

P21.034.D Analysis of genetic diversity and phylogenetic relationships of D4Z4 repeats: implication for health and disease

***Sara Pini**[1], Matteo Chiara[2,3], Valentina Salsi[1], Graziano Pesole[3,4], Rossella G. Tupler[1,5,6]*

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, [2]Dipartimento di Bioscienze, Università degli Studi di Milano, Milano, Italy, [3]Institute of Biomembranes, Bioenergetics and Molecular Biotechnologies, Consiglio Nazionale delle Ricerche, Bari, Italy, [4]Department of Biosciences, Biotechnology and Environment, University of Bari "A. Moro", Bari, Italy, [5]Department of Molecular, Cell, and Cancer Biology, University of Massachusetts Medical School, Worcester, MA, USA, [6]Li Weibo Institute for Rare Diseases Research at the University of Massachusetts Medical School, Worcester, MA, USA.

Background: Repetitive DNA represents about half of the human genome and plays a crucial role in physiology, disease and evolution. Notwithstanding this, the molecular function of repetitive DNA has been largely underestimated due to methodological/technical limitations. Here we use FSHD, a disease causally associated with D4Z4 repeats, as a model to investigate the features, configuration, and evolution of these repetitive sequences in *Homo sapiens* and other non-human primates.

Material and Methods: We developed an ad hoc computational workflow, to perform a comprehensive characterization of the size, number and distribution of the D4Z4 elements in the primate genome by analyzing the T2T-CHM13 assembly, 94 haplotype resolved telomere-to-telomere assemblies from the human pangenome project, and a selection of non-human primates.

Results: We identified hundreds of D4Z4 sequences in the genome with widespread inter- and intra-individual variability. Contrary to common knowledge, D4Z4 repeats localized not only at the subtelomeres of chromosomes 4q and 10q but also at the short arms of acrocentric chromosomes, interspersed with rDNA

operons, and at the pericentromeric chromatin of chromosome 1. We also reconstructed the evolutive history and the acquisition of functional elements within these repeats, that first appeared in old world monkeys spreading in the primates.

Conclusion: Our study offers an integrated approach for the study of repetitive elements and highlights the importance of telomere-to-telomere assemblies. Our results advocate for a systematic reanalysis and a critical review of previous studies on FSHD pathogenesis and diagnostics and offer new insights for the interpretation of D4Z4 elements biological role.

P21.035.A A human-specific amino acid replacement in a brain receptor regulating food intake

Miriam Berreiter, *Richard Ågren, Hugo Zeberg*

Karolinska Institutet, Stockholm, Sweden.

Background: The melanin-concentrating hormone receptor 2 (MCHR2) is a G protein-coupled receptor involved in energy homeostasis, stress response, and emotional regulation. A modern human-specific mutation (V324A) in MCHR2, located in the intracellular domain, distinguishes modern humans from Neanderthals, Denisovans, and all other mammals which retain the ancestral version. The functional consequences of this mutation remain unexplored.

Material and Methods: We investigated the allele frequency in large scale genomic resources including 1000 Genomes Project, gnomAD, Biobank Japan and GenomeAsia. We explored phenotypic effect using biobank data. We will conduct mammalian cell culture experiments and a BRET-based assay to compare the functional properties of the modern human (V324A) and ancestral (V324) versions of MCHR2. Given the mutation's location in the intracellular domain, we will also focus on downstream signaling pathways (e.g., cAMP, ERK, and calcium mobilization) and receptor internalization dynamics.

Results: We find the ancestral variant at frequencies approaching 1% in East Asia. Preliminary data suggest no major impact on weight or body mass index, however these phenotypic analyses are limited to mainly heterozygous carriers.

Conclusion: This project aims to uncover the functional implications of a modern human-specific MCHR2 mutation. By comparing the modern and ancestral versions, we hope to identify phenotypic consequences that may explain the selective pressures driving this mutation's fixation in modern humans.

P21.036.B Genomic Map of Poland - Building a Reference National Database for Genetic Diversity

Luiza Handschuh[1], *Malgorzata Marcinkowska-Swojak*[1], *Pawel Wojciechowski*[2], *Ireneusz Stolarek*[1], *Natalia Koralewska*[1], *Lucyna Budzko*[1], *Magdalena Rakoczy*[1], *Michal Zenczak*[1], *Piotr Lukasiak*[2], *Aleksandra Swiercz*[2], *Jacek Blazewicz*[2], *Marek Figlerowicz*[1]

[1]*Institute of Bioorganic Chemistry PAS, Poznan, Poland,* [2]*Poznan University of Technology, Poznan, Poland.*

Background: Many countries are currently implementing national genomic projects. Some initiatives, e.g. British 100,000 Genomes Project, or Estonian Genome Project, have already collected valuable data that can be used as references for population studies and personalized medicine. Until recently, Poland lacked such a reference. The Genomic Map of Poland (GMP) addressed this gap by providing the first comprehensive national infrastructure integrating genomic resources and bioinformatics tools to analyze genetic diversity within Poland.

Material and Methods: GMP was established by consortium of the Institute of Bioorganic Chemistry PAS and Poznan University of Technology. Anonymized samples (3970), representative of the Polish population were obtained from the biobank of the National Institute of Cardiology in Warsaw, collected as part of population health screening study. Additional biological material (saliva, blood) was collected within the project (2330). Whole genome sequencing (30–60x coverage) was performed with MGI and Illumina platforms.

Results: In total, we sequenced over 5,700 genomes of Polish residents, and generated four data subsets: ***Genetic Variability Map*** reflecting general genetic diversity within Poland (3,446 genomes representing all voivodeships, multiple counties); ***Polish Reference Genome*** assembled de novo using 10 trios and five sequencing technologies (DNBSEQ, ONT, PacBio, Hi-C and RNA-seq); ***Fen-Gen*** linking phenotype to genotype (1,004 genomes of athletes who underwent additional medical and physical examinations); ***Et-Gen*** reflecting genetic variability of five ethnic and regional minorities in Poland (1,236 genomes of Kashubians, Silesians, Lemkos, Highlanders and Poznan Bambers).

Conclusion: GMP presents the genetic landscape of Polish population, serving as a valuable resource for further research.

Background: Central Europe remains underrepresented in global genomic databases, limiting the interpretability of local genetic variants. The Analysis of Czech Genomes for Theranostics (A-C-G-

T) project addressed this gap by generating whole-genome sequencing (WGS) data from over 1,000 Czech adults.

Materials and Methods: Participants aged 30–55 without severe genetic diseases were enrolled if both parents originated from the same Czech region; with individuals proportionally distributed across all 14 regions of the Czech Republic. DNA libraries were prepared using PCR-free protocols and sequenced on Illumina NovaSeq 6000. Data processing followed the GATK best-practice pipeline via nf-core/sarek (v2.7.1). Technical outliers and samples with cryptic relatedness (kinship coefficient >0.0884) were removed, retaining only third-degree or more distant relatives. Population genetic analyses, including principal component analysis (PCA), were conducted to explore demographic patterns. Data were compared with global datasets, such as the 1000 Genomes Project (1KGP).

Results: The A-C-G-T database (database.acgt.cz) contains WGS data from 1,257 healthy individuals (611 females, 646 males) after removing 10 technical outliers and 23 samples with cryptic relatedness from the initial dataset (N = 1,290). In the PCA, the samples cluster with other European groups from the 1KGP, forming a distinct group that is well-separated from other clusters of European populations. An internal analysis revealed a possible genetic cline across the country.

Conclusion: This Czech-specific reference improves local variant interpretation and supports precision medicine in Central Europe. A follow-up project (A-C-G-T 2) will expand on these data by further exploring genome variation in A-C-G-T participants and analyzing patient cohorts.

P21.038.D Genome-wide identification and analysis of great apes-specific splice sites

***Zhuo Qu**, Chie Kikutake, Mikita Suyama*

Kyushu university, Fukuoka, Japan.

Background: Alternative usage of splice sites can generate multiple transcripts from a single gene locus through the insertion or deletion of exons. Variants affecting the splicing process have been systematically identified as deleterious in some studies due to their potential impact on phenotypes. However, some variants affecting the splicing process have relatively high allele frequencies, and we speculate that such variants to be benign or even beneficial for human evolution. Genetic variants acquired during evolution can serve as a source of species-specific functions, but the role of novel alternative usage of splice sites associated with these variants remains largely unknown.

Material and Methods: We used transcriptomic data from five tissues across humans, chimpanzees, rhesus macaques and mice to identify great apes-specific splicing events and the associated variants. We also analyzed the characteristics of the identified events and their effect on the transcripts or proteins.

Results: We identified 1,043 great apes-specific splicing events including 784 annotated splicing events, 203 exon shrinkage events, 41 exon extension events, and 15 pseudo-exon activations. Through comparative analysis of the identified splice site sequences across various species, we found that most of these sites in apes tend to have higher splice site strength compared to other species. Additionally, we analyzed the impact of the identified events on transcripts and protein products, and found that approximately 41.5% of these events occur within coding sequences (CDS).

Conclusion: We consider that species-specific splice sites may be one of the important mechanisms for the acquisition of novel sequences during evolution.

P21.039.A Challenges in finding correlations between homocysteine levels and MTHFR C677T/A1298C polymorphisms in Georgian population patients with thrombosis and pregnancy complications/infertility

***Ketevan Kartvelishvili**[1,2], Nino Pirtskhelani[1,2,3], Nino Kochiashvili[1], Mamuka Bokuchava[2,4], Tea Mukhuradze[4,2], Natia Popkhadze[5], Tatia Tugushi[6]*

[1]National Forensics Bureau, Tbilisi, Georgia, [2]Tbilisi State Medical University, Tbilisi, Georgia, [3]Ken Walker International University, Tbilisi, Georgia, [4]Bokhua Memorial Cardiovascular Center, Tbilisi, Georgia, [5]Invitro Life, Tbilisi, Georgia, [6]The cabinet of reproductive health Fertimed, Tbilisi, Georgia.

Background/Objectives: Two SNPs in the MTHFR gene, C677T and A1298C are associated with decreased enzyme activity, hyperhomocysteinemia, damage of blood vessels and thromboembolism. "Normal" values of homocysteine are a source of clinical confusion. The upper limit is around 15 µmol/L, while optimal level may be well below upper threshold. Any elevation above 5 µmol/l increases risk for cardiovascular disease and pregnancy complications. Our previous studies of 127 patients with thrombosis and 523 with pregnancy complications/infertility showed high distribution of MTHFR gene polymorphism. In this study, we aimed to analyze the correlations between homocysteine levels and MTHFR gene polymorphisms in these two groups of patients.

Methods: We chose 55 patients genotyped by multiplex PCR, with MTHFR(C677T;A1298C) polymorphisms and conducted homocysteine biochemical analysis.

Results: The table below represents our study results, which show that 8(57%) out of 14 female and 13(81.2%) out of 16 male patients with thromboembolisms had hyperhomocysteinemia. Of 25 female patients with pregnancy complications/infertility, in 15(60%) homocysteine levels were elevated, in 10(40%) in normal range.

Conclusion: Homocysteine levels were found to be more elevated in thrombotic patients than in the second group, but significant correlations between different genotypes and phenotypes were not detected. Considering that homocysteine levels are highly sensitive to blood sample handling and processing, they may fluctuate with patients' diet or preventing treatment and given the high prevalence of MTHFR gene polymorphisms in the Georgian population, we recommend including these polymorphisms in the thrombophilia diagnostic gene panel.

P21.040.B Immune Cell Atlas of Ancestral and Environmental Diversity in Indonesia

Muhamad Fachrul[1], *Pradiptajati Kusuma*[2], *Chelzie Darusallam*[2], *Isabella Apriyana*[2], *Isabela Alvim*[1], *Monika Novita*[2], *Sukma Oktavianthi*[2], *Andreas Christian*[2], *Bertha Utami*[2], *Prisca Limardil*[2], *Lidwina Apriliani*[2], *Murray Cox*[3], *Safarina Malik*[2], *Herawati Sudoyo*[2], *Nicholas Banovich*[4], *Irene Gallego Romero*[1]

[1]St. Vincent's Institute of Medical Research, Melbourne, Australia, [2]Mochtar Riady Institute For Nanotechnology, Tangerang, Indonesia, [3]Massey University, Auckland, New Zealand, [4]The Translational Genomics Research Institute (TGen), Phoenix, AZ, USA.

Background: Indonesia is the world's fourth most populous country, home to a diverse population of over 280 million people. The region's complex population history, ancestral components, and diverse environments present a unique immune pressure on the population. Yet, it remains consistently underrepresented in large-scale human genomic resources.

Material and Methods: We generated single-cell characterizations of peripheral blood mononuclear cells (PBMCs) from 203 individuals across Bali (representing more Island Southeast Asian-like ancestry, urban vs rural) and Papua (representing more Papuan-like ancestry, highland vs lowland) to assess how ancestral and environmental diversity impact the immune cells of Indonesians.

Results: We present preliminary results highlighting differences in cell-type proportions and cell type-specific expressions between regions (representing ancestral diversity) and villages (representing lifestyle / environment). We identified expression quantitative trait loci (eQTLs) that are both shared and specific to certain cell types, identified different patterns between regions, and also investigated overlaps with introgressed archaic haplotypes. We also discuss logistical challenges present during the project and learning points for future multisite studies.

Conclusion: We have characterized cell-type specific proportions, differential gene expression, and eQTLs within our cohort of Indonesian donors and found significant differences driven by ancestral and environmental diversities.

P21.042.D Mapping Slovenia's Genome: The Launch of a National Genomic Reference Project

Jernej Kovač[1,2], *Barbara Jenko Bizjan*[1,2], *Tine Tesovnik*[1,2], *Robert Šket*[1,2], *Barbara Čugalj Kern*[1], *Barbara Slapnik*[1], *Karolina Mužina*[1], *Blaž Vrhovšek*[1], *Ana Markež*[1], *Maruša Debeljak*[1], *Urh Grošelj*[3,4,5], *Sonja Štramec-Nemec*[6], *Alja Romšak*[7], *Sara Bertok*[8], *Alja Videtič Paska*[2], *Cene Skubic*[2], *Tadeja Režen*[2], *Lucija Raspor Dall'Olio*[2], *Kristjan Žagar*[9], *Aleš Čep*[9], *Marko Ferme*[9], *Damjana Rozman*[2], *Vita Dolžan*[2], *Milan Ojsteršek*[9], *Tadej Battelino*[3,4]

[1]Clinical Institute of Special Laboratory Diagnostics, University Children's Hospital, University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]Institute of Biochemistry and Molecular Genetics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [3]Department of Endocrinology, Diabetes, and Metabolic Disorders, University Chilren's Hospital, University Medical Centre Ljubljana, Ljubljana, Slovenia, [4]Department of Pediatrics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [5]Department of Medical Ethics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [6]Legal Department, University Medical Centre Ljubljana, Ljubljana, Slovenia, [7]Secretary Office, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [8]Centre for Rare Diseases, University Children's Hospital, University Medical Centre Ljubljana, Ljubljana, Slovenia, [9]Faculty of Electrical Engineering and Computer Science, University of Maribor, Maribor, Slovenia.

Background: National genomic diversity is a cornerstone for advancing precision medicine. The Slovenian Reference Genome Project (SRGP), launched in January 2025, aims to construct a comprehensive pangenome representative of the Slovenian population and contribute genome data to Genome of Europe collection. By integrating cutting-edge sequencing technologies, SRGP seeks to address the limitations of current reference genomes, which fail to capture globally rare yet locally prevalent genetic variations. These insights are crucial for diagnosing rare diseases, understanding common genetic disorders, and optimizing clinical treatment.

Material and Methods: SRGP involves sequencing 500 healthy adult volunteers who consented to sequencing whole genome using long-read technology. This approach ensures the ability to produce high-resolution genomic assemblies. Advanced bioinformatics pipelines, incorporating haplotype-aware de novo assembly and methylation-based phasing, will resolve complex genomic regions. The resulting pangenome will adhere to FAIR principles,

with secure data-storage and accessibility aligned with EU 1+MG initiative.

Results: Samples of 500 volunteers and their informed consents were collected. Preliminary analyses from sequencing of 8% of the cohort demonstrate the ability of the project to provide personalized genetic insights, fostering public engagement and trust. Additionally, significant improvements in variant detection within complex genomic regions are expected to be demonstrated, enabling identification of Slovenian-specific pharmacogenomic markers and rare disease-associated variants.

Conclusion: SRGP establishes a national genomic reference critical for personalized medicine and advanced diagnostics. By resolving complex genomic regions and enabling secure, compliant data sharing, SRGP, that is also part of European initiative Genome of Europe, enhances Slovenia's contribution to international genomic initiatives.

P21.043.A Kernel causality analysis of evolutionary amino acid changes reveals extensive nodes of coagulation factor IX variants in the development of haemophilia B

Alper Karagöl[1], *Taner Karagöl*[1], *Stephen J. Perkins*[2]

[1]*Department of Medicine, Royal Free Hospital, University College London, London, United Kingdom,* [2]*Research Department of Structural and Molecular Biology, University College London, Darwin Building, London, United Kingdom.*

Background: Coagulation factor IX (FIX, *F9*) is a key component of blood clotting, with mutations in FIX being associated with haemophilia B. Understanding residue changes in the evolution of FIX is essential for elucidating its structure-function relationships and the molecular basis of bleeding disorders.

Material and Methods: This study applies a kernel regression approach to perform a residue-based evolutionary analysis of FIX. Homologous sequence data were generated using Hidden Markov Model (HMMER) algorithms and were combined with functional annotations from our *F9* variant database to identify regions of evolutionary constraint and plasticity. Kernel causality analysis was utilized to estimate co-evolutionary relationships while accounting for covariates.

Results: Our findings reveal distinct patterns of conservation and epistasis. An asymmetric interdependence is suggested between the amino acid pairs Q and R. Glutamine (Q), as a kernel cause, increases arginine (R) frequencies, indicating evolutionary pathways where the introduction of glutamine compensates for the loss of arginine ($r^* = 0.1374$, $p = 0.0091$). In confirmation of this relationship, we observed nine unique R>Q variants associated with severe patient cases. The introduction of glycine (G) decreases serine (S) frequencies in homologous sequences ($r^* = -0.1383$, $p = 0.0086$), suggesting that serine substitutions derived from glycine are deleterious, a finding further supported by the *F9* variant database.

Conclusion: Our approach offers additional insights into the evolutionary forces shaping the coagulation factors and offers a framework for predicting the functional impact of genetic variations in *F9*. Our findings have broader implications for understanding protein evolution and may inform strategies for therapeutic interventions in haemophilia B.

P21.044.B Cardiogenetics in Saguenay-Lac-Saint-Jean: deciphering the founder genetic background through a collaborative model

Tania Cruz Marino[1], *Josianne Leblanc*[2], *Jessica Tardif*[2], *Marie-Jacqueline Thomas*[2], *Annabelle Pratte*[2], *Jonathan Beaudoin*[2], *Melinda Barabas*[2]

[1]*McGill University Health Center, Montreal, QC, Canada,* [2]*CIUSSS Saguenay-Lac-Saint-Jean, Chicoutimi, QC, Canada.*

Background: Saguenay-Lac-Saint-Jean (SLSJ) is a geographically isolated region in the province of Quebec, Canada. This study aims to describe the unique model of Cardiogenetics service delivery developed in SLSJ and provide evidence of the role of some probable founder alleles in the etiology of inherited cardiovascular diseases, which were previously unexplored in this population.

Material and Methods: This study was comprised of two groups: the 'affected individuals' group and the 'predictive testing group'. Patients affected with cardiomyopathies, arrhythmias, or thoracic aorta disease were referred to the Cardiogenetics Clinic between October 2014 and December 2024, and were clinically evaluated following the individual trajectory or the group genetic counseling trajectory. The predictive testing group was comprised of healthy individuals who were related by blood to individuals affected with a hereditary form of cardiovascular disease.

Results: The number of clinics performed per year constantly increased, allowing for the evaluation of 439 affected and 248 at-risk individuals. The creation of a database registry facilitated the understanding of the genotype-phenotype associations. Six genetic variants are recurrent in multiple non-consanguineous unrelated families, all of them with French-Canadian ancestry, suggesting genetic drift for these alleles in SLSJ, and enriching the understanding of the founder genetic background in this population.

Conclusion: The creation of the Cardiogenetics Clinic and the development of different evaluation trajectories have positively impacted the patients and their at-risk relatives, who benefit from personalized services, delivered in a timely manner. This experience has the potential to be replicated in other populations.

P21.045.C Shadows of the Black Death: genetic variation in *ERAP1* and *ERAP2* selected for in response to *Yersinia pestis* infection, persist in patients with autoimmune disease

Lynn Win[1], *Sarah Ennis*[2], *Guo Cheng*[1]

[1]*University of Southampton, Southampton, United Kingdom,* [2]*Human Genetics Division (MP 808)Southampton General Hospital, Southampton, United Kingdom.*

Background: ERAP genes facilitate antigen presentation. Variation in these genes underwent selection during the plague and may now impact autoimmune disease susceptibility. This study assesses the pathogenic burden of genetic variation in the *ERAP1* and *ERAP2* genes in a cohort of patients diagnosed with Crohn's disease (CD) or ulcerative colitis (UC).

Material and Methods: This study analyses the Southampton Genetics of inflammatory bowel disease (IBD) cohort which comprises of consented patients diagnosed with IBD with rich genomics and clinical data on autoimmune comorbidities ($n_{CD} = 649$, $n_{UC} = 332$); and UKBiobank patients diagnosed with IBD and controls ($n_{CD} = 67$, $n_{UC} = 106$, $n_{control} = 4506$). In the Southampton patient-only cohort, common single variants (minor-allele-count (MAC)>0.05) were tested using logistic regression for association in UC versus CD patients. GenePy and SKAT-O were used to examine whole gene burden of likely pathogenic variants.

Results: In the Southampton IBD cohort, common variants were nominally significantly differentially distributed between UC and CD patients, but these did not withstand correction for multiple testing. Gene level analysis using all GenePy scores identified a significantly higher pathogenic burden in *ERAP1* ($p = 0.0073$) in UC compared to CD patients. No differences were identified in the Southampton cohort for *ERAP2*. Analysis of concurrent autoimmune comorbidity identified individuals with a second autoimmune diagnosis had a higher pathogenic burden in ERAP2 (vs CD $p = 0.034$(theta $= 0.457$). In UKBioBank, participants diagnosed with UC had a *higher* pathogenic burden in *ERAP1* ($p = 0.0004$), and *lower* burden in *ERAP2* ($p = 0.0006$) compared to controls.

Conclusion: Genetic variation in *ERAP1* and *ERAP2* are persistent in contemporary patient cohorts.

P21.046.D Analysis of the Genetic Structure in an admixed Population from Southern Caribbean: A report from the Cartagena Cohort Study -CaReS-

Sara Mestra-Meriño[1], *Eduer Pérez*[1], *Luisa Jimenez-Rodriguez*[1], *Diana Mena-Yi*[1], *Marilyn Jimenez-Agamez*[1], *Maria Stephany Ruiz-Diaz*[1], *Edgar Vergara*[2], *Nerlis Pajaro*[2], *Elmer Fernandez*[3], *Federico Prada*[4], *Rodrigo Villegas*[5], *Vanessa Garcia-Larsen*[6], *Fernando Manzur-Jattin*[1], *Gustavo José Mora-Garcia*[1]

[1]*Universidad de Cartagena, Cartagena, Colombia,* [2]*Universidad de Sucre, Sincelejo, Colombia,* [3]*Fundacion para el progreso de la Medicina, Cordoba, Argentina,* [4]*Universidad de Argentina de la Empresa, Buenos Aires, Argentina,* [5]*Universidad de Chile, Santiago, Chile,* [6]*The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA.*

Background: Contemporary populations in Southern Caribbean are composed by a tri-hybrid admixture of European, African and Native America ancestry. Such diversity brings an opportunity to understand complex traits and human diseases; hence, descriptions of genetic structure in these populations is warrant.

Aim: Determine the genetic structure of an admixed population settled in Southern Caribbean.

Material and Methods: A cross-sectional study was conducted with adults enrolled in the Cartagena Cohort Study (CaReS). Whole blood samples were collected for genomic DNA extraction. A set of 91 Ancestry Informative Markers (AIMs) were genotyped using qPCR. A Montecarlo Markov Chain (MCMC) was performed to infer population substructure.

Results: A total of 528 adults were analyzed. A genetic structure composed by two sub-populations ($k = 2$) was found. Admixture of three ancestry groups showed a predominant contribution of European (40.0%), Native American (29.8%), and African (30.2%) features.

Conclusion: This contemporary population in Southern Caribbean showed a sub-structured genetic architecture. Further genetic association studies in this region should implement adjustments to reduce the probability of spurious associations.

P21.047.A Assessment of the population structure of Eastern Ukraine by rs3733890 in BMHT gene and rs1801133 in MTHFR gene

Serhii Slutu[1], *Tetiana Borysenko*[2], *Olena Fedota*[3]

[1]*Kharkiv National University of Radioelectronics, Khrakiv, Ukraine,* [2]*MNPE «City Clinical Hospital No. 13» of the Kharkiv City Council, Khrakiv, Ukraine,* [3]*LLC "AMS", Kharkiv, Ukraine.*

Background: Vitamin deficiency states, hyperhomocysteinemia, other metabolic features limit the use of certain drugs or cause additional prescriptions and dietary recommendations. Pharmacogenetic effects of one-carbon metabolism genes, *BMHT, MTHFR*, are known when using ademetionine, metformin hydrochloride, methotrexate, betaine hydrochloride, etc. Genetic characteristics in the world's population for these genes have wide variability. Assessment of the population structure by rs3733890 and rs1801133 is appropriate for justifying genetic testing before prescribing treatment for people with diseases of the hepatobiliary, endocrine, reproductive systems, genodermatoses, etc. in each country.

Material and Methods: Population study included people in Eastern Ukraine aged from 18 to 70 years ($n = 61$). Genotyping of SNPs was made by PCR-RFLP. An analysis of databases and projects: OMIM, Ensembl, etc. was conducted regarding rs3733890 and rs1801133.

Results: In Eastern Ukraine, the frequencies of alleles and genotypes were: for rs3733890 G:0.697, A:0.303, GG:0.443, AA:0.049, GA:0.508, for rs1801133, C:0.729, T:0.271, C/C:0.574, T/T:0.114, C/T:0.312. They do not significantly differ from the data of 1000 Genomes Project Phase 3 for Europeans: G/G:0.459, A/A:0.105, A/G:0.435 ($p = 0.979$), CC:0.406, TT:0.135, CT: 0.459 ($p = 0.942$).In all distributions, the ratio of genotypes doesn't differ from the theoretically expected equilibrium ($p > 0.001$), including the distribution of genotypes for two SNPs ($p = 0.781$). The genotypes ratio was CC/GG:0.295, CC/GA:0.262, CC/AA:0.017, CT/GG:0.115, CT/GA:0.164, CT/AA:0.033, TT/GG:0.033, TT/GA:0.082, TT/AA:0.0.

Conclusion: In Eastern Ukraine the share of genotypes for rs3733890 and rs1801133 with two or more polymorphic alleles was 44.3%. Genotyping is appropriate for clarifying the ways of correcting one-carbon metabolism, predicting the effects of therapy and its personalization.

P21.049.C PITX1 and TBX4 variants are rare in severe bilateral clubfoot: evidence from 162 Italian patients

Michela Zorzi[1], *Ronald Moura*[1], *Anna Monica Rosaria Bianco*[1], *Valentina Di Carlo*[1], *Daniela Di Bello*[2], *Adamo Pio D'Adamo*[1]

[1]*IRCCS Burlo Garofolo, Trieste, Italy,* [2]*Ospedale Pediatrico Giovanni XXIII, Bari, Italy.*

Background: Congenital clubfoot (PTC) represents one of the most common bone and joint malformations in newborns, with an incidence of 1–2 per thousand births. Although its significant impact on patients' quality of life and genetic components is well documented, with a 32.5% concordance in monozygotic twins, its

molecular basis remains largely unexplained. While previous studies have identified various transcription factors and regulators, genetic heterogeneity has complicated the identification of causative variants.

Material and Methods: We studied a cohort of 162 Italian patients with severe idiopathic bilateral clubfoot. All patients were characterized by high Pirani scores (5–6) and required Achilles tendon tenotomy. We performed genetic analysis through Sanger sequencing and SNP array, focusing on PITX1 and TBX4 genes, which are known to be involved in limb development.

Results: Our genetic analysis identified only four benign nucleotide variants in TBX4, with no significant CNVs detected in either PITX1 or TBX4. The analysis of this large independent cohort suggests that mutations in these well-characterized transcription factors play a minimal role, if any, in idiopathic clubfoot, underlining the complex genetic nature of this condition.

Conclusion: Our findings support the genetic heterogeneity of congenital clubfoot and emphasize the need for more comprehensive genetic analyses. To better understand the genetic architecture of this condition, future investigations will employ advanced techniques such as Long-Read Sequencing and Optical Genome Mapping to identify structural variants. Additionally, we plan to expand our cohort to include consanguineous families, potentially providing new insights into the genetic basis of PTC.

P21.050.D Analysis of 1,005 human genome sequences revealed striking skewing of variant density at gene level

Andreas Rump[1], *Enrique A. Martinez*[1], *Rim Khelifi*[2], *Rafifa Masmaliyeva*[1], *Emily H. Neumann*[1], *Melissa Kowal*[1], *Amilcar P. Riverol*[1], *Gregor Dombrowski*[1], *Chiara Vey*[1], *Laura Gieldon*[1], *Soumaya Mougu-Zerelli*[2], *Marc P. Hitz*[1]

[1]*Institute for Medical Genetics, Carl von Ossietzky University, Oldenburg, Germany,* [2]*Laboratory of Cytogenetics, Molecular Genetics and Human Reproductive Biology, University Hospital Farhat Hached, Sousse, Tunisia.*

Background: Genomes have regions of low or high variant density (PMID: 33741065). Whereas determination of variant density across genomes is typically performed by using a "sliding window" of arbitrary size, we focussed on determining the number of single nucleotide variants (SNVs) within all protein coding human genes across 1,000+ genomes.

Material and Methods: We examined 1,005 samples from unrelated individuals of European ancestry with different forms of congenital heart disease. 30x 150nt-paired-end genome sequencing of blood-derived gDNA. Mapping, variant calling and gene-based variant counting was accomplished with BWA, DeepVariant and VCFtools, respectively.

Results: Approximately 150 human genes show significant skewing of variant density across our cohort, i.e. these genes either have a low number of SNVs or a high number but (almost) nothing in between. Surprisingly, this skewness is confined to the gene. The flanking intergenic regions show almost the same variant density within the entire cohort. As an example of negative skewness, the CHD7 gene shows 7–52 variants in 37 samples and 198–338 variants in 961 samples. Positive skewness is seen in PTEN, where variant densitiy is dichotomous: 997 samples have <57 variants but 8 samples show 260+ SNVs. No sample has 58–259 variants. We find the same phenomenon in Tunisian and HapMap samples, but not in a dataset of 722 dog genomes (PMID: 30940804).

Prospective: Since some of the genes with skewed variant density are clinically relevant, we will search for associations of gene-specific variant density with gene expression, methylation profile, gene function and other genomic features

P21.051.A Estimating recent population split times in non-panmictic populations

J. Wall;

Oregon Health and Science University, Beaverton, OR

Standard models for estimating divergence times between populations suffer from several modeling shortfalls, including an inability to distinguish between genetic drift caused by small population sizes or longer divergence times, and the reliance on an unrealistic assumption of random mating within a population. Here we present a new method for estimating recent divergence times that utilizes information in shared identity-by-descent (IBD) segments within and between populations, and which is insensitive to assumptions about random mating or population size. We apply our approach to whole-genome sequence data from Indian caste groups sampled from the Birbhum district in West Bengal (as part of the GenomeAsia 100K project), and estimate average divergence times of ~20–100 generations between different self-identified Hindu caste groups. Comparisons between Hindu caste groups and other (e.g., Austroasiatic language-speaking but geographically co-incident) groups yield slightly older divergence time estimates, and highlight the complex structure of population assimilation/replacement that highlights most of our species' history.

P21.052.B Population genomics reveals complex genetic history of North Asian human populations

V. Stepanov;

Research Institute of Medical Genetics, Tomsk National Research Medical Center, Tomsk, Russian Federation

Background: The whole genome research on genetic diversity in human populations is accumulating significant impact for medical genetics and personalized medicine. Objective of the study is to identify population structure and reveal signals of adaptive evolution in native populations of North Asia. We also aim to demonstrate the importance of incorporating population genetic diversity and ancestry information into present biomedical research.

Material and Methods: Genome-wide analysis of genetic diversity using own WGS and SNPs array data was performed on a total sample over 2000 individuals representing 42 populations.

Results: PCA demonstrates general pattern of genetic diversity distributed according geographic locations of the populations. Major ancestral components can be distinguished as general Western- or Eastern Eurasian, and specific such as proto-Uralic, paleo-Asian, and Beringian. Uneven distribution of ROH among populations demonstrated founder effect in most North Asian populations. Analysis of genetic ancestry with ancient populations reveals significant contribution of Upper Paleolithic North Asian cultures to South and North Siberian people. Paleolithic European

hunters-gatherers and Neolithic farmers contributed to modern native South Siberian and North European populations. We demonstrate the population-specific distributions of medically relevant variants in diverse human populations.

Conclusion: Complex genetic history shaped by early migrations, isolation by distance, founder effects and natural selection has led to current genomic diversity patterns in human populations of North Asia. Future genetic studies and medical programs should take into account the genetic architecture of North Asian peoples.

The study was supported by the Russian Science Foundation grant No. 22-64-00060.

P21.053.C Discovery of ARSACS evolutionary history in the Saguenay population

***Farnaz Farahmand Fard**, Claudia Moreau, François Bouchard, Cynthia Gagnon, Elise Duchesne, Simon Girard*

University of Quebec at Chicoutimi, Chicoutimi, QC, Canada.

Background: Autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) is prevalent in the Saguenay-Lac-Saint-Jean (SLSJ), Quebec, Canada, due to its strong founder effect. The causal variant in the SACS gene (c.8844delT) is found in 94% of the patients. However, there might be different entries of different variants to the population. We aim to identify potential entry points and understand the evolutionary history of disease-associated haplotypes.

Material and Methods: Genealogical data was obtained for 166 patients and 207 parents (carriers), among which, we could genotype 71 patients. To perform our genealogical analysis, we used the genlib package in R. In addition, recruiting geneHapR package, we defined haplotypes of different lengths from our genotypes. Also, using Haploview software, we analyze and visualize patterns of linkage disequilibrium (LD) and construct haplotype blocks.

Results: Based on our genealogy data, we identified the couple with the greatest contribution to the carriers (parents)' gene pool. Through IBD sharing analysis, we observed a signal on chromosome 13, corresponding to the SACS gene known to cause ARSACS. We defined haplotypes of varying lengths (0.8, 2, 4, and 8 Mb) around the ARSACS variant and represented the haplotype phylogeny. The most prevalent haplotype was shared by 86% of the patients, while the remaining patients carried different types of less frequent haplotypes.

Conclusion and perspective: In summary, we identified different entries of ARSACS mutations to the Saguenay population. However, further assessment of patient haplotypes is required to confirm the time when the most recent ancestor haplotype has entered the population.

P21.054.D The Austrian Human Genome Project

***Vincent Beliveau**, Martina Witsch-Baumgartner, Johannes Zschocke*

Institute of Human Genetics, Medical University of Innsbruck, Innsbruck, Austria.

Background: Austria has been one of the last European countries without a national genome project. Based on the participation in the Genome of Europe initiative, jointly by the Medical Universities of Innsbruck, Graz, and Vienna, and the Center for Molecular Medicine in Vienna, we are now establishing a national genome infrastructure for Austria.

Material and Methods: The three main pillars of the Austrian genome project will be (a) the establishment of a national cohort of several thousand healthy individuals, (b) the integration of rare disease diagnostics at the six Centers for Medical Genetics in Austria, and (c) facilities for tumour sequencing and analysis. Sequencing will be performed at all participating centers. A state of state-of-the-art centralized computational infrastructure including data management, analysis, and interpretation pipelines will be established in collaboration with international partners.

Results: The primary outcome of the project will be disease, variant, and phenotype databases, registry facilities, a proband and patient access portal, and as well as computational services supporting interpretation, genotype imputation, and polygenic risks scores. The infrastructure will connect Austria's medical genomic centers and will be integrated into European genomic and health data networks.

Conclusion: The Austrian Human Genome Project will establish a critical genetic reference for the Austrian population, strengthen collaboration between genomic centers in Austria and Europe, and enhance healthcare and research capabilities in Austria.

P21.055.A Saliva: a convenient sample type enabling large-scale PacBio HiFi sequencing projects

***Deborah Moine**[1], Sarah Kingan[1], Shreyasee Chakraborty[1], Heather Ferrao[1], Kristina Weber[1], Christina Dillane[2], Mike Tayeb[2], Duncan Kilburn[1]*

[1]PacBio, Menlo Park, CA, USA, [2]DNA Genotek Inc, Ottawa, ON, Canada.

Background: Saliva is an attractive sample for large-scale genomic studies due to non-invasive self-collection and stability at room-temperature in DNA Genotek™ Oragene™ devices. DNA quality concerns limited its use with long-read sequencing, where high-quality, high-molecular-weight (HMW) DNA is key for optimal performance. Here, we demonstrate that high-quality PacBio® HiFi sequencing results can be obtained from saliva DNA collected into Oragene devices and extracted using Nanobind® kits manually or automatically with the ThermoFisher Kingfisher Apex system. HiFi data can be used for comprehensive variant calling and methylation analysis.

Material and Methods: HMW DNA was extracted from saliva or blood manually or automatically with Nanobind kits. HiFi WGS libraries were prepared on Hamilton NGS STAR system and sequenced using SPRQ™ chemistry on a Revio® system. HiFi reads were mapped against the human genome reference. Variant calling and methylation analysis were performed using SMRT® Link analysis pipelines.

Results: High-quality DNA was obtained from all samples. Manual and automated extraction generated comparable results. Sequencing coverage was 20x-40x per genome, sufficient for comprehensive WGS variant detection and methylation analysis. DNA from saliva samples is ~ 75%−95% human. Saliva and blood-paired samples were assessed for concordance in genome coverage quality and variant detection.

Conclusion: This method demonstrates that the extraction of DNA with Nanobind kits from saliva collected in Oragene devices is a viable alternative to blood for obtaining high-quality, long-read sequencing data. Non-invasive self-collection and ability to mail samples enable efficient, cost-effective recruitment for and

facilitate the use of long-read sequencing in large genomic studies.

P22 Functional Genomics

P22.001.B Mutations in Non-Coding DNA and Type-2 Diabetes: A Pipeline for Functional Validation and Predictive Modeling

João M. Nogueira, *Fábio J. Ferreira, Sofia M. Borges, Francisco Magalhães, Tiago Nogueira, Miguel Sousa, Ana Eufrásio, José Bessa*

i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal.

Background: Type 2 diabetes (T2D) is associated with severe health complications. Genetic susceptibility to T2D is linked to single-nucleotide polymorphisms that overlap with cis-regulatory regions, such as enhancers, suggesting that altered transcriptional regulation contributes to this disease's susceptibility and pathogenesis. To advance our understanding of T2D, it is crucial to functionally validate these enhancers, investigate how genetic variants and spontaneous mutations impact enhancer activity, and develop predictive models for variant effects.

Material and Methods: We selected hundreds of candidate enhancers potentially involved in T2D development using data from genome-wide association studies and epigenetic features of human islets. These sequences were tested in an enhancer-reporter vector. Through FACS sorting, we isolated single cells with candidate enhancers driving GFP expression, genotyped them, and established endocrine pancreas enhancer-reporter cell lines. To investigate the functional impact of mutations on these enhancers, we applied random Cas9-mediated mutagenesis to the GFP-controlling enhancers in these reporter lines. Additionally, we created libraries of mutated enhancers through PCR-induced mutagenesis and assessed the effects of these variations using the same enhancer-reporter vector.

Results: Hundreds of sequences were validated for enhancer activity and hundreds of enhancer-reporter lines were established. Through random mutagenesis assays, we identified key nucleotides and transcription factor binding sites critical for enhancer function. Building on these findings, we developed preliminary machine learning models that predict how mutations influence enhancer activity.

Conclusion: We propose a pipeline that advances one of the most resilient frontiers in human genetics, unraveling the impact of the non-coding genome in the development of T2D.

J.M. Nogueira: None. **F.J. Ferreira:** None. **S.M. Borges:** None. **F. Magalhães:** None. **T. Nogueira:** None. **M. Sousa:** None. **A. Eufrásio:** None. **J. Bessa:** None.

P22.002.C The Genomic Landscape Underlying the Segmentation Clock (Award Candidate)

Kurt Weir[1], *Mitsuhiro Matsuda*[2], *Xin Wang*[1], *Miki Ebisuya*[2], *Eileen Furlong*[1]

[1]*European Molecular Biology Laboratory (EMBL), Heidelberg, Germany,* [2]*Technische Universitat Dresden, Dresden, Germany.*

Background: Somitogenesis, the process whereby vertebrate embryos establish axial patterning, is controlled by a cycle of gene expression called the segmentation clock. Defects in the segmentation clock lead to congenital spinal abnormalities like scoliosis or spondylocostal dysostosis. Hundreds of genes that cycle with the clock have been identified. However, the regulatory elements involved in the segmentation clock have not been systematically elucidated to date.

Material and Methods: To address this, we generated diverse single cell -omics modalities (scRNA, scRNA+scATAC multiome, and scCutnTag for H3K27Ac) along a time course of the segmentation clock using a human in vitro model of somitogenesis.

Results: This enabled the identification of novel cycling genes as well as hundreds of regulatory elements that display cyclic accessibility and/or enhancer activity in the human segmentation clock. Integrating multi-modal single-cell information on chromatin occupancy (scATAC), chromatin activation state (scCutnTag), and gene expression (scRNA) revealed very good concordance between multiple regulatory layers, with some regular temporal shifts between them during each cycle. Selected new cycling regulatory elements can drive cyclic expression (using a luciferase reporter system) in our in vitro model of somitogenesis, indicating they are enhancers with cycling activity. Gene regulatory network reconstruction identified a potential negative feedback loop involving LEF1, DACT1, and DKK1 controlling cyclic antiphase expression, which has been proposed but not previously demonstrated.

Conclusion: By integrating multiple data modalities, we are able to identify which genes are cycling, the genomic elements regulating them, and the interactions between transcription factors and genes that direct cyclic gene expression.

D'Annunzio, Policlinico SS Annunziata, Chieti, Italy, [29]Clinical Neurology Unit, Department of Neuroscience and Rehabilitation, University of Ferrara, Ferrara, Italy.

Background: Pediatric-onset Multiple Sclerosis (POMS) has distinctive features, representing about 5% of all Multiple Sclerosis (MS) cases. The aim of this work is to detect epigenetic signatures potentially involved in the early onset of the disease.

Material and Methods: A multi-centric Italian cohort of 122 POMS cases and 53 pediatric healthy controls was typed with Infinium Methylation Epic v2.0 kit on whole blood. Data analysis was performed using a cross-package approach in R environment. We fitted multiple linear regression models on methylation M value matrix, correcting for gender and cell type composition. Differentially methylated probes (DMPs), genes (DMGs) and regions (DMRs) were selected according to an FDR adjusted p-value of < 0.05 and a mean absolute delta-beta (ADB) of 0.02. Gene Set Enrichment Analysis (GSEA) has been performed on the top 100 ranked DMGs.

Results: A total of 7,968 DMPs, 30 DMGs and 55 DMRs were identified. GSEA evidenced terms like "regulation of T-cell activation", "T-cell receptor binding" and "B-cell activation". Differences in methylation detected at the DMR level also indicate the contribution of genes already known in the context of Multiple Sclerosis such as BLK, BLNK, CHI3L2, CD19, CPT1B, PARP1 and LPCAT1.

Conclusion: Differences in methylation profiles between POMS and pediatric healthy subjects seem to be related to immunomodulation and immune system-specific cells. We conclude that the early onset of the disease may be mediated by the combined effect of relatively small methylation differences in crucial regulatory regions of genes involved in the immune and inflammatory response.

P22.004.A Unraveling ribosomal DNA variation and its expression dynamics in human populations (Award Candidate)

***Jose Miguel Ramirez**, Raquel García-Pérez, Winona Oliveros, Aisha Shah, Alba Jimenez, Pablo Perez, Miguel Vazquez, Marta Melé*

Barcelona Supercomputing Center, Barcelona, Spain.

Background: The ribosome, composed of ribosomal proteins and ribosomal RNAs (rRNAs), is essential for protein synthesis, and its disruption has a major impact in disease. While genetic variants in ribosomal proteins are linked to diverse phenotypes, rRNAs remain underexplored due to their complex genetic architecture. Ribosomal DNA (rDNA) arrays, organized in tandem repeats, exhibit extensive intra- and inter-individual variation, with copy numbers ranging from 50 to 1000. However, studies analyzing rDNA variants have been hindered by the absence of a gold-standard reference, leading to undetected variants and false positives. Notably, rDNA copy number does not correlate with rRNA expression, as copies can be epigenetically silenced. Yet, when and which rDNA variants are silenced or differentially expressed remains unknown.

Material and Methods: Leveraging the recently completed telomere-to-telomere genome assembly, we simulated short-read sequencing data with varying rDNA copy numbers, establishing, for the first time, a gold-standard reference. Based on this data, we developed rDNAcaller, a fast and robust pipeline for accurate rDNA variant detection.

Results: Analyzing data from the 1000 Genomes Project, we characterized rDNA variation across human populations, and found population-specific silencing of rDNA variants. Additionally, using the Genotype-Tissue Expression Project, we studied rRNA expression changes between tissues and individuals of different age, sex, and BMI, revealing a major effect of aging.

Conclusion: Our study provides a comprehensive view of rDNA variation, its population-level diversity, and its dynamic expression patterns, offering new insights into its implications for human health and disease.

P22.005.B Usmani-Riazuddin syndrome: functional characterization of novel c.196G>A, variant in the *AP1G1* gene and phenotypic insights from Zebrafish model

***Elisa Vinciarelli**[*1], Valentina Imperatore[*1], Jasmine Covarelli[1], Alessandra Mirarchi[1], Daniela Zizioli[2], Giuseppe Borsani[2], Sara Ferretti[2], Cataldo Arcuri[1], Paolo Prontera[3]*

[1]Department of Medicine and Surgery, University of Perugia, Perugia, Italy, [2]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy, [3]Medical Genetics Unit, University and Hospital of Perugia, Perugia, Italy.

Background: The Adaptor Protein AP-1 is a heterotetrameric complex that plays a crucial role in intracellular trafficking and polarized localization of somatodendritic proteins in neurons. Variants in the *AP1G1* gene, encoding the gamma-1 subunit of adaptor protein complex 1 (AP1γ1), have recently been associated with Usmani-Riazuddin syndrome (USRISD MIM#619467), a very

rare genetic disorder characterized by intellectual disability (ID), speech and neurodevelopmental delay.

Material and Methods: Exome sequencing was performed in a young Italian patient with motor and language delay and a moderate form of ID. Patient's fibroblasts have been studied with immunofluorescence techniques to analyze intracellular distribution of AP-1, GM130, Clathrin, TGN46 and RAB5 (Golgi and endosomes markers). The development of the central nervous system (CNS) and locomotor behavior have been studied using zebrafish model, injecting embryos with human wild-type and mutated mRNA.

Results: We have identified a de novo heterozygous variant in *AP1G1*: c.196G>A (p.Gly66Arg), absent in the GnomAD database and predicted to be damaging. In vitro studies have demonstrated differences in subcellular localization and distribution of vesicular trafficking markers. In vivo analysis has demonstrated alterations in CNS areas (diencephalon and telencephalon), growth, movement delay, a strong phenotype of motor neurons in the trunk and a severe reduction in embryo's mobility.

Conclusion: These results suggest a critical role of the *AP1G1* subunit in regulating intracellular trafficking and CNS development, proving the pathogenicity of the c.196G>A variant. Further studies are necessary to fully understand the variant's effect on cellular functionality in order to develop a potential targeted therapeutic strategy.

P22.006.C TAF1A ribosomopathy in a zebrafish model for juvenile-onset DCM

Jo M. Vanoevelen, *Kevin Van Dorsten, Ellen Lambrichs, Janine Grashorn, Godelieve Claes, Apollonia TJM Helderman-Van den Enden*

Maastricht University Medical Centre, Maastricht, Netherlands.

Juvenile-onset dilated cardiomyopathy (DCM) is a rare genetic disorder characterized by variable phenotypic expressivity, early heart failure, and poor clinical outcomes. Bi-allelic variants in *TAF1A* (TATA-Box Binding Protein Associated Factor, RNA Polymerase I Subunit A) have been implicated as a genetic cause of juvenile-onset DCM, leading to a ribosomopathy associated with myocardial fibrosis and nucleolar segregation defects in cardiomyocytes. We previously described a 16-year-old patient with *TAF1A*-related DCM, presenting with atrial electromechanical failure and arrhythmias. To investigate the underlying disease mechanisms, we established a stable *taf1a* knockout zebrafish model using CRISPR-Cas9 genome editing. Structural characterization of myocardial tissue was performed using electron and expansion microscopy to assess high-resolution ultrastructural defects. Given the known impact of *TAF1A* deficiency on nucleolar integrity, we also examined nucleolar morphology in patient-derived fibroblasts and zebrafish cardiomyocytes. Functional assessments in zebrafish embryos included high-speed video microscopy to evaluate heart rate, fractional shortening, ventricular contractility, and arrhythmia susceptibility. Our findings provide the first functional insights into *TAF1A*-related cardiomyopathy. The *taf1a* knockout zebrafish model faithfully recapitulates key disease features and establishes a foundation for further mechanistic studies and therapeutic exploration in *TAF1A*-associated DCM.

P22.007.D Transcriptome regulation analysis in osteoarthritis primary tissues identifies high-confidence effector genes

Georgia Katsoula[1,2,3], *Ana Luiza Arruda*[1], *Mauro Tutino*[1], *Peter Kreitmaier*[1], *Karan M. Shah*[4], *Diane Swift*[4], *Lorraine Southam*[1], *Jeremy Mark Wilkinson*[4], *Eleftheria Zeggini*[1,3]

[1]*Institute of Translational Genomics, Helmholtz Zentrum München – German Research Center for Environmental Health, Neuherberg, Germany,* [2]*Technical University of Munich (TUM), School of Medicine and Health, Graduate School of Experimental Medicine, Munich, Germany,* [3]*Technical University of Munich (TUM) and Klinikum Rechts der Isar, TUM School of Medicine and Health, Munich, Germany,* [4]*School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom.*

Background: Osteoarthritis is a complex joint disease affecting ~600 million individuals worldwide and lacking a curative therapy. The development of disease-modifying treatments requires a comprehensive understanding of the tissue-specific effects of genetic variation. Here, we investigate gene expression regulation in macroscopically intact and degraded osteoarthritis cartilage, synovium, and fat pad tissues.

Material and Methods: We generated RNA-sequencing data from cartilage (intact: N = 263; degraded: N = 216), synovium (N = 278), and fat-pad (N = 94) tissues and matched genotype data from peripheral blood of 321 knee osteoarthritis patients undergoing joint replacement surgery. We constructed cis- and trans-eQTL maps and meta-analyzed results across tissues to find shared and tissue-specific cis-regulatory effects. We used colocalization and causal inference analyses to identify osteoarthritis effector genes.

Results: We identified 6,646 cis-eGenes in intact cartilage, 4,639 in degraded cartilage, 6,411 in synovium, and 592 in fat pad. Of 9,738 unique eGenes, 60.6% were previously unreported in osteoarthritis. We found 1,783 eGenes specific to intact cartilage, 580 to degraded cartilage, 2,308 to synovium, and 109 to fat-pad. These are regulating genes involved in chondrocyte differentiation in intact cartilage, activation of cation channels and metalloproteinases in synovium, and interferon-gamma signaling in the fat-pad. Colocalization and causal inference analyses prioritized 51 effector genes mediating osteoarthritis risk. Of these, 25 are novel osteoarthritis effector genes.

Conclusion: This study presents the largest cis-eQTL study in osteoarthritis, the first trans-eQTL study, and the first eQTL map of osteoarthritis fat pad tissue. These findings highlight tissue-specific and shared regulatory mechanisms, offering insights for advancing osteoarthritis therapeutics.

P22.008.A Fluorescence-based CRISPR screen identifies MED12 as a new regulator of microsatellite instability

Joao Manuel Fernandes Neto[1,2], *Subramanian Venkatesan*[1], *Matheus Dias*[1], *Loredana Vecchione*[3], *Ferenc Scheeren*[4], *René Bernards*[1]

[1]*The Netherlands Cancer Institute, Amsterdam, Netherlands,* [2]*i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal,* [3]*Charité Comprehensive Cancer Center, Charité - Universitätsmedizin Berlin, Berlin, Germany,* [4]*Leiden University Medical Center, Leiden, Netherlands.*

Background: Inactivation of the DNA mismatch repair (MMR) system, due to (epi)genetic alterations of MMR genes, increases the frequency of mutations across the genome, creating a phenotype known as microsatellite instability (MSI).

Material and Methods: To detect replication slippage in cells in real time, we developed a fluorescent-reporter that becomes irreversibly activated when a slippage event occurs within a microsatellite sequence in the reporter. Subsequently, we performed CRISPR/Cas9 screens in cells carrying this reporter system to identify which genes (upon knock-out) lead to an increased rate of frameshift mutations.

Results: The activation rate of our reporter was significantly higher in MSI cell lines compared to microsatellite stable (MSS) cell lines, as expected. Additionally, KO of MMR genes MSH2 and MLH1 in MSS CRC cell line SW480 induced over 100-fold higher activation of our sensor than control genes. A genome-wide CRISPR screen in SW480 cells identified MED12 a hit. Validation studies showed that MED12 downregulates the expression of MMR genes. Consistent with this, in the TCGA colon adenocarcinoma cohort we found that MED12 mutant colon cancers that lack mutations in the known MMR genes are more likely to be of the MSI phenotype.

Conclusion: This study identified MED12 loss as a cause for MSI induction in CRC. Given that MSI is a biomarker of response to cancer immunotherapy, assessment of MED12 status might identify additional patients for immunotherapy treatment eligibility. Additional studies are needed to assess the role of MED12 in the context of Lynch syndrome, which is currently unknown.

P22.009.B TGFB1 induced TET3 dependent regulation of OTX2 super enhancer hypomethylation promotes Group3 medulloblastoma progression

*X. Chen, **D. Han**, W. Ziwei, X. Jin, L. Jiankang;*

BGI research, shenzhen, China

Background: DNA methylation patterns are widely used for medulloblastoma (MB) classification, yet the functional role of enhancer methylation remains unclear.

Material and Methods: We performed bisulfite-based genome-wide sequencing on 189 MB cases, comparing 80 classified cases with 8 normal cerebellums to identify differentially methylated regions (DMRs). Gene expression data integration and validation in 109 cases identified DMR target genes. sn-ATACseq was used to assess the impact of DMRs on chromatin accessibility and tumorigenesis.

Results: A negative correlation was observed between DMR methylation at super enhancers (seDMRs) and target gene expression, particularly in Group 3 MB (G3-MB). Genes targeted by hypomethylated seDMRs were enriched in early cerebellar development pathways. OTX2-associated hypomethylated seDMRs enhanced chromatin accessibility and oncogenic activation in progenitor-like tumor cells, worsening prognosis. OTX2 binding sites within its own hypomethylated seDMRs indicated an auto-regulatory loop. Disrupting these enhancer motifs reduced OTX2 expression and attenuated tumor growth. TET3, recruited by OTX2, catalyzed active DNA demethylation, facilitating chromatin remodeling and gene activation. TET3 was upregulated by TGF-β1/Smad2 signaling. Therapeutically, nanoparticle-coated siRNA targeting TET3 effectively suppressed xenograft tumor progression.

Conclusion: Our study reveals TGF-β1/Smad-induced TET3-dependent demethylation of OTX2 super enhancers as a key driver of G3-MB progression. Targeting this pathway offers a potential therapeutic strategy.

P22.010.C The 5000genomi@VdA project: an Italian whole genome sequencing initiative

Manuela Vecchi[1], *Alessandro Coppe*[2], *Fabio Landuzzi*[2], *Sara Trova*[1], *5000genomi@VdAConsortium*[3], *Andrea Cavalli*[2,4,5], *Stefano Gustincich*[1,6]

[1]*Non-coding RNAs and RNA-based therapeutics, Italian Institute of Technology, CMP3VdA, Aosta, Italy,* [2]*Computational and Chemical Biology, Italian Institute of Technology, CMP3VdA, Aosta, Italy, Aosta, Italy,* [34]*Center for Human Technologies, Computational and Chemical Biology, Italian Institute of Technology, Genoa, Italy,* [5]*Centre Européen de Calcul Atomique et Moléculaire (CECAM), Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland,* [6]*Center for Human Technologies, Non-coding RNAs and RNA-based therapeutics, Italian Institute of Technology, Genoa, Italy.*

Background: The 5000genomi@VdA project is a unique Italian initiative funded by the Autonomous Region of Valle d'Aosta, located in the Northwest of Italy. The project is carried out by a multidisciplinary consortium led by the Italian Institute of Technology. The project aims to sequence 5,000 genomes from healthy donors and patients with neurodevelopmental, neurodegenerative, oncological, and organ transplantation diseases. Whole genome sequencing (WGS) approaches were employed to study coding and non-coding genomic regions. Through the synergistic interaction of private-public research and health care centers, the goal is to study the role of our genes in health and disease conditions and to promote the integration of WGS into the clinical domain.

Material and Methods: Genomic DNA was obtained from whole blood and, in cancer patients, tumor and non-pathological tissues. Short-read WGS was performed on the Illumina NovaSeq 6000 platform (blood: 40x coverage; tumors: 100x coverage) and, in selected cases, long-read sequencing using the PromethION device (Oxford Nanopore Technologies). Bioinformatic analysis is based on GPU-compliant and accelerated pipelines (NVIDIA Clara™ Parabricks®).

Results: We have developed the genomic and computational infrastructures to analyze and store large genomic data sets and more than 5,000 genomes have been sequenced. We also analyzed selected unsolved clinical cases with long-read sequencing as a complementary approach to accelerate research discovery and improve diagnostic rates. Additionally, genomic analysis of healthy blood donors allows characterization of the population architecture of Valle d'Aosta.

Conclusion: This study represents a strategic blueprint healthcare model for implementing WGS into clinical practice in Italy.

P22.011.D Investigating the role of SMCHD1 in FSHD2 and BAMS: insights from pluripotent stem cell models

Rachel Eiges[1,2], *Uria Aviel*[1,2], *Shahar Rich*[1,2], *Silvina Epsztejn-Litman*[1], *Merav Hecht*[2], *Yotam Drier*[2]

[1]*Stem Cell Reserach Laboratory, Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*The Hebrew University School of Medicine, Jerusalem, Israel.*

Background: SMCHD1 is a chromatin-modifying ATPase essential for epigenetic silencing during early embryonic development and regulation of long-range chromatin interactions, potentially by antagonizing CTCF binding to DNA. Germline mutations in SMCHD1 are linked to two autosomal dominant diseases: Facioscapulohumeral muscular dystrophy type 2 (FSHD2) and Bosma arhinia microphthalmia syndrome (BAMS). FSHD2 is characterized by late-onset muscle degeneration caused by heterochromatin relaxation at the D4Z4 macrosatellite repeats due to loss-of-function (LOF) mutations, while BAMS is a rare congenital condition involving craniofacial defects arising from missense mutations in the ATPase domain of SMCHD1. Despite its clinical relevance, the functional mechanisms of SMCHD1 remain poorly understood.

Material and Methods: To elucidate SMCHD1's role, we generated SMCHD1 knockout (KO) in three human embryonic stem cell (hESC) lines using CRISPR/Cas9. These cells were characterized for DNA methylation (nanopore and bisulfite sequencing) and CTCF binding (ChIP-seq). We also introduced a BAMS-associated mutation (S135C) into hESCs and generated induced pluripotent stem cells (iPSCs) from FSHD1, FSHD2, and BAMS patients.

Results: SMCHD1 KO consistently induced ectopic CTCF binding at nearly 100 loci, including near the D4Z4 repeats, and this was independent of DNA methylation alterations. Furthermore, the BAMS-related S135C mutation did not affect CTCF binding patterns genome-wide.

Conclusion: SMCHD1 counteracts CTCF binding at specific genomic regions, including D4Z4 repeats, in a DNA methylation-independent manner. Unlike FSHD2, BAMS-related mutations do not seem to disrupt this function, suggesting distinct mechanisms underlying these diseases.

P22.012.A A new genomic tool for assessing the functionality of thousands of SNPs simultaneously

Riham MOHARAM, *Shumeng LUO, Chien Ling HUANG, Shea Ping YIP*

Department of Health Technology and Informatics, The Hong Kong Polytechnic University, HONG KONG, China.

Background: Genome-wide association studies (GWAS) have reported thousands of risk single-nucleotide polymorphisms (SNPs) associated with refractive errors and myopia. However, understanding their functional roles remains challenging. This study introduces Barcoded Single-Nucleotide Polymorphism Sequencing (BC-SNPs-seq), a novel approach to assess the functionality of hundreds of myopia-associated SNPs simultaneously.

Material and Methods: A pilot study targeted 150 SNPs linked to the *BMP4* gene, either directly associated with myopia or in linkage disequilibrium ($r^2 \geq 0.5$) with associated SNPs. Each synthetic oligo, comprising 120 bases, included a 21-base genomic sequence centred on the SNP allele, 12 bases for a unique barcode (BC), MlyI restriction enzyme sites, and primer-annealing flanking sequences. Each SNP allele was uniquely represented by 20 barcodes, resulting in 6000 synthesized oligos. The single-stranded DNA oligos were amplified and converted to double-stranded DNA (dsDNA). These oligos were incubated with nuclear extracts (NE) from ARPE-19 retinal pigment epithelium cells or Müller cells, serving as transcription factor (TF) sources. Column separation distinguished TF-bound fragments from unbound ones, and high-throughput sequencing quantified barcode counts, representing SNP-TF interactions.

Results: BC-SNPs-seq prioritised six candidate functional SNPs that bind to the transcription factors in the ocular cell lines. Two of these SNPs showed interesting results in both cell lines, warranting further investigation.

Conclusion: BC-SNPs-seq utilises unique barcodes to efficiently screen and prioritise functional SNPs from large datasets. This innovative method significantly narrows the list of candidate SNPs for detailed functional studies, enabling deeper insights into their roles in myopia development.

P22.013.B Diagnostic utility of single-locus DNA methylation mark in Sotos syndrome developed by nanopore sequencing-based episignature

Naomichi Matsumoto[1], *Nobuhiko Okamoto*[2], *Takeshi Mizuguchi*[1]

[1]*Yokohama City Univ Grad Sch Med, Yokohama, Japan,* [2]*Osaka Women's and Children's Hospital, Osaka, Japan.*

Background: In various neurodevelopmental disorders (NDDs), sets of differential methylation marks (referred to as DNA methylation signatures or episignatures) are syndrome-specific and useful in evaluating the pathogenicity of detected genetic variants. These signatures have generally been tested using methylation arrays.

Methods: Nine and seven cases of molecularly diagnosed Sotos syndrome and ATR-X syndrome, respectively, were sequenced using nanopore long-read sequencing, together with 22 controls. Genome-wide differential DNA methylation analysis was performed.

Results: Long read sequencing enabled the successful extraction of two sets of differential methylation marks unique to each of Sotos syndrome and ATR-X syndrome, referred to as long-read-based DNA methylation signatures (LR-DNAm signatures), as alternatives to reported DNA methylation signatures (obtained by methylation array). Additionally, we found that a part, but not all, of the *NSD1* CpGi were hypomethylated compared with the level in controls in both cases harboring *NSD1* point mutations and those with a 5q35 submicroscopic deletion. This difference in methylation is specific to Sotos syndrome and lacking in other overgrowth intellectual disability syndromes.

Conclusions: Simultaneous evaluation of genetic and epigenetic alterations using long-read sequencing may improve the discovery of DNA methylation signatures, which may in turn increase the diagnostic yields. As an example of the outcomes of these analyses, we propose that a single-locus DNA methylation test at *NSD1* CpGi may streamline the molecular diagnosis of Sotos syndrome, regardless of the type of *NSD1* aberration.

P22.014.C A landscape of X-inactivation during human T cell development

Björn Gylemo[1], *Maike Bensberg*[1], *Viktoria Hennings*[2,3], *Christina Lundqvist*[2], *Antonio Lentini*[1], *Olov Ekwall*[2,3], *Colm E. Nestor*[1]

[1]*Crown Princess Victoria Children's Hospital, and Department of Biomedical and Clinical Sciences (BKV), Linköping, Sweden,* [2]*Department of Rheumatology and Inflammation Research, Gothenburg, Sweden,* [3]*Department of Pediatrics, Gothenburg, Sweden.*

Background: Females exhibit a more robust immune response to both self-antigens and non-self-antigens than males, resulting in a higher prevalence of autoimmune diseases but more effective responses against infection. Increased expression of X-linked immune genes in female T cells is thought to underlie this enhanced response.

Material and Methods: Here we isolate thymocytes from pediatric thymi of healthy males (46, XY), females (46, XX), a female with completely skewed X-chromosome inactivation (46, XX, cXCI) and a female with Turner syndrome (45, X0). Using whole exome sequencing, RNA sequencing and DNA methylation data, we present a sex-aware expression profile of T cell development and generate a high-resolution map of escape from X-chromosome inactivation (XCI).

Results: Unexpectedly, XCI is transcriptionally and epigenetically stable throughout T cell development, and is independent of expression of XIST, the lncRNA responsible for XCI initiation during early embryonic development. In thymocytes, several genes known to escape XCI are expressed from only one X-chromosome. Additionally, we further reveal that a second X-chromosome is dispensable for T cell development.

Conclusion: Our study thus provides a high-resolution map of XCI during human development and suggests a re-evaluation of XCI in sex differences in T cell function.

P22.015.D Long-read sequencing analysis in Beckwith-Wiedemann syndrome caused by defects of the OCT4/SOX2 binding site

Hayate Masubuchi

National Center for Child Health and Development, Tokyo, Japan.

Background: Beckwith-Wiedemann syndrome (BWS) is an imprinting disorder with overgrowth. Hypermethylation of the *H19/IGF2*:IG-differentially methylated region (*H19*-DMR) is identified in 5% of BWS patients. The OCT4/SOX2 binding sites (OBS) involve maintaining the unmethylated *H19*-DMR. However, the precise methylation patterns in patients with OBS abnormalities remain elusive. Long-read sequencing (LRS) can detect the methylation levels separately for parental alleles. In this study, we conducted LRS to compare differences in the *H19*-DMR hypermethylation patterns between BWS patients with and without OBS abnormalities, and differences between mothers and their offspring.

Methods and Results: We have 14 sporadic BWS patients and 4 familial patients showing the *H19*-DMR hypermethylation. We performed amplicon sequence and found OBS point-mutation in 3 sporadic patients, point-mutation (chr11:2023018 C>T, hg19) in family A, and microdeletion (chr11:2022825-2025479) in family B. We performed LRS for sporadic patients with and without OBS abnormalities and all familial patients. In the patients with OBS point-mutation, the methylation levels get higher near the mutation. In the familial patients, the methylation levels are higher in offspring than in their mothers.

Assessment and Conclusion: In maternal primordial germ cells, the *H19*-DMR hypermethylation is eliminated and unmethylated after fertilization. Because the *H19*-DMR hypermethylation elimination may be insufficient, the hypermethylation levels increase with each generation. We revealed methylation patterns differences in patients with point-mutation, microdeletion, or no OBS abnormalities. Differences in the residual function of OBS may cause differences in methylation patterns.

H. Masubuchi: None.

P22.016.A Understanding the Role of Birt-Hogg-Dubé Syndrome Associated FLCN-1 In Cilia

*Damla Puçak[1], Oktay I. Kaplan[2], **Sebiha Cevik**[3]*

[1]Graduate School of Engineering and Science, Abdullah Gül University, Kayseri, Turkey, [2]School of Life and Natural Sciences Abdullah Gül University, Kayseri, Türkiye, Kayseri, Turkey, [3]School of Life and Natural Sciences Abdullah Gül University, Kayseri, Turkey.

Background: The Folliculin (FLCN) gene encodes a tumor suppressor protein implicated in ciliogenesis and associated with Birt-Hogg-Dubé syndrome, a ciliopathy characterized by ciliary dysfunction. FLCN plays a crucial role in mTORC1 activation and interacts with ciliary motor subunits KIF3A/KIF3B of kinesin-2 within cilia. Furthermore, FLCN has been shown to exhibit guanine nucleotide exchange factor (GEF) and GTPase activating protein (GAP) activities. However, the precise role of FLCN in cilia remains poorly understood. This study investigates the molecular mechanisms by which FLCN-1 controls the ciliary length and protein localization, providing functional insight into its contribution to ciliopathy pathogenesis.

Material and Methods: The model organism C. elegans was used to study the localization and function of FLCN-1. CRISPR/Cas9 was employed to create GFP-tagged FLCN-1 to investigate subcellular localization. Double mutants of flcn-1 with other GTPases, like RPI-2, were generated to assess genetic interactions in cilia structure and function. Quantitative fluorescence imaging measured changes in ciliary protein distribution, while FRAP experiments examined protein dynamics at the ciliary gate.

Results: Preliminary data indicate that FLCN-1 is important for maintaining cilia lengths and proper protein gating. In the flcn-1 null mutant, cilia are significantly elongated, and TRAM-1, normally excluded, aberrantly enters the cilia. Genetic interaction with RPI2 suggests a cooperative function in regulating ciliary gating and structural integrity.

Conclusion: This study provides new insight into the function flcn-1 in ciliogenesis. We now further our understanding of the molecular functions that underlie ciliopathies and thus provide a foundation for future therapeutic strategies to resolve ciliary defects.

P22.017.B DNA methylation in iPSC-derived cell culture models during cultivation and maturation

***Christina Kiel**, Tobias Strunz, Bernhard H.F. Weber*

University of Regensburg, Regensburg, Germany.

Background: DNA methylation is a fundamental process in the regulation of gene expression, tailored to specific cell types and developmental stages. This study aims to investigate methylation patterns across various tissues and iPSC-derived cell culture models, providing insights into key biological processes. These findings enhance the utility of cell culture systems for studying disease mechanisms and advancing therapeutic development.

Material and Methods: We analyzed DNA methylation in samples from primary human tissues (retinae, n = 21, fibroblasts, n = 4, PBMCs, n = 7), iPSCs (n = 24), and iPSC-derived cell lines, including endothelial cells (n = 8), retinal pigment epithelium (RPE, n = 48), and retinal organoids (RO, n = 47). DNA methylation was assessed using the Human MethylationEPIC Bead Chip. To

evaluate maturation dynamics, iPSC-RPE cultures were harvested at four, ten, and 14 weeks of cultivation, while ROs were analyzed at 0.5, 1, 1.5, and 2 years.

Results: Principal component analysis revealed distinct cell type-specific clustering, while pathway enrichment analysis identified specialized pathways associated with cell type-specific differentially methylated probes (DMPs). Methylation patterns in iPSC-RPE and RO cultures evolved over time, with DMPs enriched in genes critical for differentiation and structural development. Notably, 0.5-year-old ROs differed markedly from older organoids, with aged ROs showing methylation profiles resembling those of adult retinae.

Conclusion: Our findings demonstrate that methylation patterns vary across cell types and evolve during cultivation, with RO gradually converging toward the methylation profile of mature retinae. These results underscore the importance of selecting appropriate cultivation timepoints for studying disease-related processes and highlight the dynamic nature of epigenetic regulation in iPSC-derived models.

P22.018.C Somatic non-allelic homologous recombination in Parkinson's disease: evidence from monozygotic twins

Letizia Straniero[1], *Giorgia Agostinelli*[1], *Valeria Rimoldi*[1], *Giovanni Pascarella*[2], *Claudia Giudici*[1], *Luca Magistrelli*[3], *Gianni Pezzoli*[3], *Ioannis Ugo Isaias*[3], *Piero Carninci*[2], *Rosanna Asselta*[1]

[1]*Humanitas University, Pieve Emanuele, Milan, Italy,* [2]*RIKEN Center for integrative medical sciences, Yokohama, Japan,* [3]*Parkinson Institute, Milan, Italy.*

Background: Parkinson's disease (PD) is a complex neurodegenerative disorder caused by the combination of genetics and environmental factors. Recent studies suggest that somatic non-allelic homologous recombination (NAHR), especially mediated by Alu and L1 elements, contributes to genomic instability in aging and neurodegeneration.

Material and methods: DNA samples from 35 pairs of monozygotic (MZ) twins discordant for PD underwent targeted sequencing to enrich for repeated elements. Somatic NAHR events were identified using the TE-reX pipeline, focusing on recombination events mediated by Alu/L1.

Results: Over 3 million recombinations were detected, primarily mediated by Alu elements. Focusing on unique somatic recombinations, we observed a significant increase in NAHR events in PD twins compared to their healthy counterparts ($P = 0.038$), particularly in Alu-mediated recombination ($P = 0.039$). Short-distance (<100 kb) recombination events were enriched in PD patients, with a significant increase in deletions ($P = 0.0035$). Additionally, Alu-mediated events in PD patients showed specific enrichment in promoter regions. Disease duration significantly influenced NAHR accumulation, especially in inter-chromosomal and long-distance (>100 kb) events ($P = 0.031$ and $P = 0.036$, respectively).

Conclusion: This study provides a global overview of the NAHR landscape in genetically identical twin pairs discordant for PD, marking the first assessment of somatic recombination in such a peculiar cohort. PD patients exhibited a distinct recombination signature, particularly in promoter regions, compared to healthy twins. Furthermore, disease duration impacted the accumulation of somatic NAHR events. In the future, we will validate these findings in sporadic PD patients, assess their specificity against other motor disorders, and investigate the role of inflammation in NAHR dysregulation.

Background: Neanderthals had a robust build and a number of distinctive skeletal features. The hypothalamic-pituitary-somatotropic (HPS) axis, with growth hormone (GH) as a central signalling molecule, plays a crucial role in regulating skeletal development. To explore whether Neanderthal-specific genetic variations in the HPS axis contributed to their physical robustness, we examined genes encoding the relevant receptors and hormones.

Material and Methods: We performed genomic analysis of archaic genomes, meta-analyzed craniofacial morphology studies, used data from five biobanks (over one million individuals), and analyzed MRI scans of 220 individuals for craniofacial traits. A GH-dependent cell line was used for in vitro cell growth and signaling measurements.

Results: We identified two amino acid changes and a deletion in the Neanderthal growth hormone receptor (GHR). When expressed in a GH-dependent cell line and stimulated with pituitary GH, the Neanderthal GHR causes faster cell proliferation than the modern human GHR. We further show that some present-day humans have inherited the gene encoding the Neanderthal GHR and that these individuals are taller, exhibit more robust builds, and have craniofacial traits found in Neanderthals, such as short-rooted teeth and decreased mandibular height.

Conclusion: We show that the Neanderthal GHR responds stronger than the modern human GHR upon pituitary GH binding and that some present-day humans inherited this receptor variant from Neanderthals. As a result, they tend to have greater height, weight and muscle mass as well as some craniofacial and dental features reminiscent of Neanderthals.

P22.020.A Cooperative insulation of regulatory domains by CTCF-dependent physical insulation and promoter competition

Victor Sanchez Gaya[1], *Thais Ealo*[1], *Patricia Respuela*[1], *Maria Muñoz-San Martin*[2], *Elva Martin-Batista*[3], *Endika Haro*[1], *Alvaro Rada Iglesias*[1]

[1]*Institute of Biomedicine and Biotechnology of Cantabria (IBBTEC), CSIC/Universidad de Cantabria, Santander, Spain,* [2]*Service of*

Neurology, University Hospital Marqués de Valdecilla, Universidad de Cantabria and IDIVAL, Santander, Spain, [3]Centro de Biología Molecular Severo Ochoa (CBMSO), CSIC-UAM, Madrid, Spain.

The specificity of gene expression during development requires the insulation of regulatory domains to avoid inappropriate enhancer-gene interactions. In vertebrates, this insulator function is mostly attributed to clusters of CTCF sites located at topologically associating domain (TAD) boundaries. However, TAD boundaries allow some physical crosstalk across regulatory domains, which is at odds with the specific and precise expression of developmental genes. Here we show that developmental genes and nearby clusters of CTCF sites cooperatively foster the robust insulation of regulatory domains. By genetically dissecting a couple of representative loci in mouse embryonic stem cells, we show that CTCF sites prevent undesirable enhancer-gene contacts (i.e. physical insulation), while developmental genes preferentially contribute to regulatory insulation through non-structural mechanisms involving promoter competition rather than enhancer blocking. Overall, our work provides important insights into the insulation of regulatory domains, which in turn might help interpreting the pathological consequences of certain structural variants.

P22.021.B Potential role of miR-3195 in upper airways in response to SARS-CoV-2 infection

Malena Gajate Arenas[1,2], *Candela Sirvent Blanco, PHD*[1], *Angélica Domínguez de Barros*[1,2], *Omar García Pérez*[1,2], *Alma García Ramos*[1], *José E. Piñero*[1,2,3], *Jacob Lorenzo Morales*[1,2,3], *Elizabeth Córdoba-Lanús*[1,2]

[1]Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias, Universidad de La Laguna, La Laguna, Spain, [2]Centro de Investigación Biomédica en Red de Enfermedades Infecciosas (CIBERINFEC), Madrid, Spain, [3]Departamento de Obstetricia y Ginecología, Pediatría, Medicina Preventiva y Salud Pública, Toxicología, Medicina Legal y Forense y Parasitología, Facultad de Ciencias de la Salud, Universidad de La Laguna, La Laguna, Spain.

Background: miRNAs are non-coding RNA molecules that regulates multiples physiological processes. miRNAs play an important role in host-pathogen interactions, triggering the antiviral defence in cells or stimulate pro-inflammatory pathways. These facts have made miRNAs potential candidates for biomarkers of SARS-CoV-2 infection. The present study was carried out by novel techniques to determine the miRNA profile in the upper airways of mild COVID-19 cases to shed light on the early pathogenesis process of COVID-19.

Material and Methods: miRNAs expression from oropharyngeal/saliva samples belonging to 32 mild symptomatic COVID-19 patients and 20 age and gender-matched healthy controls was determined. miRNAs were isolated and sequenced by NGS technology. In the validation step miRNAs expression was determined by qPCR and by a new optimised ddPCR protocol for miRNAs analysis. An in-silico analysis was performed for target prediction.

Results: From the NGS analysis, miR-3195 was the most upregulated ($Log2FC = 5.23$; $p < 0.001$; $FDR < 0.001$), while miR-590-3p and miR-374a-5p were the most downregulated ($Log2FC = -4.36$ and -3.56, respectively, $p < 0.001$; $FDR < 0.05$). In the validation step, we could confirm miR-3195 expression to be increased among cases when compared to controls either through qPCR ($p = 0.03$) or through ddPCR ($p < 0.05$). In-silico analysis revealed *PFKFB4* as a target of miR-3195, which may be associated with cytokine release through the glycolytic pathway.

Conclusion: using novel techniques to analyse miRNA expression in the upper airway allowed us to identify potential biomarker candidates for COVID-19 pathogenesis. miR-3195 is suggested to participate in cytokine release regulation. Further studies in a larger cohort are needed to confirm these findings.

P22.022.C A whole-organism landscape of X-inactivation in humans

Svenja Löffert[1], *Björn Gylemo*[1], *Maike Bensberg*[2], *Colm E. Nestor*[1]

[1]Linköping University, Linköping, Sweden, [2]Duke University, Durham, NC, USA.

Background: X-chromosome inactivation (XCI) is a crucial, yet poorly understood process that results in silencing of one X-chromosome in each female cell. The stochasticity of this process typically obstructs bulk tissue analysis of X-linked allelic expression (AE). Non-mosaic females (nmXCI), in which the same parental X-chromosome is inactivated in all cells, however, are a natural and powerful genetic system to study X-inactivation in human bulk tissue.

Material and Methods: The GTEx database RNA-seq, WES and WGS data was leveraged to identify nm-XCI females based on heterozygous SNPs and AE analysis, detecting two additional nm-XCI females to the one previously known. Skewing of XCI was then determined by analysis of the AE of nonPAR X-chromosomal genes.

Results: We reveal non-mosaicism as a common feature of the human female population with implications for the penetrance and expressivity of X-linked diseases. Further, combined allele-resolution data of three nmXCI females allowed determination of XCI status across a total of 30 tissues, encompassing 380 X-linked genes, out of which 198 are characterized for the first time. Altogether this substantially increases our understanding of XCI in the human context and will be a useful reference for dissecting the genetic origin of pathologies exhibiting sex-bias.

Conclusion: Non-mosaicism in humans is a more common natural phenomenon than previously thought and can be leveraged as a powerful tool to study X-chromosomal diseases, their penetrance and genetic origin.

P22.023.D Investigating X chromosome inactivation patterns in X-Autosome translocations using long read sequencing and the T2T genome assembly

Esmee ten Berk de Boer[1], *Marlene Ek*[1], *Jesper Ottosson*[2], *Lovisa Lovmar*[3], *panagiotis baliakas*[4], *Marie Louise bondeson*[4], *Anna Lindstrand*[5]

[1]Karolinksa institutet, Stockholm, Sweden, [2]Sahlgrenska Universitetssjukhuset, Gothenburg, Sweden, [3]Sahlgrenska University Hospital Clinical Genetics & Genomics, Goteborg, Sweden, [4]Uppsala Universitet, Uppsala, Sweden, [5]Klinisk genetik L4:03, Stockholm, Sweden.

Background: X chromosome inactivation (XCI) is a critical mechanism in female mammals that ensures dosage compensation by silencing one of the two X chromosomes. While XCI is

typically random, genomic alterations can lead to skewed inactivation patterns. Here, we utilized long-read genome sequencing (LRS) with the PacBio Revio platform and the telomere-to-telomere (T2T) genome assembly to investigate the effects of X-autosome translocations on XCI.

Material and Methods: By combining the ability of LRS to span complex and repetitive genomic regions with the completeness of the T2T assembly, we accurately mapped translocation breakpoints. We phased the derivative and structurally healthy X chromosomes in nine carriers of X-autosome translocations. Using the epigenetic signatures from the LRS data, we (i) measured XCI, (ii) determined which X chromosome was active or inactive, and (iii) examined methylation patterns across the derivative chromosomes and translocation breakpoints.

Results: All individuals exhibited skewed XCI, indicated by methylation levels on the AR promoter (differential methylation 40–60%), confirmed by similar patterns on the RP2 promoter (differential methylation 30–70%). Preliminary analysis has shown that in two cases the derivative X is preferentially active, while in one case the structurally normal X is preferentially active. Further analysis of methylation patterns is ongoing.

Conclusion: This study highlights the power of LRS and the T2T genome in resolving structural rearrangements and their effects on epigenetic regulation. Our findings provide novel insights into the interplay between structural variants and XCI, offering a deeper understanding of their implications for female phenotypic diversity and rare disease mechanisms.

P22.024.A Single-cell eQTL mapping identifies cell type and disease-specific genetic control of COVID-19 severity

Jennifer Astley[1], *Calliope Dendrou*[1], *Steve Sansom*[1], *Julian Knight*[2], *Alex Mentzer*[2], *Yang Luo*[1], *Luke Jostins-Dean*[1]

[1]*Kennedy Institute of Rheumatology, University of Oxford, Oxford, United Kingdom,* [2]*Centre for Human Genetics, University of Oxford, Oxford, United Kingdom.*

Background: The impact of genotype on gene expression can depend on both cellular and organismal context. The COVID-19 Multi-omics Blood ATlas (COMBAT) Consortium provided an extensive blood atlas of patients with varying COVID-19 severity, integrated with sepsis and healthy controls. However, the role of genetic regulation within gene expression in a context-specific manner remains unclear.

Methods: We identified cis-expression quantitative trait loci (cis-eQTLs) across multiple blood cell types in individuals from the COMBAT study. Using tensorQTL, we analyzed single-cell transcriptomic and genome-wide genetic data from ~400,000 cells and 76 European ancestry donors. We applied an ANOVA-based approach to detect disease-modified eQTLs and used plink to find intersecting eQTL and GWAS variants and investigate potential novel disease mechanisms.

Results: Across 15 cell types, we mapped 2,607 independent cis-eQTLs in high linkage disequilibrium (R^2>0.8) with 48 infectious and 386 inflammatory disease-associated GWAS variants, including rheumatoid arthritis (RA) and inflammatory bowel disease (IBD). Notably, we found infection-specific eQTLs absent from a general population dataset (OneK1K), such as *REL*, *IRF5* and *TRAF*, all of which were differentially regulated by infection and whose variants are associated with RA and/or IBD. We also identified infection-modified eQTLs, including *RPS26* and *ADAM10*, implying these genes may play a role in specific immune cell subsets in infection.

Conclusion: Our work demonstrates that the overriding effect of genetics on gene expression in blood immune cells is independent of infection status or severity. However, small numbers of eQTLs are modified by infection, and these differences can illustrate potentially important immune biology.

P22.025.B Gene expression dysregulation in cohesin genes in Cornelia de Lange Syndrome patients derived cells

Thainá Vilella[1], *Elisabetta Di Fede*[2], *Esi Taci*[2], *Paolo Grazioli*[2], *Chiara Parodi*[2], *Beatriz Carvalho Nunes*[1], *Chong Kim*[3], *Maria Isabel Melaragno*[1], *Cristina Gervasini*[2], *Valentina Massa*[2]

[1]*Universidade Federal de São Paulo, São Paulo, Brazil,* [2]*Università degli Studi di Milano, Milano, Italy,* [3]*Instituto da Crianca HC-FMUSP, Sao Paulo, SP, Brazil.*

Background: Cornelia de Lange Syndrome (CdLS) is a rare multisystem developmental disorder caused by variants in cohesin-related genes, coding for proteins involved in regulating chromatin structure, gene transcription, and cell cycle control. CdLS presents broad phenotypic variability, but the underlying mechanisms remain poorly understood. This study investigates gene expression profiles in lymphoblastoid cell lines (LCLs) from CdLS patients to explore potential molecular mechanisms and their possible association to clinical features.

Material and Methods: LCLs derived from two patients with *NIPBL* variants and five with *SMC1A* variants were used. RT-qPCR analyzed cohesin-related gene expression. Proliferation was assessed by Ki-67 immunofluorescence, and apoptosis rates by TUNEL assay. Phenotype severity was correlated with experimental results.

Results: Patients with *NIPBL* variants exhibited a possible compensatory mechanism between *NIPBL* and *MAU2*. In *SMC1A* patients, *SMC1A* expression remained stable, while *NIPBL*, *HDAC8*, *SMC3*, *MAU2*, and *STAG2* were dysregulated. *HDAC8* upregulation in *NIPBL* variants might enhance *SMC3* deacetylation, potentially supporting cohesin recycling. *SMC1A* variants exhibited different *HDAC8* and *SMC3* expression patterns, possibly affecting cohesin functionality. Altered *NIPBL* and *STAG2* expression appeared linked to cohesin-chromatin binding, with coordinated regulation observed in milder phenotypes. Patients with elevated apoptosis indices showed reduced proliferation rates, associated with *CCND1* downregulation. In contrast, *MYC* downregulation was observed in patients with normal apoptosis levels.

Conclusion: This study underscores the relevant role of cohesin pathway gene dysregulation in CdLS pathophysiology. The different molecular alterations in cells with variants in different cohesion components could account for phenotypic variability, and suggest the need for further studies.

Background: Recent advances in sequencing have enhanced patient diagnosis; however, causal mutations remain unidentified for a significant number of patients due to limited understanding of certain variants, regulatory sequences, or sequencing challenges, such as complex rearrangements. Investigating the epigenetic landscape has become essential to improve the diagnostic yield.Diseases caused by mutations in epigenetic regulators—often associated with growth abnormalities, intellectual disability, and facial dysmorphism—are prime models for studying episignatures. Among them, Snijders Blok-Campeau syndrome (ORPHA:599082), caused by pathogenic variants in the CHD3 gene, remains largely understudied.

Material and Methods: A European cohort of 30 patients, with CHD3 variants (pathogenic, likely pathogenic or uncertain significance), was analysed using the Illumina EPIC array, identifying 142 differentially methylated probes distinguishing patients from healthy controls.

Results: These regions serve as diagnostic tools for complex cases or variants of unknown significance and help uncover deregulated pathways linked to this syndrome. Comparing methylomes of patients carrying pathogenic variants in CHD3, CHD7 (CHARGE syndrome), or CHD8 (Intellectual developmental disorder with autism and macrocephaly) genes allows us to identify distinct subgroups with unique methylation profiles. This robust CHD3 episignature aids in reclassifying variants and diagnosing atypical cases.

Conclusion: Our findings advance the field of epigenetic signatures in rare diseases. We have opened new avenues for further investigation into subtypes defined by methylome assays —such as in the context of chromatinopathies—which could refine the phenotype spectrum and help predict patient outcomes.

P22.027.D Identifying patterns of differential methylation in multiple sclerosis by positional integration approach

Nina Mele[1,2]*, Aleksander Turk*[1,2]*, Aleš Maver*[1]*, Borut Peterlin*[1]

[1]*Clinical Institute of Genomic Medicine, UMC Ljubljana, Ljubljana, Slovenia,* [2]*University of Ljubljana, Biotechnical Faculty, Ljubljana, Slovenia.*

Background: Over the past decade, several studies have explored the global methylation profile in multiple sclerosis (MS), revealing variable differentially methylated regions (DMRs) with limited consensus. To identify convergent DMRs, we integrated resulting data using a position-based integration of signals from these studies.

Materials and Methods: Systematic literature search identified eight methylome studies, which altogether reported 19,982 nominally significant DMRs. We used a rank sum approach, previously developed by our group, to statistically assess the results from heterogeneous sources. Obtained DMRs were mapped to tiled genomic intervals of 10 kbp. We assessed statistically significant accumulation of DMRs in given region using a permutation-based approach ($N = 1000$) and bootstrapping ($\alpha = 0.05$).

Results: Integration of methylation data revealed 172 significant regions ($p < 0.05$) with 2 regions displaying DMRs overlapping across four studies, 56 across three, and 114 across two. While we observed the most significant overlap for the well-characterised DMR in the HLA-DRB1 region, we also identified significant results in the non-coding regions. Particularly, we identified significant results in the T-cell receptor alpha chain joining gene cluster (TRAJ group) and lncRNAs regulating genes, involved in T-cell development and neuroinflammation. DMRs in proximity to protein-coding genes were enriched in pathways of immune cell regulation and differentiation, vitamin D signaling, and epigenetic modifications, highlighting the connection between environmental exposures and MS risk via epigenetic changes.

Conclusion: By integrating methylation signals across multiple MS studies, we identified consistent DMRs in both coding and non-coding genomic regions, which are associated with T-cell function, and genes regulated by MS-associated environmental factors.

P22.028.A Human genes crucial for tolerance to metabolically induced oxidative stress - Lessons from Fanconi Anaemia

Govind Pai[1,2]*, Davy Rockx*[1]*, Christian Griffioen*[3]*, Anneke Oostra*[1]*, Martin A. Rooimans*[1]*, Khashayar Roohollahi*[1]*, Klaas de Lint*[1]*, Rob M.F. Wolthuis*[1]*, Dagmar Wieczorek*[2]*, Patrick May*[4]*, Jan Koster*[3]*, Josephine C. Dorsman*[1]

[1]*Oncogenetics lab, Department of Human Genetics, Cancer Center Amsterdam (CCA), Amsterdam UMC, Amsterdam, Netherlands,* [2]*Institute for Human Genetics, University Hospital Düsseldorf,*

Düsseldorf, Germany, [3]Laboratory for Experimental Oncology and Radiobiology, Cancer Center Amsterdam, Amsterdam UMC and University of Amsterdam, Amsterdam, Netherlands, [4]Luxembourg Centre for Systems Biomedicine, Esch-sur-Alzette, Luxembourg.

Background: The 23 proteins of the FA/BRCA network orchestrate a precise DNA-repair process to ensure genome integrity. Fanconi Anaemia (FA) results from hereditary defects in DNA interstrand-crosslink (ICL) repair and features bone marrow failure, predisposition to acute myeloid leukaemia (AML) and head-and-neck squamous cell carcinoma (HNSCC). The sensitivity of FA cells to hyperoxia, alcohols and aldehydes indicates that metabolism of atmospheric oxygen (O_2) and alcohol is important in disease aetiology. Oxidative cellular damage is thought to drive degeneration and cancer in FA. Abrogating oxidative stress could potentially counteract degenerative processes and enhance fitness of normal FA cells.

Material and Methods: Unbiased functional-genomic CRISPR/Cas9-knockout screens under mild oxidative challenge, along with multi-omics profiling of a unique, in vitro-evolved, hyperoxia-tolerant FA-HNSCC cell line panel to find novel pathways in human cellular oxygen defence systems.

Results: CRISPR/Cas9-knockout screens in untransformed RPE1-hTERT cell models (WT vs FANCC$^{-/-}$) revealed, in addition to human orthologues of well-known yeast genes CCS, SLC31A1, SOD2, novel genes - MPV17L2, CYB5R4, and GPI - not previously linked to oxygen metabolism. CNV analysis of hyperoxia-tolerant FA-HNSCC cell lines revealed amplifications at 11q22.1–22.3 in general and 7q11.21–23, 7q22.1 unique to FA-deficient HNSCCs but not their gene-corrected counterparts. Ongoing mutation, transcriptomic and methylation analyses will yield a comprehensive understanding of genes crucial for oxygen tolerance.

Conclusion: Paraquat CRISPR-Cas9 KO screens reveal oxygen metabolism- and mitochondria-related genes. The In vitro evolved Hyperoxia-tolerant FA-C HNSCC cells are valuable for identifying genes conferring oxidative stress resistance.

P22.029.B Comparative systems genetics of endothelial and immune cells reveals shared and distinct pathways in cardiovascular disease

Stephen Watt[1], *Matiss Ozols*[1], *Arianna Landini*[2], *Kevin Bin Liu*[3], *Sodbo Sharapov*[2], *Daniela Zanotti*[2,4], *Gabriela Ivanova*[1], *Charles Solomon*[5], *Xu Dong Yang*[3], *Tolulope Balogun*[6], *Nicole Staudt*[1], *Wei Li*[3,7], *Tom Webb*[5], *David McVey*[5], *Nick Morrell*[3], *Stefan Gräf*[3,7], *Shu Ye*[5], *Nicola Pirastu*[2], *Nicole Soranzo*[2,1,3], *Mattia Frontini*[6]

[1]*Wellcome Sanger Institute, Cambridge, United Kingdom,* [2]*Human Technopole, Milan, Italy,* [3]*University of Cambridge, Cambridge, United Kingdom,* [4]*Politecnico di Milano, Milan, Italy,* [5]*University of Leicester, Leicester, United Kingdom,* [6]*University of Exeter, Exeter, United Kingdom,* [7]*Victor Phillip Dahdaleh Heart & Lung Research Institute, Cambridge, United Kingdom.*

Cardiovascular disease (CVD) is an umbrella term used to describe disease of the heart and blood vessels. The endothelial lining of blood vessels is the point of contact between blood and the vasculature, and how it responds to environmental insults could determine the progression of disease. CVD has a considerable immune component, with genome wide association studies (GWAS) identifying hundreds of risk loci associated with both CVD and autoimmune disease, many of which converge on the same candidate genes.

To investigate the genetic mechanisms at CVD loci we generated a new molecular quantitative trait loci (molQTL) dataset including; gene expression, open chromatin and enhancer activity in human umbilical vein endothelial cells (HUVEC) from a panel of 100 donors. We integrated this with previously published QTL data from our laboratory generated in three immune cell types; monocytes, neutrophils, and naïve T lymphocytes. We performed colocalisation analysis between molQTLs and 17 cardiovascular disease GWAS, including Coronary Artery Disease and Atrial Fibrillation. In addition, to directly test genetic effects on endothelial barrier integrity we used Electric Cell-substrate Impedance Sensing (ECIS) as a quantitative trait to perform genetic association analysis. We resolved hundreds of risk loci in both endothelial and immune cells, both highly pleiotropic loci that were shared across cell types and traits, and loci that were restricted to cell type relevant pathways. As an example using our molQTL and ECIS data we identified a novel isoform QTL at the IGF2BP3 gene which has recently been shown to protect against endothelial dysfunction.

P22.031.D Sex/Gender differences in circRNAs expression and function in Multiple Sclerosis

Valeria Lodde*, Ignazio Roberto Zarbo, Ilaria Campesi, Matteo Floris, Maria Laura Idda*

University of Sassari, Sassari, Italy.

Background: Multiple Sclerosis (MS) is an inflammatory autoimmune disease of the central nervous system (CNS) with a female to male ratio up to 3:1. MS exhibits sex differences in immune responses and neurodegeneration, influencing disease susceptibility and progression. Accumulating evidence highlights the key roles of circular RNAs (circRNAs) in regulating CNS and immune cell functions. This study aims to analyze the role of circRNAs in MS pathogenesis, with a particular focus on sex differences and their potential as biomarkers.

Material and Methods: A microarray assay was used to profile circRNA expression in PBMCs from female MS patients (FPwMS) compared to male MS patients (MPwMS). RT-qPCR was performed to validate the expression of selected circRNAs. Additionally, circRNA expression was analyzed in MS patients with varying disease severity and under different drug treatments. Bioinformatics analysis was employed to map interactions between circRNAs and other ncRNAs to identify the competitive endogenous RNA (ceRNA) network.

Results: Among the 14,000 circRNAs detected, 33 were found to be differentially expressed between FPwMS and MPwMS. We deeply validated 1 circRNAs upregulated and 4 downregulated in PBMCs and in serum of FPwMS and MPwMS. Furthermore, the expression levels of these circRNAs were assessed in relation to disease severity and drug treatments. CeRNA analysis identified key mRNAs, miRNAs, and lncRNAs implicated in driving MS pathogenesis.

Conclusion: Our results highlight the implication of circRNAs in MS pathogenesis with a specific focus on sex/gender differences and their potential use as biomarkers. These findings provide new insights into the molecular mechanisms underlying MS.

P22.032.A Loss of imprinting at the *RB1* locus in families with *RB1* promoter variants supports the role of transcription in establishing oocyte-specific DNA methylation at the *RB1* DMR

Deniz Kanber, *Dietmar Lohmann*

University Hospital Essen, Institute for Human Genetics, Essen, Germany.

Background: Retinoblastoma (RB) is an autosomal dominant tumour predisposition caused by mutational inactivation of the tumour suppressor gene *RB1*. Parent-of-origin effects on RB penetrance were noted in families with a specific *RB1* variant before *RB1* was found to be imprinted and were later observed for other variants, too. *RB1* imprinting is due to a differentially methylated region (DMR) in intron 2, methylated on the maternal and unmethylated on the paternal allele, where it acts as a promoter for an alternative *RB1*-transcript. Its expression interferes with expression of the regular upstream *RB1*-transcript, leading to skewed expression in favour of the maternal allele. In the growing oocyte, methylation at maternally methylated DMRs occurs via transcription traversing these DMRs. Genetic analysis of families with variants silencing expression of the regular *RB1*-transcript may provide evidence for transcription's role in establishing *RB1*-DMR methylation.

Material and Methods/Results: MS-MLPA analysis of blood DNA of 7 families with pathogenic *RB1* promoter variants revealed that all 4 individuals with a maternally transmitted variant showed hypomethylation at the DMR. All 6 individuals with a paternally transmitted variant showed normal methylation of 50%. Analysis of the RB phenotype distribution in our and published families with variants silencing expression of the regular *RB1*-transcript, showed no dependence on parental origin.

Conclusion: Our observations indicate that establishing methylation at the *RB1*-DMR in the oocyte depends on active transcription through this region. The absence of a parent-of-origin effect in families with silenced *RB1* transcription suggests that this phenomenon is mediated by imprinting at the *RB1*-DMR.

Two decades of Genome Wide Association Studies (GWAS) have yielded hundreds of thousands of robust genetic associations to human complex traits and diseases. Nevertheless, the dissection of the functional consequences of variants lags behind, especially for non-coding variants. Here we have characterised a set of rare, non-coding variants (RNVs) with large effects on haematological traits by integrating (i) a massively parallel reporter assay and (ii) in vivo gene expression and transcript relative abundance analysis of whole blood and immune cells. After extensive manual curation we identify 22 RNVs regulating genes robustly associated with the GWAS traits and perform an in-depth characterization of one of them, demonstrating its impact on megakaryopoiesis through modulation of the CUX1 transcriptional cascade. With this work we advance the understanding of the translational value of GWAS findings for variants implicated in blood and immunity.

P22.034.C Establishing Zebrafish and iPSCs-models of *ANO4* missense variants linked to neurodevelopmental and epileptic disorders

Sissy Bassani[1], *Valeria Sabatino*[1], *Martina Mocera*[1], *Gabriele Siegel*[1], *Matthias Gesemann*[2], *Anais Begemann*[1], *Stephan C. F. Neuhauss*[2], *Anita Rauch*[1]

[1]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [2]*University of Zurich, Department of Molecular Life Sciences, Zurich, Switzerland.*

Background: We previously described missense variants in *ANO4* to result in distinct phenotypes of fever-sensitive developmental

disorders associated with diverse types of epilepsy with or without cognitive impairment. These variants impair ANO4 ion channel and scramblase activity, exhibiting evidence for a dominant-negative effect. Additionally, we observed a heterozygous *ANO4* deletion in a healthy individual suggesting that the disease mechanism is likely linked to dysfunctional protein rather than haploinsufficiency.

Material and methods: To better understand genotype-phenotype correlation, we perform in vivo experiments using zebrafish model. Concurrently, we generate patients-derived iPSCs and their isogenic controls, to then differentiate both into excitatory forebrain neurons.

Results: Sequence alignment revealed that both human *ANO4* and *ANO3* align to the Zebrafish orthologue *ano3*. To test if *ano3* combines functions of both human genes, we generate knock-down fish followed by rescue experiments. *Ano3* knock-down zebrafish displayed developmental and locomotion impairment with 27% of fish exhibiting multi-organs malformations. Preliminary rescue experiments with human *ANO3* mRNA Wt partially restored the phenotype, suggesting that human *ANO4* might also be necessary for full phenotypic rescue. Overexpression of human *ANO3* mRNA Wt led to high lethality (up to 57%) and increased rate of malformations. Overexpression of human *ANO4* mRNA Wt shows a milder impact with a lower lethality rate and less malformed fish.

Conclusions: Our preliminary results suggest that the zebrafish orthologue *ano3* may function as both human *ANO3* and *ANO4*. Knock-down *ano3* affects zebrafish development and neuronal activity. Overexpression of human *ANO3* and *ANO4* independently leads to lethality and malformations.

P22.035.D The transcription factor FOXM1 reverts DNA damage-driven epigenetic erosion in aged cells

C. Sousa-Soares*, M. Mendes da Silva, J. Macedo, E. Logarinho;*

i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal

Background: DNA damage is a key driver of aging, leading to epigenetic erosion, cellular senescence, and chronic inflammation. FOXM1, a transcription factor repressed with age, is recognized as a master regulator of DNA repair. However, its role in mitigating DNA damage and preserving epigenetic integrity in aging remains poorly understood.

Material and Methods: Fibroblasts from young donors were subjected to *FOXM1* knockdown using RNA interference, while FOXM1 overexpression was induced in fibroblasts from aged donors via a lentiviral transduction system. DNA damage and protein levels of epigenetic regulators were measured by immunofluorescence. Gene expression changes were measured using RNA-seq, and changes in binding profiles of histone modifications were examined using CUT&RUN.

Results: *FOXM1* knockdown in fibroblasts from young donors downregulates essential DNA repair pathways, resulting in increased DNA damage. This promotes the proteolytic degradation of the G9a methyltransferase and a subsequent loss of the H3K9me2 epigenetic mark at the nuclear periphery. Consistent with FOXM1 repression during aging, G9a and H3K9me2 levels are reduced in aged fibroblasts. Loss of H3K9me2 at specific loci is associated with increased expression of senescence and inflammatory processes. Remarkably, overexpression of *FOXM1* in aged fibroblasts restores DNA repair gene expression and reduces DNA damage. This reinstates both G9a and H3K9me2 levels to repress genes involved in inflammation and senescence.

Conclusion: These findings establish FOXM1 as an age reversal factor capable of restoring epigenetic integrity by enhancing DNA repair, offering a promising therapeutic avenue to address the fundamental causes of aging.

P22.036.A Single-cell analysis of epigenomic changes induced by culture adaptation in human embryonic stem cells

Byunghee Kang[1]*, Yun-Jeong Kim*[2,3]*, Solbi Kweon*[4]*, Chang Pyo Hong*[5]*, Hyuk-Jin Cha*[2,6]*, Tae-Young Roh*[1]

[1]Department of Life Sciences, Ewha Womans University, Seoul, Korea, Republic of, [2]College of Pharmacy, Seoul National University, Seoul, Korea, Republic of, [3]College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul, Korea, Republic of, [4]Theragen Bio, Co., Ltd., Seongnam, Korea, Republic of, [5]YiPSCELL Inc., Seoul, Korea, Republic of, [6]Research Institute of Pharmaceutical Sciences, Seoul, Korea, Republic of.

Background: Long-term culture of H9 human embryonic stem cells (hESCs) leads to genomic and epigenetic alterations, including changes in chromatin accessibility, copy number variations (CNVs), and gene expression. Epigenetic changes play a critical role in regulating gene expression and cellular behavior during culture adaptation. These changes may give rise to culture-adapted phenotypes, such as increased survival and proliferation.

Material and Methods: Single-nuclei ATAC-seq (snATAC-seq) was conducted across four passage stages (P1-P4) to profile chromatin accessibility. Cis-coaccessibility networks and functional enrichment analyses identified key differentially accessible regions (DARs). Transcription factor (TF) activities and chromatin accessibility-based CNV estimations were also assessed.

Results: Long-term culture of hESCs resulted in distinct chromatin accessibility profiles, with elevated accessibility in high-passage populations (P3/P4) linked to centrosome organization genes. In Chr20q11.21, specific regions exhibited RNA expression patterns that correlated more strongly with changes in open chromatin rather than CNV. TEAD (transcription enhanced associate domain) family TFs were identified as key regulators of BCL2L1 and TPX2, with increased activity in higher passages.

Conclusion: Prolonged culture induces significant genomic and epigenetic adaptations, characterized by distinct transcriptional and chromatin changes that drive culture adaptation and survival phenotypes. Particularly, these changes in TEAD-regulated genes contribute to spindle assembly and anti-apoptotic phenotypes, with cell line-specific variability during culture adaptation. These findings provide valuable insights into mechanisms underlying hESC culture adaptation and highlight potential implications for maintaining genomic integrity.

P22.037.B Lead exposure alters global DNA methylation in pediatric Cystic Fibrosis patients from Georgia

Sandro Surmava[1]*, Tinatin Tkemaladze*[1,2,2]*, Nino Dabrundashvili*[1,3]*, Tsitsino Atamashvili*[1,3]*, Maia Gagua*[1,3]*, Elene Abzianidze*[1,4]*, Eka Kvaratskhelia*[1,3]

[1]Tbilisi State Medical University, Tbilisi, Georgia, [2]Givi Zhvania Pediatrics Academic Clinic of TSMU, Tbilisi, Georgia, [3]V. Bakhutashvili

Institute of Medical Biotechnology, Tbilisi, Georgia, [4]Ivane Beritashvili Center Of Experimental Biomedicine, Tbilisi, Georgia.

Background: Cystic fibrosis (CF) is the most common life-shortening autosomal recessive disorder in Caucasians that mainly affects the respiratory and gastrointestinal systems [1]. Genotype-phenotype correlations in CF twins showed that modifier genes and environmental factors also contribute to phenotypic variability in CF patients [2, 3]. Lead (Pb) is a pervasive environmental neurotoxin that does not degrade or lose potency over time, contaminates population centers worldwide, and has no safe level of exposure for children [4]. In this study we examined plasma levels of lead and analyzed global DNA methylation markers in Georgian CF patients.

Material and Methods: The study was approved by the Ethics Committee of the Tbilisi State Medical University (Tbilisi, Georgia). A total of 34 patients (age 5.5 ± 3.8) were recruited in this study. DNA was treated using the EZ DNA Methylation-Gold Kit (Zymo Research, CA, USA) according to the manufacturer's protocol. LINE-1 and Alu methylation levels were evaluated using COBRA-IRS method. The plasma lead level was quantified using atomic absorption spectrometry (Agilent 240FS AAS, USA).

Results: The mean plasma lead levels was 2.6 µg/dL. Pb exposure was correlated with methylation of the LINE-1 and Alu elements. Significantly decreased methylation was found in both elements in children with high plasma Pb compared to low plasma Pb ($p < 0.05$).

Conclusion: This study was a first try to correlate methylation status of the LINE-1 and Alu retrotransposons with plasma Pb levels in CF. The result suggests that Pb exposure increases aberrations in DNA methylation in Cystic Fibrosis.

P22.038.C Identification of circular RNA associated with human traits

Maria Laura L. Idda[1], *Maristella Steri*[2], *Marco Masala*[2], *Valeria Lodde*[1], *Mauro Pala*[2], *Francesco Cucca*[1]

[1]*University of Sassari, Sassari, Italy,* [2]*IRGB-CNR, Cagliari, Italy.*

Background: Circular RNAs (circRNAs) are single-stranded non-coding RNA depicted by a covalently closed circular structure; circRNA are generated from pre-mRNAs through back-splicing process. Recently, with the progression of high-throughput sequencing technologies, several circRNAs have been identified, and functional analyses illustrated their effect on human diseases including autoimmunity. However, studies on the function of circRNAs in immune response and autoimmunity are still lacking.

Material and Methods: Here, we present a collection of 67 total leucocyte RNA-seq datasets that were used to explore the cellular and humoral landscape of circRNAs in human samples. Using a custom pipeline for cirRNA calls exon-exon junctions we identify circRNAs expressed in the RNA-seq libraries. Next, using correlation and regression analysis, we link circRNAs with immune-related phenotypes available from the SardiNIA cohort.

Results: We identified a total of 54 specific circRNA expressed in leukocytes. Among them, 7 signals were significantly associated with immune cells levels, 9 with inflammatory molecules, and 2 showing a different behavior in males and females. Of note, we revealed a correlation between hsa_circ_0001947 levels, a circular RNA previously associated with Multiple Sclerosis, and granulocyte levels. Further analysis showed that hsa_circ_0001947 is upregulated in our Multiple Sclerosis data set and was further analyzed.

Conclusion and future prospective: This study expands our knowledge of circRNA expressions and correlation of circRNA levels with immune traits and provides a useful resource for exploring circRNAs in autoimmunity. Ongoing analyses are focused on understanding hsa_circ_0001947 role in MS and to deeply analyzed the levels of genetic regulation for circRNAs.

P22.039.D Impact of ketogenic diet treatment in GLUT1 deficiency syndrome: identification of molecular mechanisms related to phenotype changes in both pediatric and adult patients

Alessia Mauri[1,2], *Roberto Previtali*[3], *Letizia Messa*[1,4], *Francesca Fiumani*[1], *Davide Biganzoli*[1], *Stephana Carelli*[1], *Sara Olivotto*[3], *Pierangelo Veggiotti*[2,3], ***Cristina Cereda***[1]

[1]*Center of Functional Genomics and Rare Diseases, Buzzi Children's Hospital, Milan, Italy,* [2]*Department of Biomedical and Clinical Sciences, University of Milan, Milan, Italy,* [3]*Pediatric Neurology Unit, Buzzi Children's Hospital, Milan, Italy,* [4]*Department of Electronics, Information and Bioengineering, Politecnico di Milano, Milan, Italy.*

GLUT1 deficiency syndrome (GLUT1-DS) is a rare drug-resistant epilepsy caused by mutations in *SLC2A1*, encoding GLUT1, which supplies glucose to the brain. A genetic defect leads to cerebral energy deficiency, resulting in a complex spectrum of neurological symptoms. Ketogenic diet (KD) provides alternative sources for metabolism, whereas its mechanisms remain still unclear. This study aimed to investigate clinical variability and wide spectrum of *SLC2A1* variations, phenotype age-related changes, response to KD through a multi-omics approach. Analyses of 27 patients allowed the identification of different clinical phenotypes, 25 variants of which 10 novel, and correlations between variations, clinical and biochemical patterns. We explored the transcriptional profiles focusing on (a) adults versus children, both untreated; (b) children in pre- versus post-KD; (c) diet responders versus non-responders. Enrichment analysis revealed a reduction in inflammatory pathways in patients who experienced clinical improvements, whether in response to KD or during adulthood. These processes involve type I IFN signatures, which have an impact on mitochondrial signaling, suggesting a role in GLUT1-DS. Supporting these suggestions, the identified lncRNAs are related to inflammatory response, or to ketone biosynthesis process, like PAX8-AS1, for which emerges its potential role in KD response. Another pathway contributing to mitigate clinical signs is the alternative splicing of ion channel genes: P2X7 isoforms which are, in turn, linked to inflammasome. Concurrently, methylome profiles, performed by ONT, revealed altered methylation patterns in similar genes. These novel findings underline the complex interplay among transcriptional profiling, isoform switching and methylation patterns in the unresolved aspects of GLUT1-DS.

P22.040.A Epigenetically regulated genes and pathways associated with nonsyndromic cleft lip and palate identified through genome-wide DNA methylation analysis

A. Vedangi[1], *U. Radhakrishna*[2];

[1]*Department of Clinical Research, KIMS ICON Hospital, A unit of ICON Krishi Institute Medical Sciences, Visakpatnam, India,* [2]*University of Pittsburgh, Pittsburgh, India*

Background: Nonsyndromic cleft lip with or without cleft palate (NSCL/P) is the most common and severe craniofacial disorder, with both genetic and environmental causes. NSCL/P is linked to increased morbidity and mortality in childhood and adulthood. While genetic mechanisms of familial NSCL/P have been studied, epigenetic factors are increasingly implicated in orofacial development.

Materials and methods: To explore this, genome-wide DNA methylation analysis was performed on blood samples from 48 individuals, including 20 NSCL/P cases and 21 controls, using the Illumina Infinium MethylationEPIC array.

Results: Comparison of methylation profiles revealed 528 differentially methylated CpG loci, associated with 606 genes showing at least 8.0-fold methylation change, FDR $p < 5 \times 10\text{-}8$, and AUC ≥0.75. Notable genes identified include COL4A1, TP63, MSX1, PAX6, WNT6, and others previously linked to NSCL/P. Pathway analyses indicated that altered signaling in pathways such as growth hormone, Cdc42, GABA receptor, P38 MAPK, Wnt-B catenin, and BMP are associated with NSCL/P risk.

Conclusion: These findings support that NSCL/P is linked to differential DNA methylation in whole blood, which could serve as biomarkers for NSCL/P risk.

C.O.I. Disclosure:

A. Vedangi: None. **U. Radhakrishna:** None.

P22.041.B Reduction of the number of CpG dinucleotides required for episignature analysis in *CREBBP*-related Rubinstein-Taybi syndrome

Olga Zemlianaia, *Alexey Kalinkin, Anna Efremova, Alexander Tanas, Ilya Volodin, Olga Ismagilova, Anton Smirnov, Vladimir Strelnikov*

Research Centre for Medical Genetics, Moscow, Russian Federation.

Background: Genome-wide DNA methylation signature analysis, also known as episignature analysis, has proved to be an effective second-tier diagnostic tool for a number of chromatinopathies. However, there are several diseases, including CREBBP-related Rubinstein-Taybi syndrome (RTS1), for which genome-wide DNA methylation changes cannot be considered robust enough. We aim to represent an approach to the reduction of the RTS1 episignature which leads to an increase in classification accuracy.

Material and Methods: A total number of 99 samples were analysed, including the following DNA samples: 60 from patients with established pathogenic or likely pathogenic variants in the CREBBP gene, 5 from patients with detected variants of uncertain significance in the CREBBP gene, 4 from patients with syndromes phenotypically overlapping with Rubinstein-Taybi syndrome and 30 from healthy controls. Targeted methods based on high-throughput bisulfite sequencing and Sanger bisulfite sequencing were applied to measure the methylation level of the selected loci.

Results: Using machine learning techniques, we established that chr6:10556199_chr6:10556204 locus is the most significant predictor among those we had initially selected. The classification models based on targeted DNA methylation analysis methods set apart RTS1 and non-RTS1 samples with values of accuracy ≥0.9. Moreover, reduced episignature analysis shows utility in classifying samples with variants of uncertain significance in the CREBBP gene.

Conclusion: The proposed concept is quite promising in terms of increasing RTS1 detection and can be implemented on other chromatinopathies with known genome-wide episignatures.

P22.042.C In silico and molecular investigation of genomic interactions reveals shared pathways contributing to phenotypic overlap in neurodevelopmental disorders

Giovana Manilli Toccoli, *Henrique Garcia Silveira, Beatriz Nunes, Priscila Soares, Bianca Favilla, Thaina Vilella, Maria Isabel Melaragno*

Universidade Federal de São Paulo, São Paulo, Brazil.

Background: Neurodevelopmental disorders can result from variants in genes that participate in the epigenetic machinery. Patients with clinical suspicion of such conditions often present overlapping phenotypes such as intellectual disability, facial dysmorphisms, and ophthalmological abnormalities, posing challenges for research diagnostics. This study aims to investigate the phenotypic overlap among different conditions through in silico analysis of genes identified by Whole Exome Sequencing (WES) and their interactions, providing deeper insights into the genetic mechanisms underlying these disorders.

Material and Methods: Forty patients with a phenotype suggestive of neurodevelopmental disorders with normal cytogenomic tests were studied by WES. The detected gene variants were classified following the recommendations of the American College of Medical Genetics and Genomics (ACMG), followed by genotype-phenotype correlation. Gene interaction analysis was performed with in silico tools (STRING, GeneMANIA, BioGRID, Enrichr, and Cytoscape).

Results: WES results of five patients showed pathogenic and likely pathogenic variants in *CHD3*, *ARID1B*, *CREBBP*, *DNMT3A*, and *KAT6B*. These genes are involved in chromatin modulation and significantly impact the epigenetic machinery. A genotype-phenotype correlation was established for these patients, highlighting overlapping phenotypic features. In silico analysis revealed distinct interactions among these genes, which may explain the phenotypic similarities observed and the difficulty of an accurate diagnosis.

Conclusion: WES is an efficient technique to improve the diagnosis of patients with altered phenotypes and normal cytogenomic results who are under the suspicion of neurodevelopmental disorders. Moreover, WES allows the identification of genes that interact with each other, potentially guiding the diagnostic research of such patients.

P22.043.D Alternative splicing during differentiation contributes to differences in the response to type I interferon observed in monocytes and macrophages

Prumohdya Reddy, Palesa Lesole, Vanessa Meyer, ***Nikki L. Gentle***

University of the Witwatersrand, Johannesburg, South Africa.

Background: Monocytes are able to enter tissues and rapidly differentiate into macrophages in response to the microenvironment. During this process, cells undergo transcriptional changes that reflect the differences in their functions, which include differences in their response to cytokines such as type I interferons (IFNs). We therefore sought to examine how changes occurring during the differentiation process impact cytokine responses in the resulting cells.

Material and Methods: Monocytic THP-1 cells were treated with phorbol 12-myristate 13-acetate to induce differentiation into macrophages. Differentiation was confirmed using flow cytometry and microscopy. Monocytes and macrophages were then treated

with type I IFN (IFN-α) and RNA sequencing was performed. Changes in RNA abundance and isoform expression were evaluated before and after type I IFN treatment in both monocytes and macrophages. Selected alternative splicing events were validated using RT-qPCR.

Results: Monocytes and macrophages share overlap in their response to type I IFN with respect to changes in gene expression, but considerable differences are also observed between these cell types. These occur at both the level of gene expression and in the mRNA isoform profiles of each cell type. Even where genes are differentially expressed in response to type I IFN in both cell types, differences in alternative splicing diversify the response between cell types. These alternative splicing events can often be attributed to changes arising during the process of monocyte-to-macrophage differentiation.

Conclusion: This study highlights the role of alternative splicing events occurring during monocyte-to-macrophage differentiation in determining cell type-dependent responses to type I IFN.

P22.044.A Effects of PFAS on DNA methylation at human cancer susceptibility loci

P. Behboodi[1], *A. Castano*[1], *T. Pavlovic*[2], *M. Salas*[1], *M. Tariq*[1], *M. M. Rigo*[1], *R. Sarkar*[1], *Y. Zhong*[1], *A. MakohonMoore*[1], *W. Lee*[2], *M. Iwanicki*[2], *B. Tycko*[1];

[1]*HMH Center for Discovery and Innovation, Nutley, NJ,* [2]*Stevens Institute of Technology, Hoboken, NJ*

Background: Per- and polyfluoroalkyl substances (PFAS), including perfluorooctane sulfonate (PFOS), are persistent pollutants linked to increased risks of cancers and other diseases. These chemicals accumulate in biological systems and potentially disrupt epigenetic regulation. Our study focuses on the effects of PFOS on DNA methylation at risk loci for human cancers, with a hypothesis that such effects may be mediated by inflammatory signaling.

Material and Methods: Immortalized human fallopian tube epithelial (FNE) and B lymphoblastoid (GM12878) cells, modeling the precursors of ovarian cancer and B cell malignancies, were exposed to PFOS (0, 10, 25, 50 μM) or TNF-alpha (0, 50, 100, 200 ng/mL) for 48 hours. Targeted methyl-seq was performed to assess changes in net and allele-specific methylation patterns in a panel of GWAS-defined cancer susceptibility loci.

Results: In FNE cells, PFOS exposure induced concentration-dependent changes in net and allele-specific methylation spanning a regulatory SNP in the HOXD gene cluster associated with ovarian cancer. In GM12878 cells, PFOS exposure affected methylation in the S100A gene cluster and HNF1B, associated with multiple myeloma, as well as FGFR2, linked to breast cancer. Similar epigenetic changes were observed in TNF-alpha-treated cells, suggesting that inflammatory signaling may act as a mediator in PFOS-induced epigenetic alterations.

Conclusion: Our findings demonstrate that PFOS exposure alters DNA methylation at disease risk loci and suggest that such effects might be mediated through inflammatory signaling. Ongoing work includes functional tests of the inflammatory pathway hypothesis and assessing effects of PFAS at lower concentrations over longer exposures.

Background: Glycated hemoglobin (HbA1c) measures the average blood sugar level over the past three months. As a vital biomarker of blood glucose levels, it is used to diagnose Type-2 diabetes mellitus (T2D) and monitor glycemic control. Therefore, we performed a Phenome-Wide Association Study (PheWAS) and functional annotation of HbA1c-associated variants in two African populations.

Method: In this study, we utilized summary statistics of the HbA1c GWAS meta-analysis of 7,526 individuals from South Africa and Uganda to conduct a PheWAS using GWASATLAS. We also performed a functional analysis using FUMA tool. SNPs were prioritized using the SNP2GENE function, while the genes' expression patterns and shared molecular functions were explored in the GENE2FUNC.

Result: The functional annotation results identified three genome-wide significant loci with the lead SNPs rs6724428, rs148228241, and rs8045544 mapped to *GULP1*, *HBA1*, and *ITFG3* genes. The minor allele frequency for rs148228241 is 0.074 and is exclusive to African populations. Both rs8045544 and rs148228241 are significantly associated with the mean corpuscular hemoglobin concentration (MCHC). The rs6724428 variant is significantly associated with skeletal functions, reflecting the link between glucose metabolism and bone mineral density.

Discussion: Our findings highlight the intricate relationships between glucose metabolism, erythropoiesis, and skeletal health. The significant associations of HbA1c-variants with both skeletal function and MCHC underscore the potential of these variants to impact broader physiological processes. A larger study involving African individuals will be necessary to validate the link between the *HBA1* gene and HbA1C.

Salah Azaiez Institute, Tunis, Tunisia, [5]Laboratory of Molecular and Cellular Screening Processes, Centre of Biotechnology of Sfax, Sfax, Tunisia, [6]Biomedical Research Laboratory, Department of Internal Medicine 1, University Hospital, Goethe University, Frankfurt am main, Germany.

Background: Lynch syndrome is a heritable condition caused by a heterozygous germline mutation of the DNA mismatch repair genes, most commonly the *MLH1* gene [1, 2]. However, one third of the identified alterations are missense variants, for which the clinical significance is unclear in many cases [3, 4]. We have identified three *MLH1* missense alterations from Tunisian families. The classification of pathogenicity was not available for these variants, consequently diagnosis, predictive testing and targeted surveillance in affected families was impossible.

Material and Methods: This study examines three variants of uncertain significance identified in six patients with suspected Lynch syndrome. For the first time in Tunisia, we conducted functional laboratory assays to evaluate both protein stability and catalytic activity, utilizing a system incorporating clinically validated reference variants.

Results: Both p.(Leu73Pro) and p.(Pro640Thr) were found to be non-functional due to severe defects in protein stability and catalytic activity. In contrast, p.(Glu736Lys) was comparable to the wild-type protein and therefore considered a neutral substitution. Analysis of residue conservation and of the structural roles of the substituted residues corroborated these findings. In conjunction with the available clinical data, two variants fulfil classification criteria for class 4 "likely pathogenic".

Conclusion: In conjunction with clinical data of our patients, the functional results allow for classifying two of the found variants into class 4 (likely pathogenic), while no functional defects could be found in another variant. These findings will improve genetic counselling and clinical management of affected Tunisian families and other carriers of these genetic variants worldwide.

P22.047.D Dysregulated non-coding RNAs drive preeclampsia, revealing molecular mechanisms and diagnostic potential

A. koppula[1], *s. R. Sushma*[2], *G. Sudeshna*[3], *U. Radhakrishna*[4];

[1]*Andhra Medical College, Department of General medicine, Visakpatnam, India,* [2]*2.Department of Obstetrics and Gynecology, BJ Medical College Institute of Medical Post-Graduate Studies and Research, Ahmedabad, India,* [3]*Aditya Bangalore Institute of Pharmacy Education and Research Department-Department of Pharmacology, Bangalore, India,* [4]*University of Pittsburgh, Department of Anesthesiology and Perioperative Medicine, Pittsburgh, PA*

Background: Preeclampsia (PreE) is a pregnancy-related disorder characterized by high blood pressure and organ dysfunction, affecting both mothers and infants. It can impair the liver, kidneys, brain, and clotting system. While its global prevalence is 2%–10%, it affects 13%–15% of pregnancies in India. Emerging research links non-coding RNAs, including microRNAs (miRNAs), to pregnancy complications like PreE. This study investigates their role and potential as biomarkers for early detection and monitoring.

Material and Methods: Genome-wide DNA methylation analysis was performed on 20 women with severe preeclampsia and 20 normotensive controls using the Illumina Epic Array platform. Statistical and bioinformatic approaches were integrated to identify differentially methylated microRNAs associated with preeclampsia.

Results: The study identified 540 significantly differentially methylated CpG sites in 540 genes associated with preeclampsia (preE). Among these, 45 miRNA CpG sites exhibited significant methylation changes in preE and had been previously reported as being associated with the condition. These include miRNAs such as miR-675, miR-210, miR-378a, miR-411, miR-744, miR-519E, miR-525, miR-100, miR-328, miR-127, miR-379, miR-377, miR-195, miR-376c, and miR-378A. These dysregulated miRNAs are expected to target multiple coding genes, potentially contributing to preE development by regulating key cellular processes such as trophoblast proliferation, migration, invasion, apoptosis, differentiation, metabolism, and angiogenesis.

Conclusion: This study reveals significant miRNA methylation changes in preeclampsia, highlighting their potential as predictive biomarkers. These findings open avenues for personalized treatments, though further research is needed to confirm their diagnostic and therapeutic value. Exploring their target genes could deepen our understanding of preeclampsia's molecular mechanisms.

P22.048.A A new mechanistic key to functionally interrogate the regulatory genome

Rosa Maritato[1], *Alessia Medugno*[1], *Emanuela D'Andretta*[1], *Giulia De Riso, Postdoctoral fellow*[2], *Maria Laura Bacci*[3], *Claudio Mussolino*[4], ***Enrico Maria Surace***[1]

[1]*Università di Napoli Federico II, Napoli, Italy,* [2]*University of Naples Federico II, Naples, Italy,* [3]*University of Bologna, Bologna, Italy,* [4]*Medical Center, University of Freiburg, Freiburg, Germany.*

Most signals in genome-wide association studies (GWAS) are found in the noncoding regions of the genome, yet functional mechanisms to decode them are lacking. We recently described a new mechanism that controls gene expression of the *RHODOPSIN* (*RHO*) gene by combining perturbations of *cis*-regulatory elements (CREs) in "*trans*" and "*cis*." We found that by binding a short CRE within the RHO promoter with synthetic DNA-binding proteins (in *trans*), delivered into the retina by adeno-associated viral vectors (AAVs), it is possible to control the expression levels of the RHO gene (Botta et al., 2016). Furthermore, with an in vivo reporter assay carried out with AAV vectors, we have shown that the DNA sequence that the synthetic DNA-binding proteins bind in *trans*, when modified in *cis*, results in a wide variation in reporter gene expression outputs (Maritato et al., 2024). Specifically, we found that the composition and length (22 bp) of the DNA sequence interposed between two retinal transcription factors (TFs), CRX and NRL, largely controls RHO expression levels. These *trans* and *cis* perturbations argue that, in this case, the DNA sequence itself interposed between CRX and NRL contributes to their activities through a code based on specific DNA sequence of defined length, ultimately determining the levels of RHO expression. These studies may provide a new mechanistic key to functionally interpret the regulatory genome. This opens avenues to decode noncoding genetic variants across the genome and to exploit cis- and trans-regulation to encode novel therapeutic strategies.

P22.049.B Telomere shortening, oxidative stress products, and related-miRNAS as biomarkers in the response to mild SARS-CoV-2 infection

Candela Sirvent Blanco[1], *Angélica Domínguez de Barros*[1,2], *Omar García Pérez*[1,2], *Malena Gajate Arenas*[1,2], *Alma García Ramos*[1,2], *Claudia Migliazzo*[3], *José E. Piñero*[1,2,4], *Jacob Lorenzo Morales*[1,2,4], *Elizabeth Córdoba Lanús*[1,2]

[1]*Instituto Universitario de Enfermedades Tropicales y Salud Publica de Canarias, San Cristobal de La Laguna, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Infecciosas (CIBERINFEC), Insituto de Salud Carlos III, Madrid, Spain,* [3]*Università degli studi di Palermo, Palermo, Italy,* [4]*Departamento de Obstetricia y Ginecología, Pediatría, Medicina Preventiva y Salud Pública, Toxicología, Medicina Legal y Forense y Parasitología. Facultad de Ciencias de la Salud. Universidad de La Laguna., San Cristobal de La Laguna, Spain.*

Background: In infectious diseases, oxidative stress, and inflammation can modulate immune response and epigenetic machinery. Host-encoded miRNA profiles in mild COVID-19 are poorly investigated, although they can reveal information about oxidative stress and senescence on miRNA expression during disease. We evaluated ageing biomarkers, such as telomere shortening, oxidative stress indicators (TBARS and 8-OHdG), and related-miRNAs expression in response to viral infection.

Material and Methods: The study included 75 individuals with mild SARS-CoV-2 infection and 30 healthy controls. Telomere length (TL) was measured in DNA from whole blood and saliva samples. Oxidative stress biomarkers were quantified in plasma through spectrophotometry. Ageing and oxidative stress-related miRNAs (miR-155-5p, miR-34a-5p, miR-138-5p, miR-210a-3p, and miR-182-5p) expression in serum samples were assessed by qRT-PCR, followed by an in-silico (IS) analysis.

Results: TL correlated with age ($R = -0.384$, $p = 0.005$), and was shorter in infected individuals (rTL 1.46 ± 0.51 vs. 0.99 ± 0.37; $p < 0.001$). rTL was similar between the tissues analyzed ($p = 0.917$). 8-OHdG was increased in cases ($p = 0.040$), with no differences in TBARS concentrations ($p = 0.934$) compared to controls. miR-138-5p was upregulated in COVID-19 cases ($p = 0.026$) and positively correlated with 8-OHdG ($R = 0.403$, $p = 0.05$) indicating its involvement in viral processes (GO:0016032, p = 1.3e-08; in-silico). miR-210-3p was overexpressed in controls ($p = 0.008$) and miR-182-5p expression correlated with TBARS levels ($R = 0.582$, $p = 0.018$).

Conclusion: The relationship between TL and DNA damage in mild COVID-19 cases may indicate early systemic cellular damage processes. miR-182-5p might serve as an early biomarker of oxidative stress in COVID-19. Overexpression of miR-138-5p could represent a compensatory mechanism against damage caused by the infection.

P22.050.C Multiple Sclerosis patients show a depletion in Gut Microbiota keystone *genera* compared with their cohabiting Healthy Controls: a pilot study

Alen Zollo[1,2], *Andrea Corona*[1,2], *Maria Laura Terzi Mazzieri*[1], *Emerenziana Ottaviano*[1], *Alessandra Mingione*[1,2], ***Matteo Domenico Marsiglia***[1], *Alberto Priori*[1,2,3], *Elisa Borghi*[1,3], *Filippo Martinelli Boneschi*[1,2,3]

[1]*University of Milan, Milan, Italy,* [2]*CRC "Aldo Ravelli" for experimental brain therapeutics, Milan, Italy,* [3]*San Paolo Hospital, ASST Santi Paolo e Carlo, Milan, Italy.*

Background: In the complex pathophysiology of Multiple Sclerosis (MS) gut microbiota (GM) and dietary habits have been identified as significant contributors of disease development. GM dysbiosis is accompanied by alterations of immune system and immune response, due to the intricate link between GM composition, metabolite production and immune system stimulation.To minimize confounding factors, healthy controls (HC) who cohabit with MS patients have been recruited. The present study aimed at identifying possible alterations in the GM of MS patients through the 16S rRNA sequencing.

Material and Methods: 24 relapsing-remitting MS patients and healthy controls have been recruited for the study. A seven-day food diary has been administered to subjects, and food intake has been analyzed through MetaDieta software. GM composition has been characterized by sequencing the V3-V4 hypervariable regions of the 16S rRNA gene. Bioinformatic analysis have been conducted using DADA2 and Microbiome Analyst.

Results: Overall, no significative differences between MS patients compared with HC in total energy intake as major nutrients have been found.Alpha diversity metrics showed a decreased biodiversity in MS compared to HC, while no significant clustering has been found in beta diversity. MS patients show an enrichment in *Oscillibacter, Romboutsia* spp. and UBA1819, and a depletion in *Faecalibacterium, Roseburia* and *Coprococcus*, the major butyrate producing genera.

Conclusion: The absence of dietary differences between MS and HC suggests that recruiting household members as controls can minimize the impact of dietary variations between the groups.Our findings align with the existing literature, reinforcing the understanding of GM alterations in MS.

P22.052.A Reduced episignature of Sotos syndrome

Anna Efremova[1], *Olga Zemlianaia*[1], *Alexey Kalinkin*[1], *Alexander Tanas*[1], *Vladimir Strelnikov*[1,2], *Ilya Volodin*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*N.I. Pirogov Russian National Research Medical University of the Ministry of Health of the Russian Federation, Moscow, Russian Federation.*

Background: Episignature is usually detected by genome-wide methods using the Infinium MethylationEPIC microarray. In our work, we reduced the episignature of Sotos syndrome to the two most representative CpG sites and developed a classification model. This reduction allows detection of the episignature with targeted bisulfite sequencing.

Material and Methods: The most significant predictors (CpGs) in terms of classification ability were searched using Random Forest method with the Boruta algorithm. We collected DNA samples from 26 patients with pathogenic/likely pathogenic (P/LP) variants in the *NSD1* gene, 2 patients with variants of uncertain significance (VUS) in *NSD1*, 3 patients with likely pathogenic variants in *NFIX* and 11 control samples. Target CpGs methylation was assessed using bisulfite Sanger sequencing and local pipeline. The classification model was created by the support vector machine with cross-validation. The quality of the model was assessed using ROC analysis.

Results: Multiple classification models were built using single predictors and their possible combinations. The classification model based on the combination of predictors cg22497095 and cg20851828 showed the best sensitivity (99%), specificity (93%) and accuracy (94%) and was selected for further use. All samples with P/LP and VUS variants in *NSD1* were classified as Sotos syndrome samples. Control and *NFIX* samples were classified as normal samples.

Conclusion: Sotos syndrome episignature may be effectively reduced without significant loss of diagnostic significance.

P22.053.B Genes aberrantly methylated in NSCLC and CIS are enriched for olfactory transduction genes

Jonas Fend[1], *Ole Ammerpohl*[1,2]

[1]*Institute of Human Genetics, Ulm University and Ulm University Medical Center, Ulm, Germany,* [2]*Airway Research Center North, Member of the German Center for Lung Research (DZL), Grosshansdorf, Germany.*

Background: Lung cancer is the leading cause of cancer-related deaths[1]. Epigenetic changes, like DNA methylation, are key to understanding tumor biology and biomarker discovery. This study examines methylation patterns to uncover differences by tissue type and medical history.

Material and Methods: A retrospective analysis was conducted using the Gene Expression Omnibus database[2], incorporating 982 patients from five studies across three continents. The dataset included 244 normal and 54 carcinoma in situ (CIS) samples. Eligible studies were identified through a review of 937 publications (up to January 2024) using HumanMethylation 450K Array data. Differential methylation analysis (DMA) was conducted via the Wilcoxon rank-sum test (MWW).

Results: DMA was performed between normal and pathological samples, histological subtypes, and subgroups stratified by medical history. Methylation of a core set of 256 loci was consistently altered across multiple analyses (MWW, variance analysis, PCA) and ranked within the top 3000 results. Pathway enrichment analysis using Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) revealed significant alterations in the DNA methylation status of genes contributing to olfactory transduction in all samples (GO $p = 4.2 \times 10^{-13}$) and in loci associated with tumor recurrence (GO $p = 1.5 \times 10^{-13}$, KEGG $p = 1.7 \times 10^{-15}$). DMA between Short-Term Relapsers and Long-Term Survivors yielded no significant results.

Conclusion: The study identifies significant epigenetic differences between lung cancer subgroups. Olfactory transduction emerged as a key feature of methylation changes, especially in tumors that later relapsed. These findings reinforce the role of altered olfactory transduction pathways in cancer methylation and suggest a potential role in relapse prediction.

Département de Médecine Génomique des Tumeurs et Cancers, Hôpital Européen Georges Pompidou, Fédération de Génétique et de Médecine Génomique AP-HP Centre Université Paris Cité, Paris, France.*

Background: DNA methylation, an epigenetic marker, can contribute to tumorigenesis by inactivating tumor suppressor genes. In routine diagnosis, gene methylation is in most cases assessed by fragment using methylation-specific enzymes, or sequencing, after modification of unmethylated cytosines by bisulfite reaction. This method can damage DNA, or induce a conversion bias interfering with methylation analysis. Furthermore, these techniques don't allow assessment of an entire CpG island, nor do they allow sufficient sequencing depth for methylation rate assessment, or easy haplotypes phasing.

Material and Methods: These led us to evaluate two emerging technologies, to improve methylation profiling. As an alternative to bisulfite conversion, we tested first the enzymatic conversion of New England Biolabs™: Enzymatic Methyl-seq (EM-seq™), followed by PCR amplification and NGS sequencing of the region of interest. This approach is quantitative and uses a conversion method expected to reduce DNA fragmentation. The second technology tested is Oxford Nanopore long-read sequencing, which enables native DNA to be analyzed after CRISPR/Cas9 enrichment, or after adaptive sequencing. Both have been evaluated on a cohort of 6 DNA samples with methylation profiles of the SDHC promoter, including one germline mosaicism, previously characterized by pyrosequencing after bisulfite treatment.

Results: The two techniques revealed good coverage of the region of interest and showed correlations between the profiles obtained by NGS after NEB conversion versus Nanopore sequencing. Moreover, long read sequencing allows to easily phase methylation haplotypes in imprinting regions.

Conclusion: These results demonstrate the feasibility of the various techniques, and open the discussion on possible routine hospital use.

P22.055.D Impact of SDHA Mutations on Yeast Growth and Mitochondrial Function. Case Study Linking Genetic Findings to Clinical Phenotypes

Camilla Meossi[1], *Alessandro De Falco*[2], *Marco Marchi*[3], *Anna Rubegni*[1], ***Stefano Pagano***[1], *Rosanna Trovato*[1], *Claudia Nesti*[1], *Flavio Dal Canto*[1], *Emanuele Bartolini*[1], *Leonardo Salviati*[4], *Filippo Santorelli*[1]

[1]*IRCCS Fondazione Stella Maris, Pisa, Italy,* [2]*Azienda Ospedaliera Universitaria Federico II, Napoli, Italy,* [3]*2.Clinical Genetics Unit, Department of Women's and Children's Health, University of Padua, Padua, Italy; Clinical Genetics Lab, Città della Speranza Pediatric*

Research Institute, Padua, Italy., Padova, Italy, [4]Clinical Genetics Unit, Department of Women's and Children's Health, University of Padua, Padua, Italy; Clinical Genetics Lab, Città della Speranza Pediatric Research Institute, Padua, Italy., Padova, Italy.

Background: Biallelic mutations in the *SDHA* gene (MIM *600857), encoding the catalytic subunit of succinate dehydrogenase (SDH), are known to cause mitochondrial dysfunctions such as Leigh syndrome (LS), an autosomal recessive neurodegenerative disorder that primarily affects children, and it is characterized by developmental delay, lactic acidosis, ataxia, and seizures. SDHA mutations can present with variable and atypical features, complicating diagnosis. Yeast models (*Saccharomyces cerevisiae*) are used to study *SDHA* mutations and confirm their pathogenicity through complementation assays.

Material and Methods: We report a 15-year-old girl who showed neurodevelopmental regression, focal seizures, and behavioral disturbances. Genetic analysis included a trio whole genome sequencing (WGS) to identify mutations, whereas a muscle biopsy was performed to assess mitochondrial function. Functional studies in yeast helped to evaluate the pathogenicity of identified *SDHA* mutations using growth assays and enzyme activity measurements.

Results: WGS identified two heterozygous variants in *SDHA*: c.511C>T (p.Arg171Cys), classified as likely pathogenic, and c.1393C>T (p.Arg465Trp), of unknown significance. Both variants affect conserved amino acids in yeast Sdh1. Functional assays in *Saccharomyces cerevisiae* showed that the p.Arg171Cys mutation significantly impaired growth on glycerol, whereas p.Arg465Trp exhibited hypomorphic behavior. These findings support the pathogenicity of both variants and validate yeast as a model for mitochondrial dysfunction studies.

Conclusion: This case underscores the clinical variability of *SDHA*-related disorders and the importance of functional assays in confirming genetic findings. A comprehensive diagnostic approach combining genetic, biochemical, and functional evaluations is crucial in rare mitochondrial disorders, where traditional methods may be inconclusive.

P22.056.A Hidradenitis Suppurativa is associated with Non-Alcoholic Fatty Liver Disease due to dysregulated DNA methylation

S. Ghosh[1], *A. koppula*[2], *N. Saiyed*[3], *A. Vedangi*[4], *S. K. Nath*[5], *U. Radhakrishna*[6];

[1]*Aditya Bangalore Institute of Pharmacy Education and Research Department, Department of Pharmacology, Bangalore, India,* [2]*Andhra Medical College, Department of General medicine, Visakpatnam, India,* [3]*Corewell Health, Royal Oak, MI,* [4]*Department of Clinical Research, KIMS ICON Hospital, A unit of ICON Krishi Institute Medical Sciences, Visakpatnam, India,* [5]*Arthritis and Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma, OK,* [6]*University of Pittsburgh, Pittsburgh, PA*

Background: Non-alcoholic fatty liver disease (NAFLD) is a common liver disorder caused by fat accumulation in liver cells, leading to inflammation and damage. NAFLD is significantly more prevalent in hidradenitis suppurativa (HS) patients (72.9%) than in controls (24.7%). It progresses through stages from steatosis to cirrhosis, increasing the risk of liver failure and cancer. Obesity, insulin resistance, high cholesterol, and genetic factors contribute to its development. Low vitamin D levels and metabolic syndrome further elevate the risk.

Materials and Methods: Genome-wide DNA methylation analysis was conducted on 24 HS cases and 24 healthy controls using the Illumina EPIC Array platform. Statistical and bioinformatics approaches were employed to identify differentially methylated CpG sites associated with NAFLD.

Results: The study identified 25 differently methylated CpGs in 25 genes, including ABCC2, CPN1, CWF19L1, ENPP1, FTO, GCLC, IRS1, LEPR, LPIN1, MAPK10, MTTP, NR1I2, PEMT, SLC27A5, SOD2, TCF7L2, HIC1, APC, DPP4, WHSC1, MAML3, FLCN, FADS2, and BCAT1, all of which were hypomethylated except for HIC1 and APC. Dysregulation of these genes contributes to NAFLD in individuals with HS by promoting insulin resistance, altered lipid metabolism, inflammation, oxidative stress, and hepatic fat accumulation. These factors interact with the chronic inflammation observed in HS, potentially exacerbating liver injury and fibrosis, leading to the progression of NAFLD.

Conclusion: This study identifies significant methylation changes in key genes in HS, suggesting their potential as predictive biomarkers. These findings lay the foundation for personalized treatment approaches. Further research is needed to validate their diagnostic and therapeutic potential.

P22.057.B miRNA transcriptome in treatment resistant depression

Alja Videtic Paska[1], *Lucija Tudor*[2], *Matea Nikolac Prekovic*[2], *Aleš Oblak*[3], *Marko Saje*[3], *Jurij Bon*[3]

[1]*University of Ljubljana, Ljubljana, Slovenia,* [2]*Ruder Boskovic Institute, Zagreb, Croatia,* [3]*University Psychiatric Clinic, Ljubljana, Slovenia.*

Background: Major depressive disorder (MDD) is among the most prevalent mental health conditions, impacting approximately 6% of the global adult population annually. Currently available therapy for depression involves pharmacotherapy combined with psychotherapy, while dealing with poor response/nonresponse and a frequent discontinuation of treatment. The objective of the study was to give better insights into the efficacy and molecular mechanisms behind the effects of alternative methods of treatment in patients with treatment-resistant depression such as transcranial magnetic stimulation (TMS).

Material and Methods: Peripheral plasma from 11 subjects with treatment resistant depression before and after the treatment was used for library preparation for miRNA transcriptome deep sequecing on Illumina NextSeq 550 with 75 bp single-end read. miND analysis pipeline was used for NGS data processing. Statistical analysis of the preprocessed NGS data was conducted using R v4.0, along with the packages pheatmap vNA, pcaMethods v1.82, and genefilter v1.72. Differential expression analysis was performed using the quasi-likelihood negative binomial generalized log-linear model functions from the edgeR v3.32 package.

Results: In the exploratory profiling we identified over 774 mature miRNAs in each sample. Ten most abundant miRNAs in both pre- and post-treatment samples based on their average RPM (reads per 1 million microRNA reads) values were hsa-miR-451a, hsa-miR-486-5p, hsa-miR-16-5p, hsa-miR-92a-3p, hsa-miR-19b-3p, hsa-miR-103a-3p, hsa-miR-25-3p, hsa-miR-15a-5p, hsa-miR-21-5p and hsa-miR-93-5p, each with an RPM exceeding 20,000, and they constitute the core miRNome found in the peripheral blood of subjects with depression.

Conclusion: Identified miRNAs represent starting point for further exploration of changes in transcriptome of MDD.

P23 New Technologies

P23.001.C CaseSharing: A web service for enhancing rare disease case sharing with Phenopackets

Toyofumi Fujiwara[1], *Jae-Moon Shin*[1], *Eisuke Dohi*[2], *Yasunori Yamamoto*[1], *Atsuko Yamaguchi*[3], *Atsuo Kikuchi*[4], *Yousuke Kawai*[5]

[1]*Database Center for Life Science, Chiba, Japan,* [2]*National Center of Neurology and Psychiatry, Tokyo, Japan,* [3]*Tokyo City University, Tokyo, Japan,* [4]*Tohoku University, Miyagi, Japan,* [5]*National Center for Global Health and Medicine, Tokyo, Japan.*

Background: The cost of whole genome sequencing has been decreasing, making it more common in diagnosing rare diseases. Sharing case information and those with rare variants is crucial for discovering novel relationships between diseases and their associated variants or genes. Additionally, sharing case information can aid in the diagnosis of undiagnosed cases by enabling clinicians to find similar cases and compare clinical features. A federated approach connects national genome initiatives, but much case information remains isolated within clinical settings. To bridge this gap, we propose a user-based system for direct case information sharing in a standardized format. To enhance interoperability, we have utilized Phenopackets, a standard for phenotype and genetic data representation.

Methods: We developed CaseSharing (https://pubcasefinder.dbcls.jp/casesharing), a web service for managing rare disease case information. Case data are stored locally in the JSON format for privacy and security. Additionally, CaseSharingDB collects metadata—such as gene and disease names, and phenotypes—without personal data. With Phenopackets support, users can structure case information in the widely accepted format, enabling seamless sharing and integration with other clinical and research databases.

Results: A key feature of CaseSharing is its Phenopackets support, allowing interoperability between clinical and research platforms. Since case data remains local, there are no concerns about crossing national borders. Only metadata, which excludes personal details, the used for matching between users.

Conclusion: By supporting Phenopackets, CaseSharing improves rare disease research through structured and standardized data sharing. This user-based approach enhances privacy while enabling broader collaboration and facilitating novel disease-gene and disease-variant discoveries.

P23.002.D Swift and robust detection of tumor fusions: the potential of Nanopore adaptive sampling

Mathilde Filser, *Kévin Merchadou, Elisa Lemaître, Christine Bourneix, Samantha Antonio, Victor Renault, Eric Pasmant, Olivier Delattre, Julien Masliah-Planchon*

Institut Curie, Paris, France.

Background: The classification for central nervous system tumors and sarcomas emphasizes the importance of combining anatomopathological, immunohistochemical, and molecular biological markers to achieve the most accurate diagnosis. This approach increases the number of techniques required to characterize tumors and extends the time needed to reach a diagnosis. Innovative techniques capable of providing comprehensive tumor characterization within one single tool are crucial.

Material and Methods: We present approximately fifteen examples of the application of Nanopore sequencing with adaptive sampling targeted enrichment in various cases and tumor types, with a focus on brain tumors and sarcomas, encountered at the Curie Institute.

Results: These examples underscore the significance of Nanopore technology as a rapid and robust tool for tumor characterization, enabling the generation of detailed copy number profiles, the classification of tumor entities through global methylation analysis, and the detection of clinically relevant fusions. This easy-to-implement, flexible technique can be applied to a variety of tumor types without the need for multiple complex library preparations. The workflow is optimized to minimize technical time, and the launch of the bioinformatics pipeline is automated, enabling robust tumor classification in less than 10 days.

Conclusion: Bioinformatics optimizations pave the way for promising applications of Nanopore sequencing. The Sturgeon tool enables methylation classification from extremely small quantities of tumor DNA and could be used to study FFPE samples or circulating tumor DNA extracted from CSF. This application is particularly valuable when the tumor is inaccessible to surgery, facilitating the most accurate diagnosis within a reduced timeframe.

P23.003.A Performance and Utility of Illumina Protein Prep Proteomics Assay in Rare Disease Clinical Research

Matthew Brown[1], *Athanasios Kousathanas*[1], *Lily Hoa*[1], *Greg Elgar*[1], *Jamie Ellingford*[1], *Alexander Ho*[1], *Susan Walker*[1], *Ali Crawford*[2], *Simon Freedman*[2], *Michael Mehan*[3], *Parul Prabhat*[4], *Andrew Slatter*[4], *Nithya Subramanian*[4], *Yongwen Zhuang*[2], *Dalia Daujotyte*[2]

[1]*Genomics England, London, United Kingdom,* [2]*Illumina, San Diego, CA, USA,* [3]*Illumina, San Diego, CO, USA,* [4]*Illumina, Cambridge, United Kingdom.*

Background: Better methods are needed to increase the proportion of patients with rare diseases who are referred to genomic medical services and receive a successful diagnosis.

Material and Methods: We evaluated novel proteomic assays combining Standard Biotool's (SBI, formerly SomaLogic) SomaScan technology and Illumina Protein Prep to measure 6,056 proteins in serum samples from 1,530 participants in the 100,000 Genomes Project with rare diseases.

Results: Technical performance was assessed by comparing SBI SomaScan v4.1 with Illumina Protein Prep in 50 samples, yielding a median Spearman r^2 of 0.58. SOMAmer probes exceeded the limit of detection (LoD) in >84% of all samples, >96% in 80% of samples, and >99% in 50% of samples (CLSI method). The median coefficient of variation was 7.7% (Q90 12.3%). Proteomics data effectively predicted gender (AUC = 0.986) and age ($r^2 = 0.934$), consistent with UK Biobank findings. Across 19 rare disease categories, 470 proteins were differentially abundant (FDR p-value <0.05). Categories with the highest differentially abundant proteins included congenital anomalies of the kidneys (n = 178), familial thoracic aortic aneurysm (n = 50), familial hypercholesterolaemia (n = 35), hypertrophic cardiomyopathy (n = 29), and dilated cardiomyopathy (n = 27). In contrast, intrauterine growth retardation, intellectual disability,

epileptic encephalopathy, and Brugada syndrome showed few or no differentially abundant proteins.

Conclusion: This study demonstrates the Illumina Protein Prep assay's high sensitivity and strong correlation with SBI SomaScan data. The abundant differential proteins in specific disease categories highlight the potential of proteomics to advance the diagnosis of certain rare genetic diseases by elucidating disease-associated genes and pathways.

P23.004.B Comparative Clinical Utility of PacBio Long-read RNA Sequencing vs Short-read technologies in Diagnosing Rare Disorders

Carolina Jaramillo Oquendo[1], *Federico Ferraro*[2], *Htoo A. Wai*[1], *Heather Ferrao*[3], *Evita Karelioti*[4], *Liz Tseng*[3], *Harsharan Dhillon*[3], *David J. Bunyan*[5], *Jeff Zhou*[3], *Sarah Ennis*[1], *Tjakko J. van Ham*[2], *Diana Baralle*[1]

[1]*University of Southampton, Southampton, United Kingdom,* [2]*Erasmus MC, Rotterdam, Netherlands,* [3]*Pacific Biosciences, California, CA, USA,* [4]*GenomeScan B.V., Leiden, Netherlands,* [5]*Wessex Genomics Laboratory Service, Salisbury, United Kingdom.*

Background: It is estimated that up to 33% of disease-causing variants disrupt splicing, but many are missed and are under-ascertained as these are not limited to canonical splice sites. As we integrate short-read RNAseq into clinical practice, it is essential to assess potential benefits of long-read sequencing (LRS) in diagnostics. This work assesses the clinical utility of PacBio long-read RNA sequencing for detecting aberrant splicing in rare disorders.

Material and Methods: Participants with Mendelian disorders harbouring variants likely affecting splicing were recruited across the UK and the Netherlands. RNA sequencing from 22 blood samples and four fibroblast cell lines were performed following the Kinnex full-length RNA protocol. HiFi reads from the Revio instrument were processed using Read Segmentation and Iso-Seq workflow.

Results: On average samples had 11–13 million full length non-chimeric reads. Pickup rate for OMIM genes was approximately 60–65% and 63%–70% for PanelApp genes, with fibroblast samples identifying a larger number of transcripts. Novel transcripts not in catalogue accounted for approximately 14% of total transcripts in both tissues, with this proportion increasing following cycloheximide treatment in fibroblasts. This study highlights cases where LRS was key in uncovering additional information and resolving events that were previously missed.

Conclusion: Although LRS may not be suitable for all patients referred for RNA testing, it successfully captured events missed by short-reads such as intron retention, skipping of multiple exons, differential transcript usage and phasing of variants serving a as valuable complement to short-read sequencing in a clinical setting.

P23.005.C Nanowire-assisted, single-molecule sequencing by synthesis

Soren Morgenthaler Echwald, *Liu Guanghui, Philip Sellin, Niklas Mårtensson, Karin E. Blume, Kenneth W. Harlow*

Aligned Bio AB, Lund, Sweden.

Background: Phasing errors limit sequencing-by-synthesis (SBS) to read lengths of 150–200 base pairs (bp) before error rates compromise single-nucleotide resolution. Single-molecule SBS circumvents this limitation by eliminating the need for cluster amplification, which is a primary source of phasing errors. By overcoming this issue, read lengths of up to 2000 bp become feasible with current SBS chemistry.

Materials and Methods: We have adapted Aligned Bio's silicon nanowire-based sensor platform to enhance fluorescence detection in SBS sequencing. By integrating this technology with standard four-color SBS chemistry, we enable high-sensitivity, single-molecule detection across large fields of view with reduced imaging time. A modified flow cell was designed to optimize this process and ensure compatibility with existing sequencing platforms, including the Illumina MiSeq.

Results: Using nanowire-enhanced fluorescence imaging, we successfully demonstrated single-molecule SBS sequencing with standard chemistry. This approach allows for high-throughput, long-read sequencing without compromising accuracy. Furthermore, we validated the adaptability of this system for use in industry-standard DNA sequencers.

Conclusion: Nanowire-enhanced single-molecule sensing enables long-read SBS sequencing using conventional four-color chemistry. This technology offers a cost-effective, plug-and-play solution for upgrading existing SBS-based sequencing instruments into long-read platforms. By improving efficiency and reducing sequencing costs, nanowire-assisted single-molecule SBS has the potential to significantly advance next-generation sequencing applications.

P23.006.D Discovery of a Methylation Selective Cytidine Deaminase (mSCD) with potential for direct human methylome and genome sequencing

Weiwei Yang, *Yan-Jiun Lee, Rebekah M.B. Silva, Amanda DeLiberto, Colleen Yancey, Daria McCallum, Jackson Buss, Rey Moncion, Jennifer Ong, Megumu Mabuchi, Dave Hough, Peter R. Weigele, Laurence M. Ettwiller*

New England Biolabs, Ipswich, MA, USA.

5-Methylcytosine (5mC) is a key epigenetic marker involved in critical biological processes such as gene regulation, chromatin remodeling, and cell differentiation. Original methylation sequencing methods rely on bisulfite conversion, which introduces errors due to incomplete conversion and DNA degradation. These limitations have driven efforts to develop alternative approaches that preserve native DNA sequences while enabling accurate, high-throughput methylation detection. The use of a deaminase with specificity for 5mC over cytosine could revolutionize the field.

In this study, we employed a phenotype-to-genotype association approach directly on the phage fraction of a microbiome to uncover a previously uncharacterized family of deoxycytidine deaminases with methylation-selective cytidine deamination (mSCD) activity. We apply one such mSCD enzyme to human genomic DNA, followed by high-throughput short-read sequencing using Illumina and achieved high sensitivity detection of 5mC. Since mSCD directly converts 5mC, we achieve simultaneous genome and methylome sequencing. Applied to human brain samples, we demonstrate high sensitivity and specificity for methylation detection at CpG and CpA sites, expanding notably our understanding of non-CpG methylation where traditional methods fall short. Furthermore, pre-treatment with an enzyme that protects 5-hydroxymethylcytosine (5hmC), enables precise discrimination between 5mC and 5hmC.

This novel family of enzymes has the potential for broad applications, notably in the accurate genome and methylome sequencing across diverse sample types, including bacterial genomes, human tissues, and low-input materials such as cell-free DNA.

P23.007.A Resolving complex regions with a novel sequencing technology delivering long-range insights

Inga Nagel[1], *Drew Ellershaw*[2], *Maya Bajracharya*[2], *Sean Humphray*[2], *Daniel Kaschta*[1], *Saranya Balachandran*[3], *Andreas Dalski*[3], *Kristian Haendler*[3], *Eva Maria Murga Penas*[3], *Christine Zuehlke*[3], *Inga Vater*[1], *Malte Spielmann*[3]

[1]*Institute of Human Genetics, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany,* [2]*Illumina Centre, Granta Park, Cambridge, United Kingdom,* [3]*Institute of Human Genetics, University Hospital Schleswig-Holstein, Campus Luebeck, Luebeck, Germany.*

Background: Short-read genome sequencing is a powerful tool in genetic diagnostics, but it faces challenges in phasing distant variants, detecting repeat expansions, identifying complex structural variants or resolving some highly complex regions. To overcome these limitations, we applied a novel sequencing technology from Illumina, which combines on-flow-cell library preparation with proximity-based long-range information, to sequence 42 challenging samples, previously diagnosed with different techniques including long-read sequencing.

Materials and Methods: DNA was extracted from 42 EDTA blood samples using various methods, resulting in diverse DNA quality profiles. Sequencing was performed using Illumina's Constellation Mapped Read technology. Samples were chosen based on their relevance to specific genomic challenges, including distant pathogenic variants in a single gene, complex loci (e.g., *CYP21A2*), structural rearrangements, repeat expansions (e.g., *RFC1*, *FGF14*), and transposon insertions.

Results: Preliminary results show that the technology phased variants in 9 of 11 cases where short-read genome sequencing failed. In the remaining two, extensive homology regions were present between the potentially pathogenic variants. Notably, in the *EYS* gene, two variants 389 kb apart were phased, despite a medium fragment size of less than 20,000 bp. Repeat expansions were correctly identified in all three cases. The proportion of fully phased genes varied with DNA quality.

Conclusion: This novel sequencing technology demonstrates significant potential in resolving challenging genomic regions, including phasing distant variants. By leveraging proximity-based long-range information, it bridges the gap between short and long read technologies, while maintaining workflow robustness and minimizing DNA quality requirements. Further analysis will clarify its diagnostic potential.

P23.008.B Demonstrating the potential to increase diagnostic yield and equity of test provision in rapid genome testing for acutely unwell children through Constellation read technology

Emma Baple[1], *Drew Ellershaw*[2], *Lucy Mallin*[3], *Louise Fraser*[2], *Karen Stals*[3], *Jacqui Weir*[2], *Neil Goodman*[3], *Anthony Rogers*[4], *Mitch Bekritsky*[2], *Martina Owens*[3], *Joseph Leslie*[5], *Jayne Houghton*[3], *Nishanka Ubeyratna*[5], *Reham Khalaf Nazzal*[5], *Caroline F. Wright*[5], *Sean Humphray*[2], *Andrew Parrish*[3]

[1]*NHS South West Genomic Laboratory (NHS South West Genomic Laboratory Hub), Royal Devon University Healthcare NHS Foundation Trust, Exeter, United Kingdom,* [2]*Illumina Centre, Granta Park, Cambridge, United Kingdom,* [3]*Exeter Genomics Laboratory (NHS South West Genomic Laboratory Hub), Royal Devon University Healthcare NHS Foundation Trust, Exeter, United Kingdom,* [4]*Illumina, Inc. 5200 Illumina Way, San Diego, CA, USA,* [5]*Department of Clinical and Biomedical Sciences, University of Exeter Medical School, Exeter, United Kingdom.*

Background: The Exeter Laboratory has delivered the NHSE nationally-commissioned rapid sequencing service for acutely unwell children since 2019. Results have been returned to >5000 families (current diagnostic yield 43%). The service uses short-read whole genome sequencing (NovaSeq™ X). Gene-agnostic hypothesis free analysis is undertaken in parent-child trios, assuming a fully penetrant disorder. Proband only and parent-child duo testing is limited to phenotype driven gene panel analysis, leading to inequity in test provision for this group.

Material and Methods: A proof of principle study was undertaken to assess the potential of Illumina's novel

Constellation read technology to increase diagnostic yield. Twenty-eight clinically challenging cases (41 samples) were analysed, representing variable family structures, DNA quality and extraction methods. Constellation enables a simplified on-flow-cell library prep (NovaSeq™ X) and combines accurate standard clustering and SBS sequencing with long-distance cluster proximity information through DRAGEN algorithms.

Results: Proband/duo phasing was demonstrated genome wide, accurately assigning clinically relevant variants to the correct haplotype in 18/18 cases, and de-novo haplotype-of-origin identified in 5/5 cases. Constellation correctly called 2/2 variants in difficult-to-map regions intractable to standard of care WGS and enabled full characterisation of 2/3 complex structural variants (SVs).

Conclusion: Early evaluation of Constellation has shown improved mapping and variant calling in complex genomic regions, extensive genome phasing, and detection of large (>50 bp) SVs. The potential to combine the accuracy of short read WGS with ultra-long phase blocks may enable gene agnostic testing for proband and duos and accurate recurrence risk counselling informed by de-novo haplotype-of-origin data.

P23.009.C Mapping the spatial microbiome-host interactions in*Mycobacterium tuberculosis*(MTB) infected mouse lung with Stereo-seq FFPE

*J. Zhang[1,2], Y. Qiu[1], X. Liu[1], Y. Zhao[1], Y. He[1], D. Li[1], **J. Khoo**[1], Z. Shang[3], S. Liao[1], A. Chen[1];*

[1]STOmics Tech Co., Ltd., Shenzhen, China, [2]BGI Research, Shenzhen, China, [3]MGI Tech GmbH, Volmerstraße 5, 12489, Berlin, Germany

Background: MTB causes tuberculosis by surviving within innate immune cells. However, the study of interactions between the host immune system and MTB is limited. Stereo-seq FFPE makes the groundbreaking advancement by enabling simultaneous capture of host spatial transcripts and mapping of microbiome on one FFPE tissue section. Here, we apply the Stereo-seq FFPE on MTB-infected mouse lung to provide a spatial perspective on microbiome-host interactions.

Material and Methods: C57BL/6 mice were infected with MTB and were housed in an animal BSL-3. Lung tissues were collected after 4 weeks of infection for spatial RNA profiles with Stereo-seq FFPE. MTB^+ lesion were confirmed by acidic dye in adjacent sections. All analysis was performed at resolution of bin 50 (25×25 um).

Results: Compared to uninfected control mouse, 4w infected mouses revealed the distinguished cell composition with higher percentage of alveolar macrophages (AMs), B cells, T cells and monocytes, but with reduced dendritic cells (DCs). We isolated spatial gene expression of AMs and DCs within 100 μm of MTB-infected cells and analyzed the differentially expressed gene profiles when compared to corresponding cell types in control. Enrichment of NOD-like receptor signaling and Toll-like receptor signaling indicated the activities of recognition of MTB. Upregulation of NF-kappa B signaling suggested the activation of macrophages and the release of various cytokines. Above biological response to MTB have been reported.

Conclusion: Stereo-seq possesses the ability to explore dynamic interactions between host and microbiome by providing simultaneous insights from both host and microbial communities at molecular and cellular level.

P23.010.D New approach for molecular diagnosis of imprinting disorders: ONT adaptive sampling for targeted methylation analysis in Beckwith-Wiedemann syndrome

***Francesca Fiumani**[1,2], Alessia Mauri[1,3], Laura Fontana[2,4], Diana Postorivo[1], Stephana Carelli[1], Cristina Montrasio[1], Monica Miozzo[2,4], Cristina Cereda[1]*

[1]Center of Functional Genomics and Rare Diseases, Buzzi Children's Hospital, Milano, Italy, [2]Medical Genetics, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy, [3]Department of Biomedical and Clinical Sciences, DiBIC, Univerisity of Milan, Milano, Italy, [4]Medical Genetics Unit, ASST Santi Paolo e Carlo, Milano, Italy.

The molecular pathogenesis of Beckwith-Wiedemann Syndrome (BWS) involves imprinting dysregulation of two regions, IC1 and IC2, located on 11p15.5. The telomeric IC1 domain, containing lncRNA H19 and IGF2, is completely methylated in paternally derived allele and unmethylated in maternally derived allele. The centromeric IC2, that includes KCNQ1, regulatory lncRNA KCNQ1OT1, and CDKN1C, exhibits the opposite methylation pattern. The loss of methylation at IC2 is observed in 50% of BWS patients. Hence, detection of abnormal methylation pattern at 11p15.5 is essential for diagnosis. Traditionally, bisulfite treatment and methylation-sensitive restriction enzyme treatment or methylation-specific multiplex ligation-dependent probe amplification (MS-MLPA) have been used.Here, we applied Nanopore adaptive sampling approach to perform targeted analysis of the methylation status within imprinted regions, achieving molecular diagnosis of BWS.Libraries were prepared using Ligation Sequencing Kit V14 and loaded onto a flow cell R10.4.1 on PromethION2 Solo running MinKNOW software. 23 genomic regions, subject to medically significant parent-of-origin-specific methylation, were selected as targets in a BED file. Next, base-calling was performed using Dorado from Epi2Me and reads were then aligned to GRCh38 using Minimap2, generating BAM files. Base modifications were detected using Modkit and visualized in IGV, which allowed the analysis of methylation patterns among selected regions. From the comparison with healthy controls' methylation profiles, we detected an hypomethylation of IC2, involving KCNQ1OT1:TSS in one patient.Hence, the described approach allows simultaneous genome-wide assessments of methylation status and represents a

very efficient one-step method applicable to the diagnosis of imprinting disorders other than BWS as well.

P23.011.A Streamlined hybridization capture workflow for targeted long-read sequencing

E. Tseng[1], *D. Lee*[1], *C. Conner*[1], *K. Larkin*[2], *J. Jacques*[2], *A. Dvorak*[2];

[1]*Pacific Biosciences, Menlo Park, CA,* [2]*Integrated DNA Technologies, Inc., Coralville, IA*

Background: Long-read sequencing has revolutionized the study of RNA isoforms, offering unparalleled insights into the complexity of gene expression. However, cost-effective detection of rare transcripts remains a challenge. Hybrid capture can reduce sequencing costs, detect rare isoforms, and simplify analysis. Here, we combine IDT hybridization capture with PacBio full-length RNA sequencing for deep isoform characterization.

Material and Methods: We sequenced six replicates from human brain samples and a universal human reference RNA (UHRR) standard. Three replicates underwent hybridization capture, while the other three were retained as whole transcriptome samples. The hybrid capture was performed using the new xGen Hyb and Wash Kit v3 along with a custom panel targeting 29 genes associated with neurological diseases. All samples were subsequently pooled into a 12-plex Kinnex full-length RNA library sequenced on one Revio and one Vega SMRT Cell, respectively.

Results: We obtained 59.7M and 36.2M segmented reads (S-reads) evenly distributed amongst the replicates, with consistent on-target rates of 85–86% for the targeted capture data, compared to 1.2–1.3% for whole transcriptome. Targeted enrichment detected all 29 targeted genes and ~250 total known isoforms, while whole transcriptome failed to detect 7 of them and only detected ~100 total known isoforms. Transcript abundances were preserved through the hybrid capture, and replicates showed high reproducibility.

Conclusion: PacBio long-read sequencing combined with the new streamlined IDT hybridization capture workflow can provide deep coverage and discovery of known and novel isoforms of target genes in a cost-effective manner.

Background: Variants associated with severe genetic disorders typically require multiple workflows beyond NGS for resolution in diagnostic and screening applications. Complex pathogenic variants involving short tandem repeats, copy number/structural variation (CNV/SV), and differentiating from genetically similar pseudogenes confound NGS. At two independent sites we evaluated the AmplideX Nanopore Carrier Plus Kit to genotype 7 challenging targets (*SMN1/2, FMR1, HBA1/2, HBB, GBA*) using a combination of PCR enrichment, nanopore sequencing, and analysis software in a novel and unified workflow.

Methods: We tested 98 residual clinical samples that had previously been genotyped by multiple methods. Target regions of gDNA were enriched in 4 PCR reactions, barcoded, pooled, and sequenced on MinION™ flow cells (R10.4.1) with a GridION™ (Oxford Nanopore Technologies) at two different sites. AmplideX Reporter software automated analysis and variant classification. Results were compared across sites to those obtained from multiple orthogonal.

Results: Across all samples, of the >95% that passed QC, ≥95% concordant with orthogonal results and across sites for all variant types. *SMN1/2* CNV (0 to > = 3) demonstrated 97% agreement on 33 samples. *FMR1* was 100% concordant for categorical match on 11 samples. SNVs/indel/SV concordance was >98%, observed in *SMN1/2*, *HBA1/2* and *HBB* (N = 40), and *GBA* (N = 14).

Conclusion: Our results highlight the reproducibility and accuracy of nanopore sequencing and dedicated bioinformatics software to consolidate workflows and automate both the analysis and interpretation of challenging variants relevant to hereditary genetic disease. These technological advances have the potential simplify variant detection within molecular labs.

P23.013.C EpiPlex - A Platform for Multi-Target Detection of RNA Modifications

Gudrun Stengel

Alida Biosciences, San Diego, CA, USA.

Background: RNA is subject to chemical modifications that collectively represent the epitranscriptome. The most frequent modifications in human mRNA are m6A, inosine and pseudouridine. By impacting RNA splicing, stability, folding, trafficking and translation, the epitranscriptome plays an important role in the posttranscriptional control of gene expression. Dysregulation of RNA modifications has been associated with multiple diseases, making them potential targets for therapeutic interventions. Despite their important role in gene regulation, reliable commercial methods for the detection of RNA modifications are still lacking.

Material and Methods: Here we present EpiPlex RNA modification encoding, a proximity barcoding assay with sequencing readout that enables multi-target detection in a simple 1-day library prep workflow, providing the location and relative abundance of RNA modifications. The EpiPlex works with RNA-limited sample types and even with FFPE RNA. To make data analysis accessible to all scientists, we have developed EpiScout, a custom-tailored end-to-end analysis pipeline with a machine learning trained peak caller.

Results: The current version of EpiPlex detects m6A and inosine, with extendability to other modifications. In addition to providing a technological overview, we will present biological data showing how the function of the exon junction complex shapes the transcriptome-wide distribution of m6A.

Conclusion: Taken together, the EpiPlex™ platform is a user-friendly tool that enables basic research and novel applications in diagnostics and RNA therapeutics.

P23.014.D Performance evaluation of accelerated Next Generation Sequence (NGS) analysis pipelines

P. S. Samarakoon[1], *G. Fournous*[2], *L. Hansen*[1], *A. Wijesiri*[1], *S. Zhao*[3], *A. Rodriguez*[4], *T. N. Nandi*[4], *M. Ravi*[4], *A. Rowe*[2], *G. Thomassen*[5], *E. Hovig*[3,6], *S. Razick*[1];

[1]*Scientific Computing Services, Division for Research, Dissemination and Education, University of Oslo, Oslo, Norway,* [2]*Norwegian National Unit for Newborn Screening, Division for Pediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway,* [3]*Department of Tumor Biology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway,* [4]*Data Science and Learning, Argonne National Laboratory, University of Chicago, Chicago, IL,* [5]*Division for Research, Dissemination and Education, University of Oslo, Oslo, Norway,* [6]*Centre for Computational Inference in Evolutionary Life Science (CELS), Department of Informatics (USIT), University of Oslo, Oslo, Norway*

Background: Next-generation sequencing (NGS) analysis pipelines are routinely used in current clinical and research settings. However, their CPU-based NGS data processing approach has led to extended turnaround times, which affect the scaling of whole-genome sequence (WGS)-based clinical analysis and population-scale genomics studies. Two leading accelerated genomic analysis platforms - DRAGEN and Parabricks address this challenge by optimizing NGS-data processing on Field-Programmable Gate Arrays (FPGA) and Graphical Processing Units (GPUs). We present a side-by-side comparison of these platforms, addressing a clear gap in recent literature where most studies focus on evaluating single platforms in isolation.

Material and Methods: We implemented accelerated (DRAGEN and Parabricks) and CPU-only pipelines following vendor-specific and best-practices guidelines. They were then evaluated focussing on runtime, speedup, coverage-based scalability and variant calling performances. Here, Parabricks pipeline was assessed across L4, A100 and H100 GPUs.

Results: Both accelerated pipelines demonstrated shorter runtimes compared to CPU-only approaches, with Parabricks-H100 demonstrating the fastest performance, followed by DRAGEN. In mapping, DRAGEN outperformed Parabricks (L4 and A100) and matched H100 speedups. During variant-calling, Parabricks (A100 and H100) demonstrated higher speedups than DRAGEN. In coverage-based-scalability, DRAGEN and Parabricks-H100 mapping showed positive trends, while other configurations failed to scale effectively. Moreover, all variant-callers achieved high scores in both performance and concordance analysis. Furthermore, our optimized Parabricks variant-calling pipeline (developed based on GPU-profiles) demonstrated potential for further speedup enhancements.

Conclusions: We publicly released our NGS-pipelines (MIT License) and offer valuable implementation insights to address time-sensitive and scalability challenges in current clinical genomics and research settings.

P23.015.A Verification of an integrated amplification-based nanopore sequencing assay and automated software solution to genotype challenging, clinically relevant variants

Connor Parker, Juliette A. Baker, Walairat L. Wolf, Jon Kemppainen, Justin Janovsky, Jonathan Turner, Bryan J. Killinger, Cody Edwards, Monica Roberts, Theodore Markulin, Eduardo Priego, Mahesh Yarasi, Mia K. Mihailovic, Brian C. Haynes, Bradley Hall, John N. Milligan

Asuragen, a Bio-Techne brand, AUSTIN, TX, USA.

Background: Accurate resolution of variants correlated with severe genetic disorders is crucial for diagnostic and screening applications. While NGS is used broadly, it is frequently incapable of resolving complex pathogenic variants involving short tandem repeats, copy number/structural variations (CNV/SV), and pseudogenes. Here, we present verification of a method combining AmplideX PCR enrichment, nanopore sequencing, and analysis software to genotype 11 high-prevalence and challenging targets (*CFTR, SMN1/2, FMR1, HBA1/2, HBB, F8* inversions*, GBA, CYP21A2/TNXB*).

Material and Methods: We tested >425 unique samples to verify accuracy, precision, sensitivity, and specificity. Target regions were enriched with 4 PCR reactions, barcoded, pooled, and sequenced in a single assay workflow. Sequencing was performed on MinION™ flow cells (R10.4.1) with a Mk1B or GridION™ instrument (Oxford Nanopore Technologies). We developed software to automate analysis/reporting and compared results to multiple orthogonal methods.

Results: Across all variant types, verification demonstrated ≥95% concordance with orthogonal results. SNVs/indel concordance was >98% across all genes. *SMN1/2* CNV (0 to >=3) showed ≥96% agreement. *FMR1* was ≥95% concordant for repeat sizing and AGG interrupts. *GBA* and *CYP21A2/TNXB* were differentiated from their pseudogenes, enabling resolution of fusions and SVs and correct phasing of SNVs/indels. *F8* intron inversions showed 100% agreement.

Conclusion: Our results demonstrate the utility of combining nanopore sequencing with novel PCR chemistry and algorithms to resolve clinically relevant genotypes insurmountable by routine NGS using affordable, scalable technologies in a single workflow suitable for most laboratories. The software enables custom variant reporting, ClinVar classification, and in-silico novel variant predictions to streamline interpretation.

P23.016.B Constellation mapped read technology, a novel on flow cell library prep for both high quality short reads and proximity information in one prep delivering an expanded genome

*Fiona Kaper[1], Jacqueline Weir[2], Mitch Bekritsky[1], Qing Zhang[2], Vicki Thomson[2], Ines Vitoriano[2], Arun Subramaniyan[1], Michael Ruehle[1], Drew Ellershaw[2], Shunhua Han[1], Daniel Andrews[2], Daniel Andrews[2], Stephen Gaffney[2], Ritu Kundu[2], Gavin Parnaby[2], Pascal Grobecker[2], Maria Gardzielewska[2], Ivana Armogida[2], Maya Bajracharya[2], Ningxin Ouyang[1], **Sean Humphray**[2], Louise Fraser[2]*

[1]Illumina, San Diego, CA, USA, [2]Illumina, Cambridge, United Kingdom.

Background: High quality short read whole genome sequencing (WGS) delivers exceptional quality throughout most of the genome, but still struggles with more challenging regions and variant types. These challenges include variant calling in difficult-to-map regions such as pseudogenes and segmental duplications, calling structural variants, and variant phasing.

Material and Methods: Constellation technology, a simplified on-flow cell library preparation method on the NovaSeq™ X delivers an expanded genome by enhancing short read sequencing data with proximity information. Proximity information is leveraged to recover those genomic regions and variant types that are especially challenging in standard short read WGS delivering an expanded genome.

Results: To determine performance of this novel on flow cell method, the proximity analysis has been demonstrated on a range of cell lines and blood samples with a range of DNA qualities. We present improvements in small variant calling performance across the genome and highlight specific examples in difficult-to-map medically relevant genes. We also describe improvements to phasing haplotypes, enabling >98% of genes to be fully phased in a standard GM24385 (HG002) cell line sample and demonstrate how fully phased genes resolve compound heterozygotes. Finally, we describe novel methods to enable the detection of large variants, repeat expansions and complex rearrangements with the proximity mapping of short reads. We demonstrate improvements across the genome with specific examples and previously characterized balanced structural variants.

Conclusion: Constellation mapped read technology delivers an expanded genome by enhancing short read sequencing data with proximity information.

P23.017.C Redefining nanopore sequencing with Duplex Sequencing by Expansion (SBX-D): A high-accuracy, high-throughput sequencing technology

Jagadeeswaran Chandrasekar[1], *Melud Nabavi[1], Aaron Jacobs[1], Marc Prindle[1], Cynthia Cech[1], Taylor Lehmann[1], Kendall Berg[1], Alan Kimura[1], Alberto Gatto[2], Alex Lehmann[1], Ali Carroll[1], Amal Chaturvedi[2], Anasha Arryman[1], Bill Maney[2], Brent Banasik[1], Brittany Kesic[1], Charlotte Yang[1], Chen Zhao[2], Daniel Zinder[2], Dieter Heindl[3], Douglas Lopez[2], Emily Ormbrek[1], Grant Kingsley[1], Hannes Kuchelmeister[3], Hasham Saqib[2], Jason Komadina[2], Geoffrey Barrall[2], Joanne Leadbetter[1], John Mannion[2], Kevin Smith[1], Lacey McGee[1], Mahdi Golkaram[2], Majid Babazadeh[1], Maryam Shenasa[2], Matthew Lopez[1], McKenna Osentowski[1], Megan Freer[1], Megan LeProwse[1], Megan Rogers-Peckham[1], Michael Kovarik[1], Mitchell Wolfin[1], Robert Busam[1], Ron Cicero[2], Salka Barrett[1], Scott Helgesen[2], Scott Miller[1], Takeshi Harada[2], Thomas Reid[1], Robert McRuer[1], Mark Kokoris[1]*

[1]Roche Sequencing Solutions, Inc, Seattle, WA, USA, [2]Roche Sequencing Solutions, Inc, Santa Clara, CA, USA, [3]Roche Diagnostics GmbH, Penzberg, Germany.

Background: Nucleic acids are small, informatically dense molecules. Single molecule sequencing of nucleic acids is limited by the spatial differentiation of neighboring nucleotides.

Material and Methods: Here we report on Sequencing By Expansion (SBX) which solves these issues by creating an Xpandomer (Xp) surrogate molecule with >50x separation between high signal-to-noise nucleotide reporters. This voltage controllable structure produces discrete electrical signals when measured across a biological pore. Xpandomers are generated in an enzymatic, template-directed manner using a mutated Y-family DNA polymerase (Xp Synthase), expandable nucleotide triphosphates (XNTPs), and a polymerase enhancing moiety (PEM). Xp synthesis is separate from the measurement, with an on-support automated workflow. Specialized components of the Xp structure

are designed to maximize capture rate and translocation efficiency through the pore, which allows parallelized measurement on a 8M sensor array. We demonstrate the capability of this technology with Sequencing By Expansion Duplex (SBX-D) which links both strands of the target DNA in a single sequencing read. This approach uses intramolecular consensus of the complementary reads to identify discordant calls and achieve high accuracy.

Results: With 1 hour of sequencing we show >34x coverage of each individual in a 7-plex genome-in-a-bottle library, with observed duplex concordant base quality >Q39 and F1 scores of >99.6% (SNV) and >99.2% (InDel) using our SBX Variant Caller.

Conclusion: SBX is a transformative sequencing technology that pairs high throughput and high accuracy to improve existing applications and to enable innovation in biological research and molecular diagnostics.

P23.019.A A streamlined and modular workflow tuned to work across multiple sequencing platforms provides improved capture performance for intact gDNA, total RNA as well as low input FFPE

Sangwon Lee[1], *Sergey Shiryaev*[2], *Keith Chen*[2], *Brandyn Clark*[2], *Bilan Hsue*[2], *Nikki Liu*[1], *Adam Janssen*[2], *Jeff Fox*[2], *Nedda Saremi*[1], *Inlora Jingga*[1], *Kyeong-soo Jeong*[1], *Khine Win*[1], *Gilbert Amparo*[1], *Neelima Mehendale*[1], *Jayati Ghosh*[1], *Cindy Hon*[1], *Bahram Arezi*[2]

[1]*Agilent Technologies, Santa Clara, CA, USA,* [2]*Agilent Technologies, La Jolla, CA, USA.*

Background: The application of NGS in cancer may be affected by limited availability and quality of DNA and RNA, as well as the varying tumor fraction in samples. Additionally, practical factors such as workflow turnaround time, ease of use and overall assay performance play crucial roles in determining whether NGS is the preferred method for detecting mutations.

Material and Methods: Various sample types, including intact, FFPE, and cfDNA ranging in input from 1–500 ng were used. Modular workflows were utilized for library preparation/enrichment, and sequencing was performed on three platforms including Illumina Novaseq, Element Aviti, and MGI DNBSEQ G400.

Results: Library prep using 3 bacteria of varying GC content (30%–67%) shows high coverage uniformity and minimal bias (Fold80 of ~1.1). Slight modifications in bait hybridization conditions counteract the sequencer-specific AT/GC bias (e.g., Illumina *vs*. MGI) and improve coverage uniformity. Our novel fast hybridization buffer provides maximum complexity (5–7% duplicates at 6Gb for 8 pooled exome V8 libraries) while maintaining high uniformity (Fold80 of 1.4–1.57) and coverage (93–96% at 30X base coverage) across 3 sequencing platforms, specifically to address the issue of complexity loss with high multiplexing target enrichment.

Conclusion: We present a modular workflow, optimized for a wide range of sample types and inputs, standard or molecular-barcoded adaptors, fast or overnight bait hybridization, and 384UDI optimal for multiple sequencing platforms (Illumina, Element, and MGI). With small changes in the protocol, efficient long read capture (>5 kb) and sequencing can be accomplished. For Research Use Only. Not for Use in Diagnostic Procedures. PR#7001-3721

P23.020.B Synthetic DNA spike-ins to track samples for NGS sequencing

Eleonora Guidi[1,2], *Chiara Balestrieri*[1], *Giovanni Tonon*[1,2], *Dejan Lazarevic*[1,2]

[1]*Center for Omics Scienced (COSR), IRCCS Ospedale San Raffaele, Milan, Italy,* [2]*Università Vita e Salute San Raffaele, Milan, Italy.*

Background: The demand for NGS processing has grown due to advancements in library preparation and sequencing technologies, as well as reduced sample processing costs. NGS platforms have broadened the scope of genomics research, enabling studies on rare genetic diseases, cancer genomics, microbiome analysis, infectious diseases, and population genetics. As the number of samples increases, the risk of mislabeling during extraction and processing also rises.

Materials and Methods: We propose synthetic DNA spike-ins (SDSIs) for sample tracking, using a uniquely identifiable core DNA sequence approximately 160 base pairs (bps) long. Each SDSI core consists of 96 distinct DNA sequences from rare Archaea genomes, with no significant homology to Homo sapiens or viral genomes, preventing false detection or cross-identification.

Results: We tested two SDSIs across various library preparation technologies, including bead-linked Tn5, free Tn5, and enzymatic fragmentation, to evaluate their usability in a lab setting. We also assessed the optimal concentration for bioinformatic detection and the potential for contamination. Additionally, nucleic acid extraction from buccal swabs was tested incorporating SDSI.

Conclusion: The goal is to provide a reliable tool for unequivocally identifying samples before sequencing, combining this method with traditional sequencing indices to ensure high-precision results.

E. Guidi: None. **C. Balestrieri:** None. **G. Tonon:** None. **D. Lazarevic:** None.

P23.021.C Increased library conversion rate enables detection of low-frequency variants

Anna Lyander, *Vasileios Kyriakidis, Venkatesh Chellappa, Rebecka Bergström, Moa Hägglund, Johan Lindberg*

Karolinska Institutet, Solna, Sweden.

Background: Next-generation sequencing (NGS) methods have enabled a broad set of clinical applications. The cost and throughput advantages of NGS may be offset by poor base accuracy and conversion rates. With technologies reporting accuracy of Q40 and beyond, the upstream and downstream steps of the sequencing process provide opportunities for

optimization. Library conversion rate is important for the identification of rare genomic variants.

Material and Methods: We have evaluated four library preparation kits: DNA Library Prep (Watchmaker Genomics), KAPA EvoPrep (Roche), cfDNA Library Preparation (Twist Bioscience), and Illumina Cell-Free DNA Prep (Illumina). We benchmarked these against KAPA HyperPrep (Roche). A total of 30 ng of cfDNA was used for library preparation, followed by target enrichment with Twist Standard Hybridization Reagent Kit using a 118 kbp panel. KAPA EvoPlus (Roche) and DNA Library Prep (Watchmaker Genomics) will also be evaluated on genomic DNA and DNA from FFPE.

Results: KAPA EvoPrep, cfDNA Library Preparation, and DNA Library Prep kits showed a 7–10% and 12–15% increased conversion rate compared to KAPA HyperPrep, with overnight ligation and 15-minute, respectively. The conversion rate of the Cell-Free DNA Prep kit did not surpass the performance of the HyperPrep kit, and exhibited an increased GC dropout in GC rich regions associated with a significant drop in coverage.

Conclusion: A high conversion rate and even coverage over the targeted regions enable the detection of rare variants. When combined with a sequencing instrument with high accuracy, ultra-rare variants may be detected.

P23.022.D VarMeter2, a new and improved programme for predicting the effect of genome missense variants

Tadashi Kaname[1,2], *Yoshiki Yamaguchi*[3], *Noriyoshi Manabe*[3], *Shiho Ohno*[3], *Taiga Aoki*[1], *Junichi Furukawa*[4], *Akira Togayachi*[5], *Jinichi Inokuchi*[6], *Kiyoko Kinoshita*[5], *Shoko Nishihara*[5]

[1]*National Center for Child Health and Development, Tokyo, Japan,* [2]*Advanced Pediatric Medicine, Tohoku University School of Medicine, Sendai, Japan,* [3]*Institute of Molecular Biomembrane and Glycobiology, Tohoku Medical and Pharmaceutical University, Sendai, Japan,* [4]*Institute for Glyco-Core Research (iGCORE), Nagoya University, Nagoya, Japan,* [5]*Glycan and Life Systems Integration Center (GaLSIC), Soka University, Hachioji, Japan,* [6]*Forefront Research Center, Graduate School of Science, Osaka University, Osaka, Japan.*

Background: In comprehensive genome analysis, data on the predicted pathogenicity of missense variants is one of the most useful pieces of information. However, there are cases where currently available prediction programs (such as SIFT, PolyPhen-2, and CADD) are insufficient. Therefore, there is a need for the development of novel programs with high accuracy. Recently, we developed a program called 'VarMeter' based on a new inference method based on protein 3D structural changes [ref1]. In this study, we evaluated the broader applicability of VarMeter and made improvements to improve its prediction accuracy.

Material and Methods: We compared and learned structural features such as nSASA, mutation energy, and predicted local distance difference test (pLDDT) scores for 296 pathogenic variants and 240 benign variants extracted from the ClinVar database, and constructed an improved variant prediction program, VarMeter2. We used VarMeter2 to verify the prediction accuracy for the validation ClinVar dataset and missense variants of N-sulfoglucosamine sulfohydrolase (SGSH), an enzyme related to Sanfillippo syndrome A hydrolase (SGSH) missense variants using VarMeter2. We measured the enzymatic activity of the novel SGSH variants we identified and confirmed them.

Results: The prediction accuracy of the ClinVar dataset and the SGSH missense variant dataset was 82% and 84%, respectively. The enzyme activity of the novel SGSH variants that were predicted to be pathogenic was lacking.

Conclusion: VarMeter2 is one of the useful prediction programs for evaluating missense variants in comprehensive genomic analysis of rare diseases.

P23.023.A Exploring the feasibility of droplet digital PCR to improve turnaround times and improve patient outcomes in the NHS

Hollie Skinner[1], *Mark Watson*[1], *Robyn Clough*[2]

[1]*Sheffield Children's Hospital, Sheffield, United Kingdom,* [2]*St. James's University Hospital, Leeds, United Kingdom.*

Background: The demand for rapid genomic testing is rising with the introduction of personalised therapies and updated risk stratification guidelines. Many solid cancer pathways use NGS, a valuable technique that generates large quantities of data but often results in lengthy analysis times, high costs and a low proportion of actionable results. To achieve optimal patient outcomes, some treatment is required to be administered within days of specimen collection and current pathways often struggle to achieve this. For endometrial cancers, *POLE* mutational status has become integral to risk stratification and for melanoma, *BRAF* V600 mutational status is important for treatment options. Droplet digital PCR (ddPCR) offers the potential to provide rapid testing. This study aims to evaluate ddPCR for rapid *BRAF* testing in melanoma and *POLE* testing in endometrial cancer.

Material and Methods: Clinical samples, previously tested for *BRAF* and *POLE* mutations, were reanalysed using commercially available ddPCR kits. Key performance metrics, including turn-around time (TAT), assay concordance, sensitivity, and specificity, were evaluated. Additionally, workflow efficiency and scalability were analysed to determine the suitability of ddPCR for adoption within an NHS laboratory.

Results: For melanoma samples, *BRAF* testing detected mutations with 100% concordance and showed potential to reduce TAT by ~17 days. A positive test would allow for patients to begin targeted therapy sooner and a negative test can prioritise patients for further testing. Final results, including *POLE* data, will be presented at the conference.

Conclusion: ddPCR is a promising technology to provide rapid testing for patients with solid cancers.

P23.024.B Reduced transcriptional output and allelic biases from the pathogenic *SNCA* p.A53T missense variant, with implications for Parkinson's disease pathology

Hannah Macpherson[1], *Emil Gustavsson*[1], *James Evans*[1,2], *Claire Anderson*[1], *Kylie Montgomery*[1], *Jasmaine Lee*[1], *Henry Houlden*[1], *John Hardy*[1], *Nicholas Wood*[1], *Sonia Gandhi*[1,2], *Mina Ryten*[3,1]

[1]*University College London, London, United Kingdom,* [2]*The Francis Crick Institute, London, United Kingdom,* [3]*University of Cambridge, Cambridge, United Kingdom.*

Disease-associated genetic variants are often assumed to operate through a single primary mechanism across tissues, but the reality

is likely more complex. Determining the impact of genetic variants based solely on gene structure can be challenging. Since missense variants can also affect splicing, this could impact on our understanding of disease mechanism with the potential for the development of flawed therapeutic strategies. *SNCA*, a gene linked to Parkinson's disease (PD), exemplifies this complexity, as it harbours both missense variants and copy number variants (CNVs). While current antisense oligonucleotide therapies aim to downregulate *SNCA* expression, dosage may not be the sole mechanism by which missense variants and CNVs operate to cause PD. Here we used long-read RNA sequencing to explore the impact of *SNCA* c.209G>A (p.A53T) on *SNCA* expression and splicing in iPSC-derived midbrain dopaminergic neurons, the cell type progressively lost in PD. We developed an allele-specific expression (ASE) analysis pipeline which allowed us to define underlying transcript structures and identify how transcription from the mutant allele was affected. Our analysis revealed both significantly fewer transcripts from the mutant allele, and changes in transcript proportions. Cycloheximide treatment further showed that this reduction was partially due to nonsense-mediated decay.These findings raise important questions about variant interpretation and pathogenesis, with potential implications for RNA-based therapeutic strategies targeting *SNCA*. We anticipate that this effect is not unique to *SNCA* and suggest that similar allele-specific transcript proportion changes may occur in response to missense variants at other neurodegenerative disease loci.

P23.025.C PegRNA optimization for F508del correction: identifying key design features for AT-rich regions

Olga Volodina[1], *Anna Demchenko*[1], *Arina Anuchina*[1], *Oxana Ryzhkova*[1], *Valeriia Kovalskaia*[1], *Ekaterina Kondrateva*[1], *Elena Amelina*[2], *Vyacheslav Tabakov*[1], *Alexander Lavrov*[1], *Svetlana Smirnikhina*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Research Institute of Pulmonology, Moscow, Russian Federation.*

Background: We chose prime editing (PE) to develop causal treatment for patients with F508del variant in the *CFTR* gene. To reach greater efficiency of PE it is important to rationally design variable parts of guide RNA (pegRNA), such as primer binding site (PBS), reverse transcription template (RTT), and spacer. However, current guidelines are inadequate for genomic regions with GC content below 40%, a characteristic of the *CFTR* gene locus harboring the F508del variant, so it is important not only to identify the most effective pegRNA but also to understand key patterns in the selection of its variable regions.

Material and Methods: 24 plasmids with different pegRNA sequences were designed and assembled. Two patients' airway basal cells with the homozygous F508del variant in the *CFTR* gene were used in experiments with delivery of genetic constructions by non-viral methods. Editing efficiency was assessed after 72 hours using deep targeted sequencing.

Results: The best efficiency rates were detected in pegRNA19, 20, 21, 22, selected for PE2-NG tool, - 21%, 23.6%, 17.3%, 15.04%, respectively. After the data analysis, we noted that composition and length of the PBS mostly affected the efficiency - lower GC content needs a longer region, while a high GC content in the RTT only plays role when PBS is selected correctly.

Conclusion: We identified the most effective pegRNA sequences, gene correction rates were up to 24%. In addition, we managed to discover recurring motifs that may be relevant for the selection of optimal pegRNAs for the AT-rich genome regions.

P23.026.D Expanded content and improved performance of Illumina Protein Prep

Andrew Slatter[1], *Mike Dorwart*[2], *Mike Mehan*[2], *Simon Freedman*[2], *Izabel Cavassim Alves Ines*[2], *Nithya Subramanian*[1], *Dave Jones*[1], ***Yang Cao***[1], *Carlo Randise-Hinchliff*[2], *Fiona Kaper*[2]

[1]*Illumina, Cambridge, United Kingdom,* [2]*Illumina, San Diego, CA, USA.*

Background: Illumina Protein Prep (IPP) is a comprehensive high-throughput proteomics solution combining Illumina's next-generation sequencing with Standard BioTool's SOMAmer™ technology. This powerful approach utilizes SOMAmers (Slow Off-rate Modified Aptamers) to bind to proteins with high affinity. Here we present a newly updated version of IPP with an expanded menu of 9464 unique human proteins based on 11K SOMAmer panel and improved overall performance.

Material and Methods: To determine overall performance of the assay, 205 donor matched plasma and serum were split into various replicates across 24 automated runs and sequenced using NovaSeq™ systems. Comparisons per-protein were determined using 31 plasma samples for the new method compared to either the previous smaller IPP panel or the microarray readout. A Limit of detection (LoD) ratio (Q25 population/inferred LoD) was calculated using a healthy population of 200 samples.

Results: Total median precision of the assay was measured in replicates of 5 donors to be ~4.4% CV in Serum and ~5.5% CV in plasma with Q90 of ~7.1% and ~8.4% respectively. Median spearman correlation per SOMAmer were 0.92, 0.87, and 0.82 for array vs array, NGS vs NGS, and NGS vs array respectively. The percentage of protein targets that were above the LoD was ~92% in plasma and ~95% in serum.

Conclusion: This study shows that the new version of Illumina Protein Prep has good performance with high precision, high analytical sensitivity, and close agreement to the previously used microarray readout.

P23.027.A Tracking allogeneic NK cell (SAR445419) treatment by chimerism assay in patients with relapsed or refractory acute myeloid leukemia patients

Francesco Lo Presti[1], *Jacqueline Courta*[2], *Anna Regnault*[3], *Florence Gillot*[3], *Claire Mariet*[1], *Marie-Hélène Pascual*[4], *Agata Drewniak*[5]

[1]*Sanofi Research - TMU BCB T&HG, Vitry-Sur-Seine, France,* [2]*Sanofi Research - TMU BCB Project, Vitry-Sur-Seine, France,* [3]*Sanofi Research - TMU PO BSM, Vitry-Sur-Seine, France,* [4]*Sanofi Research - TMU BCB, Vitry-Sur-Seine, France,* [5]*Sanofi Research - TMU BCB Project, Amsterdam, Netherlands.*

Background: SAR445419 (SAR'419) cells are an allogeneic, off-the-shelf, donor-derived, non-genetically modified NK cell-based investigational immunotherapy evaluated in the TED17749 Phase 1, dose escalation study in six participants with relapsed or refractory AML. Monitoring SAR'419 cell persistence was required to better correlate their presence to clinical outcomes but was challenging in clinical samples.

Material and Methods: Discriminatory power of Devyser chimerism assay, based on the allele frequency of 24 indels genetic markers, was validated with 3-genome combinations (from 10 Humans). Protocol adaptations were done to monitor SAR'419 persistence in participant's blood and bone marrow samples.

Results: SAR'419 and patient baseline profiles determined informative markers discriminating patient's cells from SAR'419 batches. The method detects as low as 0.05% of allogeneic cells in 3-genome mixed samples. Confident marker profiles with as low as 0.06 ng of DNA/µL permitted the profiling of lymphodepleted patients. An 8-week SAR'419 tracking from different donors revealed a maximum presence of up to 30% of the total PBMC two weeks after administration. Their detection in bone marrow aspirates confirmed their ability to migrate to diseased areas. Atypical marker frequencies allowed the detection of potential AML presence as well as previous stem cell transplant. Faced to missing baseline patient sample, we were able to establish a "virtual screening profile" by deconvoluting each 24-marker curves.

Conclusion: This NGS assay is a suitable method to monitor confidently the persistence of SAR'419 cells in patients in Phase1 studies and can potentially be used to track any allogeneic modified cells infused into patients.

P23.028.B Reliable and comprehensive analysis of SNVs, indels and repeat expansions in ataxia-associated genes using long-read sequencing

Dorieke J. Dijkstra, *Eddy N. de Boer, Arjen J. Scheper, Dennis Hendriksen, Bart Charbon, Lennart F. Johansson, Laura Bosscher, Petra M. Grootscholten, Annelies M. ten Berge, Henny H. Lemmink, Jan D.H. Jongbloed, Birgit Sikkema-Raddatz, Cleo C. van Diemen*

University of Groningen, University Medical Center Groningen, Department of Genetics, Groningen, Netherlands.

Background: Spinocerebellar Ataxias (SCAs) are a genetically heterogenous class of progressive movement disorders, caused by SNVs, indels, and most importantly repeat expansions, in dozens of genes. Repeat expansions cannot be identified reliably through NGS, and the use of gene-specific PCR assays results in incomplete and fixed diagnostics. New causative repeat expansions are identified regularly, marking the need for a comprehensive and flexible gene panel. Here, we introduce a one-test-fits-all approach for SCA diagnostics using long-read sequencing (LRS).

Material and Methods: DNA of 12 patients was sequenced using Nanopore's 'adaptive sampling' method (Oxford Nanopore Technologies) for a neurogenetics gene panel including 27 genes known to cause SCA by repeat expansion. Data was compared to diagnostic repeat expansion data of several genes and WES data. Data was processed and analyzed using the open-source MOLGENIS Variant Interpretation Pipeline (VIP) 7.9.0.

Results: Comparison between LRS and PCR data showed 20 out of 23 repeat lengths on 7 different ataxia-related genes in 12 patients were concordant on both alleles (max 2 repeat units difference). The non-concordant repeats differed by max 4 repeat units. Additionally, the repeat motif could be determined reliably. Comparison between LRS and NGS data in 6 samples showed all 28 NGS-called indels were also found by LRS, just as 198 out of 202 NGS-based SNVs. Subsequently, 10 patients were sequenced prospectively for analysis of ataxia-related repeat expansions.

Conclusion: LRS enables adaptive, reliable and comprehensive analysis of SNVs, indels and repeat expansions in ataxia-associated genes and has the potential to increase diagnostic yield.

P23.030.D Rejuvenation and antimicrobial potential of Platelet-rich plasma (PRP) and its impact on the pathogenesis of selected diseases

Tea Becirevic[1], *Izet Eminovic*[1], *Mirza Ibrisimovic*[2], *Nadira Ibrisimovic-Mehmedinovic*[3]

[1]*Faculty of Natural Sciences and Mathematics, University of Sarajevo, Sarajevo, Bosnia and Herzegovina,* [2]*PZU Vaša Poliklinika Dr. Ibrišimović, Brčko, Bosnia and Herzegovina,* [3]*Department of Chemistry, Faculty of Science, University of Tuzla, Tuzla, Bosnia and Herzegovina.*

Background: Platelet-rich plasma (PRP) is a plasma fraction with a platelet concentration three to five times higher than baseline levels, known for activating cellular pathways that promote cell proliferation and regeneration. This study investigated PRP's dual potential: its rejuvenating effect on knee osteoarthritis and its antimicrobial properties against clinical microbial isolates.

Material and Methods: PRP's antimicrobial activity was assessed using microbial strains isolated from 100 patients with urinary and soft tissue infections. Biofilm-forming ability was identified using Tube test method and Real-Time PCR targeting the *ica* gene cluster. Changes in the metabolic activity following PRP treatment were analyzed through leucine aminopeptidase and aspartic proteinase enzyme assays and quantification of total protein content by Bradford assay. For osteoarthritis, isokinetic measurements were conducted to evaluate joint mobility, strength, and muscle endurance in patients after PRP therapy.

Results: PRP demonstrated significantly stronger antimicrobial effects compared to controls. PRP reduced aspartic proteinase activity and increased total protein content in all tested strains

except *E. faecalis*, which showed the lowest antimicrobial response after PRP treatment. Isokinetic evaluations revealed that PRP significantly enhanced joint strength, reduced pain, and improved muscle endurance in osteoarthritis patients.

Conclusion: Obtained results confirm the antimicrobial effect of PRP on clinical strains identified as strong biofilm formers, as well as its rejuvenating effect on patients with knee osteoarthritis. This study is the first to examine the impact of PRP on the metabolic activity of selected microbial isolates, demonstrating a reduction in aspartic proteinase activity and an increase in total protein content.

P23.031.A Epigenomic Breakthroughs: Redefining Diagnostic Paradigms in Genomic Medicine

*G. Carvalho[1], B. Wolff[1], L. Liro[1], M. Costa[1], R. Silva[1], E. Moura[1], Y. Oliveira[1], B. Sadikovic[2], **L. Kulikowski**[1];*

[1]Universidade de Sao PauloDepartament of PathologyCytogenomics Laboratory, Sao Paulo, Brazil, [2]Molecular Genetics Laboratory, Division of Molecular Diagnostics, London Health Sciences Centre, London, ON, Canada, London, ON, Canada

Although cytogenomic investigation methodologies have achieved significant advancements, leading to increased sensitivity in the detection of genomic variations, the understanding of the clinical relevance of these variants has not progressed proportionally. Consequently, one of the major challenges in contemporary genomic medicine is the high number of variants of uncertain clinicalsignificance, as well as a substantial proportion of patients who remain undiagnosed even after investigation with the primary methodologies. DNA methylation assessment, through approaches such as "Epi-signatures," has demonstrated significant potential in addressing this challenge, offering a newdimension of investigation. In this study, we aimed to evaluate the diagnostic applicability of methylation profiling in 29 patients with genomic variants classified as VUS and/or likely pathogenic, using the Infinium MethylationEPIC assay. From the methylation data, we applied various analytical approaches, including ontological analyses and Epi-signatures, to confirm or complement moleculardiagnoses. Our study revealed clinically relevant epigenomic alterations and enabled the diagnosis or diagnostic complementation in 12 cases, including eight cases with potentially affected biological pathways correlated with the respectiveclinical phenotypes, and six cases with conclusive or moderate epi-signatures corresponding to clinical conditions investigated using the EpiSign tool. This study thus underscores the relevance of epigenomic investigation in cases lacking a definitive diagnosis through traditional genomic methodologies, demonstrating thatthis approach can operate at both extremes: aiding in the exclusion or confirmation of diagnostic suspicions associated with a genomic variant.

P23.032.B Genome-wide detection of gross copy number alterations associated with genetic conditions using digitalMLPA

***Sander Palit**, Bas Lamers, Anne Benard-Slagter, Jan Smout, Martijn Clausen, Karel de Groot, Suvi Savola, Lisette Stolk*

MRC Holland, AMSTERDAM, Netherlands.

Background: Fast and robust characterisation of gross copy number (CN) changes is essential for cytogenetic applications. Next generation sequencing (NGS)-based approaches and optical genome mapping (OGM), as well as karyotyping and FISH, remain relatively costly, labour-intensive, and require complex bioinformatics analysis, resulting in longer turnaround times. qPCR-based methods typically only target a limited number of regions. Thus, there is an urgent need for cost-effective genome-wide CN characterisation of cytogenetic samples in a high-throughput fashion. Here, we showcase genome-wide CN characterisation at a ~2-4 Mb resolution in a panel of cell lines harbouring clinically significant CN alterations (CNAs), using SALSA® digitalMLPA™ Probemix D024 (test version) consisting of ~1200 probes.

Material and Methods: D024 was used to analyse the Coriell CNV01 panel, comprising DNA samples from 43 cell lines harbouring a diverse range of chromosomal alterations. digitalMLPA-derived PCR amplicons were sequenced on a NextSeq 1000 Sequencing System (Illumina). FASTQ files were analysed using Coffalyser digitalMLPA™ (MRC Holland).

Results: The digitalMLPA assay, D024, showed a high concordance (>98 % for 51.084 datapoints) with CN data reported by the Coriell Institute for the CNV01 panel. Detected aberrations included gains and losses of whole chromosomes, as well as subchromosomal CNAs. Samples harbouring multiple CNAs were successfully characterised.

Conclusion: Using the SALSA® digitalMLPA™ Probemix D024, a wide range of gross CN alterations can be reliably determined genome-wide in a cost-effective manner, with a short (48–72h) turnaround time in one single reaction.

P23.033.C digitalMLPA: a new frontier in the simultaneous determination of copy number and methylation status across multiple imprinting-associated differentially methylated regions

***Santiago Castanedo Fontanillas**, Marrit Rinsma, Lisette Stolk, Irene Zwarts*

MRC Holland, Amsterdam, Netherlands.

Background: Multi-locus imprinting disturbances (MLIDs) involve aberrant methylation patterns at multiple loci, which complicates the diagnosis and management for a subset of imprinting disorder patients. To address the current difficulties in studying MLIDs, we developed a new SALSA® digitalMLPA™ probemix for methylation pattern detection that combines the reliability of methylation-specific SALSA® MLPA® (MS-MLPA) with the high coverage of NGS. This could provide a robust solution for simultaneous detection of methylation aberrations across multiple loci.

Material and Methods: The methylation-specific digitalMLPA probemix (test version) was developed for simultaneous detection of the copy number (CN) in 37 targets across most autosomes, and the methylation status in 27 imprinting-associated differentially methylated regions (iDMRs). 126 control samples and over 30 positive samples (blood and cell lines) were tested. A subset of positive samples was also tested with MS-MLPA. Additionally,

some iDMRs were studied on dried blood spot (DBS) card-derived DNA samples from healthy newborns.

Results: In control samples, the expected CNs were observed and most imprinting regions had median methylation percentages between 45–64%, except for two iDMRs (86% and 94%). A positive sample with known 11p15.5 methylation aberrations showed concordant results when tested with MS-MLPA and MS-digitalMLPA. Moreover, MS-digitalMLPA detected an additional aberrant iDMR. DBS sample data was robust, demonstrating the versatility of MS-digitalMLPA across different blood-derived sample types.

Conclusion: Our results demonstrate that MS-digitalMLPA, like MS-MLPA, can accurately determine both CN and methylation status. This study underscores the potential of MS-digitalMLPA for detecting methylation aberrations across multiple loci in a single assay.

P23.034.D Evaluating variants of uncertain significance in zebrafish: a proof of concept with a COL1A2 variant

Michiel Vanhooydonck[1], *Sophie Debaenst*[1], *Eva Vanbelleghem*[1], *Hanna De Saffel*[1], *Delfien Syx*[1], *Patrick Sips*[1], *Andy Willaert*[1], *Paul J. Coucke*[1], *Bert Callewaert*[2]

[1]*Ghent University, Ghent, Belgium,* [2]*Ghent University HospitalCenter for Medical Gentics - 0K5, Ghent, Belgium.*

Background: Genomic sequencing has led to the identification of numerous variants of uncertain significance (VUS), posing challenges for clinical decision-making. While segregation studies and in silico prediction tools are helpful in VUS classification, they are not always feasible, emphasizing the need for functional testing to accurately interpret these variants.

Material and Methods: In this study, we investigated the pathogenicity of the *COL1A2* c.2123G>A VUS, identified in a 59-year-old female with recurrent fractures, using zebrafish as a model organism. Using prime editing, we previously introduced the VUS into the zebrafish genome, alongside a benign control and a known pathogenic variant.

Results: Comprehensive skeletal phenotyping revealed no significant abnormalities in the VUS zebrafish model while the positive control showed an increased number of fusions, compressions, fractures, more notochord and intervertebral ligament mineralization and more scoliosis of the vertebral column, suggesting the variant is likely benign.

Conclusion: Our findings highlight the effectiveness of zebrafish models for functional validation of VUS in *COL1A2* and underscore their potential to elucidate pathogenic mechanisms. This approach could be adapted to study VUS in other genes, offering a valuable tool for genomic screening.

P23.035.A Clinical Validation of a Haplotyped Whole Genome Sequencing Assay Using PacBio HiFi Sequencing

Nicholas Zoulias[1], *Miriam Yammine*[2], *David Corney*[3], *Haythem Latif*[3]

[1]*Genewiz from Azenta Life Sciences, Oxford, United Kingdom,* [2]*Genewiz from Azenta Life Sciences, Leipzig, Germany,* [3]*Genewiz from Azenta Life Sciences, South Plainfield, NJ, USA.*

Background: Next-generation sequencing (NGS) has enabled unprecedented insights into the molecular basis of health and disease. Short-read NGS have become integral to the diagnosis of genetic diseases, and in supporting clinical trials. Unfortunately, while current short-reads are cost-effective and scalable than ever before, they are limited in resolving complex genomic regions, detecting structural variations, and covering repetitive sequences. They do not accurately differentiate between critical *trans*/*cis* compound heterozygosity. While such challenges can be mitigated by long-read sequencing approaches, widespread clinical adoption is limited due challenges in sample handling, scalability, and cost.

Material and Methods: We report CLIA/CAP validation of a clinical long-read WGS assay for comprehensive genome-wide detection and phasing of SNVs, INDELs, CNVs, and CpG. High molecular weight DNA was extracted from blood, fragmented (~15–20 Kb), followed by SMRTbell library preparation, sequencing on PacBio Revio SMRTcell, to ~20–30x average coverage.

Results: Variant calling accuracy was assessed by comparing variant calls in healthy donors to those obtained by Illumina PCR-free WGS assay, as well as analysis of Genome In A Bottle (GIAB) well-characterized reference samples. The variant calling concordance F1 score was 0.99 and 0.98 for SNVs and INDELs, respectively. Phasing accuracy was performed by trio analysis on specific genes of interest.

Conclusion: This validated long-read WGS assay overcomes key limitations of short-reads, enabling comprehensive genome-wide detection and phasing of all variant classes. By leveraging automation and high-throughput workflows, this assay provides a powerful tool for precision genomic medicine, with the potential to improve diagnostic accuracy, treatment selection, and patient outcomes.

P23.036.B An NGS salvage pathway for solid tumour testing

Andrea Western[1], *Mark Watson*[1], *Isabel Austin-Clarke*[2], *Daniel Egan*[3], *Helen Lindsay*[3], *Paul Roberts*[2]

[1]*Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom,* [2]*Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom,* [3]*Leeds Teaching Hospital NHS Trust, Leeds, United Kingdom.*

Background: Genetic testing is a vital part of the diagnostic pathway for a growing number of cancers. High sensitivity and capacity to detect multiple variants simultaneously makes Next Generation Sequencing (NGS) panels the ideal testing solution. In Yorkshire and North-East Genomic Laboratory Hub (YNEGLH) Illumina's TruSight Oncology 500 High-Throughput (TSO500) NGS panel is used for solid tumour testing. However, for some panels over 25% of samples fail testing due to poor sample quality or limited material and the turnaround time of 3 weeks is too long if results are required urgently. Thermo Fisher's Oncomine™ Precision Assay (OPA) is a rapid, sensitive NGS pathway that requires less starting material.

Material and Methods:

- DNA and RNA TSO500 failed samples were tested on the OPA panel to assess sequencing quality and coverage.
- OPA detection of known DNA and RNA variants was assessed using control samples.
- Local turnaround times (TAT) for the TSO500 and OPA pathways were audited over a 3 month period.

Results:

- 76% low quality DNA or RNA samples passed OPA quality metrics.
- 100% DNA variants targeted by the OPA panel were detected.
- 100% RNA fusions were detected by the OPA targeted or imbalance fusion assay.
- OPA local TAT is at least 6 days shorter than the TSO500 TAT.

Conclusion: The OPA is a rapid assay which performs well with low quality samples, making it a viable salvage pathway for urgent or low-quality samples.

P23.037.C Analysis of genetic edition efficiency rate on isogenic hiPSC subjected to Prime Editing CRISPR method

Mariana Moyses-Oliveira[1], *Lais Cunha*[2], *Bruna Marquezini*[2], *Anna Kloster*[2], *Amanda Mosini*[2], *Pedro Guerreiro*[2], *Monica L. Andersen*[2], *Sergio Tufik*[2]

[1]*Associação Fundo de Incentivo à Pesquisa, São Paulo, Brazil,* [2]*Federal University of Sao Paulo, São Paulo, Brazil.*

Background: Human induced pluripotent stem cells (hiPSC) have great potential as experimental models on a variety range of fields, especially on those regarding gene edition. The aim of this study was to analyze the genetic edition efficiency rate of different CRISPR/Cas9 methodologies targeting genes associated with autism spectrum disorder (ASD) in hiPSC.

Material and Methods: hiPSC were cultivated in Essential 8 media, transfected using Lipofectamine Stem and submitted to single cell isolation using Hana cell dispenser. Prime Editing technique was employed to introduce 4 different ASD-associated missense mutations in 4 different genes (*POGZ, DEAF1, GRIN2A, SYNGAP1*). The dual-gRNA methodology was utilized to generate 30–60 kb gene deletions on the same genes. CRISPR oligos (pegRNA, gRNA) were designed using UCSC Genome Browser tracks and Prime Design tool. Genetic editing efficiency rate was calculated by dividing the number of edited colonies by the total number of colonies post-transfection.

Results: The Prime Editing efficiency rate was 0–22%, but most of the variants observed were indels in heterozygosis, and not a missense variant as planned. The amount of CRISPR oligos transfected impacted on the zygosity of the edited lines retrieved. The desired missense variants in heterozygosity were obtained with 0–2% editing rate. The dual-gRNA efficiency rate was 1–4%, all the editions obtained were aligned with the editing goals and in heterozygous state.

Conclusion: Prime Editing on hiPSC provides higher editing rates, although further optimization is required to retain patient-specific missense variants. Finally, the dual-gRNA editing method demonstrates presents with low editing efficiency but high specificity.

P23.038.D Beta evaluation of a panel of *HBA1, HBA2* and *HBB*genes using ONT/AmplideX chemistry

Tony Yammine[1], *Paul A. Wadsworth*[2], *Nathalie Bonello-Palot*[3], *Chandler Ho*[2], *Serge Pissard*[4], *Ilona Volkova*[2], *Laura Feyereisen*[5], *Hélène Moret*[1], *Emilie Landais*[1], *Carlos J. Suarez*[2], *Anne-Sophie S. Lebre*[6]

[1]*CHU Reims, REIMS, France,* [2]*Department of Pathology, Stanford University School of Medicine, Stanford, CA, USA,* [3]*APHM, Hôpital de la Timone, M2GM Laboratoire de Génétique Moléculaire, Marseille, France,* [4]*GHU Henri Mondor, Département de Génétique, Université Paris-Est Créteil (UPEC), Créteil, France,* [5]*Universite de Reims Champagne-Ardenne, Reims, France,* [6]*CHU Reims and Université Reims Champagne Ardenne, REIMS, France.*

Background: For challenging genes involved in rare inherited diseases, non-NGS methods are still required, such as PCR/CE, qPCR, Gap PCR, MLPA or Sanger sequencing. To simplify user workflow, three genes involved in thalassemia have been pooled in a new Asuragen kit including *HBA1/2* and *HBB* genes (in Mix C). We evaluated the workflow on 57 known positive and 44 negative clinical samples collected from expert clinical laboratories and reviewed genotype agreement between the assay and orthogonal methods.

Material and Methods: We evaluated the Asuragen AmplideX Nanopore Carrier Plus Kit, combining the PCR enrichment technology with Nanopore DNA sequencing. Target genes were amplified by PCR (around 1 kb amplicons) from clinical samples. Libraries were prepared, pooled, and loaded on R10.4.1 Minion or Flongle flowcells. Automated analysis and reporting was performed using released Asuragen AmplideX One Reporter software.

Results: Mix C (*HBA1/A2/HBB* genes) Minion and Flongle tests will be presented. Multiple variant types were assessed, including SNV, Indel, or SV. Variant allele phasing was determined. Variant zygosity, sequencing accuracy, and average error rate of ONT sequencing were evaluated in comparison with current clinical diagnostic standards. Overall, >95% of samples with sufficient read depth passed quality control and of those, >95% were concordant with orthogonal methods.

Conclusion: The analytical performance characteristics of the Asuragen/ONT assay, along with its ease of use and turn-around time make it a promising method for clinical use. The clinical research implementation of this assay might simplify testing conducted for both diagnostic and carrier screening purposes.

P23.039.A Whole-Genome Sequencing is a viable replacement for chromosomal microarray and Fragile X PCR testing

Sean E. Hofherr[1], *Yueyao Gao*[1], *Mark Fleharty*[1], *Niall Lennon*[1], *Victoria Popic*[1], *Katie Larkin*[1], *James H. Godsey*[2], *Peter H. Bui*[2], *Sarah T. South*[2]

[1]*Broad Institute of MIT & Harvard and Broad Clinical Labs, Burlington, MA, USA,* [2]*Quest Diagnostics Incorporated, San Juan Capistrano, CA, USA.*

Background: Chromosomal microarray analysis (CMA) is the first-line test for broad pediatric indications (global developmental delay, multiple congenital abnormalities). Fragile X testing is also performed for many of these same individuals. Whole genome sequencing (WGS) can change the paradigm by coupling CMA detection capabilities with robust small variant detection, while adding the ability to rule out expanded Fragile X alleles.

Material and Methods: A set of 102 previously tested samples initially analyzed by clinical CMA at Quest Diagnostics using Affymetrix CytoScanHD were subsequently sequenced at Broad Clinical Laboratory (BCL) using clinical 30x PCR Free WGS sequenced on Illumina NovaSeqX plus. Secondary analysis was performed using Dragen v4.3.6.

Results: 100% of the reportable events were detected by WGS. When applying the clinical CMA size filtering to the list of calls from WGS, WGS had an average of 21.89 events compared to 5.25 events from CMA. Several post processing approaches reduced the number of events for review with WGS to within +/− 10% of the number of events observed in CMA while still retaining the reportable event. For Fragile X, WGS detected trinucleotide repeats ≤45 with 100% sensitivity, and known expanded alleles were flagged as not normal in the 19 samples with known Fragile X allele status (Normal, Intermediate, Premutation, and Full).

Conclusion: In this work we demonstrated the clinical equivalency of WGS compared to traditional clinical CMA. We also highlight the additional advantages of WGS beyond CMA equivalency, including the ability to rule out Fragile X syndrome.

P23.041.C Evaluation of Long-Read Whole Genome Sequencing Technologies and Tools for SV Detection

Giancarlo Tomio[1], *Janine Meienberg*[1], *Timo Siegenthaler*[1], *Claudio Cannizzaro*[1], *Pamela Nicholson*[2], *Stefan Krebs*[3], *Gabor Matyas*[1,4]

[1]*Center for Cardiovascular Genetics and Gene Diagnostics, Swiss Foundation for People with Rare Diseases, Schlieren-Zurich, Switzerland,* [2]*Next Generation Sequencing Platform, University of Bern, Bern, Switzerland,* [3]*Laboratory of Functional Genome Analysis, Gene Center, University of Munich (LMU), München, Germany,* [4]*Zurich Center for Integrative Human Physiology, University of Zurich, Zurich, Switzerland.*

Background/Objectives: Compared to short-read sequencing (SRS), long-read sequencing (LRS) technologies provide advantages for detection of structural variants (SVs) in whole genome sequencing (WGS). Many SV callers exist but their performance differs significantly. We have optimised the preparation steps for PacBio and ONT libraries to minimise short fragment bias and tested several tools for their ability to detect a known set of challenging SVs due to multiple events or breakpoints in non-unique sequence regions.

Methods: Four DNA samples with challenging SVs previously detected by SRS (PCR-free WGS, PE150, 60x) were sequenced on a PacBio Revio as well as on an ONT PromethION platforms (30x) after library preparation optimisation. Sequencing data was analysed with the respective standard pipelines. CPU and GPU accelerated pipeline versions by Sentieon Genomics and Nvidia Parabricks were tested as alternatives. Several SV callers where applied and results manually reviewed using Integrative Genomics Viewer.

Results: Library preparation protocols including DNA shearing and size selection reduced the short fragment bias. Despite the observed differences in performance of the tested analysis pipelines and SV callers on challenging variants, LRS enabled the detection of breakpoints missed by SRS, although manual reviewing was required for full characterisation.

Conclusion: LRS can be the solution for breakpoint identification in repetitive regions and for characterisation of complex SVs not exceeding their read length. Improved SV callers and optimised library preparation protocols are vital to take full advantage of LRS in genetic testing. As current LRS technologies improve, they enable an improved future for clinical sequencing.

P23.042.D The Evaluation of Oxford Nanopore Ultra-Long sequencing approach

Zuzana Gerber, *Marc Delépine, Aurélie Leduc, Cédric Fund, Asmae Bachr, Claire Jubin, Vincent Meyer, Jean-François Deleuze*

CEA / National Center for Research in Human Genomics, Evry, France.

Background: Ultra-Long reads approach can improve de novo assembly and phasing, provide better insight into DNA sequence of repetitive regions, copy number variants and otherwise complex regions of the genome, and allows the identification of large chromosomal rearrangements and structural variants (SV). The longest known reads with this approach are over 4 Mb long.

Material and Methods: We extracted 6M cells per sample using Monarch Kit (NEB) from Ashkenazim trio reference cell lines (Coriell Institute), including HG002 individual characterised by the GIAB consortium. We prepared Ultra-Long libraries and sequenced them using PromethION R10.4.1 flowcells (ONT) with Super-accurate basecalling. We evaluated general quality metrics, SV calling performance compared to GIAB T2T reference, and assembly metrics using Hifiasm with optional HERRO correction.

Results: On average, we obtained 52 Gb of filter-passing throughput per flowcell, with an average N50 value of 56 kb, and the longest observed reads reaching >700 kb in length. Preliminary results indicate a slight improvement in F1 score for SV calling compared to standard ONT libraries. Assembly analysis is still ongoing but the error correction seems to improve both N50 metrics and the number of contigs.

Conclusion: The read length with N50 >50 kb has no competition on the sequencing market. Sufficiently mature bioinformatics tools are available for de novo assembly from Ultra-Long reads. On the downside, Ultra-Long approach requires large DNA input quantity that is incompatible with many sample types. The per-flowcell yield is lower than for standard ONT libraries but the chemistry continues to improve in both throughput and accuracy.

P23.044.B *RFC1* analysis by genome and targeted long-read sequencing (PacBio)

Katharina Lackner[1], *Rebekka Entstrasser*[1], ***Katharina Herzog, PhD***[1], *Klaus Oberhuber*[1], *Roman Praschberger*[1], *Beatrix Mühlegger*[1], *Martina Witsch-Baumgartner*[2], *Johannes Zschocke*[1]

[1]*Medical University of Innsbruck, Institute of Human Genetics, Innsbruck, Austria,* [2]*Medical University of Innsbruck - Institute of Human Genetics, Innsbruck, Austria.*

Background: Homozygous or compound-heterozygous pentanucleotide repeat expansions or truncating mutations in the *RFC1*

gene lead to cerebellar ataxia, neuropathy, and vestibular areflexia syndrome (CANVAS). Pathogenic expansions range from 250 to more than 2000 repeats, making the identification of the exact repeat expansion challenging. The newly released PureTarget Repeat Panel (PacBio) may overcome these challenges. However, for the detection of truncating mutations on the second allele a second method is required.

Material and Methods: We analysed the *RFC1* repeat region with genome long-read sequencing (PacBio) as well as the PureTarget CRISPR-Cas9 Assay (PacBio) which is designed for targeted analysis of multiple repeat regions. Data was generated by multiplex HiFi long-read sequencing on a Revio system (PacBio) and analysed either with our in-house pipeline or with the Pure Target Repeat Expansion Pipeline.

Results: Genome long-read sequencing detected shorter repeat expansions but failed to detect larger expansions due to low coverage. In contrast, PureTarget identified large RFC1-repeat expansions although for expanded alleles coverage is reduced.

Conclusion: PureTarget enables multiplex analysis for selected repeat regions and is applicable for very large expansions due to high coverage of approximately 200–300x but it is limited to those selected regions. In contrast, genome long-read sequencing only achieves a coverage of approximately 30x, which severely limits the possibility of detecting very large repeat expansions. However, the use of genome long-read sequencing enables the identification of RFC1 truncating mutations on the second allele. Additionally, it is suitable for the identification of mutations in other genes including (shorter) repeat expansions.

P23.045.C Rapid, directional tagmentation with MosaiX TM: a novel workflow utilizing TnX engineered transposase for fast and high performing DNA library preparation

Maura Costello, *Zac Zwirko, David Bays, Christianto Putra, Yanyan Liu, Gavin Rush, Joe Mellor*

seqWell, Inc., Beverly, MA, USA.

Tagmentation using Tn5 transposase can be a highly streamlined approach to sequencing library preparation, although a number of quality challenges remain. Tn5 exhibits strong insertion-site sequence bias, leading to more uneven genome coverage. Additionally, typical methods use two different transposomes to add Read 1 and Read 2 adapters, generating libraries where half of the molecules are unusable due to having the same adapter on both ends, reducing overall complexity. Consequently, researchers often choose more time-intensive methods like enzymatic fragmentation with adapter ligation.

Here we present MosiaX, a novel library preparation chemistry that employs directional tagmentation with an engineered transposase, TnX, developed through directed enzyme evolution for improved activity, reduced insertion bias, and enhanced inhibitor tolerance. In this approach, DNA is fragmented and Read 1 adapters added to the 5′ end via TnX followed by 3' ligation of Read 2 adapters, generating a higher proportion of productive library molecules. The streamlined workflow produces ready-to-sequence libraries in just 90 minutes.

Benchmarking against bead-linked Tn5 tagmentation and enzymatic fragmentation in human exome and genome applications, we observe reduced insertion bias and improved complexity relative to Tn5, and equivalent quality to fragmentase-based methods. MosiaX also enables a realistic one-day exome workflow when combined with Twist's rapid hybridization kit, requiring less than 8 hours from starting DNA to captured libraries on sequencer. Additionally, we demonstrate MosaiXTM chemistry's versatility for PCR-free workflows, UMI incorporation, and compatibility with non-Illumina sequencers. This method addresses key quality limitations of Tn5-based approaches, offering a rapid workflow without sacrificing data quality.

P23.046.D PCR-free, single-analysis approach for the rapid detection of variants in *PKD1* with targeted adaptive sampling long-read sequencing

Giulia Olivucci[1,2], *Emanuela Iovino*[1], *Tommaso Pippucci*[1], *Marta Gut*[3], *Madlen Müller*[3], *Ivo Gut*[3], *Pamela Magini*[4]

[1]*Computational Genomics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [2]*Dipartimento di Medicina di Precisione in Area Medica, Chirurgica e Critica, Università di Palermo, Palermo, Italy,* [3]*Centro Nacional de Analisis Genomico, Barcelona, Spain,* [4]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: NGS is the first-tier test for SNVs analysis, but ambiguous mapping of short reads limits the study of repetitive or duplicated regions. LRS can access and accurately map highly homologous sequences[1]. *PKD1* is characterized by high GC-content and has six pseudogenes with high sequence homology. NGS analysis of *PKD1* requires multiple steps, resulting in a labour-intensive protocol. Some authors have recently applied long-range-PCR and LRS assays to study *PKD1*, with promising results[2,3].

Material and Methods: We selected 7 patients with a known monoallelic mutation in *PKD1*. LRS was performed with Oxford Nanopore Technology (ONT) adaptive sampling, a software-based enrichment method that doesn't require additional library preparation. Reads were aligned with Minimap2 to the T2T-CHM13 human genome assembly. Variant calling was performed with Sniffles, Spectre and DeepVariant. Margin was applied for haplotag. Variants were annotated and prioritized with VEP and Rabdomyzer[4].

Results: We obtained reads with a mean N50 of 11279 bp and mean read accuracy of 98.65%. Mean coverage among all 7 samples was 23X. We accurately detected known variants in *PKD1* in all 7 samples analysed, identifying 6 SNVs and one intragenic deletion.

Conclusion: These results confirm the applicability of LRS for the study of genes with pseudogenes through a single level of analysis without PCR amplification, suggesting this technology as a feasible diagnostic tool. The use of targeted approaches might reduce the impact of sequencing errors by achieving higher coverage with lower costs. Further studies on larger cohorts are required before implementing this strategy into the clinic.

P23.047.A An undiagnosed case solved with the help of genome wide DNA methylation profiling

G. Giardino[1], *R. Romano*[1], *G. Squeo*[2], *A. De Rosa*[1], *A. Ammendola*[3], *E. Toriello*[1], *G. Gemma*[2], *M. Cantelli*[3], *E. Cirillo*[1], *V. Nigro*[4], *C. Pignata*[1], *G. Merla*[2];

[1]*Department of Translational Medical Sciences, Pediatric Section, Federico II University of Naples, Naples, Italy,* [2]*Department of Molecular Medicine and Medical Biotechnology, University of Naples*

Federico II, Naples, Italy, [3]Department of Science and Technology, University of Sannio, Benevento, Italy, [4]Department of Precision Medicine, Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy

Background: DEGCAGS syndrome is an autosomal recessive disorder characterized by global developmental delay, dysmorphic facial features and immunodeficiency due to biallelic *ZNF699* variants. A specific DNA methylation profile has been recently associated with this syndrome.This study aims to describe the immunological features of a patient with DEGCAGS syndrome, in whom diagnosis was suggested through DNA methylation profiling.

Material and Methods: CGH-array, whole exome sequencing, clinical exome and sanger sequencing were used to define the genetic diagnosis. DNA methylation was used to assess the pathogenic role of a heterozygous de novo VUS in ADNP gene identified through clinical exome.

Results: The pathogenic role of the VUS in ADNP gene was ruled out through the study of DNA methylation episignature which, instead, suggested a diagnosis of DEGCAGS syndrome. This diagnosis was later confirmed by identifying a homozygous missense c.153C>A variant in ZNF699 through Sanger sequencing. Immunological studies revealed novel findings: a significant reduction of CD4+CD45RA+ naïve T cells (12%) and CD19+ B cells (2%, 33.2 cells/μL), along with impaired T cell proliferation. The patient experienced severe lung infections, suggesting a TlowB-NK+ combined immunodeficiency (CID). Despite severe B-cell depletion, immunoglobulin levels and antibody responses remained normal.

Conclusion: This report provides the first in-depth characterization of immunological abnormalities in DEGCAGS syndrome, indicating that biallelic loss-of-function ZNF699 variants may cause syndromic CID. DNA methylation episignature proved to be a valuable diagnostic tool, highlighting its potential to improve diagnostic yield in unresolved cases.

P23.048.B The Clinician-reported Genetic testing Utility InDEx for genomic newborn screening (C-GUIDE NBS): Development and content validity

Robin Z. Hayeems[1,2], *Salma Shickh*[1], *Stephanie Luca*[1], *Elise Poole*[1], *Katharine Fooks*[1], *Amanda Pichini*[3], *Joanna Ziff*[3], *Katrina Stone*[3], *Bowen Xiao*[1], *Wendy J. Ungar*[1,2], *Pranesh Chakraborty*[4], *David Bick*[3]

[1]*The Hospital for Sick Children, Toronto, ON, Canada,* [2]*University of Toronto, Toronto, ON, Canada,* [3]*Genomics England, London, United Kingdom,* [4]*Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.*

Background: Genomic newborn screening (NBS) initiatives are emerging worldwide. Evidence of clinical utility, acceptability and performance are required to guide policy and funding decisions. Tailored to the parameters of NBS and informed by the Clinician-reported Genetic testing Utility InDEX (C-GUIDE), we aimed to develop a novel tool to quantify the clinical utility of genomic NBS, called C-*GUIDE NBS*.

Material and Methods: We identified relevant domains and modified wording of the original C-GUIDE items to create a preliminary draft of *C-GUIDE NBS*. Interviews were conducted with clinicians involved in genomic NBS to assess the relevance, comprehensibility, and comprehensiveness of the items. We quantified the number of items clinicians accepted, modified, or rejected and synthesized qualitative feedback to inform a revised version. Interviewees completed content validity questionnaires to rate the relevance and clarity of each item on a 4-point Likert scale. Scores between 0 and 1 were calculated. We finalized *C-GUIDE NBS* using a 3-step international Delphi consensus process.

Results: Interviewees ($n = 22$) indicated that eight of the preliminary 11-items were acceptable for inclusion as is, two required modifications, and one was rejected. On the revised 10-item tool, item relevance and clarity scores <0.8 prompted further item revision for the consensus process. With 26 expert panelists, item consensus and stability were achieved for a final 7-item tool.

Conclusion: The rigorously developed, expert-informed *C-GUIDE NBS* tool provides a novel measurement strategy for capturing the clinical utility of genomic NBS. Validity testing is underway, following which *C-GUIDE NBS* will be available for licensed use.

P23.049.C Towards equity evaluations in genomics: A case study on variant effect predictors

Leandra Braeuninger, *Brieuc Lehmann*

University College London, Alan Turing Institute, London, United Kingdom.

Background: Understanding genomic variant differences across populations is essential for equitable health. Genomic research faces diversity and equity challenges, with individuals of European genetic ancestry over-represented in databases (78% as of 2019). This bias limits the applicability of findings to individuals of non-European genetic ancestry. Computational genomic tools, including variable effect predictors (VEPs), can perpetuate these inequities, necessitating robust frameworks to evaluate their performance across populations.

Materials and Methods: We conducted a rapid literature review into (1) the statistical methods to (1) characterise diversity in genomic data and (2) evaluate equitable performance with respect to genetic ancestry, focusing on VEPs. Guided by this review, we developed an equity evaluation framework for genomic tools like VEPs.

Results: The literature review identified three critical needs: (1) disambiguating genetic ancestry from sociopolitical constructs such as race and ethnicity, (2) integrating technical advancements in ancestry stratification into evaluations, and (3) improving tools to evaluate VEP performance across genetic ancestry. We used VEPs as a case study for the application of our proposed equity evaluation framework while considering these needs and identified challenges of limited diversity in reference databases used in genomic equity evaluations.

Conclusion: Promoting equity in genomics requires systematic frameworks that identify biases in computational models. This work establishes a foundation for rigorously evaluating VEPs across diverse genetic ancestries, addressing current data availability limitations. By identifying critical gaps and providing a clear direction for future evaluations, it supports more inclusive genomics and enables the development of more equitable computational models in genomics.

P23.050.D A promising single DNA-based assay to test for hemoglobinopathies, congenital adrenal hyperplasia, cystic fibrosis, spinal muscular atrophy and severe combined immunodeficiency for newborn screening

Joery den Hoed[1], *Terence Fabella*[2], *Santiago Castanedo*[1], *Jan Schouten*[1], *Lisette Stolk*[1]

[1]*MRC Holland, Amsterdam, Netherlands,* [2]*Amsterdam UMC, Locatie Vrije Universiteit, Amsterdam, Netherlands.*

Background: Newborn screening is a public health program focused on early-onset conditions for which timely intervention can prevent a severe clinical outcome. Newborn screening programs mostly use biochemical assays, but those often require confirmatory testing using an independent assay due to the high number of false-positive/negative results. DNA-based tests can serve as second-tier options, but single-region assays such as qPCR and Sanger sequencing are time-consuming

Material and Methods: We are developing a SALSA® digitalMLPA™ assay that may be used to follow-up current newborn screening tests. digitalMLPA is a multiplex PCR-based technique with around 1,000 probes for the detection of copy number variants (CNVs) and selected single nucleotide variants (SNVs), using Illumina platforms for amplicon detection and quantification.

Results: The assay contains probes targeting genes associated with hemoglobinopathies (CNVs and 6 frequent pathogenic SNVs for *HBA1/2*; CNVs and 14 frequent pathogenic SNVs for *HBB*), congenital adrenal hyperplasia (CNVs and 11 frequent pathogenic SNVs for *CYP21A2*), cystic fibrosis (CNVs and 33 frequent pathogenic SNVs for *CFTR*) and spinal muscular atrophy (CNVs of exon 7 of *SMN1*). In addition, this assay contains probes targeting T-cell receptor excision circles (TRECs) for the detection of severe combined immunodeficiency. Although population-dependent, the variant detection rate for these conditions is >70–80%. Preliminary data demonstrate that the digitalMLPA assay confidently calls both CNVs and targeted SNVs in cell line-derived positive samples.

Conclusion: Our digitalMLPA assay could serve as a valuable DNA-based tool in a newborn screening setting, allowing testing of five treatable early-onset conditions at once.

P23.051.A Sequencing of repeat expansions in molecular diagnostics: comparing hybridization-based and CRISPR-Cas9-based approaches

Bettina Vignolo, *Idriz Durmish, Barbara Bangol, Oliver Wachter, Konstanze Hörtnagel*

MVZ Martinsried GmbH, Martinsried, Germany.

Background: Diagnostics for repeat diseases are typically performed with fragment-length analysis or Southern blot as separate assays for each indication, which do not provide detailed information on interruptions, methylation status or mosaics. The goal is to streamline the lab workflow for diagnostics of different repeat diseases, while simultaneously gaining more information on these regions and comparing two different enrichment methods to evaluate their efficacy in this context.

Material and Methods: Twenty repeat regions of 16 samples were enriched with a customized hybridization-based panel (Twist Bioscience) and the CRISPR-Cas9-method (PureTarget kit, PacBio). Long-read sequencing was performed on a Sequel IIe (PacBio), and data were analyzed using SeqPilot software (JSI) and Tandem Repeat Genotyping Tool (PacBio).

Results: Repeat lengths of 14 samples sequenced with the PureTarget kit were compared to previous diagnostic results, which revealed a high concordance. Methylation was detected in *FMR1* of three samples and seven samples showed mosaics (including *FXN*, *FMR1*, *DMPK* and *CNBP* genes). Only five of the samples which were hybridization-based enriched, showed the same results as previous methods. The others were either poorly covered or lacked one of the expected alleles.

Conclusion: Long-read sequencing with the amplification-free enrichment method using CRISPR-Cas9 can reproduce results from gold-standard methods and provides additional information that can be highly valuable for diagnostics of repeat diseases. While hybridization might be suitable for shorter repeats (e.g. in *ATXN1*), it has some key limitations in the detection of longer repeats and cannot give any information on methylation status.

Background: Recent technological advances have enabled transcriptomic profiling of single cells at increasing scale. Here, we leverage a novel next generation sequencing technology called Sequencing By Expansion (SBX) to achieve unprecedented throughputs for analysis of commonly used 10x Genomics single cell RNA sequencing kits.

Material and Methods: Libraries targeting 5–10k peripheral blood mononuclear cells isolated from healthy donors were prepared for SBX sequencing using an optimized workflow. Sequencing data was pre-processed to mimic paired-end reads expected by traditional bioinformatics pipelines. Sequencing throughput was assessed using the number of usable reads attained, defined as reads with valid barcodes that confidently mapped to the reference transcriptome or probe set.

Results: For the 10x 3′ kit, we obtained 3.2B usable reads in one hour of SBX sequencing, which was 7.5X throughput compared to an Illumina NovaSeqX run. SBX insert lengths were substantially longer, with 2B reads greater than 600 bp. For the 10x Flex kit, we obtained 7B usable reads in one hour of SBX sequencing, which was 15X throughput compared to Illumina. For all kits, SBX and Illumina sequencing resulted in highly correlated expression levels and detected cell types.

Conclusion: SBX sequencing demonstrated massively high-throughput across all tested kits, recovering billions of usable reads, whilst maintaining single-cell metrics comparable to those generated with Illumina sequencing. SBX's workflow presents a

solution for the escalating need for greater sequencing throughput in single-cell profiling experiments, thus facilitating the resolution of cellular subpopulations and the discovery of new biological insights.

P23.053.C Dual-fraction extraction: Efficient isolation of DNA and RNA from a single sample for genomic applications

Stefan Schmidt, *Massimiliano Memo*

Omega Bio-tek, Norcross, GA, USA.

Background: Independent recovery of DNA and RNA enables comprehensive genomic analysis, supporting applications such as pathogen detection, sequencing, and gene expression profiling. However, performing separate extractions for both nucleic acids can require large amounts of sample. A more efficient solution is needed to maximize the use of precious samples by isolating both DNA and RNA from a single sample.

Material and Methods: Here, we validate the Mag-Bind® DNA/RNA Kit, a nucleic acid extraction kit capable of eluting DNA and RNA in separate fractions from a single sample of up to 10 mg tissue or 1×10^6 cells. DNA and RNA were extracted from 5 mg of murine liver, kidney, brain, and lung tissue, as well as from 1×10^6 AD293 cells.

Results: The resulting DNA and RNA were of high-quality when analyzed via spectrophotometry. Suitability of the DNA and RNA for applications downstream was analyzed via qPCR and RT-PCR, both of which demonstrated successful amplification without inhibition.

Conclusion: The Mag-Bind® DNA/RNA Kit presents scientists with an efficient solution for obtaining both DNA and RNA suitable for extensive genomic analysis and downstream applications.

P23.054.D Integrating LLMs and knowledge graphs for Improved Data Interpretation

L. van den Biggelaar;

The Hyve, Utrecht, Netherlands

Background: Large language models (LLMs) have become essential in early drug development, aiding in the prediction of mechanisms of action, toxicity, and other properties. However, their lack of transparency and tendency for hallucinations pose challenges. By integrating annotated databases and retrieval-augmented generation (RAG), hallucinations can be minimized. To support researchers, The Hyve integrated an LLM into the Open Targets Platform (OTP) using BioChatter, an open-source framework for biomedical LLM applications.

Material and Methods: A knowledge graph (KG) was built based on OTP data to enable RAG and improve transparency. A use case was designed to assess the LLM's ability to infer relationships not explicitly present in OTP. The question, "Which GO terms are most associated with asthma?" was chosen since OTP lacks direct disease-GO_term relationships. The LLM, powered by GPT-4o, was used to query the KG.

Results: The LLM generated an accurate Cypher query and retrieved the most associated GO terms for asthma: protein binding (7546 associations), plasma membrane (4482 associations), and nucleus (4099 associations). These results confirm the LLM's ability to process KG data transparently while avoiding hallucinations.

Conclusion: Although the LLM successfully retrieved valid GO terms, more specific terms like positive regulation of transcription by RNA polymerase II would be more informative for research. The KG's structure and schema significantly impact LLM performance. However, BioChatter demonstrates great potential for drug development by enabling researchers to extract insights without requiring expertise in database querying.

P23.055.A Implementation of a multi node Beacon network for genomic data exchange in Italy

Francesca Genova[1], *Santo Diprima*[1], *Raffaella Pini*[1], *Paolo Uva*[2], *Matteo Chiara*[3], *Marco J. Morelli*[1]

[1]*IRCCS San Raffaele Scientific Institute, Milano, Italy,* [2]*IRCCS Ospedale Pediatrico Giannina Gaslini, Genova, Italy,* [3]*University of Milan, Milano, Italy.*

Background: Beacon is a data protocol developed by the Global Alliance for Genomics & Health (GA4GH) for the secure interrogation of sensitive data (1). It facilitates the discovery and retrieval of genetic, phenotypic, and clinical data for stakeholders in healthcare and research. This project aims to establish a multi-node Beacon network in Italy to demonstrate its applications and provide deployment guidelines for national interested parties. This effort aligns with international initiatives, such as the Genomic Data Infrastructure (GDI) project, which supports genomic data exchange across Europe.

Material and Methods: A multi-node Beacon network was implemented using the Beacon v2 Production Implementation (B2PI) and the Beacon v2 Reference Implementation (B2RI) tools API. The network is currently populated with synthetic genomic and phenotypic data, and stringent tests have been conducted to evaluate data querying, retrieval efficiency, and network stability.

Results: We focused on deploying a multi-node network and establishing a functional testing environment. Initial tests assessed the network's performance in handling genomic queries and its potential for larger-scale projects. Based on these results, we drafted standard operating protocols for deployment.

Conclusion: By setting up and testing a Beacon network in Italy, this project promotes the adoption of international standards for genomic data sharing and contributes to EU-funded initiatives for genomic data discovery and exchange.

P23.056.B Resolving variant phase with long-read Nanopore sequencing: a case of *MUTYH*-associated polyposis diagnosed as an incidental finding

Eleni Biliouri, *Daniel Pieh, Stanislav Lechno, Jennifer Winter, Susann Schweiger, Matthias Linke*

Institute of Human Genetics, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany.

Background: A 35-year-old woman sought genetic counseling due to family history of breast and ovarian cancer. Her mother was diagnosed with breast cancer at age 45, ovarian cancer at age 55, and passed away at 65. Predictive testing using a next-generation sequencing (NGS) tumor panel was performed, revealing a variant of unknown significance in the *MSH2* gene and two heterozygous pathogenic variants in the *MUTYH* gene as incidental findings. *MUTYH*-associated polyposis (MAP) is an autosomal recessive condition[1], necessitating determination of whether the variants are *in cis* or *trans*.

Material and Methods: Due to lack of access to the father for segregation analysis, long-range PCR based Nanopore sequencing was used to determine the phase of the *MUTYH* variants. Nanopore sequencing enables the analysis of long DNA fragments, facilitating the resolution of phase ambiguity in cases with potential biallelic variants[2].

Results: Nanopore sequencing confirmed that the two *MUTYH* pathogenic variants were in trans, establishing a diagnosis of MAP. This diagnosis enabled tailored surveillance recommendations, including regular colonoscopies to manage the increased risk of colorectal cancer.

Conclusion: This case demonstrates the utility of long-read Nanopore sequencing in resolving the phase of genetic variants, which is critical for diagnosing autosomal recessive conditions such as MAP. Establishing variant phase allowed us to provide precise risk assessment and propose effective surveillance strategies. Our findings underscore the value of advanced sequencing technologies in clinical genetics, particularly when conventional methods, such as segregation analysis, are not feasible.

P23.057.C MosaiXTM DNA Library Prep Kit for Enhanced Genotypability and Coverage Uniformity in WGS and WES sequencing

Matteo Orlandi[1], *Luca Bertoli*[1], *Filippo Lucchini*[1], *Chiara Degli Esposti*[2], *Marzia Rossato*[1,2], *Maura Costello*[3], *David Bays*[3], *Christianto Putra*[3], *Zac Zwirko*[3], *Yanyan Liu*[3], *Joe Mellor*[3], *Gavin Rush*[3], *Massimo Delledonne*[1,2]

[1]*University of Verona, Verona, Italy,* [2]*Genartis s.r.l., Verona, Italy,* [3]*seqWell Inc, Beverly, MA, USA.*

Whole Genome Sequencing (WGS) and Whole Exome Sequencing (WES) are widely used short-read sequencing methods in clinical genetics. WES offers high coverage in the coding regions and lower costs, while WGS provides broader coverage, including non-coding regions that may harbor disease-causing variants. Both technologies ensure higher per-base read quality compared to long-read sequencing, making them the standard for detecting clinically relevant variants. The choice between WGS and WES depends on specific clinical needs. A key challenge in next-generation sequencing (NGS) is the low mappability regions (e.g., pseudogenes), due to insertion-site bias and limited complexity of Tn5-based library preparation protocols. Optimized protocols can enhance mappability and genotypability, improving coverage uniformity, reproducibility, and variant calling, while simplifying the workflow and reducing the number of steps and the risk of errors. In this study, we evaluated the MosaiXTM DNA Library Prep kit from seqWell, which relies on directional tagmentation and an engineered TnX transposase for increase library complexity and reduced insertion site bias. We generated WGS and WES libraries (NA12878), the latter captured with Twist Exome 2.0 plus Comprehensive Exome Spike-in. Our results show that the MosaiXTM DNA Library Prep kit protocol achieves high coverage uniformity, strong genotypability, and excellent reproducibility across regions with varying GC content, while requiring fewer steps and less time compared to other library prep protocols. Additionally, the MosaiXTM DNA Library Prep kit demonstrated high precision in SNV and INDEL calling for NA12878 (Genome in a Bottle), closely aligning with its gold-standard variant set.

P23.058.D Microarray analysis on Illumina Infinium GSA-24v3.0 BeadChip with focus on polymorphisms covered by forensic Verogen ForenSeq Kinteligence Kit provides thousands of reliable SNPs genotypes from degraded DNA with low input

Petr Novotný[1,2], *Vlastimil Stenzl*[3], *Dana Pokorná*[1], *Pavel Šenkyřík*[2], ***Marie Korabecna***[2]

[1]*Essence Line, Prague, Czech Republic,* [2]*First Faculty of Medicine, Charles Universityq, Prague, Czech Republic,* [3]*Institute of Criminology, Police of the Czech Republic, Prague, Czech Republic.*

Background: DNA samples of ideal quality are not always available for genetic analysis, making it necessary to analyse degraded samples for kinship analysis.

Material and Methods: Control saliva samples were collected into Oragene kits and DNA was isolated. Cell-free DNA samples from sweat were obtained by rinsing the glass beads touched by study participants with Qiagen elution buffer without lysing corneocytes. The Illumina Infinium GSA24-v3.0 BeadChip microarray was used to analyse both high-quality saliva-derived DNA and degraded cell-free DNA samples at limited concentrations.

Results: Samples from two unrelated individuals were tested at different dilutions, enabling the study of 10,145 out of 10,230 forensic SNPs involved in the Verogen ForenSeq Kintelligence Kit. Quality parameters, in particular SNP call rates (SCRs) and concordance at the called site, were compared for saliva-derived and degraded sweat-derived DNA. The SCRs for the degraded samples were similar to or lower than those for the reference saliva samples of the same DNA concentration (e.g. for a concentration of about 0.01 ng/µl DNA the obtained SCRs ranged from 28.44 to 68.55% for degraded samples vs. 65.28% for reference saliva sample). However, degraded DNA showed a higher concordance with the reference sample from the same individual (above 59%) than with samples from other individuals (below 42%) after proper filtering.

Conclusion: In this pilot study, we demonstrated that Illumina Infinium GSA24-v3.0 microarrays can genotype thousands of SNPs from highly degraded DNA samples at low concentrations and suggest approaches to optimise quality control and filtering of the results obtained.

P23.059.A Exploring the use of buccal swabs as a non-invasive sampling method for third-generation genetic sequencing

Anna Franzoni, *Ilaria Triva, Cristiano Sabelli, Giulia Gorni, Michele Rosso, Simone Paghera*

Copan Italia SpA, Brescia, Italy.

Background: Third-generation sequencing (TGS) technologies demand starting samples that meet specific requirements, most commonly a DNA concentration higher than 10 ng/µL and a 260/280 absorbance ratio between 1.8 and 2.0[1].

In this study, Copan buccal FLOQSwabs® were evaluated both immediately after collection and after 12 months of storage at room temperature (RT) to determine if they meet the DNA parameters for successful TGS analyses.

Material and Methods: Five donors self-collected one buccal FLOQSwabs®, which was stored at room temperature (RT) for 12 months (T12). On the day of DNA extraction, the same donors self-collected another buccal FLOQSwabs®, which was immediately processed (T0) alongside the T12 samples. All samples were processed using QIAmp® DNA Mini Kit on QIAcube®, following lysis with NAO® Basket. DNA concentration was determined using NanoDrop™1000 and Qubit™ dsDNA BR fluorimetric assays, while DNA purity was assessed through 260/280 absorbance using NanoDrop™1000.

Results: All buccal FLOQSwabs® met the DNA concentration and purity requirements identified for successful TGS analyses (*Table 1*).

The unpaired t-test comparing T0 and T12 samples showed no significant differences in DNA concentration measured by Qubit™ ($p = 0.6049$) and NanoDrop™ ($p = 0.5550$).

Conclusion: Results suggest that buccal FLOQSwabs® can be effectively used for TGS, whether processed immediately after collection or following prolonged storage at RT, offering a non-invasive alternative to blood sampling. Further tests are currently ongoing to assess the molecular weight of the extracted DNA, aiming to verify if it exceeds 10 kbp.

Table 1

	T0 Samples	T12 Samples
Average DNA Concentration using Qubit™ (ng/µl) ± σ	43,54 ± 26,52	36,72 ± 9,93
Average DNA Concentration using NanoDrop™1000 (ng/µl) ± σ	56,92 ± 25,20	49,14 ± 12,75
Average 260 nm/280 nm Absorbance ± σ	1,89 ± 0,03	1,89 ± 0,02

P24 Treatments for Genetic Disorders

P24.001.B The Role of Antisense Oligonucleotides in Molecular Approaches to Developing Therapies for Ultra-Rare Genetic Diseases

Luciano Mottola[1,2], *Lorenzo Vaccaro*[1,3], *Mirella Massa*[1,3], *Gennaro Gandolfo*[1,2], *Sandro Banfi*[1,4], *Nicola Brunetti*[1,3], *Alessandro De Falco*[1], *Antonella De Matteis*[1,5], *Diego di Bernardo*[1,6], *Gennaro Gambardella*[1,6], *Vincenzo Nigro*[1,4], *Annalaura Torella*[4], *Davide Cacchiarelli*[1,3,7]

[1]*Telethon Institute of Genetics and Medicine (TIGEM), Armenise/Harvard Laboratory of Integrative Genomics, Pozzuoli, Italy, Pozzuoli, Italy,* [2]*European School of Molecular Medicine, Department of System Medicine, University of Milan, Milan, Italy, Milan, Italy,* [3]*Department of Translational Medicine, University of Naples "Federico II", Naples, Italy, Naples, Italy,* [4]*Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy, Naples, Italy,* [5]*Department of Molecular Medicine and Medical Biotechnology, University of Naples "Federico II", Naples, Italy, Naples, Italy,* [6]*Department of Chemical, Materials and Industrial Engineering, University of Naples "Federico II", Naples, Italy, Naples, Italy,* [7]*Scuola Superiore Meridionale (SSM, School of Advanced Studies), University of Naples "Federico II", Naples, Italy, Naples, Italy.*

Background/Objectives: The development of a functional genomic approach is critical for the treatment of many ultra-rare genetic diseases, especially in the absence of targeted clinical therapies. Once the causative genes of these diseases are identified, antisense oligonucleotides (ASOs) can be used as a molecular approach to develop personalized therapeutic solutions. ASOs are highly versatile molecules capable of targeting specific RNA transcripts to modulate their expression, effectively slowing or halting the progression of rare genetic diseases.

Methods: In line with this goal, we have developed different specific signalling systems in which ASOs induce either exon skipping or transcript degradation, depending on the specific disease-related gene variant. The reporter system utilises a luciferase vector into which the specific genetic variant is cloned, enabling us to perform functional assays to evaluate the effectiveness of ASOs. This vector will be co-transfected with antisense oligonucleotides in cellular models to conduct an in vitro luciferase-based functional assay. Two distinct strategies will be employed: the first focuses on transcript degradation, targeting variants that produce non-functional or dominant-negative mutant proteins. The second strategy involves exon skipping, designed for variants located in non-essential gene regions or in exons within in-frame splicing tracts.

Results: Every system will be analysed through luciferase assays and full-length RNAseq to determine the precise efficiency of each probe for future clinical purposes.

Conclusion: This strategy, if successful, will pave the way for the development of specific therapies for hundreds of genetic conditions for which efficient drug development is not possible to date.

P24.002.C Functionalized bioactive nano-ink for precision siRNA therapy in *FGFR2*-related syndromic craniosynostoses

Federica Tiberio[1,2], *Salvati Martina*[1], *Noah Giacon*[1], *Alessia Vita*[1], *Luca Massimi*[1,2], *Gianpiero Tamburrini*[2,1], *Lorena Di Pietro*[1], *Ornella Parolini*[1,2], *Alessandro Arcovito*[1], ***Wanda Lattanzi***[1,2]

[1]*Universita Cattolica del Sacro Cuore, Rome, Italy,* [2]*Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy.*

Background: Heterozygous activating mutations of *FGFR2* gene result in different syndromes primarily characterized by craniosynostosis. We developed a moldable nanoparticle (NP)-laden hydrogel for in situ delivery of siRNA targeting *FGFR2* to restore the maladaptive osteogenic commitment of cells in skull sutures of syndromic patients.

Material and Methods: Calvaria-derived mesenchymal stromal cells were isolated as surgical waste from 6 non-related Crouzon patients. siRNA able to silence *FGFR2* mRNA were designed and

tested in patient cells. Functionalized PLGA-PEG-Bis-sulfone NPs were produced and characterized via dynamic light scattering and scanning electron microscopy. Their biocompatibility was assessed through cell viability and proliferation assays. The intracellular trafficking of NPs was examined through live imaging and confocal microscopy. The knockdown efficacy of siRNA-NP complexes was studied in vitro using qPCR and western blotting. Finally, PLGA-PEG-Bis-sulfone NPs were 3D-printed within a hydrogel matrix and tested in patients' cells.

Results: siRNA treatment modulated the FGFR2 cascade in patient cells, as demonstrated by reduced phosphorylation of FGFR2 (48%) and of its key effector ERK1/2 (77%). Upon treatment, RUNX2 protein levels decreased by 34%, with overall reduction of osteogenic markers' expression and bone matrix deposition. NPs widely distributed in cell cytoplasm without affecting viability and proliferation. Live-cell microscopy demonstrated sustained and prolonged intracellular release of PLGA NPs from hydrogel in cell culture. Once inside the cells, NPs released siRNA able to target and modulate the overactivation of *FGFR2*.

Conclusion: The proposed bioactive nano-ink could be a promising tool for controlled release of therapeutic RNA-based drugs.

Background: Selumetinib,indicated in children aged ≥ 3 years with neurofibromatosis type 1**(**NF1) and symptomatic, inoperable, plexiform neurofibromas (PNs),reduces the volume of PNs,and improves quality of life(QoL) and pain.

Materials and methods:This retrospective, observational,independent,multicenter study on children with NF1(3–18 years) treated with selumetinib aimed to assess the clinical benefit rate (CBR) defined as the percentage of patients with complete response, or minor/partial response(MR/PR), progressive disease(PD) or stable disease(SD) according to REiNS and RANO criteria.We further evaluated safety, impact on pain,and performance status(ECOG).

Results: Seventy patients(39 males) were enrolled(median age 7.9 yrs).Target PNs were mostly in the head/neck(32%) and limbs(43%).The median PNs volume was 126.8 ml(5–3820 ml). They mostly caused pain(51%), deformity(18.5%), and motor dysfunction(16%) and received a median of 49 cycles(range 7.5–79).The radiological response is summarized in table.The median time to MR or PR was at 12 cycles(range 6–24),with the best response(−96%) at 24 cycles.These statistically significant associations emerged:PD at 12 cycles was positively associated with final PD and negatively with final CBR;SD and PR/MR at 6 cycles associated both with the SD and PR/MR at 12 months but also with the latter at the end of follow up;CBR at 12 months negatively associated with final PD and positively with final CBR. ECOG and pain significantly improved during therapy.Adverse events were mainly mild (78% ≤ grade 2)yet frequent(80%).

Conclusion: We report a strong CBR in NF1-children with PNs treated with selumetinib. Responses seen at 6 and/or 12 cycles may forecast the final response.

P24.005.B Contribution of 3D Instrumented Gait Analysis to the evaluation and follow-up of Mucopolysaccharidosis IVA (MPS IVA) patients under elosulfase alfa

Camille Porteret[1], *Steeve Brousseau*[2], *Claire Delleci*[3], *Elodie Blanchard*[4], *Emilie Doat*[5], *Didier Griffiths*[1], *Etienne Guillaud*[5], *Mathilde Majean*[2], *Patricia Reant*[6], *Christophe Richez*[2], *Guilhem Sole*[7], *Nadia Mehsen-Cetre*[2], *Cyril Goizet*[1], *Julien Van Gils*[1]

[1]*Department of Medical Genetics, University Hospital of Bordeaux, Bordeaux, France,* [2]*Department of Rheumatology, University Hospital of Bordeaux, Bordeaux, France,* [3]*Department of Physical and Rehabilitation Medicine, University Hospital of Bordeaux, Bordeaux, France,* [4]*Department of Pneumology, University Hospital of Bordeaux, Bordeaux, France,* [5]*Motor analysis platform, University of Bordeaux, Bordeaux, France,* [6]*Department of Cardiology, University Hospital of Bordeaux, Bordeaux, France,* [7]*Departement of Neurology, University Hospital of Bordeaux, Bordeaux, France.*

Background: Mucopolysaccharidosis IVA (MPS-IVA) is a rare lysosomal storage disorder caused by biallelic pathogenic variants in *GALNS*. The natural history of attenuated MPS-IVA phenotypes remains largely unexplored, with limited data on long-term outcomes under enzyme replacement therapy (ERT). This study aimed to assess the clinical evolution of attenuated MPS-IVA patients over several years of follow-up.

Material and Methods: Four attenuated MPS-IVA patients were followed for 3 to 6 years in an expert center. We applied the Morquio A Clinical Assessment Program, incorporating three-dimensional instrumented gait analysis (3D-IGA), osteodensitometry, and heart MRI to evaluate disease progression and response to ERT with elosulfase alfa.

Results: All patients showed stabilization or improvement in motor function and gait parameters. 3D-IGA provided insights into postural patterns both at rest and during walking, highlighting compensation mechanisms related to pain, particularly in the lower limbs. Significant pain reduction was reported in patients with higher baseline levels. One patient, after an 8-month ERT interruption, experienced a decline in motor function but returned to previous performance levels two years after treatment reintroduction, underscoring the importance of uninterrupted therapy to preserve motor function.

Conclusion: Follow-up data from all four treated patients demonstrated at least stabilization of autonomy and gait patterns after years of treatment. These results suggest that 3D-IGA is useful to monitor motor dynamic function and clinical improvement under ERT in real-world conditions. The data could inform new individualized recommendations to improve patient adherence to long-term treatment, adapting follow-up strategies to the specific needs of each MPS-IVA patient.

Background: Fanconi anemia (FA) is caused by mutations affecting DNA repair-associated FANC genes, with 20% of patients harboring nonsense mutations. Ataluren (PTC124) is a clinically approved translational read-through-inducing drug (TRID) for premature stop codons (PTC) with a well-established safety profile even in pediatric patients. Amlexanox is an anti-inflammatory drug able to stabilize mRNAs and induce read-through of PTCs.

Material and Methods: We compared the effect of ataluren and amlexanox in rescuing FANCA and FANCF protein synthesis in lymphoblastoid cell lines and fibroblasts from FA patients harboring nonsense mutations. We evaluated cell viability, chromosomal rearrangements after exposure to genotoxic and clastogenic agents (DEB test) and efficacy in reducing p53 levels.*FANCA* and *FANCC* mutated fibroblasts were used for micronuclei formation and lamin B1 expression studies.

Results: Ataluren restored FANCA and FANCF protein levels and p53 results significantly downregulated with associated improved cell viability and reduced chromosomal aberrations observed after DEB test. Amlexanox was partially effective only on FANCA restoration, while no effects were observed after DEB test. Moreover, ataluren significantly limited the generation of micronuclei in nonsense-mutated primary *FANCC* fibroblasts, restoring the expression of lamin B1.

Conclusion: This study paves the way for clinical development of TRIDs for FA treatment, indicating ataluren treatment as candidate approach to address the genetic instability and reduce the risk of malignant transformation in FA cells.

P24.007.D Organoids as scalable models for splice modulation therapy development in Alport syndrome

Hassan Saei[1], *Bruno Estebe*[1], *Nicolas Gaudin*[2], *Mahsa Esmailpour*[1], *Julie Haure*[1], *Olivier Gribouval*[1], *Christelle Arrondel*[1], *Vincent Moriniere*[3], *Corinne Antignac*[1], *Geraldine Mollet*[1], *Guillaume Dorval*[1]

[1]*Imagine Institute of Genetic Diseases, Paris, France,* [2]*Necker Bioimage Analysis Core Facility of the Structure Fédérative de Recherche Necker, Paris, France,* [3]*Department of Genomic Medicine for Rare Diseases, Necker-Enfants Malades Hospital, Paris, France.*

Background: Disease-causing non-coding variants are now regularly identified. Most of such variants affect mRNA splicing, eventually treatable using antisense oligonucleotides (ASOs). The development of reliable models for assessing variant pathogenicity and developing therapeutic options represents a fundamental need. Organoids are emerging as powerful tools for disease modeling. We identified several non-coding disease-causing variations in *COL4A5*, which encodes the α5 subunit of type IV collagen [α5(IV)], leading to X-linked Alport syndrome (XLAS), a hematuric nephropathy with glomerular basement membrane (GBM) abnormalities. In this study, we present a framework that combines patient-derived fibroblasts and kidney organoids to demonstrate the therapeutic efficacy of ASOs in XLAS patients.

Materials and methods: We generated an XLAS organoid model by introducing a severe deep-intronic variant in hiPSCs using CRISPR/Cas9 technology. To characterize the XLAS organoids, we employed a multi-omics approach alongside immunostaining. To quantify collagen α5(IV) deposition in the GBM, we developed a semi-automated Fiji macro for analyzing GBM collagen α5(IV) deposition.

Results: Using multiomics analysis and protein staining, we describe the development of GBM in wild-type and mutated human kidney organoids. We show that GBM maturation is a dynamic process that requires long organoid culture (culture up to day 38 of differentiation). Then, using automated quantification of

α5(IV) at basement membranes in organoids carrying the splicing variants identified in patients, we demonstrate the efficacy of ASO treatment for α5(IV) restoration.

Conclusion: These data contribute to our understanding of the development of GBM and pave the way for a therapeutic screening platform for patients.

Background: Reaching a definitive molecular diagnosis in patients with rare genetic diseases (RGDs) is crucial for proper management, counseling, and can be a starting point for the development of a therapeutic option for patients. RNA therapeutics have recently emerged as a promising tool for treating RGDs due to their ability to target almost any structure within the cell. Within the PNNR-PARADIGM project, focused on addressing missing heritability and developing therapies for RGD patients with eye disorders (EDs) and neuromuscular diseases (NMDs), we investigated three undiagnosed families to identify genetic causes and develop therapeutic approaches.

Material and Methods: genome sequencing, RT-PCR analyses, and mini-gene assays were used to identify and characterize four cryptic variants potentially affecting splicing in known ED genes. To target the splicing defects, we rationally designed 16 splice-switching antisense oligonucleotides (ssASOs) with a phosphorothioate backbone and 2'-O-methyl modifications. The molecules have been tested on patient-derived fibroblasts or HeLa cells transfected with mutant minigene by lipid-based transfection.

Results: The pathogenicity of a silent *ABCA4* variant, causing 35 bp intron retention was assessed by mini-gene assay, whereas RT-PCR analyses characterised three deep intronic variants in *CEP290* and *SDCCAG8* genes, resulting in pseudoexons formation. For each variant we identified at least one ASO able to restore normal splicing in vitro. Further testing of these molecules on disease-relevant 2D/3D models is ongoing.

Conclusion: Genetic diagnoses guide prognosis, counseling, and therapies. Our project provides proof of concept for effectively targeting disease-causing cryptic variants within the context of precision medicine.

Introduction: Heterozygous activator variants of platelet-derived growth factor beta (PDGFRβ) are associated two devastating heterogeneous ultra-rare conditions Kosaki overgrowth syndrome (KOGS), Penttinen syndrome (PS). PDGFR-targeted Tyrosine kinase inhibitors (TKIs), commonly used for hematological malignancies, are now considered potential treatments for KOGS/PS. Although five case reports have shown promising efficacy and safety, current data remain insufficient to fully assess the benefit/risk balance. The international consortium 'Knowing and Treating KOGS/PS' was established to evaluate real-life outcomes for treated and untreated individuals.

Materials and Methods: The consortium present three new cases of KOGS/PS treated with TKIs and update four previously published cases, from 6 countries.

Results: Individuals received between 6 months and 8 years of treatment (Imatinib N = 8/8, Dasatinib N = 3/8, Sunitinib N = 1/8) with an overall mean treatment duration of 43.86 months. Of the eight individuals treated, ages ranged from 6 to 57 years at the start of treatment, with five individuals starting treatment during childhood and three in adulthood. Most individuals (7/8) experienced improvement within months of starting treatment, with minimal side effects. However, some individuals encountered a plateau effect or a decrease in efficacy, prompting a switch to another TKI, possibly after functional tests.

Discussion: These early findings highlight the potential of TKIs in managing KOGS/PS. To enhance monitoring and data collection, standardized follow-up protocols and an electronic case report form have been introduced. This initiative aims to

systematically compare the natural history of treated and untreated individuals, compensating for the rarity of the disease, which makes conducting formal clinical trials challenging.

P24.010.C Prime editing-mediated correction of the *OPTN* gene in ALS patient-derived fibroblasts

Zeynal Sütkurt[1], *Büşra Göksel Tulgar*[1], *Batuhan Şanlıtürk*[1], *Muhammed Emin Sarı*[2], *Nadir Koçak*[1], *Tülün Çora*[1]

[1]*Selçuk University, Medical Genetics, Konya, Turkey,* [2]*Necmettin Erbakan University, Biology, Konya, Turkey.*

Background: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder characterized by motor neuron degeneration. ALS Type-12 is associated with biallelic mutations in the OPTN gene, leading to neuronal dysfunction. Prime Editing (PE), a CRISPR-based gene editing technology, enables precise correction of point mutations without inducing double-strand breaks or requiring a donor template. This study aims to correct the c.1242+1G>A mutation in the OPTN gene in patient-derived fibroblast cells using PE and to evaluate its efficiency in vitro.

Materials and Methods: A patient diagnosed with ALS Type 12 underwent Next-Generation Sequencing (NGS), which identified the c.1242+1G>A variant in the OPTN gene. A prime editing guide RNA (epegRNA) was designed and cloned for precise base correction. Subsequently, the epegRNA-containing plasmid was transformed into chemically competent E. coli for plasmid amplification. Patient-derived fibroblast cells were cultured and transfected using Lipofectamine 3000 with comprising SpCas9 nickase, reverse transcriptase, and an epegRNA targeting the mutation. Gene editing efficiency was assessed via high-resolution melting (HRM) curve analysis.

Results: Post-transfection, HRM curve analysis confirmed precise nucleotide correction, with an estimated 30% editing efficiency at the target site.

Conclusion: This study demonstrates the feasibility of using Prime Editing to correct the *OPTN* c.1242+1G>A mutation associated with ALS Type 12. While Prime Editing has primarily been explored in a limited number of diseases, these findings suggest its potential as a therapeutic strategy for rare genetic disorders. Further preclinical and functional studies are required to validate its long-term efficacy and assess its potential for clinical translation

P24.011.D Impaired Differentiation Capacity of MSCs in Mandibular Hypoplasia, Deafness, Progeroid Features, and Lipodystrophy (MDPL) Syndrome: An In Vitro Study

Paola Spitalieri[1], *Lara Guerrieri*[1], *Michela Murdocca*[1], *M.Giovanna Scioli*[1], *Ida Cariati*[2], *Annalucia Serafino*[3], *Monia Russo*[1], *Serena Maccaroni*[1], *Giuseppe Novelli*[1], *Federica Sangiuolo*[1]

[1]*Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy,* [2]*Department of Systems Medicine, Tor Vergata University of Rome, Rome, Italy,* [3]*Institute of Translational Pharmacology, National Research Council (CNR), Rome, Italy.*

Background: MDPL syndrome (OMIM #615381) is a rare autosomal dominant disorder caused by an in-frame deletion in the *POLD1* gene, encoding the catalytic subunit of DNA polymerase delta. It is characterized by abnormal white adipose tissue (WAT) distribution and mandibular hypoplasia, likely linked to bone-related issues. Previously, we identified early anomalous senescence in mesenchymal stem cells (MSCs) derived from MDPL-hiPSCs. This study investigates the differentiation potential of MDPL-MSCs into adipocytes and osteocytes, as a target of disease.

Material and Methods: For adipogenesis, MSCs were cultured for 21 days in MEM-alpha with specific supplements, including IBMX, dexamethasone, insulin, indomethacin, and rosiglitazone. For osteogenesis, MSCs were cultured in DMEM supplemented with FBS, dexamethasone, ascorbic acid 2-phosphate, and β-glycerophosphate. Gene expression was analyzed using RT-qPCR and TEM was used for ultrastructural analysis

Results: MDPL-MSCs exhibited a fivefold reduction in lipid droplet (LD) accumulation and smaller LDs compared to controls. Genes involved in lipid and glucose metabolism (*PPARγ, ADIPOQ*, *GLUT4*, and *FABP4*) showed decreased expression levels at transcript levels. Osteogenic differentiation demonstrated a decrease in calcium deposition in patients compared to age-matched controls as well as *ALP*, *RUNX2* and *OSTEOCALCIN* gene expression. TEM analysis revealed fewer electron-dense vesicles, nuclear deterioration, and autophagy-like macrovesicle aggregates, confirming cellular senescence.

Conclusion: MDPL highlights critical links between senescence and tissue differentiation. Dysregulation of the adipo-osteogenic balance has been associated with several pathophysiological processes, including aging, obesity, and osteoporosis. The observed defects provide a valuable model for understanding fundamental biological processes and identifying specific therapeutic targets for clinical applications.

P24.012.A A UK platform for nucleic acid therapy for rare diseases - the UPNAT consortium

Ella F. Whittle[1], *Kylie-Ann Montgomery*[1,2], *Alice Davidson*[3], *Mina Ryten*[1,4,5], *Carlo Rinaldi*[6], *Nick Lench*[7], *Catherine Ryan*[1], *Francesco Muntoni*[1], *Haiyan Zhou*[1], *UPNAT consortium*[8]

[1]*Great Ormond Street Institute of Child Health, London, United Kingdom,* [2]*Department of Neuromuscular Diseases, Queen Square Institute of Neurology, UCL, London, United Kingdom,* [3]*UCL Institute of Ophthalmology, London, United Kingdom,* [4]*K Dementia Research Institute at The University of Cambridge, Cambridge, United Kingdom,* [5]*Department of Medical Genetics, NIHR Cambridge Biomedical Research Centre, Cambridge, United Kingdom,* [6]*5.Institute of Developmental and Regenerative Medicine (IDRM), Department of Paediatrics, University of Oxford, Oxford, United Kingdom,* [7]*MRC Nucleic Acid Therapy Accelerator, Research Complex at Harwell, Harwell, United Kingdom,* [8]

Introduction: Nucleic acid therapeutics (NATs) offer great potential to treat rare diseases by targeting specific genetic causes. The rise in NAT clinical trials and approved therapies highlights their role in research to transform new ideas into new treatments and unique opportunities for preclinical and clinical studies, in which the UK has a high level of expertise.

Methods: UPNAT is the UK Platform for Nucleic Acid Therapy for rare diseases, funded by the MRC and NIHR as part of the Rare Disease Research UK Platform. UPNAT aims to advance NAT development by

creating essential resources and a national network, establishing a UK framework for NAT delivery. Key collaborators include NIHR BRCs, the UKRI NATA Hub and Genomics England.

Results: Working groups for NAT development:

1. **Target Selection**: This group is formulating guidelines for selecting genetic variants, target genes, applicable disease conditions and suitable patients for NAT and piloting their implementation within NHS services. A draft guideline has been developed and UPNAT has contributed to finalising the recently published N1C variant guidelines.
2. **Preclinical Development on individualized ASO therapy for ultra-rare diseases**: Collaborating with academic groups and international NAT consortia, the team is exploring effective pathways for developing individualised NATs at scale.
3. **Clinical Translation**: The team is streamlining clinical translation and regulatory approval by establishing data-sharing initiatives, offering training opportunities, and facilitating the creation of a NAT adverse event registry.

Conclusion: UPNAT seeks to accelerate NAT development for rare disease patients in the UK and contribute to international efforts advancing NATs.

Background: XLA is associated with mutations in Bruton tyrosine kinase (BTK) and is an ideal candidate for hematopoietic stem cell(HSC)-based gene therapy. Previously, we demonstrated in vivo correction of immune defects in BTK-knockout mice using lentiviral vectors carrying coBTK. Here, we aimed to correct the B-cell deficiency in NOD/SCID/IL2Rγ-/- (NSG) mice, by self-inactivating lentiviral vectors.

Material and Methods: CD34+ cells were isolated from bone marrow (BM) samples of three patients (P1, P2, P3) and transformed in vitro with coBTK lentiviral vector. Transduced and untransduced cells were transplanted into a total of 20 NSG mice. The development of CD19+cells in bone marrow (BM), peripheral blood (PB), and spleen were evaluated by flow cytometry and qPCR by the end of 5th week following transplantation.

Results: CD19+ engraftment was detected by flow cytometry. In bone marrow and spleen, mice transplanted with transduced stem cells had a higher number of CD19+ cells compared to non-transduced stem cells. coBTK mRNA expression was evaluated by qPCR, and detected in all samples. The mice transplanted with the transduced cells of P1 showed the most significant mRNA expression in blood and spleen($p < 0.001$).

Conclusion: The patients' stem cells were transduced, and the expression of human cells started in the relevant tissues but could not yet be detected at the protein level by flow cytometry. Our findings suggest that the approach is efficient, but the engraftment process is not extended enough to translate the new genes into functional proteins detectable by flow cytometry.

P24.014.C Innovative therapies for *FGFR3*-related skeletal dysplasias: treatment with Vosoritide in children with Achondroplasia. The experience at Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milan, Italy

***Alessandro Draghi**, Berardo Rinaldi, Valeria Nicotra, Matteo Porro, Massimo Cozzaglio, Federica Natacci, Maria Francesca Bedeschi*

Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.

Background: Achondroplasia is the most common skeletal dysplasia, characterized by disproportionate short stature. It affects over 360,000 people worldwide and may lead to medical complications, functional limitations, and psychosocial challenges. It is caused by a gain-of-function mutation in the *FGFR3* gene, resulting in impaired endochondral ossification. Until now, the only effective treatment for achondroplasia has been limb lengthening. Vosoritide is the first pharmacological treatment approved for achondroplasia. It is an analog peptide CNP that counteracts the effects of the *FGFR3* mutation, promoting endochondral bone growth. Clinical trials have shown that vosoritide improves annual growth velocity in children with achondroplasia.

Material and Methods: We prospectively collected data from periodic evaluations of 27 children treated with vosoritide, focusing on changes in key anthropometric parameters relevant for auxological monitoring, as well as data on potential treatment-related adverse events or variations in biochemical parameters used in screening.

Results: Our data demonstrated an increase in height, confirmed by an improvement in the height Z-score compared to reference growth curves. Most notably, There was an increase in annual growth velocity at 18 months post-treatment compared to baseline by approximately 2.5 cm. This is consistent with findings from recent studies on similar cohorts, particularly in individuals with achondroplasia who had poor baseline growth velocities, averaging below 5 cm per year. The most common adverse events during the study were injection-site reactions and injection-site erythema.

Conclusion: Our data confirmed findings observed in other similar cohorts, with no significant sex-related differences. However, emerging data reinforce its clinical utility.

P24.015.D Mass spectrometric profiling reveals alterations in N-Glycans in Tay-Sachs disease under autophagy-induced conditions

Melike Can Özgür[1], *Hatice Hande Basırlı*[1], *Jin Chunsheng*[2], *Daniel Bojar*[2], *Niclas G. Karlsson*[2], *Volkan Seyrantepe*[1]

[1]*Izmir Institute of Technology, Izmir, Turkey,* [2]*University of Gothenburg, Gothenburg, Sweden.*

Background: Tay-Sachs disease is a rare neurodegenerative disorder caused by mutations in the *HEXA* gene. *HEXA* gene encodes for the α-subunit of enzyme β-hexosaminidase A, which degrades GM2 ganglioside. Our research group developed a novel Tay-Sachs disease mouse model (*Hexa-/-Neu3-/-*) exhibiting neuropathological and clinical abnormalities. Previously, we identified impaired autophagic flux in the brains of *Hexa-/-Neu3-/-* mice. Moreover, we demonstrated autophagosome clearance in Tay-Sachs disease cells under lithium-induced conditions. Here, we aimed to evaluate changes in N-glycans in Tay-Sachs disease cells under autophagy induction and examined whether changes in glycan influence ER stress.

Material and Methods: The N-glycans profile was analyzed using LC-MS/MS in fibroblasts and neuroglial cells of 5-month-old *Hexa-/-Neu3-/-* mice and neuroglial cells of Tay-Sachs patients under lithium induction and nutrient deprivation. Additionally, the expression levels of ER stress-related markers were assessed in these cells using qRT-PCR and Western Blot analyses.

Results: We discovered a significant accumulation of high-mannose N-glycans, including Hex10HexNAc1, Hex8HexNAc1, and Hex9HexNAc1, as well as elevated expression levels of ER stress-related markers, CHOP and ATF-6, in Tay-Sachs disease cells compared to control groups. We found that autophagy induction causes degradation of accumulated high-mannose N-glycans associated with the downregulation of ER stress-related genes in Tay-Sachs disease cells.

Conclusion: Our study is the first to show altered high-mannose N-glycans in Tay-Sachs disease cells and suggests the presence of ER stress-mediated autophagy. Therefore, targeting N-glycans through autophagy induction may provide potential treatment strategies for Tay-Sachs disease in future studies.

P24.016.A Investigation of the therapeutic potential of intrathecal human Neu3 sialidase delivery in Tay-Sachs disease mouse model

Hatice Hande Basırlı*, Melike Can Özgür, Volkan Seyrantepe*

Izmir Institute of Technology, Izmir, Turkey.

Background: Tay-Sachs disease is a severe neurodegenerative disorder caused by mutations in the *HEXA* gene, which encodes the α-subunit of the β-hexosaminidase A (HexA) enzyme. A deficiency in HexA leads to the excessive accumulation of GM2, resulting in progressive neurodegeneration in individuals with Tay-Sachs disease. Our group developed *Hexa-/-Neu3-/-* mice, closely mimicking the neuropathological and behavioral changes with a shortened lifespan of 20 weeks. While murine sialidase Neu3 has been shown to promote GM2 degradation through a "bypass" mechanism in *Hexa-/-Neu3-/-* mice, the potential role of human Neu3 (hNeu3) in GM2 degradation remains unclear. Here, we aimed to explore human Neu3-based gene therapy using AAVrh10-hNeu3 in the *Hexa-/-Neu3-/-* mice pathology.

Material and Methods: Molecular biological and immunohistochemical analyses were performed to evaluate the therapeutic efficacy of single-dose intrathecal administration of AAVrh10-hNeu3 to 8-week-old *Hexa-/-Neu3-/-* mice.

Results: We observed an extended lifespan in *Hexa-/-Neu3-/-* mice, reaching up to 28 weeks, and improved weight and physical appearance. We also noted higher hNeu3 expression in the cortex and cerebellum of 20- and 28-week-old *Hexa-/-Neu3-/-* mice administered with 10^{11} vg/µl of AAVrh10-hNeu3. Immunohistochemical analyses revealed decreased GM2 accumulation and LAMP1 levels, alongside increased CNPase levels in 28-week-old *Hexa-/-Neu3-/-* mice compared to those of 20-week-olds across various brain regions.

Conclusion: Our findings suggest that upregulating human Neu3 expression in Tay-Sachs patients might be a promising therapeutic strategy for reducing GM2 accumulation and treating Tay-Sachs disease.

P24.018.C Exploring RNA-based strategies to rescue haploinsufficiency in a form of neurodevelopmental disorders linked to *STX1B* gene

Joana Soraia Martinheira da Silva[1], *Ludovica Menta*[1], *Michela Bellardita*[1], *Antonella Riva*[1], *Ganna Balagura*[1], *Carlotta Bon*[2], *Stefano Gustincich*[2], *Pasquale Striano*[1,3], *Federico Zara*[1,4], ***Renata Bocciardi***[1,4], *Serena Cappato*[4]

[1]*Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Sciences (DINOGMI), University of Genoa, Genoa, Italy,* [2]*Center for Human Technologies, Non-coding RNAs and RNA-based therapeutics, Italian Institute of Technology (IIT), Genoa, Italy,* [3]*Neurology and Muscular Diseases Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy,* [4]*Medical Genetics Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy.*

Background: The *STX1B* gene (*OMIM#601485*) encodes Syntaxin 1B, a key protein in neurotransmitter release, via the SNARE complex. Syntaxin 1B drives the fusion of synaptic vesicles with neuronal membranes. Variants in *STX1B* causing haploinsufficiency are linked to a form of early-onset neurodevelopmental disorders (NDDs) characterized by GEFSP9+, myoclonic-atonic epilepsy and developmental delay. This study aims to explore the therapeutic potential of RNA-based technologies, including SINEUPs - a new class of synthetic antisense long non-coding RNA (lncRNA) - and CRISPRa, a gene-editing approach using a deactivated Cas9 protein fused to transcriptional activators. These approaches aim to increase STX1B protein levels and reduce the downstream effects of haploinsufficiency.

Material and Methods: qPCR and Western Blot to evaluate the expression of *STX1B* at mRNA and protein level in neuronal-like cellular models; in silico analysis of RNA structure of *STX1B* mRNA; design and synthesis of SINEUPs targeting the regulatory regions and the coding sequence of *STX1B*; application of VPR and SAM CRISPRa strategies targeting *STX1B* gene.

Results: CRISPRa approaches using VPR and SAM systems significantly upregulate the *STX1B* gene expression at transcriptional level. Furthermore, we are currently setting up experimental conditions to screen SINEUPs targeting the human *STX1B* mRNA.

Conclusion: RNA-based therapies offer a promising approach for addressing neurodevelopmental disorders caused by haploinsufficiency. Our preliminary data suggest that the CRISPRa tools

holds significant potential for upregulating gene expression. Combining transcriptional and post-transcriptional gene modulation to restore protein levels in *STX1B*-related synaptopathies may establish a foundation for future therapeutic developments.

P24.019.D Absence of neurological manifestations in triple knock-out mice model of Tay-Sachs disease

Selman Yanbul, *Tufan Utku Çalışkan, Mustafa Can Turali, Volkan Seyrantepe*

Izmir Institute of Technology, Izmir, Turkey.

Background: Tay-Sachs disease is a lysosomal storage disorder resulting from mutations in the *HEXA* gene encoding the α subunit of lysosomal ß-hexosaminidase A enzyme that hydrolyzes GM2 to GM3 ganglioside. *Hexa-/-Neu3-/-* mice show the clinical manifestations of early-onset Tay-Sachs disease, including shortened lifespan, abnormal GM2 accumulation, neuroinflammation, neurodegeneration, and cognitive and motor function deficits. *B4Galnt1* gene encodes Beta-1,4-N-acetyl-galactosaminyltransferase-1 enzyme that facilitates the transfer of GalNAc to GM3 and GD3 to produce GM2 and GD2, respectively. In this study, we aimed to explore the neurological courses of *Hexa-/-Neu3-/-* mice by eliminating the *B4Galnt1* gene in triply-deficient mice.

Material and Methods: The cortex and cerebellum brain regions of 5-month-old *WT*, *Hexa-/-*, *B4Galnt1-/-*, *Hexa-/-Neu3-/-*, and *Hexa-/-Neu3-/-B4Galnt1-/-* mice were analyzed for neuronal death, astrogliosis and microgliosis using immunohistochemical stainings, ganglioside levels using thin-layer chromatography, and neuroinflammation-related gene expression levels using qRT-PCR.

Results: We found a significantly reduced neuronal death in *Hexa-/-Neu3-/-B4Galnt1-/-* mice compared to *Hexa-/-Neu3-/-* mice. We showed that excessive GM2 accumulation is absent in *Hexa-/-Neu3-/-B4Galnt1-/-* mice. We determined that elevated expression levels of neuroinflammation-related genes in *Hexa-/-Neu3-/-* mice were decreased in *Hexa-/-Neu3-/-B4Galnt1-/-* mice. Immunohistochemical stainings also revealed that activated astrogliosis and microgliosis in *Hexa-/-Neu3-/-* mice were notably reduced in *Hexa-/-Neu3-/-B4Galnt1-/-* mice.

Conclusion: Our study indicates that eliminating the *B4Galnt1* gene in *Hexa-/-Neu3-/-* mice rescues the neuroinflammatory and neurodegenerative symptoms of the disease. Our findings propose that the *B4Galnt1* gene might be a therapeutic target for treating Tay-Sachs patients in the future.

P24.020.A Intracerebroventricular administration of yeast-produced human recombinant lysosomal β-Hexosaminidase partially corrects GM2 ganglioside accumulation in the Tay-Sachs mouse model

Orhan Kerim INCI[1], *Andrés Felipe Leal*[2], *Angela Johana Espejo-Mojica*[3], *Carlos Javier Alméciga-Díaz*[3], *Volkan Seyrantepe*[1]

[1]*Izmir Institute of Technology, Izmir, Turkey,* [2]*Nemours Children's Health, Wilmington, DE, USA,* [3]*Pontificia Universidad Javeriana, Bogota, Colombia.*

Background: Tay-Sachs disease is a rare lysosomal storage disorder caused by mutations in the *HEXA* gene encoding α-subunit of β-Hexosaminidase A, leading to GM2 ganglioside accumulation in the central nervous system. Abnormal GM2 ganglioside accumulation causes neuropathology and leads to premature cell death in Tay-Sachs patients. Multiple therapeutical strategies have been investigated, including enzyme replacement therapy for TSD; however, there is still no effective cure (1). Previously, the efficacy of human recombinant lysosomal β-Hexosaminidases (rhHex-A) produced in yeast *P.pastoris* has been investigated in patient's fibroblasts (2). Here, we aim to explore the therapeutic potential of intracerebroventricularly (ICV) administered yeast-produced rhHex-A in a validated mouse model of Tay-Sachs disease (*Hexa-/-Neu3-/-*).

Material and Methods: The enzymatic activity of rhHex-A was measured in *Hexa-/-Neu3-/-* brain to determine its half-life. Thin-layer chromatography (TLC) and RT-PCR analysis and immunofluorescence (IF) staining with anti-GM2 / anti-LAMP1 were performed to show whether ICV-administered rhHex-A affects the GM2 accumulation and neuroinflammation in the cortex and cerebellum.

Results: TLC analysis and IF staining showed that rhHex-A administration reduced accumulated GM2 gangliosides in the cortex and cerebellum but did not extend the lifespan of the TSD mouse model. On the other hand, RT-PCR and IF staining demonstrated that rhHex-A prevents the elevated expression levels of neuroinflammation-related genes associated with astrogliosis and microgliosis.

Conclusion: Our results suggest that rhHex-A produced in yeast is functional in degrading accumulated GM2 ganglioside. However, multiple ICV administrations might be necessary to improve the neuropathology and extend the lifespan of the TSD mouse model.

P24.022.C Offering expanded carrier screening (ECS) in the UK: do professional and policy stakeholders think it is worthwhile?

Cathy Herbrand[1], *Pascal Borry*[2], *Lorraine Culley*[1], ***Kriss Fearon***[1], *Nicky Hudson*[1], *Sarah Norcross*[3], *Bronwyn Parry*[4], *Zofia H. Miedzybrodzka*[5], *Eva van Steijvoort*[2]

[1]*De Montfort University, Leicester, United Kingdom,* [2]*KU Leuven, Leuven, Belgium,* [3]*Progress Educational Trust, London, United Kingdom,* [4]*Australia National University, Canberra, Australia,* [5]*University of Aberdeen, Aberdeen, United Kingdom.*

Background: Expanded carrier screening (ECS) can identify, before conception, whether people with no known risk may pass on pathogenic variants to their children. Despite its increasing use in the UK, mostly in the private sector, there remains a lack of data and limited debate regarding the potential implementation of ECS. The aim of this study was to explore the views of key health professionals, policy experts and commercial providers on the current UK ECS offerings.

Material and Methods: Semi-structured interviews were conducted over 18 months (August 2023 - January 2025) with a purposive sample of key stakeholders with a remit or interest in providing or regulating reproductive genomic testing. Interviews were analysed with Thematic Analysis.

Results: Our study sample comprised 33 participants: 9 policy, 16 clinical and 7 commercial stakeholders. Two thirds of participants (24/33) believed ECS had significant benefits, including reducing transmission risks, increasing reproductive autonomy; and as a defence against legal liability in the IVF sector, saying it should be available for purchase if couples wanted it. Six

participants (6/33) were neutral or undecided, saying it was complex to assess the value of ECS with inconsistencies across panels and without a proper cost-benefit analysis. Only three viewed ECS as having limited utility while criticising it for increasing demand for NHS genetics services.

Conclusion: Most stakeholders were positive about ECS value, when offered with adequate information and support. However, they reported a seeming lack of concern about these issues at the national level.

Grants: Economic and Social Research Council [ES/W012456/1]

P24.025.B Comprehensive microRNA-seq transcriptomic analysis of Tay-Sachs disease mouse neuroglia revealed distinct miRNA profiles

Beyza Kaya[1], *Mehmet Emin Orhan*[2], *Seçil Akyıldız Demir*[1], *Selman Yanbul*[1], *Müşerref Duygu Saçar*[2], *Volkan Seyrantepe*[1]

[1]*Izmir Institute of Technology, Izmir, Turkey,* [2]*Abdullah Gül University, Kayseri, Turkey.*

Background: Tay-Sachs disease is a rare lysosomal storage disorder that results in the progressive accumulation of GM2 predominantly in the central nervous system due to mutations in the *HEXA* gene encoding the α subunit of the ß-Hexosaminidase A enzyme. The mouse model of Tay -Sachs disease (*Hexa-/-Neu3-/-)* exhibited neurodegeneration and neuroinflammation along with the expression of pro-inflammatory cytokines and chemokines, severe astrogliosis, and microgliosis. Here, we aim to get more insight into the disease pathology by investigating whole miRNA profiles in *Hexa-/-Neu3-/-* neuroglia.

Material and Methods: Next-generation sequencing is used to assess the entire miRNA profile of *Hexa-/-Neu3-/-* neuroglia. 1966 mouse miRNAs were screened to detect differentially expressed miRNAs. These miRNAs and their targets were identified by comparative analysis of KEGG and REACTOME-enriched pathways.

Results: We identified for the first time that significantly upregulated miR-708-5p, miR-672-5p, miR-204-5p, miR-335-5p, and miR-296-3p; downregulated miR-10b-5p, miR-615-3p, miR-196a-5p, miR-214-5p, and miR-199a-5p among 174 differentially expressed miRNAs in *Hexa-/-Neu3-/-* neuroglia compared to age-matched *WT* neuroglia. Gene enrichment analysis revealed that several target genes are implicated in key pathways related to the neuronal system, neuroinflammation, and sphingolipid metabolism associated with the pathogenesis of Tay-Sachs disease.

Conclusion: We explored up- and down-regulated miRNAs that might be associated with the neuropathological manifestations of the disease in Hexa-/-Neu3-/- mice. Our results suggest that miRNA-based therapeutic approaches could be used to improve the clinical status of Tay-Sachs disease patients.

P24.026.C A functional and molecular approach to address the heterogeneity of the response to CFTR modulators of the N1303K variant

Ludovica Menta[1], *Cristina Pastorino*[2], *Emanuela Pesce*[1,2], *Mariateresa Lena*[1], *Valeria Capurro*[2], *Serena Cappato*[2], *Federico Zara*[1,2], *Nicoletta Pedemonte*[2], *Renata Bocciardi*[1,2]

[1]*Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Sciences (DINOGMI), University of Genoa, Genoa, Italy,* [2]*Medical Genetics Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy.*

Background: Cystic fibrosis (CF) is a common genetic disorder caused by loss-of-function variants in the *CFTR* gene. CFTR modulators have been developed to correct CFTR defects and are approved for specific genotypes. The N1303K variant, the second most common CF-causing variant among Italian CF patients, exhibits trafficking and gating defects with variable response to modulators, allowing categorization into different groups based on drug response. Considering this variability, we aimed at investigating the molecular basis underlying these diverse responses to modulators of the N1303K variant.

Material and Methods: We performed a qualitative and quantitative evaluation (qPCR) of *CFTR* expression in N1303K-carrying epithelia differentiated from human nasal cells of CF and control individuals. A preliminary bulk RNA sequencing study has been also applied to selected samples.

Results: We found that *CFTR* mRNA levels are similar in all the controls and N1303K samples, except for a CF sample homozygous for the variant, which showed high basal activity further increased upon modulators treatment for which a deep molecular characterization is ongoing. Moreover, an integration of *locus*-specific expression data with the results of RNAseq analysis is also ongoing.

Conclusion: We have previously demonstrated that N1303K epithelia show different sensitivity to CFTR modulators and that this is due to intrinsic features of the epithelia. To address the molecular basis of such variability, we provided a quantitative and qualitative profile of *CFTR* expression in such samples. Our study may guide the development of novel pharmacological approaches for CF patients carrying the N1303K variant, currently lacking effective therapies.

P24.027.D Potential benefit of biotin treatment in *HSPD1* related disorders

Magnús I. Birkisson[1], *Kristján A. Ragnarsson*[1], *Eirný Þ. Þórólfsdóttir*[1], *Gloria García*[1], *Svanborg Gísladóttir*[1], *Vigdis Stefansdottir*[1], *Jon J. Jonsson*[2], *Hans T. Bjornsson*[3]

[1]*Dept. of Genetics and Molecular Medicine, Landspitali University Hospital, Reykjavík, Iceland,* [2]*Dept. of Genetics and Molecular Medicine, Landspitali University Hospital & Dept. of Biochemistry and Molecular Biology, Faculty of Medicine, Univ. of Iceland, Reykjavík, Iceland,* [3]*Dept. of Genetics and Molecular Medicine, Landspitali University Hospital & University of Iceland, Reykjavik, Iceland.*

Background: In 2004, a one-year-old boy presented with gastroenteritis, vomiting, lethargy and failure to thrive. Metabolic analysis of urine organic acids suggested holocarboxylase synthetase deficiency (HLCSD). Treatment with biotin commenced and symptoms improved, supporting working diagnosis of HLCSD. Patient later regressed and currently has severe intellectual disability, autism, epilepsy, and spastic paraplegia. Patient is fed through a g-tube and confined to wheelchair. Negative family history. Genetic re-evaluation was performed in 2023.

Material and Methods: Genomic trio-DNA was extracted from peripheral blood and sent to a reference laboratory for whole-exome sequencing.

Results: A de novo heterozygous likely pathogenic variant in *HSPD1* (NM_002156.5:c.1231G>C p.(Asp411His)) was detected. No pathogenic variants detected in *HLCS*.

Conclusion: The HLCSD working diagnosis was refuted. *HSPD1* is associated with autosomal recessive hypomyelinating leukodystrophy-4 (HLD4, OMIM #612233) and autosomal dominant spastic paraplegia-13 (OMIM #605280), with HLD4 being a better fit for the patient. The encoded protein of *HSPD1*, HSP60, forms a double-ring assembly of heptameric subunits. A dominant-negative effect could therefore explain the patients´ genotype-phenotype. Prior testing had shown heterozygosity for a *BTD* variant with 50% residual activity, and plasma biotinidase activity was 65% of normal median value. The possible contribution of the *BTD* variant on the patient's phenotype is unclear. According to published in vitro research, knockdown of HSP60 resulted in a 60% increase in reactive oxygen species levels which was ameliorated with biotin. This data supports the observed clinical improvement in the patient following biotin treatment. Further research on biotin therapy in *HSPD1* related disorders is warranted.

P24.028.A Biomarkers for hereditary transthyretin amyloidosis: a longitudinal study in Bulgarian Glu89Gln carriers

Slavko Ormandzhiev[1], *Zornitsa Pavlova*[1], *Tihomir Todorov*[1], *Teodora Chamova*[2], *Ognian Asenov*[3], *Vanyo Mitev*[4], *Ivailo Tournev*[2,5], *Albena Todorova*[1,6]

[1]*IMDL Genome Centre Bulgaria, Sofia, Bulgaria,* [2]*Clinic of Neurology, University Hospital Aleksandrovska, Medical University, Sofia, Sofia, Bulgaria,* [3]*Department of Neurology, University hospital "Alexandrovska", Medical University-Sofia, Sofia, Bulgaria, Sofia, Bulgaria,* [4]*Medical Faculty, Medical University of Sofia, Sofia, Bulgaria,* [5]*Department of Cognitive Science and Psychology, New Bulgarian University, Sofia, Sofia, Bulgaria,* [6]*Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Sofia, Bulgaria.*

Background: Hereditary transthyretin amyloidosis (ATTRv) is an autosomal dominant genetic disorder caused by pathogenic missense variants in the *TTR* gene, leading to formation of transthyretin amyloid fibrils. Clinical phenotypes vary from progressive sensorimotor and autonomic neuropathy to infiltrative cardiomyopathy.There is a Bulgarian endemic region with a high *TTR* pathogenic variant frequency c.325G>C, p.Glu109Gln (Glu89Gln) (a rare founder pathogenic variant).Neurofilaments (NFs) are found in large quantities in axons in the central and peripheral nervous system.The ubiquity of NFs in axons explains their elevated release following axonal damage by neurodegenerative processes. However, the accuracy of NfL has never been studied in detail in *TTR* mutation-specific cohorts.

Material and Methods: Serum levels of NfL will be measured five times over a 12-month period in asymptomatic Glu89Gln carriers and stage 1 polyneuropathy ATTRv Glu89Gln patients.Proximity Extension Assay, offered by Olink, combines DNA-based and antibody-based techniques for precise protein biomarker detection. The high-performance Olink Target 96 Neuro Exploratory protein biomarker panel will be used for this analysis.

Results: At the time of writing, 136 samples from 31 symptomatic patients were analyzed, with concentrations of NfL varying between ~1 pg/mL and ~180 pg/mL. The final cohort will consist of ~100 participants (patients and asymptomatic carriers), and all data needs to be collected, in order to be statistically analyzed.

Conclusion: ATTRv is highly prevalent in Bulgaria, which requires reliable diagnostics with practical applicability. The implementation of new reliable biomarkers for the prognosis and monitoring of ATTRv will enable more precise disease management and treatment evaluation.

P25 Genetic Counselling/Services/Education

P25.001.B Building relationships and collaboration in genomic medicine

Trang T. Do[1,2,3], *Melissa Martyn*[1,2,3], *Alison McEwen*[4], *Clara Gaff*[2,3,1], ***Belinda Dawson McClaren***[1,2,3]

[1]*Murdoch Children's Research Institute, Melbourne, Australia,* [2]*Melbourne Genomics Health Alliance, Melbourne, Australia,* [3]*The University of Melbourne, Melbourne, Australia,* [4]*University of Technology Sydney, Sydney, Australia.*

Background: Relationships are foundational to effective implementation and are critical to scale up genomic healthcare. This study explores relational interactions at intra- and inter- professional levels among genetic counsellors, physicians, and other non-genetic health professionals working in innovative models of mainstream genomic care.

Methods: Qualitative interviews were conducted with 29 participants: 8 physicians, 16 genetic counsellors, and 5 nurses/allied health professionals across 7 medical specialties within a publicly funded health system in Australia. Data analysis was guided by Relational Theory and the Theoretical Model for Trusting Relationships and Implementation.

Results: Participants described technical strategies to build rapport and trust via *'frequent interactions'*, such as increasing physical presence in clinics or engaging in corridor conversations about practice. GCs used co-counselling appointments with physicians to *'demonstrate expertise'* in consent discussions and counselling. Co-learning across disciplines was facilitated by relational strategies of *'empathy'* and *'authenticity'*. These strategies applied when participants' were identifying their own knowledge and practice gaps, recognizing the contribution of their colleagues to support them to improve their practice. More knowledgeable or skilled participants showed empathy to colleagues by partnering with them, being willing to share skills and knowledge, and ensuring colleagues were aware of relevant genomics education resources and activities.

Conclusion: Positive collaborations needed to scale up genomic healthcare can be achieved by leveraging technical and relational strategies with the inter-related components of the Model reinforcing one another. Variations in implementation outcomes of mainstream models may be explained by the adoption of these strategies.

P25.002.C How can clinical genetic services support 'mainstreaming' of genomics? Insights from the 10-year Melbourne Genomics program

Melissa Martyn[1,2,3], *Amy Clarke*[2,1], *Kirsty Beves*[1], *Belinda McClaren*[1,2,3], *Lisette Curnow*[4], *Catherine Beard*[5,6], *Zayne D'Crus*[2], *Cate Kelly*[2,6], *Clara Gaff*[2,1,3]

[1]*Murdoch Children's Research Institute, Parkville, Australia,* [2]*Melbourne Genomics Health Alliance, Parkville, Australia,* [3]*University of Melbourne, Department of Paediatrics, Parkville, Australia,* [4]*Victorian Clinical Genetics Services, Parkville, Australia,* [5]*Genomic Medicine and Parkville Familial Cancer Centre, Parkville, Australia,* [6]*University of Melbourne, Department of Medicine (RMH), Parkville, Australia.*

Background: The benefits of genomics are evident across a growing number of medical specialties. For patients to realise these benefits, genomics must be provided within each speciality ('mainstreaming') and not solely through clinical genetics. Melbourne Genomics Health Alliance has run a 10-year systems change program to support integration of genomics into healthcare in Victoria, Australia. Clinical genetic services have played a critical role in the program; as it draws to a close, there is a need to capture practical lessons learnt as a tool for clinical genetic services to inform future mainstreaming efforts in a range of healthcare contexts.

Methods: We took an interpretive description approach to identify how genetic services can support mainstreaming. Data sources from across the program were critically reviewed, drawing on selected models and theories of change (COM-B, diffusion of innovation) and applying a complexity lens. Iterative rounds of synthesis and validation with clinical genetic services are underway to ensure utility of final results.

Results: Two broad models (interdependent, independent) have been identified for delivery of genomic care by other specialist services, along with three types of supports needed for quality care: access to expertise; point of care resources; guardrail mechanism. Influences on model selection and what helps and hinders to embed genomics in medical specialty care are being verified.

Conclusion: Clinical genetic services are crucial in the ongoing 'mainstreaming' of genomics. This synthesis will ensure lessons from a coordinated systems change program can be practically applied in the future across diverse healthcare contexts.

P25.003.D The integration of genetic counsellors as a priority: a new model for Genetics healthcare provision in Portugal

Catarina Costa[1], *Lídia Guimarães*[1,2,3], *Ruxanda Lungu*[1], *Marina de Serra Lemos*[1,4], *Luís Azevedo*[5,6], ***Milena Paneque***[1,2,7]

[1]*i3S-Institute for Research and Innovation in Health, University of Porto, Porto, Portugal,* [2]*ICBAS-School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal, Porto, Portugal,* [3]*AAJUDE – Associação de Apoio à Juventude Deficiente, Porto, Portugal, Porto, Portugal,* [4]*CPUP-Center for Psychology, University of Porto, Porto, Portugal, Porto, Portugal,* [5]*MEDCIDS-Department of Community Medicine, Health Information and Decision Sciences, Faculty of Medicine, University of Porto, Porto, Portugal, Porto, Portugal,* [6]*CINTESIS@RISE-Center for Health Technology and Services Research, University of Porto, Porto, Portugal, Porto, Portugal,* [7]*CGPP-Center for Predictive and Preventive Genetics, University of Porto, Porto, Portugal, Porto, Portugal.*

Background: In the last decades, technological developments lead to significant advancements in Genetics. In Portugal, serious limitations persist, compromising the functioning of genetic healthcare, including a shortage of trained professionals, limited infrastructure, and inadequate integration of services into routine healthcare. This study aimed to promote discussion among medical geneticists' professionals, to outline concrete actions to address gaps in healthcare provision.

Material and Methods: Three focus groups were conducted with 19 specialists in medical genetics. The data were analyzed using the thematic analysis to extract the main themes from the discussions.

Results: Four conceptual themes emerged: (i) framing Portuguese genetic services within the European context; (ii) improving of medical genetics education and population literacy; (iii) transforming of medical genetics services; and (iv) operationalizing the change. The results demonstrated that enhancing training resources and strengthening multiprofessional teams is viewed as a way to improving the responsiveness of genetic services. The integration of genetic counsellors was identified as a top priority and a visionary step toward improving the overall healthcare system in the country, ensuring a more personalized and accessible service for individuals with genetic conditions. Integrating medical genetics into all specialties and primary care, as well as updating the national network of medical genetics, were also identified as critical areas for improvement.

Conclusion: A new care model with a multidisciplinary and collaborative approach within healthcare teams is necessary in Portugal. The findings have been compiled into recommendations to inform urgent decisions surrounding the implementation of structural changes in Portuguese genetics services.

P25.004.A Direct letters to relatives at risk of hereditary cancer - A multi-center randomized trial on healthcare-assisted versus family-mediated risk disclosure (DIRECT-study)

Hans Ehrencrona[1,2], *Anna Öfverholm, MD, PHD*[3], *Carolina Hawranek*[4], *Lovisa Lovmar*[5], *Sara Svensson*[1,2], *Sigrid Wennstedt*[6,7], *Barbro N. Hellquist*[4], *Anna Rosén*[4]

[1]*Section for Clinical Genetics, Dept of Clinical Genetics, Pathology and Molecular Diagnostics, Region Skåne, Lund, Sweden,* [2]*Division of Clinical Genetics, Department of Laboratory Medicine, Lund University, Lund, Sweden,* [3]*Department of Oncology, Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Göteborg, Sweden,* [4]*Department of Diagnostics and Intervention, Oncology, Umeå University, Umeå, Sweden,* [5]*Department of Clinical genetics and genomics, Sahlgrenska University Hospital, Göteborg, Sweden,* [6]*Department of Medical Biosciences, Umeå University, Umeå, Sweden,* [7]*Department of Clinical Microbiology, Umeå University, Umeå, Sweden.*

Background: Risk-reducing programs for hereditary breast and ovarian cancer (HBOC) and Lynch syndrome can reduce cancer morbidity and mortality in at-risk relatives. Observational studies suggest that direct contact from healthcare may increase genetic counseling (GC) uptake as compared to family-mediated risk disclosure, but randomized trials are lacking. This randomized controlled trial assessed whether direct contact via letters to at-risk relatives increases GC uptake compared to family-mediated communication alone.

Material and Methods: Between 2020–2023, HBOC or Lynch syndrome patients were randomly assigned to family-mediated disclosure (control) or family-mediated disclosure plus the offer of sending direct letters to at-risk relatives (intervention). The primary outcome was GC uptake within 12 months, measured as the

proportion of eligible relatives at risk contacting a Swedish cancer genetics clinic.

Results: A total of 165 families (median: 4 eligible relatives, range: 1–26) were randomized to control (n = 79) or intervention (n = 86). GC uptake was 67% in controls and 71% in the intervention group ($P = .23$). After adjusting for predefined variables and co-variates, there was still no significant difference between groups (OR 1.24, CI 0.79–1.95, $P = .34$). Distant relatives had lower uptake than first-degree relatives (OR 0.27, CI 0.18–0.40, $P < .001$), while female relatives had higher uptake than males (OR 2.17, CI 1.50–3.12, $P < .001$).

Conclusion: In this randomized controlled trial, GC uptake exceeded 65% in both groups. The intervention of direct letters did not show superiority over family-mediated communication alone.

P25.005.B How do genomic multidisciplinary teams foster collaboration, enabling genetic mainstreaming and precision medicine?

Alan Shui Lun Ma[1,2,3], *Katherine Mai*[1,3], *Timothy Newing*[2], *Rosie O'Shea*[2,3], *Bruce Bennetts*[1,2,3], *Gladys Ho*[1,2], *Nicole Rankin*[4], *Robyn Jamieson*[1,2,3]

[1]*Sydney Children's Hospitals Network, Sydney, Australia,* [2]*University of Sydney, Sydney, Australia,* [3]*Sydney Health Partners, Sydney, Australia,* [4]*University of Melbourne, Melbourne, Australia.*

Background: Growing demand for genomics in many subspecialties of medicine has led to massive challenges in service provision, education and upskilling for non-genetics clinicians. The Sydney Children's Hospitals Network established Paediatric genomic multidisciplinary team (MDT) meetings to address this increased demand for genomic testing, and facilitate mainstreaming. This MDT approach has been successful in genomic mainstreaming over 2000 patients since 2020 into paediatrics and subspecialties such as obstetrics, neurology and oncology.

Material and Methods: Mixed methods qualitative research was undertaken to understand the impact of the genomic MDT on adoption of genomics. Guided by the implementation science based Genomic Medicine Integrative Research and Theoretical Domains Frameworks, we designed surveys to understand the barriers and enablers to mainstreaming in the MDTs. Additionally, focus groups were arranged to explore the sustainability and feasibility of the MDT approach.

Results: 33 survey responses, from clinical genetics and 6 paediatric subspecialities, revealed that 74% agreed the MDT facilitated a genetic diagnosis. Most had incorporated MDTs into standard practice, using them for testing, results, and management discussions. Focus groups highlighted cross-disciplinary collaboration and facilitating mainstreaming in a safe environment as key MDT enablers. Sustainability barriers included the lack of administrative support, time, and the need for MDTs to adapt to clinicians' needs as they upskill in genomics.

Conclusion: We have demonstrated the vital role of genomic MDTs in facilitating mainstreaming and upskilling in genomics for non-genetics clinicians. This study adds further qualitative evidence on the implementation barriers and enablers and sustainability issues for long term feasibility.

P25.006.C 'Choosing the main character'- Healthcare professionals' attitudes towards counselling patients about genetic cancer risk disclosure to relatives. An interview study in the Swedish mainstream testing era

Anna Öfverholm[1], *Matilda Liljedahl*[1], *Agnes Elmberger*[2], *Per Karlsson*[1], *Anna Rosén*[3]

[1]*Inst of Clinical Sciences, Dept of Oncology, Sahlgrenska Academy, Gothenburg University, Göteborg, Sweden,* [2]*Dept of Learning, Informatics, Management and Ethics, Karolinska institute, Stockholm, Sweden,* [3]*Dept of Diagnostics and Intervention, Oncology, Umeå University, Göteborg, Sweden.*

Background: Healthcare professionals and patients have a shared responsibility for at-risk relatives being informed about hereditary cancer risk. Genetic counselling practices are changing in Sweden as mainstream testing is implemented in cancer services, and the responsibility for relatives is not regulated in guidelines. This study aimed at investigating attitudes towards counselling patients about risk disclosure to relatives among both genetic and non-genetic healthcare professionals handling genetic test results at cancer and clinical genetics services in Sweden.

Material and Methods: A qualitative study with reflexive thematic analysis of fourteen semi-structured interviews with healthcare professionals.

Results: We present the results as four positions that healthcare professionals hold, and move between, depending on their attitudes towards counselling patients about risk disclosure to relatives. The positions vary in terms of if healthcare or the patient is percieved as ultimately responsible for relatives being informed, and if the healthcare professional's focus is on the patient or on the relative. The positions are visualised in a four-fielder: 1. 'The patient is my one and only interest: It´s clear and quite simple'. 2. 'The patient and I are allies: It´s a joint interest'. 3. 'The at-risk relative needs to know, but the patient is in charge: It´s out of my hands'. 4. 'The patient is a mean to reach the at-risk relative: It needs to be done'.

Conclusion: These results could serve as a basis for discussions on roles and responsibilities, moving towards a best practice for genetic risk communication and counselling in the mainstream testing era.

P25.008.A Unveiling decision-making and family communication of genetic information during and after genetic counseling: Preliminary results from a qualitative prospective diary study

Maria Barbosa[1,2,3], *Sandra Pinto da Silva*[4,5], *Danya Vears*[6,7,8], *Filipa Júlio*[9,10,11], *Angus Clarke*[12], *Alison Metcalfe*[13], *Jorge Sequeiros*[1,3,14], *Liliana Sousa*[4,5], *Célia Sales*[2], *Milena Paneque*[1,3,14], *Álvaro Mendes*[1,3]

[1]*i3S – Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal,* [2]*CPUP – Centre for Psychology at the University of Porto, FPCEUP – Faculty of Psychology and Educational Sciences, University of Porto, Porto, Portugal,* [3]*CGPP – The Centre for Predictive and Preventive Genetics, IBMC – Institute for Molecular and Cell Biology, University of Porto, Porto, Portugal,* [4]*Department of Education and Psychology, University of Aveiro, Aveiro, Portugal,* [5]*RISE-Health, University of Aveiro, Aveiro, Portugal,* [6]*Biomedical Ethics Research Group, Murdoch Children's Research Institute, Parkville, Australia,* [7]*Centre for Biomedical Ethics and Law, Department of Public Health and Primary Care, Leuven, Belgium,* [8]*Department of Paediatrics, University of Melbourne, Parkville,*

Australia, [9]European Huntington Association; and Portuguese Huntington Association, Lisboa, Portugal, [10]Faculty of Psychology and Educational Sciences, University of Coimbra, Coimbra, Portugal, [11]CIBIT – Coimbra Institute for Biomedical Imaging and Translational Research, University of Coimbra, Coimbra, Portugal, [12]Cardiff UniversityDivision of Cancer and Genetics, Cardiff, United Kingdom, [13]LOHA Health Ltd, London, United Kingdom, [14]ICBAS School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal.

Background: Family disclosure of genetic information is essential to allow at-risk relatives to make informed decisions about health management and life-planning. Yet, existing research is limited and mostly retrospective. Written diaries could provide prospective insight into family communication, exploring the decision-making process in this context. We aimed to explore consultands' experiences, perspectives and decision-making on family communication of genetic information, as they undergo genetic counseling (GC).

Material and Methods: As part of a prospective, multicenter, multi-method qualitative study, we used unstructured written diaries to examine decision-making trajectories related to family communication of genetic information. Participants included consultands undergoing predictive testing for autosomal dominant late onset neurological, cardiogenetic and oncogenetic conditions. From the first GC consultation until four weeks post-result disclosure, consultands recorded (paper or email) their reflections, feelings and decisions on family communication of genetic information. Diaries were transcribed and analyzed using thematic analysis.

Results: Of the 56 participants, 24 returned their diaries totaling 57 entries, which varied per consultand (M = 2.38; R = [1-14]). Preliminary analysis of the diary contents suggests that consultands mainly reported their (a) decision-making process surrounding disclosure, (b) family communication patterns on genetic information, (c) knowledge of the condition and their family history, and (d) daily living with familial risk.

Conclusion: To our knowledge, this study is the first to employ diaries to prospectively explore consultands' decisions on family communication of genetic information. Findings from this study may clarify what influences these decisions regarding family communication and inform the development of resources to facilitate them within GC.

P25.010.C Exploring individuals' experiences with self-reported unmet need for genetic testing

***Kennedy Borle**, Larry D. Lynd, Jehannine Austin*

University of British Columbia, Vancouver, BC, Canada.

Background: In practice, healthcare systems and insurers define "need" for genetic testing based on its potential clinical utility. However, it remains unclear how the public perceives the need for genetic testing and whether this aligns with clinical utility.

Material and Methods: We recruited Canadian participants through a survey distributed through a market research company. Participants who self-reported need for genetic testing on the survey were then purposively sampled to maximize diversity on the dimensions of race, province of residence, gender, and conditions of concern, to complete a semi-structured virtual interview. We used an interpretive description approach and reflexive thematic analysis.

Results: We completed 19 interviews and found that participants' self-identified need for genetic testing was informed by their experiences with genetic information, perceptions that genetic information is actionable (clinical utility) and that it has personal meaning (personal utility). Clinical genetic testing would not have been indicated for most participants based on their personal and family history; however, they had unmet informational and psychological needs, indicating unmet need for genetic counselling. Participants described that unmet expectations for genetic testing contributed to medical distrust and dissatisfaction.

Conclusion: Public understanding of need for genetic testing is complex and varied. Participants described many perceived benefits of genetic testing that are not reflected in how need is operationalized in reimbursement decisions.

P25.011.D The critical missing piece: hospital executive leadership in implementing genomic medicine

***Clara Gaff**[1,2,3], Cate Kelly[4,1], Trang Do[5], Amelia Rahardja[1], Zayne D'Crus[1], Kathryn Katie Arkell[6], Melissa Martyn[3,1,2], Belinda McClaren[3,2]*

[1]Melbourne Genomics Health Alliance, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Department of Paediatrics, Faculty of Medicine, Dentistry and Health Sciences, The University of Melbourne, Melbourne, Australia, [3]Murdoch Children's Research Institute, Parkville, Australia, [4]Department of Medicine (RMH), Faculty of Medicine, Dentistry and Health Sciences, The University of Melbourne, Melbourne, Australia, [5]Murdoch Children's Research Institute, Melbourne, Australia, [6]Murdoch Children's Research Institute, PARKVILLE, Australia.

Background: Effective, equitable genomic care requires systemic change, particularly as use of genomics expands beyond clinical genetic services. National strategies address policy and funding, but don't guide hospital executives in making the necessary organisation-wide changes for safe, high-quality care. Without this leadership, implementation will be fragmented and inequitable. No existing frameworks guide the effective use of genomics across a hospital. We aimed to fill this gap by developing a tool to support executive-led genomics implementation.

Methods: Using the Knowledge-to-Action framework, we conducted an iterative design process with 85 hospital executives and genomic experts (14+ organisations). A multidisciplinary group, including clinical-governance experts, developed a maturity assessment tool (MAT) for hospitals. After iterating at a stakeholder workshop, five diverse hospitals tested usability. The MAT was then distilled into key actions for executives, with co-designed resources to support these actions. The resulting 'Genomics and Your Hospital toolkit' is now live.

Results: Usability testing revealed challenges in assessing genomic maturity due to siloed activities, limited awareness of their scale, and a lack of collective approaches. Hospital leaders valued the opportunity to discuss genomics through the 'shared language' provided by the MAT but still needed help prioritising implementation efforts. Therefore, 7 actions for healthcare leaders formed the resulting toolkit which received 400+ views in its first 3 weeks and an average engagement time of 4.5 minutes (benchmark: 70–90 seconds).

Conclusion: Adopted by the Government insurer, the Genomics and Your Hospital Toolkit helps hospitals plan genomic implementation, supporting equity of access across a health system.

P25.012.A Strengthening collaborative networks between medical school and tertiary care hospitals for equitable diagnosis of rare diseases in rural areas of Thailand

Vitchayaporn Emarach Saengow[1], *Paneeta Punjunya*[1], *Boontharika Prachummeung*[1], *Duangrurdee Wattanasirichaigoon*[2], *Parith Wongkittichote*[2], *Thipwimol Tim-Aroon*[2]

[1]*Maharat Nakhon Ratchasima Hospital, Nakhon Ratchasima, Thailand,* [2]*Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

Background: In rural Thailand, rare disease diagnosis and treatment gaps arise from a shortage of pediatric geneticists. This results in healthcare inequities. A collaboration between Ramathibodi Hospital and Maharat Nakhon Ratchasima Hospital implemented the RARE for 9 and PED-GRIN models. This study evaluates their effectiveness in improving diagnosis and treatment outcomes in rural communities.

Material and Methods: From July 1 to December 31, 2023, we recruited patients under 18. Participants accessed a one-stop service clinic at Maharat Nakhon Ratchasima Hospital, which included genetic testing via whole genome sequencing (WGS). Pediatric geneticists from Ramathibodi Hospital provided supervision and consultation through an online platform (teleconsultation, PED-GRIN model) for WGS interpretation, clinical management and genetic counseling recommendation. Demographic data were recorded, and the benefits were evaluated by comparing the percentage of patients receiving diagnoses and precision medicine.

Results: A total of 266 patients aged 2 months −15 years were included; 80% were diagnosed with uncontrolled epilepsy. Genetic diagnostics were performed on 230 patients using WGS. Abnormalities were detected in 70% of WGS cases, 50% of targeted gene cases, and 16.6% of CMA cases. Precision medicine was administered to 50% of the patients, and the satisfaction rate among patients and caregivers exceeded 98%. Access to diagnosis increased by 30 times compared to the previous period before the establishment of the collaboration, with a diagnostic yield comparable to international studies.

Conclusion: The collaborative pathway enhances equity for patients with rare diseases in rural areas by improving access to timely diagnosis and effective treatment.

P25.013.B Unique Experiences. The lived experience of those affected by rare chromosome or gene disorders

Sarah L. Wynn*, Lauren Roberts, Charlotte Wilmshurst*

Unique - Rare Chromosome Disorder Support Group, Oxted, United Kingdom.

Background: Unique (a UK-based charity working internationally) provides support, information and advocacy to individuals and their families/carers affected by rare chromosome or gene disorders. A survey conducted May/June 2025 sought insights into the day-to-day lived experience of those affected by these rare conditions.

Material and Methods: An online survey consisted of a mix of open text, 5-point scales and multiple choice was shared via email and Unique's social media channels. The responses were anaylysed by both statistics and thematic analysis.

Results: 2,154 people completed the survey. The majority of respondents (81% / 1731) were mothers/stepmothers caring for someone with a rare chromosome or gene disorder suggesting a potential bias towards the maternal caring maternal caring experience. 5% (111) were from affected individuals. Lack of professional awareness, low public understanding, and struggles to access appropriate information and services results in high levels of anxiety (70%,1253/1801), frustration (60%, 1073/1801) and stress (60%, 1086/1801). Having, or caring for someone, with a rare chromosome or gene disorder can strengthen family relationships and bonds, however, living with constant uncertainty, and the complexities of care and managing the condition, often also impacts social networks and relationships resulting in feelings of isolation and loneliness.

Conclusion: Living with or caring for someone with a rare chromosome or gene disorders can create significant challenges all areas of life and life chances which places strain on individuals and families. However, families and individuals often become experts in their rare chromosome and gene disorder and are determined and powerful advocates.

P25.014.C A bespoke therapeutic counselling service for the Fragile X community

Victoria Arthur

Manchester foundation trust, Manchester, United Kingdom.

Background: Fragile X syndrome and associated conditions present unique emotional and psychological challenges for individuals and their families. Standardized counselling services often lack the specific genetic and psychosocial understanding required, leaving clients to spend significant time explaining Fragile X rather than focusing on their emotional needs. To bridge this gap, a bespoke therapeutic counselling service was developed in collaboration with the Fragile X Society. This service integrates genetic counselling with person-centred therapeutic support, ensuring that clients receive informed and empathetic care tailored to their lived experiences.

Material and Methods: The service, launched in August 2023, is led by a trained genetic counsellor and registered therapeutic counsellor (BACP). Sessions are delivered remotely via Zoom or telephone, making the service accessible across the UK. Clients include individuals with Fragile X syndrome, premutation carriers, and relatives. The service provides up to six 50-minute person-centred counselling sessions, focusing on emotional processing, adjustment, and coping strategies.

Results: Since inception, 16 individuals have accessed the service, each receiving an average of six sessions. Feedback has been overwhelmingly positive, with clients reporting significant improvements in anxiety, self-awareness, and relationships. One client noted, "For the first time in a long time, I know that it is possible for me to live a happy life not dictated by anxiety."

Conclusion: This innovative service demonstrates the need for integrated genetic and emotional support in rare disease communities. Challenges, including non-attendance and policy adaptation, are being addressed to ensure sustainability. The success of this model highlights the value of specialized therapeutic genetic counselling services.

P25.015.D Team Based Care Model for Evaluating and Counselling of Neurodivergent Children with Chromosomal Copy Number Variants of Uncertain Significance

Zhuo Shao[1,2], *Julia Su*[1], *Amy Sirkin*[1], *Ali Bashar*[3], *Melissa Cornthwaite*[1], *Giuseppe Latino*[1], *Marjan Nezarati*[4]

[1]*North York General Hospital, Genetics Program, Toronto, ON, Canada,* [2]*University of Toronto, Department of Pediatrics, Toronto, ON, Canada,* [3]*York University, Toronto, ON, Canada,* [4]*Mount Sinai Hospital, Toronto, ON, Canada.*

Background: Chromosomal microarray has been used as first-line genetic test for children with autism spectrum disorders (ASD), intellectual disability (ID), and developmental delay (DD). Variants of uncertain significance (VUS) are common findings. Despite the challenge with interpreting VUS, parents of children with ASD/ID/DD often value receiving these results and appreciate genetic counseling regarding their implications.

Material and Methods: A retrospective review was conducted on 177 charts of children seen at a general Genetics clinic in Toronto, Canada, between January 2013 and June 2022 with ASD/ID/DD and a microarray finding of VUS. We assessed the clinical impact of VUS findings and implemented a novel service delivery model involving a pediatrician and genetic counselor (GC) team. Patients with dysmorphic features or complex findings were referred to a geneticist for further evaluation and testing.

Results: Among the cases reviewed, 23.7% (42/177) had CNVs susceptibility locus for ASD/ID/DD, altering recurrence risk counseling. An additional 14.7% (26/177) were carriers of autosomal recessive conditions. Actionable follow-up recommendations, including specialist referrals, imaging, and laboratory tests, were made in 25.4% (45/177) of cases, with clinical or personal utility identified in 63.8% (113/177). Of the patients evaluated via the pediatrician/GC model (51.4%, 91/177), only 4.4% (4/91) required geneticist evaluation. High satisfaction was reported with the model in both in-person and virtual settings.

Conclusion: This is the first study to document the management impact of VUS on microarray in children with ASD/ID/DD. The pediatrician-GC team model is effective, enhances service delivery, and integrates genetics into primary pediatric care.

Bonn AoR, Bonn, Germany,* [20]*Radboud university medical center, Nijmegen, Netherlands.*

Background: *CDH1* inactivation causes Hereditary Diffuse Gastric Cancer (HDGC), characterized by early-onset gastric (GC) and breast cancers (BC). While intensive surveillance and risk-reduction gastrectomy and mastectomy prevent disease progression, the cumulative costs of HDGC healthcare management remain unexplored.

Methods: We analyzed 412 HDGC-*CDH1* cases from seven European countries (Portugal, Spain, France, Norway, Sweden, the Netherlands, Germany) from 2000–2023, including 232 pathogenic variant carriers (96M:136F) and 180 negative family members. The HDGC care pathway, developed through the PREVENTABLE EU project ((www.preventable.eu), includes specialized care routes, clinical trajectories, and healthcare costs. Cumulative cost data were calculated using Portugal's healthcare system pricing lists.

Results: Of 232 carriers, 172 (74%) followed prevention routes, while 60 (26%) required treatment due to 24 early-onset cancers (8 breast, 14 stomach, 2 both) or 36 advanced cancers (12 breast, 23 stomach, 1 both). Seventeen carriers died (15 stomach, 2 breast cancer), with median follow-up of 43 months for prevention, 76 for early-onset, and 24 for advanced cases. Prevention costs averaged €4,959 (range: €142-€28,533), while early and advanced cancer treatments were 2.7-fold (€13,456; range: €1,297-€26,121) and 4-fold higher (€20,130; range: €3,800-€71,256), respectively. Monthly costs for early (€1,087) and advanced cancer treatment (€1,226) were approximately 6-fold higher than prevention (€186). Total cumulative costs: €853,008 for prevention (172 patients) versus €1,047,615 for treatment (60 patients).

Conclusion: This first European cost analysis demonstrates that HDGC treatment costs exceed prevention costs, even when prevention covers a 3-fold larger population, providing economic evidence supporting early identification and preventive care for *CDH1* carriers.

P25.017.B Response factors for declining to participate in a large-scale genomic study: the potential role of the primary care physician in improving study participation

Richard John Presutti[1], *Adrianna D. Clapp*[1], *Robert A. Vierkant*[2], *Jewel J. Samadder*[3], *Isa J. Houwink*[4], *Teresa Kruisselbrink*[5], *Margaret L. Barnhorst*[6], *Shaylee Befus*[7], *Michelle L. Bublitz*[4], *Richard Sharp*[4], *Sebastian M. Armasu*[4], *Tammy M. McAllister*[4], *Konstantinos N. Lazaridis*[4]

[1]*Mayo Clinic, Jacksonville, FL, USA,* [2]*Mayo Clinic, Rocheester, MN, USA,* [3]*Mayo Clinic, Phoenix, AZ, USA,* [4]*Mayo Clinic, Rochester, MN, USA,* [5]*Helix, Minneapolis, MN, USA,* [6]*Georgetown School of Medicine, Washington, DC, USA,* [7]*Jacksonville University, Jacksonville, FL, USA.*

Background: The future of medicine relies on individualized care based on the patient's genomic and exposomic factors. Despite the promise of genetic screening in improving health outcomes, many patients are hesitant to participate in genomic research. Primary care physicians (PCPs) play a crucial role in educating patients about genomics. This study aims to understand why patients decline participation in a large-scale study offering whole exome sequencing.

Materials and Methods: From January 2020 to May 2024, patients over 18 years old were invited via electronic messaging to participate from Mayo Clinic's campuses in Minnesota, Florida and Arizona. The study aimed to reach at least 100,000 consented participants. Those who declined were asked to select specific reasons and/or provide additional responses in free text. Data collected included age, gender, race, ethnicity, rural/urban area, and whether the patient had a PCP.

Results: Of the first 545,196 invited participants, 38,088 consented (64.7% women) and 12,705 actively declined (57.4% women). Those actively declining were 90.1% white and an average age of 61 years. Patients with a PCP were more likely to cite Electronic Health Record concerns and discomfort with research as reasons for declining ($p < 0.01$), suggesting that discussions with PCPs could address these barriers. Lack of a PCP was associated with a perception of no benefit in participation ($p < 0.01$). Older patients perceived less benefit from participating ($p < 0.01$).

Conclusion: While understanding the human genome holds great promise, barriers to research participation exist. PCPs can play an important role in patient education.

Diagnostik GmbH, Ingelheim, Germany.*

Background: In June 2024, the German Society of Human Genetics (GfH) established a Commission for Genetic Counsellors (GCs) with 86% member approval, marking a significant step for the genetic counselling profession in German-speaking countries (Germany, Austria, and Switzerland; D-A-CH). This specialized committee aims to advance the genetic counsellor profession, influence policy, and drive improvements in the field.

Material and Methods: An online workshop was conducted to define the commission's key goals, involving 85 participants from genetic centres across D-A-CH, including a comprehensive representation of German-speaking GCs and medical geneticists. The event comprised introductions of commission members, presentations, and open discussions engaging participants in a structured process to identify key priorities for future initiatives.

Results: The GfH GC commission's primary goal is to create the prerequisites for the legal recognition and effective integration of GCs into clinical-genetic services in the D-A-CH region. Responding to the increasing need for more trained professionals, standardized education aligned with the European core curriculum and internationally defined responsibilities and competencies for GCs. Seven major goals were defined and reflected in the statute of the GfH Commission for GCs.

Conclusion: Through a collaborative, international workshop involving a diverse group of GCs and medical geneticists from the D-A-CH region, the commission successfully defined strategic goals for its work. This consensus-driven approach identified the most critical requirements for the full integration of GCs into medical genetic services across the D-A-CH countries, providing a robust framework for future development and implementation of the GC profession.

P25.019.D Polygenic risk in practice: An evaluation of genetic health care providers' learning needs and preferences

Jennifer Berkman[1], *Amy Clark*[1], *Courtney K. Wallingford*[1], *Amy Nisselle*[2], *Bronwyn Terrill*[3], *Mary-Anne Young*[3], *Paul James*[4], *Aideen McInerney-Leo*[1], *Tatiane Yanes*[1]

[1]*The University of Queensland, Brisbane, Australia,* [2]*Murdoch Children's Research Institute, Parkville, Australia,* [3]*Garvan Institute of Medical Research, Sydney, Australia,* [4]*Peter MacCallum Cancer Centre, Melbourne, Australia.*

Purpose: Polygenic risk scores (PRS) provide an estimate of the genetic contribution to health conditions. Genetic health professionals (GHPs) report they do not have the knowledge and skills required for using PRS, representing a barrier to testing implementation. This study aimed to explore GHP learning needs and identify strategies to promote engagement in PRS education.

Methods: Australian and USA-based GHPs with prior experience in PRS use were eligible to participate in focus groups/interviews ($n = 30$), which were transcribed and analysed using content analysis. Interview guide and collected data were mapped to the COM-B model of behaviour change to identify target areas for intervention.

Results: All GHPs felt motivated to pursue PRS education due to a belief it would optimise patient care and ensure they met professional standards. Reported learning needs included key PRS concepts, result interpretation and effective patient communication. However, there was variability in the amount of PRS knowledge that GHPs felt was necessary to integrate testing into clinical practice, highlighting the need for modular programs to

address specific learning needs. GHPs reported that PRS training opportunities and protected time for attendance would increase capability. A need for clinical guidelines was identified as an area of priority to facilitate GHPs' use of PRS. Opportunities to support PRS use included quick reference resources, embedded practice models such as multidisciplinary teams and strategic support.

Conclusion: Our data highlights the complexity of PRS education and will be used to support delivery of targeted PRS educational materials as part of a broader implementation strategy.

P25.020.A Navigating the unknown: a qualitative study of parental responses to a prenatal genetic mosaicism result

Johanne Farø[1], *Simon Horsholt Thomsen*[1,2,3], *Ingeborg Rytter Stenstrup*[1,4], *Ida Vogel*[1,2,5], *Stina Lou*[1,4]

[1]*Center for Fetal Diagnostics, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,* [2]*Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark,* [3]*Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark,* [4]*DEFACTUM – Public Health Research, Central Denmark Region, Aarhus, Denmark,* [5]*Department of Gynaecology and Obstetrics, Aarhus University Hospital, Aarhus, Denmark.*

Background: Prenatal detection of placental mosaicism challenges genetic counseling, as predicting fetal involvement and clinical impact is difficult. This creates a complex situation for expectant parents, who must manage uncertainty and waiting time for diagnostic results and pregancy outcomes. This study explores the experiences and counseling needs of parents who were prenatally diagnosed with confined placental mosaicism and chose to continue pregancy.

Material and Methods: An exploratory, qualitative study design was used based on semi-structured interviews. Participants were recruited from two Departments of Clinical Genetics. Fourteen interviews were conducted six months postpartum, recorded, and transcribed verbatim. Data were analyzed using reflexive thematic analysis.

Results: The diagnosis of confined placental mosaicism introduced unexpected uncertainty, significantly impacting the parents' daily lives. Following genetic counseling, many struggled with the lack of clear answers. Nonetheless, most found the consultation reassuring, offering hope despite the ongoing uncertainty, which included worry about the future, fear of losing the child or undergoing a late-term abortion. During pregnancy, parents used coping strategies, such as avoidance or seeking support from their closest relationships. After birth, worry decreased remarkably. However, two couples decided not to have more children, fearing they might face a similar experience again.

Conclusion: A diagnosis of confined placental mosacism creates uncertainty among parents, emphasizing the need for specialized genetic counseling. At the time of the conference, specific suggestions for enhancing genetic counseling will be presented.

P25.021.B Collective decision process on counselling for recessive syndromes in genes predisposing to solid tumors

Sanz Judit[1], ***Nuria Dueñas***[2,3,4], *Carrasco Estela*[5], *Ana Raquel Jimenez*[6], *Lorena Moreno*[7], *Elia Grau*[7], *Marta Pineda*[2,4], *Catalan working group on Hereditary Cancer Predisposition Syndromes*[8]

[1]*Hereditary Cancer Program, Althaia Xarxa Assistencial Universitària de Manresa, Manresa, Spain,* [2]*Hereditary Cancer Program, Catalan Institute of Oncology (ICO), l'Hospitalet de Llobregat, Spain,* [3]*Hereditary Cancer Program, Catalan Institute of Oncology (ICO), Girona, Spain,* [4]*Hereditary Cancer Group, Molecular Mechanisms and Experimental Therapy in Oncology Program, Institut d'Investigació Biomèdica de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, Spain,* [5]*Hereditary Cancer Genetics Group, Vall d'Hebron Institute of Oncology, Barcelona, Spain,* [6]*Hereditary Cancer Program, Consorci Sanitari de Terrassa, Terrassa, Spain,* [7]*Hereditary Cancer Program, Department of Gastroenterology, Hospital Clínic Barcelona, Barcelona, Spain,* [8]

Background: The Catalan Guidelines on Hereditary Cancer Predisposition Syndromes in Non-Hematologic Adult Cancers recommends offering reproductive counseling (RC) to individuals carrying a germline pathogenic variant (gPV) in cancer predisposition genes. This study describes the decision-making process regarding RC for recessive syndromes (RS) in genes predisposing to solid tumors.

Material and Methods: The Delphi method was used to survey about RC on RS associated to solid-tumour susceptibility genes. A coordinating group analyzed PV prevalence, offspring risk, syndrome severity and international and national guidelines recommendations. A multidisciplinary panel of 64 experts working in hereditary cancer in Catalonia's public healthcare system was summoned to answer several rounds of REDCap-based questionnaire, with statements accepted at ≥75% consensus.

Results: After two consultation rounds and a validation joint meeting, the agreements were:

- Monoallelic gPV carriers should receive RC on the RSin families with affected members of the RS or consanguinity.
- Carriers of gPVs in *MUTYH*, *ATM*, *BRCA2*, and *PALB2* should be informed of the recessive syndrome and offered reproductive counseling.
- Counseling on RS is not recommended for syndromes associated with genes with a prevalence <1/250 unless family history is indicative.
- Genetic testing for the partner will be offered to biallelic *MUTYH* gPV carriers. A decision remains pending in the third round regarding extending this offer to carriers of gPVs in ATM, BRCA2, and PALB2 based on family history.

Conclusion: RC is recommended for monoallelic carriers with RS affected family members or consanguinity. However reproductive counseling should be also offered to carriers of most prevalent genes.

P25.023.D Assessing knowledge gaps and educational needs on rare diseases among medical students, healthcare trainees, and physicians: a national survey

Karin Writzl[1], *Nataša Teran*[1], *Nina Vodnjov*[1], *Borut Peterlin*[1], *Nevenka Kregar Velikonja*[2]

[1]Clinical Institute of Genomic Medicine, UMCL, Ljubljana, Slovenia, [2]Faculty of Health Science, Novo Mesto, University of Novo Mesto, Slovenia.

Background: Rare diseases, which have a genetic etiology in 80% of cases, are often underrecognized in medical education. This study aimed to assess the knowledge of rare diseases among medical students, health science students, and physicians, and to identify their educational needs in this area.

Material and Methods: The survey involved 163 medical students, 248 healthcare science students, and 393 physicians, including 52% specialists, 30% dentists, and 18% medical residents. The survey assessed participants' understanding of rare diseases, awareness of key facts, and educational preferences.

Results: The survey revealed significant knowledge gaps. While 90% of respondents had heard of rare diseases, only 15% could define them or estimate their prevalence. Physicians significantly underestimated their frequency, with more than half believing they occur less than 1 in 10,000 individuals. Limited awareness was also noted regarding the genetic origins of rare diseases: only 46% of healthcare science students and 69% of medical students knew the most common cause is genetic. Both groups reported low confidence in their preparedness to manage rare disease patients—only 13% of medical students and 25% of healthcare science students felt adequately trained. Over 90% of respondents supported rare disease education in curricula, with most favoring expert-led lectures and case-based learning.

Conclusion: The findings highlight significant knowledge gaps and a strong demand for enhanced education on rare diseases in medical and health science curricula. The results will guide the development of targeted educational curricula for medical students and healthcare professionals.

P25.024.A artificial intelligence-simplified information to advance reproductive genetic literacy and equitable care

Marjan Naghdi[1,2], *Ping Cao*[1,2], *Rick Essers*[1,2], *Malou Heijligers*[1], *Aimee Paulussen*[1,2], *Arie van der Lugt*[3], *Robert A. C. Ruiter*[3], *Wendy A.G. van Zelst-Stams*[1,4], *Andres Salumets*[5,6], *Masoud Zamani Esteki*[1,5,2]

[1]Maastricht University Medical Center, Maastricht, Netherlands, [2]GROW Research Institute for Oncology and Reproduction, Maastricht University, Maastricht, Netherlands, [3]Faculty of Psychology and Neuroscience, Maastricht University, Maastricht, Netherlands, [4]Radboud University Medical Center, Nijmegen, Netherlands, [5]Karolinska Institutet, and Karolinska University Hospital, Stockholm, Sweden, [6]Institute of Clinical Medicine, University of Tartu, Tartu, Estonia.

Background: Reproductive genetic testing and counseling holds the potential to support a personalized approach to managing genetic disorders. However, low health literacy and complex medical information often hinder patient understanding, leading to over- or under-use of testing. This issue is raising concerns that the fertility industry exploits patient vulnerability for profit. To address this challenge, a bottom-up approach is necessary to empower patients with accessible and sufficiently accurate information to attain equitable care.

Material and Methods: We conducted a comparative observational study to assess the performance of four large language models (LLMs) in simplifying patient education materials (PEMs). We collected thirty PEMs on six topics from authorized websites and simplified them using a consistent prompt. We then measured readability improvements using seven standardized metrics and assessed the accuracy of the simplified texts by experts (n = 30).

Results: LLMs significantly enhanced the readability of patient materials. Although Gemini yielded greatest readability improvements, reducing text complexity to the recommended readability standards for PEMs, GPT-4 demonstrated the highest accuracy by preserving essential medical information. These findings emphasize the need to balance accessibility with content integrity, as excessive simplification may lead to omission of critical health information.

Conclusion: AI-driven tools can bridge health literacy gaps and improve equitable access to reproductive care. Their integration into patient education may enhance informed decision-making, reduce healthcare disparities, and alleviate the communication burden on providers. However, careful evaluation of AI-simplified PEMs is required to ensure simplification does not lead to critical omissions, which may result in patient dropout from critical testing.

P25.025.B Developing a medical visualisation approach for innovative teaching materials in clinical genetics

Eve Laws[1], *Alain Verloes*[2], *Siobhan Kerr*[1], ***Jonathan Berg***[1]

[1]Ninewells Hospital and Medical School, University of Dundee, Dundee, United Kingdom, [2]Departement de Génétique, Université Paris Cité, Paris, France.

Background: Teaching of genetics for healthcare has to be accessible to individuals from a range of backgrounds with diverse learning styles, where traditional text-based materials may be insufficient. Simultaneously, there is a greater requirement for genetic knowledge for providers of healthcare at different levels.

Materials & Methods: We used a novel illustrative approach to create genetic/genomic learning resources. Our approach drew on Medical Visualisation techniques and has considerable commonality with the use of illustrated abstracts and infographics. We used large numbers of illustrations supported by concise text and creative analogies to enhance engagement. A translation table was built to expedite translation into any other European language.

Results: Our open access illustrated guide to basic concepts in clinical genetics (https://discovery.dundee.ac.uk/en/publications/berg-and-laws-survival-guide-to-genetics), targeted at medical students, has also proved of interest to a wider audience of genetics healthcare professionals, including genetic counsellors and specialist doctors in training. It has been adopted by the APOGeE project as a general resource, with translation into French. Initial feedback from a cohort of undergraduate medical students showed that all respondents felt more confident in their understanding (75% definitely more confident, 25% somewhat more confident). 100% of students felt that the subject was covered in the right depth.

Conclusion: Our medical visualisation approach to genomic learning resources shows promise for future development. A second resource for genetics counselling is near completion, and has allowed use of techniques inspired by graphic novels. This allows depiction of complex and hard to teach counselling concepts in a highly innovative fashion.

P25.026.C Navigating Genetic Counselling and Cancer Risk in Transgender and Gender-Diverse Patients

Sumudu S. Perera Kimmantudawage[1], *Joshua Schultz*[2,3], *Ingrid Winship*[1,4]

[1]*Department of Genomic Medicine, The Royal Melbourne Hospital, Melbourne, Victoria, Australia,* [2]*Monash Genetics, Monash Hospital, Melbourne, Victoria, Australia,* [3]*Department of Paediatrics, Faculty of Medicine, Dentistry and Health Sciences, The University of Melbourne, Melbourne, Victoria, Australia,* [4]*Department of Medicine, The University of Melbourne, Melbourne, Victoria, Australia.*

Background: Transgender and gender-diverse (TGD) individuals face unique challenges in genetic counselling, particularly regarding cancer risk assessment. Existing screening guidelines do not adequately consider gender-affirming treatments, leading to gaps in risk stratification. This case highlights the complexities of counselling a transgender man with erythropoietic protoporphyria (EPP) with a family history of breast cancer, who underwent gender-affirming top surgery requiring testosterone therapy.

Material and Methods: A 30-year-old transgender man (assigned female at birth(AFAB)) with clinically diagnosed EPP was assessed for hereditary cancer risk given a strong maternal family history of breast cancer. Risk stratification was conducted using CanRisk, incorporating his gender identity, hormone therapy, and prior top surgery. The case was reviewed against current international guidelines on genetic counselling for TGD individuals.

Results: Genetic analysis confirmed likely pathogenic in-trans FECH variants, supporting the EPP diagnosis. This case exemplifies the challenges of applying standard risk models to patients whose risk-profiles are altered by gender-affirming interventions. CanRisk classified the patient as moderate risk for breast cancer based on AFAB status, though it did not account for top surgery. Given potential residual breast tissue and the uncertain impact of testosterone, counselling emphasised self-examination and physician follow-up.

Conclusion: This case highlights the urgent need for gender-inclusive genetic counselling guidelines and the development of personalised risk assessment models that incorporate gender-affirming treatments. Integrating these considerations into clinical practice, and refining risk models through further research is essential to improving care and reducing healthcare disparities among TGD individuals.

P25.027.D Integrating rare variants and PRS in breast cancer prediction and patients counselling

Mariarosaria Adduci[1,2], *Antoine Dahine*[1,2], *Omaima Belakhdar*[1,2], *Giulia Brunelli*[2], *Margherita Iovino*[1,2], *Elena Pasquinelli*[1,2], *Elisabeth Widen*[3], *Max Tamlander*[3], *Simone Pesaresi*[1,2], *Francesca Ariani*[1,2,4], *Chiara Fallerini*[1,2,4], *Romina D'Aurizio*[5], *Alessandra Renieri*[1,2,4]

[1]*Medical Genetics, University of Siena, Siena, Italy,* [2]*Department of Medical Biotechnologies, Med Biotech Hub and Competence Center, University of Siena, Siena, Italy,* [3]*Institute for Molecular Medicine Finland, FIMM, HiLIFE, University of Helsinki, Helsinki, Finland,* [4]*Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy,* [5]*CTGLab, Institute of Informatics and Telematics (IIT), National Research Council (CNR), Pisa, Italy.*

Background: Advances in Polygenic Risk Scores (PRS) have shown potential for improving risk prediction. However, the combined contribution of rare germline variants and PRS to breast cancer susceptibility remains largely underexplored.

Material and Methods: Exome sequencing and genome-wide PRS assessment on 211 female cancer patients. Stratification into four risk categories for rare variants: i) high, ii) medium iii) low, iv) no P/LP variants in known cancer driver genes, and three risk categories for PRS: high (10 percentile), low (90 percentile) and intermediate. Odd ratio (OR) combination was calculated on UK biobank.

Results: The integration of combined risk assessment improved patients counselling, especially for invasive decisions such as bilateral mastectomy and oophorectomy. For example, the most *BRAC1/2* mutation carriers fell in the intermediate PRS having an OR of 4.52 (95% CI: 3.8–5.37, $p < 0.001$), while one fell in the high PRS raising OR to 11.47 (95% CI: 9.62–13.67, $p < 0.001$) and three in the low PRS having an OR of 1.68 (95% CI: 1.41–2, $p < 0.001$). Even more interesting, *ATM/CHEK2* intermediate risk variants patients falling in high risk PRS reached OR of 6.58 (95% CI: 5.52–7.85, $p < 0.001$) which is higher than *BRCA1/2* with intermediate or low PRS and to whom surgery should be suggested.

Conclusion: Overall, our results demonstrate that integrating PRS and rare variant analysis significantly enhances patient stratification and appropriate counselling in breast cancer. Moreover, they lay the groundwork for the development of new guidelines for more personalized genetic counselling.

P25.028.A Consensus European strategies for ensuring quality genetic counselling in cancer prevention and care

J. Matt McCrary[1], *Joelle Ronez*[1], *Tim Ripperger*[1], *Els Van Valckenborgh*[2], *Anke Bergmann*[3]

[1]*Hannover Medical School, Hannover, Germany,* [2]*Sciensano, Brussels, Belgium,* [3]*University Clinic Würzburg, Würzburg, Germany.*

Background: Genetic counselling is critical to the integration of genetics into cancer care, facilitating informed patient decision making and more accurate diagnoses. However, new strategies are needed to guarantee equitable access to counselling throughout the European Union (EU) - given current healthcare workforce shortages and increasing demands for genetic testing, genetic counselling risks becoming a bottleneck constraining the integration of genetics into cancer prevention and care. This project aimed to identify strategies for addressing common European literacy, workforce, and reimbursement barriers to genetic counselling identified in prior work.

Material and Methods: Genetics, oncology, and patient stakeholders from all EU Member States were invited to an online Delphi survey. Over two phases, participants rated 19 strategies proposed by the research team and other participants according to their Importance, Urgency, and Feasibility and selected their top three priority strategies.

Results: 77 individuals (28 geneticists; 14 oncologists; 18 genetic counsellors; 16 patient representatives; 1 qualified 'other') participated (62% response rate), with each Member State represented. Five strategies met pre-defined consensus thresholds and received a clear plurality of priority ratings: 1) EU-wide genetic counsellor recognition; 2) Including genetics expertise in oncology guideline creation; 3) Shared legal EU genetic counsellor registration/education; 4) Mandatory genetics in oncology fellowship/continuing education; 5) Mandatory counselling reimbursement when clinical guidelines are met. Genetic counsellors rated

solutions #1 and #3 more favorably than geneticists and oncologists ($p < .03$).

Conclusion: The five priority strategies provide clear directions for future European action. Upcoming and recently started EU actions will pilot their implementation.

J. McCrary: None. **J. Ronez:** None. **T. Ripperger:** None. **E. Van Valckenborgh:** None. **A. Bergmann:** None.

P25.029.B Establishing a joint Nordic master's program in genetic and genomic counselling: The Nordic network in genetic and genomic counselling (NNGGC) initiative

Rebecka Pestoff[1,2], *Marianne Lodahl*[3], *Essi Ylistalo*[4], *Mari Laaksonen*[4], *Vigdis Stefansdottir*[5], *Eirný Þöll Þórólfsdóttir*[5], *Hákon Högnason*[5], *Wenche Listol*[6], *Cathrine Bjorvatn*[6], *Åshild Lunde*[7], *Birgitte Diness*[8], *Charlotta Ingvoldstad-Malmgren*[9,10]

[1]*Clinical Genetics Dept, Linkoping, Sweden,* [2]*Linköping University, Linköping, Sweden,* [3]*Danish Society of Medical Genetics, Copenhagen, Denmark,* [4]*Tampere University of Applied Sciences, Tampere, Finland,* [5]*The National University Hospital of Iceland, Reykjavik, Iceland,* [6]*Haukeland University Hospital, Bergen, Norway,* [7]*Bergen University, Bergen, Norway,* [8]*Copenhagen University Hospital, Copenhagen, Denmark,* [9]*Karolinska University Hospital, Stockholm, Sweden,* [10]*Uppsala University, Uppsala, Sweden.*

Background: The Nordic Network in Genetic and Genomic Counselling (NNGGC) is a collaboration involving educational and clinical institutions from Denmark, Finland, Iceland, Norway, and Sweden. The network aims to advance education and awareness in the field addressing the growing need for trained genetic counsellors.

Objective: The goal is to establish a joint, quality-assured Master's program in genetic and genomic counselling. The program will train professional genetic counsellors, considering the unique contexts of each Nordic country, and strengthen multidisciplinary and enhance higher education collaboration.

Methods: The program will build on an EBMG-accredited program established at Linköping University in 2021, integrating clinical and academic training with University Hospitals. The curriculum will join expertise and resources, offering diverse learning experiences and research opportunities. A significant portion of the program will be delivered online, supporting the UN Agenda 2030. The program will be primarily taught in English, adding native language practical components in practical experience.

Results: Key planning and implementation activities include funding applications to the Nordic Ministry, establishing agreements, identifying stakeholders, and managing the implementation process. Notable events include on-site meetings in 2024 in Stockholm and in Copenhagen to work on planning for funding.

Conclusion: This Nordic collaboration aims to establish a quality-assured joint Nordic Master's program in genetic and genomic counselling. The initiative aims to increase the number of EBMG-accredited genetic counsellors, promote awareness and growth of the profession in the Nordic region, and provide a basis for future legal recognition, leading to enhanced patient safety.

P25.030.C Preconception carrier screening tests for X-linked disorders in racially and ethnically diverse community: Challenges to culturally competent screening and counseling

Shachar Zuckerman, *Shulamit Brafman, Sari Lieberman*

Shaare Zedek Medical Center, Jerusalem, Israel.

Background: Preconception carrier screening tests (PCSTs), particularly for X-linked disorders, pose unique challenges when offered to ethno-cultural minorities, due to cultural norms, accepted religious practices, and possible labeling of the female partner. Israeli PCSTs, including fragile-X carrier testing, are sponsored by the Ministry of Health to all citizens. Our aim is to assess the efficacy of standard fragile-X PCSTs among the Jerusalem Arab community, by studying the genetic counseling (GC) process and the rate of prenatal diagnosis (PND) and terminations of affected pregnancies.

Material and Methods: We performed a retrospective analysis on a cohort of Arab women who presented for GC upon identification as *FMR1* carriers (56–150 repeats) between 2010–2022.

Results: Overall, 32 women received GC (aged 17–42), nine of which under the age of twenty-one. All were married except one who was engaged. Sixteen (50%) were pregnant while receiving their results (10–27 weeks of gestation). Three woman had sons with intellectual disabilities. Ten women (31%) chose to perform fragile-X PND: three underwent PGT, four CVS and three AC, in which two affected fetuses were detected, and their pregnancies were terminated. Their genetic counselors felt that many of these patients were not aware of the unique characteristics of the test before taking it and were overwhelmed with the ramifications for themselves, their current/future pregnancies, and marital relationships.

Conclusion: Low uptake of prenatal genetic testing reveals the limitations of PCSTs for a specific community. Implementation of culturally competent screening tests and GC will allow an informed decision for every women/couple.

P25.031.D Understanding public attitudes toward cascade testing. A Mixed-Methods Study

Lea Godino[1,2], *Linda Battistuzzi*[3], *Liliana Varesco*[4], *Paolo Chiari*[5], *Alvisa Palese*[6], *Daniela Turchetti*[1,7]

[1]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, Bologna, Italy,* [2]*Department of Biomedicine and Prevention, University of Rome "Tor Vergata", Rome, Italy, Roma, Italy,* [3]*Medical Oncology Unit 2, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genova, Italy,* [4]*Unit of Hereditary Cancer, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genova, Italy,* [5]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy, Bologna, Italy,* [6]*Department of Medicine, University of Udine, Udine, Italy, Udine, Italy,* [7]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy, Bologna, Italy, Bologna, Italy.*

Background: Although detecting genetic predisposition to severe conditions offers the opportunity for personalized prevention in family members, only a minority of at-risk relatives seek cascade counselling and testing. This study aims to explore public perspectives and needs, to understand barriers limiting cascade testing uptake.

Material and Methods: A convergent parallel mixed-methods design was used. A questionnaire exploring knowledge and attitudes regarding cascade genetic testing was developed and assessed through cognitive interviews. An improved online

version based on interviews results was then disseminated through social media.

Results: Cognitive interviews revealed four key challenges in understanding genetic information: (1) difficulties with genetic terminology and scientific jargon, causing anxiety and reducing comprehension; (2) ambiguities about "genetic testing" and "family," leading to confusion; (3) misinterpretations of "genetic risk" as a diagnosis rather than a probabilistic concept; and (4) conflation of "authorization" and "responsibility" in communication, exacerbated by privacy concerns. Iterative testing improved the questionnaire's clarity and reliability.From 11/11/2024 to 18/01/2025 N = 576 individuals responded; 92.7% expressed interest in knowing their genetic risk. Individuals willing to receive information showed higher knowledge levels (score: 3.39 ± 0.84 vs. 2.93 ± 0.96, $p = 0.005$). While 72.5% would like to be informed by healthcare professionals of any genetic condition in their family, only 44.6% would delegate this responsibility if they were the probands diagnosed with the inherited condition. Analysis of the factors influencing attitudes toward cascade testing is ongoing.

Conclusion: Genetic terminology should be adapted to meet the information needs of the public; improving knowledge may help promote adherence to cascade testing.

P25.033.B Assessment of genetic education needs to implement a mainstream process in a tertiary paediatric hospital in Italy

Vera Giacomazzi[1], *Nicoletta Dasso*[2], *Francesca Catapano*[3], *Christophe Cordier*[4], *Francesca Faravelli*[5]

[1]*UOC Clinical Genomics and Genetics, UOC Medical Genetics, IRCCS Istituto Giannina Gaslini, Genova, Italy,* [2]*Department of Health Professions, UOC Clinical Genomics and Genetics, IRCCS Istituto Giannina Gaslini, Genova, Italy,* [3]*Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy,* [4]*MEDISYN SA, Lausanne, Switzerland,* [5]*UOC Clinical Genomics and Genetics, IRCCS Istituto Giannina Gaslini, Genova, Italy.*

Background: Understanding genetics is crucial for healthcare providers to effectively manage data and ensure high-quality patient care, in particular in such a rapidly evolving scenario. Global assessment of deficiencies in genetic training, both in formal education and continuing education, has prompted various countries to take action.

Material and Methods: In this study, conducted in a paediatric tertiary hospital in Italy, a questionnaire was sent to non-genetic clinicians. Data is now being gathered on nurses and obstetricians. The aim is to assess readiness to engage with genomic information, interest in further training, insights on existing procedures and attitudes towards mainstream clinical practice.

Results: In total, 123 medical doctors and, as of now, 45 obstetricians and nurses responded. On average, responders did not feel entirely confident in handling genetic topics, education received was perceived as inappropriate to manage such information, 93% of responders reported wanting to participate to genetic educational activities and the majority of them were interested in all topics proposed. A guideline governed mainstream approach to genetic testing was perceived as necessary.

Conclusion: Consistent with findings from other countries, our study revealed a significant knowledge gap. The study on this sample of Italian practitioners showed the general inappropriateness of formal genomic education, the will to participate to training activities and the receptivity for mainstream implementation. Our goal is to facilitate the acquisition and application of genetic knowledge in everyday medical practice, ultimately improving patients' understanding of their conditions and empowering them to make informed decisions.

P25.034.C Do digital tools support a diversity of patient values? A qualitative study using the Genetics Adviser

Suvetha Krishnapillai[1], *Marc Clausen*[1], *Daena Hirjikaka*[1], *Rita Kodida*[1], *Chloe Mighton*[1], *Salma Shickh*[1], *Emma Reble*[2], *Jordan Sam*[1], *Ella Adi-Wauran*[2], *Nancy Baxter*[1], *June Carroll*[3], *Andrea Eisen*[4], *Christine Elser*[3], *Geoff Feldman*[5], *Emily Glogowski*[6], *Raymond Kim*[7], *Jordan Lerner-Ellis*[2], *Adena Scheer*[1], *Serena Shastri-Estrada*[2], *Cheryl Shuman*[2], *Emily Seto*[2], *Quynh Pham*[7], *Kasmintan Schrader*[8], *Hanna Faghfoury*[7], ***Yvonne Bombard***[2,1,9]

[1]*Unity Health Toronto, Toronto, ON, Canada,* [2]*University of Toronto, Toronto, ON, Canada,* [3]*Sinai Health System, Toronto, ON, Canada,* [4]*McMaster University, Toronto, ON, Canada,* [5]*Patient Partner, Toronto, ON, Canada,* [6]*Sanofi, New York, NY, USA,* [7]*University Health Network, Toronto, ON, Canada,* [8]*BC Cancer, Vancouver, BC, Canada,* [9]*Genomics Health Services Program, Toronto, ON, Canada.*

Background: Digital health applications can engage patients in shared decision-making in accordance with their values. Despite the well-established role of patient values in shared decision-making, little is known about the range of values held by diverse populations and how they inform decision-making for genomic testing, particularly for value-ladened decisions about learning secondary or incidental findings (IF) from exome sequencing (ES). Aim To explore the range of values raised when deciding upon IFs to receive from ES and how these values are supported by the Genetics Adviser Methods We conducted semi-structured qualitative interviews with participants undergoing ES and choosing which IFs to receive as part of the Genetics Adviser RCT (Trial registration number: NCT04725565, PMID: 35487723). Interviews were analyzed using interpretive description methods Results Decision-making was described as predetermined and occurred within a 'black box' before using the Genetics Adviser. This 'black box' describes a complex system of motivational factors involved in decision-making (Fig 2). Three overarching values emerged from unpacking this 'black box', including: a sense of family stewardship, an information imperative, and preserving agency (Fig 3). These values spanned multiple themes. Participants appreciated using Genetics Adviser to confirm their predetermined decision by clarifying, contextualizing, and instilling confidence in their decision.

Conclusions: Participants entered decision-making with a predetermined decision guided by three core values, which were supported by the Genetics Adviser. These findings challenge the dogma surrounding decision support and genetic counselling in clinical genetics and can inform how digital tools can better support patient values.

P25.035.D Systemizing Genetic Health Delivery: A Virtual Clinic Model for Expanding Access to Remote Areas in Saudi Arabia

Amal Mohammed Al Hashem[1,2,3], *Munira Alshehri*[4]

[1]*King Fahad Specialist Hospital, Dammam, Saudi Arabia,* [2]*Seha Virtual Hospital, Riyadh, Saudi Arabia,* [3]*Alfaisal University, Riyadh, Saudi Arabia,* [4]*King Abdullah University of Science and Technology, Riyadh, Saudi Arabia.*

Background: Access to specialized genetic services remains a challenge in remote areas, particularly for rare diseases. To address this, we established a virtual genetic clinic in 2021 under SEHA Virtual Hospital, the world's largest virtual hospital, officially recognized by Guinness World Records in 2024. This clinic provides equitable access to genetic counseling, metabolic services, and prenatal diagnostics across Saudi Arabia. We present the results of the first 100 patients, service challenges, solutions, and outcomes.

Methods: The virtual clinic integrates multidisciplinary services, including clinical genetics, metabolic clinics, genetic counseling, dietetics, and advanced genetic testing. To overcome logistical barriers, we implemented home-visit services for sample collection and medication delivery. Telemedicine platforms were adapted to low-bandwidth settings, with local providers facilitating patient engagement. The national newborn screening program's results were integrated, offering a hotline for positive cases, and general dietitians were trained to support metabolic care remotely.

Results: The clinic serves 120 patients per month, with a 55% diagnostic yield for positive genetic cases. Among the first 100 patients, 32.2% were from the West, 24.4% from the North, and 13.3% from the Central region. The South (11.1%) and East (7.8%) were underrepresented, likely due to limited local genetic testing. Challenges such as poor internet connectivity and cultural hesitations were addressed through home visits and telemedicine.

Conclusion: This virtual clinic has significantly improved genetic healthcare access, reducing travel burdens and enhancing patient outcomes, demonstrating telemedicine's potential to improve healthcare equity.

P25.036.A It's all about the VOUS: inconclusive prenatal CMA results, and the role of the genetic counselor

Tehila Klopstock[1], *Omri Weiss*[1], *Sharon Zeligson*[1], *Reeval Segel*[1,2]

[1]*Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*Faculty of Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel.*

Background: On 01/02/2019 Chromosomal Microarray Analysis (CMA) replaced Karyotyping as the standard prenatal genetic test in Israel. As a result, genetic counselors and their counselees needed to contend with variants of unknown significance (VOUS). If no sonographic fetal structural malformations are detected, most medical centers in Israel allow counselees to decide whether they want VOUS to be reported, preventing dilemmas caused by such results. The purpose of this study is to estimate the frequency of VOUS in prenatal CMA, and to evaluate factors influencing counselees' decisions.

Methods: A 6-year retrospective analysis (02/2019–01/2025) of 1,883 prenatal CMA samples was performed regarding test indication (advanced maternal age or personal choice), medical center (two institutes), and genetic counselor identity (15 counselors).

Results: A VOUS was detected in 7.6% (143/1,833) of tested samples. Most counselees (1,042/1,883) preferred VOUS not to be reported (55% vs. 45%, $p < 0.00002$). Of the three above variables tested, only one significantly influenced this decision. Depending on counselor identity, a range of 37–90% of counselees refrained from including VOUS in their results.

Conclusion: Despite rapid progress in the ability to accurately classify CMA variants, many variants are still classified as VOUS. To alleviate additional uncertainty and stress in pregnancies, medical centers allow counselees to decide whether to receive uncertain results or not. Our study showed that counselees tend to opt out of receiving VOUS. In our cohort, of the factors tested, counselor identity was the only one to influence the counselee's decision, emphasizing the importance of genetic counseling.

P25.037.B Genetic Counselling and Information in Autism and Related Psychiatric Conditions: A Swedish Clinical Trial

Samuelle Fajutrao Falk[1,2,3], *Ashraf Yahia*[1,2], *Yali Zhang*[1,2], *Maria Johansson Soller*[4,5], *Boris Chaumette*[6,7,8], *Kristiina Tammimies*[1,2]

[1]*Center of Neurodevelopmental Disorders, Centre for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Solna, Sweden,* [2]*Department of Highly Specialized Pediatric Orthopedics and Medicine, Astrid Lindgren Children's Hospital, Karolinska University Hospital, Region Stockholm, Stockholm, Sweden,* [3]*North Stockholm Psychiatry, Region Stockholm, Stockholm, Sweden,* [4]*Molecular Medicine and Surgery (MMK), Rare disease group, Karolinska Institutet, Solna, Sweden,* [5]*Department of Clinical Genetics, Akademiska Hospital, Uppsala, Sweden,* [6]*Université Paris Cité, Institute of Psychiatry and Neuroscience of Paris (INSERM U1266), Institut Pasteur (CNRS UMR3571), Paris, France,* [7]*GHU-Paris Psychiatrie et Neurosciences, Hôpital Sainte Anne, Paris, France,* [8]*Department of Psychiatry, McGill University, Montreal, QC, Canada.*

Background: Autism is highly heritable and often co-occurs with attention-deficit hyperactivity disorder (ADHD), anxiety, and depression. Limited knowledge exists on communicating genetic information related to autism and co-occurring conditions to autistic individuals, and its impact. This observational clinical study (NCT06740760) evaluates whether providing genetic information on autism and related psychiatric disorders enhances understanding and empowerment in autistic adolescents and young adults.

Material and Methods: A total of 60 autistic participants have been included and randomized into two active groups: one receiving a 1-hour genetic counseling session with a clinician and the other receiving the information via leaflet. The main outcome measure is the Modified Genetic Counseling Outcome Scale-24 (mGCOS-24). Secondary outcome measures include Generalized Anxiety Disorder-7 (GAD-7) and Patient Health Questionnaire-9 (PHQ-9). For those with earlier genetic data available (1), polygenic scores (PGS) for autism, ADHD, depression, and anxiety have been calculated and will be communicated as a percentile range in comparison to two population cohorts.

Results: We have finalized the recruitment, and 42 have completed the study. The main demographics are presented in Table 1. The average percentiles of PGS within the study individuals were 70 for autism PGS, 63 for ADHD PGS, 68 for

anxiety PGS, and 32 for depression PGS. We will present the results from the trial outcomes.

Table 1. Demographic information on study participants.

	Genetic counseling group (n = 33)	Genetic information leaflet group (n = 31)	P-value
Men	17 (52%)	16 (52%)	NS
Women	16 (48%)	15 (48%)	NS
Age in years (mean, range)	24 (16–30)	25 (19–30)	NS
Individual genetic results	16 (48%)	15 (48%)	NS
Occupation			
Employed	11 (33%)	14 (45%)	NS
Student	15 (45%)	11 (35%)	NS
Neither a student nor employed	11 (33%)	8 (24%)	NS
Healthcare contacts			
General practice	8 (24%)	8 (26%)	NS
Psychiatric outpatient clinic	24 (73%)	12 (39%)	P < 0.05*
Additional diagnoses			
ADHD	21 (64%)	19 (61%)	NS
Depression	11 (33%)	9 (29%)	NS
Anxiety	11 (33%)	8 (26%)	NS
Genetic condition	4 (12%)	2 (6%)	NS
None	10 (30%)	12 (39%)	NS

Conclusion: This study will provide insights into the impact of genetic information on the understanding, well-being, and empowerment of autistic adolescents and young adults, potentially guiding future clinical practices.

P25.038.C The VEDOCO-study: Attitudes towards and experiences with voluntary insurance and cardiac and oncological predictive genetic testing in the Netherlands

*Marlies N. van Lingen[1], Janine V. Meulenkamp[1], **Noor Giesbertz**[2], Arjan Houweling[3], Imke Christiaans[4], Wendy Van Zelst-Stams[5], J. Peter van Tintelen[1], Margeet G.e.m. Ausems[1], L. M. van den Heuvel[1,6]*

[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Amsterdam UMC, AMC, Amsterdam, Netherlands, [4]University Medical Centre Groningen, Groningen, Netherlands, [5]Radboud University Medical Center Dept of Human Genetics (836), Nijmegen, Netherlands, [6]Netherlands Heart Institute, Utrecht, Netherlands.

Background: Dutch insurers are, under circumstances, allowed to use genetic information when offering a life or disability insurance. Concerns about the impact of a positive genetic test on obtaining these insurances are often mentioned as a barrier for at-risk relatives (ARRs) to seek genetic counselling and predictive testing. We therefore assessed ARRs' expectations and the experiences of carriers with insurance applications.

Material and Methods: We conducted a cross-sectional retrospective survey study in five genetic centers. Adult ARRs of probands with inherited cardiac or oncological conditions who received genetic counselling between Dec 2016 and July 2022 were invited to complete an online survey.

Results: The survey was completed by 283 of 2359 (12%) invited participants (mean age 50.4 years (SD 14.5); 54% female) from families with inherited cardiac (48.9%) and oncological (51.1%) disorders. 85.2% was carrier, of whom 30.7% reported symptoms. A minority (33.2%) recalled receiving information about insurance during pretest counselling. 27.8% anticipated that genetic testing would have consequences for future insurance applications. Two thirds (65.6%) of carriers (applying for life insurance; 18/26(69.2%), or disability insurance; 3/6(50%)) were unconditionally accepted. Qualitative open answer analysis showed both positive and complicated experiences during these insurance applications.

Conclusion: Over a quarter of counselled ARRs expected that genetic testing would influence future voluntary insurance applications. Two thirds of applications were unconditionally accepted, the procedure was however experienced as burdensome in a few cases. Our findings suggest that insurance regulations and potential application difficulties pose barriers for ARRs seeking genetic counselling and predictive testing.

P25.039.D Community-Oriented, Hospital Level Genetics: A New Approach to Improve Access for Underserved Communities

Yoel Gofin[1], *Fadel Tibi[2], Eliana Fanous[3], Shay Ben shachar[4], Rivka Sukenik Halevy[1]*

[1]Genetic Institute, Meir Medical Center, Kfar Saba, Israel, [2]Sharon Shomron District, Clalit Health Services, Tayibe, Israel, [3]Schneider Children's Medical Center, Petah Tikva, Israel, [4]Clalit Innovation, Clalit Health Services, Ramat Gan, Israel.

Background: Certain populations in Israel are at increased risk for genetic syndromes but have limited access to genetic testing.

Material and Methods: We founded a community-based, pediatric genetics clinic in the Muslim-Arab city of Tayibe, Israel. Children with suspected genetic conditions of consanguineous parents, or families with two or more affected siblings were referred by local staff. The clinic was staffed by a Meir Medical Center (MMC) clinical geneticist and tests were analyzed at the MMC Genetics Institute. Blood samples were collected during initial visit. Tests were publicly funded, with no parental involvement in administrative procedures required. A control group consisted of MMC pediatric genetics clinic patients.

Results: During the clinic's first year, 30 children from 19 families were assessed. No patients were lost to follow-up, compared to 8 (28%) in the MMC group. Average time to receipt of test results was shorter in the Tayibe group and the diagnostic rate was higher, with 27.6% receiving a diagnosis (42.9%, excluding autism cases). Questionnaires from Tayibe clinic families

showed that most parents had previously received recommendations for genetic counseling but did not comply, mostly due to lack of interest.

Conclusion: We believe our first-year experience with the Community-Oriented, Hospital Level Genetics Clinic shows success and promising results of this model, with advantages in almost all parameters, compared to the traditional, hospital-based clinic. Factors such as faster time-to-results, greater family adherence and satisfaction, and zero lost to follow-up rate suggest considering implementing this model for providing genetic services to other underserved populations.

P25.040.A Genetics First Approach: Expanding the Utility of Genetic Testing and Improve Patient Outcomes

Rotem Greenberg[1], *Noa Shefer Averbuch*[2], *Lena Sagi-Dain*[3], *Noa Ruhrman Shahar*[4], *Idit Maya*[4], *Dina Yagel*[5], *Nesia Kropach*[6], *Ran Balicer*[1], *Shay Ben-Shachar*[1]

[1]*Clalit Innovation, Ramat Gan, Israel,* [2]*Schneiders Children's Medical Center, Petah-Tikva, Israel,* [3]*Genetics Institute, Carmel Medical Center, Haifa, Israel,* [4]*Raphael Recanati Genetic Institute, Belinson Hospital, Clalit, Petah-Tikva, Israel,* [5]*Genomic center, Clalit, Petah-Tikva, Israel,* [6]*Pediatric Genetics Unit, Schneider Children's Medical Center, Petah-Tikva, Israel.*

Introduction: The increasing demand for genetic testing and a global shortage of geneticists has significantly strained healthcare systems worldwide. This highlighted the need for new strategies to increase testing accessibility, reduce wait times, and enhance patient care quality.

Materials and Methods: We implemented a four-step program, "Genetics First," to empower non-geneticist physicians (NGPs) to play an active, initiator role in genetic initiatory role in genetic and molecular diagnosis. The steps included (1) establishing criteria to identify suitable clinical domains, (2) selecting clinical indications within the domain through expert panel review, (3) designing tailored education and workflows for NGPs across indications, and (4) monitoring test outcomes and providing further support for complex cases. The test outcomes were compared between NGPs and clinical geneticists (CGs).

Results: One hundred and fourteen endocrinologists completed the program. During the study, 260 gene panels were performed for monogenic diabetes. NGPs initiated 68% of these tests, contributing to a 107% increase in referral rates. The overall diagnostic yields were 30%, with no significant difference in yield between NGPs and CGs.

Conclusion: This study demonstrates the feasibility and impact of involving NGPs in genetic testing, offering a paradigm shift that could expand access to genetic testing and improve patients' care and clinical outcomes.

C.O.I. Disclosure:

R. Greenberg: None. **N. Shefer Averbuch:** None. **L. Sagi-Dain:** None. **N. Ruhrman Shahar:** None. **I. Maya:** None. **D. Yagel:** None. **N. Kropach:** None. **R. Balicer:** None. **S. Ben-Shachar:** None.

P25.041.B Telegenetics: Opportunities and Perceptions in Bulgaria

Hristo Ivanov[1,2], *Iglika Sotkova*[1,2], *Vili Stoyanova*[1]

[1]*Medical University Plovdiv, Department of Medical Genetics, Plovdiv, Bulgaria,* [2]*Medical center Neuro Ped Gene LTD, Plovdiv, Bulgaria.*

Background: Telegenetics, a specialized branch of telemedicine, utilizes digital communication technologies to provide genetic counseling and services remotely. This approach aims to improve access to genetic expertise, particularly in underserved regions. This study explores the adoption of tele-genetics in Bulgaria, focusing on patients' perceptions, accessibility, and the impact on service delivery.

Material and Methods: A mixed-methods approach was employed, combining quantitative analysis of demographic data from 350 tele-genetic consultations conducted in Bulgaria (March 2022 - December 2024) with qualitative surveys assessing patients attitudes towards remote genetic services. Data was collected from telegenetic consultations facilitated via platforms like Healee, Zoom, and Viber and phone calls, ensuring a diverse participant pool.

Results: The analysis revealed increased accessibility to genetic services in remote areas, reducing travel burdens and associated costs for patients. Among the 350 participants, 97% reported high satisfaction levels, emphasizing the convenience and psychological benefits of tele-genetic consultations. Barriers included technological literacy, regulatory challenges, and concerns about standardized practices.

Conclusion: Telegenetics demonstrated significant potential in improving genetic service delivery, especially in regions with limited access to specialized care. The findings support the hypothesis that telegenetics can bridge healthcare disparities, though challenges like regulatory frameworks and digital proficiency need to be addressed. The Covid-19 pandemic served as a catalyst for adoption but highlighted the necessity for long-term infrastructure and policy development. Telegenetics holds promise for expanding genetic healthcare access in Bulgaria. Future efforts should prioritize policy standardization, infrastructure improvement, and professional training for sustainable integration.

P25.042.C Art and Genetics: we are not different, we are unique

Paola Tesolin[1,2], *Domizia Pasquetti*[1], *Aurora Santin*[1,2], *Beatrice Spedicati*[1,2], *Luigi Memo*[1], *Giorgia Girotto*[1,2]

[1]*Institute for Maternal and Child Health IRCCS Burlo Garofolo, Trieste, Italy,* [2]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy.*

Background: Iconodiagnosis is the practice of searching for clinical signs suggestive of diseases in people depicted in artworks. We aim to employ art to teach the general public about genetics and to share the educational potential of iconodiagnosis for the medical profession.

Material and Methods: We collected ~800 artworks depicting subjects affected by genetic diseases and other conditions. The pictures were included in a custom-made database with artistic descriptions and reports of the phenotypical features with HPO terms defined by a multidisciplinary team of geneticists. For each representation, a molecular diagnosis was hypothesised.

Results: We will produce a theatrical show focused on iconodiagnosis. The use of scientific methods and terminology will guarantee complete immersion in the world of genetics while offering spectators the possibility to observe artworks from an entirely different perspective. Moreover, we will organise several workshops: Some will be directed to the general public to teach them about rare diseases, while others will be for students and clinicians to practice their ability to perform a "gestalt" diagnosis, raising the discussion on the represented conditions.

Conclusion: The general public will learn about genetic diseases, while students and experts will discover new ways to train the ability to observe, an essential skill for all clinicians. All participants will rediscover the importance of empathy towards patients, considering not only their clinical condition but also their life experiences. The key message will be that we are all genetically different and perfection does not exist; thus, our differences may be the common meeting point.

P25.043.D Personalized breast cancer screening acceptability in women population from Navarra

Ane Miren Sagardia[1], *Berta Ibañez*[2], *Paula Peiro*[3], *Monica Arasanz*[4], *Angel Alonso*[2,1]

[1]*Hospital Universitario Navarra, Pamplona, Spain,* [2]*Navarrabiomed, Pamplona, Spain,* [3]*Clínica Ginefiv, Madrid, Spain,* [4]*IVIRMA, Bilbao, Spain.*

Background: Scientific evidence showed the necessity of adapting breast cancer screening programs from a "one fits all" perspective to a personalized perspective. An important pillar of the implementation process is women acceptability. One of the objective of NAGENMx project is to investigate women vision towards the implementation of personalised breast cancer screening in Navarra region.

Material and Methods: An online questionnaire survey focused on exploring acceptance of personalized risk based breast cancer screening was conducted, with a general population breast cancer risk group (n = 269) and a high breast cancer risk group (n = 209). Results of the acceptability questions were quantified in the Likert scale and summarized with descriptive statistics.

Results: Both groups showed a high agreement on implementing personalized screening (mean = 4.3; SD = 1.1; mean = 4.0; SD = 1.2) and also on conducting more mammograms if their risk is high,(mean = 4.7; SD = 0.6; mean = 4.5; SD = 0.9). But agreement was lower regarding having less mammograms if their risk was low (mean = 3.0; SD = 1.4; mean = 2.7; SD = 1.4).

Conclusion: There is a positive attitude towards personalized screening implementation and increasing prevention if the risk is higher, but there is a lower acceptance to have less mammograms if breast cancer risk is low. This acceptability is shown to be lower among women with high risk of developing breast cancer or already had breast cancer. This could be due to perceived risk and their personal experience. This study has been extended and additional results showed that education about personalized breast screening improves people understanding increasing acceptability.

P25.044.A Mainstreaming oncogenetic services in a large HMO setting

Revital Bruchim[1], *Sara Haim*[1], *Adi Szmulewicz*[1], *Gili Reznick Levi*[1], *Miri Berger*[1], *Tamar Shapira Cohen*[1], *Lia Supino-Rosin*[1], *laura Diskin*[1], *Eyal Reinstein*[2], *Mordechai Shohat*[1]

[1]*Megalab Maccabi, Rechovot, Israel,* [2]*Maccabi, Tel Aviv, Israel.*

Background: Germline genetic testing is increasingly recognized as crucial for treatment planning in cancer care. In Israel, the national healthcare system covers genetic testing for common BRCA mutations for patients with breast, ovarian, or pancreatic cancers. Additionally, healthy relatives can seek testing for reassurance, surveillance, or preventive measures. This shift has led to a new model of genetic testing, aimed at improving clinical decision-making and enhancing patient management through risk-reduction strategies and tailored therapies The goal is to improve access to oncogenetic services and reduce waiting times for patients and family members.

Material and Methods: Maccabi Healthcare Services (MHS), serves 25% of Israel's population, launched a centralized genetic counseling program to optimize genetic testing access. The program involves five certified genetic counselors who triage testing requests based on personal and family medical histories using a simple questionnaire. Requests are categorized into three groups: high-risk patients with cancer or known mutation in relatives, low-risk healthy individuals with a familial cancer history, and those with unique genetic syndromes requiring face-to-face counseling.

Results: From June 2020 to December 2024, the program reviewed 20,895 questionnaires. Among these, 13.5% were cancer patients, 8% had family members with a mutation, and 66.5% had family history of cancer. Only 6.1% required face-to-face counseling.

Conclusion: This triage system significantly reduced waiting times, enabling faster access to genetic testing and counseling. Ongoing evaluations ensure the program remains efficient and effective in meeting patient needs. This approach demonstrates how centralized genetic counseling can enhance healthcare services and improve patient outcomes.

P25.045.B Unlocking the Potential of Genetic Screening in Pediatric Cancer: Spanish Expert Consensus on newborn Testing, CANGUR project

Estela Carrasco[1,2], *Hector Salvador Hernandez*[3], *Adrià Lopez-Fernandez*[1,2], *Barbara Rivera*[4,5], *Mar Borregan*[3], *Diana Salinas*[3], *Adela Escudero*[6], *Laura Trujillano*[1], *Anna Cueto*[1], *Albert Català*[3], *Lucas Moreno*[1,7], *Judith Balmaña*[1,2]

[1]*Hospital Vall d'Hebron, Barcelona, Spain,* [2]*VHIO-Vall Hebron Institut Oncologia, Barcelona, Spain,* [3]*Hospital Sant Joan de Déu, Barcelona, Spain,* [4]*Hereditary Cancer Program IDIBELL-ICO, Barcelona, Spain,* [5]*Gerald Bronfman department of Oncology, Montreal, QC, Canada,* [6]*La Paz, Madrid, Spain,* [7]*VHIR-Vall Hebron Institut de Recerca, Barcelona, Spain.*

Background: The newborn heel prick test screens for treatable diseases, improving morbidity and mortality through early diagnosis. Next Generation Sequencing technologies could expand screening to include more diseases. This project aims to pre-select pediatric cancer susceptibility genes for discussion and consensus with genetics and oncology professionals, evaluating which genes could be candidates for newborn screening in our healthcare system.

Material and Methods: A committee of experts (N = 12: genetic counselors, pediatric oncologists, geneticists, and adult

oncologists) used Catalonia public Health pediatric cancer gene list (N = 114; 80 hematologic and 34 solid genes) to assess clinical actionability based on three criteria (Phase I): 1) Tumor onset before age 6, 2) Tumor surveillance guidelines for children under 6, 3) Clinical utility assessment. Selected genes will undergo expert-based (N = 55) consensus agreement assessed with DELPHI methodology (Phase II). Gene review material has been developed, and workshops for clinical and ethical debates were organized.

Results: 21 genes and 2 conditions were pre-selected in Phase I: *ALK, APC, BLM, CTR9, DICER1, GATA2, MEN1, NF1, RB1, REST, RET, SDHB, SMARCA4, SMARCB1, SAMD9, SAMD9L, SUFU, TP53, TRIM28, VHL, WT1*, CMMRD *(MLH1, MSH2, MSH6, PMS2)*, and FANCONI ANEMIA *(FANCA, FANCN-PALB2, FANCD1-BRCA2, FANCS-BRCA1)*. This Phase I gene list will be proposed for expert consensus agreement (Phase II).

Conclusion: Genetic testing for pediatric cancer susceptibility within newborn screening is complex and requires a multidisciplinary team's expertise.

P25.046.C Rare disease patients' and relatives' perception of the diagnostic journey/health care - a nationwide membership online survey

Charlotta Ingvoldstad Malmgren[1,2,3], *Stephanie Juran*[4], *Jamie Luckhaus*[5], *Maria Johansson Soller*[6]

[1]*Center for Rare diseases, Clinical genetics, Karolinska University hospital, Stockholm, Sweden,* [2]*Center for research ethics and bioethics, Uppsala University, Uppsala, Sweden,* [3]*Department of molecular medicine and surgery, Karolinska instututet, Stockholm, Sweden,* [4]*Rare diseases Sweden, Stockholm, Sweden,* [5]*Department of Women's and Children's Health, Uppsala University, Stockholm, Sweden,* [6]*Department of molecular medicine and surgery, Stockholm, Sweden.*

Background: Rare diseases Sweden is a national patient organisation for rare disease. Rare diseases Sweden is an umbrella organisation covering 52 specific diagnose organizations, having almost 17000 members.

Method: A member online survey, including questions on their diagnostic journey and health care needs, was sent out in 2021, and resulted in 1443 responses.

Results: These results include a subgroup of 942 members covering 120 different diagnoses. Over half have a rare disease and the other half are caregivers. Slightly more than one third of the include conditions include Intellectual disability, and one in five include motor impairment. Almost half of the conditions include complex health care needs. 23 % have a general onset at congenital/newborn life stage, 13 % as toddler and 4 % at adulthood. For 60 % the age of onset can vary. Over 1/3 were diagnosed in <6 months. Nearly half were diagnosed within a year whereas for 1 in 10 it took over 10 years to get their diagnosis. 443 underwent genetic testing and 335 received a genetic diagnosis. 1 out of 5 have not seen an expert of expert in their rare health condition. The group for whom it took > 10 years to receive a diagnosis, had to a lesser extent been in contact with a specialist in their condition, their healthcare need were less met, and they had less trust in healthcare system and healthcare professionals.

Conclusion: The study provides valuable insight in the self-assessed diagnostic journey and healthcare of individuals with rare diseases.

P25.048.A Pilot study on the preference and comprehension of data visualization in cancer predisposition genetic counselling

Diogo Nogueira[1,2], ***Celia Azevedo Soares***[1,3,4]

[1]*Centro de Genetica Medica, Unidade Local de Saude de Santo Antonio, Centro Hospitalar Universitario do Porto,Porto, Portugal, Porto, Portugal,* [2]*Instituto de Ciências Biomédicas de Abel Salazar, Universidade do Porto, Porto, Portugal, Porto, Portugal,* [3]*Unit for Multidisciplinary Research in Biomedicine, Universidade do Porto/ Instituto de Ciências Biomédicas Abel Salazar, Porto, Portugal Laboratory for Integrative and Translational Research in Population Health, Universidade do Porto, Porto, Portugal, Porto, Portugal,* [4]*Departamento de Ciências Médicas, Universidade de Aveiro, Porto, Portugal, Aveiro, Portugal.*

Background: Genetic counseling necessitates effective communication of complex genetic risks for informed decision-making. Data visualization can enhance understanding, improve risk perception, and empower individuals to make informed health choices.

Material and Methods: Participants were recruited from a genetics clinic in Porto, Portugal. Exclusion criteria included being underage, sensory limitations, a prior cancer diagnosis, and employment in the healthcare sector. Educational levels were categorized into three groups. Eligible individuals participated in semi-structured interviews to assess data visualization preference and comprehension.

Results: A sample of 63 participants, stratified by education level (low, medium, high), reviewed five visualization formats: bar graphs, tables, pictograms, circle graphs, and clock graphs. Bar graphs (30.2%) and tables (28.6%) were most preferred and demonstrated the highest interpretation accuracy. Participants with lower education levels favored pictograms and tables, while those with medium and higher education preferred bar graphs, suggesting familiarity with these formats. Clock graphs were least preferred and understood, with only 7.9% selecting them and a comprehension rate of 33.3%.

Conclusion: Bar graphs and tables were generally preferred and understood by our participants. However, preferences varied significantly across different educational levels. Findings suggest the need for tailored visualization strategies to optimize communication and improve risk comprehension among individuals with diverse educational backgrounds.

P25.050.C Empowering Choices: Mapping Tools and Innovations to support NIPT Pre-Test Counseling

Eva Van Steijvoort[1], *Hilde Peeters*[2]

[1]*Department of Public Health & Primary Care, KU Leuven, Leuven, Belgium,* [2]*Departement of Human Genetics, KU Leuven, Leuven, Belgium.*

Background: Various tools and interventions have been developed to support pre-test counseling for non-invasive prenatal testing (NIPT), aiming to empower patients as they navigate important reproductive choices. In this review we aim to identify and map the existing tools and interventions to support NIPT pre-

test counseling, we examine their key characteristics and the outcomes of their evaluations.

Material and Methods: A comprehensive literature search is being conducted using PubMed, Web of Science, and CINAHL. Title and abstract screening, full-text review, and data extraction is being performed independently by two reviewers. Key characteristics, including intervention type, format, delivery mode, content focus, stakeholder involvement, interactivity, target population, evaluation metrics, and reported outcomes, are being synthesized descriptively.

Results: We identified a wide range of interventions that have been developed and/or evaluated, including (digital) decision aids, educational videos, group based counseling, training programs for health care professionals, etc. While these interventions demonstrate potential for enhancing comprehension and ensuring informed consent, their success depends on rigorous design, cultural sensitivity, and equitable accessibility. Addressing challenges related to health literacy, language barriers, and integration into existing systems is essential to complement traditional counseling approaches and promote patient-centered care.

Conclusion: Emerging digital interventions hold great promise, but further research is required to ensure they are effective, accessible and tailored to the needs, values, and preferences of diverse stakeholders. This review highlights key gaps and provides recommendations, stressing the importance of collaboration with end-users and comprehensive evaluation to fully realize the potential of evidence-based counseling tools.

E. Van Steijvoort: None. **H. Peeters:** None.

P25.051.D The evolving landscape of cancer germline genetic testing; how are carriers being identified?

Adrià López Fernández[1], *Júlia Reig*[1], *Estela Carrasco, Genetic Counselor*[1], *Eduard Pérez*[1], *Laura Duran-Lozano*[2], *Mara Cruellas*[1], *Alejandra Rezqallah*[1], *Carla Dies*[3], *Noemí Tuset*[3], *Anna Moreno*[2], *Laia Martinez*[3], *Sara Gonzalez*[4], *Conxi Lázaro*[4], *Alejandro Moles*[1], *Berta Campos*[1], *Judith Balmaña*[1]

[1]*Vall d'Hebron University Hospital, Barcelona, Spain,* [2]*Vall d'Hebron Institute of Oncology, Barcelona, Spain,* [3]*Arnau de Vilanova University Hospital, Lleida, Spain,* [4]*Catalan Institute of Oncology, Barcelona, Spain.*

Background: Germline genetic testing in cancer susceptibility is complex. This study aims to: (1) assess the indications for cancer germline genetic testing, (2) identify the yield of pathogenic variants (PV) for each indication, and (3) quantify PV carriers identified outside traditional criteria.

Material and Methods: Retrospective analysis was conducted using a hereditary cancer unit registry (2019–2024). Testing indications were classified into: (1) traditional criteria-based panel testing (2) mainstream testing for therapeutic purposes (3) predictive cascade testing, (4) confirmation of secondary findings (SF: PV in cancer susceptibility genes during genomic testing), and (5) reflex germline testing of tumoral PV suspicious of germline origin.

Results: Germline testing increased 61% (from 764 tests in 2019 to 1230 tests in 2024). Of the 5703 tests, 63% were based on traditional criteria, 31% on predictive testing, 5% on mainstream testing, and 1.3% on tumour or secondary findings. Overall, 1261 cancer-predisposing PV carriers were identified, 6% (80/1261) of whom were detected outside traditional criteria. Carrier yields were 13% for panel testing, 43% for predictive testing, and 50% for tumour PV reflex testing (Table 1).

Conclusion: Predictive genetic testing encompasses one third of the indications with one of the highest yield. Human and structural resources in germline genetic testing should focus on predictive genetic testing. Tumour testing and secondary findings from genomic analysis represented 6% of PV identification and would not have been identified by other means. These techniques require complex pathways for identification, interpretation and referral.

Indication of germline testing (2019–2024)	# tests performed (N = 5703)		# carriers identified (N = 1261)		Yield of the indication (carriers/ indication)	
	n	%	n	%	n	%
Criteria-based panel testing	3573	63	414	33	414/3573	12
Mainstream panel testing	310	5	41	3	41/310	13
Predictive single testing for a familial PV	1746	31	758	60	758/1746	43
Confirmation of SF from genomic testing	19	0,3	19	2	19/19	100
Reflex testing of tumoral PV	55	1	29	2	29/55	53

P25.053.B Enhancing genetics education through an undergraduate journal club: a pilot study

Kakha Bregvadze, *Elene Abzianidze, Eka Kvaratskhelia, Tinatin Tkemaladze*

Tbilisi State Medical University, Tbilisi, Georgia.

Background: Journal Clubs (JCs) remain underexplored in undergraduate medical education (UME). This study evaluates the effectiveness of a JC implemented at the Department of Molecular and Medical Genetics, Tbilisi State Medical University, for 2nd- and 4th-semester students in the 6-year Medicine program.

Material and Methods: In 2021, a voluntary JC was introduced with the aims of enhancing genetics knowledge, literature analysis skills, and performance across multiple domains among undergraduate students. The JC was promoted through social media, emails, and personal communication. Biweekly meetings involved student presentations on recent articles covering broad topics in genetics and genomics with faculty mentorship. Discussions followed each presentation, and anonymous peer feedback was collected. A mixed-methods approach, including a 13-question Likert-scale survey and face-to-face interviews, was used to evaluate the JC.

Results: A total of 26 students completed the survey. Students overwhelmingly reported a positive JC experience and increased interest in genetics. All students believed JC enhanced their ability to understand and utilize primary literature. The majority felt the JC improved their understanding of biostatistics (75%) and enhanced communication and teamwork skills. All students would recommend JC to peers and they all expressed a desire for JCs to be implemented in other courses.

Conclusion: The undergraduate student-led JC enhanced students' interest in genetics, research analysis skills, and soft skills such as communication and teamwork. Expanding JC

initiatives could provide educational benefits for undergraduate medical students.

P25.054.C Comprehensive Premarital Genetic Screening in Abu Dhabi: A Model for Genetic Disease Prevention

M. Al Ameri[1], *S. Al Marzooqi*[1], *W. Mohammed*[1], *H. Hasan*[2], *S. Al Hosani*[3];

[1]*Department of Health, Abu Dhabi, United Arab Emirates,* [2]*Abu Dhabi Public Health Center, Abu Dhabi, United Arab Emirates,* [3]*SEHA, Abu Dhabi, United Arab Emirates*

Background: Premarital genetic screening is a key public health strategy in the UAE, particularly in Abu Dhabi, to reduce the prevalence of genetic disorders and enable informed reproductive decisions. High consanguinity rates in the region, combined with a significant genetic disease burden, underscore the need for a robust screening protocol. This initiative aims to provide couples with insights into genetic risks, thereby supporting informed choices and reducing hereditary disease transmission.

Method: The Abu Dhabi program has expanded the scope of premarital screening in the UAE, expanding from 2 conditions to a comprehensive panel covering 570 genes associated with over 840 autosomal recessive disorders.

Results: A total of 1192 couples underwent premarital genetic testing between October 2022 and September 2024 across 22 clinics in Abu Dhabi. Of these, 159 (13.3%) couples were identified as genetically incompatible. The most frequent observed gene mutation among the tested couples was in *CYP21A2* (13%, n = 21), followed by mutations in the *USH2A* gene, found in 11% (n = 17) of cases, *MEFV* (9%, n = 14), and *ABCA4* (8%, n = 12). Nine (5.6%) of the couples were a carrier of two gene mutations, 1 (0.6%) couple was a carrier of three gene mutations and the remaining (93.8%) were a carrier of one gene mutation.

Conclusion: Abu Dhabi's comprehensive premarital genetic screening program highlights the value of a comprehensive approach in reducing hereditary disease prevalence. The program findings underscore the value of premarital genetic screening in culturally similar contexts and its potential to influence future policies in precision health and prevention.

P25.055.D The evolving scope of professional practice of roles within clinical genomic services

Roberta Rizzo[1], *Diana Baralle*[2]

[1]*Association of Genetic Nurses and Counsellors, London, United Kingdom,* [2]*Clinical Genetics Soceity, London, United Kingdom.*

As genomic medicine evolves, professional roles within specialist services must adapt to meet the increasing complexity of patient care. The Association of genetic nurses and counsellor (AGNC) and Clinical Genetics Soceity (CGS) in the UK collaborated on updating a previous framework builds on previous definitions, refining the scope of practice for *Clinical Geneticists, Genetic Counsellors, Genomic Associates*, and the newly introduced *Genomic Practitioner* role. It aims to enhance clarity, efficiency, and collaboration across the United Kingdom's genomic services.

A key focus of this update is **Mainstreaming**, which expands the role of genomic professionals in supporting non-genetic healthcare providers. This includes clearer responsibilities for providing guidance on referrals, interpreting genomic results, and leading specialist nurse-led mainstreaming teams in areas such as familial hypercholesterolemia and breast cancer screening.The **Research** section has also been strengthened, reflecting the growing involvement of genomic professionals in *gene therapy trials, psychosocial research, and variant interpretation studies*. This highlights the increasing emphasis on evidence-based genetic counselling and patient-centred genomic research.

We present the updated framework, which aims to be **aspirational**, providing a forward-looking vision of how roles can evolve to streamline a cohesive service delivery, improve patient outcomes, and integrate genomic expertise into mainstream healthcare. By clearly delineating responsibilities, this document supports a dynamic, collaborative approach to genomic medicine across the NHS and beyond.

C.O.I. Disclosure:

R. Rizzo: None. **D. Baralle:** None.

P25.057.B Genetic counsellors as agents of change: National transformation of clinical pathways and upskilling of healthcare professionals in genomic testing for Familial Hypercholesterolaemia

Melanie S. Watson[1], *Deborah Leetham*[2]

[1]*University Hospital Southampton NHS, Southampton, United Kingdom,* [2]*Northumbria University, Newcastle Upon Tyne, United Kingdom.*

Background: The NHS Long Term Plan set out the ambition to identify 25% of patients with Familial Hypercholesterolaemia (FH) within 5 years. The National FH Transformation Project aimed to identify effective strategies to increase detection of patients with FH. To support mainstreaming of FH testing and to transform FH pathways.

Material and Methods: A Clinical Pathway Initiative process mapped case finding in FH. A competency framework was developed against which educational resources were mapped. The clinical pathway and competency framework was utilised to underpin the content of a pilot FH workshop. A series of workshops were delivered. A pre and post quiz evaluated the educational intervention on the day. The demand for this workshop far outweighed the capacity to deliver. Therefore, a MOOC (Massive Open Online Course) was developed to meet the demand and ensure sustainability of this programme. Evaluation of this programme was determined through completion of an online survey.

Results: The Workshop: 95 delegates attended from a wide range of healthcare professionals. Pre & Post quiz results showed a significant increase in knowledge.The MOOC: 171 registered from 41 countries; 40% UK; 3% North America. The post course survey reported that 88% found the course met their expectations and they were applying this knowledge to their current clinical practice.

Conclusion: This approach to a National Education Programme has established the feasibility of mass online education of healthcare professionals in a disease specific context. Further research is required to explore the impact of this education and training in the clinical mainstream.

P25.058.C From Ideas to Impact: The ESHG-Young Committee's Achievements

Mridul Johari[1,2], *Ileana - Delia Sabau*[3,2], *Ana Raquel Silva*[4,5], *Silvia Kalantari*[6,5,7], *Ana Rita Matos*[8,5], *Rhys M. Dore*[9,5], *Magdalena*

Mroczek[10,5], Mathys Wéber[11,5], Nelson Martins[12,5], Juliana Miranda Cerqueira[13,14,5], European Society of Human Genetics - Young Committee[15]

[1]Harry Perkins Institute of Medical Research, Perth, Australia, [2]European Society of Human Genetics - Young Committee, European Society of Human Genetics, Vienna, Austria, [3]Synevo, Bucharest, Romania, [4]Serviço de Genética Médica, Departamento de Pediatria, Unidade Local de Saúde Santa Maria, Lisboa, Portugal, [5]European Society of Human Genetics - Young Committee, Vienna, Austria, [6]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [7]Medical Genetics Unit, Department of Diagnostic Medicine, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [8]i3S - Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal, [9]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [10]Department of Biomedicine, University Hospital Basel and University of Basel, Basel, Switzerland, [11]Service de Génétique Médicale, CHU Toulouse, Toulouse, France, [12]Center for Medical Genetics, Ghent University Hospital, Department of Biomolecular Medicine, Ghent, Belgium, [13]University of Tampere, Faculty of Medicine and Health Technology, Tampere, Finland, [14]Faculdade de Ciências da Nutrição e Alimentação, Universidade do Porto, Porto, Portugal, [15]

Background: ESHG-Young (ESHG-Y) is now in its sixth year and continues to represent young researchers in Human Genetics across Europe. By fostering connections and spearheading educational and professional development initiatives, ESHG-Y has grown into a cornerstone for empowering future leaders in genetics.

Methods: ESHG-Y representatives actively serve in the ESHG-SPC, shaping platform and plenary sessions at the annual ESHG conference. We are also involved in EduComm, Policy and Ethics Committee, and ERN-Ithaca, promoting connections with several organisations under ESHG. The committee maintains strong partnerships with the African Society of Human Genetics (AfSHG), American Society of Human Genetics, Human Genetics Society of Australasia, and several national Young Geneticists Societies (YGS) from European countries.

Results: In 2024, the ESHG-Y organized several symposia, educational sessions, and workshops at the annual ESHG conference. It was instrumental in the 34th European Dysmorphology Meeting and a webinar on Non-Invasive Fetal Autopsy in collaboration with ERN-Ithaca. Collaboration with AfSHG and Jackson Laboratory (US) led to a Functional Genomics webinar.We published our commentary 'Termination of pregnancy and laws in Europe' in EJHG, describing insights from the corresponding ESHG 2023 workshop in Glasgow. Additionally, the committee formed meaningful connections with seven YGS in Europe.

Conclusion: The ESHG-Y marks 2025 as an election year for a new board after completing its first revised full term (2022–25), marked by impactful contributions. We remain dedicated to fostering innovation, international collaboration, and developing future leaders in Human Genetics.

P25.059.D How should polygenic risk scores be used for cardiovascular disease prevention? A multi-stakeholder qualitative exploration of implementation scenarios and challenges

Dennis Vermazeren[1], *Jeroen van Rooij[1], André Uitterlinden[2]*

[1]Erasmus MC, Rotterdam, Netherlands, [2]Erasmus Medical CenterDept Internal Medicine, Laboratory of Population Genomics, Rotterdam, Netherlands.

Background: Combining polygenic risk scores (PRS) with clinical risk factors into a comprehensive risk profile (CRP) has the potential to improve risk stratification and enable personalized cardiovascular disease (CVD) prevention. However, implementation challenges persist, including defining clinically actionable thresholds, communicating personalized risk, promoting behavior change, structuring follow-up, mapping stakeholder priorities, and addressing ethical concerns. Overcoming these hurdles is vital for translating CRPs into effective clinical practice.

Methods: Within the GOALL project and the TeamPerMed consortium, we developed four implementation scenarios for CRPs in CVD prevention to encourage multidisciplinary discussion and collaboration. Using qualitative research, we will explore stakeholder perspectives on the feasibility, desirability, and acceptability of CRPs across various life stages. These insights will inform the design of future CVD prevention strategies and pilot implementation programs.

Results: By the ESHG conference, we will have developed a preliminary framework for the use of CRPs in CVD prevention. This framework will define clinically actionable thresholds, best practices for personalized risk communication, strategies to use CRPs to promote behavior change, and optimal follow-up monitoring structures. Future qualitative research will refine these elements by incorporating a diverse set of stakeholder views.

Conclusion: This study lays the groundwork for integrating polygenic risk scores with clinical risk factors into CRPs for CVD prevention. By systematically addressing the most pressing implementation barriers through qualitative research, our work will advance personalized cardiovascular risk prediction and prevention. Ultimately, our findings will inform future clinical trials and facilitate the integration of genomic and clinical data into routine healthcare applications.

P25.060.A Challenges in variant reclassification: lessons from four clinical cases and the genetic counsellor's role

Andrea Ros Peña[1], *Belen García[1], Barbara Masotto[1], Montserrat Pauta[1], Maria Ruiz[1], Marta Murillo[1], Sandra Bonache[1], Elisabeth Castellanos[1], Ignacio Guillermo[2]*

[1]Germans Trias i Pujol Hospital, Badalona, Spain, [2]Hospital Universitari Germans Trias i Pujol Ctra. de Canyet, s/n 08916 Badalona, Badalona, Spain.

Background: Categorizing genetic variants is challenging, and reclassification is common. Studies show that increasing uncertainty leads to heightened anxiety, mistrust, and confusion. We present 4 cases where reclassification impacted patient and family diagnoses and care.

Material and Methods:

Results: PATIENT A) A 61-year-old patient with familial hypertrophic cardiomyopathy (HCM) and a heterozygous, likely pathogenic NM_001018005.1 c.109A>G variant in *TPM1*, which co-segregated with HCM in the family. Consequences: Non-carrier family members were excluded from follow-up, and one relative pursued preimplantation genetic testing. Reclassification: Variant of uncertain significance (VUS) (PM2, PP1, BP4).

PATIENT B) A 36-year-old patient with MODY and a heterozygous NM_000545.6 c.-160_-154dup likely pathogenic variant in *HNF1A*. Consequences: Cascade testing and endocrinological follow-up for the carrier daughter. Reclassification: benign (BA1, BP5).

PATIENT C) A 79-year-old patient with hypermobility and aortic dilation with a heterozygous, likely pathogenic

NM_000138.4:c.370A>G variant in *FBN1*. Consequences: Cascade testing for the daughter and cardiological follow-up. Reclassification: VUS (PM2, BP4).

PATIENT D) A 39-year-old patient with arrhythmogenic right ventricular dysplasia and two heterozygous pathogenic variants: NM_198056.3: c.5902_5905dupATCT in *SCN5A* and NM_000256.3: c.667G>A in *MYBPC3*. Consequences: Cascade testing, inclusion on cardiological follow-up, and reproductive implications. Reclassification: SCN5A: VUS (PM2 + PVS1). MYBPC3: Likely benign (BS1).

Conclusion: These cases underscore the clinical significance of variant reclassification. Addressing this possibility during genetic counselling—including for pathogenic and likely pathogenic variants—can help reduce emotional distress and enhance patient preparedness. Collaboration with healthcare providers is essential, as reclassification directly impacts diagnosis and follow-up care for both patients and their families.

P25.061.B The (long) road to licensure

Vigdis F. Stefansdottir, *Eirny Th Thorolfsdottir, Hakon B. Hognason*

Landspitali University HospitalGenetics & Molecular Medicine, Reykjavik, Iceland.

The profession of genetic counselling, established over 50 years ago, has been present in Iceland since 2006 when the first MSc-trained genetic counsellor started working there. Currently, there are three qualified genetic counsellors at Landspitali University Hospital in Reykjavik, with two more expected to graduate and join the Icelandic GC team by 2027.Efforts to establish professional licensure were first made in 2010. They were denied. In 2022, a new application was sent, supported by the Directorate of Health and medical geneticists at Landspitali.In May 2024, the Icelandic Ministry of Health agreed to the application and introduced a regulation defining the profession's scope, including educational requirements, rights, responsibilities, and employment conditions. To qualify for licensure, candidates must hold a minimum of a two-year master's degree in genetic counselling from an accredited institution, aligning with European and international standards, including those set by the European Society of Human Genetics and the American Society of Human Genetics. The regulation also applies to professionals trained outside the EEA and Switzerland, allowing licensure based on equivalent qualifications.The regulation emphasizes the importance of professional ethics, ongoing expertise, and compassionate, respectful patient care. It aims to standardize genetic counselling in Iceland, ensuring high professional standards, ethical conduct, and the protection of patient rights. Following the regulation and in line with Icelandic law, eligible GCs could now apply for licensure and by October 2024, all three qualified genetic counsellors in Iceland had received their licenses.

P25.062.C Transition Care for Adolescents with Hereditary Cancer in Singapore: A Foundation for Future Work

Tasmyn Dale Scriven[1], *Jianbang Chiang*[1], *Shao-Tzu Li*[1], *Joanne Ngeow*[1,2]

[1]*Cancer Genetics Service, Division of Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore,* [2]*Lee Kong Chian School of Medicine, Nanyang Technology University, Singapore, Singapore.*

Background: Hereditary cancer syndromes may require surveillance and management beginning in childhood or early adolescence. Upon reaching adulthood, a transition to adult clinics becomes necessary. Literature on transition care highlights the anxiety experienced by patients as they navigate changes in the healthcare setting. However, there is limited literature on transition of care for adolescents with hereditary cancer syndromes. The Cancer Genetics Service in National Cancer Centre Singapore (NCCS) manages patients with hereditary cancer syndromes through virtual multidisciplinary clinics, such as a specialised 'GenoDerm' clinic for hereditary cancer conditions with cutaneous manifestations. However, there is absence of a structured transition care program for adolescents with other hereditary cancer syndromes.

Materials and Methods: A retrospective medical record review was conducted to evaluate the existing transition clinic to enhance care for adolescents with hereditary cancer syndromes.

Results: During the five-year period from 2020 to 2024, twenty-nine adolescents (mean age 19.8 ± 2.2 years, equal gender distribution) were referred from their paediatric specialties to NCCS for genetic counselling and further management. Majority of the patients (19/29, 65.5%) had Neurofibromatosis Type 1 (NF1). The remaining 34.5% had different hereditary cancer syndromes, with 30.0% of this group lost to follow-up, suggesting a gap in the current transition system for non-NF1 patients.

Conclusion: Transition care is critical in ensuring continuity of care, as well as empowering adolescents to take charge of their health. Further work is needed to improve and strengthen the transition process for adolescents with hereditary cancer in Singapore, particularly for those without NF1.

P25.063.D Detection of carriers of hereditary diseases among healthy individuals: basis for expanded genetic screening

Marta Tyrkus[1,2], *Ivanna Shymanska*[1,3], *Yevheniya Shargorodska*[2], ***Solomiia Tamara Sobechko***[1,4], *Danuta Zastavna*[2]

[1]*Medical Scientific Genetic Center "LeoGENE", 7h Maksymovycha St., Lviv 79058, Ukraine, Lviv, Ukraine,* [2]*Institute of hereditary pathology NAMS of Ukraine, Lviv, Ukraine,* [3]*Lviv State Regional Clinical Perinatal Center, 6 Dzhordzha Vashynhtona St., Lviv 79032, Ukraine, Lviv, Ukraine,* [4]*Ivan Franko National University of Lviv, Lviv, Ukraine.*

Background. Knowledge of carrier status for mutations associated with hereditary diseases enables couples to make informed decisions about family planning. Population-level carrier screening provides valuable insights into prevalence of genetic diseases in a specific region or among particular groups.

Material and Method. DNA from blood leukocytes was isolated using a salting-out method. A carrier sequencing panel of 450 genes was performed at Invitae Laboratory on 24 couples from the Lviv Region of Ukraine.

Results: NGS testing of 48 individuals showed that 16 were carriers of one hereditary disease (HD), 15 of two, 5 of three. Additionally, two individuals were carriers of four HD, one was a carrier of five, and one - of six. The most commonly detected mutations were in the *HFE* gene (25%), *GALT* gene (10.4%), *DHCR7* (6.25%), *GJB2* gene (6.25%) *CFTR* gene (4.16%), *PAH* gene (4.16%), *AIRE* gene (4.16%), and *GAA* gene (4.16%). Pathogenic variants of *CYP21A2, SMN1, 1HPS1, CLN3, ATP7B, ETFA, G6PC, NAGLU, CLRN1, CNGB3, SLC22A5, NR2E3, ETFA* were also detected. Two matching pairs were found. In the first couple, both partners are carriers of the *CFTR* gene variants, the second couple - of the *DHCR7* gene and were classified as high risk.

Conclusions: A significant part of the tested individuals (66.7%) were carriers of two or more hereditary diseases, which indicates a high prevalence of pathological gene variants in this sample. Such a distribution of mutations may indicate the need for more expanded genetic screening to identify carriers of key HD among healthy individuals.

P25.064.A A comparison between monosomy X and mosaic Turner syndrome- What is the appropriate genetic counseling in each case?

Adi Ben-Yehuda[1], *Omri Weiss*[1], *Orit Lobel*[1], *Sharon Zeligson*[1], *Reeval Segel*[1,2]

[1]*Shaare Zedek Medical Center, Medical Genetics Institute, Jerusalem, Israel,* [2]*The Hebrew University of Jerusalem, Faculty of Medicine, Jerusalem, Israel.*

Background: Genetic counseling when a fetus is found to have a mosaic chromosomal anomaly is challenging, especially when the diagnosis is Mosaic Turner Syndrome (MTS). We studied the clinical data of fetuses and individuals found to have full monosomy X (45,X) or MTS from the cytogenetic and microarray labs in Shaare Zedek Medical Center, in order to better understand the phenotypes, for appropriate genetic counseling.

Material and Methods: We reviewed all cases found to have 45,X or MTS in our labs, between the years 2009–2024. We checked the referral reasons, type of sample tested (blood or prenatal sample) and age at diagnosis.

Results: 57 cases of 45,X and 69 cases of MTS were diagnosed. Of the 57 cases of full monosomy X, 44 (77%) were diagnosed prenatally. The referral reasons were mainly missed abortion and IUFD. Only 13 cases (23%) were diagnosed postnatally, mainly at a very young age. Of the 69 cases of MTS, 9 were excluded due to complex karyotypes. 55/60 (92%) were diagnosed posnatally and Only 5/60 (8%) were diagnosed prenatally. The main referral reasons were recurrent miscarriages (28/60, 47%), infertility (13/60, 22%) and short stature (6/60,10%).

Conclusion: Our data show that most cases of full monosomy X were diagnosed prenatally, tested for severe phenotypes, while most cases of MTS were diagnosed in adult age, with a much milder phenotype. Our observations suggest that the genetic counseling should be different for full monosomy X Vs. MTS.

P25.065.B Improving Patient-Centered Collaboration and Driving Innovation in Rare Disease Care: Insights from the ERN ITHACA 2024 Patient Advisory Board Workshop, Buccarest 2024

Anne Hugon[1], *Dorica Dan*[2,3], *Tanja Zdolšek Draksler*[4,5], *ERN ITHACA Consortium - Patient Advisory Board ERNITHACA*[6], *Pr Alain Verloes ERN ITHACA Consortium - Coordination Team*[6]

[1]*APHP Assistance Publique-Hôpitaux de Paris - Université de Paris, Dept. of Genetics, ERN ITHACA, Paris, France, Paris, France,* [2]*ePAG Patient Advisory Board ERN ITHACA Chair, Paris, France, France,* [3]*Romanian Prader Willi Association, Romania, Zalau, Romania,* [4]*ePAG Patient Advisory Board ERN ITHACA Vice Chair, Paris, France,* [5]*IDefine Europe, Foundation for the Advanced Treatment of Rare Genetic Diseases, Slovenia, Ljubljana, Slovenia,* [6]

Background and Objectives: The ERN ITHACA Patient Advisory Board meeting in Bucharest on 12 December 2024 brought together 60 participants, including ePAGs, clinicians, and online attendees. The event aimed to foster collaboration across the rare disease community by sharing best practices, exploring patient journeys, and promoting interdisciplinary teamwork. Presentations focused on innovative strategies in rare disease management, including patient-led guidelines, multidisciplinary clinic models, and novel data collection approaches.

Material and Methods: The workshop was structured into two main components. First, participants learned from each other through presentations and flash talks, showcasing best practices such as care coordination initiatives and global registries. Topics also included patient-led guidelines and data management strategies to enhance research. The second component, "The Patient Journey," addressed challenges like diagnosis, grief, and mental health, featuring testimonies and group discussions. Parallel working groups explored family resilience and grief management strategies, promoting dynamic exchanges between patients, families, and professionals.

Results and Impact: Feedback from participants revealed high satisfaction, with an overall rating of 4.68/5. Attendees appreciated actionable insights from the best practice sharing sessions (4.57/5) and the emotional depth of the patient journey discussions (4.68/5). The workshop successfully promoted patient-centered care and interdisciplinary collaboration. Suggestions for improvement included adding more interactive exercises, diversifying topics, and incorporating additional patient stories.

Conclusion: This event highlighted the importance of inclusive, collaborative initiatives and set the foundation for future workshops, including the next Patient Workshop in Bergen, Norway (December 2025), focusing on global care perspectives.

P25.066.C The Orphanet Newborn Screening Bibliographical Knowledgebase

Perrine Renard, *Hélène Jagline, Caterina Lucano, Valérie Lanneau, Nicolas Chevrollier, Charlotte Rodwell, Marc Hanauer, Ana Rath*

INSERM, US14 - Orphanet, Paris, France.

Background: Newborn screening (NBS) is a cornerstone public health measure aimed at early identification of rare, often genetic, conditions during the neonatal period aiming to implement appropriate measures as early as possible to prevent or limit the negative consequences of these diseases on children's health. The Rare 2030 project, commissioned by the European Parliament, emphasized the need for harmonized NBS strategies across Europe to enhance the diagnosis of rare diseases. Key recommendations included sharing health technology assessment data and best practices to support informed and transparent decision-making.

Material and Methods: In response, Orphanet launched an open access NBS library in 2023, designed to centralize and disseminate knowledge in this field. This resource, available in English and French, is a comprehensive bibliographical database including 823 articles so far dating back to 2008, annotated with the corresponding disease ORPHAcode to facilitate retrieval of information. The library is updated monthly through a systematic literature survey including the one transmitted by French High Authority for Health (HAS) and is supported by AFM-Téléthon.

Results: Our study will show the evolution over the years of the number and distribution of publications between the different categories of the library (global scientific, epidemiological, social, economic and regulatory evidence). A particular focus will also be

made on the growing number of articles relating to the Next-Generation Sequencing (NGS) gene-based screening methods for NBS.

Conclusion: By fostering knowledge-sharing and promoting evidence-based practices, the Orphanet NBS library is a vital tool contributing to the harmonization of NBS strategies across Europe.

P25.067.D Non-directiveness in genetic counselling: development of a scoping review protocol

*Ana F. Couto[1], Maria Barbosa[2,3,4], Angus J. Clarke[5], Liliana Sousa[1], **Álvaro Mendes**[2,6]*

[1]Department of Education and Psychology, RISE-Health, University of Aveiro, Aveiro, Portugal, [2]i3S – Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal, [3]CGPP – The Centre for Predictive and Preventive Genetics, IBMC – Institute for Molecular and Cell Biology, Universidade do Porto, Porto, Portugal, Porto, Portugal, [4]FPCEUP – Faculty of Psychology and Educational Sciences and CPUP – Centre for Psychology, University of Porto, Porto, Portugal, [5]Cardiff University School of Medicine, Institute of Medical Genetics, University Hospital of Wales, Cardiff, United Kingdom, [6]CGPP – The Centre for Predictive and Preventive Genetics, IBMC – Institute for Molecular and Cell Biology, Universidade do Porto, Porto, Portugal.

Background: Genetic counselling (GC) has traditionally adhered to the principle of non-directiveness (ND) to help individuals make decisions that align with their values and circumstances, without steering them toward specific choices. While ND has been the subject of considerable debate, with some commentators even suggesting a departure from the term, it remains relevant to discussions of GC's ethos and practice. We have developed a scoping review protocol following PRISMA and JBI guidelines, aiming to document the concepts, meanings, values, and practices associated with ND in GC.

Material and Methods: Relevant articles were identified through searches in Scopus, Web of Science, PubMed, and PsycInfo in January 2025 using terms such as "genetic counsel* OR geneticist AND non-directiv* OR nondirectiv* OR non directiv* OR neutrality OR autonomy OR patient-cent* OR patient cent* AND genetic test." Inclusion and exclusion criteria followed the Population, Concept, and Context (PCC) framework, covering original peer-reviewed articles in English from 1975 onward, since this was the first published definition of GC (by the American Society of Human Genetics). All research methods were considered, while grey literature was excluded. Commentary and review articles were included to capture diverse ideas, values and research findings on ND in GC.

Results: The search yielded 1151 papers; we will now proceed to duplicate removal, data extraction, and analysis.

Conclusion: This is the first comprehensive literature review examining the concept of ND and how it is used within GC.

P25.068.A A new contest dedicated to DNA Day in Georgia: "Art Genome"

***Eka Kvaratskhelia**[1,2], Tinatin Tkemaladze[1], Sandro Surmava[1], Elene Abzianidze[1,3]*

[1]Tbilisi State Medical University, Tbilisi, Georgia, [2]V. Bakhutashvili Institute of Medical Biotechnology, Tbilisi, Georgia, [3]Ivane Beritashvili Center Of Experimental Biomedicine, Tbilisi, Georgia.

Background: European and American Societies of Human Genetics, as well as many other national societies support DNA Day events all over the world, including annual essay and video contests [1, 2, 3]. Since these contests are open only to students in grades 9–12, the Georgian Society of Medical Genetics an Epigenetics (GSMGE) and Tbilisi State Medical University (TSMU) have partnered in 2023 to launch a new contest, "Art Genome", for university students as part of the activities of DNA Day.

Material and Methods: Biomedical students from Georgian and international programs were eligible to present their works (digital or traditional art). The artworks were relevant to the specified topics. Scoring was based on the following criteria: compliance with the topic of the competition (5 pts); technical capabilities (5 pts); originality (5 pts); total 15 pts.

Results: A total of 70 art works were submitted in 2023 and 2024. First, second, and third place winners were declared through the judging process. Judges were recruited from the active membership of GSMGE and Tbilisi State Academy of Arts. Winners were awarded monetary prizes. All participants received a certificate of participation. In addition, hands-on workshops "Artificial Intelligence in Diagnosis of Rare diseases" and "CRISPR-Cas9 LacZ Gene Editing" were organized for participants and winners.

Conclusion: The Art Genome contest promotes deepening knowledge in the field of genetics, developing interest in science and developing creative thinking.

P25.069.B Benefits of blended learning in medical genetics education

*Thomas Bomersbach[1], Angélique Baillia[1], Antoine Ducornet[1], Philippe Frossard[1], Evan Gouy[2], **Anne-Sophie S. Lebre**[3]*

[1]Université Reims Champagne-Ardenne (URCA), Direction du numérique, Pôle Ingénierie Pédagogique et Production Audiovisuelle, REIMS, France, [2]Lyon Est Medical Faculty and Research on Healthcare Performance Laboratory (INSERM U1290), Claude Bernard University Lyon, LYON, France, [3]CHU Reims and Université Reims Champagne Ardenne, REIMS, France.

Background: We introduced blended learning (BL) into medical genetics courses. This transition was challenging, but collaboration with instructional designers allowed to make our discipline a pilot program for Reims Medical School.

Methods: Teaching was overhauled with objectives: 1) to revise the pedagogical scenarization, 2) to encourage students to return to classes. We developed a pathway available on the university's Moodle platform (7 modules, 30 sequences), adopted an asynchronous e-learning and synchronous approaches for lectures and tutorials, respectively.

Results: With BL, we ensured a coherent integration between distance and face-to-face learning and created more concise and varied teaching materials (e.g. short videos, podcasts, flashcards). Short assessments were scheduled after each module on Moodle, and using an audience response system (Wooclap). Students could post questions on a Moodle discussion forum, with responses provided on a weekly basis. A final satisfaction survey is conducted and Moodle learning analytics are analyzed. After two years of implementing this new course, our goals have been met and student attendance has consistently increased.

Conclusion: Our approach addresses demographic challenges: a decrease in the number of teachers and an increase in the number of medical students. Some of these tools are shared with the midwifery and pharmacy curricula. This transformation requires significant time investment for initial design, ongoing maintenance of materials, and responses on the forum. The diversification of teaching materials adds depth to the courses, surpassing the traditional "student handout" approach. The introduction of BL represents an original and ambitious approach, embraced by both teachers and students

P25.070.C Educational project in medical school for preparation in complex genetic counseling: breaking bad news and anamnesis collection

Chiara Francesca Longo[1], *Giovanni Micheloni*[1], *Roberto Valli*[1], *Annalia Cianflone*[2], *Lucy Costantino*[3], *Fulvio Ferrara*[1], *Elena Mandorino*[3], *Francesco Pasquali*[1], *Lucia Tararà*[1], *Elena Ferioli*[1], *Andrea Moriondo*[1], *Mario Picozzi*[1], *Giovanni Porta*[1]

[1]*Università dell'Insubria, Varese, Italy,* [2]*Laboratory of Cytogenetics and Molecular Biology, Ospedale di Circolo, ASST Sette Laghi, Varese, Varese, Italy,* [3]*CDI - Centro Diagnostico Italiano, Milano, Italy.*

Background: Enhanced understanding of human genome, coupled with advancement in sequencing technology has led healthcare professionals towards precision medicine and its four "P" theory (Flores et al., 2013). Currently, patients may be guided by inaccurate information which derived from direct to consumer genetic tests and the management of incidental findings. Therefore a relationship of trust with the geneticist becomes fundamental. Breaking Bad News (BBN) is a complex clinical task that should be recognized as competency in the training of healthcare professionals (Saleh et al., 2022), as well as the integration with ethics consultation to address distress arising from ethical and cultural dilemmas.

Material and Methods: Communication models from a neurocultural perspective and biofeedback serve as advanced tools for managing complex social dynamics, allowing for the identification of areas for improvement from an intergenerational and cross-cultural perspective.Recent studies on feedback in healthcare training based on facial expressiveness (Woods et al., 2024; Singh et al., 2021) could enable an accurate assessment of the effectiveness of doctor-patient communication in the genetic field and provide appropriate communication standards.

Results: We will compare the collected data with the measurement of the trainee's self-awareness to identify areas for improvement and establish a protocol for genetic counseling in various contexts, with a focus on burnout prevention, time optimization, and resource management in patient care.

Conclusion: The proposed training project integrates biofeedback and expressive analysis to enhance BBN skills in healthcare students, optimizing genetic counseling in cross-cultural and intergenerational contexts while preventing professional burnout.

P26 Ethical, Legal and Psychosocial Aspects in Genetics

P26.001.D Parent perspectives on whole genome sequencing for Autism Spectrum Disorder

Michael J. Szego[1,2], *James A. Anderson*[3,2], *Stephen W. Scherer*[3,2]

[1]*Unity Health Toronto, Toronto, ON, Canada,* [2]*University of Toronto, Toronto, ON, Canada,* [3]*The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Given the level of genetic heterogeneity associated with ASD, whole genome sequencing (WGS) is a powerful research and diagnostic tool. Due to the potential for secondary findings and the currently limited treatment options available, parent and patient perspectives on the use of WGS in this context are much needed.

Material and Methods: Parents (and qualified children) enrolled in an ASD genomics study were invited to participate in semi-structured interviews about their experiences with WGS. The interviews occurred prior to genomic sequencing (time 1) and after sequencing results were returned (time 2). Eighteen participants were interviewed for time 1 and time 2, respectively. Analytic techniques consistent with interpretive description were then used.

Results: Four themes emerged: contribution to science, hope for treatment, understanding cause and responsibility. The motivation to contribute to science was a prominent theme at both timepoints. By contrast, the hope for treatment identified at time 1 shifted to disappointment at time 2, when it became clear that results would not lead immediately to treatment. Identification of a genetic cause of ASD was associated with relief by some parents, and responsibility by others, depending on how they ascribed blame/blamelessness.

Conclusion: A diagnosis of ASD was an inclusion criterion for the genomic study we recruited from. Though children in this study would have access to standard of care treatments, their parents clearly harboured hope for additional treatment options following WGS. Researchers and clinicians employing WSG need to further reinforce how sequencing is not a panacea for disorders like ASD.

P26.002.A Understanding the experience of an uncertain newborn screening result (Award Candidate)

Faye Johnson[1], *Fiona Ulph*[1], *Rhona Macleod*[1], *Kevin W. Southern*[2]

[1]*The University of Manchester, Manchester, United Kingdom,* [2]*The University of Liverpool, Liverpool, United Kingdom.*

Background: Whole genome sequencing (WGS) is being incorporated into mainstream healthcare, including newborn screening (NBS). In addition to clinically useful information, WGS produces uncertain results that lack available prognostic information. Research suggests uncertain NBS results have negative psychological impact at a crucial life stage. This study sought to create a theory to better understand why this occurs.

Material and Methods: This qualitative study investigated the experiences of parents of children with Cystic Fibrosis Screen Positive Inconclusive Diagnosis, an example case of an uncertain result from current NBS. The researcher interviewed 16 parents from NHS trusts around England. Data collection and analysis used grounded theory methods to create a transferable theory.

Results: The theory charts parents' experience through four phases of adaptation: 'destruction of the family story'; 'reconstructing the story'; 'reclaiming the story'; and 'withstanding imposed incongruity'. Core to parents' experience is the 'square peg, round hole' paradox: this type of NBS result does not fit well with medical services, communications and understanding that

currently appear unable to accommodate uncertainty. Although uncertain results are not diagnoses, the concept of a diagnosis received undue focus in communication and management of the result, risking unnecessary medicalisation and distress. Parents were negatively affected by experiences, such as interactions with medical services, that disrupted their progress through the phases of adaptation.

Conclusion: The outcomes of the study emphasise the need to modify medical services, communications and understanding in order to healthily accommodate the range of results that will be produced in the genomic era.

C.O.I. Disclosure:

F. Johnson: None. **F. Ulph:** None. **R. Macleod:** None. **K.W. Southern:** None.

P26.004.C Scope, context and implications for practice of familial genomic information: a UK workshop report

Helena Carley[1], *Tara Clancy*[2], *Susie Weller*[1], *Anneke M. Lucassen*[3]

[1]*Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [2]*University of Manchester, Manchester, United Kingdom,* [3]*Director of the Centre for Personalised Medicine, University of Oxford, Oxford, United Kingdom.*

Background: Genomic information is often relevant to more than one family member. This can present conflicting obligations to healthcare professionals (HCPs): balancing patient confidentiality with prevention of harm to another person. In 2020, a case in the UK High Court (ABC vs St George's Healthcare NHS Trust) established that HCPs have a legal 'duty to consider' disclosing information to a relative who is at risk of serious harm. UK professional guidance have long recommended this, but how to apply it in clinical practice is not always clear.

Material and Methods: A workshop was held in November 2023 to identify areas of consensus to inform future professional guidance. 53 participants attended, including patient representatives, HCPs from different specialities, lawyers and academics. Four presentations covered the key clinical, ethical and legal considerations and were followed by a facilitated discussion. A transcript of the workshop was analysed, themes identified and summarised in a report.

Results: Three main themes were identified and will be discussed in more detail: (1) Patient and familial perspectives and considerations; (2) Healthcare professional perspectives and considerations; (3) The role of legal structures.

Conclusion: This workshop clarified the UK legal position and how this aligns with existing professional guidance. A duty to consider relatives may be enacted by using anonymised familial information without specific consent. Resources and further professional guidance are needed to support both HCPs (including those working in non-genetic specialisms) and patients in sharing information. It is crucial to work with patient organisations to co-develop and disseminate these.

P26.005.D Informed Consent: An Unexpected Barrier for Inclusivity in Research on Public Engagement

Isabel R.A. Retel Helmrich[1], *Diewertje Houtman*[1], *Wendy Geuverink*[2], *Joosje Kist*[1], *Rosan Lechner*[1], *Lidewij Henneman*[3], *Martina Cornel*[4], *Sam Riedijk*[1], *De DNA dialogen consortium (The DNA dialogues consortium)*[5]

[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Amsterdam UMC, Amsterdam, Netherlands,* [3]*Amsterdam UMC, Vrije Universiteit Amsterdam, Dept. Human Genetics, Community Genetics, Amsterdam, Netherlands,* [4]*Professor of community geneticsAmsterdam UMC, location AMC, Reception B0Human Genetics / APH researc, Amsterdam, Netherlands,* [5]

Background: In the Dutch DNA Dialogues we aim for inclusive public and stakeholder engagement (PSE) to enable societally aligned policy making for human germline gene editing (HGGE). We engage groups not typically included in PSE, and encounter challenges with obtaining informed consent. In research, the informed consent procedure is intended to safeguard informed decision making and autonomy of participants, through standardized information letters and consent forms. This qualitative study reports on the challenges and aims to explore alternative approaches for inclusive consent procedures.

Materials and methods: We organized over 26 dialogues, which were audio recorded, about HGGE in different settings with diverse publics. We consulted key figures that have familiarity with and are trusted by communities. Together, we identified barriers for inclusivity and based on these co-created alternative approaches regarding language, information provision, options for completion and how and by whom the materials are presented.

Results: The traditional informed consent procedure is a barrier for inclusivity as perceived by researchers and participants alike, due to the logistics being time-consuming and burdensome, complex language, low trust in science or government institutions, and functional disabilities. Accessible language and tailoring based on i.e. design and options for completion is essential. Contact and familiarity with the researcher(s) and key figures should be enabled to facilitate trust. Key figures recommended to provide options for implicit, verbal or anonymous consent.

Conclusion: We argue that traditional consent procedures in research on PSE should be replaced by tailored approaches co-created with key figures, while maintaining voluntariness of participants.

P26.006.A Perspectives of individuals at risk of genetic frontotemporal dementia on presymptomatic genetic testing

Charlotte Graafland, Laura Donker-Kaat, Eline M. Bunnik

Erasmus MC, Rotterdam, Netherlands.

Background: Presymptomatic genetic testing (PT) for autosomal dominant frontotemporal dementia (FTD) is not taken up as often as initially expected. Few qualitative studies have explored considerations around PT in individuals at risk of genetic FTD. This interview study explores considerations around and experiences with PT in Dutch carriers, non-carriers and individuals at 50% risk of genetic FTD.

Material and Methods: 28 semi-structured qualitative interviews were conducted with Dutch pre-symptomatic confirmed carriers ($n = 11$), individuals at 50% risk ($n = 14$), and confirmed non-carriers ($n = 3$) of genetic FTD about PT, with an average age of 43.7 years. Data were analyzed using inductive thematic analysis.

Results: Reasons in favor of PT included wanting to know and to relieve uncertainty, hoping to test negative, relevance for life planning, informing children's reproductive decision-making, explaining future symptoms, and contributing to the common good. Reasons against PT were fearing psychological impact, fearing effects on employment, insurability or mortgage,

maintaining hope, and no immediate relevance for life planning, partly due to uncertainty surrounding age of onset. Reasons were similar in all groups, but were weighed differently. Decision-making processes were influenced by age, family and friends, and personal experiences with FTD.

Conclusion: Decision-making regarding PT in FTD is highly personal, and seems to be influenced by the individual's tolerance for uncertainty and perceived actionability of genetic information. When supporting individuals at risk of FTD in decision-making, genetic counselors should take into account an individual's characteristics, previous experiences with FTD, the role of family and friends, and clinical heterogeneity.

Guido MWR de Wert[1], *Carla G. van El*[2], *Angus Clarke*[3], *Christophe Cordier*[4], *Florence Fellmann*[5], *Maurizio Genuardi*[6], *Sabine Hentze*[7], *Hülya Kayserili*[8], *Milan Macek, M.D.*[9], *Rhona Macleod*[10], *Bela Melegh*[11], *Álvaro Mendes*[12], *Emmanuelle Rial-Sebbag*[13], *Vigdis Stefansdottir*[14], *Lisbeth Tranebjaerg*[15], *Fiona Ulph*[16], *Francesca Forzano*[17]

[1]*Maastricht University, Maastricht, Netherlands,* [2]*Amsterdam University Medical Center, Amsterdam, Netherlands,* [3]*Cardiff University-Division of Cancer and Genetics, Cardiff, United Kingdom,* [4]*MEDISYN SA, Lausanne, Switzerland,* [5]*FeelGood Onco, Clarens, Switzerland,* [6]*Universita Cattolica del Sacro Cuore, Rome, Italy,* [7]*EMBL, Heidelberg, Germany,* [8]*Koc University School of Medicine (KUSOM) Medical Genetics Department, Istanbul, Turkey,* [9]*Motol University Hospital - 2nd Faculty of Medicine, Charles University, Prague, Czech Republic,* [10]*Genetic MedicineSt Mary's Hospital, 6th Floor, Manchester,* [11]*University of Pécs, Pécs, Hungary,* [12]*i3S, IBMCUnIGENe and Centre for Predictive and Preventive GeneticsUniversidade do Porto, Porto, Portugal,* [13]*Inserm UMR 1295, Toulouse, France,* [14]*Landspitali University HospitalGenetics & Molecular Medicine, Reykjavik, Iceland,* [15]*Vipperod, Denmark,* [16]*University of ManchesterDivision of Psychology & Mental Health, School of Health Sci, Manchester,* [17]*Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.*

Background: Cascade testing (CT) is still underused and faces barriers. ESHG contributes to ongoing discussions on how to responsibly optimise informing at-risk relatives and uptake of testing. Recommendations were drafted based on an ethical analysis under what circumstances CT is justified, or its case might be less compelling, based on its proportionality, the actual utility of CT and the judicious use of finite resources.

Material and Methods: ESHG's Policy and Ethics Committee (PEC) and invited experts prepared the draft, ESHG membership consultation was from 25 June until 1 August 2024. Suggestions were integrated where appropriate. The ESHG Board approved the final version by 23 December 2024.

Results: In cases of high risk of serious, avoidable harm a more active approach towards CT is suggested including a more directive approach in counselling, more active support for the proband in passing information to relatives, direct contacting, and allowing the balancing of confidentiality when this is necessary to avoid high risk of serious harm, taking account of national regulations and jurisdictions. In contrast, more caution is advised in more complex cases where the balance of benefits and harms of CT are less clear, such as when penetrance is low, or actionability is limited. This more cautious approach does not call for directivity, direct contact or the relaxing of medical secrecy. The focus, then, shifts to cascade counselling, rather than cascade testing.

Conclusion: Balance between possible benefits and harms is important to assess the proportionality and optimal conditions of CT and cascade counselling.

P26.008.C Beyond genomic newborn screening: Using infants' data as a lifetime resource

Danya F. Vears[1,2,3], *Fiona Lynch*[4,3,2], *Stephanie Best*[3,5,6], *Clara Gaff*[7,2,3], *Lilian Downie*[2,8,3], *Alison D. Archibald*[2,3,8], *Christopher Gyngell*[2,3], *Ilias Goranitis*[3,5], *Riccarda Peters*[3], *Sebastian Lunke*[8,3], *Zornitza Stark*[8,2,5]

[1]*Centre for Biomedical Ethics and Law, KU Leuven, Leuven, Belgium,* [2]*Murdoch Children's Research Institute, Parkville, Australia,* [3]*University of Melbourne, Parkville, Australia,* [4]*Deakin University, Geelong, Australia,* [5]*Australian Genomics, Parkville, Australia,* [6]*Peter MacCallum Cancer Centre, Parkville, Australia,* [7]*Melbourne Genomics Health Alliance, Parkville, Australia,* [8]*Victorian Clinical Genetics Service, Parkville, Australia.*

Background: Genomic sequencing has the potential to improve newborn screening (NBS) programs by detecting severe childhood-onset conditions, facilitating early intervention and improving health outcomes for children. Yet little research has investigated using genomic NBS data as a lifetime resource.

Material and Methods: To address this, we conducted focus groups with parents of babies who had participated in BabyScreen +, a pilot study that screened 1000 babies in Victoria, Australia for >500 conditions. Focus groups were conducted online and analysed using inductive content analysis.

Results: 32 parents of infants from the BabyScreen+ study participated across eight focus groups. This comprised 29 mothers and 3 fathers; 2 had received a high chance result. Most thought data from genomic NBS should be stored and relooked at throughout the child's life. In terms of potential subsequent analyses, our participants believed certainty that a genetic condition will develop was critical in deciding whether they wanted to receive that information. Although treatability was viewed as important by many, some participants thought they would want to receive information about untreatable and potentially life-limiting conditions because it would give them an opportunity to plan for the future. An age-dependent, staged approach to receiving information was often favoured, although a proportion of parents would want to receive everything as early as possible.

Conclusion: Our findings suggest parents are generally willing for their child's genomic data to be stored and used long-term to improve health outcomes. This knowledge can help inform policy regarding data uses and development of genomic NBS programs.

P26.009.D Perspectives of Belgian genetic professionals on the reporting of results within reproductive genetic carrier screening

Kaatje Goossens, *Eva Van Steijvoort, Pascal Borry*

KU Leuven, Leuven, Belgium.

Background: Since 2019, a reproductive genetic carrier screening (RGCS) offer including more than 1000 genes associated with autosomal recessive and X-linked conditions has been available in Belgium to reproductive partners with a desire to have children. This study sought to investigate the perspectives of Belgian genetic professionals regarding results reporting within RGCS, drawing on their experiences from the past five years.

Material and Methods: Semi-structured interviews were conducted between December 2023 and April 2024 with trained genetic professionals who had direct experience with RGCS. Participants were asked about their views on reporting individual versus couple-based results, incidental findings (IFs), and variants of unknown significance (VUSs) in the context of RGCS. An inductive coding approach was applied to develop an initial codebook which was further refined as additional concepts emerged.

Results: Eighteen trained genetic professionals from six different centres participated. Most favoured couple-based reporting and reporting actionable IFs, but opposed to reporting VUSs in the context of RGCS. Opinions on whether to apply an opt-in or opt-out approach for individual results were mixed, while there was stronger consensus supporting this approach for IFs. Views of participants were mostly shaped by the perceived objective of RGCS, the availability of qualitative pre-test counselling and practical considerations.

Conclusion: This study provides insights into the perspectives of Belgian genetic professionals on the reporting of results within RGCS. While current approaches were broadly endorsed, challenges such as the need to expand counselling capacity were identified to ensure a responsible implementation of RGCS.

P26.010.A A two-decade text mining analysis of language evolution in ESHG conference abstracts

Andrada Ciuca[1], *Jools Kasmire*[2,3], *Sarah Wynn*[4], *William Newman*[5,6], *Ramona Moldovan*[1,5,6]

[1]*Babes-Bolyai University, Cluj, Romania,* [2]*UK Data Service, Cathie Marsh Institute, University of Manchester, Manchester, United Kingdom,* [3]*Department of Social Statistics, School of Social Sciences, University of Manchester, Manchester, United Kingdom,* [4]*Unique, Rare Chromosome and Gene Disorder Support Group, Oxted, United Kingdom,* [5]*Division of Evolution, Infection and Genomic Sciences, School of Biological Sciences, University of Manchester, Manchester, United Kingdom,* [6]*Manchester Center for Genomic Medicine, St. Mary's Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: Language in healthcare and genetics is dynamic and shapes how we interact. Patient organizations and professional bodies have increasingly introduced guidelines to promote inclusivity and sensitivity in language, particularly regarding disability. However, an analysis into how language has evolved in genetics context remains underexplored.

Methods: A text-mining and natural language processing (NLP) approach was applied to 35.745 abstracts accepted at ESHG conference between 2001 and 2021. NLP included data preparation, consolidation and frequency analysis. Specific sets of words related to genetics (e.g., "mutation," "variant"), conditions (e.g., "disease," "disorder"), individuals (e.g., "patient," "proband"), and descriptors (e.g., "diagnosed," "impacted") were included. Linear regression was used to assess temporal changes.

Results: Significant changes in language were observed across all word sets. For genetics set, term "variant" showed increase over time ($p < 1 \times 10^{-3}$), while "mutation" had a non-significant decreasing trend. For conditions set, terms "condition" ($p < 1 \times 10^{-3}$), "syndrome" ($p = 0.017$), "disease" ($p < 1 \times 10^{-3}$), "disorder" ($p < 1 \times 10^{-3}$) and "diagnosis" ($p < 1 \times 10^{-3}$) increased with time, while term "illness" remained constant. For individuals set, terms "patient" ($p < 1 \times 10^{-3}$), "individual" ($p = 0.005$), and "proband" ($p < 1 \times 10^{-3}$) increased, while terms "person", "subject," and "case" remained constant. For descriptor set, increases were observed for "diagnosed" ($p < 1 \times 10^{-3}$) and "impacted" ($p < 1 \times 10^{-3}$), while "affected" and "suffering from" remained constant.

Conclusions: The findings indicate a shift toward more neutral and inclusive language in genetics-related abstracts over the past two decades. These trends reflect broader efforts to align scientific communication with guideline recommendations emphasizing language sensitivity and inclusivity. Results have implications for automated text analysis, abstract preparation, and development of language guidelines.

P26.011.B Multi-cancer early detection based on cell-free tumor DNA: an ethical exploration

Maria Siermann, *Hafez Ismaili M'hamdi, Adri Voogd, Guido de Wert*

Maastricht University, Maastricht, Netherlands.

Background: Multi-cancer early detection (MCED) tests are emerging and could be used as population screening. MCED promises early detection of over 50 types of cancer using a blood test and analyzing cell-free tumor DNA. Ethical analysis of MCED is crucial for its responsible development and implementation.

Material and Methods: Based on the ethical core of the screening criteria of the WHO (based on Wilson and Jungner), we provide an ethical exploration of MCED using the principles of 'proportionality', 'respect for autonomy', and 'justice'.

Results: Proportionality requires that the benefits of MCED outweigh its potential harms for participants. The promised benefits of MCED include improvement of cancer screening and prevention or postponement of cancer-related mortality and morbidity. However, study results so far raise questions about the test quality and the diagnostic performance metrics. It is uncertain whether the potential health gains outweigh the false-positives, false-negatives and the accompanying adverse physical, psychological and financial implications. To respect autonomy, individuals should receive understandable and well-balanced information about the test and not experience undue pressure towards using these tests. Additionally, meaningful follow-up actions, such as treatment, should be available. Justice requires that the costs of MCED and follow-up care are balanced against expected health gains and alternative government expenditures, especially pertaining to public health screening. Independent evaluation of MCED, with a critical eye towards commercial interests at play, is crucial.

Conclusion: It is not yet clear whether this screening meets the requirements of proportionality, justice and respect for autonomy. Caution is therefore urgently advised.

P26.012.C Nothing About Us, Without Us Leading, The International Federation for Indigenous Genomics

Maile Taualii[1], *Alex Brown*[2], *Nadine Caron*[3], *Maui Hudson*[1], *Ngiare Brown*[4], *Phillip Wilcox*[5], *Rodney Haring*[6], *Laura Arbour*[7], *Wyeth Wasserman*[7]

[1]*The International Federation for Indigenous Genomics, Volcano, HI, USA,* [2]*Australian National University, Canberra, Australia,* [3]*University of British Columbia, Vancouver, BC, Canada,* [4]*Djanaba Wellbeing, Wollongong, Australia,* [5]*University of Otago, Otago, New Zealand,* [6]*Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA,* [7]*University of British Columbia, Victoria, BC, Canada.*

Background: "*The genomic health divide must be kept in check and ultimately bridged through equitable economic investment, clinical research, and provision and use of genomic services and technologies globally*." WHO, 2017 This proclamation became the backbone of the Silent Genomes Project, which commenced in April 2018. Although the impetus was the lack of genomic reference data for Canadian Indigenous people noted by clinical geneticists using sequencing for clinical diagnosis, the project scope grew to address genomic inequity at multiple levels. One mechanism to address the genomic inequity was the International Indigenous Genomics Advisory Committee (IIGAC), comprised of international Indigenous experts to provide external guidance on the project, as well as providing insight into international advancements in this area.

Methods: In March of 2023, the IIGAC and additional international Indigenous scholars explored ethically acceptable ways to ensure Indigenous reference data are available for patient care internationally, while being protected from misuse.

Results: The meeting outlined key goals to explore how Indigenous genomic data and background variant databases can be shared internationally in a culturally safe manner to benefit patients with rare diseases, while respecting and integrating FAIR and CARE principles and the operationalization of ethical frameworks, governance processes, and technical infrastructures and consider international genomic and phenotypic data sharing that are Indigenous led.

Conclusion: IFIG aims to share guidance with research granting agencies, research ethics boards and publishers of genomic research so they are able to exert processes to meet their accountability to Indigenous genomic data sovereignty.

P26.013.D Public perception and willingness to participate in somatic gene therapy first-in-human trials: a Belgian survey study

Phaedra Locquet[1,2], *Margaux Reckelbus*[2,1], *Eva Van Steijvoort*[2], *Pascal Borry*[2], *Bram Korbmacher*[1,2], *Sofie Gordts*[1,2], *Lauren Vanceer*[1,2], *Isabelle Huys*[1]

[1]*Department of Pharmaceutical and Pharmacological Sciences, KU Leuven, Leuven, Belgium,* [2]*Department of Public Health and Primary Care, Centre for Biomedical Ethics and Law, KU Leuven, Leuven, Belgium.*

Background: Genetic disorders affect millions, yet only 10% of patients receive effective treatment. Gene editing technologies show promise, but first-in-human trials face challenges in defining inclusion criteria and encouraging patient participation. This study addresses a critical gap in understanding public perceptions in Belgium, essential for the responsible development and adoption of gene therapy trials.

Material and Methods: A cross-sectional online survey using convenience sampling was conducted in Belgium with adults (18+) recruited through local pharmacies. The survey included 12 items assessing self-reported knowledge of and willingness to accept gene therapy. To evaluate willingness to accept, hypothetical vignettes were used, which varied by treatment characteristics (e.g., side effects, efficacy, limited evidence), patient age (5, 20, 65 years), and symptomatic status (symptomatic, asymptomatic with uncertain or expected future symptoms). Descriptive statistics summarised all items included in the questionnaire.

Results: Our preliminary study sample consists of 143 participants, of whom 61% had completed higher education, 56% had children, and 86% had heard of gene therapy before. Many participants expressed generally positive attitudes despite unknown long-term effects (79%), side effects (66%), and uncertain effectiveness (77%). However, key barriers included fears of altered identity (36%), external pressure (36%), and skepticism about its novelty (34%). Willingness to accept gene therapy was high across different vignettes, but it declined in scenarios involving asymptomatic patients, regardless of age.

Conclusion: Our initial results indicate a positive trend for gene therapy in symptomatic scenarios, along with a noticeable trend of reluctance toward its preventive use in genetic conditions.

P26.014.A Receiving results from genomic newborn screening: Findings from the BabyScreen+ study

Erin Tutty[1,2], *Anaita Kanga-Parabia*[1,2], *Nathasha Kugenthiran*[1], *Jade Caruana*[1], *Lilian Claire Downie*[3,2], *Clara Gaff*[4,2], *Nitzan Lang*[5], *Sebastian Lunke*[5,2], *Katrina Scarff*[5], *Zornitza Stark*[5,2,6], *Stephanie Best*[2,6], *Alison D. Archibald*[5,2,1]

[1]*Murdoch Children's Research Institute, Parkville, Australia,* [2]*The University of Melbourne, Melbourne, Australia,* [3]*Victorian Clinical Genetics Service, Parvkille, Australia,* [4]*Melbourne Genomics Health*

Alliance, Parkville, Australia, [5]Victorian Clinical Genetics Service, Parkville, Australia, [6]Australian Genomics Health Alliance, Parkville, Australia.

Background: Genomic newborn screening (gNBS) can improve health outcomes for infants. More evidence is needed to inform population-scale implementation, however, including benefits and harms to parents. BabyScreen+ piloted gNBS for 1000 newborns in Victoria, Australia. Conditions screened were severe with onset and treatment available by five years-of-age. High chance results were followed by genetic counselling and diagnostic testing. We explored parental experiences of receiving gNBS results.

Material and Methods: In this qualitative study, parents were interviewed at three months post-result. Data were analysed using inductive content analysis, informed by Interpretive Description methodology.

Results: Twenty-one parents participated (18 low chance results; 3 high chance results). Participants described having confidence in the decision to have gNBS and did not report feeling overly anxious while waiting for results. Some participants described being in a "newborn blur" when the result was disclosed, but none felt disclosure should be delayed beyond the newborn period. A low chance result provided participants with psychosocial benefits including reassurance and empowerment. Participants who received high chance results described the disclosure as a "shock" and appreciated prompt genetic counselling. Unexpected subsequent diagnoses in other family members added to the psychosocial impact. Other psychosocial impacts and support needs differed based on the diagnosis. Participants valued the clinical utility of the high chance gNBS results.

Conclusion: Participating in gNBS provides psychosocial benefits to parents who receive a low chance result. The anxiety produced by a high chance result was balanced by its clinical utility and the availability of genetic counselling.

P26.015.B Psychological support for Huntington's Disease: a Cognitive Behavioural Therapy informed intervention

Madalina Radu[1], *Stefan Trif*[1], *Simona Samoila*[1], *Filipa Julio*[2], *Astri Arnesen*[2], *Andrada Ciuca*[1], *Ramona Moldovan*[1,3,4]

[1]*Babes-Bolyai University, Cluj, Romania,* [2]*European Huntington Association, Moerbeke Waas, Belgium,* [3]*Division of Evolution, Infection and Genomic Sciences, School of Biological Sciences, University of Manchester, Manchester, United Kingdom,* [4]*Manchester Center for Genomic Medicine, St. Mary's Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: Literature is limited in comprehensive evidence supporting the impact of psychological intervention for individuals living with Huntington's Disease (HD). This study aims to investigate the impact of a cognitive behavioural therapy (CBT) for HD. This builds on and extends the *Moving Forward* project of the European Huntington Association.

Methods: The study includes individuals across three categories: individuals at risk of HD, premanifest HD, or with an HD-negative genetic test. The recruitment was facilitated by the Romanian national HD registry. The psychological intervention is CBT-based and consist of eight online individual sessions followed by two group sessions. Assessments was performed at pre-intervention, post-intervention and after the group sessions. The primary outcomes are anxiety, depression and quality of life.

Results: To date, 14 participants have been recruited and study is expected to complete recruitment of 20 participants by end of February. Among the recruited participants, 42% ($n = 6$) have a negative genetic test, 29% ($n = 4$) are at risk, and 29% ($n = 4$) have a positive diagnosis. The cohort is 50% female ($n = 7$). Preliminary results show statistically significant improvements in quality of life ($t = 4.429$, $p = 0.011$), and improvement trends in depression ($t = 1.944$, $p = 0.124$). Anxiety ($t = 0.214$, $p = 0.841$) did not show change.

Conclusion: The project is currently ongoing. Based on the data collected and analysed so far and in a similar previous project conducted by the EHA we expect to see improvement in all psychological outcomes measured. This project will contribute to the current evidence showing the impact of the psychological interventions for individuals impacted by HD.

P26.016.C Regional disparities in access to gene therapies in the European Union, United States, Japan, and China

Riya Mohan, *Margaux Reckelbus, Pascal Borry*

KU Leuven, Leuven, Belgium.

Background: Understanding the regional differences in approved gene therapies, clinical trial development, and regulatory frameworks is crucial for ensuring equitable access and addressing justice issues in advanced therapeutics. This review aimed to evaluate the differences between the US, EU, Japan, and China and offer policy recommendations to promote harmonization between these countries and regions.

Materials and Methods: A critical review of literature, including peer-reviewed articles, policy documents, national regulatory guidelines, and grey literature was conducted. Sources were selected based on their relevance to accessibility, regulatory disparities, and the selected countries/regions under consideration.

Results: Gene therapy approvals show significant regional disparities, with the U.S. leading with 23 approved therapies, followed by the EU with 16. Few products are accessible worldwide reflecting challenges in obtaining cross-border approvals. Moreover, access is uneven within regions, such as the EU, with high-income countries having better accessibility. High costs and complex reimbursement processes exacerbate these issues, with some products being withdrawn from the market due to pricing disputes. Regulatory differences, such as differing data needs, further delay access in countries, like Japan, where gene therapy products are not available until years after a product is ready for approval. Clinical trial activity mirrors these disparities, with China's growing number of trials potentially reshaping the landscape.

Conclusion: Harmonizing regulations across regions could streamline the approval process for therapies, making them more efficient and reducing disparities. Key solutions include incentivizing cost reductions through streamlined manufacturing, adopting payment models like rebates or value-based payments, and aligning evidence and reimbursement requirements.

P26.017.D Beyond the test: patient and provider perspectives on secondary findings in Middle Eastern genomic medicine

Sara Abdulrahman Alkaff, *Fahad Abdulrahman Algaeed, Ahmed Aqeel Alanazi*

King Saud Medical City, Riyadh, Saudi Arabia.

Background: The advent of whole-genome sequencing and whole-exome sequencing has introduced secondary findings (SFs) into clinical genomics, raising ethical and practical challenges. This study explores perspectives on SF disclosure among pediatric patients' families and genetic professionals in the Middle East.

Material and Methods: A cross-sectional study surveyed 287 families of pediatric patients who underwent genetic testing and 154 genetic professionals across multiple Middle Eastern sites. Families were interviewed using structured questionnaires to assess their awareness and preferences regarding SF disclosure, while professionals evaluated their perspectives on SF disclosure and familiarity with ACMG recommendations.

Results: Among families, 124 (43.2%) were aware of SFs, and 163 (56.8%) preferred full disclosure. Of these, 153 (93.87%) supported reporting life-threatening but non-preventable conditions. In contrast, 151 (98%) of professionals supported delaying disclosure of adult-onset conditions in pediatric cases. The only significant association identified was between perspectives on the disclosure of life-threatening but preventable conditions ($P < 0.0001$,Fisher's exact test). Additionally, 106 (69%) of professionals reported that if SFs were not disclosed, they would still document them in patient records. The majority (93.5%) of professionals were familiar with ACMG guidelines.

Conclusion: The findings reveal differences in attitudes between genetic professionals and families regarding SF disclosure. Given the variation in individual preferences, genetic professionals should respect patients' beliefs and preferences when discussing SF disclosure. Additionally, as many professionals support delaying the disclosure of adult-onset disorders in pediatric patients, an ethical framework is needed to guide discussions with parents, ensuring informed decision-making while respecting future autonomy.

P26.019.B Navigating decisions in preimplantation genetic testing: a 15-year perspective of the Dutch national indications committee for preimplantation genetic testing

***Vyne van der Schoot**, Rio Kramers, Eline Bunnik*

Erasmus MC, Rotterdam, Netherlands.

Background: Preimplantation genetic testing (PGT) has been available as a reproductive technique to prevent genetic anomalies in offspring for decades. In the Netherlands in 2009, a national indications committee (LIC) was tasked with guiding decisions on its applicability to every new medical indication, with the aim of safeguarding the ethical acceptability of the use of PGT. This paper reflects on the committee's 15-year journey.

Material and Methods: For this study, we analyzed relevant documentation (i.e. letters, reports, minutes) of the LIC, between 2009–2024.

Results: The LIC considered PGT to be acceptable for 134 of 192 (70%) conditions they were consulted for. The criteria 'severity and nature of the disease', 'risk' and 'treatment options' were documented for the majority. Other criteria from the LIC´s decisional framework (e.g. 'additional medical criteria' and 'psychological and moral considerations') were mentioned for a minority of conditions. Only for a few conditions, the severity was explicitly appraised and characterized. There was a modest increase in requests over the years; however, the nature of assessments remained consistent.

Conclusion: In 15 years, the LIC has shaped the application of PGT for a broad variety of genetic conditions. Through its case-by-case approach, guided by a decisional framework, the LIC has been able to assess a complex interplay of disease characteristics, whilst being faced with ambiguity of genetic conditions. The LIC has safeguarded the ethical acceptability of PGT in the Netherlands, and serves as a promising model for a future in which new and rare genetic conditions will continuously be identified.

V. van der Schoot: None. **R. Kramers:** None. **E. Bunnik:** None.

P26.020.C Moving beyond the mismatch between professional and citizen perspectives in genomics: The curious case of incidental and secondary findings within the Can.Heal project

***Marlies Saelaert**, Chloé Mayeur, Wannes Van Hoof*

Sciensano, Brussels, Belgium.

Background: When analysing genomic data, clinically relevant findings that exceed the initial aim of sequencing can be identified, both accidentally as incidental findings (IFs) or on purpose as secondary findings (SFs). The evolution toward large genomic data infrastructures will increase the identification of IFs and SFs. Ethical frameworks should be developed to guide the trustworthy management of these findings.

Material and Methods: In the context of the Can.Heal project, a literature review concerning public engagement initiatives on genomics has been conducted, including 45 publications. Subsequently, a stakeholder workshop has been organised with 43 onco-genomic professionals to integrate their perspectives into an ethical framework for genomic data use.

Results: At first sight, the general public and professionals have a different approach to IFs and SFs. Whereas citizens consider the personal impact of additional genomic results in general, professionals specifically focus on the systemic impact of SFs on the healthcare system. However, these different perspectives can be complementary and they may be explained by different levels of genetic literacy and different interpretations of key concepts in genomics. Moreover, beyond the different perspectives of citizens and professionals, shared interests can be identified, such as respect for autonomy, the importance of relatives, and the significance of counselling.

Conclusion: A trustworthy management of IFs and SFs requires a move beyond the disparities between different stakeholders. Identifying underlying and shared values and clarifying key concepts may uncover a common ground on which an ethical framework for genomic data use can be founded.

Background: Genome sequencing has revolutionised the diagnosis of rare diseases, but it can also reveal additional findings (AF) (incidental (IF) or secondary findings (SF)).

Methods: The DEFIDIAG-DS study, ancillary to a PFMG pilot project, offered parents of children with Intellectual developmental disorder in order to allow them (excluding minor children) to access to SF ACMG list version 2. This longitudinal mixed-method study, combined questionnaires and semi-structured interviews to explore reasons declining SF, and/or shifts his/her opinion along the consent process and the consequences of receiving SF.

Results: 2,500 parents were offered SF and 85% opted-in. This rate being highly variable between the 13 participating centres (64%–97%). Overall, 65 SF (3%) were returned. 76 parents, who opted out, completed questionnaires and 34 parents who had received SF were interviewed at result delivery and 19 one year later. Over 95% of parents expressed satisfaction with the information provided and the time given to consider it. Following the SF report, over 93% of parents expressed satisfaction due to the medical actionability and the opportunity to inform their family members. While 45% initially reported concerns about the results, this figure decreased to 28% after one year. At one year, 28% of parents reported lifestyle changes, but many adjusted their medical follow-up. 94% shared the results with their families, with positive feedback.

Conclusion: Providing clear information is crucial in the overall process. and Future research should focus on evaluating the clinical utility of SF, particularly in terms of preventing deaths and detecting subclinical conditions.

P26.023.B Responding to recruitment barriers in community-engaged genetics research

Kirsten A. Riggan[1], *Jane Q. Yap[2], McKenna Horstmann[3], Preya Agam[2], Yvonne Bombard[4], Roel Feys[5], Assata S. Kokayi[2], Karen M. Meagher[2], Marsha Michie[3], Kiran Musunuru[6], Kelly E. Ormond[1], Sabina Rubeck[3], Rosario Isasi[5], Megan A. Allyse[7]*

[1]ETH Zurich, Zurich, Switzerland, [2]Mayo Clinic, Rochester, MN, USA, [3]Case Western Reserve University, Cleveland, OH, USA, [4]University of Toronto, Toronto, ON, Canada, [5]University of Miami, Miami, FL, USA, [6]University of Pennsylvania, Philadelphia, PA, USA, [7]Mayo Clinic, Jacksonville, FL, USA.

Background: There is growing consensus on the importance of community-engaged research on the clinical translation of genetic therapies to foster productive relationships and engender trust in research findings. However, the literature has reported it is difficult to recruit and enroll participants.

Material and Methods: Our U.S.-based study is recruiting from ten diverse genetic condition communities to explore perspectives on prenatal gene editing. We designed a systematic approach to optimally facilitate recruitment among these genetic condition communities. We also report on adaptations to recruitment design in response to identified barriers.

Results: We established a dedicated community engagement outreach team to identify community organizations for recruitment partnerships. The outreach team met weekly to strategize across conditions and review contact approaches and response rates. Factors that impacted response included: limited organizational bandwidth, direct communication with organization

leadership and community members, and interest in research partnerships. Response rates were higher for organizations representing less widely known genetic conditions, even though larger organizations had more expansive research recruitment infrastructure. We modified the recruitment design to include outreach to regional branches. In response to organizations stated preferences and needs, we also considered financial contributions, participation in community events, publicizing the research partnership, and following recommended modes of recruitment. We have successfully partnered with organizations for eight genetic conditions and reached enrollment targets for four; engagement is ongoing.

Conclusion: Successful recruitment from genetic condition communities is possible by establishing mutual partnerships with organizations. Partnerships are strengthened when community values are prioritized in recruitment design.

P26.024.C Forum OncoGenEtica: ethical concerns among Italian healthcare professionals about equitable access to preventive measures for individuals predisposed to cancer

*Linda Battistuzzi[1], Cristina Oliani[2], Maria Grazia Tibiletti[3], **Daniela Turchetti**[4], Stefania Sciallero[1], Liliana Varesco[1], Maurizio Genuardi[5,6]*

[1]IRCCS Ospedale Policlinico San Martino, Genova, Italy, [2]AULSS5 Polesana, Regione Veneto, Rovigo, Italy, [3]ASST Settelaghi, Varese, Italy, [4]University of Bologna - S.Orsola-Malpighi HospitalMedical Genetics, Bologna, Italy, [5]Section of Genomic Medicine, Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy, [6]Medical Genetics Unit, Department of Laboratory and Infectious Sciences, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy.

Background: Modeled on the UK Genethics Forum, Forum OncoGenEtica was established in 2014 to provide Italian healthcare professionals working in cancer genetics and hereditary cancer with opportunities to discuss ethically complex cases. The first three years of activity were described previously. We report here on the cases discussed between 2017 and 2024.

Material and Methods: Quantitative data synthesis and qualitative content analysis of the case reports were performed.

Results: Overall, 15 meetings were held, and 59 cases were discussed. The median number of participants was 35 (18–59), with non-genetics professionals increasing from 5% in 2017 to 20% in 2024. The main ethically relevant issues discussed were: communication of genetic risk in cascade testing; genetic testing for late-onset conditions in minors and young adults; informed consent and genetic counseling in mainstream genetic testing pathways; interpretation and application of privacy legislation; the right to know; the right not to know; value conflicts with colleagues; complexity and uncertainty in returning results. Administrative barriers, financial constraints, and organizational inefficiencies in healthcare institutions, and a fragmented health data system across Italian regions were cross-cutting themes.

Conclusion: Diagnostic approaches to identify individuals with a hereditary susceptibility to cancer continue to expand, providing important opportunities for cancer prevention through early detection, targeted surveillance and risk-reducing surgeries. At the same time, as more non-genetics professionals participate in Forum OncoGenEtica, discussions reveal ethical concerns regarding the capacity of the public Italian healthcare system to ensure timely, appropriate, and equitable access to preventive care for cancer-prone individuals.

P26.025.D Exploring decision-making and experiences regarding health-related direct-to-consumer genetic testing (DTC-GT) among Dutch consumers

***Danny Bruins**[1], Esther A.M. Bührman[1], Martina C. Cornel[1], Margeet G.E.M. Ausems[2], Marc H.W. van Mil[2], Olga C. Damman[1], Tessel Rigter[1]*

[1]AmsterdamUMC, Amsterdam, Netherlands, [2]UMC Utrecht, Utrecht, Netherlands.

Background and Objectives: There is a significant research gap in European studies qualitatively assessing the decision-making and experiences of individuals that have undergone health-related direct-to-consumer genetic testing (DTC-GT). We employed an interview-based approach to investigate these elements among Dutch consumers of health-related DTC-GT.

Materials and Methods: We conducted semi-structured, one-on-one interviews with twenty Dutch citizens that underwent health-related DTC-GT in the last ten years to examine their decision-making and experiences therewith. Participants were recruited via diverse sampling methods, including research agencies, social media ads, and snowballing.

Results (preliminary): Participants were often inspired by experiences of previous consumers of DTC-GTs (relatives or acquaintances), discounts, and/or adverse experiences in/with the public healthcare system to undergo DTC-GT. Not all participants considered potential negative consequences of undergoing DTC-GT during decision-making. Actions undertaken by participants influenced by DTC-GT results included consulting regular and alternative healthcare professionals, initiating supplementation of vitamins and other micronutrients, and taking potentially adverse medical actions such as stopping earlier-prescribed medication and refusing advised vaccinations. Testing of participants' children (minors) was also observed. Participants were content with taking a health-related DTC-GT, and advocated for increasing accessibility thereto.

Conclusion (preliminary): Dutch consumers of health-related DTC-GT overall appeared pleased with what DTC-GT yielded them and did not regret their decision. However, we observed several unwanted side-effects of DTC-GT usage, such as inspiring potentially adverse medical decisions, and increasing pressure on the public healthcare system. These side-effects are concerning and not in line with stimulating responsible societal implementation of genetic testing.

P26.026.A Dutch national consensus-based recommendations for the disclosure of unsolicited findings during clinical genetic testing

***Helger G. Yntema**[1], Ilse Feenstra, PHD[1], Brigitte H.W. Faas[1], Margje Sinnema[2], Monique Gerrits[2], Marjolein Kriek[3], Claudia Ruivenkamp[3], Mariet W. Elting[4], Quinten Waisfisz[4], Abeltje Polstra[4], Ellen van Binsbergen[5], Klaske Lichtenbelt[5], Karin Huijsdens-van Amsterdam[5], Wilhelmina S. Kerstjens-Frederikse[6], Birgit Sikkema-Raddatz[6], Frans*

Hogervorst[7], Noor Giesbertz[7], Hennie Brüggenwirth[8], Malgorzata I. Srebniak[8], Daphne Stemkens[9], Vyne van der Schoot[8]

[1]Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands, [2]Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands, [3]Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands, [4]Department of Human Genetics, Amsterdam UMC, Amsterdam, Netherlands, [5]Department of Genetics, University Medical Centre Utrecht, Utrecht, Netherlands, [6]Department of Genetics, University Medical Centre Groningen, Groningen, Netherlands, [7]Netherlands Cancer Institute, Amsterdam, Netherlands, [8]Department of Clinical Genetics, Erasmus Medical Centre, Rotterdam, Netherlands, [9]Dutch Society of Clinical Genetics, Utrecht, Netherlands.

Background: The primary aim of clinical genetic testing is to identify the genetic cause of a patient's condition. With the widespread implementation of exome- or genome-wide tests, the possibility to identify variants that fall outside the scope of the clinical question, so-called unsolicited or incidental findings, arises. How to deal with these findings has been an issue of debate for decades, leading to numerous recommendations and guidelines, leaving the Dutch genetic centers with their nonsynonymous local policies on unsolicited findings until 2021.

Material and Methods: A national working group, consisting of clinical geneticists and clinical laboratory geneticists representing all genetic centers in the Netherlands, discussed various aspects of unsolicited findings in clinical genetic postnatal germline testing, with the aim to compose recommendations on disclosure of such findings. All genetic workflows (targeted and exome or genome wide tests) were taken into account and all types of unsolicited findings were included (single nucleotide, copy number and structural variants).

Results: A national consensus-based guideline, including a flow diagram, has been developed on how to address unsolicited findings during clinical genetic testing. Furthermore, standardized informed consent forms and patient information material were implemented. All genetic centers follow the national policy, but unsolicited findings are locally discussed in multidisciplinary committees.

Conclusion: The Dutch consensus-based recommendations on unsolicited findings meet the needs of stakeholders involved, can be useful when drawing up policy documents and may add to the harmonization and quality assurance of genetic diagnostic testing in Europe.

P26.027.B Public attitudes towards genomic data sharing in Portugal: Familiarity with genetics and why it matters

***Claudia De Freitas**[1,2,3], Pedro Sá Couto[4], Liliana Sousa[5], João Tavares[6], Alina Humenyuk[7], Anna Middleton[8], Alvaro Mendes[9,10]*

[1]Institute of Public Health of University of Porto - EPIUnit, Porto, Portugal, [2]Associate Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal, [3]Department of Public Health and Forensic Sciences and Medical Education, Faculty of Medicine, University of Porto, Porto, Portugal, [4]Center for Research and Development in Mathematics and Applications (CIDMA), Department of Mathematics (DMAT), University of Aveiro, Aveiro, Portugal, [5]Departament of Education and Psychology, University of Aveiro, RISE-Health, Portugal, Aveiro, Portugal, [6]School of Health Sciences, University of Aveiro, RISE-Health, Aveiro, Portugal, [7]Department of Mathematics (DMAT), University of Aveiro, Aveiro, Portugal, [8]Kavli Centre for Ethics, Science and the Public, Faculty of Education, University of Cambridge, Cambridge, United Kingdom, [9]i3S – Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal, [10]CGPP – The Centre for Predictive and Preventive Genetics, IBMC – Institute for Molecular and Cell Biology, University of Porto, Porto, Austria.

Background: The success of multi-country, data-intensive initiatives like EU's +1 Million Genomes depends largely on political support and investment. However, another significant but often-unheeded factor is public willingness to share genomic data. EU countries that lack understanding of public knowledge and perspectives about genomics risk being inadequately prepared to address emerging ethical and social issues. These issues can undermine public trust and reduce willingness to share data, ultimately threatening the completeness of EU genomic databases. This is the first national-level study of public familiarity with genetics and attitudes toward genomic data sharing in Portugal.

Methods: Cross-sectional study performed on a sub-sample of the global online survey Your DNA, Your Say including 2058 residents in Portugal. Participants were asked about their familiarity with genetics and willingness to share genomic data with: 1) medical doctors; 2) non-profit researchers; and, 3) for-profit researchers. Data were analysed using descriptive and inferential statistics.

Results: Only 41% of participants are familiar with genetics. Participants' willingness to share genomic data varies according to data processing actors. Nevertheless, 73.6% are willing to share data with at least one actor. Participants who are unwilling (10.8%) or uncertain (15.6%) about sharing data are significantly less likely to be familiar with genetics (OR:0.65; 95%CI 0.45–0.92 and OR:0.70; 95%CI 0.52–0.95), compared to those willing (reference group).

Conclusion: Unfamiliarity with genetics is associated with unwillingness to share genomic data. Efforts to promote public knowledge of genetics are crucial to increase public resolve to share genomic data and ensure ethical participation in genomics research.

P26.029.D Incidental genomic findings in large scale research: using the 3-I framework to reveal policy considerations

***Suzanne M. Onstwedder**[1,2,3], Carla van El[2,3], Wendy Rodenburg[1], Adrian Thorogood[4], Martina Cornel[2,3], Tessel Rigter[2,3,1]*

[1]National institute for Public Health and Environment, Centre for Health Protection, Bilthoven, Netherlands, [2]Amsterdam UMC, Department of human genetics, Section community genetics, Amsterdam, Netherlands, [3]Amsterdam Public Health Research Institute, Personalized Medicine Programme, Amsterdam, Netherlands, [4]The Terry Fox Research Institute, Vancouver, BC, Canada.

Background: Incidental findings (IF) can be yielded in genomic research that analyzes data from healthy or ill participants. The need for clear IF policies grows along with the increase in international genomic research, data collection and sharing efforts. This study aims to inform policy discussions and decisions about IF.

Material and Methods: We interviewed key stakeholders involved in Canadian, European, or international research projects. We used the 3-I framework for interview design and analysis, which distinguishes interests (i.e. agendas), ideas (i.e. values), and institutions (i.e. policy structures, e.g. laws) as factors that impact policy decisions. We integrated the three bioethical principles into this framework: respect for persons, beneficence, and justice.

Results: Interviewees were from Canada (n = 7) and Europe (n = 4). Different IF policies are followed and practiced. Policy decisions are impacted by varying interests, ideas, and institutions. Prioritization of distinct interests and ideas varies between policies. Key policy considerations are: determining whose interest is prioritized; determining what is of best interest to the participant; determining who is responsible for what when research and healthcare institutional frameworks create tension; determining what is just and a fair distribution of benefits and burdens between individuals and populations; and determining how scarce time and money should be allocated.

Conclusion: Explicating policy considerations can help to further discuss and decide how IF policies will impact not only research participants, but also patients, citizens, professionals, the public and diverse populations. Technologies, cultural values, and laws and regulations evolve over time. Therefore, continuous discussions should be held.

P26.030.A Leveraging consensus methods to develop reliable outcome measures for responsible data stewardship in the cloud

Bronwyn D. Walsh, *Vasiliki Rahimzadeh*

Baylor College of Medicine, Houston, TX, USA.

Background: Unique ethical, legal, and social issues arise when managing access to large, publicly-funded genomic datasets in the cloud, especially when they are repurposed for research or have value for commercial cloud service providers. As global genomic repositories migrate to cloud-based platforms, we lack understanding of what stewardship outcomes matter most in overseeing access to sensitive, human genomic data in the cloud. Repositories and data stewards require practical, easy-to-use tools to track progress on stewardship outcomes, and enable transparent reporting to prospective genomic data contributors.

Material and Methods: We combined a scoping review of the cloud governance literature for frameworks, guidelines, policies, and best practices with a three-round modified Delphi study to validate core outcomes of responsible stewardship.

Results: Our scoping review of 560 articles yielded 8 stewardship outcome categories- transparency, authentication, auditing, security, sustainability, standardization, consent and compliance, and community engagement- each with measurable outcomes. Nearly 40 international data access committee members, privacy officers, repository managers, and other data management professionals participated in Round 1 of the Delphi to rank the importance and feasibility of the outcomes.

Conclusion: While the Delphi study is in-progress, we expect to generate a set of core stewardship outcomes and develop specific, measurable criteria. Together, the core outcomes + measurable criteria will create a stewardship impact assessment instrument for cloud-based repositories. Further, we expect to determine minimum standards that repositories need to achieve these outcomes. This will assist in more clearly delineating the minimum standards of ethical data stewardship, not only locally but globally.

C.O.I. Disclosure:

B.D. Walsh: None. **V. Rahimzadeh:** None.

P26.031.B Hidden DNA: the unseen risk of misdiagnosis in genetic testing after bone marrow transplantation

B. Hébrard[1], *A. Lunati-Rozie*[1], *C. Berger*[1], *C. Nativelle*[1], *A. de Becdelièvre*[1,2], *B. Funalot*[1,2], *P. Fanen*[1,2], *M. Konyukh*[1];

[1]*APHP, Department of Genetics, Henri Mondor University Hospital, Créteil, France,* [2]*Paris Est University, INSERM, IMRB, Créteil, France*

Background: Genetic testing often relies on DNA extracted from peripheral blood. However, unreported bone marrow transplants can lead to misdiagnoses by introducing genetic material unrelated to the patient. In France, approximately 1,500 transplants occur annually, yet many healthcare professionals remain unaware of the implications. This lack of communication can result in diagnostic errors, inappropriate medical management, and psychosocial consequences. In 2023, France introduced its first recommendations for genetic testing on transplant DNA, but official guidelines remain absent.

Materials and Methods: This study investigated genetic test prescriptions using blood-derived DNA from transplant patients. After identifying laboratory discrepancies, we developed a questionnaire to assess healthcare professionals' awareness, practices, and use of alternative sampling methods.

Results: Preliminary responses (n = 59) reveal significant variability in awareness based on professional background. Laboratory-experienced professionals (technicians, geneticists) displayed high knowledge, while clinicians (genetic counselors, non-geneticist physicians, nurses) showed more heterogeneous results.

Conclusion: This study, the first of its kind in France, highlights gaps in awareness and the lack of European guidelines for molecular biology laboratories and prescribers. Our findings emphasize the need for education, communication strategies, and training programs. Ensuring that the correct patient, not the transplant, is analyzed is imperative. One patient may have the genetic results of another person.

C.O.I. Disclosure:

P26.032.C Disparities in access to gene therapy in the European Union: Ethical and regulatory challenges

Margaux Reckelbus, Riya Mohan, Phaedra Locquet, Eva Van Steijvoort, Isabelle Huys, Pascal Borry

KU Leuven, Leuven, Belgium.

Background: Gene therapies offer groundbreaking advancements in medicine, providing potential cures for previously untreatable genetic disorders. However, ensuring equitable access to these therapies presents a critical ethical challenge within the European Union (EU). This review aimed to assess the adequacy of the EU's centralized market authorization framework and alternative pathways, such as the Hospital Exemption (HE) and Compassionate Use Program (CUP), in addressing access disparities.

Material and Methods: We conducted a critical review of the literature, including peer-reviewed articles, policy documents, regulatory guidelines, and grey literature. Sources were selected based on thematic relevance to key ethical challenges: access, affordability, and geographical disparities.

Results: Although the EU's centralized framework guarantees high safety, quality, and efficacy standards, its implementation

reveals substantial barriers. High costs create significant financial challenges for healthcare systems and individuals, disproportionately affecting low-income countries and regions. Geographic disparities, amplified by fragmented national regulations and uneven healthcare infrastructure, limit patient access, particularly in rural areas. Alternative pathways like HE and CUP aim to improve access but are hindered by inconsistent implementation at the national level.

Conclusion: This review highlights the need for a more cohesive and inclusive EU regulatory framework to ensure equitable access to gene therapies. Addressing economic and geographical barriers is important to realize the full potential of these innovations for all EU citizens.

P26.033.D Psychosocial Impact of Genetic Testing for Hereditary Hearing Loss (HHL): a Perspective Patient-based Survey

Domizia Pasquetti[1], *Beatrice Spedicati*[1,2], *Stefania Zampieri*[1], *Anna Morgan*[1], *Giulia Pianigiani*[1], *Elisa Rubinato*[1], *Federica Perino*[2], *Alessandro Pecori*[1], *Maria Pina Concas*[1], *Luca Pellegrini*[3], *Umberto Albert*[3], *Giorgia Girotto*[1,2]

[1]*Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy,* [2]*Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy,* [3]*Department of Mental Health, Azienda Sanitaria Universitaria Giuliano Isontina - ASUGI, Trieste, Italy.*

Background: HL is the most common sensory deficit worldwide (approximately 70% non-syndromic and 30% syndromic forms). Genetic etiology is identified in ~half of HL cases and, despite the known benefits of genetic testing, the psychosocial impact of this test need to be studied deepen, especially for syndromic forms where management is extremely difficult.

Material and Methods: We designed a prospective study with two age-based cohorts and two time points: after pre-test counselling (T0) and two weeks after post-test counselling (T1). Validated scales, including the DASS-21 (anxiety/depression), EQ-5D-5L (quality of life), CBCL (behavioural/emotional problems), and CPAS (obsessive-compulsive traits/intolerance of uncertainty), will be administered to participants and families at each time-point.

Results: Results aim to evaluate the psychosocial outcomes of genetic testing in HL, focusing on differences between children and young adults as well as isolated and syndromic HL forms. We hypothesize that parents, particularly when the diagnosis involves a syndromic form of HL (where at the time of diagnosis not all the signs could be present), may experience stress, indirectly affecting the child's well-being and behaviour. Conversely, young adults may exhibit varied psychosocial responses.

Conclusion: Mental health disorders represent an increasing public health concern. Evaluating the psychosocial impact of genetic testing for HL provides insights into patient needs, offers opportunities to enhance care, and allows for the exploration of associations between molecular diagnoses and psychosocial phenotypes, thereby improving the HHL genotype-phenotype correlations. This is especially pertinent with NGS data, which often enables a molecular diagnosis even before symptoms onset.

P26.034.A Polygenic Risk Scores in the Clinic. A qualitative Study of Healthcare Providers and Researchers' Perspectives on Ethical Challenges

Lara Andreoli[1], *Hilde Peeters*[2], *Kristel Van Steen*[3], *Kris Dierickx*[1]

[1]*KU Leuven, Leuven, Belgium,* [2]*Centre for Human GeneticsUniversity Hospital of LeuvenBE 0419.052.173, LEUVEN, Belgium,* [3]*ULiège, Liege, Belgium.*

Background: Substantial research efforts have started worldwide to foster the clinical translation of Polygenic Risk Scores (PRS). Understanding the views of key stakeholders becomes timely to critically inform the socio-ethical debate, impact future health policy, and currently missing guidelines supporting best practices in healthcare contexts.

Material and Methods: We performed 25 in-depth semi-structured interviews investigating the perspectives of European researchers and healthcare providers from different specialties (clinical genetics, oncology, cardiology, psychiatry) on the ethical and social implications related to the prospective clinical use of PRS. Interview transcripts are currently being analysed thematically with the software NVivo. We expect our final analysis and first draft to be ready by April 2025.

Results: Here we report our preliminary findings on participants' perspectives regarding (1) the appropriate use of the technology and (2) key ethical questions in patient care. Under (1) participants identify general principles of appropriate use that should apply across conditions. The appropriateness of PRS uses is also discussed via disease-specific examples at different stages of the clinical pathway (primary and secondary prevention, diagnosis, prognosis). Theme (2) collects views on the interpretation and communication of the technology, and the potential for patients' harm. Finally, participants express their views and uncertainties on the relevance of PRS findings to family members and the acceptability of testing of minors.

Conclusion: At the conference the first author will present the final and complete thematic analysis of the interviews and discuss the implications and limits of the findings in the light of the broader literature.

P26.036.C Improving the effectiveness of information, consent and non-opposition practice for genetic analysis in France through a transdisciplinary approach: the example of the INFOGENETIC-FR project

Noémie DUBRUEL[1], *Eléa Rodriguez*[1], *Brenda Bogaert*[2], *Bettina Couderc*[1], *Sophie Julia*[1], *Julien Mancini*[3], *Sandrine De-Montgolfier*[4], *Laurent Pasquier*[5], *Pierre Saintigny*[2], ***Emmanuelle Rial-Sebbag***[1]

[1]*Cerpop UMR 1295 Inserm – Université de Toulouse, Bioethics team ; UNESCO Chair Ethics, Science and society, Toulouse, France,* [2]*Centre Léon-Bérard, Lyon, France,* [3]*MD, Professor, SESSTIM, Aix-Marseille Université, Inserm, IRD, APHM, Aix-Marseille, France,* [4]*SESSTIM, Aix-Marseille University,Inserm, IRD, Aix-Marseille, France,* [5]*CHU - Hopital Sud, Rennes, France.*

Background: Prior information and consent are essential rights to uphold individual autonomy, a fundamental bioethical principle in health care and research. This is particularly critical in the context of genetic analysis, where methods and technological advancements have increased complexity, making it challenging for professionals to provide clear and understandable information to patients/research participants.France's 2021 bioethics law

addressed these challenges by improving the legal requirements for genetic analyses and refining opt-out procedures. Analysis of the impact of these legal changes needs to be complemented by an study of information, consent and opt-out procedures practices on the ground to capture the full range of issues.

Material and Methods: Here, we present the objectives and methods of the INFOGENETIC-FR project which aims to identify information and consent needs of adult patients/research participants and to analyse professional practices. We bring together legal, ethical, sociological and public health scholars, and use a participatory research methodology to achieve a truly transdisciplinary approach. Starting from an ethical/legal analysis, we analyze, by means of a literature review, qualitative and quantitative analyses, patients and professionals needs, the issues they encounter in practice and the questions raised by research ethics assessment.

Results: We expect to provide information-tools to help health professionals communicate with their patients/research participants.

Conclusion: We promote the active involvement of all stakeholders, an essential step to ensure the production of tools guaranteeing that the rights to information and consent in the evolving field of genetics are fully respected, while providing information tailored to individual needs.

P26.038.A Assessment of standards of development of core outcome sets for mental health. Implications for pharmacogenetics trials in psychiatry

Stefan A. Trif[1], *Andrada Ciuca*[1], *Kirkham J. Jamie*[2], *Ramona Moldovan*[3,1,4]

[1]*Babes-Bolyai University, Cluj, Romania,* [2]*Centre for Biostatistics, The University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom,* [3]*Division of Evolution, Infection and Genomic Sciences, School of Biological Sciences, University of Manchester, Manchester, United Kingdom,* [4]*Manchester Center for Genomic Medicine, St. Mary's Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: There is important uncertainty regarding what represents the most effective outcomes to be measured in mental health trials. Standardization of outcome measures is crucial for ensuring consistency and comparability across trials and diagnoses. The Core Outcome Set—STAndards for Development (COS-STAD) represent the minimum set of recommendations for Core Outcome Set (COS) development initiatives. This study provides a baseline evaluation of COS development standards for mental health to assess their suitability for use in psychiatry pharmacogenetics trials.

Methods: A search of the COMET database identified 113 published and ongoing studies. Seven COS studies were eligible for inclusion. Two independent reviewers assessed the COS against the 12 COS-STAD criteria.

Results: Six COS studies were included in the analysis, covering five different domains as per the DSM-V. None of the studies met all the COS-STAD standards. The number of standards met ranged from 6 to 11, with a median of 8. Five of the 12 criteria were met by all studies (i.e., defining the setting, defining the health condition, defining the population, involvement of healthcare professionals, and involvement of patients) while only one study met the intervention criterion.

Conclusion: This is the first study to assess the application of COS-STAD in mental health, highlighting a significant need for improvement. Key issues identified include the lack of clarity regarding the intervention where COS can be used, inadequate inclusion of patient perspectives, and ambiguity in outcome definitions and language. This assessment is a first step into further developing COS for psychiatry pharmacogenetics trials.

P26.040.C Towards a responsible implementation of genome wide tests in screening

Mirjam Plantinga[1], *Corrette Ploem*[2], *Guido de Wert*[3], *Jacobien Niebuur*[1], *Irene van Langen*[1], *Imke Christiaans*[1], *Lidewij Henneman*[2], *Martina Cornel*[4], *Tessel Rigter*[2,5], *Helger Yntema*[6,7], *Marieke van Dooren*[8,9], *Daphne Stemkens*[9], *Cor Oosterwijk*[10], *Sanne vd Hout*[11]

[1]*UMCG, Groningen, Netherlands,* [2]*Amsterdam UMC, Amsterdam, Netherlands,* [3]*Maastricht University, Maastricht, Netherlands,* [4]*Amsterdam UMC, Ammsterdam, Netherlands,* [5]*RIVM, Bilthoven, Netherlands,* [6]*Radboud UMC, Nljmegen, Netherlands,* [7]*VKGL, Nijmegen, Netherlands,* [8]*Erasmus MC, Rotterdam, Netherlands,* [9]*VKGN, Utrecht, Netherlands,* [10]*VSOP, Utrecht, Netherlands,* [11]*Hogeschool Zuyd, Maastricht, Netherlands.*

Background: The rise of genome wide sequence techniques has made broad DNA analysis and interpretation possible. This allows expansion of screening for (the risk for) diseases. Although this opens many new avenues for preventive medicine, it also comes with substantial challenges. Our research has identified stakeholder-supported requirements for responsible implementation.

Methods: The research consisted of three interconnected parts: 1) describing the normative genomic screening framework; 2) discussing possibilities for genome wide testing in three screening settings (population screening, opportunistic genome screening and direct-to-consumer (DTC) genome screening; 3) conducting a stakeholder analysis to investigate broad perspectives towards genome wide screening and requirements for responsible implementation.

Results: The stakeholder analysis identified three perspectives, also brought forward in the normative analysis: 1) legislation and guidelines on screening play a key role in protecting screening participants; 2) the autonomy of screening participants should be respected as much as possible; 3) secondary findings should be minimalized and the quality of the screening offer should be optimized. The normative analysis further stressed the importance of proportionality (benefits outweighing costs). Acceptance for implementation was highest for the setting of population screening and lowest for DTC genome screening.

Conclusion: Two main conclusions are drawn: 1) a broader analysis and interpretation of the genome is less easy to justify from the perspective of principles of responsible screening compared to targeted screening; 2) responsible implementation of genomewide testing in the context of screening is best guaranteed within the population screening setting and least in the context of DTC genome screening.

P26.041.D More of the same? Israel's expanded carrier screening for cystic fibrosis

Tamar Nov-Klaiman[1], *Ruth Horn*[1], *Aviad Raz*[2]

[1]*University of Augsburg, Augsburg, Germany,* [2]*Ben-Gurion University of the Negev, Beer-Sheva, Israel.*

Background: Cystic fibrosis (CF) is known as the most prevalent life-limiting genetic disease among individuals of European ancestry. Most countries with a high CF prevalence offer CF testing through newborn screening (NBS) to facilitate early diagnosis and treatment and improve health outcome. Israel, however, chose a unique approach to CF testing. It does not offer NBS, but since 2008 it offers population genetic carrier screening (GCS) with public funding. Carrier couples with increased chance for an affected child receive funding for prenatal testing or in vitro fertilization and preimplantation genetic testing. Recently, the Israeli mutation panel for CF dramatically expanded from 18 to over 70 mutations. This study explores the ethical, social and policy-related implications of this expansion, especially with reference to NBS.

Material and Methods: Literature and document-based analysis was conducted.

Results: The Israeli policy focuses on the provision of reproductive options to couples through GCS. However, the expected lower CF birth rates reduce the likelihood of implementing NBS. This arguably shifts the balance between treatment and prevention (through selective reproduction), further towards prevention.

Conclusion: The unlikely prospect of NBS implementation is of ethical relevance as it negatively impacts future individuals with CF who will not benefit from early diagnosis. Since the expanded panel cannot detect all cases due to incomplete coverage of mutations and partial uptake in the population, NBS and GCS have complementary roles. Together they promote both a wider scope of reproductive choices and better outcomes for individuals born with the condition.

P26.042.A Death anxiety and depression levels of elderly individuals with Alzheimer's disease

Mihriban Kızıltan[1], *Hülya Şenol*[1], *Serdal Işıktaş*[1], ***Şükrü Tüzmen, Vice Dean, Faculty of Dentistry, EMU***[2,3]

[1]*Cyprus Health and Social Sciences University, Faculty of Social Sciences and Humanities, Morphou via Mersin 10, Turkey,* [2]*Eastern Mediterranean University (EMU), Faculty of Dentistry, Famagusta via Mersin 10, Turkey,* [3]*GenBiomics R&D, Eastern Mediterranean University, Technopark, Famagusta via Mersin 10, Turkey.*

Background: Alzheimer's disease is known as the most common type of Dementia. More than 70 relevant genetic regions are related to this disease. The APOE ε4 variant of the APOE gene is a significant genetic risk factor for Alzheimer's disease. Genetic cases of frontotemporal dementia are mostly caused by mutations in MAPT, C9ORF72 or GRN. BIN1 are also linked to Alzheimer's disease (NIH, 2024). There are 55.2 million people with dementia globally and this number will rise to 139 milyon in 2050 (WHO, 2022).

Material and Methods: In this quantitative study, personal information form, the Geriatric Depression Scale and the Abdel-Khalek Death Anxiety Scale were administered to 378 elderly individuals with mild Alzheimer's and dementia symptoms living in North Cyprus. SPSS 26.0 program and parametric tests were used to analyze the data.

Results: It was determined that the geriatric depression levels of participants between the ages of 65–70 ($X = 2.633$) and of university graduates ($X = 2.711$)were higher than other participants. The death anxiety of female participants is higher than that of male participants. There is no significant relationship between the geriatric depression scale and the Abdel-Khalek death anxiety scale ($r = -.066$; $p > .05$).

Conclusion: During aging period, individuals may have psychological problems such as depression and death anxiety. Identifying these problems and taking the necessary precautions are important to preserve the quality of life of the elderly people.

P26.043.B THE IMPACT OF GENETIC INNOVATIONS ON PUBLIC HEALTH: A STUDY OF PREVENTIVE HEALTHCARE STRATEGIES

M. Sajedifar[1], *M. Radkish Saki*[2], *S. Sajedifar*[3], *M. R. mahsaradkishsaki@yahoo.com*[4];

[1]*BSBI/Gene Exploration Tech, Berlin, Germany,* [2]*Gene Exploration Tech, Berlin, Germany,* [3]*Mashhad Madical University/ Research Dep., Mashhad, Iran, Islamic Republic of,* [4]*Gene exploration tech, Esfahan, Iran, Islamic Republic of*

Genetic innovations, such as gene editing, genomic sequencing, and AI-driven data analysis, are transforming healthcare by enabling early disease detection, prevention, and personalized treatment. This study explores the role of these technologies in improving preventive healthcare, while addressing challenges related to accessibility, privacy, and ethics. The analysis of survey responses and expert interviews reveals broad support for genetic technologies but highlights significant barriers, particularly in equitable access and data privacy concerns. Despite these challenges, genetic innovations are seen as critical for reducing the prevalence of major public health issues, including cancer, diabetes, and heart disease. The study emphasizes the need for strong public policies to ensure responsible use of genetic data, alongside investment in education and healthcare infrastructure to make genetic testing widely accessible. Ethical frameworks are essential to guide the application of gene editing, ensuring it is used safely and equitably. Future research should focus on addressing the gaps in long-term impacts of genetic screening, developing unbiased AI tools, and ensuring inclusivity in genetic research. By overcoming these barriers, genetic innovations can lead to more equitable healthcare and improved public health outcomes globally.

P26.044.C Impact of the EU IVDR on your clinical genetics laboratory

Szymon Kierat, *Elaine O'Neill, Davide Rigamonti, Michał Szymonik*

SGS Belgium NV – Notified Body 1639, Antwerpen, Belgium.

Background: The IVDR 2017/746 is the current legislation governing IVDs in the EU market. It has major implications for IVD manufacturers, with significantly expanded requirements for clinical evidence, post-market surveillance, and device traceability. Perhaps less broadly understood is the impact on clinical

laboratories, as it introduces new obligations for in-house devices in healthcare settings, and restricts the use of such devices when a CE-marked alternative is available. This potentially increases the financial burden and pressure on the healthcare system to ensure that devices used within their laboratories comply with this stricter regulatory oversight. We aim to explore the impact of these new rules on clinical genetics laboratories and describe strategies for compliance with EU law.

Material and Methods: Legislation, scientific literature, ISO 15189, other ISO standards, and industry guidelines were reviewed for best practices in the subject matter, including exploring the context of rare diseases and orphan IVDs.

Results: We have summarized the CE-marking process for tests under the IVDR, how to select and implement them in clinical laboratories, and the requirements for demonstrating IVDR compliance of in-house assays. Moreover, we compared requirements for in-house IVDs with requirements for IVDs manufactured on an industrial scale.

Conclusion: The IVDR includes significant obligations, not just for IVD manufacturers but also for clinical laboratories. New requirements and restrictions will also impact laboratories that develop in-house assays or modify commercial assays for their use. Understanding the rules and timeline of their application is critical to enabling laboratories to plan and stay compliant with law.
