Tephra impact on vegetation

Tephra impact on vegetation

Objective:

to investigate experimentally the main factor dictating the impacts of tephra on plant leaf physiology

Plant species chosen for the experiment

Rice

- Hairless leaves
- Stomata on the upper and lower surfaces

Tomato

- Pubescent leaves
- Stomata on the lower surface

Experimental procedure: growth conditions

Experimental procedure: tephra application

Physical damage of the plant: decreased growth

Control plant

Tephra-treated plant

Lower biomass of tephra-treated plants

Number of days after the first tephra application

cab/ie

Lower sugar content in tephra-treated plants

A diagram illustrating the process of photosynthesis. On the left, a red circle contains the inputs: 'CARBON DIOXIDE', 'WATER', and 'ENERGY'. A red arrow points from this circle to a green leaf in the center. From the leaf, another red arrow points to a chemical structure of glucose on the right, which is also circled in red. The background is a blue sky with a sun in the top left corner.

◆ Control ● Tephra covered leaves

Dark stage

Chemical energy + CO₂ = sugar

Conclusions: plant response to tephra stress

Direct effect 5- 7 days

Plant resistance: avoidance

- Stomatal closure
- Heat shock
- Pigment degradation

- Decreased photoprotection function!
- Down-regulation of photosynthetic activity!

Acquired resistance 7-14 days

Plant resistance: tolerance

- Thermal regulation
- Activation of antioxidant system
- Stabilization of photosynthetic efficiency
- Pigment degradation
- Higher CO₂ concentration

Decreased sugar synthesis

Tephra weathering

Objectives :

- (1) to identify the ways of fungi-tephra interaction;
- (2) to assess the effect of fungi on biochemical and biophysical weathering of tephra;
- (3) to assess the response of organic matter and weathering to a tephra-mediated increase in soil fungal activity.

Fungi enhanced chemical weathering?

Electron microprobe analysis

Conclusions

The results of microscopic and molecular analyses demonstrate that tephra colonization by fungi started less than 1 year after the eruption.

There is evidence of physical penetration of fungi into tephra. However, there is no indication of fungi-driven chemical weathering of tephra after two years following deposition

- Pinatubo ash → sieved with a 250 μm mesh

Particle size distribution

- Physiological measurements, extractions, ...

→ What are the impacts of tephra deposits?
