KEYWORDS. Rhenium • Catalysis • Carbon Dioxide • Electrochemistry • Carbon Economy

ABSTRACT: The electrochemical reduction of CO₂ (CO₂RR) into value-added chemicals offers a promising route toward a circular carbon economy and reduced reliance on fossil fuels. A detailed understanding of the structural and electronic factors governing the performance of molecular CO₂RR electrocatalysts is essential for the design of efficient, tunable systems. Here, we report a series of rhenium(I) complexes, *fac*-[Re^I(6,6'-(R)₂-bpy)(CO)₃Cl] (bpy = 2,2'-bipyridine; R = mesityl (mes), 2,4,6-triisopropylphenyl (trip), or isophthalic acid (phth)) and evaluate their electrocatalytic activity. Among these, *fac*-[Re^I(6,6'-(mes)₂-bpy)(CO)₃Cl] exhibited the highest performance, enabling selective CO₂-to-CO conversion for 1 hour with Faradaic efficiency (FE) > 97%, representing an enhanced activity level for a Re-bpy catalysts. Single-crystal X-ray diffraction and density functional theory (DFT) calculations indicated that favorable CO₂ binding could be promoted by the tilting of the 6,6'-(mes)₂-bpy ligand (from the Re–CO coordination plane), providing mechanistic insight into the observed enhancement. The study consequently demonstrates a rational correlation between the CO₂ electrocatalytic performance of Re-bpy catalysts and their structural variations, as derived from X-ray data and corroborated by computational modeling.

While CO₂ is an essential component of the dark cycle of some photosynthetic systems, the recent dramatic rise in CO₂ atmospheric levels can no longer be compensated by photosynthetic systems or other living organisms, leading to the known consequence of climate change.¹⁻² To this end, one mitigation strategy for increasing CO₂ levels is to convert it into value-added feedstock, such as CO, CH₄ or other branched aliphatic derivatives, which require chemically catalyzed processes. Some possible CO₂ reduction products and the corresponding standard redox potentials in aqueous solution (E° / V vs. SHE) are summarized in Eq. 1–5.³⁻⁴ Note that the thermodynamics of these transformations, including the proton reduction reaction (Eq. 6), are very similar, and are thus difficult to differentiate solely based on thermodynamic considerations. As hydrogen will systematically represent a competitive pathway to CO₂ reduction catalysis, product analysis is always key to evaluate the catalytic performances.

Molecular electrocatalysts for CO₂ reduction such as rhenium 2,2'-bipyridine derivatives,⁵⁻⁶ iron porphyrins,⁷⁻⁸ cobalt and nickel phthalocyanine⁹⁻¹¹ or copper polypyridines¹² have received increased interest due to their high activity, selectivity and tunable electrochemistry through judicious ligand design. These catalysts are well-known to offer high selectivity for the

reduction of CO₂ to CO in homogeneous phase by a two-electron process. In the early eighties, Lehn and coworkers reported the rhenium(I) tricarbonyl 2,2'-bipyridine complex, *fac*-[Re^I(bpy)(CO)₃Cl] (**1**) that was active as a homogeneous catalyst for the reduction of CO₂ to CO under photo- and electrocatalytic conditions.⁵⁻⁶ Since then, a plethora of [Re^I(bpy)(CO)₃Cl] derivatives have been developed and this category of homogeneous catalysts for the CO₂ to CO reduction is amongst the most prevalent. The effect of the 2,2'-bipyridine substituents on the electrocatalytic activity has also been studied.¹³⁻¹⁵ In addition, with the development of molecular photoelectrodes, [Re^I(bpy)(CO)₃Cl]-type catalysts have attracted sparking interest for surfaces functionalization,¹⁶ including enhanced photocatalytic activity on TiO₂ reported by Reisner and coworkers,¹⁷ or on Cu₂O as photocathode for CO₂ reduction reported by Grätzel, Mayer and coworkers,¹⁸ and more recently, in quantum dot-sensitized NiO photocathode for electrochemical CO₂ reduction by the group of Tian¹⁹ or on silicon substrates.²⁰⁻²¹

Substituent effects on [Re^I(bpy)(CO)₃Cl] catalysts have been extensively explored to modulate the CO₂ reduction activity. In 2010, Kubiak and coworkers investigated electron-donating and -withdrawing groups at the 4,4'-positions of 2,2'-bipyridine (**Figure 1**, Re-a) and found that 4,4'-di-*tert*-butyl substitution enhanced electrocatalytic CO₂-to-CO conversion, achieving a second-order rate constant of 1000 M⁻¹s⁻¹.¹³ Similarly, Müller, Polo, and colleagues varied 4,4'-substituents to assess their photocatalytic CO₂ reduction reaction (CO₂RR) activity (**Figure 1**, Re-b).²² Complexes bearing electron-donating groups (–CH₃, –OCH₃) exhibited slower excited-state quenching with sacrificial donors such as BIH and TEOA compared to electron-withdrawing groups (–Br, –COOH, –CO₂CH₃). However, the former reacted more rapidly with CO₂ upon one-electron reduction, underscoring the trade-off between photophysical and chemical steps.

Costentin, Chardon-Noblat, and co-workers examined 5,5'-substituted bpy ligands (**Figure 1**, Re-c,d) and showed that conjugated carboxylic or non-conjugated phosphonate esters diminished the activity via electron-withdrawing effects.¹⁴ In general, such groups lower the overpotential (η) but reduce turnover frequency (TOF), whereas electron-rich substituents enhance TOF at the expense of increased η .

To overcome this trade-off, functionalization in the second coordination sphere (SCS) has emerged as a powerful strategy, with precedents in biomimetic chemistry,²³⁻²⁴ hydrogen evolution,²⁵ and O₂ evolution catalysis.²⁶ In CO₂RR, SCS modifications in Fe-tetraphenylporphyrins, such as pendant trimethylanilinium, enhance activity via through-space electrostatic effects.²⁷⁻²⁸ Similar concepts have been applied to Re catalysts,²⁹⁻³⁶ including installation of local proton sources,³²⁻³³ intramolecular hydrogen-bond donors,³⁴ and ionic groups proximal to the active site³⁵ to stabilize the metal-carboxylate intermediate.

For [Re^I(bpy)(CO)₃Cl] (**1**), the 6,6'-positions offer close proximity to the Re center and are ideal for SCS functionalization. In 2017, Nippe *et al.* introduced a redox-active imidazolium group (**Figure 1**, Re-e), which shifted the onset potential 100–150 mV positive relative to **1** and improved the corresponding activity.³¹ Incorporation of a phenyl-2,6-diol moiety (**Figure 1**, Re-f) as a local proton source enabled catalysis after the first reduction wave, achieving a TON of 14.1 at –1.7 V vs. Ag/AgCl in MeCN/H₂O (5%).³² Jurss and co-workers installed pendant aniline groups (**Figure 1**, Re-g) in *ortho*-, *meta*-, or *para* positions, finding that the meta-substituted complex exhibited the highest TOF (239 s^{–1}) and a Faradaic efficiency (FE) of 89% in MeCN/4% TFE.³⁴ Lewis base groups in the SCS (**Figure 1**, Re-h) have also been shown to orient Brønsted acids, enhancing FE to 84% and achieving TON = 14.³⁶ Matsubara and co-workers combined hydroxy and trimethylammonium substituents (**Figure 1**, Re-i) to couple proton delivery with Coulombic stabilization, lowering the overpotential in DMF/H₂O.²⁸ Marinescu and colleagues further probed pendant amines (**Figure 1**, Re-j) at the 6,6'-positions, finding that NH₂ groups increased FE with applied potential, reaching 83%, whereas NMe₂ analogues displayed moderate, potential-independent FE (41–65%).³⁵

Figure 1. Chemical structure of selected examples of Re-based complexes used for CO₂ to CO electrocatalytic reduction.

Collectively, these studies establish that SCS engineering can modulate redox properties, overpotentials, and CO₂ binding kinetics in Re–bpy catalysts, offering multiple levers to enhance activity and selectivity. Here, we target this site with sterically demanding aromatic substituents (**Figure 2**) to simultaneously tune electronic structure, suppress dimerization, and probe SCS effects on product selectivity and intermediate stabilization. We prepared mesityl (mes, **2**: [Re^I(bpy^{mes})(CO)₃Cl]), 2,4,6-triisopropylphenyl (trip, **3**: [Re^I(bpy^{trip})(CO)₃Cl]), and isophthalic acid (phth, **4**: [Re^I(bpy^{phth})(CO)₃Cl]) derivatives and evaluated their electrocatalytic CO₂RR performance in the absence and presence of weak proton sources (methanol, phenol, and 2,2,2-trifluoroethanol), benchmarking against the prototypical [Re^I(bpy)(CO)₃Cl] (**1**) and rationalizing the difference in electrocatalytic performance via comprehensive density functional theory (DFT) computational studies.

Results and Discussion

Synthesis. The desired 6,6'-(Br)₂-2,2'-bipyridine ligand was obtained through the copper-assisted homo-coupling of 2,6-dibromo-pyridine. Afterwards, two types of substituents were coupled through a typical Suzuki coupling reaction (**Figure 2**). Coupling to electron-rich substituents, namely 2,4,6-trimethylphenyl (mes) and 2,4,6-triisopropylphenyl (trip) gave rise to the two corresponding 6,6'-functionalized 2,2'-bipyridine ligands, i.e. bpy^{mes} and bpy^{trip}, respectively. Coupling to the electron-poor isophthalic acid derivative gave rise to the corresponding bpy^{phth} ligand. The Suzuki coupling took place at reflux in toluene/methanol mixture in the case of bpy^{mes} and bpy^{trip}, and in a methanol/water mixture in the case of bpy^{phth}. The corresponding 6,6'-(R)₂-2,2'-bipyridine were isolated in moderate to excellent yield (56–94%). The formation and purity of these ligands was confirmed by ¹H NMR, ¹³C NMR and high-resolution mass spectrometry.

The four targeted complexes (**1–4**, **Figures 1** and **2**) were prepared in yields greater than 60 % by reacting one equivalent of the appropriate ligand (bpy, bpy^{mes}, bpy^{trip} and bpy^{phth}) with one equivalent of [Re^I(CO)₃Cl]. In the case of complexes **1–3**, the reaction proceeded smoothly in refluxing toluene for 24 hours, whereas complex **4** required extensive heating in methanol for four days as the solubility of the bpy^{phth} prevented carrying out the reaction in toluene. The extended reaction time most probably originated from the increased bulkiness of this ligand, disfavoring access to the chelation site. Complexes **1–3** are soluble in most common solvents: they are highly soluble in acetone, acetonitrile and dimethylformamide (DMF), and have moderate solubility in dichloromethane and chloroform but show poor solubility in water. Complex **4** bearing the isophthalic moiety is only soluble in DMF and DMSO and sparingly soluble in acetonitrile. The complexes were characterized by ¹H and ¹³C NMR, high-resolution mass spectrometry (HRMS), UV-vis absorption, steady-state and time-resolved photoluminescence spectroscopy along with electrochemical measurements. In addition, single crystals suitable for X-Ray diffraction were obtained for complexes **2** and **3** by the slow diffusion of hexane into a chloroform solution of the complexes, while crystals of **4** were obtained by slow diffusion of diethyl ether into a methanolic solution of **4** (**Figure 3**). The XRD structure revealed a 6-coordinate geometry for the Re(I) center with three CO groups occupying one face of the octahedral (*fac*) and the chloride occupying the axial position. Varying degrees of tilting between the bipyridine plane and the Re–CO coordination plane were observed (**Figure 3**, bottom).³⁷ Complexes **2** and **4** exhibited the largest tilt angle of 23.53° and 21.28°, respectively, while complex **3** displayed a significantly low tilt angle of 7.20°.

Photophysical properties. UV-vis absorption and photoluminescence spectra of complexes **1–4** were recorded in argon purged DMF and are all displayed in the supporting information (**Figure S18**). The complexes displayed the typical metal-to-ligand charge transfer (MLCT) transitions around 370–380 nm.³⁸⁻³⁹ Ligand-based transition are also observed at wavelength below 310 nm. These absorption features and corresponding molar absorption coefficients are gathered in **Table 1**.

The introduction of substituents in the 6,6' positions of the 2,2'-bipyridine had only marginal effects on the ground-state absorption properties, as complexes **2–4** exhibited similar absorption features and molar absorption coefficients as complex **1**.^{22, 40} When irradiated around 375±5 nm, complexes **1–3** exhibited steady-state photoluminescence with maxima that are centered between 630 and 640 nm, in agreement with the literature value of 642 nm reported for complex **1** in dichloromethane.⁴¹⁻⁴² Complex **4** exhibited a marked blue-shift of the photoluminescence, with a maximum centered at 607 nm in DMF (**Figure S18**). The excited state of complex **1** decayed mono-exponentially in argon purged DMF with a corresponding excited-state lifetime of 28 ns, once again consistent with the reported value of 39 ns in dichloromethane.⁴¹ The three other complexes exhibited slightly shorter excited-state lifetime, that ranged from 10 to 15 ns.

Electrochemistry and electrocatalytic CO₂ reduction. Cyclic voltammetry (CV) experiments of complexes 1-4 were carried out using a 1 mM concentration of complex dissolved in dry DMF in the presence of 0.1 M Bu₄NPF₆ supporting electrolyte. The three electrodes setup consisted of a glassy carbon working electrode, a platinum counter electrode and an

Ag/AgCl reference electrode. DMF was chosen as solvent in these experiments as it allowed to fully solubilize the four complexes, allowing fair comparison between the redox potentials and electrocatalytic activity of these complexes in identical conditions. The oxidation window comprised two oxidation events. For complex 1, the first oxidation was irreversible and assigned to the metal-centered Re^{II/I} oxidation resulting in the loss of Cl⁻ which is then oxidized at more positive potential.⁴³ Notably, the reversibility of the first oxidation event is enhanced for complexes 2-4, as evidenced from the variable scan rate cyclic voltammetry (Figures S19-S22). Thus, this oxidation event changed from irreversible for 1 to quasi-reversible for 2 and 3 possessing the hydrophobic units and then becomes fully reversible for complex 4 with the isophthalic unit in its SCS (Figure S22). Complexes 1-4 exhibited a reversible one-electron reduction wave followed by a second irreversible wave (Figure 4 and Table 2), which are ascribed to ligand-centered reduction followed by an irreversible Re^{II/I} reduction.^{6, 44-45} The first reduction occurred at $E_{1/2} = -1.30$ V for the parent complex 1. This reduction event was slightly shifted to more negative values upon the introduction of electron donating units, i.e. -1.38 V and -1.31 V for complexes 2 and 3, respectively. Similarly, the introduction of electron-withdrawing units slightly shifted the potential of the first reduction event to more positive potentials for complex 4, i.e. -1.21 V. Thus, the difference between the first reduction potential of complex 2 and 4 is around 170 mV. It is important to note that the reduction event of complex 4 becomes broad and difficult to observe when the cathodic window is recorded after the anodic scan (Figure 4, cyan dashed line). Conversely, when the cathodic scan is recorded first up to -1.50 V and using freshly polished electrode (Figure 4, blue trace) the first reduction wave becomes discernible and reversible. This observation highlights the potential for chemical change upon oxidation and potential deposition on the electrode, presumably via oxidative decarboxylation.⁴⁶

^arecorded in DMF with 0.1 M (Bu₄N)PF₆ supporting electrolyte, scan rate 100 mV/s, glassy carbon working electrode (d = 2 mm, A = 0.03 cm²) vs. Ag/AgCl reference electrode and Pt counter electrode at 20 °C. In this system $E_{1/2}(\text{Fc}^+/\text{Fc}) = 0.45 \pm 0.01$ V. E_c : potential of cathodic wave, E_a : potential of anodic wave, $E_{1/2}$ half-wave potential of reversible event.

Figure 4. Cyclic voltammetry of $[\text{Re}^{\text{I}}(\text{bpy})(\text{CO})_3\text{Cl}]$ **1** (black), $[\text{Re}^{\text{I}}(\text{bpy}^{\text{mes}})(\text{CO})_3\text{Cl}]$ **2** (red), $[\text{Re}^{\text{I}}(\text{bpy}^{\text{trip}})(\text{CO})_3\text{Cl}]$ **3** (green), and $[\text{Re}^{\text{I}}(\text{bpy}^{\text{phth}})(\text{CO})_3\text{Cl}]$ **4** sweeping (blue) $0.0 \text{ V} \rightarrow -1.50 \text{ V} \rightarrow 0 \text{ V}$ and (cyan) $0.0 \text{ V} \rightarrow 2.0 \text{ V} \rightarrow -2.0 \text{ V} \rightarrow 0 \text{ V}$. All experiments were carried out at a concentration of 1 mM of complex in DMF and under argon. Reduction potentials are summarized in **Table 2**. Conditions: 0.1 M $(\text{Bu}_4\text{N})\text{PF}_6$ supporting electrolyte, scan rate 100 mV/s , glassy carbon working electrode ($d = 2 \text{ mm}$, $A = 0.03 \text{ cm}^2$) vs. $\text{Ag}|\text{AgCl}$ references electrode and Pt counter electrode at 20°C . In this system $E_{1/2}(\text{Fc}^+/\text{Fc}) = 0.45 \pm 0.01 \text{ V}$.

Plots of the current vs. the square root of the scan rate for the first reduction event in complexes **1–4** (**Figure S23**) confirmed that this step is reversible and diffusion controlled for the four complexes. This facilitates the use of the Randles-Ševčík equation (see SI) that yielded the corresponding diffusion coefficient (D , $\text{cm}^2 \text{ s}^{-1}$) for each complex.^{46–47} Using this equation, diffusion coefficients of 4.8×10^{-5} , 1.7×10^{-6} , 3.5×10^{-6} and $1.4 \times 10^{-5} \text{ cm}^2 \text{ s}^{-1}$ were determined for complexes **1** through **4**, respectively (**Table 2**). For complexes **2** and **3**, the trend in diffusion coefficient is consistent with the fact that the bulky hydrophobic groups slow down the diffusion rate by one order of magnitude compared to **1**. Complex **4**, bearing the hydrophilic isophthalic acid units, diffuses three times slower than the parent complex but still faster than complexes **2** and **3**. This probably stems from the fact that complex **4** is only disubstituted on each phenyl ring whereas complexes **2** and **3** bear trisubstituted derivatives. These diffusion coefficients are in the same range of analogous mono-aryl substituted rhenium-bpy complexes (**Re-g**, **Figure 1**, $D = 1.3 \times 10^{-5} - 1.72 \times 10^{-5} \text{ cm}^2 \text{ s}^{-1}$) reported recently by Jurs and coworkers³⁴ as well as in close range to the one reported by Dempsey and coworker for ferrocene, i.e. $2.7 \times 10^{-5} \text{ cm}^2 \text{ s}^{-1}$ in MeCN .³⁴

Next, the four complexes were tested as electrocatalysts for CO_2 reduction using CO_2 saturated DMF in the presence and absence of proton source. Since the first report of Hawecker, Lehn, and Ziessel in 1984,⁶ where enhancement in catalytic current was observed when 10% of water was added to a DMF solution of catalyst **1**, the CO_2 electrocatalytic enhancement due

to the addition of proton sources became well documented in the literature.^{7, 44, 48} In here, three proton sources of varying strength were used, i.e. 2,2,2-trifluoroethanol (TFE), methanol (MeOH), and phenol (PhOH) with reported pK_a range of 23.5 to 29.0 in DMSO.⁴⁹ Values in DMF were not available in the literature. MeOH as a poor acidic proton source has recently been employed in CO_2 electroreduction.^{50–51} The use of different proton sources provides insight into the CO_2 electrocatalytic performance in terms of stability, activity, and overpotential.

To assess the catalytic efficiency of these novel catalysts, cyclic voltammetry was first recorded for each catalyst under saturated CO_2 conditions in the absence of a proton source. For all catalysts, current enhancement was observed at the onset of the second reduction potential (**Figure 5**) with the stark exception of catalyst **2** where a slight catalytic current is observed at the first catalytic wave (*vide infra*). Owing to the irreversibility of the second reduction event under argon atmosphere, the catalytic potential of each catalyst was determined from the value of the potential at midpoint of the catalytic current ($E_{\text{cat}/2}$, **Table 3**, ESI-Section 6), which lies in the steepest portion of the catalytic wave.⁵² The variation in the value of potential at $E_{\text{cat}/2}$ is smaller than that determined from the peak current (i_{cat}). This enables to determine the overpotential from the difference between $E_{\text{cat}/2}$ and $E^{\circ}_{\text{CO}_2/\text{CO}}$ in DMF.

An $E_{\text{cat}/2}$ of -1.68 V was determined for catalyst **1** in CO_2 saturated conditions in the absence of any proton source (**Figure 5** and **Figure S24**) whereas catalysts **2** and **3** have the corresponding $E_{\text{cat}/2}$ value negatively shifted by 60 mV and 200 mV , respectively (**Table 3**, **Figure 5** and **Figures S25–S26**). This observation was expected as the electron-donating Mes and Trip substituents render the corresponding catalysts more difficult to reduce, as discussed earlier. Interestingly, catalyst **4**, with its isophthalic acid group, shifted the CO_2 reduction event 140 mV more positive than the reference catalyst ($E_{\text{cat}/2} = -1.54 \text{ V}$ for **4** vs. -1.68 V for **1**). Although complex **4** initially appeared to exhibit catalytic activity after the first reduction, similar to catalyst **2**, further controlled potential electrolysis (CPE) experiments revealed that its activity was short-lived in the presence of MeOH as the proton source (see below).

The performance of an electrocatalyst for CO_2 reduction is evaluated by comparing the peak current of the catalytic wave in presence of CO_2 (i_{cat}) with the current value of the same event but in the absence of CO_2 (under argon, i_p). In case of an efficient catalyst, rapid conversion due to high turnover of CO_2 by the catalyst can result in a high value of i_{cat} compared to i_p (i_{cat}/i_p).³ For all catalysts, the catalytic activity, dictated by the value of i_{cat}/i_p , and the potential at half of the catalytic wave current ($E_{\text{cat}/2}$) are both enhanced in the presence of 2,2,2-trifluoroethanol, phenol or methanol (**Table 3**, **Figures S24–S27**), with the exception of catalyst **4**, for which the catalytic potential is slightly shifted to more negative value with the presence of 3 M PhOH (-1.57 V) and drastically shifted to -1.93 V in the presence of 3 M TFE, likely triggering the proton reduction process. In the absence of proton source, catalyst **2** displayed an i_{cat}/i_p value that is twice that of the other catalysts. This observation is most probably due to residual water in the cell or in the solvent that serves as proton source. Among all proton source used in this study, MeOH produced the most significant positive shift in catalytic potential ($E_{\text{cat}/2}$), with catalyst **1**, **2** and **4** exhibiting nearly identical ranges for $E_{\text{cat}/2}$ between -1.39 V and -1.46 V . Conversely, catalyst **3** exhibited an $E_{\text{cat}/2}$ of -1.59 V in the presence of 6.2 M MeOH. Reference catalyst **1** catalyzed the CO_2 reduction in the absence of proton sources at $E_{\text{cat}/2}$ of -1.68 V with an i_{cat}/i_p of 3.4, which is in good agreement with the i_{cat}/i_p of 4.4 reported by Nippe and coworkers for the same catalyst in acetonitrile without a proton source.³¹ In the presence of 6.2 M MeOH, the $E_{\text{cat}/2}$ for this catalyst shifted positively to -1.39 V with an i_{cat}/i_p of 7.7. Compared to **1**, the newly studied catalysts displayed improved i_{cat}/i_p values in the presence of MeOH with the exception of catalyst **4** bearing the isophthalic groups, that showed slightly lower i_{cat}/i_p of 5.7. Remarkably, catalyst **2** featuring the dimesityl group stands out with an i_{cat}/i_p of 21.3, nearly four times greater than that of reference catalyst **1** and double that of catalyst **3** (i_{cat}/i_p of 11.1).

Figure 5. Cyclic voltammetry of 1 mM DMF solutions of $[\text{Re}^{\text{I}}(\text{bpy})(\text{CO})_3\text{Cl}]$ **1** (a), $[\text{Re}^{\text{I}}(\text{bpy}^{\text{mes}})(\text{CO})_3\text{Cl}]$ **2** (b), $[\text{Re}^{\text{I}}(\text{bpy}^{\text{trip}})(\text{CO})_3\text{Cl}]$ **3** (c), and $[\text{Re}^{\text{I}}(\text{bpy}^{\text{phth}})(\text{CO})_3\text{Cl}]$ **4** (d) recorded under Ar (black), CO_2 (red) and CO_2 in the presence of 6.2 M MeOH (blue). Plots with other proton sources are shown in ESI Section 6 with catalytic performance summarized in **Table 3**. Inset in B shows an enlarged portion of the CV where the pre-catalytic wave is observed near the first reduction event of **2**. Conditions: 0.1 M $(\text{Bu}_4\text{N})\text{PF}_6$ supporting electrolyte, scan rate 100 mV/s, glassy carbon working electrode ($d = 2$ mm, $A = 0.03$ cm 2) vs. Ag|AgCl references electrode and Pt counter electrode at 20 °C. In this system $E_{1/2}(\text{Fc}^+/\text{Fc}) = 0.45 \pm 0.01$ V.

Table 3. Catalytic performance of catalysts **1-4** under CO_2 in DMF in absence and presence of proton source; 2,2,2-trifluoroethanol (3 M TFE), phenol (3 M PhOH) and methanol (6.2 M MeOH).

Figure 6. Controlled potential electrolysis (CPE) experiment at -1.80 V (vs. Ag/AgCl) of CO_2 -saturated DMF solutions in the presence of 6.2 M MeOH for the blank (grey), and with 1 mM of catalyst **1** (black), **2** (red), **3** (green) and **4** (blue). (A) Current-time plot for 1 hour CPE experiment. (B) product distribution analysis (circles: CO, squares: H_2) from the 1 hour CPE experiment along with the rinse test (magenta) by which the working electrode used with catalyst **2** was gently dipped in DMF and then the electrolysis was repeated in CO_2 saturated freshly made electrolyte in the presence of 6.2 M MeOH (inset) the corresponding charge-time plot. (C) Bar chart for the analysis of the gaseous product for CO (black solid bars) and H_2 (dashed bars), the CO Faradaic efficiency is indicated on the top of the bar for each catalyst.

To further evaluate the long term electrocatalytic CO_2 activity of these catalysts, controlled potential electrolysis experiments were conducted at an applied potential of -1.80 V vs. Ag/AgCl using 1 mM of the desired catalyst in DMF with 6.2 M MeOH and a glassy carbon working electrode ($A = 3.1$ cm^2). As illustrated in **Figure 6**, catalysts **1-4** exhibited varying performances in CO_2 reduction. Catalyst **2** displayed the highest current value over the course of one hour, averaging -5.5 mA. It achieved a total

charge of 20.3 C and produced 102 μmol of CO along with a Faradaic efficiency (FE) of 97% and no trace of H_2 detected. Rinsing experiments, whereby the electrode was removed after the CPE experiment using catalyst **2** showed minimal activity, with a charge accumulation and gas analysis similar to that recorded for the blank (**Figure 6B**). The unmodified reference complex (**1**) ranked second in reactivity under the same experimental conditions, yielding half the amount of CO (50 μmol) compared to **2**, with a FE of only 76% and trace amounts of H_2 . The FE of **1** was twice that reported by Nippe for the same catalyst in MeCN with 10% water as the proton source.³¹ In contrast to **1** and **2**, catalysts **3** and **4** demonstrated drastically reduced activity for CO_2 reduction, resulting in charge accumulation over one hour of 4.5 C for **3** and 2.7 C for **4**. The current density for **4** was also observed to decrease significantly after 30 minutes of electrolysis, indicating a loss of activity. For catalysts **3** and **4**, only a minimal amount of CO was detected (7 - 11 μmol) and only traces of H_2 , while no other products dissolved in the liquid phase were detected, thereby confirming their low activity. The significantly reduced catalytic performance of catalyst **4** along with its rapid deactivation is likely due to the electron-withdrawing nature of the carboxylic acid groups attached to the $6,6'$ positions. These groups likely destabilize the electron-deficient metal center in the metallocarboxylate reaction intermediate ($\text{CO}_2\text{H-Re}^{\text{I}}$), which is crucial for the CO_2 reduction reaction.^{30-31, 34} In contrast, this intermediate can be stabilized by the electron donating groups, as manifested effectively in catalyst **2**. The same reasoning applies to catalyst **3** with the Trip groups, however, the -1.8 V applied potential may not be significantly advantageous for **3**, as the catalytic wave observed for this catalyst is the most negative among those studied. Additionally, the requirement to apply a potential even more negative than -1.8 V, as used in this study, is not desirable for catalysis. Control experiments in the absence of catalyst demonstrated negligible CO formation over the duration of one hour, with hydrogen being the sole product generated. Altogether, these experiments confirmed that **2** is acting as an efficient homogeneous molecular CO_2RR catalyst and highlights that the SCS significantly influences the catalytic performance of the Re-bpy catalyst for CO_2 reduction. The modification of the SCS with the electron-donating mesityl group not only increased the catalytic activity but also shifted the potential required for catalysis to better align with the first reduction wave, thereby enhancing the longevity of the resulting catalyst. Conversely, the introduction of either larger electron-donating Trip groups or electron-withdrawing isophthalic groups reduced the activity for CO_2 reduction in DMF with MeOH (6.2 M) as the proton source.

Computational modeling. To rationalize these observations and gain insight into the activation pathways for CO_2 reduction, density functional theory calculations at the MN15 level,⁵³ in combination with the SMD solvation model⁵⁴ for DMF were performed. The computed reaction pathways are represented in **Figure 7**, with the computed values for each step presented in **Table 4**. We started our mechanistic investigation with the first reduction potential of the $[\text{Re-Cl}]^0$ or $[\text{Re-DMF}]^+$ complexes. The four catalysts, whether bearing Cl or DMF axial ligands exhibit reduction potentials that span a narrow range, i.e. $E_1 = -1.47$ to -1.66 V and $E_4 = -1.32$ to -1.44 V. Following this first reduction event, the catalysts can either undergo ligand loss (Cl or DMF) according to steps ΔG_1 and ΔG_2 or a second reduction with concerted ligand loss as indicated by E_2 and E_5 in **Figure 7**. Among the catalysts investigated, the catalyst bearing the bulkiest substituent (**3**) exhibited the lowest free energy changes of 5.2 kcal mol^{-1} and -0.7 kcal mol^{-1} for chloride ion and DMF dissociation, respectively. The computed potential for the subsequent reduction of the penta-coordinated $[\text{Re}]^0$, resulting in the active two-electron reduced species $[\text{Re}]^{\text{II}}$, also lies within a narrow-computed range, i.e. $E_3 = -1.44$ to -1.59 V. Furthermore, the reduction of $[\text{Re-Cl}]^{\text{II}}$ with the concerted loss of Cl^- requires a more negative potential ($E_2 = -1.75$ to -2.00 V), whereas the reduction of $[\text{Re-DMF}]^0$ with the concerted loss of DMF results in a lower energy requirement with computed potentials of $E_5 = -1.49$ to -1.63 V. Thus, at this stage it appears that the formation of the doubly reduced species is thermodynamically feasible for all catalysts, but that the free energy cost and the computed potentials are overall more favorable once the initial chlorido ligand has been replaced by the solvent. Additional pathways were also computed, such as the disproportionation of the mono-reduced species, $[\text{Re-DMF}]^0$ and $[\text{Re-Cl}]^{\text{II}}$. Although thermodynamically feasible, they do not exhibit systematic differences between the catalysts examined in this study.

Figure 7. Computed activation steps for $[\text{Re-Cl}]^0$ and solvated $[\text{Re-DMF}]^+$ species.

Interestingly, the computed free energy values for the CO_2 binding to the doubly reduced species ($[\text{Re}]^-$) to form carboxylate intermediates ($[\text{Re-CO}_2]^-$) (ΔG_3 highlighted in green in **Figure 7**) ranges between $7.0 \text{ kcal mol}^{-1}$ for the most active catalyst featuring the mesityl-moiety (**2**) to $13.4 \text{ kcal mol}^{-1}$ for the least active catalyst featuring the excessively bulky trip-moiety (**3**), thereby indicating a more favorable CO_2 binding free energy for catalyst **2**. At first glance, these results could appear counter-intuitive as the mesityl groups are expected to also provide a significant steric hindrance for CO_2 binding, especially compared to the parent *fac*- $[\text{Re}^{\text{I}}(\text{bpy})(\text{CO})_3\text{Cl}]$

catalyst. Interestingly, a closer look at the computed geometries of the different catalysts indicated that the active catalyst **2** displayed a significant tilting of the 2,2'-bipyridine unit compared to the other catalysts (**Figure 8**), as reported for other active catalysts.³⁷ This was also confirmed by X-Ray crystallography (**Figure 3**). Specifically, theoretical calculations allowed to determine a tilt angle of 6° for **1**, 20° compared to 23.53° (XRD) for **2**, and 2.5° compared to 7.20° (XRD) for **3**. As ΔG_3 represents the only computed energy where significant differences were observed, it could thus represent a key step within the catalytic cycle and suggests that the bending of **2** may account for the higher activity of this complex in overall CO_2 conversion.

The protonation of $[\text{Re-CO}_2]^-$ to generate $[\text{Re-COOH}]^0$ species are computed to be energetically favorable (ΔG_4) which can be further reduce to form $[\text{Re-COOH}]^-$ at potentials (E_5) lower than those required for the activation of the catalyst (E_2). Following C–OH bond cleavage step (ΔG_6) leads to generation of $[\text{Re-CO}]^0$ and evolution of CO completes the catalytic cycle. An alternative pathway could be the C–OH bond cleavage at $[\text{Re-COOH}]^0$ intermediate followed by a reduction step to generate the common $[\text{Re-CO}]^0$ species but the associated free energy changes (ΔG_5) are significantly higher compared to the associated free energy changes (ΔG_6) for C–OH bond cleavage from $[\text{Re-COOH}]^-$ species indicating that a reduction first type pathway is more likely to be the operative mechanism similar to other $[\text{Re}^{\text{I}}(\text{bpy})(\text{CO})_3\text{Cl}]$ -type catalysts.⁵⁵ Interestingly, the energetics of the mechanistic steps following CO_2 binding do not exhibit any strong correlation with the structural differences and CO_2 reduction reactivity of the complexes.

Table 4. Summary of computed reduction potentials (E in V vs Fc^+/Fc) and free energy changes (ΔG in kcal mol^{-1}) for $[\text{Re}(6,6'-(\text{R})_2\text{-bpy})(\text{CO})_3\text{X}]$ pre-catalysts (**1-4**). Note that the corresponding experimental redox value are tabulated in Table 3 using Ag/AgCl reference electrode, $E_{1/2}(\text{Fc}^+/\text{Fc}) = 0.45 \pm 0.01 \text{ V}$ vs Ag/AgCl .

Re	E_1	E_2	E_3	E_4	E_5	E_6	E_7	ΔG_1	ΔG_2	ΔG_3	ΔG_4	ΔG_5	ΔG_6
1	-1.58	-1.97	-1.55	-1.42	-1.53	-1.33	-1.70	9.9	-0.4	8.4	-13.3	5.7	-2.9
2	-1.66	-2.00	-1.59	-1.44	-1.63	-1.25	-1.65	9.3	0.8	7.0	-13.1	5.5	-3.8

Figure 8. Calculated structures for catalysts **1**, **2**, **3** and **4**, from left to right. The tilting angles were in agreement with those determined from the crystal structure (**Figure 3**).

Conclusion

Three 6,6'-substituted 2,2'-bipyridine ligands were synthesized using Suzuki coupling reaction between 6,6'-dibromo-2,2'-bipyridine and the corresponding 2,4,6-trimethylphenyl (Mes), 2,4,6-triisopropylphenyl (Trip) and isophthalic (Phth) boronic acid. These groups vary in their bulkiness and electron donating ability, allowing for fine tuning of fundamental properties. These ligands were used for the synthesis of a series of $\text{Re}(\text{I})$ complexes that were evaluated for CO_2 reduction and benchmarked against the prototypical $[\text{Re}^{\text{I}}(\text{bpy})(\text{CO})_3\text{Cl}]$ catalyst, in the absence and presence of weak Brønsted acids. Although the introduction of bulky mesityl and triisopropylphenyl groups had minor effects on the first reduction event at -1.30

V, the potentials of the second reduction event shifted to more negative values under inert conditions to -1.91 V for **2** and -1.96 V for **3** compared to -1.68 V for **1** and -1.70 V for **4**, respectively. Methanol positively impacted the electrocatalytic activity represented by i_{cat}/i_p , following trend in activity where $2 > 3 > 1 > 4$ with $i_{\text{cat}}/i_p = 21.3 > 11.1 > 7.7 > 5.7$. CPE experiments conducted at -1.80 V for one hour indicated highest turnover number of 16 achieved by the most active catalyst **2**, followed by the literature structurally unmodified catalyst **1** with TON ~ 7 , whereas the least active catalysts **3** and **4** displayed minimal TON ~ 1 .

Experimental and theoretical calculations point towards the tilting between the bipyridine plane and the Re-CO coordination plane in catalyst **2**, in addition to the incorporation of electron donating groups, as key factors controlling the catalysis. Indeed, whereas potentials shifts are well understood based on electronic factors, geometric contributions are currently less rationalized. In the present case, it appears that the tilting of catalyst **2** favors the key insertion of CO₂ compared to the other catalysts, which is paramount to initiate the reductive chemistry. This can be the factor rendering catalyst **2** faster and more efficient than **1**, **3**, and **4** and as a consequence, the competing hydrogen formation reaction and/or other deactivation processes are minimized. This represents an approach that warrants future investigations in the coming future.

Experimental section

¹H-NMR and ¹³C NMR spectra were recorded on a Bruker AC-300 Avance II (300 MHz) or a JEOL JNM-ECZL R (400 MHz and 600 MHz) at 293 K. Chemical shifts are reported in parts per million and referenced to the residual protonated solvent peak in the ¹H NMR spectra and the residual solvent peak in the ¹³C NMR spectra [CDCl₃: 7.26 ppm (¹H) and 72.16 ppm (¹³C); d₆-DMSO: 2.50 ppm (¹H) and 39.52 ppm (¹³C)]. High-resolution ESI-MS was performed with a Q-Exactive orbitrap from ThermoFisher using reserpine as the internal standard. Samples were ionized by electrospray ionization (ESI). UV-vis absorption spectra were recorded on an Agilent Cary 60 spectrophotometer in a quartz cuvette with a 1 cm path length. Molar absorption coefficients were determined in at least two independent measurements with less than 5 % standard deviation.

Time-resolved and steady-state photoluminescence spectra were recorded on an FS5 Spectrofluorometer from Edinburgh Instruments equipped with a time-correlated single photon counting module. The steady-state photoluminescence spectra were recorded using a 150 W Xenon arc lamp as the excitation source. The photoluminescence was detected at a right angle to the excitation beam using a single photon counting PMT-900 in a temperature-stabilized housing. The spectra were integrated for 0.1–0.2 s at each wavelength. Time-resolved photoluminescence data were collected on the FS5 spectrofluorometer using the time-correlated single photon counting technique (TCSPC). Excitation was achieved with a 450±5 nm diode laser (EPL-450, 85 ps pulse width at 10 MHz) for rhenium complexes. Photons reaching the detector were accumulated to reach a count of 5,000.

Cyclic voltammetry (CV) was performed with an Autolab PGSTAT 100 potentiostat using a standard three-electrodes cell, i. e., a glassy carbon disk working electrode (d = 2 mm, A = 0.03 cm²), a platinum wire counter electrode and an aqueous Ag/AgCl reference electrode. Experiments were performed in dry DMF with 0.1 M TBAPF₆ as supporting electrolyte at a scan rate of 0.1 V/s.

Computational Methods. All geometries were fully optimized at the MN15 level of density functional theory,⁵³ in conjunction with the SMD continuum solvation model⁵⁴ for DMF using the def2-TZVP basis set on Re⁵⁶ and the def2-SVP basis set⁵⁶ on all other atoms. Non-analytical integrals were evaluated using the integral=(grid=ultrafine) option as implemented in the Gaussian 16 software package.⁵⁷ The nature of all stationary points was verified by analytic computation of vibrational frequencies, which were also used for the computation of zero-point vibrational energies and molecular partition functions. Partition functions were used in the computation of 298 K thermal contributions to the free energy employing the usual ideal-gas, rigid-rotator, harmonic oscillator approximation.⁵⁸ Free-energy contributions were added to single-point MN15 electronic energies computed using SMD continuum solvation model for DMF at the optimized geometries obtained with the initial basis with def2-TZVPP basis set on Fe and Re and the def2-TZVP basis set on all other atoms to arrive at final composite free energies. The reduction potentials are computed in reference to Fe^{+/0} couple.

Single crystal determination was performed on a MAR345 image plate detector using MoK α radiation generated by an Incoatec 1 μ S microfocuss source (Montel mirrors) at ambient conditions. The unit-cells, data reduction and absorption correction (multi-scan method) were conducted using CrysAlisPro⁵⁹ software package. The structure was solved by dual space direct methods SHELXT⁶⁰ and refinement by full-matrix least-squares against F² using SHELX-2019/3.⁶¹ All non-hydrogen atoms were refined anisotropically and hydrogen atoms were placed at calculated positions and refined in riding mode.

Materials. Acetonitrile (99.9 %, VWR), dichloromethane (99.9 %, stabilized with about 0.002 % of 2-methyl-2-butene, VWR), diethyl ether (99.9 %, VWR), ethanol absolute (99.9 %, VWR), acetone (99.9 %, VWR), ethylene glycol ($\geq$ 99.5 %, Roth), methanol (99.9 %, VWR), n-hexane

(97 %, VWR), dimethylformamide (99.9 %, VWR), ammonium hexafluorophosphate (99 %, Fluorochem), tetra-n-butylammonium hexafluorophosphate ($\geq$ 98 %, TCI), ammonium chloride ($>$ 99 %, Acros Organics), aluminum oxide for chromatography (neutral, Brockmann I, 40–300 μ m, 60 Å, Thermo Fisher), silica gel for flash column chromatography (60 Å, 40–63 μ m, ROCC), hydrochloric acid (37 %, VWR), sodium chloride (99.5 %, Acros Organics), 2-bromopyridine (99 %, TCI), 4,4'-bipyridine (98 %, across), n-Butyl lithium (2.5 M-hexane, Sigma-Aldrich), copper(II) chloride (CuCl₂) (99 %, across), rhenium(I) pentacarbonyl chloride (Re(CO)₅Cl) (99 %, Sigma), 5-Boronisophthalic acid (99 %, BLDPharm), 2,4,6-triisopropylphenylboronic acid (99 %, BLDPharm), 2,4,6-trime-thylphenylboronic acid (99 %, BLDPharm).1,1,1-trifluoroethanol (99 %TCI), phenol (99 %, TCI) tetra-n-butylammonium hexafluorophosphate (99 % electroanalysis, Sigma-Aldrich), deuterated acetonitrile (99.8 %D, Eurisotop), deuterated dimethylsulfoxide (99.8 %D, Eurisotop), were purchased from commercial suppliers and used as received. Water was purified by a Millipore Milli-Q system. [Re(bpy)(CO)₃Cl] was prepared according to a literature procedure.³ Tetrakis(triphenylphosphine)palladium(0), [Pd(P(C₆H₅)₃)₄] ([Pd(PPh₃)₄]) was prepared following literature procedure⁶² and stored in the dark at –20 °C. All reactions were conducted under inert atmosphere unless otherwise stated.

Synthesis

6,6'-Dibromo-2,2'-bipyridine This precursor was prepared according to a literature procedure with slight modifications.⁶³ Typical procedure involved using rigorously dried reagents and glassware. n-butyl lithium (2.5 M-hexane, 12.15 mL, 30.4 mmol, 1.2 equiv) was added over 1 hour to a –70 °C cooled suspension of 2,6-dibromopyridine (6.0 g, 25.3 mmol, 1 equiv) in anhydrous diethylether (24 mL) in a three-neck round bottom flask kept under argon. CuCl₂ (1.40 g, 15.7 mmol, 0.5 equiv) was then added and stirred for 30 minutes. The reaction mixture was thoroughly bubbled with dry air for 40 minutes. HCl (6 M, 60 mL) was subsequently slowly added to quench the reaction mixture that was then filtered and the solid product was washed with 0.5 M HCl. More product was obtained by extracting the filtrate with CHCl₃. The resulting combined brown solid was recrystallized from hot CHCl₃. The desired product was obtained as white crystals (2.37 g, 60 % yield) which were filtered off and washed with pentane. ¹H NMR (400 MHz, CDCl₃, δ (ppm)): 8.39 – 8.34 (m, 2H), 7.66 (td, *J* = 7.8, 0.7 Hz, 2H), 7.49 (dd, *J* = 7.9, 0.9 Hz, 2H).

6,6'-Dimesityl-2,2'-bipyridine (bpy^{mes}) This was synthesized according to a literature procedure with slight modifications.⁶⁴ To a suspension of 6,6'-dibromo-2,2'-bipyridine (0.80 g, 2.54 mmol, 1 equiv) in toluene (170 mL), were added mesitylboronic acid, (1 g, 6.1 mmol, 2.4 equiv) and methanol (20 mL). Aqueous Na₂CO₃ (2 M, 32 mL) was then added, and the mixture was bubbled with argon for 10 minutes before adding [Pd(PPh₃)₄] (0.157 g, 0.127 mmol, 0.05 equiv). The reaction mixture was bubbled with argon for an additional 5 minutes before being refluxed for 72 h. Afterward, the reaction mixture was cooled to room temperature, the organic layer was taken and washed with saturated Na₂CO₃ solution (100 mL). The aqueous layer was washed with DCM (100 mL x 3 times) and the combined organic phases (toluene and DCM) were dried over anhydrous MgSO₄, filtered and evaporated under reduced pressure to obtain the title compound as a white solid (0.63 g, Yield 64%). ¹H NMR: (300 MHz, CDCl₃, δ (ppm)): 8.38 (dd, *J* = 8.0, 1.1 Hz, 2H), 7.80 (t, *J* = 7.8 Hz, 2H), 7.21 (dd, *J* = 7.6, 1.1 Hz, 2H), 7.01 – 6.95 (m, 4H), 2.35 (s, 6H), 2.12 (s, 12H).

6,6'-Di-(2,4,6-triisopropylphenyl)-2,2'-bipyridine (bpy^{trip}). To a suspension of 6,6'-dibromo-2,2'-bipyridyl (0.5 g, 1.59 mmol, 1 equiv) in toluene (170 mL), were added 2,4,6-triisopropylphenylboronic acid, (1.0 g, 4.03 mmol, 2.52 equiv) and methanol (7.5 mL). Aqueous Na₂CO₃ (2 M, 7.5 mL) was then added, and the mixture was bubbled with argon for 10 minutes before adding [Pd(PPh₃)₄] (0.100 g, 0.08 mol, 0.05 equiv). The reaction mixture was bubbled with argon for an additional 5 minutes before being refluxed for 72 h. Afterward, the reaction mixture was cooled to room temperature, the organic layer was taken and washed with saturated Na₂CO₃ solution (100 mL). The aqueous layer of the reaction was washed with DCM (100 mL x 3 times) and the combined organic phases (toluene and DCM) were dried over anhydrous MgSO₄, filtered and evaporated under reduced pressure to obtain the title compound as a white solid (0.84 g, Yield 94%). ¹H NMR (400 MHz, CD₂Cl₂, δ (ppm)): 8.41 (dd, *J* = 8.0, 1.1 Hz, 2H), 7.81 (t, *J* = 7.8 Hz, 2H), 7.26 (dd, *J* = 7.6, 1.1 Hz, 2H), 7.13 (s, 4H), 2.97 (p, *J* = 6.9 Hz, 2H), 2.68 – 2.54 (m, 4H), 1.32 (d, *J* = 6.9 Hz, 12H), 1.13 (dd, *J* = 7.9, 6.8 Hz, 24H). ¹³C NMR (400 MHz, CD₂Cl₂, δ (ppm)): δ 159.22, 155.67, 149.01, 146.59, 136.90, 136.57, 125.16, 120.73, 118.79, 34.53,

30.42, 24.00, 23.95, 23.86. HRMS m/z (calcd for $[\text{bpy}^{\text{trip}}+\text{H}]^+$ $[\text{C}_{40}\text{H}_{35}\text{N}_2+\text{H}]^+$ 561.4209, found 561.4221).

6,6'-Di-(5-isophthalic acid)-2,2'-bipyridine (bpy^{phth}) To a suspension of 6,6'-dibromo-2,2'-bipyridyl (0.80 g, 2.54 mmol, 1 equiv) and 5-boronoisophthalic acid (1.35 g, 6.42 mmol, 2.5 equiv) in methanol (12 mL), was added aqueous Na_2CO_3 (2 M, 12 mL) and the mixture was bubbled with argon for 10 minutes before adding $[\text{Pd}(\text{PPh}_3)_4]$ (0.157 g, 0.127, 0.05 equiv). The reaction mixture was bubbled for an additional 5 minutes and refluxed for 72 h. Afterward, the reaction mixture was cooled to room temperature and the resulting white-brown solid was filtered, the solid was washed with 20 mL H_2O . The resultant aqueous phases were combined and acidified with HCl (6 M) to pH ~ 2-3 to give a white precipitate which was filtered and washed with water, small portions of cold ethanol and diethylether and then dried under vacuum (0.64 g, Yield 56%). ^1H NMR (400 MHz, $\text{D}_2\text{O}/\text{NaOD}$, δ (ppm)): 8.59 (d, J = 1.6 Hz, 4H), 8.44 (d, J = 7.8 Hz, 2H), 8.34 (t, J = 1.6 Hz, 2H), 8.10 (t, J = 7.8 Hz, 2H), 7.95 (d, J = 7.8 Hz, 2H). ^{13}C NMR (400 MHz, d_6 -DMSO, δ (ppm)) δ 167.07, 155.60, 154.43, 139.97, 139.73, 132.65, 131.77, 131.03, 121.93, 120.63. HRMS m/z (calcd for $[\text{M}-\text{H}]^-$ $[\text{C}_{26}\text{H}_{15}\text{N}_2\text{O}_8-\text{H}]^-$ 483.0823, found 483.0828)

$[\text{Re}(\text{bpy}^{\text{mes}})(\text{CO})_3\text{Cl}]$ (2) Pentacarbonylchlororhenium(I), $[\text{ReCl}(\text{CO})_5]$ (100 mg, 0.276 mmol, 1 equiv) and 6,6'-dimesityl-2,2'-bipyridine (bpy^{mes}) (108 mg, 0.276 mmol, 1 equiv) were suspended in toluene (15 mL) and refluxed at 120 °C for 24 h. After cooling to room temperature, the reaction mixture was filtered to remove any unreacted solid and the filtrate was reduced to 3 mL. Diethyl ether (10 mL) was then added and the solution was left for 2 hours to allow the precipitation of a yellow solid, which was filtered and washed with diethyl ether and dried in vacuum to afford a yellow product (125 mg, 65% Yield). ^1H NMR (300 MHz, $\text{DMSO}-d_6$, δ (ppm)): 8.79 (dd, J = 8.4, 1.3 Hz, 2H), 8.33 (t, J = 7.9 Hz, 2H), 7.53 (dd, J = 7.7, 1.2 Hz, 2H), 7.29 – 7.09 (m, 2H), 6.97 (d, J = 7.3 Hz, 4H), 2.27 (s, 6H), 2.05 (s, 6H). HRMS m/z (calcd for $[\text{M}+\text{Na}]^+$ $[\text{C}_{31}\text{H}_{28}\text{O}_3\text{N}_2\text{ClRe}+\text{Na}]^+$ 719.12102, found 719.12152) and (calcd for $[\text{M}-\text{Cl}+\text{MeCN}]^+$ $[\text{C}_{33}\text{H}_{31}\text{O}_3\text{N}_3\text{Re}]^+$ 702.18895, found 702.18953)

$[\text{Re}(\text{bpy}^{\text{trip}})(\text{CO})_3\text{Cl}]$ (3) Pentacarbonylchlororhenium(I), $[\text{ReCl}(\text{CO})_5]$ (100 mg, 0.276 mmol, 1 equiv) and di-(2,4,6-tiisopropylphenyl)-2,2'-bipyridine (bpy^{trip}) (108 mg, 0.276 mmol, 1 equiv) were suspended in toluene (15 mL) and refluxed at 120 °C for 24 h. After cooling to room temperature, the reaction mixture was filtered off, and the filtrate volume was reduced to 3 mL. Diethyl ether (10 mL) was added which resulted in the formation of a yellow precipitate that was collected by filtration, washed with diethyl ether and dried under vacuum to afford pure product. (170 mg, 71% Yield). ^1H NMR (400 MHz, $\text{DMSO}-d_6$, δ (ppm)): 8.85 – 8.72 (m, 2H), 8.27 (t, J = 8.0 Hz, 2H), 7.73 (d, J = 6.8 Hz, 2H), 7.09 (d, J = 2.1 Hz, 4H), 2.97 – 2.80 (m, 2H), 2.44 (s, 4H), 1.28 – 1.10 (m, 24H), 0.91 (dd, J = 15.0, 6.8 Hz, 12H). ^{13}C NMR (400 MHz, CDCl_3 , δ (ppm)): 164.63, 158.08, 151.48, 147.08, 145.39, 136.83, 129.93, 122.75, 121.99, 120.89, 34.67, 30.90, 30.83, 25.73, 25.69, 24.06, 24.04, 23.34, 22.62. HRMS m/z (calcd for $[\text{M}+\text{Na}]^+$ $[\text{C}_{43}\text{H}_{52}\text{O}_3\text{N}_2\text{ClRe}+\text{Na}]^+$ 887.30882, found 887.30949) and (calcd for $[\text{M}-\text{Cl}+\text{MeCN}]^+$ $[\text{C}_{45}\text{H}_{55}\text{O}_3\text{N}_3\text{Re}]^+$ 870.37675, found 870.37766)

$[\text{Re}(\text{bpy}^{\text{phth}})(\text{CO})_3\text{Cl}]$ (4) Pentacarbonylchlororhenium(I), $[\text{ReCl}(\text{CO})_5]$ (100 mg, 0.276 mmol, 1 equiv) and 6,6'-di-(5-isophthalic acid)-2,2'-bipyridine (bpy^{phth}) (134 mg, 0.276 mmol, 1 equiv) were suspended in methanol/toluene (1/1, 30 mL) mixture and heated at reflux for 96 h. The reaction mixture was concentrated to half its volume and filtered giving a yellow solid which was washed with diethylether (15 mL) and acetonitrile (10 mL). Subsequently, the solid was solubilized in MeOH/DMF mixture (1/0.2, 5 mL) which upon slow ether diffusion (10 mL) precipitated. The precipitate was filtered and washed with ether to afford a yellow solid (134 mg, 61 % Yield). ^1H NMR (400 MHz, DMSO , δ (ppm)) δ 13.40 (s, 4H), 8.92 (d, J = 7.4 Hz, 2H), 8.60 (t, J = 1.6 Hz, 2H), 8.49 – 8.37 (m, 4H), 8.23 (s, 2H), 7.91 (dd, J = 7.7, 1.1 Hz, 2H), 7.28 – 7.08 (m, 6H). ^{13}C NMR (400 MHz, $\text{DMSO}-d_6$, δ (ppm)) δ 166.59, 161.48, 158.11, 142.54, 141.12, 134.89, 133.83, 132.47, 132.10, 131.48, 128.36, 124.96, 118.64. HRMS m/z (calcd for $[\text{M}-\text{Cl}+\text{MeCN}]^+$ $[\text{C}_{31}\text{H}_{19}\text{O}_{11}\text{N}_3\text{Re}]^+$ 794.05437, found 794.05503)

ACKNOWLEDGMENT

This work was supported by the Fonds de la Recherche Scientifique (F.R.S.-FNRS) under grant CDR n°40020332. This publication benefited from the support of the Walloon Region as part of the financing of the FRFS-WEL-T strategic axis. L.T.-G. is a Chercheur Qualifié of the Fonds de la Recherche Scientifique – FNRS. A.A, S.D.K., K.R. B. E. and L.T.-G. gratefully acknowledge the UCLouvain for financial support. The work at Brookhaven National Laboratory (M.Z.E.) was carried out under contract DE-SC0012704 with the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences. A.L and S. G acknowledge the CERCA Program / Generalitat de Catalunya, and Severo Ochoa Excellence Accreditation CEX2024-001469-S funded by MCIU / AEI / 10.13039/501100011033. MICINN for PID2022-140143OB-I00 and Generalitat de Catalunya for the project 2021 SGR 01583.
