

How radar can be supported by gravimeters for estimating hail intensity

M. Van Camp, L. Delobbe,
S. Wilfert,
A. Watlet, O. Francis, and D. Delforge

Superconducting gravimeter?

Gravity time series 2004-2012

Observed signal

Modeled tide

After correcting for
Earth tide

X10 →

Gravity time series 2004-2012

Atmospheric pressure

After correcting for tide and pressure

X2.5 →

Gravity time series 2004-2012

Observed signal
(after correcting for
tide & pressure)

Polar motion

After correcting for
tide, pressure, pole

From Chen et al., GRL 2013

Hydrological effects on g

Seasonal variations !
(g lower during winter
because more water is
above the gravimeter)

$\times 10$

$$4 \text{ nm/s}^2$$
$$\Leftrightarrow$$
$$4 \times 10^{-10} g$$

We work at a few $10^{-10} g$ level

Measuring hail?

Radar: 250 m in range, 1 deg. in azimuth
(1.7 km at 100 km)

Which accuracy? Difficult to characterize
Raingauge? Too local: $\ll \text{m}^2$ scale!

Gravimeter able to
weigh water at the
50 ha scale !
→ Direct, traceable

Measuring rain and hail?

Radar $\Leftrightarrow$ converting reflectivity into actual rain/hail falls...
...but which accuracy?

Raingauge? $\rightarrow$ convective storms exhibit strong spatial variations over short distances

- 1) Ground clutter (beam hits objects)
- 2) Overshooting (beam above rain)
- 3) Radar calibration
- 4) Radome & atmospheric attenuation
 $\rightarrow$ underestimation
- 5) vertical profile of reflectivity
(melting zone= overestimation)
- 6) Conversion reflectivity-rain rate

Underground gravimeter as rain gauge: Sensitivity cone

90% →
 $r = 9.9 z$
~ 300 m (here)

☺ As the radar, gravimeter
integrates
 $-1 \text{ nm/s}^2 \Leftrightarrow 2.5 \text{ mm water}$
...minus because water is
above the gravimeter

Selection of events

Short events (~1h)
Probability hail > 50%
(Waldvogel algorithm)

Why hail?

Radars known to overestimate it
→ reflectivity depends on (diameter)⁶

The underground gravity stations

The radar

Rochefort: spring
LaCoste gPhone
gravimeter

BE

Membach SG

Rochefort SG

85 km

DE

33 km

Radar Wideumont

LU

54 km

Walferdange SG

FR

C-Band (5 cm, 5 GHz) weather radar

Membach: cumulative rainfall

☺ Timing & amplitude

Membach: cumulative rainfall

☹ Amplitude
😊 timing

Walferdange, Rochefort: cumulative rainfall

Gravity effect of flash flood
of the cave underneath
gravimeter

Gravity effect of
precipitation above
gravimeter

12 events @Membach

Gravity, Air pressure & Radar differences

Noise sources

- Atmospheric effect: pressure recovers at a same level after the hail fall:

Max. 1.6 hPa difference before/after event → if 10% of error on the correction: $0.5 \text{ nm/s}^2 \Leftrightarrow 1.2 \text{ mm rain}$

- Evapotranspiration: negligible within a few hours
- ☹️ Raingauge not WMO compliant
- Runoff ?
 - Events are short: ~1 hour
 - Different in WLF, RCH and MEM;
 - Ground not saturated: all events between May & September, no significant rain 4 days before

Conclusions

- 21 events 2006-2017
- Strong event (>10 mm / 1 h) are rare: 1-2/year
- Signature of intense precipitation clearly visible in gravity data, timing agree within minutes
- Gravimeter detects most of the intense events,
- Radar tends to overestimate w.r.t. gravimeter: most probably due to hail (6/12 cases in Membach; 1/4 in Walferdange, 0/2 in Rochefort)
- Ongoing: looking for all strong rainfall events (>100)
