WILEY

Dear Colleagues,

On behalf of the UEG Scientific Committee, I would like to express our deepest gratitude for your invaluable contributions as abstract reviewers for the UEG Week 2024 original programme. Your efforts in the abstract reviewing process are vital to maintaining the high scientific quality and relevance of UEG Week. I am aware of the significant time and dedication required for this task, and without your expertise, we could not have achieved the exceptional standards of our abstract-based sessions. Your hard work ensures that UEG Week continues to be the premier international meeting in the field of digestive diseases

Thank you once again for your dedication and support!

We received a total of **3,540 abstracts** for UEG Week 2024. In total, **2,208 abstracts** were accepted. **236 abstracts** will be delivered as **oral presentations** and **1,972** as **posters**. I am even more pleased to tell you that standards have again reached a very high level and we can expect most interesting research and great presentations. This high volume and high standard confirm that UEG Week remains the most important forum at which to present your best research.

We have received **90 video cases** and **416 clinical cases** which were formally evaluated by the Scientific Committee and invited experts for presentation. As in previous years, late breaking abstracts have been scored by the Scientific Committee.

The quality of reviewing this year was excellent, but if you have any further (positive or negative) comments, please do let us know! Finally, but most importantly, thanks to all investigators both within and outside Europe who have submitted their research to the meeting, and who are contributing to making UEG Week 2024 a great success!

Julia Mayerle
Chair of the UEG Scientific Committee

CROHN'S DISEASE AND ULCERATIVE COLITIS EXHIBIT PRE-DIAGNOSTIC ANTIBODY SIGNATURES WITH SHARED AND DIVERGENT CHANGES TOWARDS DISEASE ONSET

A.R. Bourgonje^{1,2}, S. Andreu-Sánchez³, R. Gacesa¹, G. Innocenti⁴, I.N. Kalka⁵, S. Klompus⁵, S. Leviatan⁵, A. Weinberger⁵, B. van der Vegt⁶, J. Fu³, E. Segal⁵, A.P. Zhernakova³, T. Vogl⁴, R.K. Weersma¹

Introduction: Inflammatory bowel diseases (IBD), encompassing Crohn's disease (CD) and ulcerative colitis (UC), is a chronic debilitating. Current clinical practice is focused on managing disease flares and complications, requiring lifelong medical treatment and/or surgery. However, a paradigm shift in IBD care is needed, moving from treatment of established disease towards creating opportunities for prevention of disease development. Such strategies recently proved successful in rheumatoid arthritis and type 1 diabetes. Before being able to achieve this, however, preclinical disease biomarkers are urgently needed. IBD is characterized by unique immunological changes early in development.

Although >300 IBD-specific antibody responses have been identified¹, systemic antibody epitope repertoires of preclinical IBD remain elusive. This study aimed to profile systemic antibody responses at unprecedented depth in individuals before and after the onset of IBD, aiming to identify preclinical disease biomarkers.

Aims & Methods: This study included individuals participating in the Life-lines Cohort Study, a large prospective population-based cohort study in the Netherlands including 167,000 individuals with longitudinal follow-up. Participants without IBD at baseline were screened for any reported IBD diagnosis during follow-up (2006-2021). Individuals who reported IBD during follow-up and with available serum samples were included. Samples at baseline (pre-diagnosis) and during follow-up (post-diagnosis) were used to profile antibody repertoires against 344,000 rationally selected microbial-, food-, and immune antigens using phage-display immunoprecipitation sequencing (PhIP-Seq).

Results: A total of 178 new-onset cases with IBD were identified. Median follow-up time until diagnosis was 3.9 (IQR: 3.4-4.3) years. Most individuals newly developed UC ($n=123$, 69.1%), followed by CD ($n=44$, 24.7%), and undetermined IBD (IBD-U, $n=11$, 6.2%). A total of 5,174 antibody responses were observed in 5-95% of participants. Fifty-nine antibodies were differentially abundant (FDR<0.05) pre-diagnosis vs. post-diagnosis, 14 of which (24%) were previously reported in established IBD¹. Thirteen were more (22%) and 46 less (78%) frequently observed post-diagnosis. Individuals developing IBD exhibited reduced frequencies of antibody

responses against EBV-associated peptides post-diagnosis, e.g. Epstein-Barr nuclear antigen-1 (EBNA-1) and capsid protein V26, and other herpesviruses including varicella-zoster virus (VZV), herpes simplex virus type 1 (HSV-1), and noroviruses. Conversely, significantly increased antibody responses were observed against bacterial flagellins (notably from *Lachnospiraceae* and pathogenic (e.g. *Legionella*) bacteria) in individuals developing CD, already before disease onset. Individuals developing UC showed elevated antibody responses mainly against viruses (e.g. human adenovirus C, enteroviruses B/C) and particular pathogenic bacterial species (e.g. pneumococcal histidine triad proteins) post-diagnosis compared to pre-diagnosis.

Conclusion: This study represents the first comprehensive and high-resolution analysis of the exact antigenic nature of systemic antibody responses changing during the transition from preclinical to established IBD. Distinct antibody responses appear years before IBD diagnosis, indicating potential involvement in pre-clinical disease development. Furthermore, post-diagnosis, lower frequencies of antibody responses against EBV may suggest reduced immunogenicity against this virus in early disease pathogenesis.

Introduction: Enzymatic modification of gliadin peptides by human transglutaminase 2 (TG2) is pivotal in celiac disease (CeD) pathogenesis. ZED1227, an oral TG2 inhibitor, shows promise in preventing gluten-induced mucosal damage and symptoms. This study aims to further elucidate the molecular mechanisms underlying the therapeutic efficacy of ZED1227 in CeD.

Aims & Methods: Duodenal biopsy samples were collected from 125 patients with CeD in a phase 2a clinical trial with ZED1227 (CEC-3/CEL; EudraCT-2017-002241-30). Samples were obtained before and after a 6-week gluten challenge (3g/day). Participants received ZED1227 (10mg/day, 50 mg/day, or 100 mg/day) or placebo. RNA extracted from the biopsies underwent next-generation RNA sequencing (RNA-seq) analysis.

Results: Our analysis revealed that after a 6-week gluten challenge, 377 genes exhibited differential expression in the placebo group. Under low-dose ZED1227 (10 mg) treatment, 150 genes remained differentially expressed, primarily affecting metabolism-related pathways but not the interferon- γ (IFN- γ) response. However, higher doses of ZED1227 (50 mg and 100 mg) completely eliminated gluten-induced gene expression changes, including those associated with the IFN- γ response, showing a dose-dependent effect on gene regulation.

Notably, almost half of the gluten induced genes that were suppressed by ZED1227 were related to the IFN- γ response. Initial analysis of human leukocyte antigen (HLA) genotypes suggested that the impact of ZED1227 on mucosal architecture and the IFN- γ response may be modulated by an individual's HLA-DQ2 or -DQ8 genetic background, providing valuable insights into its therapeutic potential in CeD.

Conclusion: ZED1227 effectively prevents gluten-induced mucosal damage in patients with CeD and beneficially modulates gene expression associated with mucosal integrity and the immune response, particularly of the IFN- γ pathway that is central to CD4 T cell mediated CeD pathogenesis. These data corroborate and further elucidate key pathways of intestinal damage in CeD and may suggest new biomarkers of mucosal injury.

Contact E-Mail Address: eivind.ness-jensen@ntnu.no

Introduction: Coeliac disease (CD) is an immune-mediated disorder of the small intestine triggered by dietary gluten. The diagnosis is based on serological testing and histological examination. Selective immunoglobulin (Ig) A deficiency is a more common condition amongst CD patients than in the general population, complicating the use of IgA antibodies to diagnose CD. Current guidelines suggest testing for the level of total immunoglobulin A (IgA) and the level of specific anti-transglutaminase 2 (TG2) IgA in the search for CD. Only when severe IgA deficiency is found, immunoglobulin G (IgG) based testing is recommended.

In a pilot study for validating a dual TG2 IgA/IgG screening assay, we found CD patients primarily responding with TG2 IgG antibodies and not TG2 IgA, despite IgA sufficiency (1). Thus, these patients risk never being diagnosed.

Aims & Methods: The aim of this study was to assess the additional benefit of testing for TG2 IgG alongside TG2 IgA in screening for CD in adults. The study was based on the fourth Trøndelag Health Study (HUNT4), a population-based study of 56,000 adult (>20 years of age) Norwegians (2). Serum samples were analysed using a combined TG2 IgA and IgG assay and the seropositives were invited to endoscopy with duodenal biopsies for histological confirmation (Marsh grade 3).

The prevalence of primary TG2 IgG responders and the positive predictive value (PPV) of TG2 IgG among TG2 IgA negative participants were calculated.

Results: Serum from 54,505 participants were analysed and 1107 were seropositive. The present study included 593 participants with histological examination and CD was confirmed in 403 participants. Primary TG2 IgG response was found in 75 participants, of whom four got CD confirmed.

None of these four participants had total IgA deficiency. The PPV of TG2 IgG for CD among TG2 IgA negative participants was 5.3% (95% confidence interval 3.5-7.1). In comparison, the PPV of TG2 IgA was 77.0% (73.6-80.4).

Conclusion: This population-based screening for CD among adults found a small group of individuals with CD that risk not being diagnosed using the current diagnostic guidelines, due to primary TG2 IgG response in the absence of IgA deficiency. However, TG2 IgG is still too unspecific to be used in the screening of CD in the general population.

OP004

IMPACT OF TRANSGLUTAMINASE 2 INHIBITOR ZED1227 ON SYSTEMIC LIPIDOMIC RESPONSES IN CELIAC DISEASE: A GLUTEN CHALLENGE STUDY

V. Dotsenko¹, A. Dickens², T. Hyötyläinen³, B. Tewes⁴, T. Zimmermann⁴, R. Mohrbacher⁴, M. Oresic^{2,5}, M. Mäki¹, K. Viiri¹

Contact E-Mail Address: valeriia.dotsenko@tuni.fi

Introduction: Celiac disease (CeD) is an autoimmune disease triggered by dietary gluten in genetically predisposed individuals. This study aimed to explore the systemic plasma lipidomic biomarkers in treated CeD patients undergoing a gluten challenge and to assess the effect of the transglutaminase 2 inhibitor, ZED1227.

Aims & Methods: Mass spectrometry-based lipidomic profiling was applied to plasma samples obtained from 47 CeD patients. The samples were collected at baseline (gluten-free diet, GFD) and post-gluten challenge (PGC). Patients underwent a 6-week gluten challenge and were randomly divided into 2 groups: the placebo drug group (PGCp, $n = 19$) and the group with a daily oral administration of 100mg ZED1227 (PGCd, $n = 28$). Comparative analyses were performed between the groups, with adjustments for BMI, age, sex, and country of origin.

Results: Significantly different gluten-induced serum lipid profiles between GFD vs. PGCp and between GFD vs. PGCd were detected, as 46 lipids were differentially expressed in the first and six in the latter comparison. Additionally, kidney function, measured as glomerular filtration rate and plasma creatinine, decreased significantly in gluten challenge. This correlated with alterations in medium-chain fatty acylcarnitines (CARs), and the function was restored by ZED1227. This suggests that specific carnitines could be early biomarkers for the systemic effects of gluten ingestion in CeD patients.

Conclusion: This study highlights the potential of lipidomic analysis as a tool for early detection of systemic responses to gluten in CeD. The differential lipidomic profiles between the drug and placebo groups suggest that ZED1227 attenuates gluten-induced lipidomic alterations.

OP005

INTESTINAL INFLAMMATION AND ASSOCIATED CHANGES OF CYTOKINE AND TRANSMITTER TRANSCRIPTS IN THE BRAIN DURING ACTIVE CELIAC DISEASE IN THE HUMANIZED NOD DQ8 MOUSE MODEL

A. Pesi¹, M. Wiegel¹, P. Frankenbach¹, E. Verdu², P. Bercik², D. Schuppan^{1,3}

¹Medical University Mainz - Institute of Translational Immunology, Medical University Mainz; Mainz/D, Institute of Translational Immunology, Mainz, Germany, ²McMaster University, Hamilton, Canada, ³Beth Israel Deaconess Medical Center, Division of Gastroenterology, Boston, United States of America

Contact E-Mail Address: alinpesi@uni-mainz.de

Introduction: Celiac disease (CeD) is triggered by gluten peptides that bind to HLA-DQ2 or -DQ8 in the small intestinal lamina propria which leads to gluten specific TH1 T cell activation and expansion, small intestinal inflammation, villous atrophy and intraepithelial lymphocytosis (IEL) (1, 2).

With emphasis on the gut-brain axis we analyzed the consequences of active CeD inflammation on immune cell activation in the brain.

Aims & Methods: CeD is associated with symptoms of foggy mind, chronic fatigue and depression (3, 4). The immunological communication between the gut and brain axis has not been studied in-depth in CeD, including the relation of behavior and mental functioning with intestinal immune activation and resultant inflammatory changes in the blood and the brain.

NOD-DQ8 mice were sensitized to gliadin and fed a gluten-containing or gluten-free diet for 2 weeks. Key transcripts in the small intestine and brain were analyzed using qPCR and compared to FACS data of both organs.

Results: The brain is an active site of induced inflammation subsequent to CeD induction of the gut, with a highly significant upregulation of cerebral IL17a, IL23a, IL22b, IL6, IL33, Nlrp3 and COX2. Moreover, the brain dopamine/noradrenaline and neuroactive tryptophan metabolism was upregulated by enhanced production of dopamine beta hydroxylase, kynurenine-3-monooxygenase (KMO) and quinolinate phosphoribosyl transferase (Qprt).

Conclusion: The significant proinflammatory cytokine production in the brain of humanized NOD DQ8 mice with active CeD confirms a gut-brain immune communication in CeD. This is accompanied by elevated transcript levels of inflammation-induced mediators.

Importantly, enzymes encoding neurotransmitter synthesis are upregulated, which may explain fatigue and mental dysfunction in patients with active CeD.

EFFICACY AND SAFETY OF TEGOPRAZAN IN FUNCTIONAL DYSPEPSIA: A MULTICENTER, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED CLINICAL STUDY

T. He¹, J. Zhang¹, R. Feng², L. Zhong³, M. Lin⁴, Q. Xiang⁵, X. Chen⁵, H. Chen², L. Liu¹

Contact E-Mail Address: ht3711@163.com

Introduction: Functional dyspepsia (FD) is one of the most common diseases of the digestive system, which comprises two subtypes, postprandial distress syndrome (PDS) and epigastric pain syndrome (EPS). Acid suppression therapy has been recognized as the first-line treatment for *H.pylori*-negative FD patients. Potassium-competitive acid blocker (PCAB), a novel acid suppressant, has the characteristics of faster onset of effect and more stable acid suppression compared with traditional proton pump inhibitor (PPI). However, there has been no prospective study of PCAB for FD treatment.

Aims & Methods: This study was therefore conducted to investigate the efficacy and safety of PCAB in FD patients, and initially explore the effects of PCAB on gut microbiota. Patients diagnosed with FD were included prospectively. Eligible subjects were randomly assigned to the trial group and placebo group by 2:1, respectively, to receive Tegoprazan or placebo treatment with 50mg once a day for 2 weeks. 7-point global overall symptom scale (GOSS) was used to evaluate the relief of dyspepsia symptoms (primary endpoint) before the trial and at 1 and 2 weeks after randomization. Quality of life was assessed using the short form Nepean dyspepsia index (SFNDI). The generalized anxiety disorder-7 (GAD-7) and patient health questionnaire -9 (PHQ-9) were used to evaluate anxiety and depression, respectively. Stool samples were collected for 16SrRNA sequencing to evaluate gut microbiota alterations. Blood samples were collected to detect blood routine and blood biochemistry, and drug-related adverse events reported by subjects were collected to evaluate the safety of Tegoprazan.

Results: A total of 84 subjects were randomized, including 55 in the trial group and 29 in the placebo group. Among the subjects, 58.3% (49/84) were females, the median age was 51.00 (38.75, 55.00) years, and the mean BMI was 21.21 ± 3.06kg/m². For FD subtypes, EPS accounted for 44.0% (37/84), and no significant difference between the two groups was evident. In addition, there were no significant differences in the GOSS score, GAD-7 score and PHQ-9 score between the two groups at baseline. In the ITT analysis, the overall response rate was 25.5% (14/55) in the trial group and 17.2% (5/29) in the placebo group at 1 week, with no significant difference between the two groups (*P*=0.392). The 2-week response rate was 38.2% (21/55) in the trial group and 27.6% (8/29) in the placebo group, with no significant difference between the two groups (*P*=0.331). The results of PP analysis were consistent with ITT analysis. In the analysis of FD subtype, the response rate of EPS receiving Tegoprazan for 1 week was 45.8% (11/24), and that of the placebo group was 7.7% (1/13), with significant difference between the two groups (*P*=0.027). The response rate at 2 weeks of treatment with Tegoprazan was 50.0% (12/24), and the response rate after 2 weeks of placebo treatment was 15.4% (2/13), with no significant difference between the two groups (*P*=0.074).

No significant difference was found between Tegoprazan and placebo on PDS ($P > 0.05$). In terms of gut microbiota, after 2 weeks of Tegoprazan treatment, the abundance of fecal genus *streptococcus* increased significantly ($P < 0.001$), especially *streptococcus salivarius*.

There were no significant differences in the incidence of adverse events between the trial group and the placebo group ($P > 0.05$). No severe adverse events occurred in this study.

Conclusion: Tegoprazan is suitable for short course treatment of EPS. For patients requiring long-term treatment with Tegoprazan, the benefits of acid suppression should be weighed against the risk of intestinal microbiota dysbiosis. Tegoprazan had a similar safety profile to placebo.

Disclosure: Nothing to disclose.

OP008

CHARACTERISING THE DUODENAL IMMUNOLOGICAL ENVIRONMENT AND IMMUNOMODULATORY EFFECTS OF HIGH-DOSE PROTON PUMP INHIBITOR THERAPY IN FUNCTIONAL DYSPESIA

M. Ceulemans¹, P. Huyghe¹, J. Toth¹, I. Jacobs², J. Cremer², L. Wauters¹, J. Tack¹, T. Vanuytsel¹

¹KU Leuven, Translational Research Center for Gastrointestinal Disorders, Leuven, Belgium, ²KU Leuven, Allergy and Clinical Immunology, Leuven, Belgium

Contact E-Mail Address: matthias.ceulemans@kuleuven.be

Introduction: The pathophysiology of functional dyspepsia (FD) is still incompletely understood, although duodenal immune activation with increased eosinophil and mast cell numbers have been reported¹. However, advanced characterisation of the duodenal immune infiltrate beyond routine histology is largely lacking.

Acid suppression with proton pump inhibitors (PPI) is the first line therapy for FD. A routine PPI course was shown to have additional anti-inflammatory effects in the duodenum², although the underlying mechanisms remain to be studied.

Aims & Methods: We aimed to perform the most extensive characterisation of the duodenal immunological environment in FD so far, and assess the immunomodulatory effects of high-dose PPI therapy. Gastroduodenoscopy with duodenal biopsies was performed in Rome IV FD patients before and after 4 weeks PPI (pantoprazole 40mg bid) and healthy controls (HC). Eosinophils and mast cells were quantified via histology and in fresh single cell suspensions by flow cytometry on an LSR Fortessa flow cytometer (BD). Similarly, T cell subsets were characterised by flow cytometry. Gastrointestinal (GI) symptoms were recorded through questionnaires (PAGI-SYM). Cortisol awakening response (CAR), as well as mast cell tryptase and eosinophil derived neurotoxin (EDN) in duodenal biopsy supernatants were measured using ELISA. Data were analysed with Mann-Whitney *U* tests and paired *t* tests, or by linear or mixed models in SAS software.

Results: Data from 30 FD patients (25 F, mean $\pm$ SD age 32 ± 13 yr.) before and after PPI, and 30 HC (23 F, 30 ± 10 yr.) at baseline were obtained. GI-specific symptoms were higher in FD vs controls and decreased after PPI, while CAR was reduced after PPI (Table).

Duodenal tryptase but not EDN release was higher in FD vs. HC. Mast cell numbers were similar at baseline via histology and flow cytometry, but increased after PPI with an increased side scatter profile ($P = 0.06$) reflecting less degranulation.

Eosinophil numbers were not different, although PPI altered their surface marker expression with decreased IL5R α ($P = 0.02$) and CD63 ($P = 0.08$) but increased CD69 ($P = 0.03$) expression. Cytotoxic T cell maturation was elevated in FD with higher CD45RA- but lower CD45RA+ CD8+ T cells, driven

by higher effector memory CD8+ T cells ($P = 0.02$) and lower TEMRA CD8+ T cells ($P = 0.01$). CD45RA- and CD45RA+ CD8+ T cell levels tended to normalise after PPI, while naive Tregs increased after therapy.

Variable (mean $\pm$ SD)	HC	FD	FD vs. HC (p-value)	FD + PPI	FD vs. FD + PPI (p-value)
PAGI-SYM score	0.37 $\pm$ 0.41	2.42 $\pm$ 0.84	<0.0001	1.76 $\pm$ 0.96	0.0002
Cortisol awakening response (ng/mL)	3.94 $\pm$ 1.73	3.95 $\pm$ 2.58	0.33	2.87 $\pm$ 1.97	0.05
Duodenal tryptase (μ g/g biopsy)	0.38 $\pm$ 0.17	0.60 $\pm$ 0.32	0.004	0.53 $\pm$ 0.31	0.33
Duodenal EDN (μ g/g biopsy)	4.69 $\pm$ 2.48	4.81 $\pm$ 2.88	0.62	5.28 $\pm$ 4.32	0.78
Mast cells (% leukocytes)	2.97 $\pm$ 1.38	2.49 $\pm$ 1.12	0.16	3.02 $\pm$ 1.51	0.04
Eosinophils (% leukocytes)	2.69 $\pm$ 1.40	2.39 $\pm$ 1.14	0.47	2.33 $\pm$ 1.54	0.26
CD45RA+ CD8+ T cells (% CD8+ T cells)	21.37 $\pm$ 9.28	15.84 $\pm$ 11.77	0.009	18.86 $\pm$ 12.62	0.08
CD45RA- CD8+ T cells (% CD8+ T cells)	78.62 $\pm$ 9.29	84.16 $\pm$ 11.76	0.008	81.14 $\pm$ 12.63	0.07
Naïve Treg cells (% CD4+ T cells)	1.23 $\pm$ 1.62	1.15 $\pm$ 1.40	0.92	1.78 $\pm$ 1.55	0.04

Conclusion: High-dose proton pump inhibitors improved symptoms in FD and reduced an objective marker of stress. Interestingly, duodenal tryptase release was increased in FD, although not supported by differences in duodenal mast cells or eosinophils, measured via flow cytometric evaluation. Our data suggest that advanced techniques should complement routine histological evaluation in FD to confirm previously reported immune alterations, which may have overestimated the extent of duodenal immune activation in FD. Lastly, subtle alterations in cytotoxic T cell maturation status were normalised after high-dose PPI therapy, which warrants further investigation.

Introduction: There has been a resurgence in the use of bismuth quadruple therapy (PPI, bismuth, tetracycline and metronidazole) in Europe with the commercialisation of a three-in-one single-capsule formulation, but the experience with this regimen is still limited.

Aims & Methods: To evaluate the effectiveness and safety of the three-in-one single-capsule in the European Registry on *Helicobacter pylori* Management (Hp-EuReg).

International, multicenter, prospective, non-interventional registry aimed to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists (Hp-EuReg). All infected adult patients treated with 10-day single-capsule according to data sheet (3 capsules/6h) or alternative three times a day (4 capsules/8h) prescriptions were systematically registered at AEG-REDCap e-CRF until December 2023. Variables included: Patient's demographics, previous eradication attempts, prescribed treatment, adverse events, and outcomes. Modified intention-to-treat (mITT) and per-protocol (PP) analyses were performed, and data were subject to quality review.

Results: Of the 70,683 patients included in the Hp-EuReg, 11,130 (16%) received single-capsule bismuth quadruple therapy. The majority of these patients were naïve (77%), with an average age of 51 years, 61% female and 14% with peptic ulcer. Overall, the single-capsule achieved a high eradication rate based on the mITT (92%) and PP (93%) analyses. Effectiveness (mITT) was higher when using the single-capsule as a first-line treatment (94%), but it had also high effectiveness as a rescue therapy, both in second-line (88%) or subsequent lines of therapy (3rd-6th lines: 84%) (Table 1).

Compliance with treatment (>90% of drug intake) was reported in 97% of cases and was the factor most closely associated with the effectiveness of treatment. Adverse events (26%) were generally mild and transient; only 0.1% of patients reported serious adverse events, leading to the discontinuation of treatment in 1.7% of patients.

	Use, N (%)	mITT, N (%)	95% CI	PP, N (%)	95% CI
Overall	11,130 (16*)	10,441 (92)	(91-93)	10,248 (93)	(92-93)
1 st line (naïve)	8,551 (77)	8,041 (94)	(93-94)	7,909 (94)	(94-95)
2 nd line	1,783 (16)	1,659 (88)**	(86-89)	1,621 (89)	(87-90)
3 rd to 6 th line	796 (7.2)	741 (84)	(81-87)	718 (85)	(83-88)

*Of the total of treatments included in the Hp-EuReg up to December 2023 (i.e., N= 70,683); **achieved over 90% effectiveness when therapy was optimised (i.e., using standard-dose PPIs, that is 40 mg omeprazole equivalent twice a day); mITT: modified intention-to-treat; PP: per-protocol; N: total number of patients analysed, 95% CI –confidence interval.

Table 1. Three-in-one single-capsule effectiveness in first-line and consecutive rescue treatment lines.

Conclusion: The 10-day treatment with single-capsule bismuth quadruple therapy achieves *H. pylori* eradication in approximately 90% of patients by mITT in real-world clinical practice, both as a first-line and rescue treatment, with a favourable safety profile.

VONOPRAZAN-DUAL AND TRIPLE THERAPIES WERE NON-INFERIOR TO BISMUTH-BASED QUADRUPLE THERAPY AS FIRST-LINE THERAPY FOR *HELICOBACTER PYLORI* INFECTION IN CHINA: A THREE-ARM, RANDOMIZED CLINICAL TRIAL

K.S. Cheung^{1,2}, T. Lyu¹, Z. Deng¹, S. Han¹, L. Ni¹, J. Wu¹, J.T. Tan², H.Y. Ng³, W.K. Leung², W.-K. Seto^{1,2}

Contact E-Mail Address: mongolhorse2002@gmail.com

Introduction: There are currently no studies comparing vonoprazan-dual, vonoprazan-triple therapies and classic bismuth quadruple therapy.

Aims & Methods: We aimed to compare efficacy of vonoprazan-dual or triple therapies and bismuth-quadruple therapy for treatment-naïve *Helicobacter pylori* (HP) infection in Southern China, where primary resistance rates of clarithromycin and levofloxacin are >30%.

Between March 2022 and August 2023, treatment-naïve HP-infected adults were randomly assigned to receive one of the three 14-day regimens (1:1:1 ratio): vonoprazan-dual (VA-dual; vonoprazan 20mg twice daily and amoxicillin 1g thrice daily), vonoprazan-triple (VAC-triple; vonoprazan 20mg/amoxicillin 1g/clarithromycin 500mg twice daily), or bismuth-quadruple therapy containing bismuth, esomeprazole, tetracycline and metronidazole.

Primary outcome was noninferiority in HP eradication, evaluated by UBT 4-6 weeks post-treatment by intention-to-treat (ITT) (based on all recruited subjects who took at least one dose of treatment regimen, and those lost to follow-up were considered as treatment failure cases), modified intention-to-treat (mITT) (based on patients who took at least one dose of the treatment and completed follow-up) and per-protocol (PP) analysis (based on subjects who completed 14-day treatment and rechecked UBT). Bonferroni-adjusted p-value of <0.017 was used to determine statistical significance. Primary outcome was noninferiority in HP eradication, evaluated by UBT 4-6 weeks post-treatment by intention-to-treat (ITT) and per-protocol (PP) analysis (based on subjects who completed 14-day treatment and rechecked UBT).

Comparative non-inferiority between bismuth-quadruple and VA-dual or VAC-triple was assessed by one-sided μ test and derivation of a two-sided 95% confidence interval (CI), with noninferiority being determined by a lower 95% CI end more than -10% with a Bonferroni-adjusted p-value of <0.017. A two-sided p-value of 0.05 was used to define statistical significance for other analyses.

Results: 298 subjects (mean age:35.7±8.4 years; male:134 [45.0%]; body mass index:23.2±3.5 kg/m²; VC-dual:100, VAC-triple:98, bismuth-quadruple:100) were enrolled, and 292 (98.0%) had UBT rechecked. ITT analysis showed both VA-dual (eradication rate of 96.0%) and VAC-triple therapies (95.9%) were non-inferior to bismuth-quadruple therapy (92.0%) (difference:4.0%, 95% CI:-2.9% to 11.5%, p<0.001; and 3.9%, 95% CI:-3.1% to 11.5%, p<0.001, respectively). mITT analysis also showed non-inferiority of VA-dual and VAC-triple therapies to bismuth-quadruple therapy (97.0% and 96.9% vs 95.8%, with difference:1.1% and 1.1%, p=0.002 and 0.002, respectively).

Similar observation was noted for PP analysis (96.7% and 96.7% vs 97.4%, with difference:-0.7% and -0.7%, p=0.009 and 0.010, respectively) (Table 1). The frequency of adverse events was 39.0%, 56.1% and 71.0% in VA-dual, VAC-triple and bismuth-quadruple therapies, respectively.

	VA-dual vs bismuth-quadruple therapy			VAC-triple vs bismuth-quadruple therapy			VA-dual vs VAC-triple therapy		
	VA-dual therapy	VAC-triple therapy	Bismuth-quadruple therapy	Difference (95% CI)	Non-inferiority p-value	Difference (95% CI)	Non-inferiority p-value	Difference (95% CI)	Non-inferiority p-value
ITT	96.0% (96/100)	95.9% (94/98)	92.0% (92/100)	4.0% (-2.9% to 11.5%)	<0.001	3.9% (-3.1% to 11.5%)	<0.001	0.08% (-6.3% to 6.5%)	0.005
mITT	97.0% (96/99)	96.9% (94/97)	95.8% (92/96)	1.1% (-4.9% to 7.6%)	0.002	1.1% (-5.1% to 7.5%)	0.002	0.01% (-5.8% to 6.1%)	0.004
PP	96.7% (89/92)	96.7% (87/90)	97.4% (75/77)	-0.7% (-6.9% to 6.1%)	0.009	-0.7% (-7.1% to 6.0%)	0.010	0.01% (-6.3% to 6.5%)	0.006

Abbreviation: VA-dual, vonoprazan dual; VAC-triple, vonoprazan triple; CI, confidence interval; ITT, intention-to-treat analysis; mITT, modified intention-to-treat analysis; PP, per protocol analysis
The p-values were adjusted for multiple comparisons using Bonferroni's correction. The significance level was set at 0.05/3 = 0.017 for each comparison.

Table 1. *Helicobacter pylori* eradication rates of vonoprazan-dual, vonoprazan-triple and bismuth-quadruple therapies

Conclusion: VA-dual and VA-triple therapies were non-inferior to bismuth-quadruple therapy in Southern China. Given the lower adverse effects and fewer antibiotic use, VA-dual therapy is the preferred first-line treatment for HP infection.

Introduction: Linaprazan glurate (LG) is a next generation P-CAB, a prodrug to linaprazan, with an excellent clinical efficacy in erosive esophagitis (1-2).

The acid control properties of LG were assessed by the holding time ratio (HTR) i.e., percentage of time with intragastric pH>4, during Day 1 and 14 of LG administered once daily (QD) or twice daily (BID) at 3 dose levels. Pharmacokinetic (PK) profiles for LG and Linaprazan were determined and PK parameters, area under the plasma concentration time profile (AUC) and peak plasma concentration (C_{max}) derived.

Aims & Methods: 73 healthy subjects randomized into six dosing groups and received LG, a total of 67 subjects completed the study and had at least one evaluable pH measurement (Table 1).

Measurement of intragastric pH was performed during 24 hours on Day 1 and on Day 14, by means of a pH-measuring electrode in the stomach inserted by the nasogastric route. Intragastric pH was measured every sec-

ond. The pH>4 HTR is presented as the mean of the 10 min median per dose group and day. Blood samples for PK parameters were also collected.

Results: There was a rapid onset of intragastric acid control achieved already within 90 min after the intake of the first dose of LG, irrespective of dose level, with a clear dose response. The HTRs presented in Table 1 show a dose response with pH>4 HTR similar at Day 1 and Day 14. Already on Day 1, the pH>4 HTR reached approximately 90% in the two highest dosing groups (50 mg and 75 mg BID), with a minor difference in acid control between these doses, particularly at steady state (Table 1).

Linaprazan AUC and C_{max} increased approximately in proportion to dose and were comparable on Day 1 and Day 14. AUC and C_{max} for LG was approximately 10-fold lower than for linaprazan.

A *post-hoc* analysis of the pH>4 HTR excluding the initial 90 min after first dosing (pH>4 HTR 1.5-24h) showed that the pH>4 HTR 1.5-24h was close to the Day 14 pH>4 HTR in all dosing cohorts, suggesting a pH-control near steady state already 1.5 hours after the first dosing. It is noteworthy that a pH>4 HTR 1.5-24h above 90% is seen, not only in the 75 mg BID group as noted in the primary endpoint, but also in the 50 mg BID group (Table 1). Comparing 50 mg QD and 25 mg BID, a more sustained pH>4 HTR was seen with BID dosing, with more than 10-15 percentage points higher pH>4 HTR already from the start, indicating a better pharmacodynamic yield when dividing the dose.

There was one serious adverse event in the study, a concussion that occurred before the first dose of LG. The most observed treatment emergent adverse event (TEAE) was headache. There was no dose related increase in TEAEs or other findings as assessed by physical examinations, vital signs, ECG, and laboratory parameters.

Day	Statistics	25 mg LG	50 mg LG	75 mg LG	25 mg LG	50 mg LG	75 mg LG
		QD (N=12)	QD (N=12)	QD (N=13)	BID (N=9)	BID (N=11)	BID (N=10)
Day 1 pH >4 HTR	n	12	12	12	9	11	9
	Mean (SD)	48.0 (23.23)	64.6 (13.33)	68.1 (23.48)	76.0 (13.52)	87.4 (8.62)	94.5 (4.18)
Day 1 (1.5-24h) pH >4 HTR	n	12	12	12	9	11	9
	Mean (SD)	51.0 (24.91)	68.9 (14.02)	73.7 (24.78)	80.5 (14.12)	91.5 (8.98)	98.1 (3.10)
Day 14 pH >4 HTR	n	12	12	11	9	11	8
	Mean (SD)	48.5 (30.62)	63.9 (20.09)	87.2 (11.44)	76.9 (20.13)	95.7 (5.55)	99.0 (1.54)

Table 1: Descriptive statistics of percentage of time within intragastric pH categories- based on 10-minute medians of pH.

Conclusion: A rapid onset of pH>4 HTR was seen with LG with a clear dose response. The two highest dosing groups achieved above 90% pH>4 HTR excluding the initial 90 min after the first dose.

Repeated oral doses of LG 25, 50 and 75 mg QD and BID for 14 days were safe and well tolerated.

Introduction: 96-98% of patients survive acute pancreatitis (AP), but in the post-AP phase, patients are at high risk of morbidity and mortality. The primary objective of the GOULASH PLUS (ISRCTN63396106) longitudinal, observational multicentre study is to investigate the development of chronic pancreatitis (CP) following AP. The GOULASH PLUS trial reached 50% of the planned patient enrolment. This interim data analysis aims to understand the time course evolution of CP after AP.

Aims & Methods: 360 patients were yearly followed after AP. We formed four groups according to the baseline morphology status of the pancreas: 1) AP with one episode, 2) RAP with two episodes, 3) ECP with characteristic signs on imaging or three or more episodes of AP 4) CP: Ultrasound or CT were used in the first and third year, whereas, endoscopic ultrasound or magnetic-resonance-cholangiopancreatography in the second and fourth year of follow-up.

Results: Among the 360 patients followed after AP, 269 (74.7%) had AP, 42 (11.7%) RAP, 27 (7.5%) ECP, and 22 (6.1%) had CP at the time of the baseline AP episode. The following data represent the results at 1, 2, 3, and 4 years after AP. In the AP group, ECP was developed in 3%, 12%, 14%, and 18%, whereas, CP was diagnosed in 1%, 6%, 6%, and 11%, respectively. In the RAP population, ECP was developed in 17%, 19%, 21%, and 42% while CP developed in 0%, 0%, 4%, and 8%. In the ECP patient group, CP was developed in 12%, 25%, 35%, and 36%. 15% of patients had exocrine pancreatic insufficiency (EPI) at the first year visit, while this increased to 21% by the fourth annual visit.

Conclusion: RAP and ECP accelerate CP development. Due to the fast progression, it is important to find risk factors and biomarkers associated with recurrence and early morphology changes and to define possible early interventions to avoid or delay the progression to CP.

Introduction: Johanson-Blizzard syndrome (JBS) is a rare autosomal recessive genetic disorder characterized by congenital exocrine pancreatic insufficiency, nasal wing aplasia, and various symptoms of varying severity. Although we have previously identified bi-allelic loss-of-function mutations in the *UBR1* gene as the genetic cause of JBS, the precise molecular pathomechanism remains unknown. Since loss of *UBR1* can be partly compensated in mice, no model system has existed to fully recapitulate the phenotype of JBS patients.

Aims & Methods: We have employed *in vitro* differentiation of human pluripotent stem cells (PSCs) to unravel the molecular mechanism of pancreatic insufficiency in JBS. Our collection includes JBS-specific PSCs derived from patient's iPSCs, isogenic controls, and CRISPR/Cas9-engineered hESCs, enabling advanced disease modeling.

Results: *UBR1*-deficient and proficient PSCs exhibited comparable growth and differentiation patterns until the pancreatic progenitor (PP) stage, consistent with a normal pancreatic primordium in JBS patients. To explore later stages of pancreatic development, we employed xenograft and *ex vivo* culture models. Remarkably, grafts from *UBR1*-deficient PPs showed a significant absence of acinar pancreatic tissue after 8 weeks. Our immune cell-free model highlights a potential cell-intrinsic cause of pancreatic tissue degeneration in JBS.

Currently, we are conducting time-resolved *ex vivo* and xenograft analyses alongside our *in vitro* differentiation into ductal, acinar, and endocrine organoids, to intricately dissect the degeneration processes. *UBR1* functions as an E3 ubiquitin ligase in the N-end rule pathway, playing a crucial role in regulating protein degradation. Consistent with its function, global quantitative proteomics revealed a stage-specific upregulation of multiple proteins in *UBR1*-ablated cells starting from the PSC and PP stages. To pinpoint potential disease-causing substrates of JBS, we are currently establishing an E3-ligase substrate trapping strategy.

Conclusion: In summary, our sophisticated JBS model enables us to recapitulate the disease mechanism of this rare and severe syndrome not only in the pancreas but also beyond, offering valuable insights into its pathophysiology.

Introduction: While advanced pancreatic cancer is a malignant tumor with a high mortality rate and poor prognosis, early-stage pancreatic cancer, including carcinoma in situ (CIS), has a favorable prognosis and may be treatable with curative resection. However, several recent reports have shown that even in some cases of early-stage pancreatic cancer, recurrence in the remnant pancreas can occur. Pathologically, the tumor occasionally spreads laterally along the main pancreatic duct, presenting challenges in determining the extent of surgical resection.

Recently, two types of changes in pancreatic parenchymal volume, called focal pancreatic parenchymal atrophy (FPPA) and upstream pancreatic atrophy (UPA), have been reported to indicate the presence of early-stage pancreatic cancer.

It has been reported that in cases of advanced pancreatic cancer with FPPA in previous imaging studies, greater extension along the pancreatic duct has been found. However, in early-stage pancreatic cancer, a comprehensive pathological evaluation of the correlation between cancer location and pancreatic atrophy has not been adequately explored.

Aims & Methods: In early-stage pancreatic cancer without mass, preoperative assessment of intraductal cancer extension along the main pancreatic duct is necessary to determine the extent of surgical resection.

This study aimed to investigate the association between the pattern of pancreatic parenchymal atrophy and intraductal cancer extension using a substantial number of resected specimens of early-stage pancreatic cancer.

Thirty-two patients with early-stage pancreatic cancer who underwent surgery at five participating centers were enrolled. Of the patients, twenty-seven had CIS, and five had microinvasive carcinoma. Pancreatic atrophy was defined as narrowing of the parenchyma compared to the surrounding parenchyma and was classified as either FPPA (partial atrophy surrounding the pancreatic duct stenosis) or UPA (global atrophy caudal to the site of duct stenosis).

We evaluated the correspondence between atrophy on preoperative computed tomography (CT) images and pathologic cancer extension in detail. The length of cancer extension along the main pancreatic duct was calculated as 5 mm per section of a surgically resected pathology specimen (5 mm wide) in which cancer was present. Intraductal cancer extension was defined as an extension exceeding 10 mm.

Results: Preoperative CT revealed FPPA, UPA, and no parenchymal atrophy in 13, 13, and 6 patients. The lateral distance of cancer extension was significantly longer in cases with FPPA than in those without atrophy (median: 20.0 mm vs. 5.0 mm, $P = 0.005$). Furthermore, a significant difference was observed in the distance of cancer extension between the UPA group and the group without atrophy (median: 20.0 mm vs. 5.0 mm, $P = 0.03$). Intraductal cancer extension was present in all but one case of FPPA. 69% (9/13) of the cases with UPA showed intraductal cancer extension, whereas cases without atrophy showed no intraductal cancer extension. Importantly, two patients with FPPA or UPA showed positive resection margins during surgery, and three patients with FPPA or UPA showed recurrence in the remnant pancreas.

Conclusion: The presence of FPPA and UPA indicates lateral cancer extension in early-stage pancreatic cancer. In cases presenting with FPPA and UPA, caution should be exercised while determining the extent of surgical resection. Preoperative assessment of the pancreatic parenchyma may provide valuable insights for determining the extent of surgical resection.

Introduction: Chronic pancreatitis (CP) is a complex inflammatory disorder characterized by progressive destruction of the pancreatic tissue, with fibrotic transformation of the tissue as a major morphological feature. The incidence of the disease is steadily increasing, but no specific therapy is currently available, making the identification of new therapeutic targets a priority.

Plasminogen activator inhibitor-1 (SERPINE1/PAI-1) has been implicated in various pathological processes, including fibrosis and inflammation. However, its specific involvement in the pathogenesis of CP is not yet fully understood.

Aims & Methods: We therefore aimed to explore the role of PAI-1 in the development of CP and assess the therapeutic potential of PAI-1 inhibitors as antifibrotic agents to prevent the progression of CP.

The PAI-1 expression of the pancreatic tissue was determined in mouse and human pancreatic tissue samples with immunohistochemistry. CP was induced in FVB/N mice with 8X50 µg/kgbw i.p. cerulein injection, given every hour, every 3 days for a total of 5 times. PAI-1 activity was inhibited with a specific inhibitor, which was administered per os at a dose of 10 mg/kgbw for 6 consecutive days after the 3rd cerulein treatment. To assess the extent of inflammation and fibrosis hematoxylin-eosin and Crossman's trichrome staining were performed, and biochemical assays were used to determine amylase activity and hydroxyproline concentration. PAI-1 expression and location in the pancreas was examined by RT-qPCR and immunofluorescence co-staining.

Results: PAI-1 expression was significantly higher in pancreatic tissue samples obtained from CP patients. After induction of CP in mice, the body weight and the pancreatic weight/body weight ratio significantly reduced, whereas histopathology showed significant pancreatic atrophy

and fibrosis. This was also confirmed by the increased hydroxyproline concentration and decreased amylase activity of the pancreatic tissue. The gene expression of SERPINE1 increased in pancreas tissue and fibroblast cell culture in CP group, moreover the elevated PAI-1 signal localization suggests a possible expression role for activated stellate cells. Administration of PAI-1 inhibitor resulted in a decrease in both body weight and pancreatic weight loss rates, additionally the atrophy, tissue fibrosis, hydroxyproline concentrations and SERPINE1 gene expression were significantly decreased compared to the CP group.

Conclusion: Our results indicate an elevation in PAI-1 expression in CP, with the potential for fibrosis and tissue atrophy reduction by the inhibition of PAI-1. These findings propose PAI-1 as a promising therapeutic target for the treatment of chronic pancreatitis.

Introduction: PERT aims to alleviate nutrient malabsorption symptoms and restore the nutritional status of patients with PEI. To achieve this, the PERT dose must be optimized for each patient. It is unknown whether the optimal PERT dose varies depending on the underlying cause of PEI.

Aims & Methods: A prospective, multicenter, European registry of PEI was designed involving expert pancreatic centers. Patients diagnosed with PEI of any cause, confirmed by an expert clinician from January 2021, were included. The initial enzyme dose was determined by the clinician and adjusted as necessary during follow-up. The optimal dose in each patient is defined as the dose that achieves the therapeutic goal. A proton pump

inhibitor (PPI) could be added to the enzyme therapy if needed. Results are expressed as median and IQR and analyzed using the U-Mann-Whitney and Kruskal Wallis tests.

Results: 678 patients with PEI who achieved the therapeutic goal are analyzed (mean age 61.2±13.8 years, 63.6% male). The cause of PEI was chronic pancreatitis (CP) in 340 patients (50.1%), pancreaticoduodenectomy (PD) in 116 (17.1%), pancreatic cancer (PC) in 99 (14.6%), acute pancreatitis (AP) in 68 (10.0%) and other in 56 patients (8.2%). The table shows the optimal dose of PERT for the main meal and the daily dose. Patients with PEI secondary to PD and PC required a significantly higher enzyme dose to achieve the therapeutic goal than patients with CP or AP ($p<0.001$). Similarly, patients with PC (78.8%) and PD (74.1%) required a PPI more often than patients with CP (37.2%) or AP (44.1%) ($p<0.001$).

Cause of PEI	Optimal enzyme dose (Ph.U.) with the main meal	Optimal daily enzyme dose (Ph.U.)
Pancreatic cancer	70,000 (50,000-100,000)	210,000 (150,000-325,000)
Pancreatoduodenectomy	75,000 (55,000-100,000)	225,000 (175,000-350,000)
Chronic pancreatitis	50,000 (40,000-70,000)	150,000 (120,000-210,000)
Acute pancreatitis	40,000 (25,000-50,000)	100,000 (75,000-200,000)

Conclusion: The optimal dose of PERT and the need for a PPI are different for different conditions causing PEI. This study demonstrates, for the first time, that patients with PEI following PD and PC require a significantly higher enzyme dosage than those with PEI resulting from CP or AP to alleviate symptoms and restore nutritional status.

Introduction: Polygenic scores (PGS) use the results of genome-association studies (GWAS) to calculate the aggregate effect of trait-associated variants carried by the individual. To date, PGS have primarily been used to model the individual risk of disease onset using summary statistics from susceptibility GWAS, typically with modest clinical relevance. For example, we can identify 1.5% of the population with a threefold increased risk of IBD onset (Khera et al.).

Much less is known about the impact of this onset PGS burden on the presentation and progression of patients with diagnosed IBD. Previous studies have failed to identify an effect of onset PGS on early onset vs late onset presentation (Serra et al.) and CD severity (Lee et al.).

Aims & Methods: We hypothesised that an increased genetic susceptibility burden for IBD has a direct impact on the severity of an individual's IBD disease course.

We genotyped 8179 patients with IBD (3688 CD; 4491 UC), linking them with registry data that captures medical interactions throughout patients' lifetimes. Patients who required 2+ IBD-related hospitalizations, 2+ IBD-related major surgeries, 1 IBD-related hospitalization and 1 IBD-related major surgery or use of systemic corticosteroids (≥ 5000 mg) in the first 3 years of diagnosis were defined as severe. We conducted a GWAS comparing severe patients (N=1203 UC; N=1165 CD) to those who had a less severe disease course (N=3288 UC; N=2523 CD).

We calculated individual PGS for UC and CD among individuals using the PSG scores from Middha et al. (based on De Lange et al. summary statistics) and association tests controlling for age of onset, year of onset, sex and diagnostic cohorts.

Results: We identified a significant difference in PGS between individuals with less severe and severe disease course for both CD ($\beta=0.23$, $p=2.17 \times 10^{-9}$) and UC ($\beta=0.3$, $p<1 \times 10^{-16}$).

Next, we split the cohort into quintiles by PGS and generated a stratified Kaplan-Meier curve for time to hospitalisation and surgery. Remarkably, for both outcomes and in both CD and UC the curves were ranked according to their PGS quintiles with lower ones consistently having a lower risk of adverse outcomes compared to the higher quintiles, suggesting an additive effect of genetic susceptibility on IBD severity.

In a time to event proportional hazards analysis, compared to the 20% of patients with lowest PGS, the top 20% had a much quicker time to hospitalization (CD: HR=1.79 (1.55-2.07), $p=1.82\times10^{-15}$; UC: 1.68 (1.46-1.94), $p=7.92\times10^{-13}$) and surgery (CD: 2.76 (2.19-3.47), $p=4.69\times10^{-18}$; UC: 2.03 (1.54-2.68), $p=5.57\times10^{-7}$).

Conclusion: To our knowledge, this work is the first systematic evidence of a link between IBD disease susceptibility genetics and the severity of the phenotype – patients with a higher genetic burden suffer from a more severe IBD presentation and quicker progression, suggesting that the etiology of the disease susceptibility and severity is not orthogonal.

PGS will not become the singular tool for predicting patient severity, however these are useful to add to the prognostic toolkit. Genotyping required to calculate the PGS can be done for less than €100 and can be combined with known clinically actionable pharmacogenomic variant tests and, in the future, additional targeted PGS of severity, drug response and comorbidity risk.

Introduction: For the diagnosis of Inflammatory bowel diseases (IBD) the full spectrum of available tools should be considered. Besides non-invasive and invasive imaging, clinicians increasingly employ fecal Calprotectin as biomarker. Quantification of Calprotectin in stool is used for the diagnosis and assessment of gastrointestinal diseases, mainly for the evaluation of IBD, as calprotectin levels significantly correlate with endoscopic disease activity.

By contrast, the biological function of calprotectin within the human gut lumen remains enigmatic and experimental studies demonstrated conflicting results. Calprotectin is believed to be present as a tetrameric pro-

tein complex (S100A8/S100A9)₂, but the quaternary protein structure of S100A8 and S100A9 in the human gut lumen is still unknown and might explain divergent biologic actions observed for calprotectin.¹

Aims & Methods: We analysed stool samples obtained from patients with IBD by size-exclusion chromatography and subsequent LC-MS/MS analysis to resolve the quaternary protein structure of S100A8 and S100A9. Next, Calprotectin ELISAs used in clinical routine diagnostics were incubated with different S100A8 and S100A9 configurations to assess binding specificity. To define biological functions of S100A8 and S100A9 during gut inflammation, we orally exposed mice in enteritis and colitis models to recombinant human S100A8 and S100A9 proteins. Further, we genetically inactivated S100a9 in murine models and treated mice with an oral S100A9 inhibitor. Finally, we identified molecular mechanism controlled by human S100A8 and S100A9 homodimers using untargeted phenotyping.

Results: We frequently detected S100A8 and S100A9 dimers in stool from IBD patients, while S100A8 and S100A9 dimers were absent in healthy individuals. Moreover, we observed in three independent IBD cohorts that S100A8 and S100A9 homodimers are mainly present in the human gut during inflammation. More specifically, levels of S100A9 homodimer significantly correlated with active IBD compared to patients in remission. Importantly, S100A8 and S100A9 homodimers were not detectable by four fecal calprotectin assays in clinical use. Genetic deletion of S100a9 ameliorated experimental enteritis and colitis in numerous models. In accordance, pharmacologic inhibition of S100A9 protected against acute and chronic colitis. Moreover, oral administration of human recombinant S100A8 and S100A9 homodimers aggravated experimental enteritis and colitis, while the tetrameric calprotectin complex had no effect on gut inflammation. We demonstrate that human S100A8 and S100A9 homodimers trigger CD4⁺ and CD8⁺ T cell pathogenicity and drive chronicity of gut inflammation, as S100A8 and S100A9 homodimers required adaptive immunity in experimental colitis.

Conclusion: Collectively, we identified the quaternary protein structure of calprotectin in the human gut lumen during inflammation and reveal a diagnostic gap for fecal Calprotectin assays used in clinical routine diagnostics. Moreover, we demonstrate that human S100A8 and S100A9 homodimers drive chronicity of gut inflammation by directly activating CD4⁺ and CD8⁺ T cells, which might resemble the underlying cause of chronic unresolved gut inflammation in IBD. Taken together, our findings suggest novel diagnostic and therapeutic approaches in inflammatory diseases of the gut.

Introduction: Genome-wide association studies (GWAS) have successfully identified many genetic regions linked to inflammatory bowel diseases (IBD) but since these often involve non-coding variants, the causative genes remain largely unknown (1).

Matching cis-expression Quantitative Trait Loci (cis-eQTLs) in relevant tissues may help pinpoint candidate genes (2).

Yet matching cis-eQTL can be found for 50% of risk loci with the available eQTL datasets (3). An explanation is that these cis-eQTLs only appear under inflammatory conditions, known as response-QTLs (reQTLs)

Aims & Methods: Toll-like receptor (TLR) and T cell receptor (TCR)-stimulated whole-blood cell cultures were carried out in a cohort of 406 healthy individuals (EC P2015/425). All individuals were genotyped using Illumina's OmniExpress BeadChips. RNA sequencing was performed using QuantSeq 3' mRNA-Seq Library Prep Kit FWD. The cis-regulome of the immune system was examined using QTL-tools and colocalization (4) was performed with summary statistics from the last IBD meta-GWAS (5)

Results: The cohort included 248 females and 159 males without any past medical history, use of medications or smoking habits. We identified 13679 cis-eQTLs (FDR ≤ 0.05) corresponding to 6496 eGenes. Cis-eQTLs that influence the same gene across resting and stimulated conditions were merged into "cis-regulatory modules" (cRM) if they exhibited similar "eQTL association patterns" (EAPs). This yielded 8401 monogenic cRM with 4.695 of them not operating in resting condition, requiring stimulation to be detected.

Next, we colocalized EAPs generated from our cohort with disease associated pattern (DAP) identifying IBD risk loci. This colocalization assumes that if a risk locus influences disease risk by altering gene expression, the DAP for this locus and the EAP should show similar patterns of variant associations, as quantified by the θ metric. We found 187 correlations ($|\theta| > 0.6$) spanning 39 risk loci and encompassing 68 genes. Of note, 19.2% of these correlations were associated with reQTLs, facilitating the colocalization of EAPs with 11 risk loci that would have been overlooked without stimulation. The long non-coding gene *AJ009632.2* is a remarkable example illustrating the relevance of immune stimulation. A positive correlation was observed by colocalizing eQTL captured in resting condition which suggested that the eQTL linked to *AJ009632.2* may increase disease risk. Contrarily, after stimulation, EAP linked to *AJ009632.2* displays an inverse trend. This striking example stresses the need to have a deep knowledge about a regulatory variant before considering it as positively or negatively associated with disease.

Another example is illustrated by *CTSS*, a gene which encodes cathepsin S protein, a lysosomal enzyme expressed by immune and epithelial cells in response to inflammation, regulating antigen presentation and taking

part in degradation of extracellular matrix. The reQTL linked to *CTSS* in our dataset matched the DAP related to the rs4845604. Table 1 shows DAP-EAP correlations which highlight potentially relevant candidate genes

Coordinates	Diseases	Gene	Resting condition θ (p-val)	TCR stimulation θ (p-val)	TLR 4 stimulation θ (p-val)	TLR7/8 stimulation θ (p-val)	True reQTL

Introduction: Inflammatory bowel disease (IBD) - characterized by chronic inflammation of the gastrointestinal tract - is believed to be caused by an interplay of host genetics, environment and gut microbiome. Recent studies have started investigating the role of somatic DNA mutations in immune-mediated disorders (1, 2). Somatic mutations are mutations that are not present in the germline, but are acquired later in life. We hypothesize that somatic mutations in gut tissue in inflammation-related genes could contribute to the pathogenesis of IBD.

Aims & Methods: Therefore, we investigated somatic mutation patterns in 589 intestinal biopsies of 268 IBD patients and 17 non-IBD controls. We performed whole exome sequencing (WES) on DNA isolated from blood and bulk RNA sequencing (RNAseq) on RNA isolated from intestinal biopsies. Somatic mutations were called using the mutect2 software which compares RNAseq data to the reference genome and the WES data. Somatic mutations were subsequently filtered to reduce the chance of sequencing errors (somatic mutation presence >25% of the RNAseq reads, coverage of at least 10 RNAseq reads). We used 4 gene sets of interest, monogenic very-early-onset IBD (VEO-IBD) genes (n=103), monogenic primary immunodeficiency genes (n=475), the most recent IBD GWAS candidate genes (n=318) and all genes in the IBD GWAS loci (n=3504) and tested whether somatic mutations were more often present in these gene sets compared to the rest of the genome. Finally, we used the MOLGENIS Variant Interpretation Pipeline which uses the CAPICE pathogenicity prediction score and the Clinvar variant database to annotate the called and filtered somatic mutations as benign, likely benign, VUS, likely pathogenic, or pathogenic (3).

Results: We identified 400544 somatic mutations (average 745 per biopsy). We observed a significantly higher accumulation of somatic mutations in the gut biopsies of IBD patients compared to non-IBD controls (p=2e-04). This difference was bigger when only likely pathogenic and pathogenic (LP/P) somatic mutations were considered (p=3e-14). We observed a significant enrichment of somatic mutations in the genes of all 4 gene panels in the biopsies of IBD patients compared to controls (VEO-IBD p=0.0006, PID p=0.0001, GWAS candidate p=0.0015, GWAS loci p=0.0003). Biopsies taken from inflamed tissue contained statistically significantly more LP/P somatic mutations in PID, GWAS candidate and GWAS loci genes. 273 somatic mutations identified in IBD biopsies have been previously reported to the Clinvar database, including stop-gain point mutations in HPS1 c.517C>T and HPS4 c.1132C>T, pathogenic missense mutation IL10RA c.301C>T and pathogenic missense mutation in STAT1 c.884C>A. In-depth analysis of a subset of key genes in the IBD pathogenesis revealed multiple LP/P mutations in several patients in both JAK1 (n=35 LP/P) and JAK2 (n=31 LP/P), primarily in the FERM and protein kinase domains. Additionally, we observed 21 LP/P mutations in PLCG2, a gene in which missense mutations can cause immune dysregulation. (4)

Conclusion: Here, in the largest somatic mutation study in IBD patients to date, we show that there is an increased accumulation of likely pathogenic and pathogenic somatic mutations in gut tissue, particularly in genes in which mutations can cause monogenic very-early-onset IBD and/or primary immune deficiencies. Thus, we show that that somatic mutations in the gut could contribute to the pathogenesis of IBD.

Introduction: Autoantibodies against integrin $\alpha\beta 6$ have recently been associated with ulcerative colitis (UC), its preclinical phase, and UC outcomes. However, data on the diagnostic utility of the autoantibody and its dynamics are scarce.

Therefore, we aimed to examine the diagnostic capacity of the anti- $\alpha\beta 6$ autoantibody. Moreover, we assessed its utility in defining a specific phenotype of UC and ascertained its temporal dynamics in relation to the disease course.

Aims & Methods: Using an in-house assay based on the ELIA technology (Thermo Fisher Scientific, Uppsala, Sweden), anti- $\alpha\beta 6$ IgG autoantibodies were measured in serum from adult patients with suspected IBD in the Swedish inception cohort SIC IBD (discovery cohort, n=473) and the Norwegian population-based inception cohort IBSEN III (validation cohort, n=570). A cut-off of 400 $\mu\text{g/L}$ was applied, corresponding to the lower calibrator for IgG (4 $\mu\text{g/L}$) and the 96th percentile of healthy individuals. The course of UC was categorized as indolent or aggressive at 12 months, based on a composite outcome of colectomy, hospital admission for active disease, treatment refractoriness towards ≥ 2 biological agents, or >2 courses of corticosteroids/cumulative dose of >2.5 g. Inflammatory proteins (n=92) were measured (Olink Proteomics, Uppsala). Welch's t-test was used with Benjamini-Hochberg correction, applying a 5% false discovery rate (FDR). Linear-mixed models were applied to investigate differences in autoantibody expression between diagnosis and three months follow-up.

Results: The discovery cohort comprised 327 IBD patients and 146 symptomatic controls without any discernible evidence of IBD, and the validation cohort included 366 IBD patients and 204 symptomatic controls. Patients with UC and those with colonic Crohn's disease in the discovery cohort had higher median anti- $\alpha\beta6$ levels compared to symptomatic controls. The anti- $\alpha\beta6$ autoantibody demonstrated a sensitivity of 73% and a specificity of 84% for distinguishing UC from CD and symptomatic controls in the discovery cohort and 79% and 91%, respectively, in the validation cohort.

Anti- $\alpha\beta6$ positivity was associated with a severe UC phenotype, characterized by more extensive colitis ($p=0.008$), severe Mayo endoscopic activity ($p=0.005$), and pronounced systemic inflammation, defined as higher hsCRP ($p=0.04$) and lower albumin concentrations ($p=0.01$), in the discovery cohort. However, no association of f-Calprotectin was observed. Higher endoscopic activity in anti- $\alpha\beta6$ positive UC patients was confirmed in the validation cohort. In both cohorts, an increasing extent of inflammation and endoscopic activity was observed with higher median levels of anti-integrin $\alpha\beta6$.

Five proteins (SYND1, IL-17A, GZMB, MMP1, CXCL13) were significantly up-regulated in anti- $\alpha\beta6$ positive UC patients in the SIC-IBD, and two of them (IL-17A and GZMB) were validated in the IBSEN III cohort. Compared to patients with indolent UC, patients with an aggressive course presented with higher anti- $\alpha\beta6$ levels at diagnosis in the discovery cohort ($p=0.02$) and potentially also in the validation cohort ($p=0.13$). A significant interaction of disease course was observed in autoantibody levels between diagnosis and 3 months in the SIC cohort ($p<0.0001$), as the levels decreased in patients with indolent UC but not in those with an aggressive course.

Conclusion: Anti- $\alpha\beta6$ autoantibodies demonstrate a diagnostic capacity for UC and define a severe phenotype of the disease. Its temporal dynamics differ between patients with an aggressive and an indolent disease course.

Disclosure: EP, RM and NR are employed by Thermo Fisher Scientific.

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease affecting 5 million people worldwide, characterized by mucosal inflammation that can extend throughout the colon [1].

Current treatments often have limited efficacy or severe side effects [2].

As, there are no established criteria for selecting the most effective treatment for IBD, innovative preclinical drug testing systems are of major importance.

Aims & Methods: The aim of this study was to evaluate the effects of biological therapy using ulcerative colitis patient-derived personalized co-culture models of colonic epithelial and immune cells under inflammatory conditions.

The effects of upadacitinib (UPA) and ozanimod (OZA) were tested in personalized co-cultures of colonic epithelial cells and macrophages derived from UC patients ($n=12$) and control (Con) individuals ($n=11$). Inflammation was induced with inflammatory cytokines TNF- α (10 ng/mL) and IFN- γ (10 ng/mL). Barrier integrity was measured by transepithelial electrical resistance (TEER). Expression of *TNF- α* , *CCL5*, and *CXCL9* genes was evaluated using qRT-PCR. Secretion of cytokines in the epithelial cells and macrophages culture media was investigated using a flow cytometry-based target protein assay. Data comparison was conducted using the Shapiro-Wilk test and the Wilcoxon rank-sum test. A difference between the values was considered significant when $p \leq 0.05$ or $p_{adj.} \leq 0.05$.

Results: In cell cultures stimulated with inflammatory cytokines, barrier permeability increased (TEER decreased – Con: by 452.03 $\Omega \cdot \text{cm}^2$, UC: 39.3 $\Omega \cdot \text{cm}^2$), which partially recovered after removal of inflammatory factors (TEER increased – Con: by 65.91 $\Omega \cdot \text{cm}^2$, UC – only 47.31 $\Omega \cdot \text{cm}^2$). Epithelial integrity was restored after incubation with UPA and OZA (TEER increased – Con: by 116.82 $\Omega \cdot \text{cm}^2$ (UPA), by 193.77 $\Omega \cdot \text{cm}^2$ (OZA); UC: by 226.64 $\Omega \cdot \text{cm}^2$ (UPA), by 188.5 $\Omega \cdot \text{cm}^2$ (OZA)). At the molecular level, overnight stimulation with TNF- α and IFN- γ increased expression of *CXCL9* gene in epithelial cells (UC: fold change (FC) = 3064.49 $p_{adj.} = 2.07 \times 10^{-5}$; Con: FC = 664.44, $p_{adj.} = 2.00 \times 10^{-2}$) and macrophages (UC: FC = 140.47 $p_{adj.} = 0.01$; Con: FC = 314.43, $p_{adj.} = 0.01$) in both groups. Co-culture treatment with UPA and OZA showed important trend of patient-specific responses to each therapeutic agent, which probably was the most important factor of non-significant values for observed changes in *CCL5*, *CXCL9*, *TNF- α* expression analysing summarized data. The flow cytometry-based target protein assay revealed that TNF- α and IFN- γ can influence inflammatory cytokine secretion in both epithelial cells and macrophages of UC patients and Control individuals, which can be further modified by novel biological therapy agents – UPA and OZA.

Conclusion: In conclusion, treatment with TNF- α and IFN- γ reduced epithelial barrier integrity and induced increased expression of inflammatory cytokines in epithelial cells and macrophages. Biological therapy (UPA or OZA) tended to restore disrupted barrier integrity. However, the response to novel biological therapy agents (UPA and OZA) on gene expression in

both cell types and inflammatory cytokine levels in the cell culture media showed varying impacts and effectiveness, thereby revealing individualized responses of subjects to different biological preparations.

Introduction: Inflammatory bowel diseases are complex conditions characterized by heterogeneity at clinical, immunological, molecular, genetic, and microbial levels. The most effective approaches to induce clinical remission and control inflammation in these diseases are biologic and JAK-inhibitor therapies. However, a significant proportion of patients do not respond to treatment.

Consequently, the identification of predictive biomarkers of clinical response to the different available therapies could improve the selection of patients who may benefit from the most appropriate treatment.

Aims & Methods: A multiomic study (transcriptomic, proteomic, metabolomic and metagenomic) was performed in 53 patients with active Crohn's disease (CD) and 50 patients with active ulcerative colitis (UC) before and after 14 weeks of treatment (anti-TNF, ustekinumab, vedolizumab or tofacitinib). Responders and non-responders patients were categorized based on endoscopic findings. Samples (serum, urine, stool and intestinal biopsies) were used for RNA-seq analysis, liquid chromatography-mass spectrometry, nuclear magnetic resonance, and 16S rRNA gene sequencing.

Results: Our findings revealed multiple mRNAs, proteins and metabolites associated with the response to different treatments. Differential gene expression analyses in intestinal tissue showed that the main differences were detected between responders versus non-responders UC patients to anti-TNF, vedolizumab and tofacitinib. Proteomic analysis found numerous differentially expressed proteins between the study groups. Additionally, ROC curves revealed two proteins with good predictive value to discriminate between CD and UC patients responders versus non-responders to anti-TNF treatment (AUC=0.81 and AUC=0.96, respectively). Metabolomics showed up-regulation of 21 lipoproteins in serum from CD patients responders to ustekinumab compared to non-responders. Metabolic analysis pathways identified enrichment in ketone and butyrate metabolism, mitochondrial electron transport chain, carnitine synthesis, and oxidation of chain fatty acids. Regarding metagenomic results, only differences were found in microbial composition in responders versus non-responders UC patients treated with anti-TNF.

Conclusion: This study provides early insights into shifts in gene and protein expression in intestinal tissue, alterations in serum and urine metabolites, and changes in gut microbiota as potential predictors of response to biologics and JAK-inhibitor treatment.

Further research is needed to validate these results and assess their clinical significance in identifying patients most likely to benefit from each therapeutic approach.

Disclosure: Nothing to disclose.

IMMUNE-CELL SPECIFIC BIOMARKER OF EARLY INTESTINAL INFLAMMATION: NEUTROPHIL ELASTASE DEGRADED FRAGMENT OF TYPE III COLLAGEN IS ELEVATED IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

T. Tsapanou Katranara¹, M. Pehrsson¹, M. Sorokina Alexdóttir¹, V. Domislovic², Z. Krznaric², M.A. Ainsworth³, T.L. Boye⁴, C.S. Steenholdt⁴, A.-C. Bay-Jensen¹, M. Asser Karsdal¹, J.H. Mortensen¹

Introduction: Inflammatory Bowel Disease (IBD) is characterized by epithelial barrier injury of the gastrointestinal (GI) tract. The disease course encompasses abnormal immune responses and excessive secretion of proteases from immune cells. Neutrophils are the first to migrate into the inflamed interstitial matrix, where type III collagen is significantly deposited. Detection of mucosal inflammation in early stages is crucial to prevent cumulative clinical damage, as a delayed diagnosis can hinder effective treatment.

Thus, we aimed to develop a biomarker that reflects early intestinal inflammation prior to it becoming medically evident; allowing us to distinguish patients that would respond to an anti-inflammatory treatment.

Aims & Methods: A competitive enzyme-linked immunosorbent assay targeting a human neutrophil elastase derived fragment of type III collagen was developed (C3-HNE). The validation was conducted by assessing its dilution recovery, matrix spiking, interference, and inter- and intra-assay variation.

The biological relevance was evaluated in commercial samples, one pre-clinical, and two clinical studies. In the preclinical study, C3-HNE was measured in serum samples from a dextran sodium sulfate (DSS)-induced colitis rat model. In the commercial samples and clinical cohorts, C3-HNE was measured in serum from patients with IBD and healthy donors (HD). To compare the biomarker levels between groups, two-way ANOVA with an uncorrected Fisher's LSD, and Mann-Whitney U-tests or Kruskal-Wallis (Dunn's corrected) were conducted.

Results: The novel biomarker C3-HNE was successfully validated, resulting in a technically robust assay with acceptable technical parameters (Table 1). In both clinical cohorts and commercial samples, C3-HNE levels were significantly higher in patients with Crohn's disease (CD), ulcerative colitis (UC) and IBD than in HD ($p<0.01$, $p<0.05$ and $p<0.05$) (Table 1). In the preclinical study, the analysis revealed significant difference in the C3-HNE levels between the control and DSS groups on day 4 ($p=0.02$). Additionally, C3-HNE was released earlier (day 1) in the timeline than the elevation of the current disease activity (DAI) score (day 7) (Table 1).

Conclusion: C3-HNE is elevated in patients with CD, UC and IBD compared with HD. Furthermore, C3-HNE reflects early stages of clinically apparent mucosal damage during experimental colitis. This biomarker holds the potential to identify early mucosal damage or acute inflammation in the GI tract; nevertheless, additional studies are needed to evaluate its clinical validity.

Introduction: Patients with ulcerative colitis (UC) often have unpredictable response over time. Using clinical parameters has proven useful, however, deeper understanding of the molecular and cellular mechanisms that influence therapeutic outcomes in head-to-head trials is lacking.

Here we performed a large-scale transcriptomics analysis of tissue biopsies derived from moderate-to-severe UC patients treated with vedolizumab (VDZ) or adalimumab (ADA) in the VARSITY trial (Sands, 2019).

Aims & Methods: The aim of this study was to identify biomarkers of response to VDZ and ADA treatment. We performed bulk RNA sequencing of 954 biopsies collected using the flexible sigmoidoscopy from pre-treatment/baseline, week (w)14 and w52. Our dataset comprised complete longitudinal tissue sampling of n=151 non-responders, n=117 responders based on clinical remission at w52. We employed comparative analysis to pinpoint differentially expressed genes (DEG) and differential pathways for ADA and VDZ treated patients. We then employed systems network strategies to identify gene modules (Choobdar, 2019) associated with clinical parameters.

Finally, we utilized multivariate trajectory model (Nagin, 2018) to characterise longitudinal patient trajectories based on study endpoints and integrated transcriptomics signatures to patient variable response (Schreiber, 2023).

Results: Variable baseline gene expression profile was associated with prior exposure to anti-TNF α , corticosteroid or immunomodulator treatment. DEG and gene-modules linked to VDZ response in tissue biopsies revealed inflammatory, fibrotic, epithelial, and neuronal pathways, including but not limited to JAK/STAT, G-Protein Coupled Receptor signalling, ECM interactions, oxidative phosphorylation, and neuroglial signatures. Importantly, these consistent gene and gene-module predictors of clinical remission were detected at pre- and post-treatment (w14 and w52) to VDZ. For ADA treated patients, no DEG and gene-modules were significantly associated with treatment-response at baseline after FDR correction. Upon relaxing stringency, we were able to find pathways such as neutrophil degranulation, MAPK signalling, and Fc-mediated immune regulation linked to ADA response.

Cell type contributions were in silico inferred with deconvolution analysis of bulk gene expression data. In agreement with the pathway analysis, we identified epithelial, plasma, stromal populations as baseline biomarkers of response to VDZ, while specific CD4⁺, CD8⁺ T cell subsets, follicular B cells and inflammation-associated fibroblasts were significantly elevated in non-responders compared to the responders to VDZ from baseline to post-treatment. In ADA non-responding patients, CD4⁺ T cells were significantly increased compared to responders at baseline and post-treatment. Gene-module predictors were linked to distinct patients' trajectories based on symptoms; the greatest correlations with transcriptomics findings were observed between our extreme responding groups from trajectory analyses.

Conclusion: We present first-of-a-kind analysis using large-scale clinical trial integrating longitudinal bulk RNA-seq analysis with clinical outcomes in response to two different therapies. For VDZ, as opposed to ADA, we were able to find strong baseline predictors also preserved after treatment. We hope that similar approaches could support clinical precision medicine applications to help patients achieve faster and lasting disease control.

Introduction: Tofacitinib is an oral JAK1 and JAK3 inhibitor approved for the treatment of ulcerative colitis (UC). Despite its proven efficacy, about 40-60% of patients fail to respond to it due to mechanisms not understood. Our aim is to identify the cellular subsets and genes involved in the response and/or resistance to tofacitinib using single-cell RNA sequencing (scRNA-seq) and *in vitro* functional experiments.

Aims & Methods: Colon biopsies from patients with active moderate to severe UC starting tofacitinib 10 mg bid for 8 weeks and 5 or 10 mg bid thereafter were collected at baseline and during follow-up and processed by single-cell RNA sequencing. Patients were classified as responders (R) or non-responders (NR) based in clinical, endoscopic, and histological criteria. Tofacitinib's impact on macrophages and fibroblasts was assessed using M-CSF monocyte-derived blood macrophages and primary colonic fibroblasts under various inflammatory stimuli (LPS, TNF, and IFN γ).

Results: Thirteen out of thirty-one patients enrolled in this study responded to tofacitinib treatment. ScRNA-seq analysis demonstrated partial recovery of the epithelium and a decrease of plasma cells, inflammatory fibroblasts, and neutrophils in R.

Importantly, the proportion of T cells remained unaltered. These findings were transcriptionally and histologically validated. Contrary to R, tofacitinib did not drive any of these changes, instead ongoing inflammation induced an increase in the proportions of neutrophils, inflammatory INHBA⁺ macrophages and inflammatory monocytes in NR after treatment. ScRNA-seq analysis also revealed changes in the transcriptional signature of certain resident populations, including the anti-inflammatory FOLR2⁺ macrophages and the lamina propria fibroblasts. In R, tofacitinib induced a more tolerogenic profile in both populations whereas in NR, both populations upregulated the expression of inflammatory genes during follow-up. In *in vitro* monocyte-derived macrophages tofacitinib was able to block the inflammation induced by IFN γ and TNF.

However, the response to LPS was intensified by tofacitinib as seen by the increased expression of genes normally associated with an inflammatory phenotype (INHBA, CLEC5A) and cytokines (CXCL1, IL6).

In contrast to macrophages, fibroblasts showed an overall down regulation of inflammatory genes in response to tofacitinib regardless of the stimuli. Nonetheless, when fibroblasts were exposed to supernatants from LPS/tofacitinib-treated macrophages, they adopted a more inflam-

matory profile. In response to LPS stimulation monocyte-derived macrophages secrete high levels of the anti-inflammatory IL-10. The transcriptional profile of LPS-stimulated macrophages treated with a blocking anti-IL-10 antibody (Cuevas, Víctor D *et al*, 2022) highly correlated with the genes upregulated in FOLR2+ macrophages from tofacitinib NR patients. Cytosig analysis from scRNA-seq data confirmed significantly increased IL-10 signaling in macrophages from NR patients compared to R before starting treatment with tofacitinib.

Conclusion: Our data underscores the pivotal role of macrophages in orchestrating responses to tofacitinib and strongly suggests that IL-10 blockade in these cells in the context of ongoing inflammation may explain the exacerbated disease in those patients who become refractory. Understanding the mechanisms underlying “drug escape” may aid in ensure efficacy, limit drug failure, and potentially guide follow-up therapeutic decisions.

Introduction: The phenotype and behavior of immune cells have been linked to cellular energy metabolisms, leading to the emergence of a new field of immunometabolism. The crucial role of the gut microbiota in immune system maturation and functions and the relatedness of mitochondria and bacteria suggest a role for the gut microbiota in intestinal epithelial and immune cell energy metabolism. The gut microbiota and its metabolites have a critical role in establishing and maintaining health and in the pathogenesis of diseases, including inflammatory bowel disease (IBD). Following an *in vitro* screening, we showed that indole-3-propionic acid (IPA) stimulates mitochondrial respiration of CD4+ T cells. IPA is a microbiota-derived tryptophan metabolite shown to be decreased in the feces of patients with IBD and which plays a crucial part in regulating intestinal immune tolerance, improving mucus barrier function and suppressing intestinal inflammation.

Aims & Methods: We aim at exploring the mechanisms involved in the anti-inflammatory effects of IPA. SCENITH technology (Single-cell energetic metabolism by profiling translation inhibition) was used to screen and identify the effect of metabolites on energy metabolism of specific subpopulations in mixed immune cell systems in both *in vitro* and *in vivo*. Seahorse, Mitotracker, metabolomics, proteomics experiments were used to explore the role of identified metabolites on energy metabolism in purified cells *in vitro*. Antibiotic-depleted gut microbiota, dextran sodium sulfate-induced colitis and adoptive reinfusion experiments in mice were used to evaluate the effects of metabolites on cellular energy metabolism and their anti-inflammation function *in vivo*.

Results: Using SCENITH technology on human blood mononuclear cells (PBMCs), we showed that IPA stimulates mitochondrial respiration of CD4+ T cells, by promoting fatty acid/amino acid oxidation rather than traditional glucose metabolism in the CD3/CD28 activation setting. Similar results were observed in mouse CD4+ T cells. In parallel with cellular energy reprogramming, IPA impacts CD4+ T cell behavior by favoring Treg over the Th17 phenotype *in vitro*. Blocking mitochondrial respiration with oligomycin or long-chain fatty acid metabolism with etomoxir inhibit IPA effects on T cells phenotype. IPA is a relatively weak Aryl hydrocarbon receptor (AhR) agonist. Using an AhR inhibitor (CH-223191) or AhR KO T cells, we showed that the effect of IPA on CD4+ T cell energy metabolism

was not dependent on AhR. In microbiota-depleted mice, the alteration in mitochondrial respiration of small intestine and colon CD4⁺ T cells was rescued by IPA administration. In DSS-induced colitis, IPA administration increases mitochondrial respiration of CD4⁺ T cells by enhancing the oxidation of fatty acids and amino acids in the colon. Adoptive reinfusion of CD4⁺ T cells from IPA-treated mice into Rag2 KO mice induced protection against intestinal inflammation, confirming that IPA protective effects are mediated by CD4⁺ T cells.

Conclusion: Collectively, our study reveals from a whole new perspective that the anti-inflammatory effects of IPA are mediated by metabolic reprogramming of CD4⁺ T cells toward the enhancement of mitochondrial respiration, thereby leading to an anti-inflammatory phenotype and eventually protection in colitis context in mice. This study paves the way for the development of new therapeutic strategies in IBD.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive and lethal human cancers. In recent years, bacteria resembling gut microbiota have been found within pancreatic cancer tissues, suggesting their potential influence on tumor growth and prognosis. However, the details remain insufficiently elucidated. Therefore, we clarified the characteristics of the tumor microbiota using resected pancreatic cancer specimens from our institution and to analyze their relationship with the tumor microenvironment and prognosis.

Aims & Methods: We analyzed formalin-fixed paraffin-embedded (FFPE) sections from 162 PDAC patients who underwent surgery between April 2008 and March 2017 in our institution.

DNA were extracted from FFPE using Quantitative polymerase chain reaction (qPCR) and in situ hybridization (ISH) targeting 16S rRNA. Microbial community was explored by using 16S metagenomics from FFPE. The profile of intratumoral bacteria was compared with clinical information, pathological findings including tumor-infiltrating T cells, tumor-associated macrophage, fibrosis, and alterations in four main driver genes (KRAS, TP53, CDKN2A/p16, SMAD4) in tumor genomes.

Results: Among 162 cases, 52 showed amplification in qPCR targeting 16S rRNA and positive ISH reactions targeting 16S rRNA within tumor tissues. The presence of bacteria commonly found in gut microbiota such as Proteobacteria and Firmicutes was observed within tumor tissues of these 52 cases. Comparison with paired normal tissues (N=26) revealed differences in α diversity ($P<0.01$) and β diversity ($P<0.01$), suggesting the presence of a unique tumor microbiota. Subsequently, we divided the 52 cases into two groups based on the median survival period.

We identified one bacterial species was dominant in the long-term survival group and ten were in the long-term survival group using Linear Discriminant Analysis Effect Size. Comparison of bacterial profiles between

cases with good and poor prognosis revealed a significant positive correlation between a shorter survival time and the presence of anaerobic bacteria such as *Bacteroides*, *Lactobacillus*, and *Peptoniphilus*. 24 cases which were positive for at least one of the three prognostic bacteria were compared with 28 cases negative for all of them, there were not significant correlation with tumor size, pathological stage, fibrosis, and alterations in four main driver genes, but significant correlation with the lower degree of tumor-infiltrating T cells positive for CD4, CD8, and CD45RO ($P<0.01$, $P<0.01$, $P<0.01$, respectively).

Conclusion: We identified multiple bacterial species within pancreatic cancer tumors associated with prognosis. Increased abundance of *Bacteroides*, *Lactobacillus* and *Peptoniphilus* along with the progression of pancreatic cancer suggests their involvement in worsening prognosis through tumor immunity.

CHRONIC STRESS ACCELERATED COLORECTAL CANCER PROGRESSION BY DISTURBING THE BALANCE OF GUT MICROBIOTA

Q. Li¹, J. Yang²

¹Sichuan University-University of Oxford Huaxi Joint Centre for Gastrointestinal Cancer, Frontiers Science Center for Disease-Related Molecular Network, West China Hospital, Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China, ²West China Hospital, Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China

Contact E-Mail Address: 2375435621@qq.com

Introduction: Chronic stress has been well-documented to exacerbate the progression of colorectal cancer (CRC), yet the role of the gut microbiota in this process remains elusive.

Aims & Methods: Subcutaneous MC38 tumor models and AOM/DSS-induced murine CRC models were utilized to evaluate the tumor-promoting effects of chronic restraint stress. Antibiotic cocktail (ABXs) administration and Fecal microbiota transplantation (FMT) were employed to determine whether the gut microbiota shaped by chronic stress could potentiate CRC progression. 16S rRNA gene sequencing was conducted to analyze microbiota alterations induced by chronic stress.

Results: Chronic stress significantly accelerated CRC progression in both subcutaneous and AOM/DSS-induced models (all $P < 0.05$), while ABX administration in AOM/DSS-induced models attenuated this effect ($P = 0.9897$). Notably, Mice receiving FMT from the chronic stress group exhibited a higher tumor burden compared to FMT from controls ($P < 0.01$), indicating that the gut microbiota may be involved in the progression of CRC induced by chronic stress.

Further analysis of the disturbed gut microbiota revealed a significant depletion of *Lactobacillus* in CRC models with chronic stress. Specifically, *Lactobacillus johnsonii*, *Lactobacillus gasseri* and *Lactobacillus plantarum* were reduced and inversely correlated with tumor numbers in AOM/DSS induced mouse models, respectively (all P value < 0.05). Interestingly, chronically stressed mice harbored fewer CD8⁺ T cells and IFN- γ ⁺ CD8⁺ T cells within colon tumors compared to controls, however, this disparity was abrogated upon ABX administration.

Furthermore, mice receiving FMT from the chronic stress group exhibited a paucity of CD8⁺ T cells and IFN- γ ⁺ CD8⁺ T cells in tumors relative to FMT from control group, suggesting that the chronic stress-shaped gut microbiota may dampen the anti-tumor effects of CD8⁺ T cells.

Additionally, we found that CD8⁺ T cells in tumor were positively associated with relative abundance of *Lactobacillus johnsonii*, *Lactobacillus gasseri* and *Lactobacillus plantarum*, respectively (all $P < 0.05$). Collectively,

these results suggest that the reduction of *Lactobacillus* species under chronic stress conditions may dampen CD8⁺ T cell anti-tumor immunity, thereby promoting CRC progression.

Conclusion: Our study indicates that chronic stress may promote the progression of CRC by reducing intestinal *Lactobacillus* bacteria, and the possible mechanism is to weaken *Lactobacillus*-mediated CD8⁺ T cell anti-tumor immunity. Future investigations should focus on elucidating the mechanisms by which specific *Lactobacillus* species modulate CD8⁺ T cell function and tumor immunity, as well as exploring the therapeutic potential of *Lactobacillus*-based interventions in managing stress-related CRC exacerbation.

Disclosure: Nothing to disclose.

Introduction: Intestinal bacteria with 7 α -dehydroxylating (7 α DH) activity are able to produce the secondary bile acids, such as deoxycholic acid (DCA). Higher concentrations of DCA are linked to a higher risk of colorectal cancer (CRC) risk, yet underlying molecular mechanisms demonstrating a causal role of DCA are still unclear. This includes a recently demonstrated immunomodulatory effect of secondary bile acids, which may contribute to CRC pathogenesis.

Here, we aim to investigate the tumor-promoting and immunomodulatory role of DCA in a gnotobiotic CRC mouse model.

Aims & Methods: Germ-free wildtype mice were colonized with a simplified bacterial consortium, the bile acid converting microbiota (BACOMI). BACOMI is able to produce DCA due to the 7 α DH activity of *Clostridium scindens* (+7 α DH). Control mice were colonized with BACOMI without *C. scindens*, lacking 7 α DH activity (-7 α DH) and DCA. A sub-group of mice was treated with AOM/DSS to induce colonic tumors. Bacterial abundances were measured in colonic content via qPCR, cecal bile acid composition was analyzed using LC-MS/MS and colonic tissue was analyzed using qPCR and immunofluorescence-staining. Primary T-cells and macrophages were isolated from the colon as well as mesenteric and iliac lymph nodes and analyzed by flow cytometry.

Results: DCA was exclusively present in mice colonized with the BACOMI consortium and led to higher colonic tumor numbers compared to mice colonized with BACOMI without *C. scindens* (+7 α DH = 20.5 tumors $\pm$ 7.5 SD vs. -7 α DH = 7.9 tumors $\pm$ 2.0 SD), in particular for small- and medium-sized tumors. Presence of DCA also resulted in shorter colon lengths and lower levels of butyrate in cecal content. In BACOMI colonized mice, the treatment with AOM/DSS promoted colonic colonization by *C. scindens* compared to mice without AOM/DSS treatment.

Even without AOM/DSS treatment, the presence of *C. scindens* and DCA resulted in significantly higher numbers of Ki67⁺ epithelial cells in colonic crypts and more pronounced hypoxia in the colonic epithelium. Colonic expression of genes involved in CRC pathogenesis (e.g., *Axin2*, *Ccnd1*, *Myc*), bile acid metabolism (e.g., *Nr1h4*, *Nr0b2*, *Slc51b*) as well as immune

responses (e.g., *Nfkb1*, *Rorc*, *Ilgam*) was upregulated in mice with DCA. Sub-types of Foxp3⁺ regulatory T-cells were more abundant in mesenteric and iliac lymph nodes whereas numbers of Ly6C high macrophages were lower in the colon and mesenteric lymph nodes of mice with DCA compared to mice lacking DCA.

Conclusion: In a gnotobiotic mouse model for CRC, the presence of microbially-derived DCA promotes colonic tumorigenesis *in vivo*. Even in the absence of chemically-induced tumorigenesis, DCA stimulates the expression of markers closely associated with CRC and promotes colonic epithelial proliferation.

These findings strongly imply a causal role of DCA in the development of CRC. Additionally, DCA shows immunomodulatory effects, which may demonstrate another mechanistic link of how DCA affects intestinal health.

Disclosure: Nothing to disclose.

Introduction: Chronic inflammation in patients with inflammatory bowel disease (IBD) increases the risk of colorectal cancer (CRC). Both sporadic CRC (SCRC) and colitis-associated CRC (CAC) bear similar mutational patterns, including *APC*, *KRAS*, and *TP53* mutations.

However, the dysplasia to carcinoma sequence in CAC is different in that adenomatous transformation often starts with *TP53* and not with *APC* mutations (characteristic of SCRC).

This illustrates that to understand epithelial- and immune cell changes involved in CAC etiology, it is critical to study pre-cancerous tissues instead of end stage disease.

Aims & Methods: We aimed to provide a detailed characterization of the epithelial and immune cell transcriptome in cancers, dysplastic lesions and adjacent normal tissue of both CAC and SCRC patients, using GeoMx Digital Spatial Profiling, to identify chronic inflammation-induced transcriptional changes that predispose for dysplasia and cancer development in IBD. We collected FFPE tissue of 13 IBD patients with either dysplasia (colitis-associated dysplasia (CAD)), CAC, or both. 6 patients without IBD with sporadic dysplasia (SD) or SCRC were used as a control. An expert IBD pathologist scored the tissues to define 3 regions: histologically non-inflamed non-dysplastic mucosa (adjacent normal mucosa: ANM), dysplasia (SD/CAD) or cancer SCRC/CAC). GeoMx Digital Spatial Profiling was used for spatial transcriptomic analysis of both the epithelial and immune cell compartment.

Immunohistochemistry was performed to study immune cell composition. Data analyses were performed using R. Multivariate linear modelling was used for gene and pathway differential expression analyses (significance $p < 0.01$).

Results: Differential gene expression analysis in the epithelial compartment showed that the region with most differentially expressed genes (n=408) was the ANM. Interestingly, transcriptional pathways related to T cell immune responses were downregulated (“Cytotoxicity” and “Lymphocyte Trafficking”) in ANM of CAC patients, as compared to SCRC patients.

Furthermore, we observed decreased intraepithelial T lymphocytes (IELs) abundance in CAC by deconvolution of transcriptional data, which was confirmed by immunohistochemistry (83.71 vs 50.79 IELs cell density/mm², p<0.05). Reduction in IELs in ANM of CAC patients was accompanied by decreased *IL15* expression in epithelial cells, a cytokine critical for IEL recruitment. In the immune compartment, most transcriptional differences were observed in dysplastic tissue (415 differentially expressed genes), with the “T cells” pathway being the most differentially expressed in CAD regions versus SD. Genes encoding for T cell activation were upregulated in CAD, including *CD69*, *ICOS* and *GZMB*, while at the same time, increased gene expression of T-cell checkpoint molecules such as *LAG3*, *CTLA4* and *TIGIT* was observed.

Conclusion: In conclusion, we demonstrated altered cytokine gene expression patterns in ANM of CAC patients versus SCRC patients, including decreased *IL15* expression, a cytokine critical for IEL attraction. This was accompanied by decreased IELs numbers, potentially compromising immunosurveillance and clearance of pre-malignant cells. In contrast, dysplastic tissues in IBD patients were more infiltrated with immune cells, amongst which T cells, as compared to SD patients. Increased expression of T cell checkpoints in the CAD compartment however suggests an immunosuppressed state in CAD.

Together, this study may add a novel concept to how chronic inflammation-induced cell adaptations may favour dysplasia development and progression to cancer.

REBLEEDING AND MORTALITY IN ACUTE UPPER GASTROINTESTINAL BLEEDING WITH VARICES: INSIGHTS FROM A PROSPECTIVE MULTI-CENTER STUDY IN UK HOSPITALS

G. Nigam¹, J. Grant-Casey², K. Oakland³, S. Hearnshaw⁴, V. Jairath⁵, L. Estcourt², M.F. Murphy², S. Travis⁶, A. Douds⁷, J. Leithead⁸, A. Stanley⁹, UK upper GI bleed group

Introduction: Acute upper gastrointestinal bleeding (AUGIB) is a common emergency, with 10% linked to varices¹, requiring swift evaluation.

Aims & Methods: We conducted a prospective multi-center study from 3 May to 2 July 2022, involving adults (>16 years old) presenting with AUG-IB in 152 UK hospitals. We evaluated the patient characteristics of those identified to have varices on index endoscopy as the cause of bleeding and used regression analysis to identify predictors of rebleeding and mortality.

Results: Of 4278 AUGIB cases undergoing endoscopy, 10% (418/4278) were noted to have varices (91% oesophageal, 16% gastric, and 2% duodenal). Median age was 58 yrs and 80% (338) were new admissions. At presentation, 76% (330) had known chronic liver disease (Child-Pugh categories: A:3%, B: 85%, C: 12%)., 13% (54) were on antiplatelets and 15% (61) on anticoagulants.

At presentation, 35% (145) had a history of previous AUGIB, 45% (189) were on non-selective beta-blocker prophylaxis and 23% (98) were on a variceal band ligation programme. Glasgow-Blatchford score (GBS) stratified patients into 13% medium-risk (GBS 2-6), 44% higher-risk (7-11), and 29% very high-risk (≥12).

For pre-endoscopy management: 66% (278) received PPI, 65% (269) vasopressors (98% terlipressin, 2% octreotide) and 56% (235) antibiotics. Endotracheal intubation for endoscopy was required for 33% (137) and admission under critical care for 20% (82). Time to endoscopy from presentation: 0-12 hrs:36%, 12-24 hrs:24%, and >24 hrs:32%. Stigmata of recent bleeding observed in 72% (300) – 41% blood in the upper GI tract and 64% high risk markings on varices. Variceal therapy applied in 67% (281 – 91% banding, 10% injection therapy), Danis stent 2% (7) and Sengstaken tube 3% (14). 17% (69) had evidence of further in-patient bleeding after index endoscopy. 26% (109) needed >1 endoscopy during inpatient stay, and 2% (8) underwent transjugular intrahepatic portosystemic shunt. 67% (281) were transfused ≥1 packed red blood cells, 15% (66) platelets, and 20% (86) fresh frozen plasma.

Median length of stay was 7 days (IQR 4-11) and in-hospital mortality was 13% (54). In a multi-variable logistic model assessing predictors of rebleeding and mortality, significant factors for rebleeding included use of pre-endoscopic vasopressors (OR=2.49, 95%CI:1.59-3.88), pre-endoscopic antibiotics (OR=0.4, 95%CI:0.28-0.59) and presence of endoscopic

stigmata (OR=6.89,95%CI:5.11-9.30). For mortality, the significant factors were very high-risk GBS (OR=4.83,95%CI:2.71-24.09), presence of endoscopic stigmata (OR=3.8,95%CI:2.82-138.72) and the use of endotherapy (OR=0.04,95%CI:0.001-0.53).

Conclusion: Pre-endoscopic vasopressors were associated with increased risk of rebleeding, while pre-endoscopic antibiotics with decreased risk. Endoscopic stigmata was significantly associated with both rebleeding and mortality, with endotherapy a crucial influencer for reducing mortality. These findings offer valuable insights for risk stratification and guide appropriate therapeutic interventions in managing AUGIB with varices as per international guidelines.

Introduction: The pre-emptive transjugular intrahepatic portosystemic shunt (TIPS) within 72 hours is recommended. Nevertheless, recent research emphasizes the challenges associated with timely provision of TIPS within this limited timeframe.

Aims & Methods: The objective of this study was to assess the impact of time for performing TIPS on patient outcomes and identify a more appropriate timeframe. This study enrolled patients referred to our hospital for TIPS procedure between January 2012 and December 2021. The duration between the recent variceal bleeding episode and TIPS procedure was documented. Predetermined outcomes were assessed in relation to various groups at four distinct time intervals: 72 hours, 5 days, 14 days, and 28 days. The primary outcome was the long-term survival rate.

Results: A total of 1180 patients were included in the study. There were no significant differences in patient outcomes between the early and late TIPS groups when patients grouped by 72 hours, 14 days, and 28 days. However, when comparing the late TIPS (>5 days) group to the early TIPS (≤5 days) group, a significantly lower 5-year survival rate was observed in the late TIPS group (71.0% vs 80.4%; HR, 1.88; 95% CIs, 1.14-3.12; P = 0.014). The variceal rebleeding rate did not show a significant difference between the two groups (P = 0.91).

Conclusion: Early TIPS within a 5-day window may confer a survival benefit in contrast to TIPS procedures performed beyond this timeframe. It may be advisable to expand the timeframe for pre-emptive TIPS to align with current clinical practices.

Disclosure: Nothing to disclose.

Introduction: The combination of Atezolizumab plus Bevacizumab (atezobeva) has changed the treatment landscape of advanced hepatocellular carcinoma (HCC), but its efficacy and safety in patients with impaired liver function or portal hypertension is still debated.

Aims & Methods: In this multicenter, real-life, study we compared 247 patients with unresectable HCC treated with atezobeva, matched to 494 patients treated with tyrosine kinase inhibitors (TKIs). We evaluated the impact of liver function and decompensation on treatment outcomes.

Results: Patients in the atezobeva group showed longer median overall survival (OS; 18-30 vs 10-20 months, p<0.0001), longer time to progression (TTP; 13-60 vs 10-10 months, p=0.0002) and increased progression-free survival (PFS; 10-50 vs 6-10 months, p<0.0001) compared with the TKIs group. Although survival was better in Child Pugh A patients than in Child Pugh B patients (20-20 vs 9-83 months, p=0.0008), no clear differences in TTP and overall treatment safety were observed. Liver decompensation occurred in 63 (25-51%) patients, specifically 41 (27-89%) Child Pugh A and 22 (51-16%) Child Pugh B and was associated with worse survival (10-50 vs 20-20 months; p=0.006).

Among decompensated patients, 26 patients (41-26%) were able to resume atezobeva after decompensation, achieving an OS comparable to those who never decompensated (20-87 vs 20-2 months; p=0.77), and significantly better than those who permanently stopped treatment (8-07 months; p=0.02).

Treatment interruption following decompensation was an independent predictor of survival (HR 2.04, 95% CI 1.25-3.33, p=0.004), while ALBI score 2-3 (HR 2.21, 95%CI 1.07-4.55; p=0.03), Child Pugh class B (HR 1.81, 95% CI 1.03-3.18; p=0.04), portal hypertension (HR 2.54, 95%CI 1.37-4.72; p=0.003) and sAEs (HR 1.71, 95%CI 1.04-2.82; p=0.04) emerged as predictors of decompensation. Time to decompensation was similar for patients with ALBI 2, regardless of Child Pugh class, and the probability of recovery from decompensation was similar for Child A and B patients.

Conclusion: In this real-life multicentric study atezobeva was effective in both Child Pugh A and B patients. Child Pugh B patients despite their higher risk of decompensation have an equal chance of recovery.

The possibility to resume treatment after an episode of decompensation highlights the necessity of integrated hepato-oncological management, optimizing the therapeutic efficacy of atezobeva.

Introduction: Hepatic resection is recommended as a curative treatment for hepatocellular carcinoma (HCC), but it may not always be feasible due to tumor localization, liver function, and comorbidities. On the other hand, carbon ion radiotherapy (CIRT) has recently become covered by health insurance in Japan, offering low invasiveness and promising local control. In this study, we compared the treatment outcomes of primary HCC between hepatic resection and CIRT.

Aims & Methods: We compared the treatment outcomes of CIRT (CIRT group, n=111) and hepatic resection (HR group, n=947) for primary HCC from September 2010 to June 2022. Patient backgrounds were adjusted using inverse probability of treatment weighting (IPTW), and we compared the recurrence-free survival (RFS) and overall survival (OS).

Results: CIRT group: HR group, median age 74 (IQR 67-82) years: 71 (65-77) years (p<0.001), male 81 cases (73.0%): 748 cases (79.0%) (p=0.1), PS 0/1=71 cases (64.0%)/40 cases (36.0%): 890 cases (94.0%)/57 cases (6.0%) (p<0.001), Child-Pugh classification A/B=102 cases (91.9%)/9 cases (8.1%): 899 cases (94.9%)/48 cases (5.1%) (p=0.2), solitary/multiple tumors=104 cases (93.7%)/7 cases (6.3%): 729 cases (77.0%)/218 cases (23.0%) (p<0.001), tumor size 3.7 (2.6-5.5) cm: 3.3 (2.2-5.3) cm (p=0.07). The CIRT group had a higher median age, poorer PS, and more solitary cases. The median RFS before IPTW adjustment was 2.3 years in the CIRT group and 2.8 years in the HR group with no significant difference (p=0.1), and there was no significant difference after IPTW adjustment (p=0.5). The median OS was 7.4 years in the CIRT group and 10.1 years in the HR group with a significant difference before IPTW adjustment (p=0.01), but the difference disappeared after IPTW adjustment (9.6 years vs. 10.1 years, p=0.6). In cases with a maximum tumor diameter of 4 cm or more, which is covered by insurance, there was no significant difference in RFS and OS before and after IPTW adjustment (RFS: p=0.8, 0.4; OS: p=0.4, 0.5). Multivariate analysis for RFS and OS showed that treatment modality (CIRT/HR) was not a significant factor (p=0.06, 0.2).

Conclusion: Carbon ion radiotherapy demonstrated comparable local control and prognosis to hepatic resection, suggesting its potential as one of the options for curative treatment.

Introduction: Variceal bleeding (VB) is a severe and life-threatening complication in patients with cirrhosis, often leading to significant morbidity and mortality. The Baveno VII consensus recommends early transjugular intrahepatic portosystemic shunt (pre-emptive TIPS, or pTIPS) placement within 72 hours of acute VB in select cirrhotic patients to reduce the risk of re-bleeding and improve survival rates. However, the comparative effectiveness of pTIPS with delayed TIPS or no intervention remains unclear.

Aims & Methods: This study aimed to evaluate the benefits of pTIPS in reducing early relapse of VB, compared to delayed TIPS or no intervention, in a referral center setting. Cirrhotic patients with VB and Child-Pugh Class C<14, or B>7 with active bleeding were retrospectively selected between 2016 and 2022 for two control groups: those who underwent TIPS placement after 7 days (Group A) and those who did not undergo TIPS placement (Group B). Additionally, patients who received pre-emptive TIPS placement between August 2022 and January 2024 were prospectively included.

Results: A total of 47 patients were included (pTIPS group=19, Group A=11, and Group B=17). There were no statistically significant differences between the groups regarding age, gender, aetiology of cirrhosis or Child-Pugh and MELD scores (p>0.05). Early relapse rates (under week 6) were significantly lower in the pTIPS-group (5.3%) versus Groups A (63.6%) and B (35.3%) (p<0.001 and p=0.030, respectively).

There were no significant differences in 30-day mortality and length of stay between the pTIPS-group and the whole control group (A+B) (p=0.683 and p=0.269, respectively). Hepatic encephalopathy was significantly lower in the pTIPS-group (after pTIPS placement) compared to Group B (31.6% vs.

81.8%, $p=0.008$). Readmission rates because of VB were significantly lower in the pTIPS group compared to the whole control group (A+B) (0% vs. 39.3%, $p<0.001$).

Conclusion: This real-life study demonstrates that pre-emptive TIPS placement significantly reduces the early relapse rates of variceal bleeding in cirrhotic patients compared to delayed TIPS or no intervention. The lower rates of early relapse, decreased readmissions due to VB, and reduced occurrence of hepatic encephalopathy suggest that pTIPS could play a crucial role in lowering morbidity and complications in these patients. While 30-day mortality rates showed no significant differences between the pTIPS group and the control groups, the decreased need for subsequent interventions and hospital readmissions may translate into improved long-term outcomes and reduced healthcare costs. These results support the proactive use of pTIPS in clinical practice for selected patients with acute VB to optimize patient care and outcomes. Further studies with larger sample sizes and longer follow-up periods are needed to validate these findings and further refine the guidelines for pTIPS placement in this context.

Introduction: Post endoscopy upper gastrointestinal cancers (PEUGIC) can be missed opportunities to diagnose earlier or even prevent cancer. PEUGIC in patients undergoing endoscopic surveillance for pre-malignant conditions (e.g. Barrett's oesophagus) are an important quality metric. A process for identifying PEUGIC and performing root cause analysis was piloted and the results are described.

Aims & Methods: The aims of the project were to develop a system to identify all PEUGIC in the English NHS and to allow endoscopy providers to conduct standardised root causes analysis of their PEUGIC via an online platform. This study allows local learning from PEUGIC and quantifies the reasons why PEUGIC occur at a national level.

PEUGIC occurring 3-36 months after a non-diagnostic (index) endoscopy between 2017 and 2023 were identified from final or provisional registrations in the National Cancer Registration and Hospital Episode Statistics Datasets held by the National Cancer Registration and Analysis Service. Data for root cause analysis were uploaded onto a secure root cause analysis portal following local hospital review. Only PEUGIC following surveillance endoscopy were included in this analysis.

Results: 305 PEUGIC were examined by local reviewers in 13 hospitals in England. 40 were excluded, due to errors in provisional cancer data. Data were available for 220 PEUGIC (83%). 54 PEUGIC (26%) were undergoing surveillance for either Barrett's oesophagus (87%) or chronic atrophic gastritis (13%).

Table 1 shows the PEUGIC root cause analysis based on World Endoscopy Organisation categorisation (Kamran Endoscopy 2023). Inadequate assessment or decision making was found in 11% of PEUGIC. Findings in addition to the pre-malignant lesion: oesophageal PEUGIC focal lesion 17%; gastric PEUGIC focal lesion 29%. For oesophageal PEUGIC, 40% were diagnosed 3 months after the recommended surveillance date and 10% were interval cancers. In gastric PEUGIC, 29% were diagnosed 3 months after the recommended surveillance date and 29% were interval cancers.

Gastric PEUGIC tended to present more advanced stage 2 cancer or greater (43% vs 22.5% oesophageal). 2% of oesophageal and 14.3% of gastric PEUGIC were considered potentially avoidable by reviewers. Treatment appeared adversely affected with more invasive or palliative not curative treatment in 17% of oesophageal and 43% of gastric PEUGIC. Reviewers considered that 4% of PEUGIC led directly to a premature death.

PEUGIC categorisation	Number of cases
1. Lesion detected, adequate assessment and decision making but PEUGIC occurred	34 (63%)
2. Lesion detected, inadequate assessment and decision making	6 (11%)
3. Possible missed lesion, endoscopy and decision making adequate	14 (25%)
4. Possible missed lesion, endoscopy or decision making inadequate	0

Table 1 Root causes of surveillance endoscopy PEUGIC.

Conclusion: Inadequate assessment or decision making was noted in 11% of surveillance PEUGIC. Focal lesions were noted at non-diagnostic endoscopy in 19%. 43% of gastric surveillance patients presented with stage 2 cancer or greater and adverse treatment outcomes occurred in 22% of surveillance PEUGIC.

Introduction: Endoscopic recognition of premalignant conditions, such as Barrett’s oesophagus (BO), gastric atrophy (GA) or gastric intestinal metaplasia (GIM) offers an opportunity to prevent advanced upper gastrointestinal (UGI) cancer. However, since their prevalence in the general population is poorly defined, there are no diagnostic key performance indicators (KPIs) in UGI endoscopy.

We hypothesised that the prevalence of premalignant UGI lesions is underestimated due to poor endoscopic recognition.

Aims & Methods: The aims of this study are to determine the prevalence of premalignant UGI conditions among patients referred for an UGI endoscopy and estimate the rate of missed diagnosis. PROSPERO is a prospective, multicentre study recruiting patients across 11 hospitals in the UK referred for UGI endoscopy (NCT04843397). Patients with previous endoscopy in the last 3 years or undergoing surveillance of known premalignant disease were excluded. All patients underwent 10-picture standard photodocumentation and a standardised biopsy protocol including a minimum of 4 gastric biopsies (2 antrum and 2 body) and 4 oesophageal biopsies (2 proximal and 2 distal) in addition to targeted biopsies of endoscopic lesions. The prevalence of premalignant conditions in our prospective cohort was compared to an equal-sized, matched, historic cohort of consecutive patients at a single institution. The missed rate of premalignant lesions was calculated by comparing endoscopic detection to gold-standard histopathological diagnosis.

Results: To date, 600 patients have been recruited, of which 455 (mean age 58yrs, 42% male and 52% referred on cancer or urgent pathways) had histological data available. Premalignant UGI pathologies were diagnosed in 60 patients (13.2%), including 25 cases of BO (5.5%; mean length 2.2cm), of which three harbouring dysplasia, 36 cases of GA/GIM (7.9%) and one case of duodenal adenoma with dysplasia (0.2%). There were 7 cases of UGI cancer (1.5%). Strikingly, only 9 GA/GIM cases (25%) were suspected endoscopically and 68% of GA/GIM cases actionable for surveillance based on the MAPS guidelines were not reported by the endoscopist. The rate of histological diagnoses of GA/GIM in the historic cohort was significantly lower (1.3% vs 7.9%; p<0.0001). There was no significant difference in the duration of endoscopy between cases where premalignant gastric pathology was recognised compared to those

where it was not (12.0 vs 15.4 mins; $p>0.05$). Premalignant stomach was more likely to be recognised endoscopically by gastroenterologists than surgeons or nurse endoscopists. ($p=0.03$).

Conclusion: In this prospective cohort study, the overall prevalence of any premalignant UGI condition in the UGI endoscopy population is 13%. We found that the rate of endoscopic recognition of premalignant stomach is inadequate, with up to 75% of cases potentially missed. Rigorous training and diagnostic KPIs are warranted to improve quality in UGI endoscopy.

HOT VERSUS COLD-SNARE ENDOSCOPIC MUCOSAL RESECTION FOR NON-AMPULLARY DUODENAL LESIONS: CONSOLIDATING THE COLD REVOLUTION INTO CLINICAL PRACTICE

A. Beany^{1,2}, E.J. Aguila^{2,3}, A.A. Wawer^{2,4}, D. Bawa², J. Tan^{2,4}, R. Singh^{4,2}

Introduction: Endoscopic mucosal resection (EMR) has increasingly gained acceptance as a minimally invasive intervention for the treatment of duodenal lesions. Despite the overall good results, there can be significant morbidity associated with performing EMR in the duodenum. Data comparing hot- and cold-snare approaches in the duodenum are currently scarce.

Aims & Methods: Our aim was to assess the efficacy and safety of hot-snare EMR (H-EMR) versus cold-snare EMR (C-EMR) for the resection of non-ampullary duodenal lesions. A prospectively collected database of duodenal lesions treated using EMR at a single tertiary medical center between 2010 and 2023 was performed. Patient demographics, lesion and procedure characteristics, outcomes, and adverse events were analyzed using R statistical software. The lesion size and procedural time were analyzed using the Mann-Whitney U test while clinical outcomes were analyzed using the Fisher's exact test. Cost savings were calculated from the averted use of clips.

Results: Seventy-one cases of non-ampullary duodenal lesions resected using the EMR technique were included (46 H-EMR; 25 C-EMR). Fifty-one lesions were resected en-bloc (31 H-EMR vs 20 C-EMR) while 20 lesions were resected in a piecemeal fashion (15 H-EMR vs 5 C-EMR). Similar demographics, lesion, and procedure characteristics were observed in both cohorts. Technical success was 100%, and no delayed perforations occurred in either cohort. Lesions resected via H-EMR had higher rates of immediate perforation (2.2% vs 0%; $p=1.0$) and delayed bleeding (9.1% vs 0%; $p=0.28$) compared to C-EMR. Interestingly, recurrence rates were higher in the H-EMR arm (15.2% vs 8%; $p=0.70$). C-EMR technique achieved a crude cost saving from clips alone of USD \$135 per patient compared to the H-EMR technique.

Conclusion: While both cohorts demonstrated excellent technical success, there was a trend towards lower adverse events and recurrence rates, as well as cost savings, when C-EMR technique was used for non-ampullary duodenal lesions. Larger prospective comparative trials are warranted to bolster the present evidence and shape the approach of tackling these rarely encountered but clinically significant lesions safely and effectively.

EFFICACY ANALYSIS OF ENDOSCOPIC INJECTION COMBINED WITH ORAL CORTICOSTEROIDS FOR PREVENTING ESOPHAGEAL STRICTURE FOLLOWING CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION

Y. Liu¹, X. Luo¹, B. Xia¹, J. Yang¹

¹West China Hospital of Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China

Introduction: Endoscopic submucosal dissection (ESD) is the standard treatment for superficial esophageal cancer. Previous studies have indicated that patients with a circumferential mucosal defect of $\geq 3/4$ post-ESD are at a significantly increased risk of developing postoperative esophageal stricture. Previous research suggests that the incidence of esophageal stricture can be reduced by either endoscopic injection or oral administration of corticosteroids. However, the effectiveness of combined endoscopic injection and oral corticosteroids in preventing post-circumferential ESD esophageal stricture has not been fully analyzed.

Aims & Methods: This retrospective study included patients who underwent circumferential esophageal ESD with a mucosal defect of $\geq 3/4$ at West China Hospital, Sichuan University, from January 2014 to August 2023. Patients were divided into two groups based on whether they received corticosteroids to prevent esophageal stricture: the steroid group and the non-steroid group. The steroid group received multiple uniform injections of 80 mg triamcinolone acetonide directly into the esophageal

lesion immediately after ESD and started oral prednisolone on the third day post-operation, continuing for eight weeks; the non-steroid group did not receive corticosteroid prevention. The main outcomes measured were the incidence and timing of stricture formation.

Results: A total of 221 patients were included in the study, with 150 in the steroid group and 71 in the non-steroid group. The incidence of post-ESD esophageal stricture was 43.33% (65/150) in the steroid group and 47.89% (34/71) in the non-steroid group, with no significant difference ($P=0.564$). However, in patients with a full circumferential mucosal defect (100%), the incidence of stricture was 100% (16/16) in the non-steroid group and 76.67% (46/60) in the steroid group, a difference that was statistically significant ($P=0.032$). For patients with a defect of 3/4 to 1, the incidence was 32.73% (18/55) in the non-steroid group and 21.11% (19/90) in the steroid group, with no significant difference ($P=0.120$).

In follow-up analysis, the median time to stricture occurrence was 9 weeks (range 1.29-82.43 weeks), with median times of 9.86 weeks (range 3.71-82.43 weeks) in the steroid group and 5.27 weeks (range 1.29-49 weeks) in the non-steroid group, a statistically significant difference ($P<0.001$). For patients with a full circumferential mucosal defect, the median time to stricture occurrence was 8.5 weeks (range 1.29-49 weeks), while for patients with a defect of 3/4 to <1, the median time was 9.14 weeks (range 4.57-82.43 weeks), with no significant difference between these groups ($P=0.390$).

Conclusion: Overall, while endoscopic injection combined with oral corticosteroids does not significantly reduce the overall risk of post-circumferential ESD esophageal stricture, it can effectively extend the time to stricture occurrence. Particularly, patients with a full circumferential ESD benefit significantly from this treatment strategy, showing a reduced incidence of postoperative esophageal stricture, suggesting that such patients may benefit more from the combined use of endoscopic injection and oral corticosteroids.

ENDOSCOPIC CLOSURE OF A CONGENITAL TRACHEO-ESOPHAGEAL FISTULA USING A NEW ENDOSCOPIC, THROUGH-THE SCOPE, SUTURING DEVICE IN A YOUNG BOY – A CASE REPORT

M. Ellrichmann¹, G. Ivanov², I.D. Ellrichmann³, M. Mumm³, A. Meinzer², C.C. Conrad¹, R. Bergholz²

Introduction: Tracheoesophageal fistula (TEF) is a congenital or acquired pathology characterized by communication between the posterior tracheal and the anterior esophageal wall. Congenital TEF type E, “H” fistula without esophageal atresia, accounts for only 4% of cases. So far, minimal-invasive surgical techniques are accepted as first line therapy. Endoscopic interventions have been described to be safe and effective in the management of TEF, with lower morbidity and mortality compared to surgical interventions.

Aims & Methods: We present a case of a successful endoscopic closure of a TEF using a new endoscopic, through-the-scope suture device (TTS-SD, X-Tack, Boston Scientific).

Results: A 37-month-old boy presented at our clinic in early 2023 with recurrent postprandial coughing, choking and bronchopulmonary infections. At index endoscopy only a small pore was detected without evidence of a relevant TEF. Patient was rescheduled after 6 months. Over this period, symptoms significantly worsened with non-percentile-appropriate growth/weight gain.

At follow-up (FU) endoscopy a significant H-fistula was noted at 13 cm from the dental arch. After freshening the fistula pore with argon plasma coagulation (APC), a fully covered, self-expanding metal stent (fcSEMS) of 10x80 mm was inserted. This stent dislodged into the stomach after a few days and was replaced by a larger fcSEMS (20 mm diameter), which was only tolerated for another few days.

Immediately after removal, the TEF was closed endoscopically using three TTS clips. The boy was symptom-free for 3 weeks post-intervention, but then experienced a sudden recurrence of the known symptoms. Endoscopically, the clips were completely dislodged, the TEF was detectable again. Another attempt with TTS clips yielded identical results. In March 2024, an endoscopic closure was performed using the novel TTS-SD, which can be applied through the working channel of a regular gastroscope.

After freshening the scarred fistula with APC and brushes, four helices were screwed into the submucosa, the defect was continuously sutured in a cross-cross pattern. Immediately after the intervention the patient was free of symptoms. Endoscopic FU after 2 and 6 weeks showed persistent closure of the TEF with complete resolution of symptoms.

Conclusion: Congenital TEFs can be effectively managed using endoscopic techniques. In young children, fcSEMS appear to be less efficacious when compared to direct closure of the fistula. The introduction of the novel TTS-SD, has enabled successful treatment of the TEF in the present case.

The utilization of the TTS-SD represents a significant advancement in our therapeutic armamentarium for managing these complex cases especially in a small working space. However, there is need for long-term follow-up data.

Disclosure: Prof. Dr. Mark Ellrichmann received lecture honorarium, consultation fees and study support from Boston Scientific.

Introduction: The incidence of oesophageal adenocarcinoma (OAC) has increased worldwide and is associated with high mortality.[1] Surgery is considered the backbone of curative intent treatment for locally advanced disease but is associated with a high procedure-related morbidity and mortality [2-4].

Aims & Methods: We present 3 cases of suspected deep submucosal (T1b sm2-3) or muscular invasive (T2) OAC who had no distant or nodal disease, were unfit for surgery, declined chemoradiotherapy and consented to endoscopic full thickness dissection (EFTD) of their tumour. Disease staging was with a combination of endoscopic imaging, endoscopic ultrasound and positron emission tomography and computed tomography.

Prior to resection the lesion was delineated and marked using soft coagulation. A submucosal tunnel was dissected (Spray coag. effect 4.2) towards the suspected area of deep invasion. Once invasion was detected a muscularis propria (MP) incision (EndoCut Q) was made 10mm away (oral-side) until the peri-oesophageal space was reached.

To minimise the area of excised MP the submucosal plane was entered distal from the lesion in retroflexion (via a second tunnel) and an incision into the MP was made 10mm caudal to the invasive component.

Saline-immersion with use of a water exchange device was used to increase visualisation in the peri-oesophageal space and connect both muscular incisions. The margins of the tunnel and MP were then dissected. Subsequently a fully covered self-expanding metal stent was placed to cover the entire defect.

On post-operative day (POD) 2 all patients were restarted with fluids. Oral intake was increased over several days to semi-solid. Broad-spectrum antibiotics were started during the procedure and continued for a total of 5 days. Mean time to discharge was POD 5 (range 3–7 days).

Results: In 2 cases the OAC was poorly differentiated with deep submucosal invasion (pT1b sm3). The third case was a moderately differentiated OAC with MP-invasion (pT2). In each case EFTD provided local clearance of tumour. Initial 30-day follow-up showed no evidence of complications. Patients were followed up from the date of resection to present (range 1–16 months) without evidence of local recurrence or metastatic disease.

Conclusion: Three patients with locally advanced OAC who declined alternative treatments underwent successful endoscopic full thickness resection. No evidence of disease recurrence was found on endoscopy, imaging and pathology during follow-up to date.

These results suggest local endoscopic therapy should be considered in selected patients with locally advanced OAC, especially if ineligible for conventional treatment.

WHEN A MISFORTUNE DOES NOT COME ALONE: CHALLENGES AND COMPLICATIONS OF BILIARY AND DIGESTIVE TRACT ANASTOMOSIS BY ENDOSCOPIC ULTRASOUND

D. Abrantes¹, J. Cortez Pinto¹, B. Morão¹, R. Loureiro¹, E. Barjas¹, L. Glória¹

¹Unidade Local de Saúde de Loures-Odivelas, Hospital Beatriz Ângelo, Gastroenterology, Loures, Portugal

Contact E-Mail Address: dani-abrantes@hotmail.com

Introduction: Malignancies involving the duodenum, major papilla, head of the pancreas and distal common bile duct can lead to malignant biliary and gastric outlet obstruction. When clinical presentation of biliary and duodenal obstruction is simultaneous, these tumors are usually at the late stage of the disease and the only option is palliative treatment to improve the quality of life of these patients.

Aims & Methods: We describe a dual biliary and digestive tract drainage by endoscopic ultrasound (EUS) in a patient with metastatic squamous cell carcinoma (SCC) of the cervix causing dilation of the bile duct, bulb and stomach with sleeve infiltration at the level of the hepatic hilum and duodenal arch.

Results: A 67-year-old woman, performance status 0, diagnosed with SCC of the cervix in 2022 underwent curative treatment. In February 2024 was admitted due to jaundice and vomiting progressing for 2 months. Computed tomography revealed dilatation of the bile duct, bulb and stomach with sleeve infiltration of the duodenal arch. Endoscopic ultrasound (EUS) identified a heterogeneous lesion causing obstruction of the middle third of the bile duct, confirming the diagnosis of metastatic SCC of the cervix. After discussion with multidisciplinary team, the patient was proposed for palliative treatment.

Subsequently, she underwent EUS-guided gastrojejunostomy with placement of a 20x10mm lumen-apposing metal stent (LAMS). Bile duct drainage wasn't done due to absence of bile duct dilatation over 12mm as the total bilirubin levels frankly decreased with corticotherapy.

However, a week later, the total bilirubin levels increased and a biliary drainage was proposed, attempting access to the papilla through gastrojejunostomy, a procedure complicated by migration of the gastric end of the LAMS into the peritoneal cavity. The guidewire was immediately placed, the LAMS was mobilized into the stomach, concurrently initiating broad-spectrum antibiotic therapy.

Despite this initial event, it was decided to proceed with EUS-guided choledocoduodenostomy after identifying the bile duct, placing a 6x8mm LAMS with the distal end released outside the bile duct and positioning a fully covered 40x10mm metal biliary stent coaxially to the LAMS as a rescue, with the end below the confluence and no evidence of contrast extravasation on fluoroscopy. The procedure was complicated by respiratory distress with symptomatic relief after pneumoperitoneum drainage. Recovery was uneventful and the patient was discharged 5 days after biliary drainage and is well after 30 days of follow up.

Conclusion: EUS guided procedures such as biliary drainage and gastrojejunostomy are likely to spread quickly in clinical practice for the treatment of concomitant malignant biliary and gastric outlet obstruction. The following case is presented due to the importance of recognizing and managing intraprocedural complications associated with LAMS.

Introduction: Severe submucosal fibrosis (SSF) in early gastric cancer (EGC) is known to cause technical difficulty for endoscopic resection.^{1,2} Various methods have been reported to tackle this problem. However, there is no established consensus on the management of this situation.

Endoscopic intermuscular dissection (EID) has been successfully used in the rectum to overcome SSF.³

The procedure involves the dissection between the circular and longitudinal layers of the muscularis propriae. Recently, the procedure has been used in the stomach for en bloc resection of a neuroendocrine tumor.⁴ We report a case endoscopic resection of early gastric cancer with severe submucosal fibrosis where EID was used to attain a negative vertical margin.

Aims & Methods: We aim to demonstrate the use of EID in the stomach to overcome the challenge of SSF in endoscopic resection of early cancer. An 81 year male underwent an upper endoscopy for heaviness and discomfort in the epigastrium for few months. It revealed an approximately 25mm lesion around a healed ulcer scar at the gastric angle on the lesser curvature side with irregular surface and vascular pattern and a clear demarcation line. Biopsy showed high grade dysplasia and endoscopic resection was planned. Since the lesion was over a healed ulcer scar, and endoscopy showed convergence of gastric folds towards the lesion, SSF was expected. The resection was started by conventional endoscopic submucosal dissection in retroflexion and a tunnel was created under the distal side of the tumor. However, after the incision and initial submucosal dissection, we encountered SSF. We decided to carefully dissect in the intermuscular plane underneath the fibrotic area by identifying and separating the circular and longitudinal muscle layer. Similar method was used on the oral side where EID was performed after initial ESD and tunnel was completed. Resection was accomplished and the circular muscle defect in the middle of the ulcer was closed with multiple endoclips.

Results: Total procedure time was 60 minutes. En bloc specimen measured 56mm x 40mm. There were no immediate or early complications. Patient was started on soft diet on post procedure day 1 and discharged on day 5. Pathology was tubular adenoma with high grade dysplasia. Horizontal and vertical margins were negative and specimen contained the muscle layer.

Conclusion: This case demonstrates the feasibility of EID in the stomach without any special accessories or equipment. EID can be used to overcome severe submucosal fibrosis in early gastric cancer. Further studies on wider applicability of gastric EID in clinical practice would be worthwhile.

ANTI-REFLUX MUCOSAL ABLATION -MUCOPLASTY (ARMA-P) AS A MODIFICATION OF ARMA FOR THE MANAGEMENT OF PROTON PUMP DEPENDENT OR REFRACTORY GASTROESOPHAGEAL REFLUX DISEASE (GERD). A PILOT STUDY IN A HIGH PREVALENCE REGION OF THE WORLD

A.H. Raina¹

¹Burjeel Hospital, Gastroenterology and Hepatology, Abu Dhabi, United Arab Emirates

Contact E-Mail Address: hameedraina49@gmail.com

Introduction: Gastroesophageal reflux disease (GERD) is common and found in 8.7 to 33.1% of the population in the middle east(1).

Proton Pump Inhibitor (PPI) is the most common modality of treatment used. Anti reflux Mucosal Ablation (ARMA) is a novel simple minimally invasive endoscopic therapy for PPI dependent or refractory GERD(2).

However, it takes about 4-6 weeks to see its effects and long-term response is not guaranteed.

Further, there is a risk of immediate and delayed bleeding and ulcer formation. Certain modifications like in ARMS(3) can shorten the time of its response, enhance its effectiveness, and make it safer and long lasting.

Aims & Methods: The study aimed to modify the ARMA technique to shorten its response time and enhance its effectiveness and safety in United Arab Emirates which is a high prevalence region for GERD in the world. All adult patients with proven severely symptomatic GERD for more than five years with Hill's grade I to III were recruited.

All patients underwent ARMA in endoscopy suit under general anaesthesia. The standard technique of ARMA was applied. Deep ablation was done till the appearance of the muscle layer. About 1 cms of gap was kept unablated between the esophageal mucosa and the gastric mucosa and along the greater curvature side to prevent stricture. The ablated area spread on about 1.5 to 2cms. The setting used were 1.6 to 1.8 l/min flow rate and 80-100-watt voltage. About 5-8 normal endoclips were used for mucoplasty. The endoclips were applied across the ablated area closing the edges to prevent any bleeding, shorten the scarring time and enhance its effectiveness. All the procedures were performed as out patients. Check EGD was performed after one and three months.

Clinical follow up was done at 2 weeks, four, 12, 24 and 48 weeks. pH metry tests were repeated at three, six and twelve months to confirm or rule out recurrent GERD.

Results: Six patients who consented were included in the study. Four were females and two were males. Mean Age was 43 years (IQR 31-55 years). The average time for ARMA-P was 47 ± 8 minutes. All the procedures were uneventful. Two patients complained of moderate retrosternal pain which responded well to analgesics and PPI during first three days of the procedure.

No immediate or delayed bleeding, perforation, any other adverse events were noted in any patient. PPI were stopped two weeks of the procedure in all the patients.

All the patients did well off PPI only after two weeks of the procedure. Check EGD showed proper healing and adequate scarring, forming a tight flap valve of the cardia around the GE junction as early as four weeks post procedure. All the six patients are asymptomatic and off PPI at 12 months of follow up.

Conclusion: Mucoplasty after ARMA using endoclips makes the results of ARMA faster, safer, more effective, and long lasting. However, large randomized studies are required to validate these findings

MANAGEMENT OF LUMEN APPOSING METAL STENT DISLOCATION DURING ENDOSCOPIC ULTRASOUND-DIRECTED TRANSGASTRIC ERCP WITH A DEDICATED ENDOSCOPIC SUTURING DEVICE

E. Palmeri¹, P. Hindryckx¹

¹Ghent University Hospital Dept. of Gastroenterology, Dept. of Gastroenterology, Ghent, Belgium

Contact E-Mail Address: epalmeri94@gmail.com

Introduction: A 37-year-old woman was referred to our unit because of typical biliary colics with transient cholestasis. Her relevant medical history included a cholecystectomy and a sleeve gastrectomy, later on converted to a gastric bypass.

After multidisciplinary discussion, we opted for an endoscopic ultrasound-directed transgastric ERCP (EDGE) using a 20/10 lumen-apposing metal stent (LAMS).

Due to the previous sleeve gastrectomy, the LAMS had to be placed between the jejunum and the excluded antrum. According to international expert recommendations, the ERCP was scheduled two weeks post-LAMS placement to allow for tract maturation [1].

Nevertheless, the proximal flange of the LAMS dislocated during duodenoscope introduction and ended up in the peritoneal cavity. A decompressing needle was placed and the proximal flange was retrieved in the peritoneal cavity under fluoroscopic guidance, using a therapeutic gastroscope.

After a non-successful attempt to reposition the proximal flange through the fistula tract in the jejunum, a guidewire was placed through the LAMS lumen in the excluded antrum. A bridging attempt with a 22mm x 10 cm fully covered enteral stent through the LAMS lumen failed.

Subsequently, intraperitoneal endoscopic closure of the fistula towards the excluded antrum was performed with the X-tack system.

Next, we removed the LAMS and the enteral stent from the peritoneal cavity and completely sealed the fistula tract from the jejunal side with x-tack endosutures and clips.

The patient was put on antibiotics and could start oral feeding the day after the procedure. Besides moderate abdominal pain the first 2 days after the procedure and a transient elevation of the CRP, the further clinical course was uneventful.

Aims & Methods: The rescue intervention was conducted with a gastroscope with 3,8 mm working channel. A 22 x 10 cm fully covered enteral SEMS was used in the attempt of bridging the excluded antrum. X-tack endosuture system was chosen to achieve the closure of the fistula.

Results: The X-tack system proved to be an effective tool in addressing not only the intraluminal perforation but also in the intraperitoneal endoscopic closure of the fistula extending towards the excluded antrum.

Conclusion: This case illustrates the potential of endoscopic suturing devices as minimally invasive alternatives to surgery for management of large iatrogenic perforations.

CYSTO-GASTRIC BYPASS OS POST-TRAUMATIC HEPATIC SUBCAPSULAR COLLETION USING LUMINAL APPPOSITION STENT

C. Solak¹, E.L.A. Artifon², M. Facanali³, F. Martins Acras¹, R. Maziero¹

Introduction: Ultrasound-guided drainage is already a consolidated and advantageous option in relation to percutaneous drainage, as it promotes greater comfort and safety in addition to shorter hospital stays. The luminal apposition stent (LAMS) has further increased the effectiveness and safety of ultrasound-guided drainage, as it has a larger diameter lumen, improving drainage efficiency and enabling intraluminal access with a standard endoscope. Proximal and distal flanges promote a lower stent migration rate. Its main indications are for the drainage of intra-abdominal liquid collections, decompression of obstructed bile ducts, creation of anastomoses or creation of fistulous tracts between organs that can facilitate other specific endoscopic interventions.

Aims & Methods: We report the case of a 43-year-old male patient, victim of a motorcycle x truck collision, initially diagnosed with a clavicle fracture. Opting for conservative treatment, he was discharged from hospital. Thirty days after the accident, he sought medical attention due to pain and increased abdominal volume. Abdominal computed tomography (CT) showed grade III liver laceration, with hepatic subcapsular collections, the largest measuring 21x18x12cm, in addition to a collection next to the hepatocolledocus suggestive of biliary fistula.

Results: We opted for endoscopic retrograde cholangiopancreatography (ERCP) and ultrasound-guided drainage of the collections. During ERCP, papillotomy was performed to correct the proximal biliary fistula. During ultrasound endoscopy, a subcapsular lesion was assessed in close contact with the gastric wall, followed by ultrasound-guided drainage using LAMS. There was drainage of 3,000mL of hematic-purulent content. Endoscopic control after 7 days revealed improvement in the capsular pattern. On the 14th day of evolution, the LAMS was removed, followed using 2 double-pigtail stents to maintain residual drainage. Two CT scans were performed 30 and 60 days after the procedure, with complete resolution of the collection observed on the last CT scan.

Conclusion: Several cases are reported in the literature of the use of LAMS for drainage of intra-abdominal collections, however, for subcapsular lesions, only one reported case was found and, like ours, there was a satisfactory result. The use of LAMS for this type of intervention is uncommon, but it suggests that it is an effective alternative. Prospective studies are needed to better evaluate the efficacy of LAMS in hepatic subcapsular lesions.

Disclosure: Nothing to disclose.

Introduction: In patients with rectal cancer, deep submucosal invasion is not an independent risk factor for lymph node metastasis (absolute risk: 2.6%). [1] Total mesorectal excision is associated with high rates of morbidity (12.1%-13.4%) mortality (1%-1.5%) and recurrence (3%-6%).[2,3] Valuable options include Transanal minimally invasive surgery (TAMIS) [4], endoscopic full-thickness resection (FTR) using a dedicated device for rectal lesions up to 20 mm[5] and endoscopic intermuscular dissection (EID) for distal rectal lesions. [6] We describe a case of endoscopic knife-assisted FTR for a deeply invasive T1 proximal rectal cancer.

Aims & Methods: A 61-year-old patient with concomitant esophageal (cT2N0M0) and pharyngeal (cT3N2M0) squamous cell cancers in treatment with chemo-radiotherapy was referred with a incidentally detected rectal lesion. Endoscopy showed a sessile 25-mm proximal rectal lesion with a demarcated and slightly depressed central area (Paris 0-Is+IIC, JNET-3). MRI raised suspicion of muscularis propria involvement.

Following a multidisciplinary team discussion, endoscopic resection was chosen considering the patient's active oncologic comorbidities. Due to the lesion size, using a FTR device was not feasible, and EID was unsuitable for the proximal rectum.

Therefore, endoscopic submucosal dissection (ESD) with knife-assisted FTR was performed. Initially, a pocket-creation method was used to reach and assess the point of deepest invasion at the center of the lesion. Loss of the dissection plane due to the lesion adhering to the muscularis propria at its center (revealed by saline-immersion in the pocket) necessitated FTR. Thus, a circular mucosal incision was made, followed by trimming and submucosal dissection to isolate the central deep invasion. Clips, rubber bands, and surgical wires were used to apply traction and enhance access to the resection plane. A full-thickness resection of the muscularis propria with the electrosurgical knife around the center of the lesion was performed. The resection defect was carefully washed with sterile saline and closed with clips. Antibiotic peri-procedural prophylaxis was administered.

Results: The post-procedural course was uneventful, and the patient was discharged home 24 hours after the resection. Histopathology revealed R0 resection of a low-grade intestinal-type adenocarcinoma with a central deep submucosal invasion in contact with the muscular layer without muscularis propria involvement, tumor budding, or perineural invasion (pT1, Kikuchi level sm3). Focal lymphovascular invasion was observed. Given the patient's clinical status endoscopic and radiologic follow-up was advised by a multi-disciplinary team.

Conclusion: The staged approach of pocket creation, assessment of deep SMI and planned endoscopic knife-assisted FTR for a deeply invasive T1 proximal rectal cancer was safe and effective, allowing for R0 deep resection margins.

Introduction: GALAXI 2 & 3 are identically designed 48-week, randomized, double-blind, double-dummy, placebo (PBO)- and active-comparator, treat-through registrational trials assessing the efficacy and safety of IV induction and SC maintenance therapy with guselkumab (GUS), a dual-acting IL-23p19 subunit inhibitor, in participants (pts) with moderately to severely active Crohn's disease (CD).

Primary results of each study were previously reported; here we explore the impact of biologic therapy exposure on efficacy outcomes with GUS compared to PBO in the pooled GALAXI 2 & 3 dataset.

Aims & Methods: Pts with inadequate response or intolerance to conventional therapy or biologic therapy (BIO-ir), active CD (CDAI 220–450 + mean daily SF>3 or AP>1), and SES-CD≥6 (≥4 for isolated ileal disease) were randomly assigned 2:2:2:1 at week (Wk) 0 to GUS 200mg IV q4w (x3)→100mg SC q8w, GUS 200mg IV q4w (x3)→200mg SC q4w, UST IV→SC, or PBO. In each trial, the composite co-primary endpoints were:

1. Clinical response at Wk12 + clinical remission at Wk48, and;
2. Clinical response at Wk12 + endoscopic response at Wk48, comparing each GUS regimen to PBO. Major secondary endpoints included clinical remission at Wk12 and endoscopic response at Wk12. Analyses of BIO-ir and BIO-naïve subgroups in the individual trials were prespecified; pooled analyses were performed post hoc.

Results: In the pooled dataset, 52% (378/730) of pts randomized to PBO or GUS had a prior history of BIO-ir and 42% (305/730) were BIO-naïve (6% [47/730] had prior exposure to biologics but no documented failure). At Wk12, GUS achieved higher rates of clinical remission and endoscopic response compared to PBO in the overall population and BIO-ir and BIO-naïve subgroups (Table). For the composite co-primary endpoints, both GUS regimens also achieved higher rates of 1) clinical response at Wk12 +

clinical remission at Wk48 and 2) clinical response at Wk12 + endoscopic response at Wk48 compared to PBO in the overall population and BIO-ir and BIO-naïve subgroups.

Overall population			Participants with a history of inadequate response or intolerance to at least 1 prior biologic* (BIO-ir)			Participants with no history of exposure to biologics* (BIO-naïve)			
	PBO N=148	GUS 200mg IV combined ^b N=582		PBO N=78	GUS 200mg IV combined ^b N=300		PBO N=61	GUS 200mg IV combined ^b N=244	
Clinical remission at Wk12	28 (18.9%)	274 (47.1%) Δ 28.0% P<.001*		15 (19.2%)	138 (46.0%) Δ 26.9% P<.001*		10 (16.4%)	121 (49.6%) Δ 32.1% P<.001*	
Endoscopic response at Wk12	18 (12.2%)	215 (36.9%) Δ 25.2% P<.001*		5 (6.4%)	87 (29.0%) Δ 22.6% P<.001*		11 (18.0%)	113 (46.3%) Δ 27.7% P<.001*	
	PBO N=148	GUS 100mg ^c N=286	GUS 200mg ^d N=296	PBO N=78	GUS 100mg ^c N=153	GUS 200mg ^d N=147	PBO N=61	GUS 100mg ^c N=116	GUS 200mg ^d N=128
Clinical response at Wk12 + clinical remission at Wk48 (composite co-primary endpoint)	18 (12.2%)	137 (47.9%) Δ 35.8% P<.001*	152 (51.4%) Δ 39.0% P<.001*	10 (12.8%)	70 (45.8%) Δ 33.2% P<.001*	73 (49.7%) Δ 37.4% P<.001*	7 (11.5%)	60 (51.7%) Δ 40.4% P<.001*	70 (54.7%) Δ 41.8% P<.001*
Clinical response at Wk12 + endoscopic response at Wk48 (composite co-primary endpoint)	8 (5.4%)	104 (36.4%) Δ 30.7% P<.001*	110 (37.2%) Δ 31.8% P<.001*	4 (5.1%)	55 (35.9%) Δ 30.9% P<.001*	46 (31.3%) Δ 26.7% P<.001*	4 (6.6%)	47 (40.5%) Δ 33.0% P<.001*	56 (43.8%) Δ 36.5% P<.001*

Data are presented as n (%); Δ% (adjusted treatment difference) vs PBO; p-value vs PBO. Adjusted treatment differences and p-values were based on the common risk difference by use of Mantel-Haenszel stratum weights and the Sato variance estimator. The stratification variables used are baseline CDAI score (≤300 or >300), baseline SES-CD score (≤12 or >12), BIO-ir status (Yes or No; this variable used only in analyses of the overall population), and baseline corticosteroid use (Yes or No). Population N values reflect the primary analysis set, defined as all randomized participants who received at least 1 (partial or complete) dose of study intervention and had a screening SES-CD score ≥6 (or ≥4 for participants with isolated ileal disease). PBO pts not in clinical response at week (Wk) 12 switched to UST.

Endpoint definitions: clinical remission, CDAI < 150; endoscopic response, ≥50% improvement from baseline in SES-CD or SES-CD ≤ 2; clinical response, ≥100-point reduction from baseline in CDAI or CDAI < 150. Participants with treatment failure or missing data were considered to not have met the endpoint.

- a. Anti-TNF agents or vedolizumab
b. Participants assigned to either GUS 200mg IV every 4 weeks (q4w) (x3)→100mg SC q8w or GUS 200mg IV q4w (x3)→200mg SC q4w. At the Wk 12 assessment, GUS participants had only received GUS IV.
c. Participants assigned to GUS 200mg IV q4w (x3)→100mg SC q8w
d. Participants assigned to GUS 200mg IV q4w (x3)→200mg SC q4w
* Nominal p-value

Table. Efficacy of guselkumab (GUS) and placebo (PBO) for short- and long-term clinical and endoscopic endpoints in all participants and BIO-ir and BIO-naïve subgroups in the pooled GALAXI 2 & 3 dataset.

Conclusion: In pooled analyses of the double-blind GALAXI 2 & 3 trials, GUS was efficacious versus PBO in pts with CD regardless of prior biologic therapy exposure in both short-term (Wk12) endpoints and long-term (Wk12 + Wk48) composite endpoints.

Introduction: Phase III trials have demonstrated the efficacy of risankizumab (RZB), this being the first humanised monoclonal IgG1 antibody which targets the interleukin 23 p19 subunit, in moderate-to-severe Crohn's disease (CD). However, real-world data in induction with this drug is scarce. The aim of the study was to assess the real-world short-term effectiveness and safety of RZB in multi-refractory patients with CD.

Aims & Methods: Adult CD patients that had received induction doses with RZB in the ENEIDA registry—a large prospectively maintained Spanish database promoted by the Spanish Working Group in Crohn's and Colitis (GETECCU)—were included. Clinical and demographical data including number of previous biologics and advanced therapies were included. The primary endpoint was steroid-free clinical remission evaluated at any point between weeks 8 and 12 (Harvey-Bradshaw [HB] score <5). Secondary endpoints included steroid free clinical remission at the end of follow-up, clinical, biochemical improvement (C-reactive protein (CRP) and/or faecal calprotectin (FC)), need for CD-related surgery and adverse events related with the drug. The data are presented as median (range), and frequencies and percentages. Statistical analysis was performed using the Chi-square or Fisher's test, and the Student-*t* test or U-Mann-Whitney test as appropriate.

Results: 417 CD patients (52% male) were included: median age was 50 (18-84) years, median disease duration 14 years, 27% were smokers. Regarding Montreal classification, 49% were L1, 10% L2, and 38% L3. Most of the patients presented inflammatory pattern (47%), 32% presented structuring, 21% penetrating behavior and perianal disease was present in 24%. 48% had abdominal CD surgery and 41% presented extraintestinal manifestations. Only 8% received concomitant immunosuppressives with RZB. Regarding previous exposure to biologics or JAK inhibitors, only 3% were naïve, 49% had been exposed to 1-2 advanced therapies and 48% to 3 or more biologics or JAKs. After induction 58% of the patients achieved steroid-free clinical remission and at the end of the follow-up steroid-free clinical remission was observed in 62% of the patients. Median FC decreased from week 530 µg/g (week 0) to 333 µg/g after induction ($p < 0.001$). Regarding CRP, this decreased from median 7 mg/L at week 0 to 4.7 mg/L after induction ($p = 0.002$). 15 patients (3.5%) underwent intestinal resection. 23 patients (5.5%) presented adverse events including 6 infections.

Conclusion: This is the largest cohort study of real-world data with RZB,

and it includes highly refractory patients with CD and multiple prior drug failures. RZB induction provided a steroid-free clinical remission in nearly 60% of patients and a significative improvement in biomarkers. Safety was consistent with the known profile of RZB in previous trials.

Introduction: The safety and efficacy of mirikizumab (miri), an anti-IL-23p19 antibody, for moderately-to-severely active ulcerative colitis (UC) have been shown in Phase 3 trials (LUCENT-1 and -2; NCT03518086, NCT03524092). Extended induction with 3 additional intravenous (IV) doses of miri induced clinical response at Week (W)24 in more than 50% of patients who did not initially achieve clinical response to induction with miri at W12. Among the clinical non-responders, some had achieved partial response at W12 (Table 1).

We assessed response over time in clinical non-responders at the end of induction who received extended induction with miri for an additional 12W.

Aims & Methods: In LUCENT-1, patients (N=1281) were randomly assigned 3:1 to receive miri 300mg or placebo IV at W0, W4, and W8. Patients not achieving clinical response with miri 300mg IV at W12 of LUCENT-1 (n=272) received extended induction treatment with open-label miri 300mg IV at W12, W16, and W20 (LUCENT-2). Symptomatic remission, symptomatic response, bowel urgency (BU) remission, and BU change from baseline at W16 and W20 are reported (definitions in Table 1) in addition to the previously disclosed outcomes at W24.

For categorical variables, number and percentage of patients who are responders/remitters were presented. For continuous variables, mean change from baseline with standard deviation (SD) was used. Missing data were imputed as non-response.

Results: Among patients who were clinical non-responders to 12W of initial induction treatment (n=272), 53 (19.5%); 73 (26.8%); 101 (37.1%) achieved symptomatic remission and 144 (52.9%); 169 (62.1%); 197 (72.4%) patients achieved symptomatic response at W16, W20, and W24, respectively.

Among miri induction non-responders with Urgency Numeric Rating Scale (NRS) score ≥ 3 at induction baseline (n=256), 10.9% achieved BU remission at W16, 14.8% at W20, and 19.9% at W24. There was a 1.8 ± 2.4 (mean $\pm$ SD) point reduction in Urgency NRS scores at W16, 2.1 ± 2.5 reduction at W20, and 2.5 ± 2.7 reduction at W24 (Table 1).

Outcomes for miri IV extended induction	W12 (W0 extended induction)	W16 (W4 extended induction)	W20 (W8 extended induction)	W24 (W12 extended induction)
	Miri induction non-responders* 300 miri IV, Q4W N= 272	Miri induction non-responders* 300 miri IV, Q4W N= 272	Miri induction non-responders* 300 miri IV, Q4W N= 272	Miri induction non-responders* 300 miri IV, Q4W N= 272
Clinical response ^b	0	n/a	n/a	146 (53.7)
Symptomatic remission ^c	13 (4.8)	53 (19.5)	73 (26.8)	101 (37.1)
Symptomatic response ^d	83 (30.5)	144 (52.9)	169 (62.1)	197 (72.4)
BU remission ^e (Nx= 256)	18 (7.0)	28 (10.9)	38 (14.8)	51 (19.9)
BU change from baseline ^f [mBOCF; mean (SD)]	-1.2 (2.2)	-1.8 (2.4)	-2.1 (2.5)	-2.5 (2.7)

Data reported as n (%) unless otherwise indicated.
Abbreviations: BU=bowel urgency; IV=intravenous; mBOCF=modified baseline observation carried forward; miri=mirikizumab; N=patient population; n=patient subpopulation; Nx=number of patients with Urgency Numeric Rating Scale ≥3 at induction baseline; Q4W= every four weeks; SD=standard deviation; W=week
*The miri induction non-responder population only included patients who continued to the maintenance trial (LUCENT-2)
^bDefined as ≥2-point and ≥30% decrease in Modified Mayo Score from baseline; rectal bleeding =0 or 1 or ≥1-point decrease from baseline
^cDefined as stool frequency =0 or stool frequency =1 with ≥1-point decrease in Modified Mayo Score from baseline; rectal bleeding=0
^dDefined as at least a 30% decrease from baseline in the composite clinical endpoint of the sum of stool frequency and rectal bleeding subscores
^eDefined as Urgency Numeric Rating Scale score=0 or 1
^fChange from baseline in Urgency Numeric Rating Scale score; range 0 to 10; a lower score indicates less severe bowel urgency

Table 1. Clinical outcomes for the mirikizumab induction non-responder patient population.

Conclusion: Among patients who were clinical non-responders to induction at W12, more than 50% achieved clinical response after 3 additional induction doses with miri. A proportion of patients benefited earlier from extended induction at W16 and W20, respectively, regarding symptomatic response and remission, and BU outcomes. The results demonstrate continued symptomatic improvement and further support the potential benefit of extended induction treatment.

Contact E-Mail Address: thisamatsu@ks.kyorin-u.ac.jp
Introduction: The QUASAR program (NCT04033445) evaluated guselkumab (GUS), a dual-acting interleukin (IL)-23p19 subunit inhibitor that potentially neutralizes IL-23 and binds to CD64 (a receptor on cells that produce IL-23), in patients (pts) with moderately to severely active ulcerative colitis (UC). Induction Week 12 (Week I-12) nonresponders to intravenous (IV) GUS received subcutaneous (SC) GUS through Week I-24.¹ Week I-24 responders were eligible for maintenance therapy. Here, we present the efficacy and safety of maintenance SC GUS among GUS Week I-24 responders.

Aims & Methods: Pts who were not in clinical response (see Table for definition) at Week I-12 after IV GUS 200 mg or 400 mg received SC GUS 200 mg at Weeks I-12, I-16, and I-20. Those who were in clinical response at Week I-24 (GUS Week I-24 responders) received SC GUS 200 mg every 4 weeks during the maintenance study in a blinded fashion and were evaluated as part of the nonrandomized study population. Clinical, symptomatic, endoscopic, histologic, and patient-reported outcome measures at maintenance Week 44 (Week M-44) and safety throughout the maintenance study are reported for GUS Week I-24 responders.

Results: Overall, 123 of 203 (60.6%) Week I-12 nonresponders to IV GUS achieved clinical response at Week I-24 and entered the maintenance study phase. Induction baseline characteristics of GUS Week I-24 responders were: 74.8% had severe disease (modified Mayo score 7-9), 77.2% had a Mayo endoscopy subscore of 3, median C-reactive protein was 5.0 mg/L (upper limit of normal, 3 mg/L), and 59.3% had a history of inadequate response or intolerance to biologic or Janus kinase inhibitor therapy for

UC. At Week M-44, 67.5% of the pts maintained clinical response and 30.1% were in clinical remission. Additional efficacy outcomes are shown in the Table. The proportion of GUS Week I-24 responders in symptomatic remission (defined as a stool frequency subscore of 0 or 1 and not increased from induction baseline, and a rectal bleeding subscore of 0) at maintenance baseline (58.5%) was sustained through Week M-44 (56.9%). Adverse events (AEs) were reported for 78.0% of GUS Week I-24 responders, serious AEs for 5.7%, and serious infections for 1.6%. No opportunistic infections or deaths occurred. No new safety concerns were identified.

	GUS 200 mg SC q4w N=123 n (%)
Clinical remission ^b	37 (30.1)
Endoscopic improvement ^c / Endoscopic normalization (remission) ^d	44 (35.8) / 21 (17.1)
Corticosteroid-free clinical remission ^e	37 (30.1)
Maintenance of clinical response ^f	83 (67.5)
Histologic-endoscopic mucosal improvement ^g	34 (27.6)
Fatigue response ^h	49 (39.8)
Maintenance of clinical remission ⁱ , N=20	10 (50.0)

GUS=guselkumab; PROMIS=Patient-Reported Outcomes Measurement Information System; pts=patients; q4w=every 4 weeks; SC=subcutaneous; Week M-44=maintenance Week 44.

Note: Includes only pts with modified Mayo score 5-9 at induction baseline.

^a Clinical response was defined as a decrease from induction baseline in the modified Mayo score by $\geq 30\%$ and ≥ 2 points, with either a ≥ 1 -point decrease from induction baseline in the rectal bleeding subscore or a rectal bleeding subscore of 0 or 1.

^b Clinical remission was defined as a Mayo stool frequency subscore of 0 or 1 and not increased from induction baseline, a Mayo rectal bleeding subscore of 0, and a Mayo endoscopy subscore of 0 or 1 with no friability present on the endoscopy.

^c Endoscopic improvement was defined as an endoscopy subscore of 0 or 1 with no friability present on the endoscopy.

^d Endoscopic normalization (remission) was defined as an endoscopy subscore of 0.

^e Corticosteroid-free clinical remission was defined as clinical remission at Week M-44 without any use of corticosteroids for ≥ 8 weeks prior to Week M-44.

^f Maintenance of clinical response was defined as clinical response at Week M-44 among pts in clinical response at maintenance baseline.

^g Histologic-endoscopic mucosal improvement was defined as achieving a combination of histologic improvement (defined as neutrophil infiltration in $<5\%$ of crypts, no crypt destruction, and no erosions, ulcerations or granulation tissue according to the Geboes grading system [i.e., Geboes score ≤ 3.1]) and endoscopic improvement.

^h Fatigue response was defined as a ≥ 7 -point improvement from induction baseline in the PROMIS Fatigue Short Form 7a.

ⁱ Maintenance of clinical remission was defined as clinical remission at Week M-44 among pts in clinical remission at maintenance baseline.

Table. Efficacy Outcomes at Maintenance Week 44 for GUS Induction Week 12 Nonresponders Who Achieved Clinical Response^a at Induction Week 24.

Conclusion: In this refractory population of GUS Week I-24 responders, maintenance treatment with GUS provided clinical benefit across a range of clinically relevant efficacy endpoints. Safety results were consistent with the overall population and safety profile of GUS in its approved indications.

Introduction: Mirikizumab, an anti-IL-23p19 antibody, has demonstrated efficacy and safety in moderately-to-severely active ulcerative colitis (UC) Phase 3 trials (LUCENT-1 and -2; NCT03518086, NCT03524092). A treatment goal for patients with UC is corticosteroid (CS)-free remission. We assessed the CS-sparing effect of mirikizumab among the extended induction patient population receiving CS at induction baseline.

Aims & Methods: In LUCENT-1, patients in the modified intention to treat mirikizumab group (n=868) received mirikizumab 300 mg intravenously (IV) at Week (W)0, W4, and W8. Patients receiving mirikizumab on CS at baseline (n=351) remained on their stable baseline dose (prednisone ≤20 mg/day or equivalent, budesonide MMX 9 mg/day, or beclomethasone 5 mg/day) during induction (W0 to W12).

Patients not achieving clinical response (≥2-point and ≥30% decrease in Modified Mayo Score from baseline; and rectal bleeding=0 or 1, or ≥1-point decrease from baseline) at W12 (n=272) entered LUCENT-2 open label (OL) extended induction and received 300 mg mirikizumab IV at W12, W16, and W20.

Extended induction responders at W24 (n=144) entered OL maintenance and received 200mg mirikizumab subcutaneously (SC) Q4W until W52. CS taper was initiated if clinical response was achieved at W24 or earlier based on investigator discretion if symptomatic improvement was evident.

Patients who discontinued CS and remained off throughout the study were considered "discontinued." Descriptive statistics for efficacy outcomes were summarized. Missing data were imputed as non-response.

Results: Of the 272 mirikizumab patients in the extended induction population, 118 received CS at induction baseline.

The mean prednisone equivalent dose was 15mg. At W24, among the 62/118 (52.5%) who achieved clinical response and continued with maintenance, 8 (12.9%) discontinued CS, 2 (3.2%) achieved clinical remission off CS, and 8 (12.9%) achieved symptomatic remission off CS.

At W52, 43/62 (69.4%) of the extended induction responders discontinued CS, 18 (29.0%) achieved clinical remission off CS, and 37 (59.7%) achieved symptomatic remission off CS. Among patients with non-missing data who completed W52 of mirikizumab treatment, 89.6% had discontinued CS (Table).

		Mirikizumab Extended Induction Responders ^a (N=62)	
		Observed n/Nx (%)	NRI n (%)
Week 24	Clinical remission ^b and off CS	2/62 (3.2)	2 (3.2)
	Symptomatic remission ^c and off CS	8/62 (12.9)	8 (12.9)
	Discontinued CS ^d	8/53 (15.1)	8 (12.9)
Week 52	Clinical remission ^b and off CS	18/50 (36.0)	18 (29.0)
	Symptomatic remission ^c and off CS	37/52 (71.2)	37 (59.7)
	CS-free remission ^e	16/49 (32.7)	16 (25.8)
	Discontinued CS ^d	43/48 (89.6)	43 (69.4)

Abbreviations: CS=corticosteroid; N =number of patients in analysis population; n=number of patients in the specified category; NRI=non-responder imputation; Nx=number of patients with non-missing values

^a Patients without response at week 12 treated with mirikizumab extended induction and responded at week 24. Clinical response defined as ≥2-point and ≥30% decrease in Modified Mayo Score from baseline; and rectal bleeding=0 or 1, or ≥1-point decrease from baseline

^b Defined as stool frequency subscore=0 or 1 with ≥1-point decrease from induction baseline, a rectal bleeding subscore=0, and an endoscopic subscore=0 or 1 (excluding friability)

^c Defined as stool frequency subscore=0 or 1 with ≥1-point decrease from induction baseline, a rectal bleeding subscore=0

^d Patients discontinued CS and remained off through Week 52

^e Clinical remission at Week 52 + symptomatic remission at Week 40 + off CS for ≥12 weeks

Table. Corticosteroid-Sparing Effect of Mirikizumab in Extended Induction Population Receiving Corticosteroids at Induction Baseline

Conclusion: Nearly 70% of extended induction responders discontinued CS by W52. CS-sparing effect of mirikizumab in patients with moderately-to-severely active UC is clinically meaningful and aligns with the treatment goal of CS discontinuation.

Introduction: Limiting exogenous fat intake is proposed as a preventive measure against obesity^[1]. Despite the elucidation of the molecular process of fatty acid uptake in enterocytes, there is no specific inhibitor that has been proven to effectively prevent obesity by inhibiting fatty acid absorption. Sterol O-acyltransferase 2 (SOAT2) is an enzyme responsible for esterifying free cholesterol and fatty acids into cholesteryl esters^[2,3]. Evidence suggests the importance of intestinal SOAT2 in controlling dietary fatty acid absorption, hinting that targeting intestinal SOAT2 could be a promising approach to modulating the incidence of diet-induced obesity. Nanoparticles are vehicles that augment the efficacy of drug delivery and therapy^[4-7]. A novel nanoparticle system specifically designed to deliver SOAT2 siRNAs into the small intestine would be a promising therapeutic option to modulate intestinal fatty acid uptake and prevent obesity.

Aims & Methods: The role of intestinal SOAT2 in obesity was evaluated using intestine-specific SOAT2 knockout (*Soat2*^{-/-KO}) mice through biochemical analyses, isotopic tracer methods, fluorescent palmitic acid assays, and western blot. Subsequently, a novel nanoparticle system composed of poly (D, L-lactic-co-glycolic acid)-block-polyethylene glycol (PLGA-b-PEG) polymer as the core and chitosan (CS) shell, which serves as a protective layer against stomach acid, was developed to facilitate intestinal delivery and *Soat2* inhibition. Mice were orally administered SOAT2 siRNA/CS-PLGA nanoparticles to evaluate their therapeutic efficacy against obesity. To elucidate the underlying mechanisms of how intestinal SOAT2 regulates fatty acid uptake, a SOAT2 knockdown Caco-2 (shSOAT2) cell model was established. Fatty acid uptake, immunofluorescence, mRNA expression profiling, siRNA library screening, subcellular distributions, and ubiquitination of CD36 protein were employed in shSOAT2 cells to assess the ubiquitination and degradation of CD36. Co-immunoprecipitation, immunofluorescence, and western blot were carried out to explore the underlying mechanism by which SOAT2 knockdown regulates CD36 ubiquitination.

Results: *Soat2*^{-/-KO} mice were capable of preventing the development of dietary-induced obesity due to reduced intestinal lipid absorption. Then, the *Soat2* siRNA/CS-PLGA nanoparticle system can specifically deliver SOAT2 siRNAs into the small intestines of mice and effectively inhibit intestinal lipid uptake, thus resolving obesity. In revealing the underlying mechanism by which intestinal SOAT2 regulates fatty acid uptake, we found enhanced CD36 ubiquitination and degradation in enterocytes upon SOAT2 inhibition. Insufficient free cholesterol esterification promotes endoplasmic reticulum stress and the recruitment of E3 ligase RNF5, which activates CD36 ubiquitination in SOAT2 knockdown enterocytes.

Conclusion: The SOAT siRNA/CS-PLGA nanoparticle system offers advantages such as being non-invasive, having low systemic toxicity, and ensuring higher compliance. Our work shows the promising translational relevance of intestinal-specific SOAT2 siRNA-based therapy to prevent obesity. Although SOAT2 is known as a regulator of cholesterol homeostasis, our data provide additional evidence for the role and mechanism of SOAT2 in regulating intestinal fatty acid absorption, suggesting that inhibition of this enzyme might serve as 'a stone to hit two birds'.

EFFECTS OF ORAL XYLITOL ON SUBSEQUENT ENERGY INTAKE, GASTROINTESTINAL HORMONES AND GLYCEMIC CONTROL IN HEALTHY ADULTS

E. Flad^{1,2}, A. Altstaedt^{1,2}, J.F. Rehfeld³, C. Beglinger⁴, L. Van Oudenhove⁵, B.K. Wölnerhanssen^{1,2}, A.C. Meyer-Gerspach^{1,2}

Introduction: As sugar consumption contributes to the development of metabolic disease including obesity and type 2 diabetes, a reduction in daily sugar consumption has been proposed as preventive and therapeutic strategy by the World Health Organization [1].

Artificial low-caloric high-intensity sweetener, e.g. acesulfame potassium (ace-K), are often used to replace sugar as they provide sweetness without calories. However, they do not stimulate the secretion of gastrointestinal (GI) satiation hormones and thus lack a satiating effect. Xylitol, a natural low-caloric bulk sweetener, has gained popularity as sugar alternative by offering beneficial properties such as being low-glycemic and low-insulinemic while preserving sweet taste and stimulating the secretion of GI satiation hormones [2].

The effect of orally administered xylitol on subsequent energy intake is not yet known.

Aims & Methods: Therefore, the objective of this study was to investigate the effect of an oral administration of xylitol compared to sucrose, ace-K and tap water on total energy intake during an *ad libitum* test meal, the secretion of GI satiation hormones and glycemic control.

In this randomized, controlled, double-blind crossover trial, 20 healthy adults with normal weight [age: 27.45 ± 7.86 years, BMI: 23.04 ± 1.41 kg/m² (mean $\pm$ SD)] received oral preloads containing either 33.5 g xylitol, 33.5 g sucrose, 0.1675 g ace-K dissolved in 300 mL water or 300 mL pure water in four different study visits. Fifteen minutes later, participants were served an *ad libitum* test meal where they were allowed to consume as much as they want for 20 minutes. Total energy intake was assessed by calculating the calories of the preloads and weighing food and drinks before and after the test meal.

Additionally, blood samples were collected at fixed time points to measure plasma cholecystokinin (CCK), glucagon-like peptide-1 (GLP-1), glucose and insulin concentrations.

Results: The results show that total energy intake was significantly lower after xylitol and ace-K compared to sucrose ($p_{\text{Tukey}} = 0.03$ and $p_{\text{Tukey}} < 0.01$, respectively), with no differences between xylitol and ace-K or water ($p_{\text{Tukey}} = 0.93$ and $p_{\text{Tukey}} = 1.00$, respectively). Plasma CCK concentrations increased significantly after xylitol and sucrose (for both, $p_{\text{Tukey}} < 0.01$), but not after water ($p_{\text{Tukey}} = 0.35$), with a significantly higher increase after xylitol compared to sucrose, ace-K or water (for all comparisons, $p_{\text{Holm}} < 0.01$). Plasma GLP-1 concentrations increased significantly after xylitol and sucrose ($p_{\text{Tukey}} = 0.02$ and $p_{\text{Tukey}} = 0.03$, respectively), but not after ace-K or water ($p_{\text{Tukey}} = 0.19$ and $p_{\text{Tukey}} = 0.39$, respectively), with no significant differences between xylitol and sucrose, ace-K or water (for all comparisons, $p_{\text{Holm}} = 0.66$). Plasma glucose concentrations increased significantly after sucrose ($p_{\text{Tukey}} < 0.01$), but not after xylitol, ace-K or water (for all, $p_{\text{Tukey}} = 0.34$, $p_{\text{Tukey}} = 0.86$ and $p_{\text{Tukey}} = 0.75$, respectively), with no significant differences between xylitol and ace-K or water (for both comparisons, $p_{\text{Holm}} = 0.46$). Plasma insulin concentrations increased significantly after sucrose ($p_{\text{Tukey}} = 0.01$), but not after xylitol, ace-K or water ($p_{\text{Tukey}} = 0.08$, $p_{\text{Tukey}} = 0.89$ and $p_{\text{Tukey}} = 1.00$, respectively), with no significant differences between xylitol and sucrose, ace-K or water (for all comparisons, $p_{\text{Holm}} = 0.27$).

Conclusion: An oral preload with xylitol prior to an *ad libitum* test meal induces the release of CCK and results in reduced total energy intake compared to an oral preload with sucrose.

DURABLE EFFECTS OF DUODENAL ABLATION USING ELECTROPORATION COMBINED WITH SEMAGLUTIDE TO ELIMINATE INSULIN THERAPY IN PATIENTS WITH TYPE 2 DIABETES; THE 24-MONTH RESULTS

C.B.E. Busch¹, K. van den Hoek¹, A. van Baar¹, S. Meiring¹, F. Holleman², M. Nieuwdorp³, J.J. Bergman¹

Introduction: Progressive hyperglycemia in type 2 diabetes (T2D) leads to the need for exogenous insulin therapy in many patients, which is associated with weight gain and hypoglycemia. Studies have shown that hydrothermal duodenal mucosal ablation improves glycemic control by improving insulin resistance. Re-Cellularization via Electroporation Therapy (ReCET) is a novel endoscopic procedure that uses electroporation to

induce duodenal mucosal renewal. This technology uses pulsed electric fields to induce natural cell death through an apoptosis-like process without generating heat, thereby eliminating the risk of thermal damage to deeper layers of the duodenum.

In this study, we aimed to eliminate insulin treatment in T2D patients with a single ReCET procedure combined with a GLP-1 receptor agonist (GLP-1RA, semaglutide). Here, we present our 24-month results.

Aims & Methods: Single-arm, single-center, first-in-human study in 14 patients with T2D (28-75 years, body mass index (BMI) 24-40 kg/m², glycosylated hemoglobin (HbA1c) $\leq 8.0\%$, basal insulin dose $< 1\text{U/kg/day}$, C-peptide ≥ 0.2 nmol/L). All patients underwent the ReCET procedure under deep sedation followed by a 2-week isocaloric liquid diet. Thereafter, semaglutide was titrated up to 1 mg/week. Primary feasibility endpoints were procedure time (catheter in-out), technical success, and % of patients tolerating GLP-1RA. Primary safety endpoints were (serious) adverse events ([S]AEs) and hypoglycemic events. Efficacy endpoint was the percentage of patients off exogenous insulin at 6 months while maintaining HbA1c $\leq 7.5\%$. Baseline and follow-up glycemic and metabolic data and treatment satisfaction scores were assessed.

Results: The technical success rate of the ReCET procedure was 100% (14/14 patients) with a median axial treatment length of 12cm. The median procedure time was 58 minutes (IQR 49–79). No device-related SAEs or severe hypoglycemic events were observed. The maximum dose of semaglutide was tolerated by 13 (93%) patients. At 6 and 12 months, 12 (86%) patients were still not using insulin, yet showed significant improvements in glycemic control (HbA1c) and metabolic parameters (Table 1). Eleven patients completed the 24-month follow-up; one patient withdrew consent after 18 months while in good glycemic control. All eleven remained off insulin with adequate glycemic control.

	Baseline	6 months	p-value	12 months*	p-value	18 months	p-value	24 months	p-value

Liver fat fraction, %	9.2 (6.0 - 15.4)	6.3 (4.3 - 10.5)	0.030	4.2 (3.0 - 10.0)	0.016	NA	NA	3.9 (1.8 - 9.8)	0.006

Table 1. Glycaemic and metabolic secondary endpoints. Values are presented as median (interquartile range). Differences between the baseline, 6, 12, 18 and 24 months data were assessed using the Wilcoxon signed-rank paired test. *One patient was excluded due to steroid use.

**One patient was excluded since GLP1-RA was discontinued once sensor was placed.

Conclusion: These results suggest that duodenal ReCET is feasible and safe. Combined with semaglutide, ReCET eliminated the need for insulin therapy in 86% of patients until 12 months post-treatment while improving glycaemia and metabolic health. Patients who were off exogenous insulin at 12 months had a durable glycaemic response and remained insulin-free at 24 months.

Disclosure: Unrestricted research grant from Endogenex.

Introduction: DA is a promising disease-modifying endoscopic treatment for type 2 diabetes (T2D), which targets hypertrophied duodenal mucosa. The FDA-cleared RFVA system (Aqua Medical Inc., Pleasanton, CA) is an emerging technique for DA. This is a single-use, through-the-scope (10.5 FR), circumferential ablation catheter, and an electrosurgical generator that uses RF energy to convert saline into heated vapor at the catheter tip which is released into the duodenum creating a 2 cm treatment zone. The ablation is performed under direct visualization without fluoroscopy. We investigated the RFVA system in a first-in-human pilot dose-escalation study,

Aims & Methods: We aimed to assess the safety, tolerability, and efficacy of RFVA for DA in patients with T2D (NCT05887635). This was a prospective single-centre study enrolling 27 patients with uncontrolled T2D (glycated hemoglobin (HbA1c) 7.5-10%) despite ≥1 oral antidiabetic drug (OAD). DA was performed under general anaesthesia after a 4-week run-in period to ensure stable glycaemic control.

Patients were admitted overnight and given a modified post-procedure diet for 14 days. The ablation targeted ≥9 cm of the post-ampullary duodenal mucosa. The initial RFVA dose was 180 J single application (n=2). Once acute safety was established the next patients received 180 J double application (n=11).

After establishing chronic safety over four weeks, the final patients received 200 J double application (n=14). The primary outcomes were change in HbA1c at 12- and 24-weeks, and the number of serious adverse events (SAE).

Results: Twenty-seven patients with a mean (SD) T2D duration of 6 years (2.6) underwent DA. The mean age was 54 years (6.6), 48.2% were male, and the mean baseline BMI was 30.3 kg/m² (4.2). The baseline HbA1c was 8.5% (0.7) and fasting glucose was 8.9 mmol/L (2.6). The technical success of DA was 100%.

The mean number of ablations delivered per patient was 5 (180 J single), 14 (180 J double), and 18 (200 J double). In the second half of the cohort, the mean endoscopy time was 43.6 minutes (9.2), catheter time was 30.6 minutes (7), and ablation length was 14.3 cm (1.8).

The change in HbA1c at 4 weeks and 12 weeks was -0.9% (0.9; p<0.001) and -1.2% (1.1; p<0.0001), respectively without change in OADs (Table 1). At 12 weeks, 80% (n=20) undergoing double application had a >0.5% reduction in HbA1c. All patients were discharged the next day with no SAE or unanticipated device-related events. There were no episodes of severe hypoglycaemia.

Abdominal pain was the most common, self-limiting adverse event with five deemed mild and two moderate (requiring temporary oral antispasmodics). A 4-week follow-up endoscopy and duodenal biopsy (n=27) showed no stricture and normal mucosal histology.

Change at 12 weeks (double application)	Mean change (SD)*	P value†
HbA1c - %	-1.2 (1.1)	<0.001
Fasting fingerstick glucose - mmol/L	-1.8 (1.9)	<0.001
Post-prandial fingerstick glucose - mmol/L	-3.5 (2.4)	<0.001
Fasting blood glucose - mmol/L	-1.5 (2.3)	=0.003
HOMA-IR	-1.1 (2.0)	=0.016
Weight - kg	-2.4 (5.0)	=0.024
Body mass index - kg/m ²	-0.9 (1.9)	=0.024

*Compared to baseline values

†Data analysed using t-test

Table 1 – Clinical outcomes for patients undergoing duodenal ablation.

Conclusion: DA using RFVA is a safe, well-tolerated, and relatively quick endoscopic procedure for the management of poorly controlled T2D. Early efficacy data shows a clinically significant reduction in HbA1c at 4- and 12-weeks.

Introduction: Obesity, characterised by excessive body fat accumulation, not only undermines physical health but also poses significant risks to mental well-being. Recent evidence has demonstrated the substantial benefits of Semaglutide in promoting weight loss among individuals with diabetes. Semaglutide, a glucagon-like peptide-1 (GLP-1) receptor agonist, not only aids in glycaemic control but has also shown remarkable efficacy in reducing body weight.

Therefore, in this study, we investigated the effect of oral Semaglutide on weight loss in individuals with overweight or obesity but without diabetes mellitus.

Aims & Methods: The aim of the study was to evaluate the effectiveness and safety of oral Semaglutide when combined with dietary and lifestyle modifications, compared to dietary and lifestyle modifications alone, for the treatment of overweight or obesity in adults without type 2 diabetes. This randomized controlled trial was conducted in the department of Gastroenterology, Asian Institute of Gastroenterology, Hyderabad from June 2022 to December 2023. Consecutive consenting patients of both genders aged 18 years or older with either a BMI of 30 or greater or a BMI of 27 or greater with one or more treated or untreated weight-related coexisting conditions (i.e., prediabetes, hypertension, dyslipidemia, obstructive sleep apnea, or cardiovascular disease).

All the eligible participants after screening were randomized into two groups (Group 1 and 2) by block randomization (block size of 4 and 6) using computer generated random number. Participants in both groups received individual counselling sessions to help them adhere to a re-

duced-calorie diet (500- kcal deficit per day relative to the energy expenditure estimated at the time) and increased physical activity (with 150 minutes per week of physical activity, such as walking). Participants in group 1 also received oral Semaglutide along with diet and exercise. Treatment was initiated with the 3 mg once-daily dose.

The dose was increased to 7 mg and then maximum of 14mg per day in 2-4 weeks interval based on patient tolerance. Participants were assessed for gastrointestinal complaints (nausea, vomiting) during escalation and follow-up. (ClinicalTrials.gov ID: NCT05442450)

Results: A total of 116 (58 per each group) individuals were recruited into the study. Mean percentage(SD) change in body weight from baseline to week 28 was - 10.47% (SD 5.3) with Oral Semaglutide versus 2.4 (SD 4.5) with dietary and lifestyle changes alone ($p < 0.001$). The mean weightloss noted with Semaglutide was 9.19kg (SD 4.7) compared to 2.3kg (SD 4.5) with dietary and lifestyle measures alone. Subjects who received oral Semaglutide have reported >5%, >10%, >15% and >20% weightloss in 51/58 (87%), 28/58 (48%), 13/58 (22.4%) and 4/58 (6.9%) respectively. Subjects received only dietary and lifestyle changes have lost >5% of baseline weight in 14/58 (24%), >10% in 6/58 (10.34%) and none lost more than 15% of baseline weight.

Similarly, body mass index, waist circumference, HbA1C, fasting insulin and CRP were significantly improved with combination of Semaglutide with lifestyle measures. ($p < 0.001$). Body composition analysis revealed a significant change in body fat mass of -7.3 kg (4.8%) with maintained muscle mass in patients who received oral Semaglutide compared to those who underwent diet alone. Adverse events include severe nausea and vomiting noted in the three patients receiving the oral Semaglutide requiring discontinuation of the drug.

Conclusion: In adults with overweight or obesity but without type 2 diabetes, oral Semaglutide combined with dietary and lifestyle modifications resulted in a significant and clinically meaningful reduction in body weight compared to dietary and lifestyle modifications alone.

ELUCIDATING THE NON-CANONICAL ROLES OF STK3 IN THE CROSSTALK BETWEEN HIPPO AND WNT SIGNALING PATHWAY

F. Xie¹, W. Kang¹, B. Chen¹, Y. Lyu¹, D. Leung¹, K.F. To¹

¹The Chinese University of Hong Kong, Department of Anatomical and Cellular Pathology, State Key Laboratory of Translational Oncology, Li Ka Shing Institute of Health Science, Sir Y.K. Pao Cancer Center, Hong Kong, Hong Kong

Contact E-Mail Address: xiefuda@link.cuhk.edu.hk

Introduction: Serine/Threonine Kinase 3 (STK3) is conventionally recognized as a key regulator in the Hippo pathway. Activation of STK3/4 initiates the phosphorylation of Lats1/2 and subsequently YAP1, leading to its degradation. While STK3 has traditionally been acknowledged as a tumor suppressor in various cancer types, recent studies have revealed its oncogenic role in the development of gastric cancer (GC). Intriguingly, the intricate mechanisms underlying the non-canonical functions of STK3 remain largely uncharted.

Aims & Methods: In this study, our objective is to elucidate the upregulation pattern and the specific mechanisms of STK3 in advancing gastric tumorigenesis. The regulatory influence of YAP1 on STK3 was assessed through a combination of RNA-sequencing (RNA-seq), western blot, and ChIP-qPCR assays. This relationship was subsequently validated using gene knockout mouse models and rescue assays involving colony formation and invasion activity testing. The clinical correlation between YAP1 and STK3 was validated by both online datasets and immuno-histochemistry (IHC) of tissue microarrays.

Furthermore, RNA-seq and TCGA-based functional enrichment analysis were employed to predict the oncogenic roles of STK3, supported by single-cell RNA-seq GSVA analysis. These predicted outcomes were confirmed through siRNA-mediated functional assay including spheroid formation and organoid growth assays.

The downstream target of STK3 was identified via RNA-seq and western blot analysis, with further validation carried out through co-immunoprecipitation and immunofluorescence. The *in vivo* functions of STK3 were demonstrated by subcutaneous xenograft formation and peritoneal metastasis models.

Results: STK3 expression was reduced by siRNA-mediated YAP1 deletion at both mRNA and protein levels. Treatment with YAP1 inhibitors led to a dose-dependent inhibition of STK3 expression.

Notably, MNNG-induced tumors in *Yap^{-/-}/Taz^{-/-}* mice showed no STK3 expression. The deletion of STK3 resulted in a partial attenuation of the oncogenic activity of YAP1. Concurrent elevation of YAP1 and STK3 was detected across multiple online datasets and our in-house cohort.

Bioinformatic analysis revealed that STK3 would participate in DNA damage response and stemness acquisition processes. Knockdown of STK3 led to reduced sphere formation ability, xenograft size, and expression levels of stemness markers.

Deletion of STK3 increased the sensitivity of GC organoids and xenografts to 5-fluorouracil treatment, resulting in decreased organoid sizes, limited metastasis, and downregulation of tumor malignancy markers. Activation of the Wnt pathway and the downstream stemness regulators were strongly associated with the upregulation of STK3.

Deletion of STK3 reduced the levels of phosphorylated GSK-3 β and prevented the nuclear accumulation of β -catenin. Co-IP assays revealed the directly interaction between STK3 and GSK-3 β . IHC staining of mouse xenografts confirmed the *in vivo* inhibition of Wnt signaling following STK3 deletion.

Conclusion: Our study investigated the upregulation mechanism and non-canonical oncogenic roles of STK3 in the progression of GC. YAP1, a typical downstream component in the Hippo pathway, was demonstrated to transcriptionally activate STK3 expression.

Meanwhile, this work also identified STK3 as a promoter of DNA repair and stemness acquisition through activation of the GSK-3 β / β -catenin axis, shedding light on the diverse functional patterns of Hippo signaling in GC progression.

Disclosure: Nothing to disclose.

Introduction: In up to 40% of gastro-oesophageal reflux disease (GERD) patients, heartburn symptoms persist despite PPI treatment. This may be due to exposure of the oesophageal mucosa to other refluxate components such as weakly acidic (pH5) bile salts, leading to oxidative stress in epithelial cells and micro-inflammation, potentially resulting in release of mediators which activate sensory nerve fibres. High mobility group box 1 (HMGB1) is a nuclear protein found in oesophageal epithelial cells, which is actively secreted during cellular oxidative stress. Once released, HMGB1 binds to receptors including TLR2, TLR4, and RAGE to induce NF- κ B-mediated inflammatory signalling. We aimed to determine the mechanism of release and potential downstream impacts of HMGB1 in GERD.

Aims & Methods: Oesophageal biopsies were obtained from consented healthy volunteers (n=10) and GERD patients categorised as functional heartburn (FH; n=7), non-erosive reflux disease (NERD; n=13), and erosive reflux disease (ERD; n=13) based on clinical assessment. Biopsies were analysed by bulk RNA-sequencing to determine commonly up-regulated genes between NERD and ERD patients compared to HC. Protein expression of TLR2, TLR4, and RAGE was assessed with immunohistochemistry. NE-1 cells were challenged with pH5 media and/or 500 μ M deoxycholate (DCA), and pre-treated with 50 μ M curcumin, for 2 hours. Cellular translocation of HMGB1 over 10 minutes was measured with immunofluorescence and release of HMGB1 over 20 minutes was measured with ELISA.

Results: Bulk RNA-seq revealed that HMGB1 is one of 11 commonly over-expressed genes in NERD and ERD compared to HC (adjusted $p < 0.01$). Compared to pH7, incubating NE-1 cells at pH5 or DCA alone did not induce HMGB1 release or nuclear translocation, however, the combination of pH5 and DCA caused HMGB1 translocation, represented as increased cytosolic:nuclear fluorescence ratio ($p < 0.0001$). Similarly, HMGB1 release from cells was induced only in response to pH5 + DCA ($p < 0.01$). Pre-treatment with the antioxidant curcumin ameliorated increase in HMGB1 cytosolic:nuclear ratio ($p < 0.001$) and ablated HMGB1 release ($p < 0.05$) caused by weakly acidic bile salts. TLR2 and TLR4 were expressed on oesophageal epithelial cells. Expression of TLR2 was not altered between GERD phenotypes and HCs. Whereas, the percentage of DAPI+ cells which were TLR4+ ($P < 0.05$), as well as fluorescence intensity of TLR4 ($p < 0.05$) in the oesophageal mucosa was higher in ERD compared to HC. RAGE was rarely but exclusively expressed on CD45+ cells located both intra-epithelially and in mucosal papillae.

The number of RAGE+CD45+ cells/field of view was higher in ERD oesophageal mucosa compared to HC ($p < 0.05$). In NERD and ERD patients, a proportion of RAGE+ cells were in close apposition to CGRP+ nerve fibres in papillae of the oesophageal mucosa.

Conclusion: The induction of HMGB1 release from oesophageal epithelial cells by weak acid (pH5) and bile salts –which is inhibited by the antioxidant curcumin describes a novel molecular pathway and new treatment target for GERD. Indeed, increased expression of the HMGB1 receptor, TLR4, in the oesophageal mucosa of ERD patients provides further evidence that this pathway is highly relevant to GERD pathophysiology. The expression of HMGB1 receptor RAGE in CD45+ cells and association with sensory nerve fibres further supports HMGB1 as a potential molecular target for future development.

Introduction: The contribution of the tumor microenvironment and extracellular matrix to the aggressive biology of Gastric Cancer (GC) has been recently characterized (1).

During GC progression striking changes in the lymphatic vessels (LVs) occur and lymphatic metastasis is the commonest feature of GC spread, representing the most significant prognostic factor determining the clinical outcomes (2).

Recent evidence supporting a functional link among EMILIN-1, an Extra Cellular Matrix component (ECM), tumour growth and lymph-angiogenesis has been provided. EMILIN-1 represents a key structural element in the maintenance and function of LVs and displays anti-proliferative effects through the interaction with $\alpha 4 \beta 1$ integrin, as demonstrated in skin and colon cancer (3,4,5). Interestingly, $\alpha 4$ integrin is transcriptionally repressed in GC, but not in the normal gastric epithelium (7), suggesting a crucial mechanism exerted by the integrin/EMILIN1 recognition also in this context.

Aims & Methods: The aim of this study is to analyze the possible role of EMILIN-1 as a molecular regulator in the context of GC development and progression.

We performed Immunofluorescence staining of human gastric biopsy samples from normal and neoplastic tissues collected during the endoscopy procedures. Biopsies from pre-malignant lesions were also included. For *in vivo* experiments, we used the syngeneic YTN16 gastric cancer cell line (7) which was injected subcutaneously and intraperitoneally in genetically modified EMILIN-1 mice. In alternative, carcinogenesis was induced in mice using N-methyl-N-nitrosourea (MNU). GES-1 (normal stomach mu-

cosa), and several GC cell lines representative of different GC stages and histotypes (i.e. AGS, Hs746.T, NCI-N87 and KATO-III) were employed for *in vitro* experiments.

Results: EMILIN-1 is diffusely deposited in normal gastric mucosa and is significantly decreased in malignant and pre-neoplastic samples; this finding correlates with the presence of aberrant LVs. EMILIN-1 mutant mice (knock out and E955A knock in) developed tumors earlier compared to WT animals: 20 days post-injection of YTN16 cells, tumors developed in EMILIN-1 mutant mice were larger and displayed a significant increase of lymphangiogenesis. Treatment of transgenic mice with MNU associated with an increased number of tumors, exacerbated aggressive lesions and higher levels of LV abnormalities.

To unveil the main mechanisms responsible for EMILIN-1 reduction we treated *in vitro* fibroblasts and LECs (the major cellular sources of EMILIN1 in the gastric microenvironment) with conditioned media derived from GC cells lines; dramatic effects on EMILIN1 expression were observed, both at the mRNA and protein levels. Small-RNAseq analysis on culture media allowed us to identify miR125a-5p as a possible molecular regulator of EMILIN-1 levels in this context.

Conclusion: This study demonstrates for the first time that loss of EMILIN-1 in GC leads to lymphatic dysfunction and proliferative advantages that sustain tumorigenesis, and assess the use of our animal model as a valuable tool to verify the fate of GC upon loss of EMILIN-1.

CYTOPROTECTIVE CARBON MONOXIDE SIGNALING IS MITOCHONDRIA-ORIENTED AND ENHANCES GASTRIC MUCOSAL ABILITY TO COUNTERACT PATHOLOGY-DRIVEN DISINTEGRATION EVOKED BY NON-STEROIDAL ANTI-INFLAMMATORY DRUG

Introduction: Carbon monoxide (CO) is an endogenous gaseous messenger produced by the enzymatic activity of heme oxygenase with anti-inflammatory and anti-oxidative properties [1].

Pharmacological CO donors with ability to release small amounts of CO exerted gastroprotective effects against injuries induced by ethanol, ischemia/reperfusion or non-steroidal anti-inflammatory drugs (NSAIDs) [2,3]. Interestingly, further studies revealed that low concentrations of CO influence mitochondrial bioenergetics and respiration by binding to heme proteins in electron transport chain (ETC), resulting in cytoprotective action [4].

Therefore, novel and unique strategy based on “click chemistry” has been invented by the Binghe Wang Lab (Georgia State University, USA) to deliver CO directly to the mitochondria [5].

However, this approach is yet to be implemented in GI pharmacology. Moreover, mitochondria as a fundamental target of endogenous CO-signaling in pathogenesis and prevention of GI pathologies has been ignored.

Aims & Methods: Therefore, we aimed to prove for the first time that mitochondrial rather than stochastic CO-signaling contributes in gastric mucosal integrity maintenance under pathogenic conditions.

We also evaluated if targeted mitochondrial delivery of novel CO-prodrug described by Zheng et al. (Nature Chemistry 2018) [5] (working name: BW-mito-CO) protects gastric mucosa against acute injury evoked by NSAIDs representative, acetylsalicylic acid (ASA).

Thus, male Wistar rats were pretreated intragastrically (i.g.) with:

- 1) DMSO/H₂O as vehicle,
- 2) BW-mito-CO (0.2, 1, 5 mg/kg) and CO-release activating “click”-moiety,
- 3) selected, the most effective dose of BW-mito-CO (5 mg/kg) + rotenone, a mitochondrial complex I inhibitor (5 mg/kg). Subsequently, gastric mucosal injury was induced by i.g. administration of ASA (125 mg/kg).

Gastric mucosal damage and gastric mucosal blood flow (GBF) have been assessed by planimetry and laser flowmetry, respectively. Proteome profiling and molecular targets screening in gastric mucosal biopsies was performed using mass spectrometry-based proteomics. BW-mito-CO platform was synthesized in house according to Zheng et al. (Nature Chemistry 2018) [5].

Results: BW-mito-CO dose-dependently reduced the area of ASA-induced gastric mucosal damage, with the most notable effect observed at the dose of 5 mg/kg, while GBF remained without significant changes. Rotenone did not alter the protective effect of BW-mito-CO.

Proteomic analysis revealed that BW-mito-CO (5 mg/kg) significantly up-regulated proteins related to the tricarboxylic acid cycle and cytoprotective agents associated with gastric mucosal defense, including calpains

and treofil factor that were mostly altered in opposite manner by ASA. Pretreatment with BW-mito-CO upregulated mitochondrial complex I hemoproteins that were not affected by ASA.

Conclusion: We conclude that gastric mucosal CO-signaling mostly relies on its impact on mitochondrial compartments. Increased mitochondrial bioavailability of CO counteracts pathology-driven proteomic shifts in gastric mucosa. Implementation of mito-targeted CO delivery platforms appeared here as a novel and promising approach to GI pharmacology vs NSAIDs-induced gastric mucosal injuries. Mitochondrial CO signaling seems to mechanistically depend on its capacity to activate mitochondrial complex I and to enhance gastric mucosal ability to maintain its integrity under pathological conditions [Founding source: National Science Centre (Poland): 2019/33/B/NZ4/00616; Ministry of Science and Higher Education (Poland): Perty Nauki PN/01/0279/2022].

Introduction: Gastric microbiota (GMI) plays a significant role in metabolome shaping and it is also potentially involved in gastric oncogenesis.^{1,2} This international prospective cohort study investigates bacterial communities in stomachs with clinically, histologically, and serologically profiled precancerous conditions.

Aims & Methods: The aim of the study was to evaluate whether a certain GMI composition could be related to a specific gastric pathological condition, in order to investigate its oncogenic potential. 112 biopsies from oxyntic and antral mucosa (healthy stomachs [HS] 36; Hp+ Gastritis (G): 21 atrophic [AG] and 22 non-atrophic [NAG]; Autoimmune G. [AIG] 33) were endoscopically obtained from 53 subjects (GE= 27; IT= 26). Serology was tested by Gastropanel. Histology assessment applied validated criteria, as the OLGA-staging system. GMI-communities were profiled by gastric biopsies 16S rRNA sequencing, calculating bacterial genus abundances

across the tested conditions. a- (Faith PD, Observed Features, Shannon Entropy) and b- (PCoA) diversity were valued. The correlation of GMI with clinicopathological variables was tested by Spearman-test. P<0.05 was considered significant.

Results: Multivariate testing revealed significant correlation only for diagnostic categories (p=.0001) in the study of the correlation between GMI-profile (all biopsy samples) and sex, age, country (GE vs IT), alcohol intake, smoking habit, PPI assumption, samples compartment (antrum vs corpus), and diagnostic category.

HS samples featured the highest a-diversity and, compared to each category, b-diversity was sensibly higher, with elective abundance of *Solobacterium*, and *Eubacterium Sulci* genera (p<.05). In oxyntic and antral mucosa of NAG and AG samples, *Helicobacter* genus harmed the microbial community, leading to extremely low a-diversity and is significantly b-diverse from HS. Opposite to Hp+, AIG-GMI featured the microbial community similar to HS, with a prevalence of genus *Granulicatella*, *Pauljensenia*, *Rothia*, *Parvimonas*, and *Veillonella* (p<.05).

This finding was further supported by the clustering of AIG and HS on the same side of the PCoA graph. By applying Spearman test, GMI profile showed significant correlation with patients' clinicopathological profile:

- Normal histology positively correlated with *Solobacterium* and *Eubacterium* and inversely with inflammatory score (polymorphs and lymphocytes) and with G17 and Pg2 (p<.05)

- Hp+ NAG and AG positively correlated with inflammatory score (p<.05), with Pg1, Pg2 and Pg1/Pg2, and inversely correlated with APCA values (p<.05)

- In oxyntic AIG samples, pseudopyloric atrophy positively correlated with *Gemella*, *Granulicatella*, and *Veillonella*, while *Leptotrichia* and *Rothia* with IM atrophy (p<.05)

- *Gemella*, *Granulicatella*, *Haemophilus parainfluenzae*, *Pauljensenia*, *Rothia* and *Veillonella* positively correlated with APCA (p<.05), and inversely correlated with Pg1 (as marker of oxyntic atrophy).

Conclusion: This study explored microbiota composition in gastric precancerous conditions. The present study provides evidence of clinico-biological correlation between GMI and precancerous atrophy and inflammation.

The present results significantly link microbes others than Hp as promoters of the gastric inflammation and, ultimately, in gastric oncogenesis. The overlaps of GMI composition between HS and AIG may provide a biological rationale for the lower cancer risk of AIG compared to Hp+ atrophic patients.³

These results support the potential use of GMI profiling as add-on information in ranking the cancer risk in patients harboring gastric precancerous conditions.

Introduction: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed nonalcoholic steatohepatitis (NASH/MASH) and fibrosis. 966 patients with biopsy confirmed NASH were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo administered once daily.

Dual primary endpoints at Week 52 were achieved with both resmetirom 80 mg and 100 mg: NASH resolution with no worsening of fibrosis (NR) or ≥ 1 -stage improvement in fibrosis with no worsening of NAS (FI). We evaluated the baseline and effect of resmetirom compared with placebo on fibrosis biomarkers PRO-C3 and P3NP/ELF.

Aims & Methods: Pearson's correlation was used to examine the association between 2 PRO-C3 ELISA assay methods (ELISA GEN1 and ELISA GEN2, NORDIC BIOSCIENCE) using PRO-C3 baseline data (N=919). The rest of the analyses used the ELISA GEN2 assay. Mean SD or SE and median [Q1, Q3] were calculated to summarize PRO-C3 data. ANCOVA was used for comparisons between resmetirom 80 or 100 mg vs. placebo in PRO-C3 change from baseline at week 52 (wk52CHG), while controlling for baseline PRO-C3 level.

Mean difference with 95% CI and nominal P-values were obtained from the ANCOVA. Scatterplots and Spearman's correlations with 95% CIs were used to assess the associations between P3NP/ELF and PRO-C3 both at baseline and wk52CHG.

Results: The two PRO-C3 assays ELISA GEN1 and ELISA GEN2 data were positively associated with a Pearson's correlation of 0.78 (P-value <0.0001). At baseline, PRO-C3 was mean (SD)=137 (71.7) ng/ml. At week 52, PRO-C3 wk52CHG for 100 mg resmetirom=-23.05 (4.76), 80 mg=-17.93 (4.61) and placebo=-0.19, 4.07 with mean difference (95% CI) in PRO-C3 wk52CHG between 80 mg and placebo=-16.9 (-27.0, -6.76; p=0.0011); 100 mg and placebo=-22.1 (-32.3, -11.84; p<0.0001).

Larger reductions in PRO-C3 mean (SD) on the resmetirom arms were observed in F3 patients: 80 mg=-22.42 (6.38) and 100 mg=-27.42 (6.72) compared with placebo=-0.50 (5.46). Baseline P3NP and ELF were correlated with PRO-C3 (0.563 and 0.458, respectively).

The wk52CHG in P3NP was positively associated with wk52CHG in PRO-C3 (0.557, 0.548 and 0.524 for 100 mg, 80 mg and placebo; respectively). A weaker positive correlation between wk52CHG for ELF and PRO-C3 (0.483, 0.484 and 0.487 for 100 mg, 80 mg and placebo, respectively) were also observed.

Conclusion: Two Pro-C3 assays (ELISA GEN1 and ELISA GEN2, NORDIC BIOSCIENCE) were correlated at baseline, indicating ELISA GEN2 assay was reasonable for measuring PRO-C3 levels. For PRO-C3 ELISA GEN2,

drug effects were statistically significant for both doses of resmetirom vs. placebo. The assay was more sensitive in detecting resmetirom effect in F3 patients. ELF and PRO-C3 was less strongly correlated than P3NP and PRO-C3.

Introduction: Metabolic dysfunction-associated steatohepatitis (MASH) increases the risk of cardiovascular (CV) events and liver fibrosis. Semaglutide, a glucagon-like peptide-1 (GLP-1) receptor agonist, reduces CV risk associated with overweight and obesity in the absence of diabetes and has a profound effect on weight reduction and MASH resolution. Management of MASH may benefit from a deeper understanding of the mechanistic basis of semaglutide-induced MASH resolution.

Aims & Methods: This study used a multi-omics approach to investigate the effects of semaglutide on the hepatic microenvironment and fibrosis development in the context of semaglutide-induced MASH resolution. GLP-1 receptor expression was assessed using RNA *in situ* hybridization and immunohistochemistry in human liver tissue and immunohistochemistry in liver tissue from DIO-NASH and CDA-HFD mice. The effect of semaglutide treatment on liver fibrosis was also assessed using liver transcriptome analysis in both of these mouse models of MASH. Proteomic analyses of 4,979 proteins using the SomaScan Platform were conducted

on serum samples from 293 patients with MASH who received semaglutide or placebo in a phase 2b study (NCT02970942), and an independent cohort of 141 patients with MASH and 89 healthy volunteers.

Results: GLP-1 receptor mRNA or protein expression were not detected in human or mouse liver tissue. However, semaglutide improved histological markers of fibrosis and expression of genes involved in collagen turnover in two distinct mouse models of MASH; one that phenocopies the metabolic-associated features of human disease and another that exhibits non-abdominal obesity-induced advanced steatohepatitis and rapid fibrosis. In semaglutide-treated patients with MASH, proteomics identified 72 proteins significantly associated with MASH resolution after 72 weeks of treatment. These 72 proteins were also identified as differentially expressed in patients with MASH who were not treated for MASH, relative to healthy individuals.

In semaglutide-treated patients with MASH, the abundance of the 72 proteins was similarly altered; however, semaglutide reverted the altered disease profile to that seen in non-pharmacologically treated healthy individuals. In contrast, changes in the levels of the 72 proteins in patients who received placebo were negligible.

Notably, changes in the abundance of 26 of the 72 proteins were significant even after correction for weight loss. Although most of these 26 proteins are associated with metabolic functions, several are implicated in fibrosis-related pathways and CV disease (e.g. ADAMTSL2 and ACY1), and hepatocellular carcinoma (e.g. SERPINC1).

Conclusion: Based on circulating proteomic profiling, semaglutide-induced MASH resolution is associated with changes in multiple pathogenic pathways even after correction for weight loss. Semaglutide appears to re-balance the expression levels of disease-associated proteins in MASH to levels found in healthy individuals.

Introduction: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo controlled Phase 3 trial evaluating the efficacy of resmetirom in patients with biopsy-confirmed nonalcoholic steatohepatitis (NASH) and fibrosis. 966 patients with biopsy-confirmed NASH were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo administered once daily.

Histologic endpoints were assessed after 52 weeks. Dual primary endpoints at Week 52 were achieved with both resmetirom 80 mg and 100 mg: NASH resolution with no worsening of fibrosis (NR) or ≥ 1 -stage reduction in fibrosis with no worsening of NAS (FR).

Aims & Methods: Adults with ≥ 3 metabolic risk factors, liver stiffness ≥ 8.5 kPa, hepatic fat $\geq 8\%$, biopsy-confirmed NASH with F1B-F3 fibrosis, and NAS ≥ 4 were eligible to participate in MAESTRO-NASH. In this analysis, the relationship of changes in (1) FibroScan CAP, (2) Fibroscan VCTE, and (3) alanine aminotransferase (ALT) to histological response (NR and/or FR) in the resmetirom 80 mg, resmetirom 100 mg, and placebo groups was assessed.

Results: Patients with biopsy-confirmed NASH with fibrosis had high metabolic risk including obesity (mean BMI=36), type 2 diabetes (70%), hypertension (78%), and 10-year ASCVD risk score>14. Baseline mean (SD) FibroScan VCTE was 13.3 (6.8), 13.6 (7.1), and 12.9 (5.6) kPa for the resmetirom 80 mg, resmetirom 100 mg, and placebo groups. Baseline ELF across all fibrosis groups was 9.8 (0.87). FIB-4 across all dose groups was 1.3. CAP improved with resmetirom treatment. CAP improvement in individual resmetirom patients predicted both NR and FI responses; however, even no change in CAP predicted biopsy responses higher than the mean for placebo. A CAP improvement in placebo patients did not predict an FI on biopsy. VCTE was improved over time (1-3 years) relative to placebo in resmetirom treated patients. Resmetirom treated patients, even those with no VCTE improvement, had higher NASH resolution and fibrosis improvement responses than the mean placebo response rates. VCTE improvement was poorly predictive of a placebo FI or NR response; worsening of VCTE in placebo patients predicted a lower-than-average NASH resolution and fibrosis improvement. Both doses of resmetirom significantly reduced ALT approximately 30% relative to placebo. In resmetirom treated patients, higher % reductions in ALT were associated with higher NR and FI on biopsy. For resmetirom treated patients without a reduction in ALT, the NASH resolution and fibrosis improvement responses were predicted to be higher than the mean placebo biopsy responses.

Conclusion: ALT was reduced and CAP and VCTE improved was by resmetirom relative to placebo. However, biopsy responses were not always associated with changes in these markers. Additional analyses, including artificial intelligence (AI)-based assessments of histological response, are ongoing.

Contact E-Mail Address: Joern.Schattenberg@unimedizin-mainz.de

Introduction: There is an unmet need to evaluate non-invasive biomarkers for monitoring and predicting change in fibrosis in patients with metabolic dysfunction-associated steatohepatitis (MASH) who are receiving treatment. Several biomarkers have been validated for grading and staging in MASH, including the Agile 3+ score, which can identify advanced fibrosis in non-alcoholic fatty liver disease. Agile 3+ was applied to patients enrolled in a clinical trial of semaglutide to investigate the score's ability to monitor treatment effect and to predict change in fibrosis stage.

Aims & Methods: Data were from a phase 2b study in which patients with MASH and fibrosis stage 1-3 were randomised to 72 weeks' treatment with subcutaneous semaglutide 0.1, 0.2 or 0.4 mg, or placebo, once daily (NCT02970942).

For this analysis, Agile 3+ scores were calculated at baseline and weeks 28, 52 and 72 using liver stiffness measurements (LSM) from vibration-controlled transient elastography (VCTE) (where available), alanine- and aspartate aminotransferase levels, platelet count, age, sex and diabetes

status. A mixed model for repeated measures was used to assess treatment effect on Agile 3+ (missing values were not imputed) during the on-treatment period. Change from baseline in Agile 3+ at weeks 28, 52 and 72 and its association with histological fibrosis improvement at week 72 in the 0.4 mg semaglutide and placebo arms was examined using logistic regression with an interaction effect between relative change in Agile 3+ and treatment. Odds ratios (OR) for improvement in fibrosis of ≥1 stage at week 72 associated with a 0.5-fold change in Agile 3+ at each time point were calculated.

Results: The numbers of patients with Agile 3+ data at baseline and weeks 28, 52 and 72 were 208, 210, 209 and 203, respectively. Mean baseline Agile 3+ (standard deviation) was 0.50 (0.28), 0.61 (0.27) and 0.55 (0.30) for semaglutide 0.1, 0.2 and 0.4 mg, respectively, and 0.46 (0.30) for placebo. Agile 3+ was significantly reduced with semaglutide 0.4 mg vs placebo at weeks 28 (estimated treatment ratio 0.64 [95% confidence interval (CI) 0.48; 0.87]; p=0.004), 52 (0.63 [0.48; 0.83]; p=0.001) and 72 (0.59 [0.41; 0.85]; p=0.005). In the placebo group, associations between a decrease in Agile 3+ at weeks 28 and 52 and improvement in fibrosis at week 72 were significant (OR [95% CI] 4.10 [1.50; 11.19]; p=0.006 and 3.71 [1.28; 10.75]; p=0.016, respectively). A similar trend was seen in the semaglutide 0.4 mg group, but this did not reach significance. For changes in Agile 3+ at week 72, the trend did not reach significance for either the placebo or semaglutide groups. Although this analysis is limited by patient drop-out during the study, the results indicate that changes in Agile 3+ as early as week 28 may be predictive of histological changes at week 72.

Conclusion: Semaglutide demonstrated a significant treatment effect on Agile 3+, with change in Agile 3+ partially predicting histological outcomes, irrespective of treatment allocation. A decrease in Agile 3+ was associated with an improvement in histological fibrosis.

Introduction: MAESTRO-NASH (NCT03900429) is an ongoing 54-month, randomized, double-blind, placebo-controlled Phase 3 trial evaluating efficacy of resmetirom in patients with biopsy-confirmed non-alcoholic steatohepatitis (NASH/MASH) and fibrosis. 966 patients with biopsy confirmed NASH were randomized 1:1:1 to resmetirom 80 mg, resmetirom 100 mg, or placebo once daily. Dual primary endpoints at Week 52 were achieved with both resmetirom 80 mg and 100 mg: NASH resolution with no worsening of fibrosis (NR) or ≥ 1 -stage improvement in fibrosis with no worsening of NAS (FI). The benefit of resmetirom in patients with and without indicators of increased alcohol consumption above protocol-allowed limits for NASH/MASH was assessed on biopsy endpoints and MRI-PDFF (liver fat reduction).

Aims & Methods: Carbohydrate Deficient Transferrin (CDT) was collected longitudinally in all patients over 52 weeks. Post-randomization, a PEth test was performed in patients suspected of increased alcohol consumption. Patients with baseline or post-baseline CDT $>2.5\%$ (ULN 2.47) and/or a PEth $>20\text{ng/ml}$ (ULN 20ng/ml) were assigned to a possible "MetALD" subgroup. Analyses were performed on 782 patients who had both a baseline and Week 52 biopsy.

Results: Of the 782 patients, 75 patients (9.6%) were included in the MetALD subgroup and 707 were not. Baseline characteristics, mean (SD), for the MetALD and non-alcohol subgroups included Age=57.7 (10.5), 60.1 (10.7); percent male=59%, 42%; Presence of diabetes=50.7%, 67.9%; CDT%=2.2 (1.0), 1.6 (0.3); BMI 33.0 (5.5), 35.8 (6.6); MRI-PDFF=21.7% (7.4), 17.4 (6.5); Fibroscan VCTE=13.4 (6.7), 13.2 (6.6); Fibroscan CAP=348.5 (38.5), 347.0 (38.7); FIB-4=1.67 (0.69), 1.37 (0.66); AST=45.6 (21.8), 40.3 (22.9); ALT=55.2 (24.8), 55.5 (32.2); GGT=117.9 (170.8), 75.3 (85.6); Bilirubin=0.69 (0.31), 0.65 (0.29); MCV=92.3 (5.8), 90.3 (5.6); Platelets=200, 229; NAS (median)=5 (5,6), 5 (5,6); and %F3=66.7, 62.5.

For the group of patients with low or no alcoholic consumption: Patients treated with 80 mg and 100 mg resmetirom doses (n=224 and 228, respectively): 29.9% and 36% had NR, 29% and 33.3% had FI, 59.2% and 71.2% showed a $\geq 30\%$ reduction from baseline in MRI-PDFF. For patients treated with placebo (n=255), the corresponding results were 10.3%, 13.7%, and 24.5%.

For the possible MetALD group: Patients treated with 80 mg and 100 mg resmetirom doses (n=34 and 20, respectively): 29% and 35% had NR, 35% and 30% had FI, and 88% and 81% showed a $\geq 30\%$ reduction from baseline in MRI-PDFF. For patients treated with placebo (n=21), the corresponding results were 10%, 19%, and 14%.

Conclusion: A total of 75 (9.6%) of patients had possible MetALD during the first 52 weeks of MAESTRO-NASH. Baseline characteristics showed a higher mean GGT and FIB-4 in the MetALD versus low alcohol group. Response rates to resmetirom in patients with suspected MetALD were similar to those without MetALD.

Introduction: Pancreatic cancer (PC) is characterized by an aggressive biology and high tumor heterogeneity causing considerable variations in therapy response. Patient-derived organoids (PDOs) reflect parental tumor features and may represent a powerful preclinical tool to predict drug response and advance personalized treatment.

Aims & Methods: We have generated a living organoid biobank with >100 PDO lines derived from treatment-naïve and pretreated PC patient primary tumor and metastases with a reliable efficacy, and previously developed a pharmacotyping-guided prediction model to prognosticate patient therapy response.

Following up our initial feasibility trial (Beutel, 2021), we now validated the model accuracy in real-life in a higher number of PC patients (41 cases). Additionally, a limited set of 6 PDO pairs were derived from the same patients at two distinct timepoints, followed by pharmacotyping and whole exome sequencing (WES).

Results: Real-life chemotherapy responses in 41 patients matched to pharmacotyping-guided predictions with overall 80.0% accuracy, 89.3% sensitivity, and 64.7% specificity. Particularly, successful response prediction for first and second-line regimens culminated with an accuracy of 85.7% in naïve patients.

Prediction power was nevertheless lower in pretreated patients with a precision of 58.3% for subsequent chemotherapy lines. Retrospective analysis of patient clinical data finally showed that the administration of a therapy prognosticated to be efficient ultimately translated into a longer progression-free survival.

Moreover, the implementation of an automated pipetting system and the subsequent miniaturization of screenings enhanced our process capacity, conferring the possibility to extend our drug panel to a second list of approved targeted agents and significantly reducing the time before pharmacotyping.

The access to longitudinal biopsies allowed to conduct WES on 12 PDOs to capture a comprehensive genetic profiling over the time of treatment, notably revealing a CHEK2-mutated patient responding over time upon PARP inhibitor maintenance therapy, in line with our PDO-based prediction, highlighting the robustness of our method and algorithm. Tracking clonal evolution in longitudinal biopsies by WES revealed lower mutational burden and therapy-driven genetic alterations upon progression.

Finally, to decipher molecular mechanisms driving PC chemoresistance with an unprecedented accuracy level, we took advantage of our phenotypically and therapeutically-profiled PDO living biobank and employed sin-

gle-nucleus multiomic approaches, capturing simultaneously the transcriptome as well as the chromatin landscape, of chemoresponsive and non-responsive PC PDOs and of a unique longitudinally-collected case study.

This allowed us to identify transcriptomic and epigenetic variabilities in a longitudinal setting across several sequential therapeutic lines.

Conclusion: We report a robust and clinically-relevant companion tool for therapy-response prediction, one more step towards a PDO therapeutic profiling-guided personalized medicine in clinical routine.

Additionally, uncovering expression signatures driving chemoresistance may strikingly enhance patient stratification and therefore advance precision oncology in PC.

A NOVEL LIQUID BIOMARKER GASTRIC ADEQUACY TEST FOR THE CAPSULE SPONGE

A. Bartram¹, S. Pavagada¹, A. Ustaoglu¹, M. di Pietro¹, R.C. Fitzgerald¹

¹University of Cambridge, Early Cancer Institute, Cambridge, United Kingdom

Contact E-Mail Address: alexander.bartram1@nhs.net

Introduction: The offer of a non-endoscopic capsule sponge in individuals on anti-reflux medication has been demonstrated to increase the detection of Barrett's Esophagus compared with GP usual care¹. To determine whether the sponge has reached the stomach, the cellular component of the capsule sponge sample is fixed and undergoes histopathological examination to identify gastric gland groups. In around 8% of cases the sponge is deemed inadequate on histopathological examination².

The current process of gastric quality control testing is a time intensive process at the laboratory level, results in patients being recalled to clinic when samples are inadequate and increases cost - all of which may have impact on potential future wider scale use of the capsule sponge.

We hypothesised that secreted proteins and glycoproteins that are released into the preservative fluid could be used as an adequacy marker and that lectins might provide a cost-effective biomarker.

Aims & Methods: We aimed to identify and validate a novel lectin biomarker using the cell-free liquid fraction of the capsule sponge sample to classify samples which have reached the stomach (adequate) compared to those which did not reach the stomach (inadequate). Triplet endoscopic biopsy samples from n=5 patients, of Normal Esophagus (NE), Barrett's Esophagus (BE) and Gastric Cardia (GC) were screened with 20 distinct fluorescein isothiocyanate conjugated lectins, each with a specific carbohydrate binding preference, using immunofluorescence staining. Lectins which demonstrated differential binding in favour of GC were selected for further testing to determine whether biomarkers could be detected in the liquid fraction of the capsule sponge sample.

We developed a direct Enzyme Linked Lectin Assay (ELLA) using HRP conjugated lectin to enable retrospective validation of 126 liquid based patient samples (18 histopathologically inadequate and 108 adequate samples). Data underwent statistical analysis using the Mann-Whitney U test and AUROC analysis.

Results: Immunofluorescence staining demonstrated that *Cytisus scoparius* (CSA) lectin and Peanut Agglutinin (PNA) lectin showed preferential binding to GC tissue samples, primarily in the apical mucin caps and foveolar cells of the columnar epithelium. After ELLA optimisation, horseradish peroxidase conjugated CSA lectin was shown to successfully bind to the liquid fraction of the capsule sponge sample. Using the n=126 patient sample cohort, lectin CSA demonstrated excellent classification between inadequate and adequate samples, AUROC 0.94 (0.88-1.0 95%

CI, $p < 0.0001$) with sensitivity of 87.96 (80.49 – 92.83 95% CI) and specificity of 94.44 (74.24 – 99.72 95% CI) at the selected threshold, Mann Whitney U test ($p < 0.0001$).

Conclusion: We successfully demonstrate on a large retrospective cohort that lectin CSA can accurately classify the adequacy of capsule sponge samples, using the cell-free liquid based portion of the sample alone. This could reduce overall recall rate, optimise laboratory processing and reduce costs.

DISSECTING THE HINDRANCE OF HEDGEHOG PATHWAY IN INTRAHEPATIC CHOLANGIOCARCINOMA: A STEP TOWARDS TARGETED THERAPY

S. Paradiso¹, G. Carpino¹, P. Infante², L. Di Marcotullio², D. Quaglio³, C. Di Meo³, M. Franchitto⁴, T. De Luca⁵, B. Botta³, E. Gaudio¹, D. Alvaro⁵, V. Cardinale⁵

Introduction: Cholangiocarcinoma (CCA) comprises a heterogeneous group of cancers affecting the biliary tree and is considered one of the deadliest cancers. CCA incidence and mortality are increasing dramatically worldwide in the last decades. CCA prognosis is dismal (5-year survival rate <20%) due to various aspects including late diagnosis, poor response to chemotherapy and lack of well-established targeted therapeutic options.

One of the foremost patho-biological features of CCA is the high inter- and intra-tumoral heterogeneity, which has limited the discovery of biomarkers and novel therapeutic alternatives, hampering the development of tools for early diagnosis and effective treatment, with unfavorable implications on patient outcome.

From an anatomical outlook, CCA is classified into intrahepatic (iCCA), perihilar (pCCA) and distal (dCCA). Furthermore, iCCA shows distinct histological subtypes which led the World Health Organization (ICD-O-3.2) to categorize it into *small* and *large* bile duct-type. Noteworthy, thus far no data exist concerning the correlation of molecular traits and specific iCCA subtypes. Indeed, this marked heterogeneity strikingly restricts the possibility of translational research and represents an utmost aspect to be scrutinized.

The Hedgehog (Hh) pathway is one of the molecular networks involved in the pathogenesis of iCCA. As a matter of fact, it is fundamental in various hallmarks of iCCA, including tumor growth, survival, migration, cancer stem cells activation and epithelial-mesenchymal transition. In the light of these observations, targeting this cascade for therapeutic purposes in iCCA is possible owing to evidence of Hh's pathogenetic role in the disease.

Aims & Methods: This study aims to evaluate, *in vitro*, in primary and established cell lines, a novel natural chemical compound called Glabrescione B (GlaB) that specifically inhibits Gli1, a transcriptional factor downstream of Hh pathway.

Using Trypan Blue Exclusion test, the dose- and time-dependent response of free GlaB and hyaluronic acid (HA)-encapsulated GlaB (HA-GlaB) has been evaluated. MTS assay has been performed to determine the IC₅₀. Western blot has been used to analyze the target protein expression levels. Wound-healing assay has been achieved to assess the cell migration. Colony formation assay has been performed to rate the colony-forming ability of cancer cells. Flow cytometry analysis has been accomplished to investigate cell death. The results were confirmed in at least three independent experiments and the quantitative data were reported as the mean ± SEM. Student's t-tests for paired samples were used to assess differences among two groups. A p-value of <0.05 was considered statistically significant (* $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$).

Results: Our findings demonstrate that both free GlaB and HA-GlaB treatments significantly reduce iCCA cell rate viability, migration, colony-forming ability, and Gli1 levels in a dose- and time-dependent manner ($0.05 < p < 0.001$), leading to a decisive decrease in cancer cells invasiveness. Ultimately, compared to controls, early evidence from flow cytometry reveals an induction of necrosis and apoptosis as a result of drug administration.

Conclusion: Hedgehog pathway dysregulation is well known to be correlated with the development and progression of various cancers, including iCCA. A novel natural compound, named Glabrescione B, is able to inhibit cancer cells growth, survival, invasiveness and to induce cancer cell death. Taken together, these data provide insight into a new and potentially beneficial natural compound for the management of iCCA *in vivo*.

Introduction: Locally advanced esophageal cancer (EC) is treated with neoadjuvant chemo(radio)therapy (nCRT) followed by surgery, but only a modest percentage of patients (16-43%) achieves a pathological complete response post-nCRT.

The addition of immune checkpoint inhibition (ICI) targeting programmed death-1 or its ligand (PD-1/PD-L1) is explored to increase response rates, yet adequate patient selection methods are lacking. PD-L1 expression's predictive value in biopsies is inconsistent due to intra- and intertumoral heterogeneity, and the influence of nCRT on ICI response is unclear. Novel imaging methods are crucial to understand PD-L1 heterogeneity in order to ultimately select patients for ICI.

Aims & Methods: This ongoing study aims to assess the safety and feasibility of the innovative technique ultrasound guided quantitative fluorescence molecular endoscopy (US-qFME) using the fluorescently labelled ICI drug durvalumab-680LT before and after nCRT in EC patients to visualize, for the first time, PD-L1 drug distribution from the macroscopic to the cellular level. A durvalumab-680LT dose-optimization was performed in which up to now fifteen EC patients scheduled for nCRT were included in either the control (not receiving durvalumab-680LT), 4.5 mg, or 15 mg cohort. The next five patients will receive 25 mg durvalumab-680LT, after which the most optimal dose group will be expanded with 16 patients. US-qFME procedures were performed both before and after nCRT, consisting of *in vivo* fluorescence signal visualization, quantification by mucosal and ultrasound-guided spectroscopy measurements of healthy esophageal tissue, tumor and/or lymph nodes, and collection of biopsies.

Subsequently, *ex vivo* analyses were performed for quantification of fluorescence signals, correlation to histology and visualization of tissue drug distribution and drug target cells.

Results: Higher fluorescence signals were visualized *in vivo* in tumor compared to healthy tissue. *Ex vivo* quantification of the fluorescence signals revealed higher median fluorescence signal intensities in tumor biopsies compared to healthy esophageal tissue pre-nCRT in both the 4.5 mg and 15 mg dose cohorts with a broad range in signals in the tumor (94.8 a.u. [41.0-131.7] vs. 31.0 a.u. [24.6-38.1] ($p=0.125$), and 103.9 a.u. [40.7-197.6] vs. 27.1 a.u. [25.8-40.8] ($p=0.0625$), respectively).

Similar results were found during both mucosal and ultrasound-guided spectroscopy with higher signals in tumor tissue both *in vivo* and *ex vivo* compared to healthy tissue. The signals in healthy tissues of patients receiving the tracer were comparable to both tumor and healthy tissue in the control cohort (26.2 a.u. [21.5-37.6] and 11.7 a.u. [11.3-19.0]). An SDS-PAGE experiment confirmed the tracer's integrity and stability in the mucosa. During fluorescence microscopy, only a dose of 15 mg durvalum-

ab-680LT was sufficient to visualize membrane-bound durvalumab. Analyses post-nCRT are still ongoing. No (serious) adverse events occurred.

Conclusion: Durvalumab-680LT administration was safe and specifically targeted the tumor tissue as higher signals were found in tumor than in healthy tissue. In addition, the broad range in signals in the tumor tissue indicates, as expected, an inter- and intra-patient difference in PD-L1 expression.

These preliminary findings show the potential of the novel combination of durvalumab-680LT and US-qFME to guide future patient selection for ICI therapy. Further analyses are ongoing, including correlation to PD-L1 staining and fluorescence microscopy to visualize drug distribution and potential drug-target interactions.

Introduction: The Wnt signaling pathway and the p53 signaling pathway are key regulators in colorectal cancer (CRC) biology. For the development of new potential therapeutic approaches, a deeper understanding of the interactions between these pathways is required. We have developed a high-throughput arrayed phenotypic screening platform that combines multiplexed CRISPR/Cas9 ribonucleoprotein (RNP) knockouts with fluorophore pathway reporters, nuclear immunohistochemistry staining and fluorescence imaging. This allowed us to perform phenotypic analysis of knockout and pathway activation effects on a single-cell level to uncover new connections between Wnt and p53 signaling.

Aims & Methods: We established CRISPR/Cas9 RNP-based multiplexed knockouts both in colorectal cancer cell lines and patient-derived colorectal cancer organoids. We produce single guide RNA (sgRNA) by *in vitro* transcription. Utilizing RNPs for genome editing and mutating specific target genes allows for fast and precise editing and fewer off-target effects when compared with traditional plasmid or lentivirus-based CRISPR delivery methods. Furthermore, the small molecular size of an RNP editing complex provides the opportunity to easily multiplex several target gene knockouts or increase individual knockout efficiency by targeting the same gene with several sgRNAs simultaneously. We experimentally determined the ideal amount of individual sgRNAs to use in order to maximize knockout efficiency of a single target gene.

Using our optimized RNP knockout platform, we then conducted an arrayed phenotypic screen with 180 CRC-relevant target genes in 6 HCT116-derived adherent cell lines with different mutational backgrounds in the Wnt & p53 signaling pathways. After cell fixation and staining of nucleus and cell body, we used fluorescence microscopy images for cell segmentation *in silico*. This allowed us to monitor the transcriptional activity in p53 and Wnt/ β -catenin signaling as well as the cell morphology on a single cell basis.

Results: We were able to show that gene knockout efficiency is highly dependent on the individual sgRNA used. Furthermore, we demonstrated that combining up to four sgRNAs that target the same gene in one knockout experiment significantly increases overall efficiency while not significantly affecting cell growth and viability when compared to using a single sgRNA. Using four target guides per gene, we succeeded in establishing high-efficiency CIRPSR/Cas9 RNP knockout protocols with >90% pooled knockout efficiency in adherent colorectal cancer cell lines using lipofection for complex delivery and >40% pooled knockout efficiency in patient-derived colorectal cancer organoids using electroporation.

In the arrayed phenotypic screen, we were able to detect pathway activation and deactivation using a fluorophore-based reporter system coupled to DNA transcription factor binding sites of Transcription Factor 7 Like 2 (TCF7L2) for Wnt signaling and a fluorescent immunohistochemistry staining for p53.

Conclusion: Our innovative approach combining CRISPR/Cas9 RNP technology with detailed imaging and phenotypic analysis has proven to be a powerful tool in dissecting the roles of the Wnt and p53 signaling pathways in colorectal cancer. This approach can be easily scaled to any other set of genes or signaling pathway of interest. Moving forward, we intend to verify target genes of interest discovered in our arrayed phenotypic screen in patient-derived colorectal cancer organoids.

Introduction: As the most abundant antibody in the gastrointestinal tract, IgA is an essential component of mucosal immunity due to generation of immune protection against invading pathogens. Interestingly, elevated systemic IgA titres are associated with steatotic liver diseases (SLD). Yet, the underlying mechanism responsible for systemic IgA accumulation is still not fully understood. Due to its control of IgA transport into the gut lumen, either from the liver via bile as well as across intestinal epithelium, the polymeric immunoglobulin receptor (pIgR) is one of the key regulators of IgA localization.

Aims & Methods: Here, our aim was to determine the contribution of pIgR-dependent IgA secretion to the development of steatohepatitis. First, we assessed systemic and faecal IgA titres in a cohort of biopsy-proven metabolic dysfunction-associated steatotic liver disease (MASLD) patients.

Additionally, pIgR expression and IgA levels were assessed in different parts of the gut-liver axis in wild-type (*Wt*) mice fed chow or methionine- and choline-deficient (MCD) diet for 4 weeks to induce murine SLD. To study alterations in hepatic injury resulting from shifts in IgA titres, *Wt* and pIgR-deficient (*pIgR*^{-/-}) mice were fed MCD diet for 4 weeks.

Moreover, IgA-deficient bone marrow was transplanted into *Wt* and pIgR^{-/-} mice which were then fed MCD diet, allowing us to further elucidate the specific effect of circulatory and intestinal IgA disturbances on murine steatohepatitis.

Results: MASLD patients had higher IgA titres in serum and stool in comparison to healthy individuals, which positively correlated with hepatic fibrosis. Similar changes in IgA concentrations were found in various murine MASLD models.

Importantly, while increased faecal IgA levels associated with the induction of pIgR in murine colon epithelium, pIgR expression in the liver as well as in the distal small intestine was reduced during hepatic fibrosis in MCD-fed mice. Hence, altered site-specific pIgR regulation and aberrant hepatic IgA secretion might result in elevated systemic IgA deposition, thereby promoting SLD. In line, pIgR^{-/-} mice, which lack intestinal IgA and accumulate IgA in circulation, developed more hepatic inflammation and injury associated with increased neutrophil and macrophage infiltration compared to their *Wt* littermates after MCD diet. IgA-deficient bone marrow transplantation prevented aggravated hepatic injury and steatohepatitis in pIgR^{-/-} mice, indicating that pIgR-mediated systemic IgA accumulation exacerbates SLD.

Conclusion: Our research identified pIgR-dependent regulation of IgA secretion as an important mechanism contributing to the severity of murine steatohepatitis.

Disclosure: Nothing to disclose.

SINGLE-CELL SEQUENCING REVEALS THE HETEROGENEITY OF IMMUNE MICROENVIRONMENT OF TYPE 1 AND TYPE 2 AUTOIMMUNE PANCREATITIS WITH ACTIVATION OF HIF-1A INDUCED FIBROSIS RESPONSE THROUGH VISFATIN

J. Li¹, W. Li¹, D. Zhang¹, Z. Jin¹, H. Huang¹

Introduction: Autoimmune pancreatitis (AIP) is a chronic inflammatory condition of the pancreas that is characterized by immune-mediated tissue damage and fibrosis and has been categorized into two distinct subtypes^[1].

Notably, storiform fibrosis is an important characteristic among the two types of AIP, especially in type 1^[2].

Although interest in AIP is growing, its pathophysiological mechanisms remain poorly understood. The immune microenvironment is crucial in the inflammatory and fibrotic processes of AIP, but the complexity and diversity of involved immune cells have not been fully characterized. In both subtypes of AIP, various immune cells coexist and interact, potentially leading to pathogenic and fibrotic responses.

The hypoxia-inducible factor 1- α (HIF-1 α) pathway is a key molecular pathway in AIP-related fibrosis. HIF-1 α is a transcription factor that responds to hypoxic conditions and regulates the expression of various genes involved in angiogenesis, metabolism, and fibrosis^[3].

Activation of HIF-1 α can lead to the induction of fibrogenic responses, which are central to the pathology of AIP.

Recent studies suggest that VISFATIN, an adipocytokine associated with inflammation and fibrosis, may act as a downstream effector of HIF-1 α ^[4], but the details of this interaction and its impact on the fibrosis in AIP have yet to be elucidated^[5].

Aims & Methods: In our study, we performed single-cell RNA sequencing in pancreatic lesion of type 1 AIP and type 2 AIP acquired by endoscopic ultrasound-guided fine-needle aspiration, and peripheral blood mononuclear cells from these patients before and after glucocorticoid therapy, integrated with previous published normal pancreas tissue.

We also conducted immunofluorescence staining and functional experiments to examine the mechanism. We aimed to unravel the immune microenvironment complexity in AIP and explore immune cell heterogeneity, activation states, and the potential involvement of HIF-1 α and VISFATIN in fibrosis development.

Results: Based on our single-cell data analysis, we summarized the expansion of B cell and plasma cell that existed in pancreatic lesion of type 1 AIP with various cell subgroup, as well as identify a significant pathogenic differentiated trajectory in B cell subgroup. Additionally, we also observed the expansion of Tfh, T helper CD4+ T cell and a novel NAMPT related CD4 T cell in pancreatic lesion of type 1 AIP. Importantly, our analysis reveals HIF1A+ classical monocytes are enriched in peripheral blood and pancreatic lesion of both two types of AIP. Through cell-cell interaction estimation, we also identified HIF1A+ classical monocytes is the key effective cell group which interacts with pancreatic stellate cells in high level, and Visfatin plays key roles in this biological procedure in both type 1 and type 2 AIP. We further identified and verified the HIF-1 α is involved in transcriptional activation of NAMPT by directly binding to the promoter, and the secretory visfatin could promote the fibrosis of pancreatic stellate cells through activation of TLR4 and ROS. Exogenous visfatin injection could exacerbate the pancreatic fibrosis in AIP mice model and the phenotype could be reversed through treatment of visfatin inhibitor. Moreover, the unregulated serum levels of visfatin in type 1 AIP and type 2 AIP patients comparing to healthy people are also initially verified.

Conclusion: In conclusion, our study depicted the dynamic change of peripheral blood and pancreatic lesion in type 1 and type 2 AIP patients. Additionally, we uncover a mechanism for visfatin induced AIP related pancreatic fibrosis.

MODELING EARLY ONCOGENIC EVENTS IN PANCREATIC CYSTIC NEOPLASIA IN A GNAS AND KRAS DRIVEN STEM CELL DERIVED ORGANOID MODEL

Introduction: Intraductal Papillary Mucinous Neoplasias (IPMN) are cystic neoplasias of the ducts of the pancreas. They usually occur at advanced age and can progress to invasive adenocarcinomas.

While there are morphological and spatial features to assess the progression risk, a mutational footprint defining the progression risk remains to be identified. IPMNs often harbor an activating mutation of either GNAS or KRAS or both, but neither interaction nor signaling crosstalk is well understood.

Aims & Methods: Here, we use a patient-derived induced pluripotent stem cell (iPSC) model system, that endogenously harbors either the wildtype GNAS gene or a GNAS R201C mutation and is equipped with an inducible oncogenic KRAS^{G12D} cassette. The various iPSC genotypes were differentiated towards the pancreatic lineage to ultimately form pancreatic duct-like organoids (PDLO)[1,2], followed by transplantation onto the porcine urinary bladder (PUB) – our ex vivo scaffold for long-term culture[3]. Dysplasia, mucin expression and cyst size were subsequently analyzed. Furthermore, we performed transcriptomic bulk RNA-sequencing and proteomic profiling of the PDLOs.

Results: Already two weeks post transplantation onto the PUB a substantial amount of KRT19 positive ductal structures were observed independent of the genotype. Classification of dysplasia over a time of up to 8 weeks showed that high grade-like dysplasia was only present in grafts with a GNAS^{R201C} background. This effect was further enhanced by additional oncogenic KRAS^{G12D}. In ductal structures an expression progression over time of Mucin 1, 2, 5AC and CA19-9 was observed.

Expression of Mucin 2 was only observed in GNAS^{R201C} -harboring grafts, while Mucin 5AC and CA19-9 was the strongest in double mutant grafts. In double mutant ductal structures, the highest amount of Ki67 positive

nuclei was observed. In a GNAS^{WT} background, induction of KRAS^{G12D} led to a strong increase of P21 positive senescent cells, which was again lower when GNAS was also mutated. *In vitro* GNAS^{R201C} led to a higher proliferation of PDLOs and a higher proliferative capacity was maintained upon KRAS^{G12D} induction. On transcriptomic and proteomic level, a decreased oncogene induced senescence signature was observed when comparing KRAS^{G12D} induced GNAS^{R201C} organoids to KRAS^{G12D} GNAS^{WT} organoids. Additionally, double mutant organoids showed a significantly decreased control of genomic stability and an increased angiogenesis and inflammation. Preliminary *in vitro* data indicate that double mutant PDLOs have a 1.9 fold increased amount of cells with double strand breaks compared to WT PDLOs.

Conclusion: These results show an effect of GNAS^{R201C} on early dysplasia formation and progression which was further enhanced by KRAS^{G12D}. Additionally, the increased proliferative and decreased senescent phenotype hints at a GNAS^{R201C}-driven bypass of oncogene induced senescence, which was further supported by transcriptomic and proteomic analysis. The expression pattern of PDLOs indicate early alterations of genomic stability and signaling interaction with adjacent microenvironment. The decreased genomic stability and increased proliferation may explain the increased progression towards low and high grade-like dysplasia in our *ex vivo* model system. Our genuine patient-derived iPSC model featuring an endogenous GNAS^{R201C} will allow us to closely investigate the early formation of IPMNs and timewise resolve their transition towards an invasive phenotype to further unravel the mechanisms of IPMN formation and the collaborative pro-oncogenic signaling of KRAS^{G12D} with GNAS^{R201C}.

Introduction: Cirrhosis is a world-widely prevalent disease with a high global burden: approximately one million deaths worldwide are attributed to cirrhosis each year, and cirrhosis is the 11th leading cause of death¹. Fibrosis and cirrhosis develop after a long period of persistent inflammation, which can be caused by a variety of factors such as hepatitis B or C virus, obesity, high alcohol consumption, autoimmune diseases, cholestatic diseases, and so on². However, current clinical treatments for cirrhosis are mainly focused on improving complications such as portal hypertension. Although some patients with early-stage fibrosis may benefit from treatment to remove the cause of fibrosis, there is currently no effective treatment for advanced fibrosis or cirrhosis itself. Bortezomib (B) is a reversible inhibitor of the chymotrypsin-like site of the 20S proteolytic core within the 26S proteasome and is currently mainly used to treat multiple myeloma³. B has been shown to improve fibrosis of the skin, lungs and kidneys^{4,5}.

Aims & Methods: We aimed to evaluate the efficacy of B to improve advanced parenchymal and biliary liver fibrosis in rats and potential underlying mechanisms. Advanced liver fibrosis was induced in 8-week-old rats by intraperitoneal injection of thioacetamide (TAA) for 12 weeks or bile duct ligation (BDL) for 3 weeks. Rats with advanced fibrosis were divided into 2 groups: intravenous injection of B at 0.1 mg/kg in PBS (B) or injection of PBS alone three times a week for 3 weeks (fibrotic controls, FC). Age matched rats with no intervention served as normal controls (NC). Portal vein pressure was measured after anesthesia before sacrifice. Liver and renal function parameters were determined to evaluate liver inflammation and potential toxicity of B. HE and Masson staining were used to evaluate liver inflammation and fibrosis. Liver collagen was quantified via hydroxyproline content. Fibrosis-related gene and protein expression were determined by RT-qPCR and Western blot. Liver samples were subjected to NGS analysis. LX-2 human hepatic stellate cells and LO2 human hepatocytes were cultured with different concentrations of B for 24 h. Cell apoptosis was quantified via flow cytometry.

Results: B treatment induced a decreased portal vein pressure (mmHg), though the p-values did not yet reach statistical significance in the two fibrosis models (B vs FC: TAA, 6.86 ± 0.76 vs 11.42 ± 2.37; BDL, 9.49 ± 2.92 vs 18.57 ± 16.83). On the other hand, B treatment decreased ALT and AST in both fibrosis models, while serum creatinine and bilirubin levels remained unchanged, indicating a beneficial effect of B on liver function with no apparent liver or renal toxicity. Morphometry and biochemical quantification showed a significant amelioration of fibrosis, as evidenced by liver hydroxyproline content and Masson-positive area.

Gene set enrichment analysis indicated the upregulation of pro-inflammation-related Ugt2b7 and anti-proliferation-related gene Marvled1; while the key regulator in ubiquitin-mediated proteolysis and cell cycle pathways Cdc20 decreased after treatment with B, so did the Cdc20 protein. B-treated hepatic stellate cells but not hepatocytes showed prominent apoptosis.

Conclusion: Bortezomib induces activated hepatic stellate cell apoptosis and has a prominent antifibrotic potential in parenchymal and biliary fibrosis.

Introduction: Primary sclerosing cholangitis (PSC) is an inflammatory disorder of the bile ducts, in which Inflammatory bowel disease (IBD) concomitantly occurs (PSC-IBD). Substantial differences in clinical presentation are observed between PSC-IBD and ulcerative colitis (UC).

Aims & Methods: In this study we aim to find distinct pathomechanisms for PSC-IBD using single-cell RNA sequencing. Forty-seven colonic samples of PSC-IBD (n=24), UC (n=18) and non-IBD subjects (n=5) were collected. Whole biopsies were dissociated into single cells using one-step collagenase digestion. Library preparation was done with 10x Genomics and sequencing was performed on an MGI2000 sequencer. Then, differential abundance, differential expression, cell-cell interaction analyses, and heritability analyses were performed. Stainings for DUOX2 and HLA-DR were performed on paraffin embedded colon mucosal slides

Results: In total, 71,798 high quality cells identified 54 distinct cell types, including a new type of epithelial cells: DUOX2+ enterocytes. DUOX2+ enterocytes are almost exclusively present in inflamed colon and can act as antigen presenting cells through the expression of MHC2 on its surface. A general shift in cell type composition upon inflammation was observed, comparable between PSC and UC samples. However, an increased abundance was seen for stem cells in non-inflamed (NI) PSC, and not in UC-NI nor non-IBD controls.

Additionally, we found distinct gene expression patterns between PSC and UC inflammation: while activation of inflammatory monocytes was observed in PSC inflammation, several types of fibroblasts were activated

upon UC inflammation. Through heritability analysis, we also highlighted how mucosal follicular B and CD4+ activated Fos-Hi cells carry the heaviest burden of PSC risk genes.

Conclusion: We describe DUOX2+ enterocytes, which may play a role in both PSC and UC colitis inflammation through antigen presentation. Furthermore, we show that intestinal inflammation in PSC-IBD, as compared to UC, is characterized by distinct mucosal cell composition and cell-specific gene expression patterns. PSC colitis, and not UC, is driven by activation of inflammatory monocytes, with antigen presentation through HLA-DRB1, and activation of specific CD4+ T cell subsets. Additionally, an increased abundance of stem cells in PSC-NI could be related with the increased colorectal cancer risk in PSC-IBD.

PREDICTING LYMPH NODE METASTASIS IN EARLY GASTRIC CANCER THROUGH TWO-STEP MACHINE LEARNING USING WHOLE SLIDE PATHOLOGY IMAGES

B. Lee¹, B. Keum¹, Y. Jeon¹, H. Chun¹¹Korea University, Seoul, South Korea**Contact E-Mail Address:** bomee26288@gmail.com

Introduction: In Early Gastric Cancer (EGC), if the risk of lymph node metastasis (LNM) is negligible, endoscopic curative resection is performed preferentially. If LNM is suspicious, additional gastrectomy with lymphadenectomy should be performed.

Recently, as artificial intelligence has revolutionized medical field, several studies have been conducted to predict LNM applying machine learning in stomach.

The risk of LNM is determined by primary tumor. It is necessary to pick up on fine and diverse morphologic patterns within H&E stained tissue slide. Therefore, the aim of this study is to develop machine learning algorithm for predicting LNM status in patients with EGC using H&E stained WSI.

Aims & Methods: This multicenter study involved five cohorts, including Hanyang University Guri Hospital (HGH), Kangbuk Samsung Medical Center (KBSMC), Seoul St. Mary's Hospital (SS), International St. Mary's Hospital (ISH), and Korea University Medical Center (KUMC). The cohorts were randomly divided into training, validation, and test sets.

Whole slide pathology images were annotated and divided into 512 * 512-pixel patches using ASAP software. Expert pathologists used spline on the rectangle region of interest (ROI) to annotate areas of tumor tissue.

In the first step, Deep Lab V and SE-ResNext101 were trained on 7029 patches from three early gastric cancer (EGC) datasets to segment differentiated and undifferentiated gastric cancer.

In the second step, morphological features inferred by the trained segmentation network from whole slide images (WSI) of primary EGC were used to predict lymph node metastasis (LNM) status.

Results: The data consisted of 243 cases from 5 cohorts. The number of cases in each cohort was 61, 84, 59, 14, and 25, respectively.

The classification results of differentiated/undifferentiated tumor and normal tissue are described.

We represented differentiated tumors as orange, undifferentiated as brown, and normal cells as light orange (apricot color). When visualizing patch images, ground truth, and predictions from both internal and external datasets, we observed significant similarity.

And the performance of the classifier at the patch and slide level, as well as internal and external cohorts.

A mean AUROC of 0.7487 and a mean accuracy of 0.7 were achieved in predicting LNM status in the test set using XGBoost.

Conclusion: Our study is the first proof of concept that machine learning trained with deep learning of whole slide images may be able to predict LNM in early gastric cancer.

The clinical feasibility of this machine learning algorithm could empower clinicians to make informed decisions regarding the appropriate treatment for early gastric cancer patients immediately following biopsy.

Disclosure: No conflict.

A MACHINE LEARNING PREDICTIVE MODEL FOR POST-ENDOSCOPIC SUBMUCOSAL DISSECTION BLEEDING IN PATIENTS WITH EARLY-STAGE GASTRIC CANCER: INSIGHTS FROM A MULTICENTER STUDY

K. Takahashi¹, H. Maruyama^{1,2}, K. Kojima¹, N. Nakajima¹, H. Sato¹, K.-I. Mizuno¹, S. Sugitani², S. Terai¹

Contact E-Mail Address: kazuya911@hotmail.co.jp

Introduction: Endoscopic submucosal dissection (ESD) is a widely used minimally invasive treatment for early gastric cancer (EGC). Post-ESD bleeding, which occurs in 3.1–6.5% of cases, is the most common complication^{1,2}. With Japan's aging population, more patients with EGC are receiving antithrombotic agents, increasing the risk of bleeding. Accurate prediction of post-ESD bleeding facilitates the implementation of effective preventive measures.

Machine learning (ML) models can predict clinical outcomes and aid in identifying crucial factors³. Thus, a predictive model based on pre- and intra-operative data may prove useful for predicting post-ESD bleeding and elucidating its key contributing factors.

Aims & Methods: This study aimed to develop an ML predictive model for post-ESD bleeding in patients with EGC, using a large sample dataset obtained from a multicenter study, and to investigate the key factors associated with post-ESD bleeding.

This multicenter study included patients who underwent ESD for EGC at Niigata University Hospital and Murakami General Hospital between 2012–2023. Patient data such as age, sex, development of post-ESD bleeding, comorbidities, and intake of antithrombotic agents (i.e., direct oral anticoagulants [DOACs], warfarin, or antiplatelets) were pulled from medical records. The lesion locations and specimen sizes were also recorded. Clinical characteristics were compared between the patients without post-ESD bleeding (control group) and those with bleeding (bleeding group). The factors associated with post-ESD bleeding were investigated using a logistic regression model. A predictive ML model was then constructed using pre- and intra-operative data. An extreme gradient-boosted tree classifier, a commonly used ML algorithm, was used to construct the model. To train it, the data were randomly partitioned so that 80% were used for training and 20% for testing. The area under the curve (AUC) was calculated for each model using the test dataset. Shapley additive explanations values, a quantitative method to evaluate the contribution of each variable to the model, were calculated to determine the key variables related to post-ESD bleeding.

Results: A total of 1,084 consecutive patients who underwent ESD for EGC were included, of whom 63 (5.8%) developed post-ESD bleeding. The median age [interquartile range] was significantly higher in the bleeding group than in the control one (77.0 [71.0–81.0] vs. 75.0 [70.0–79.0], $p=0.040$), although the female ratio was similar (22.2% vs. 25.0%, $p=0.623$). The frequencies of DOACs (39.7% vs. 9.0%, $p<0.001$), warfarin (27.0% vs. 4.8%, $p<0.001$), and P2Y12 receptor antagonist use (12.7% vs. 2.8%, $p<0.001$) were significantly higher in the bleeding group.

Multivariate logistic regression analysis showed significant associations between post-ESD bleeding and DOACs (odds ratio [OR]: 10.50, 95% confidence interval [CI]: 5.48–20.00, $p<0.001$), warfarin (OR: 10.70, 95% CI: 4.57–24.80, $p<0.001$), and P2Y12 receptor antagonist use (OR: 4.09, 95% CI: 1.55–10.80, $p<0.001$). Our ML model with all variables was able to predict post-ESD bleeding with an accuracy of 93.3% and exhibited an AUC of 0.83 (95% CI: 0.76–0.91). The use of DOACs and warfarin were the top two contributing factors in the ML model.

Conclusion: Post-ESD bleeding was predicted with high accuracy using an ML model, revealing that DOACs and warfarin represent key factors related to post-ESD bleeding. For patients predicted to experience bleeding, meticulous hemostasis measures such as post-ESD ulcer closures may be necessary.

Introduction: According to Lyon 2.0 consensus¹, a definitive diagnosis of gastro-esophageal reflux disease (GERD) requires endoscopic and/or pH-metry criteria. The recently developed and validated high-resolution manometry (HRM) metric termed the Milan Score² integrates four HRM variables related to GERD (ineffective esophageal motility (IEM), esophago-gastric junction (EGJ) contractile integral, EGJ morphology and straight leg raise (SLR) maneuver response) to quantify risk for definitive reflux. However, prediction of response to medical and surgical

GERD treatment using the Milan Score has not been studied. The aim of this study is to evaluate the ability of the Milan Score to predict treatment outcome in patients with persistent GERD symptoms.

Aims & Methods: Data from patients who underwent HRM and pH-metry for persistent GERD symptoms were prospectively collected. Demographic, clinical and pathophysiological (HRM and pH-metry) data were extracted from the database, including the GERDQ questionnaire, Milan Score and acid exposure time (AET). A Milan Score ≥ 137 (risk rate 50%) and AET $> 6\%$ were considered positive for GERD. Change in GERDQ was measured in patients with both pathologic and non-pathologic AET and Milan Score. The two methods were compared using the McNemar test to determine the non-inferiority of the Milan Score in comparison with the AET and Choen's k coefficient was calculated to quantify the level of agreement. Receiver operating characteristics (ROC) analysis was performed using Milan Score and AET in determining improvement in GERDQ.

Results: Among 157 patients enrolled (median age 48 years, median body mass index (BMI) 24.6 Kg/m², 47% males), 67 (42.7%) had a positive Milan Score, 59 of which (88.1%) had a pathologic AET. Patients with a positive Milan Score had higher BMI and worse GERD-related metrics on HRM and pH-metry. Medical treatment was offered to 99 patients, and anti-reflux surgery to 45 subjects, therefore statistical analysis was performed in 144 patients. Overall, clinical improvement favored surgical over medical treatment (53% vs. 33%, $p=0.027$), and both treatments were more effective in patients with pathologic AET compared to patients with non-pathologic AET (medical: 52.9% vs. 22.2%, $p=0.002$; surgical: 69.6% vs. 36.4%, $p=0.038$). Similarly, patients with a pathologic Milan Score had better outcomes compared to patients with a non-pathologic Milan Score (medical: 61.5% vs. 13.8%, $p<0.001$; surgical: 76.9% vs. 21.1% surgical, $p<0.001$). A non-pathologic Milan Score failed to predict good treatment response in 16.7% of the patients, while a negative AET in 24.4%. The AET failed to demonstrate its superiority in predicting treatment response when compared with the Milan Score ($p=0.130$) and the Choen's k coefficient was 0.62 (good agreement). ROC analysis showed an area under the curve of 0.790 for Milan Score and 0.715 for AET in predicting improvement in GERDQ.

Conclusion: The Milan Score is non-inferior to the AET in predicting response to medical and surgical GERD management. The Milan Score could therefore help identify patients who could benefit from an escalation of medical or surgical management.

THE OPTIMAL DURATION OF PH-MONITORING: TESTING THE VALIDITY OF LYON 2.0 RECOMMENDATIONS FOR PROLONGED WIRELESS PH MEASUREMENT

R.-L. Rusu¹, M. Fox², R. Sweis³, S.S. Zeki¹, J.M. Dunn¹, A. Anggiansah¹, J. Jafari¹, A. Learoyd⁴, T. Wong¹
¹Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ²Klinik Arlesheim & Zürich University, Center for integrative Gastroenterology, Arlesheim, Switzerland, ³University College Hospital, London, United Kingdom, ⁴Faculty of Life Sciences & Medicine, King's College London, Department of Population Health Sciences, London, United Kingdom

Contact E-Mail Address: radu75ro@yahoo.com

Introduction: The Lyon 2.0 Consensus accepts that wireless pH monitoring provides equivalent information to catheter-based studies and recommends 96-hr wireless pH studies for gastroesophageal reflux disease (GERD) diagnosis.¹ However, the pH sensor may detach early, and 24-hr and 48-hr studies are routine (and cost-efficient) in many centers. Published studies have used different analyses to summarize prolonged pH data, including “average acid exposure time (AET),” “worst-day AET,” and “dominant pattern analysis.”

Aims & Methods: This study aimed to determine (i) when a shorter recording time is sufficient for conclusive diagnosis of GERD; (ii) the impact of prolonged pH studies on patients with an inconclusive diagnosis of GERD based on 24- and 48-hr measurements; (iii) the replicability and diagnostic yield of 24-hr, 48-hr, and 72-hr studies compared with the 96-hr reference standard; (iv) the performance of different analyses of prolonged pH data. We analyzed endoscopy and pH data from 944/2045 (46%) consecutive patients (age 46.5 ± 14.6 years, 65% F) referred for investigation of typical reflux symptoms off medication that had at least 92-hr measurement. Patients were classified at 24, 48, and 72-hr against the 96-hr reference standard. AET <4% was considered conclusively negative, and AET >6% conclusively positive for GERD. Los Angeles (LA) esophagitis was an independent marker of disease.

The effect of prolonging pH measurement on GERD diagnosis was evaluated using average day, worst-day, and dominant pattern analysis (≥2 negative or positive days). Receiver operating curve (ROC) analysis was performed on the 24- and 48-hr pH data in patients with normal endoscopy, LA A and B esophagitis. Groups defined by 24-hr AET thresholds from 1% to 7% were followed up to 96 hr to assess when 24-hr data were sufficient for conclusive diagnosis.

Results: The proportion of patients with inconclusive results (average AET 4-6%) reduced from 113 at 24 hours to 40 at 96 hours (35% of the subgroup; p=0.02), with similar results for dominant pattern analysis, but not for worst-day analysis (p=0.2). When 24- and 48-hr test periods were assessed, prolonging average day studies to 72 and 96 hr increased conclusive GERD diagnosis to 71% and 65%, respectively.

On dominant pattern analysis, prolonging pH studies up to 96-hr in the subgroup of patients with inconclusive diagnoses at 48-hr showed a decrease in inconclusive diagnoses from 100% to 59% (p < 0.05).

A stepwise improvement in diagnostic accuracy and yield was observed from 24, 48, and 72-hr measurements compared to the 96-hr reference standard (p<0.00001 for trend).

On ROC analysis, 24-hr AET > 6.4% and 48-hr AET > 6.1% predicted GERD based on 96-hr measurements in all patients with normal endoscopy (table). 93% of patients with LA grade B esophagitis had AET >6%.

Only 2.6% of patients with a 24-hr AET ≤ 2.0% had GERD at 96 hr. Over 93% of these had physiologic acid exposure (AET <4%) on reference standard 96-hr studies. When the analysis was repeated for 48-hr data, there was a <1% probability of GERD at 96 hr.

Negative and inconclusive vs conclusive GERD	Endoscopy	Cut-off AET %	Sensitivity %	Specificity %	AUC	PPV %	NPV %
24 hr	Normal (n = 808)	6.4	100	99.6	1	98.9	100
	LA A (n = 61)	6	100	100	1	100	100
	LA B (n = 60)	8.7	73.8	94.4	0.89	96.8	60.7
48 hr	Normal (n = 808)	6.1	100	100	1	99.9	100
	LA A (n = 61)	6	100	100	1	100	100
	LA B (n = 60)	6.4	94.4	94.4	0.9	97.4	84.8

Conclusion: This study confirms that prolonging studies from 24-hr catheter-based or 48-hr wireless pH measurements to ≥72-hr is sufficient for conclusive GERD diagnosis; however, clearly negative (< 2% AET) or positive results (> 6% AET) from 24-hr studies are sufficient to exclude or confirm GERD. Prolonged pH studies of up to 96-hr duration improve the diagnostic yield for conclusive GERD. Analysis methods that utilize average day AET or dominant pattern are preferred.

RXC008: FIRST-IN-CLASS GASTROINTESTINAL-TARGETED POTENT PAN-ROCK INHIBITOR FOR TREATMENT OF FIBROSTENOTIC CROHN'S DISEASE

E. Kilgour¹, K. Houslay¹, A. Marshall¹, M. La Montagna¹, K. Anderson¹, S. Bos², S. van Welden², J. Celis², K. Eckersley¹, C.D. Jones¹, A. Belfield¹, H. Mckeever¹, H. Timmis¹, R. Armer¹, D. Laukens², C. Philips¹

Contact E-Mail Address: e.kilgour@redxpharma.com

Introduction: Redx Pharma is developing RXC008, a gastrointestinal (GI)-restricted highly potent and selective 'pan-ROCK' inhibitor (inhibits rho-associated coiled-coil kinase ROCK1 and ROCK2) to treat fibrostenosis due to Crohn's disease. ROCK1/2 are key signalling kinases in fibrosis and suppression of ROCK activity is highly efficacious in multiple rodent models of fibrotic disease. Systemic inhibition of both ROCK1/2 leads to hypotension limiting its therapeutic use; RXC008 is therefore designed to be restricted to the GI tract with minimal systemic exposure.

Aims & Methods: RXC008 potency was determined against ROCK1 and ROCK2 isolated enzymes in a biochemistry assay, by surface plasmon resonance (SPR) against ROCK2 and in a T853-pMYPT1 (Thr853 phospho-Myosin Phosphatase Target Subunit 1) cell assay. Anti-fibrotic efficacy was determined *in vivo* using the 9-week chronic dextran sulphate sodium (DSS) and the 45-day adoptive T-cell transfer (AT) murine models of colitis, by staining with Masson's Trichrome and by Magnetic Resonance Imaging (MRI). Gene expression changes were assessed by RNAseq. T853-pMYPT1 was measured in tissue and cells by ELISA. RXC008 concentrations were measured by Liquid Chromatography with Tandem Mass Spectrometry in colon tissue and plasma.

Results: RXC008 inhibited ROCK1 and ROCK2 with 1.19/1.3nM potencies respectively in biochemical assays, displayed picomolar affinity for ROCK2 binding in SPR, and suppressed T853-pMYPT1 levels in HAP1 cells expressing ROCK1 and ROCK2 with a potency of 4.6nM. Blood pressure provides a sensitive biomarker for peripheral pan-ROCK inhibition. Minimal plasma exposure of RXC008 and no clinical signs associated with hypotension were detected in rats administered oral doses up to 1000 mg/kg/day for 28-days.

In a dog telemetry study, minimal plasma exposure of RXC008 and no effect on blood pressure were detected at oral doses up to 1000mg/kg, while an intra-venous dose of 1mg/kg gave plasma compound concentrations ten-fold above the HAP1 cell IC50 together with a significant reduction in blood pressure.

In the DSS model, oral dosing (po) of 10mg/kg RXC008 once daily (QD) attenuated the disease activity index (diarrhea, body weight, hematochezia) and significantly ($p<0.0001$) suppressed colon fibrosis measured by Trichrome staining and MRI. In this model, RXC008 modulated the expression of >2000 genes ($p\leq 0.01$, log2 fold change) in the colon, including fibrotic genes Col1a1 and TGF β , the extra-cellular matrix gene Wisp2 and tissue repair genes AhR and IL-22R α .

Monotherapy RXC008 (10, 30 or 100 mg/kg po QD) reduced the fibrosis score in the AT model ($P<0.05$), in contrast the anti-inflammatory agents anti-p40 or anti-TNF α alone had no effect on fibrosis. RXC008 (3, 10 and 30 mg/kg po QD) also significantly ($p<0.05$) reduced fibrosis in combination with anti-TNF α . Minimal to no plasma exposure of RXC008 was detected in the AT model despite efficacious GI tissue exposure. RXC008 significantly reduced T853-pMYPT1 levels in colon tissue in healthy and AT mice. Ex-vi-

vo, RXC008 suppressed T853-pMYPT1 in fibroblasts (pIC50s: 7.83, 9.55, 9.02) isolated from fibrostenotic resection tissue from three Crohn's Disease patients.

Conclusion: RXC008 suppresses fibrosis in animal models of colitis and is being developed as a novel first-in-class therapy to inhibit fibrotic stricture formation in patients with Crohn's Disease. A first-in-human clinical trial (IS-RCTN82038982) commenced in February 2024 and will include assessment of T853-pMYPT1 in tissue biopsy samples for target engagement.

Contact E-Mail Address: brian.feagan@alimentiv.com

Introduction: Tumor necrosis factor-like cytokine 1A (TL1A) is a mediator of inflammation and fibrosis in CD. Tulisokibart, an anti-TL1A monoclonal antibody, demonstrated robust efficacy without adverse safety signals during the 12-week induction period in adults with moderately to severely active CD in the multicenter, open-label, phase 2a APOLLO-CD study.¹ We report long-term efficacy and safety data for tulisokibart from the APOLLO-CD open-label extension (OLE).

Aims & Methods: Responders to tulisokibart induction at 12-weeks (defined as a decrease from baseline in CD activity index [CDAI] of ≥ 100 points or CDAI < 150 at week 12) were given the opportunity to enter the OLE study, whereas 12-week non-responders discontinued the study. At week 14, responders were randomized to receive intravenous tulisokibart 100 mg or 250 mg every 4 weeks until week 170. Reported here are the endoscopic, clinical, and biomarker endpoints through week 50 in the intention-to-treat population. Safety was evaluated in all patients who received ≥ 1 dose of tulisokibart. Descriptive statistics were used to summarize observed data.

Results: 53 of 55 patients completed the 12-week induction period, 37 were considered induction responders and were randomized to receive tulisokibart 100 mg (n=19) or 250 mg (n=18). A greater proportion of patients who were biologic-naïve entered the OLE in the tulisokibart 250 mg vs 100 mg group (44% vs 21%). Improvements in clinical, endoscopic, and biomarker outcomes observed were generally maintained through week 50 in both dose groups. At week 50, a greater proportion of patients achieved clinical and endoscopic outcomes with tulisokibart 250 mg vs 100 mg (Table).

In addition, normalization of high-sensitivity C-reactive protein (hsCRP) favored the 250 mg dose vs the 100 mg dose. During the 12-week induction period, 78% of patients reported AEs. At week 50, AEs were reported in 83% and 84% of patients receiving tulsokibart 250 mg and 100 mg, respectively, and were mostly mild-to-moderate in severity. Serious AEs occurred in 6% of patients receiving tulsokibart 250 mg and 11% of patients receiving tulsokibart 100 mg.

The most frequently occurring AEs of special interest (>10% of patients in either dose group) were urinary tract infection (11% vs 16%), COVID-19 (11% vs 11%), upper respiratory tract infection (6% vs 16%), bronchitis (11% vs 0%), clostridium difficile infection (11% vs 0%), and influenza (0% vs 11%).

Conclusion: At week 50, maintenance of treatment efficacy was generally observed in 12-week induction responders. A trend for higher maintenance efficacy with tulsokibart 250 mg vs 100 mg maintenance treatment was observed at week 50. Tulsokibart was well tolerated with no safety signals identified through 50 weeks of treatment. Larger trials are needed to confirm these findings.

	Week 12 Tulsokibart ^a (n = 55)	Week 50 Tulsokibart 100 mg (n = 19)	Week 50 Tulsokibart 250 mg (n = 18)
Endoscopic response ^b	13 (24)	3 (16)	5 (28)
Clinical remission ^c	27 (49)	8 (42)	10 (56)
Clinical response ^d	37 (67)	11 (58)	12 (67)
Composite endoscopic and clinical response ^e	9 (16)	3 (16)	4 (22)
Composite biomarker and clinical response ^f	n = 49 17 (35)	n = 16 4 (25)	n = 17 6 (35)
Normalization of hsCRP ^g	n = 36 5 (14)	n = 9 0	n = 16 5 (31)
Normalization of fecal calprotectin ^h	n = 44 6 (14)	n = 14 2 (14)	n = 16 2 (13)

All data are n (%).

^aDuring the 12-week induction period, patients received intravenous tulsokibart 100 mg on day 1 and 500 mg at weeks 2, 6, and 10. All patients treated with tulsokibart with baseline CDAI and SES-CD scores were included in the full analysis set population.

^bEndoscopic response was defined as a decrease in SES-CD total score $\geq 50\%$ from baseline.

^cClinical remission was defined as CDAI score <150.

^dClinical response was defined as either a decrease of ≥ 100 points in CDAI from baseline or CDAI score <150.

^eComposite endoscopic and clinical response was defined as a decrease in SES-CD score $\geq 50\%$ from baseline and either a decrease of ≥ 100 points in CDAI from baseline or CDAI score <150.

^fComposite biomarker and clinical response was defined as a decrease in hsCRP or fecal calprotectin $\geq 50\%$ from baseline and either a decrease of ≥ 100 points in CDAI from baseline or CDAI score <150 (evaluated in patients with ≥ 1 elevated biomarker at baseline).

^gNormalization of hsCRP was defined as a concentration of <5 mg/L among patients with elevated levels at baseline.

^hNormalization of fecal calprotectin was defined as a concentration of <250 $\mu\text{g/g}$ among patients with elevated levels at baseline.

Table. Clinical, endoscopic and biomarker outcomes at week 12 and among 12-week induction responders at week 50.

Introduction: Tumour necrosis factor-like ligand 1A (TL1A) is a novel therapeutic target for inflammatory bowel disease. Patients (pts) with moderately to severely active ulcerative colitis (UC) treated with the anti-TL1A antibody, RO7790121 (formerly PF-06480605 and RVT-3101), showed significant endoscopic improvement and adequate safety in the phase 2a TUSCANY trial.¹

Here, we report data from the global, randomised, double-blind, placebo-controlled, dose-ranging phase 2b TUSCANY-2 (NCT04090411) trial evaluating the efficacy and safety of subcutaneous (SQ) doses of RO7790121 in adult pts with moderately to severely active UC (total Mayo Score [tMS] ≥ 6 , endoscopic subscore ≥ 2) who had previously failed conventional/advanced therapy.

Aims & Methods: Pts were randomised to receive RO7790121 SQ 50mg, 150mg, 450mg or placebo (PBO) monthly during the 12-week induction period and RO7790121 SQ 50mg, 150mg or 450mg monthly during the treat-through 40-week maintenance period. Efficacy endpoints were assessed at weeks 14 and 56 in the induction and maintenance intent-to-treat analysis sets, respectively.

The primary efficacy endpoint was clinical remission at week 14 by tMS. Safety was assessed throughout the induction and maintenance periods. The secondary endpoint of clinical remission using modified Mayo Score (mMS) is aligned to updated FDA guidance. Other secondary endpoints included clinical remission (by tMS and mMS) at week 56 and endoscopic improvement at weeks 14 and 56. Efficacy analysis by pre-defined biomarker subgroups was also performed.

Results: Overall, 245 pts were randomised and treated; 228 completed the induction and 224 entered the maintenance period of the study. At week 14, 25.5%, 23.3% and 23.9% of pts in the RO7790121 50mg, 150mg, 450mg arms, respectively vs 11.6% in PBO experienced clinical remission by tMS ($p > 0.05$ [Table]). The proportion of pts achieving clinical remission using mMS at week 14 was 29.8%, 35.0% and 31.8% in the RO7790121 50mg, 150mg, 450mg arms, respectively vs 11.6% in PBO (nominal $p < 0.05$). Improvements in clinical remission were sustained throughout the maintenance period (Table). A greater proportion of pts demonstrated endoscopic improvement across all doses of RO7790121 vs PBO at week 14 and week 56. Numerically greater treatment effects were observed in biomarker-positive pts relative to all-comer pts. During the induction period, 47.8% (117/245) of pts reported ≥ 1 treatment-emergent adverse event (TEAE). The most common TEAEs (occurring in $\geq 5\%$ pts overall) were anaemia (5.3%) and headache (5.3%). In the induction period, 10 pts experienced serious TEAEs (PBO=4; 50mg=3; 450mg=3); 2 treatment-related (PBO=1; 450mg=1). No pts discontinued the study due to TEAEs. A generally similar safety profile was observed during the maintenance period.

Conclusion: Data from the phase 2b TUSCANY-2 dose-ranging study suggests that RO7790121 has a favourable benefit/risk profile with clinically meaningful improvements in pts with moderately to severely active UC. A phase 3 study will be conducted to confirm these results.

	PBO (n=43)	50mg (n=47)	150mg (n=60)	450mg (n=88)
Induction, week 14				
Clinical remission by tMS, * % (90% CI)	11.6 (5.8–22.9)	25.5 (15.4–37.2)	23.3 (15.0–34.0)	23.9 (16.6–32.1)
Clinical remission by mMS,† % (90% CI)	11.6 (5.8–22.9)	29.8 (19.9–42.3)	35.0 (25.1–45.2)	31.8 (23.7–40.8)
Endoscopic improvement,‡ % (90% CI)	18.6 (9.6–30.2)	40.4 (28.3–53.5)	38.3 (27.8–48.6)	40.9 (32.1–50.0)
Maintenance, week 56§	N/A**	50mg (n=42)	150mg (n=26)	450mg (n=28)
Clinical remission by tMS, * % (90% CI)		31.0 (19.4–43.3)	34.6 (20.9–52.6)	39.3 (23.8–56.5)
Clinical remission by mMS,† % (90% CI)		31.0 (19.4–43.3)	38.5 (23.3–56.4)	35.7 (20.9–52.7)
Endoscopic improvement,‡ % (90% CI)		38.1 (25.6–52.0)	39.3† (23.8–56.5)	50.0 (33.3–66.7)

Data cut-off: 3 March, 2023.

n=number of participants in the analysis set with observed data or NRI, excluding a total of seven participants with missing data due to medical or operational complications resulting from COVID-19.

*Primary endpoint: defined as tMS ≤ 2 with no individual sub score > 1 .

†Secondary endpoint: defined per FDA definition with an mMS 0–2 (endoscopic subscore=0 or 1, ≥ 1 point decrease from baseline to achieve a stool frequency subscore=0 or 1, and rectal bleeding subscore=0).

‡Defined as endoscopic subscore=0 or 1.

§Analyses were conducted for all dose groups; however, maintenance efficacy results are presented only for pts receiving the same dose during the induction and maintenance periods.

Efficacy data from pts who received a lower dose in maintenance vs induction demonstrated sustained efficacy (data not shown).

**As PBO was not administered during the maintenance period, no data for week 56 are shown.

†For the endoscopic improvement endpoint at week 56 with the 150mg dose, data were available for n=28 pts.

CI, confidence interval; COVID-19, coronavirus disease 2019; FDA, Food and Drug Administration; mMS, modified Mayo Score; N/A, non-applicable; NRI, non-responder imputation; PBO, placebo; pts, patient; tMS, total Mayo Score.

Table. Summary of efficacy outcomes at week 14 and week 56

FIRST IN HUMAN STUDY OF SOR102, A NOVEL, ORALLY DELIVERED BISPECIFIC ANTI-TNF/ANTI-IL-23 DOMAIN ANTIBODY IN CLINICAL DEVELOPMENT FOR THE TREATMENT OF INFLAMMATORY BOWEL DISEASE

C. Sattler¹, E. Wahab², P. Wedel¹, C. Garasi², V. Jairath³

¹Sorriso Pharmaceuticals, Sandy, United States of America,

²MAC Clinical Research, Manchester, United Kingdom, ³Western University, Department of Medicine, Division of Gastroenterology, London, Canada

Contact E-Mail Address: vjairath@uwo.ca

Introduction: SOR102 is a novel, orally delivered, bispecific antibody construct that neutralizes TNF α and IL-23 activity within GI tissue, targeting the site of inflammation and potentially limiting systemic exposure and immunosuppression¹.

Systemic TNF α /IL-23 inhibition recently demonstrated encouraging clinical efficacy in patients with ulcerative colitis² suggesting additive benefit of dual TNF α /IL-23 inhibition, observed as early as 4 weeks of dosing³, although safety and efficacy of long-term systemic combination therapy is unknown. SOR102 contains two humanized single domain antibodies (SDA) targeting TNF α and IL-23p19 connected by a trypsin-labile linker, enabling monomer separation within the small intestine. SOR102 inhibits TNF α and IL-23 activity pre- and post-trypsin cleavage. SOR102 SDAs were engineered for high stability among intestinal and inflammatory proteases to enable oral dosing.

This Phase 1, first-in-human study (SOR102-101; NCT06080048) consists of 3 parts. Parts 1 and 2 enrolled healthy subjects (HS) and evaluated single ascending (SAD) and multiple doses (MD) of SOR102, respectively.

Aims & Methods: SOR102-101, Parts 1 and 2, was a randomized, double-blind, placebo-controlled, SAD and MD study in HS aged 18 to 55 years that evaluated the safety and tolerability of SAD (Part 1) and MD (Part 2) of SOR102, the concentration of intact SOR102 and its monomers (SOR102-TNF α and SOR102-IL-23) in serum and faeces (Parts 1 and 2) and urine (Part 2), and the incidence of anti-drug antibodies (ADA) (Part 2).

In Part 1, HS were randomized 6:2 to active and placebo treatment into one of 4 ascending dose cohorts. HS were administered a single oral (PO) SOR102 dose ranging approximately between 100mg and 4000mg, or placebo.

In Part 2, HS were randomized 8:2 to active (approximately 1200mg PO BID) or placebo (PO BID) administered for 7 days. Safety and tolerability, faecal, serum and urine concentrations of SOR102 and its monomers, and ADA levels were assessed at predetermined times.

Results: All 42 enrolled participants completed the study. Seven adverse events (AE) were observed, all occurring in Part 1. AE severity was mild or moderate. There was one treatment-related AE (loose stools) of mild intensity and 17 hours duration occurring in the lowest dose cohort.

SOR102 and its monomers were not detected in serum. In Part 1, faecal concentrations of active (via antigen-binding ELISA) monomers were detected at all dose levels, peaking on Day 2 and 3 post-dose, with generally higher concentrations observed in higher-dose cohorts.

The highest faecal concentrations were observed in the third dose cohort on Day 2 post-dose (SOR102-TNF α $\approx$ 260 mcg/mL; SOR102-IL-23 $\approx$ 130 mcg/mL). In Part 2, active monomer faecal concentrations were observed during all dosing days; the highest faecal concentrations observed were SOR102-TNF α $\approx$ 1,700 mcg/mL and SOR102-IL-23 $\approx$ 5,400 mcg/mL. In Parts 1 and 2, intact SOR102 faecal concentrations were on average $\geq$ 800-fold lower than monomer concentrations.

Conclusion: SOR102 was well tolerated at all tested doses. Systemic exposure of SOR102 and its monomers was not observed, supporting its gut selectivity. Low levels of intact SOR102 and high levels of SOR102 monomers in faeces confirm that SOR102 is efficiently cleaved after oral dosing, as designed. Monomer faecal concentrations were observed at all doses in Part 1 and generally increased with each ascending dose, peaking on Day 2 and 3 after administration. In Part 2, monomer faecal concentrations were observed across all dosing days, peaking at >1700 mcg/mL.

MH002, AN OPTIMIZED LIVE BIOTHERAPEUTIC PRODUCT, PROVIDES EFFICACY IN ACUTE POUCHITIS: RESULTS FROM A PILOT STUDY

S. Vermeire¹, P. Dewint², T. Lobaton Ortega³, M. Allocca⁴, F. Scaldaferri^{5,6}, S. Possemiers⁷, L. Haazen⁷, S. Bolca⁷

Introduction: Pouchitis is an inflammatory disease of the pouch in patients with ulcerative colitis who underwent total colectomy with ileoanal pouch anastomosis. There is no approved treatment for acute pouchitis at present.

First-line treatment consists of antibiotics or probiotics. MH002 is an optimized consortium of 6 non-pathogenic, well characterized commensal bacteria with immune modulating, wound healing and gut barrier protective effects, and is in clinical development for ulcerative colitis.

Aims & Methods: This multi-center, open-label pilot study (EudraCT 2021-006656-14) explored the efficacy and mechanistic effects of MH002 in acute pouchitis. Eligible subjects with a modified pouchitis disease activity index (mPDAI) ≥ 5 and mPDAI endoscopic score ≥ 2 and with symptoms lasting ≤ 4 wks, received 400mg MH002 once daily for 8 wks.

Clinical, biochemical, endoscopic, and histologic disease activity was assessed at baseline and wk8. Pouch biopsies were assessed by an IBD pathologist who was blinded to the time points and clinical outcomes.

Exploratory efficacy endpoints (N=13) included mPDAI remission (mPDAI < 5 and a reduction of ≥ 2 points from baseline), symptomatic response (a reduction of clinical PDAI ≥ 2 points), endoscopic response (a reduction of endoscopic score of ≥ 2 points), and histologic response (a reduction of histologic PDAI ≥ 2) at wk8.

Changes from baseline in severity of urgency (NURS), Robart's histopathologic index (RHI), and faecal calprotectin (FCP) concentrations, were also evaluated.

Results: MH002 was safe and well tolerated with no evidence of adverse reactions when administered for 8 wks (Abstract Vermeire et al.). At wk8, 6/13 (46%) subjects achieved mPDAI remission. Symptomatic, endoscopic, and histologic response rates were 5/13 (39%), 5/13 (39%), and 2/13 (15%), respectively.

Clinical, endoscopic, and histologic PDAI scores were improved at wk8 in 11/13 (85%), 7/13 (54%), and 3/13 (23%) subjects, respectively. In total, 8/13 (62%), 9/13 (69%), and 8/13 (62%) subjects reported an improvement in severity of urgency at wk2, wk4, and wk8, respectively.

Over 8 wks, the number of ulcerations observed endoscopically decreased in 7/13 (54%) subjects, and the RHI improved in 9/13 (69%) subjects. Decreases in FCP were observed as early as wk2 in the subgroup achieving clinical remission (N=6), with a reduction of 68%, 71%, and 80% in median FCP at wk2, wk4, and wk8, respectively (Table 1).

FCP at wk8 (mg/kg), median	12	354.5	(111.0; 483.5)	5	89.0	(22.0; 479.0)	7	355.0	(327.0; 429.0)

Table 1. Changes (n, mean or median, IQR) in clinical, endoscopic, histologic, and biochemical disease activity observed upon treatment with MH002 in subjects achieving vs. not achieving mPDAI remission at wk8.

Conclusion: In this exploratory study in patients with acute pouchitis, 8-wk treatment with MH002 resulted in consistent and clinically meaningful improvements with a remission rate of 46% according to the mPDAI. These results warrant further development of MH002 in a phase 2/3 study.

Introduction: The Phase 3 QUASAR Maintenance Study evaluated the efficacy of maintenance treatment with subcutaneous (SC) guselkumab (GUS), a dual-acting IL-23p19 subunit inhibitor, in patients (pts) with ulcerative colitis (UC) who achieved clinical response following IV GUS induction treatment.

Here, we report Week(Wk) 44 efficacy and safety results for GUS treatment compared with withdrawal (placebo) and by history of treatment with biologics/Janus kinase (JAK) inhibitors.

Aims & Methods: At maintenance baseline, clinical responders to 12 weeks of GUS IV induction from QUASAR Phase 2b and Phase 3 induction studies (NCT04033445) were randomized 1:1:1 to GUS 200 mg SC q4w, GUS 100 mg SC q8w, or PBO (GUS withdrawal).

The primary analysis population included randomized and treated pts in the Maintenance Study with a modified Mayo score of 5-9 at induction baseline. Key clinical, symptomatic, histologic, and endoscopic efficacy endpoints and safety events were evaluated through Wk 44.

Results: Of the 568 pts included, 240 (42.3%) had a history of inadequate response or intolerance to biologics/JAK inhibitors, 309 (54.4%) were biologic/JAK inhibitor naïve, and 19 (3.3%) were biologic/JAK inhibitor experienced without documented inadequate response or intolerance. Among pts with inadequate response or intolerance to biologics/JAK inhibitors (anti-TNFs [87.9%], vedolizumab [49.2%], or tofacitinib [20.0%]), 48.3% had inadequate response or intolerance to two or more biologic/JAK inhibitor therapies.

At induction baseline, pts with a history of inadequate response or intolerance to biologics/JAK inhibitors had longer disease duration (mean 9.94 vs 6.25 yrs) and more severe endoscopic disease (Mayo endoscopy subscore=3, 79.6% vs 56.7%) compared with pts with no such history.

Results for key efficacy endpoints are included in Table 1. At Wk 44, clinical remission was achieved by 40.0% of GUS-treated pts (vs 8.0% of withdrawal pts, nominal p<0.001) who had inadequate response or intolerance to biologics/JAK inhibitors, and 54.2% of biologic/JAK inhibitor

naïve pts who were treated with GUS (vs 25.9% of withdrawal pts, nominal $p < 0.001$). The proportions of pts who met the key endpoints were generally higher in the biologic/JAK inhibitor naïve subpopulation compared with the subpopulation of pts with prior inadequate response or intolerance to biologics/JAK inhibitors across treatment groups, however, the treatment differences were generally greater in pts with prior inadequate response or intolerance to biologics/JAK inhibitors. Through Wk 44, adverse events for these subpopulations were consistent with the overall population, and no new safety concerns were identified.

	History of Inadequate Response/ Intolerance to Biologics/JAK Inhibitors			Biologic/JAK Inhibitor Naïve

Biologic/JAK inhibitor experienced without documented inadequate response or intolerance to biologics/JAK inhibitors: placebo, n=7; GUS 100 mg, n=6; GUS 200 mg, n=6. All p-values were nominal. P-values were based on the CMH test, stratified by clinical remission status at maintenance baseline and induction treatment, except for the maintenance of clinical remission, which was based on the Fisher's exact test. Adjusted treatment difference was based on the Wald statistic with CMH weight.

^{a1} Clinical remission: A Mayo stool frequency subscore of 0 or 1 and not increased from induction baseline, a Mayo rectal bleeding subscore of 0, and a Mayo endoscopy subscore of 0 or 1 with no friability.

^{a2} Maintenance of clinical remission: Clinical remission at Wk 44 among pts in clinical remission at maintenance baseline.

^{a3} Maintenance of clinical response: Clinical response at Wk 44 among pts in clinical response at maintenance baseline.

^{a4} Symptomatic remission: A stool frequency subscore of 0 or 1 and not increased from induction baseline, and a rectal bleeding subscore of 0.

^{a5} Endoscopic improvement: An endoscopy subscore of 0 or 1 with no friability present on the endoscopy.

^{a6} Histo-endoscopic mucosal improvement: Achieving a combination of histologic improvement (neutrophil infiltration in <5% of crypts, no crypt destruction, and no erosions, ulcerations or granulation tissue per Geboes grading system) and endoscopic improvement.

^{a7} Endoscopic normalization: An endoscopy subscore of 0. ^b Pts who had a prohibited change in UC medication, an ostomy or colectomy, a dose adjustment (including a sham dose adjustment), or discontinued study agent due to lack of efficacy or an adverse event of worsening of UC or other reasons except for COVID-19 related reasons (excluding COVID-19 infection) or regional crisis in Russia and Ukraine prior to the Wk 44 visit were considered not to have achieved the endpoint. Pts who were missing one or more components pertaining to a specified endpoint at Wk 44 were considered not to have achieved the endpoint.

Table 1. Endpoints at maintenance Week 44 by history of biologic/JAK inhibitor therapy: Primary analysis population.

Conclusion: Maintenance treatment with both GUS dosing regimens resulted in greater improvements compared with placebo withdrawal across key clinical, symptomatic, endoscopic, and histologic endpoints at Wk 44 regardless of prior history with biologics/JAK inhibitors. Safety results for both GUS maintenance dose regimens were comparable across subpopulations by treatment history and consistent with the known safety profile of GUS.

Introduction: Risankizumab (RZB), a monoclonal antibody targeting the interleukin-23 p19 subunit, has previously demonstrated the ability to improve clinical and endoscopic outcomes during induction (ADVANCE, MOTIVATE) and maintenance (FORTIFY) in patients with moderately to severely active Crohn’s disease (CD) regardless of the number of prior biologic failures.¹⁻³ As sustained clinical and endoscopic improvements are important goals in CD, we evaluated the long-term outcomes of RZB by the number of prior biologic failures in patients who received long-term RZB maintenance treatment in the ongoing FORTIFY open-label extension (OLE) substudy.⁴

Aims & Methods: The FORTIFY OLE enrolled patients who completed 52 wks of maintenance therapy with subcutaneous RZB 180 mg, RZB 360 mg, or placebo (withdrawal) in the FORTIFY substudies or RZB phase 2 OLE. All patients received RZB 180 mg every 8 wks (q8w) starting at wk 56, except for those who received prior rescue therapy (single dose of RZB 1200 mg followed by RZB 360 mg q8w) as they continued RZB 360 mg q8w in the OLE. Patients who demonstrated an inadequate response (increased symptoms plus an objective marker of inflammation) during the OLE could also receive rescue therapy (single dose of RZB 1200 mg followed

by RZB 360 mg q8w). This analysis included all patients who completed 2 years of RZB treatment in the FORTIFY OLE (following 1 additional year of randomized maintenance-see footnotes for complete patient population); herein referred to as 152-wk maintenance completers. We assessed clinical and endoscopic outcomes by the number of prior biologic failures (0, 1, ≥2) in each dose group as well as in a pooled dose group. Outcomes assessed at wk 12 (induction) and wk 52 (maintenance) are shown in the Table for reference.

Results: Among the 710 patients who were 152-wk maintenance completers, approximately 1/3 of patients failed 0 (n=210, 30%), 1 (n=227, 32%), ≥2 prior biologics (n=273, 38%), respectively. Baseline demographics and characteristics were similar across subgroups, although patients who failed ≥2 prior biologics generally had more severe disease, as defined by disease duration, SES-CD, FCP, and CRP. Across the subgroups of patients who failed 0, 1, and ≥2 prior biologics, rates of clinical remission (per CDAI and SF/APS), endoscopic response, endoscopic remission, and ulcer-free endoscopy were sustained through wk 152 with RZB maintenance therapy in the pooled RZB 180 mg and RZB 360 mg maintenance groups (Table). Results for the RZB 180 mg and RZB 360 mg groups are also shown in the Table. For almost all endpoints, patients who failed 0 prior biologics demonstrated numerically higher responses, followed by patients who failed 1, and then ≥2 prior biologics (Table).

Endpoint Number of Prior Failed Biologics, n/N (%)	Week 12 of Induction ^a		Week 52 of Maintenance ^b			Week 152 Completers of Open-Label Extension ^c		
	PBO IV	RZB 600 mg IV	PBO SC (Withdrawal)	RZB 180 mg SC	RZB 360 mg SC	Pooled RZB 180+ 360 mg SC	RZB 180 mg SC	RZB 360 mg SC

Table. Clinical and Endoscopic Outcomes at Week 12 (Induction), Week 52 (Maintenance), and Week 152 (in Open-Label Extension). APS, abdominal pain score; CDAI, Crohn’s Disease Activity Index; COVID-19, coronavirus disease 2019; IV, intravenous; NRI-MI, nonresponder imputation-multiple imputation; OLE, open-label extension; PBO, placebo; q8w, every 8 weeks; RZB, risankizumab; SC, subcutaneous; SES-CD, Simple Endoscopic Score for Crohn’s Disease; SF, stool frequency. NRI-MI was used to handle missing data due to COVID-19 or NRI only if no missing data was due to COVID-19. ^aIncludes randomized patients who received at least one dose of study drug during the 12-week induction period in ADVANCE or MOTIVATE and had baseline eligible SES-CD of ≥ 6 (≥ 4 for isolated ileal disease). ^bIncludes randomized patients who responded to 12 weeks of IV RZB induction therapy in ADVANCE or MOTIVATE and received at least one dose of study drug in FORTIFY substudy 1. ^cIncludes all patients who received at least one dose of study drug in the FORTIFY OLE (substudy 3) and 2-year of data matured. The FORTIFY OLE enrolled patients who completed 52 weeks of maintenance dosing in the FORTIFY substudy 1 or 2 or RZB phase 2 OLE. All patients received SC RZB 180 mg every 8 weeks, starting at week 56, except for patients who had prior rescue therapy (single IV RZB 1200 mg, followed by SC RZB 360 mg every 8 weeks) who continued the 360 mg dose every 8 weeks in the OLE. Patients who demonstrated an inadequate response (increased symptoms plus objective marker of inflammation) during the OLE could also receive rescue therapy (single dose of RZB 1200 mg followed by RZB 360 mg q8w). Clinical and endoscopic outcomes were assessed in 152 wks completers in OLE. ^dCDAI clinical remission: CDAI <150. ^eSF/APS clinical remission: Average daily SF ≤2.8 and not worse than baseline of the induction study and average daily AP score ≤1 and not worse than baseline of the induction study. ^fEndoscopic response: Decrease in SES-CD >50% from baseline of the induction study (or for patients with isolated ileal disease and a baseline SES-CD of 4, at least a 2-point reduction from baseline of the induction study). ^gEndoscopic remission: SES-CD ≤4 and at least a 2-point reduction versus baseline of the induction study and no subscore >1 in any individual variable, as scored by a central reviewer. ^hUlcer-free endoscopy: SES-CD ulcerated surface subscore of 0 in patients with SES-CD ulcerated surface subscore ≥1 at baseline, as scored by a central reviewer.

Conclusion: Patients who completed 2 years of RZB treatment in the FORTIFY OLE demonstrated sustained clinical and endoscopic improvements regardless of the number of prior biologic failures. Biologic naïve

patients demonstrated the most improvement, followed by those who failed 1, and then ≥ 2 prior biologics, suggesting the benefits of RZB in early treatment.

Introduction: The Phase 3 QUASAR Maintenance Study (NCT04033445) evaluated the efficacy of maintenance treatment with SC guselkumab (GUS), a dual-acting IL-23p19 subunit inhibitor that binds to CD64 (a receptor on cells that produce IL-23), in patients with ulcerative colitis (UC). Here we report the corticosteroid sparing effects of maintenance treatment with GUS compared with GUS withdrawal (placebo [PBO]) through Week (Wk) 44.

Aims & Methods: At maintenance baseline, clinical responders to 12 weeks of GUS IV induction were randomized 1:1:1 to GUS 200 mg SC q4w, GUS 100 mg SC q8w, or GUS withdrawal (PBO). Patients who were receiving oral corticosteroids upon entry into the maintenance study were required to begin tapering their daily corticosteroid dose at Wk0, unless medically not feasible. Corticosteroid use and corticosteroid-free clinical remission at Wk44 were assessed.

Results: The primary analysis population included 568 patients (induction baseline: mean age, 40.7yr; mean UC duration, 7.8yr; mean modified Mayo score, 6.9 [63.9% with severe disease]; Mayo endoscopy subscore of 3, 66.4%). At maintenance baseline, 38.9% (221/568) of patients were receiving oral corticosteroids and the mean daily prednisone-equivalent corticosteroid dose (excluding budesonide and beclomethasone dipropionate) was similar across all treatment groups (17.3, 15.0, and 14.9mg/day, respectively, for GUS withdrawal, GUS 100mg, and GUS 200mg groups).

	GUS Withdrawal (Placebo)	GUS 100mg SC q8w	GUS 200mg SC q4w
Primary analysis population, N	190	188	190
Clinical remission at Wk44 (multiplicity-controlled), ^{a1,b} n (%)	36 (18.9%)	85 (45.2%)	95 (50.0%)
Adjusted treatment difference (95% CI) ^c		25.2 (16.4, 33.9)	29.5 (20.9, 38.1)
P-value ^d		P<0.001	P<0.001
Clinical remission at Wk44 and not receiving corticosteroids for ≥8 wks prior to Wk44 (multiplicity-controlled) ^{a1,b}	35 (18.4%)	85 (45.2%)	93 (48.9%)
Adjusted treatment difference (95% CI) ^c		25.7% (17.0%, 34.5%)	29.0% (20.5%, 37.6%)
P-value ^d		<0.001	<0.001
Clinical remission at Wk44 and not receiving corticosteroids for ≥12 wks prior to Wk44 ^{a1,b}	35 (18.4%)	85 (45.2%)	93 (48.9%)
Adjusted treatment difference (95% CI) ^c		25.7% (17.0%, 34.5%)	29.0% (20.5%, 37.6%)
Nominal P-value ^d		<0.001	<0.001
Patients receiving oral corticosteroids at maintenance baseline, n (%)	75 (39.5%)	73 (38.8%)	73 (38.4%)
Eliminating oral corticosteroids ≥12 wks prior to Wk44, ^{a2,b} n (%)	27 (36.0%)	51 (69.9%)	48 (65.8%)
Adjusted treatment difference (95% CI) ^c		33.5% (19.0%, 48.0%)	29.2% (14.4%, 44.0%)
Nominal P-value ^d		<0.001	<0.001
Eliminating oral corticosteroids ≥8 wks prior to Wk44 and in clinical remission at Wk44, ^{a2,b} n (%)	10 (13.3%)	35 (47.9%)	29 (39.7%)
Adjusted treatment difference (95% CI) ^c		34.2% (21.4%, 47.1%)	25.8% (13.1%, 38.6%)
Nominal P-value ^d		<0.001	<0.001
Primary analysis population: Randomized and treated patients with a modified Mayo score 5-9 at induction baseline.			

^{a1} Clinical remission is defined as a stool frequency subscore of 0 or 1 that has not increased from induction baseline, a rectal bleeding subscore of 0, and an endoscopy subscore of 0 or 1 with no friability present. ^{a2} Eliminating oral corticosteroids by a designated time point is defined as not requiring any oral corticosteroid treatment from that time point until maintenance Wk44. ^b Patients who had an ostomy or colectomy, a dose adjustment, a prohibited change in UC medications, or discontinued study agent due to lack of efficacy or an AE of worsening of UC or other reasons except for COVID-19 related reasons (excluding COVID-19 infection) or regional crisis in Russia and Ukraine prior to Wk44 were considered not to have achieved the endpoint. ^c The adjusted treatment difference and confidence intervals were based on the Wald statistic with Cochran-Mantel-Haenszel (CMH) weight. ^d The p-values were based on the CMH test, stratified by clinical remission status at maintenance baseline (Yes/No), and induction treatment (guselkumab 400 mg IV, guselkumab 200 mg IV, placebo IV crossover to guselkumab 200 mg IV).

Table 1. Corticosteroid use and corticosteroid-free clinical remission at Week 44: Primary analysis population.

Among patients who were receiving oral corticosteroids (excluding budesonide and beclomethasone dipropionate) at maintenance baseline, the mean decreases from baseline in the average daily prednisone-equivalent corticosteroid dose at Wk44 were greater in the GUS 100mg and 200mg groups compared with the withdrawal group (-10.22 and -10.25 vs -7.35mg/day, respectively, both nominal p<0.001).

As early as Wk8, higher proportions of patients in both GUS treatment groups had eliminated oral corticosteroid use through Wk44 compared with the withdrawal group (65.8% [48/73] and 64.4% [47/73] for GUS 100mg and GUS 200mg groups, respectively, vs 32.0% [24/75] for withdrawal group, both nominal p<0.001). At Wk44, higher proportions of patients in the GUS treatment groups vs withdrawal group had eliminated oral corticosteroid use (Table 1).

Higher proportions of patients in the GUS treatment groups were in clinical remission at Wk44 and had eliminated oral corticosteroid use for at least 8 weeks prior to Wk44, compared with patients in the withdrawal group (Table 1).

Among GUS-treated patients, 180 achieved clinical remission at Wk44 and 178 (98.9%) of them had eliminated oral corticosteroids at least 8 weeks prior to Wk44.

Conclusion: In patients with UC, maintenance treatment with GUS 100mg SC q8w and GUS 200mg SC q4w sustained clinically meaningful efficacy through Wk44 and allowed successful elimination of concomitant corticosteroids.

Contact E-Mail Address: joanatorres00@gmail.com

Introduction: The 52-week, phase 3 True North (TN) study (NCT02435992) demonstrated the efficacy and safety of ozanimod (OZA), a highly selective sphingosine 1-phosphate receptor 1 and 5 modulator, in patients (pts) with moderately to severely active ulcerative colitis (UC). A prior analysis reported the long-term safety of OZA up to ~4 y from TN baseline through Week (W) 142 of the ongoing TN open-label extension (OLE; NCT02531126).

Aims & Methods: This analysis assessed the cumulative long-term safety of OZA with an additional year of exposure (pt disposition available until OLE W190 [up to ~5 y of OZA]). All pts who entered the OLE from TN (ie, clinical nonresponders at W10 and those who lost response during main-

tenance or completed maintenance at W52) were included in this analysis. Treatment-emergent adverse events (TEAEs) were monitored from the first dose of OZA in TN or the OLE through data cutoff; exposure-adjusted incidence rates (EAIRs) per 100 patient-years (PY) are presented. Lab abnormalities, including absolute lymphocyte count (ALC) reductions, were assessed during the OLE through data cutoff.

Results: A total of 823 pts entered the TN OLE. At data cutoff, 43.0% of pts had completed OLE W190 and total OZA exposure was 2681 PY. Overall, the cumulative safety assessments did not meaningfully change with an additional year of OZA exposure (Table). EAIRs of TEAEs, serious TEAEs, and TEAEs leading to treatment discontinuation remained consistent, and there were no new cases of malignancy, bradycardia, third-degree atrioventricular (AV) block, myocardial ischemia, ischemic stroke, pulmonary embolism, deep vein thrombosis, or macular edema with an additional year of OZA exposure. Three pts newly developed infections; however, only 1 pt had a serious infection (keratouveitis), which was not related to treatment. Two additional pts experienced mild hypertension. Reductions in ALC <500 cells/μl were common in the OLE (57.2%), but few pts had ALC <200 cells/μl (6.6%). Occurrence of ALC <200 cells/μl was not temporally associated with serious or opportunistic infections. Most alanine aminotransferase and aspartate aminotransferase elevations were transient and resolved without treatment interruption, and no serious hepatic events occurred.

	Up to ~4 y of OZA exposure ^a (n=823) Total PY ^c = 2536		Up to ~5 y of OZA exposure ^b (n=823) Total PY ^c = 2681			Up to ~4 y of OZA exposure ^a (n=823) Total PY ^c = 2536		Up to ~5 y of OZA exposure ^b (n=823) Total PY ^c = 2681

COVID-19	103 (12.5)	4.3	103 (12.5)	4.1	Deep vein thrombosis	3 (0.4)	0.12	3 (0.4)	0.11
Serious infection	44 (5.3)	1.8	45 (5.5)	1.7	Macular edema	3 (0.4)	0.12	3 (0.4)	0.11
Malignancy	18 (2.2)	0.71	17 (2.1)	0.63	Cystoid macular edema	3 (0.4)	0.12	3 (0.4)	0.11
Bradycardia	3 (0.4)	0.12	3 (0.4)	0.11					

Table. Cumulative safety assessments during TN and the TN OLE in all pts who entered the OLE.

^aData cutoff of June 30, 2023. ^bData cutoff of January 10, 2024. ^cTotal PY was calculated as the sum of the number of years on study contributed by each pt from time of first dose to last date on study. ^dEAIRs were calculated as number of pts/PY × 100. ^eTN OLE is an ongoing study. Individual TEAE terms may not add up as harmonization of final data is pending. ^fFor the 5 pts who newly reported a serious TEAE, events included 1 pt each with UC exacerbation, colitis, pancreatitis, and umbilical hernia, and 1 pt with ulcerative keratitis and keratouveitis.

Conclusion: The ongoing safety profile of OZA is consistent with previous analyses, with no new safety concerns identified. Long-term OZA use representing 2681 PY of exposure continues to be well tolerated in pts with moderately to severely active UC.

Introduction: Ustekinumab (UST), a monoclonal antibody targeting the p40 subunit of interleukins IL-12 and IL-23, has been approved by the European Medicines Agency for the treatment of ulcerative colitis (UC) in 2019. Although clinical effectiveness and safety of UST in UC have been shown in clinical trials, long-term real-world data are limited, especially beyond one year of follow-up.

Aims & Methods: We collected data from the IBDREAM registry¹, a telemedicine platform for IBD patients, and the Initiative on Crohn and Colitis (ICC) registry². Both Dutch multicentre registries collect prospective observational data from IBD patients. Adult patients with UC who received at least one intravenous and two subcutaneous doses of UST with no prior history of colectomy were included. The two primary outcomes were corticosteroid-free clinical remission, defined as Simple Clinical Colitis Activity Index (SCCAI) ≤ 2 , and corticosteroid-free biochemical remission, as defined by fecal calprotectin $\leq 250\mu\text{g/g}$, at week 52 and week 104. Furthermore, data on effectiveness up to week 156, drug persistence rate, dose escalations, concomitant medication use and adverse events were collected.

Results: A total of 127 patients were included, 53 (41.7%) of which were female. Median age at baseline was 49 (IQR: 26). Seven patients (5.5%) had not previously been treated with at least one biological and/or small molecule agent, while 35.4%, 30.7%, and 28.3% of patients had previously been treated with one, two or at least three different advanced therapies, respectively.

Effectiveness results are summarised in Table 1. At week 52 and week 104, 39.4% and 39.2% of patients were in corticosteroid-free clinical remission and 36.8% and 33.9% of patients were in corticosteroid-free biochemical remission, respectively. At these timepoints, 39.2% and 37.1% of patients who had clinically active disease at baseline (n=75) achieved corticosteroid-free clinical remission. In the subgroup of patients with biochemically active disease at baseline (n=56), 47.2% and 40.6% achieved corticoste-

roid-free biochemical remission. Similar rates were observed at week 156, although less patients reached this follow-up time. Drug persistence rate was 77.2% after one year, and 65.6% after two years. A total of 39 patients discontinued UST before completing two years of follow-up; 27 of these patients stopped during the first year. Seventeen patients discontinued UST because of primary non-response, sixteen due to secondary loss of response and nine because of other reasons (including colorectal carcinoma (n=1), sustained remission and side effects). Sixty-two adverse drug reactions were recorded in 36 patients and eight patients required hospitalisation during follow-up.

	Corticosteroid-free clinical remission	Corticosteroid-free clinical remission, subgroup with clinically active disease at baseline (n=75)	Corticosteroid-free biochemical remission	Corticosteroid-free biochemical remission, subgroup with biochemically active disease at baseline (n=56)
Baseline	22/101 (21.8%)		22/86 (25.6%)	
Week 12	44/87 (50.6%)	27/60 (45.0%)	29/88 (33.0%)	14/44 (31.8%)
Week 24	43/80 (53.8%)	29/53 (54.7%)	29/75 (38.7%)	17/38 (44.7%)
Week 52	28/71 (39.4%)	20/51 (39.2%)	25/68 (36.8%)	17/36 (47.2%)
Week 104	20/51 (39.2%)	13/35 (37.1%)	19/56 (33.9%)	13/32 (40.6%)
Week 156	8/23 (34.8%)	5/15 (33.3%)	11/28 (39.3%)	10/19 (52.6%)

* total number of patients differs per group due to missing data or not yet reaching follow-up time at time of data analysis

† patients were considered corticosteroid-free if they were not using systemic corticosteroids at the respective timepoints

Table 1. Clinical and biochemical effectiveness of ustekinumab over time*†

Conclusion: In this real-world study, over one third of patients with UC were in corticosteroid-free clinical and/or biochemical remission two years after starting UST. The medication was relatively effective, despite the partly treatment-refractory study population. UST was well-tolerated and no new safety signals were identified. The study results indicate that UST is an effective and safe long-term therapy for patients with UC.

Introduction: Delayed bleeding is a common adverse event following endoscopic resection of colorectal tumors. Although prophylactic clip closure following endoscopic mucosal resection is reported decreased delayed bleeding rate, the evidence is lacking with regard to colorectal endoscopic submucosal dissection (ESD).

Aims & Methods: This multicenter randomized controlled trial was conducted at 4 Japanese institutions (Kure Medical Center and Chugoku Cancer Center, Asahi General Hospital, Yokohama Rosai Hospital, and Kitakyushu Municipal Medical Center), and aimed to evaluate the efficacy of prophylactic clip closure following colorectal ESD to prevent delayed bleeding. Patients undergoing ESD for 20-50 mm colorectal tumor were enrolled and randomly assigned to closure or non-closure groups. The primary endpoint was delayed bleeding rate, defined as overt bleeding that required endoscopic hemostasis and/or reception of blood transfusions.

Results: The closure and non-closure groups comprised 150 and 149 cases in the intention-to-treat (ITT) analysis, while 142 and 141 cases in the per-protocol (PP) analysis. Patient characteristics, lesion factors, and clinicopathological characteristics of resected lesions were well balanced between the groups. In the ITT analysis, delayed bleeding was 1.3% (2/150) in the closure group, and 8.7% (13/149) in the non-closure group (odds ratio [OR] 0.14; 95% confidence interval [CI] 0.03-0.64; $p = 0.003$). While in the PP analysis, delayed bleeding was 0.7% (1/142) in the closure group, and 8.5% (12/141) in the non-closure group (OR 0.08; 95%CI 0.01-0.59; $p = 0.001$). Delayed perforation was not occurred and post-ESD coagulation syndrome rate (20.0% vs. 20.1%) was not significantly different between the groups.

The multivariate logistic regression analyses revealed prophylactic clip closure was identified as a significant independent preventive factor of delayed bleeding (OR 0.22; 95%CI 0.05-0.76; $p = 0.015$).

Conclusion: The prophylactic clip closure following colorectal ESD is recommended as it reduces delayed bleeding rate (Clinical trial registration number: UMIN000043675).

Disclosure: Nothing to disclose.

RANDOMIZED CONTROLLED TRIAL OF A CLOUD-BASED ARTIFICIAL INTELLIGENCE (AI) COMPUTER-AIDED DIAGNOSIS (CADX) SYSTEM IN NON-EXPERT ENDOSCOPISTS

R. Kader¹, P. Bassett², Y. Kabir¹, S. Cheung¹, L. Macabodbod¹, A. Jayanthi¹, M. Chand¹, L.B. Lovat¹, CADDIE Investigators Team
¹University College London, Wellcome/EPSCRC Centre for Interventional and Surgical Sciences (WEISS), London, United Kingdom, ²Statsconsultancy Ltd, London, United Kingdom

Contact E-Mail Address: rawen158@hotmail.com

Introduction: Non-expert endoscopists' optical diagnosis (OD) of colorectal polyps falls short of 'resect and discard' and 'diagnose and leave' thresholds. Previous CADx studies are limited to locally deployed hardware AI systems and are mainly evaluated in expert endoscopists. CADDIE is a cloud-based CADx system that receives the live image stream from the endoscopy screen via the hospital's internet network, where the AI algorithm processes the images and outputs its diagnosis (adenoma, non-adenoma or uncertain) on the endoscopy screen.

We aimed to assess the performance of the real-time cloud-based CADDIE system when colonoscopy is undertaken by non-expert endoscopists (adenoma detection rate below 30%).

Aims & Methods: We enrolled 739 patients between April 2021 - Dec 2022, scoped by 32 endoscopists in 9 UK hospitals. Each endoscopist was limited to a maximum of 60 procedures and required to perform more than 20% of this target. Patients were block randomised in a 1:1 ratio to standard of care (SOC) or intervention (CADDIE), stratified by endoscopist and indication. OD accuracy of humans alone (SOC arm) and humans aided by CADDIE (CADDIE arm) were compared to the CADDIE system's stand-alone performance in the CADDIE arm.

High Confidence Optical Diagnosis	Study Arm	Accuracy		Adjusted Analysis	
		n / N	% (95% CI)	% difference (95% CI) (+)	p-value
Small/diminutive (≤10mm)	Human (SOC)	145 / 185	78.4 (71.7, 84.1)	8.1 (0.4, 15.7)	0.04
	Human (CADDIE)	155 / 186	83.3 (77.2, 88.4)	4.5 (-2.0, 11.0)	0.18
	CADDIE	160 / 182	87.9 (82.2, 92.3)	-	-
Diminutive (≤5mm)	Human (SOC)	110 / 133	82.7 (75.2, 88.7)	3.4 (-5.6, 12.4)	0.46
	Human (CADDIE)	105 / 129	81.4 (73.6, 87.7)	4.7 (-3.8, 13.2)	0.28
	CADDIE	103 / 119	86.6 (79.1, 92.1)	-	-

n = Total polyps correctly diagnosed
N = Total number of polyps optically diagnosed
(+) = Percentage difference of CADDIE stand-alone performance in CADDIE arm minus human alone OD in SOC arm (Human SOC) or human OD aided by CADDIE in CADDIE arm (Human (CADDIE))

Results: There were 615 evaluable patients after exclusions as pre-defined in the study protocol. There were 523 eligible polyps (270 SOC arm, 253 CADDIE arm). The CADDIE system diagnosed 17.8% of polyps (45/253) as "uncertain".

Human alone (SOC) OD accuracy was 75.9%, human OD aided by CADDIE was 80.2%, whilst the stand-alone CADDIE system was significantly higher than both at 87.5% ($p=0.005$ and $p=0.04$, respectively). Similarly, in the sub-analysis of small/diminutive polyps (≤10mm), human alone OD accuracy was 73.8%, human OD aided by CADDIE was 79.0%, whilst the CADDIE system was significantly higher than both at 87.9% ($p=0.001$ and $p=0.02$). Although results were not significant for diminutive polyps (≤5mm), the

trend was towards higher accuracy in the CADDIE system (86.6%) compared to humans alone and human OD aided by CADDIE (77.3%; $p=0.05$). In sub-analyses of high-confidence (HC) OD, the CADDIE system's accuracy for ≤ 10 mm polyps was significantly higher (87.9%) than humans alone (78.4%; $p=0.04$), with no difference to humans aided by CADDIE (83.3%; $p=0.18$). For HC OD of ≤ 5 mm polyps, where the sample size is smaller, the CADDIE system's accuracy was higher (86.6%) but not significant compared to humans alone (82.7%; $p=0.46$) and humans aided by CADDIE (81.4%; $p=0.28$).

The OD-derived colonoscopy surveillance interval accuracy was 87.2% in humans alone (SOC), 86.8% in humans aided by CADDIE and 90.9% for the CADDIE system.

Conclusion: We demonstrate proof of concept and robust results for a cloud-based CADx system. Further research is warranted in the human-computer interaction to optimise non-expert endoscopists' OD performance to that of CADx systems.

Introduction: Sodium picosulfate (SP)/magnesium citrate (MC) and polyethylene glycol (PEG) plus ascorbic acid are recommended by Western guidelines as laxative solutions for bowel preparation. The standard formulation for bowel preparation is PEG; however, it requires a large dose and has a distinctive taste that is considered unpleasant. SP/MC requires a small dose and ensures fluid intake because it is administered in another beverage. Therefore, clinical studies have shown that SP/MC is superior to PEG in terms of acceptability.

Aims & Methods: Our aim was to compare the novel bowel cleansing method (test group) consisting of SP/MC with elobixibat hydrate and the standard bowel cleansing method consisting of PEG plus ascorbic acid (standard group) in patients preparing for outpatient colonoscopy. This was a multicenter, single-blind, non-inferiority, randomized controlled trial. Patients 40-69 years of age scheduled for outpatient colonoscopy were enrolled. Patients with a history of abdominal or pelvic surgery, constipation, inflammatory bowel disease, or severe organ dysfunction were excluded. The target number of study participants was 540 (standard group, 270 cases; test group, 270 cases). The primary endpoint was bowel cleansing (Boston Bowel Preparation Scale [BBPS] score ≥ 6). Secondary endpoints were patient acceptability, adverse events, polyp/adenoma detection rate, number of polyps/adenomas detected, degree of bowel cleansing according to BBPS (BBPS score ≥ 8), degree of bowel cleansing according to Aronchik scale, and bowel cleansing time. The non-inferiority margin for the primary endpoint was 10%. A study protocol of the present study has already been published in a peer-reviewed journal.

Results: Of 540 participants enrolled, efficacy was analyzed in 524 participants (test group, $n=263$; standard group, $n=261$) in the full analysis set. Non-inferiority of the test group was demonstrated for the primary endpoint (BBPS ≥ 6): 96.2% vs. 97.7% for test and standard group, respectively difference was -1.5%, [95%confidence interval (CI), -4.8 to 1.6%] with $P<0.001$ for non-inferiority. For the secondary endpoint BBPS ≥ 8 was lower in test group (79.5% vs 91.2%: difference -11.7% [95% CI, -17.8 to -5.8%]). Patient acceptability was superior in the test group in the key questions (1. Was the bowel preparation medication easy to use? 2. Were all bowel preparation medications administered internally? 3. What is your overall impression of the bowel preparation? 4. How did the bowel preparation medicine taste? 5. Would you like to use the same bowel preparation medicine for your next colonoscopy?) Adverse events were similar in both groups.

Conclusion: A new regimen of elobixibat plus sodium picosulfate with magnesium citrate was non-inferior in bowel cleansing and superior in patient's acceptability compared to split-dose 2-L polyethylene glycol with ascorbic acid.

Contact E-Mail Address: tommyrizkala@outlook.com

Introduction: Computer-Aided Diagnosis (CADx) is emerging as a tool to assist endoscopists in differentiating neoplastic from non-neoplastic small polyps during colonoscopy. In clinical practice, the application of optical diagnosis strategies, such as “the resect and discard” and the “leave-in-situ”, vary according to the polyp location. This study aimed to evaluate the impact of polyp location (proximal colon vs. distal colon) on the diagnostic performance of CADx systems for small polyps (<5mm) identified during colonoscopy.

Aims & Methods: A comprehensive literature search was conducted in MEDLINE, Scopus, and Embase databases, with the last search performed on March 12, 2024. Studies evaluating the stand-alone performance of real-time CADx for predicting the histology of colorectal polyps ≤5mm in size were included. Studies without pathological confirmation or with fewer than 50 patients were excluded. The primary endpoints were the sensitivity and specificity of the CADx in the proximal and distal colon. Secondary outcomes were the negative predictive value (NPV), positive predictive value (PPV) and accuracy of the CADx alone in the proximal and distal colon. The distal colon comprised the rectum and sigmoid, while the proximal colon comprised the portion extending from the descending colon to the cecum.

Results: We included 11 studies for analysis with a total of 7,782 polyps (≤5mm). CADx accuracy was significantly lower in the proximal colon compared to the rectosigmoid in terms of specificity (62% versus 84%; risk ratio (RR): 0.78 [95% confidence interval (CI): 0.72-0.84], I²=47.08%), NPV (64% versus 93%; RR: 0.71 [95% CI: 0.64-0.79], I²=74.69%), and accuracy (81% vs 86%; RR: 0.95 [95% CI: 0.91-0.99], I²=72.50%). On the other hand, sensitivity (87% vs 87%; RR: 1.00 [95% CI: 0.98-1.02], I²=0%) and PPV (87% vs 76%; RR: 1.11 [95% CI: 1.06-1.17], I²=53.85%) were comparable.

Conclusion: The diagnostic performance of CADx appears to depend on the location of the polyp, being substantially lower for proximal than distal lesions, mainly due to a lower specificity in the proximal colon.

Introduction: Early detection and removal of colorectal adenomatous lesions is effective in reducing the incidence and mortality of colorectal cancer. To achieve this, it is important to improve the detection of colorectal lesions. Newly endoscopy technology, texture and color enhancement imaging (TXI) is expected to enhance visibility of lesion by adjusting the color, structure, and brightness of images taken with white-light imaging (WLI) using EVIS X1 system (Olympus Medical Systems Co., Tokyo, Japan). Our previous retrospective study indicated that TXI improve the detection of colorectal neoplastic lesions. However, it is unclear that ability of detection in TXI is superior to that of WLI.

Aims & Methods: We conducted a prospective multicenter randomized controlled trial to verify the efficacy of TXI in the detection of colorectal neoplastic lesions, when compared with WLI (jRCT1032230089). This trial was conducted at 8 institutions in Japan between May and November 2023. The eligibility criteria included patients aged 20–80 years who were scheduled for screening, post-endoscopic surveillance, or work-up for a positive fecal immunochemical test or abdominal symptoms. Patients were randomly assigned (1:1) to TXI or WLI (control group).

In all colonoscopies, EVIS X1 system and CF-EZ1500DI were used. The primary endpoint was mean adenoma per procedure (MAP) in per protocol set (PPS). Other endpoints included adenoma detection rate (ADR), advanced ADR (advanced adenoma: more than 10 mm in diameter, villous or tubulovillous in histology, or high-grade dysplasia), polyp detection rate (PDR), and flat polyp detection rate (FDR).

We assumed the TXI mode observations to have an improvement effect of MAP with a difference of $\delta=0.3$ on WLI and the standard deviations of MAP in TXI and WLI were expected to be 1.8 and 1.3, respectively. The required number of subjects for analysis was calculated to be 960, considering an expected dropout rate of 10%, when the two-sided significance level was set at 0.05 and power at 0.8.

Results: A total of 960 patients were enrolled. In PPS, 896 patients were analyzed (451 in TXI and 445 in WLI). In MAP, there was no statistically significant difference between the groups (TXI: 1.4 [95% CI: 1.2-1.6] vs. WLI: 1.5 [1.3-1.7]). ADR was similar in the groups (57.21% [52.49-61.82] vs. 55.96 [51.20-60.63]). Advanced ADR tend to be higher in TXI than WLI (11.09% [8.34-14.35] vs. 8.54[6.11-11.53]).

PDR was significantly higher in TXI than WLI (82.48% [78.65-85.88] vs. 74.38 [70.06-78.38]. FDR was significantly higher in TXI than WLI (76.50% [72.31-80.34] vs. 70.34 [65.86-74.55]).

Conclusion: This trial could not show the superiority of TXI over WLI in MAP and ADR. However, it showed that of TXI over WLI in PDR and FDR, indicating that TXI may have ability to detect more flat colorectal lesions which have malignant potential or are difficult to detect.

Introduction: Immune-mediated inflammatory diseases (IMID) involve immune dysregulation, potentially damaging various organs [1]. Gut microbiome regulates immune homeostasis, and abnormality of it is associated with various inflammatory diseases [2,3]. However, previously reported biomarkers have considerable limitations.

Findings are often specific or inconsistent across studies, and while some studies assess common microbial patterns across diverse diseases, they often overlook disease pathobiology. To address this, we conducted a consensus-based approach to identify and dissect robust biomarkers common or unique to different IMIDs.

Aims & Methods: We collected and uniformly profiled public human gut metagenome data of IMIDs, using universal bacterial core gene-based taxonomic profiling [4] and pangenome-based functional profiling. A total of 2,252 samples from 18 studies of 28 case-control sub-cohorts of IMIDs (10 for Crohn's disease;CD, 9 for ulcerative colitis;UC, 4 for ankylosing spondylitis;AS, 2 for chronic obstructive pulmonary disease;COPD, 2 for multiple sclerosis;MS, and 1 for psoriasis;PsO) were included as discovery set, and 253 samples from 3 studies for 7 case-control sub-cohort sets of CD or UC were included as external validation set. Cross-cohort and one-study-leave out validations were performed for the discovery set, and the external validation set was evaluated using the trained model from the IMID discovery set. For the individual marker analysis, significance scores were combined for each criteria, including disease diagnosis, and inflammatory bowel disease (IBD) and nonGI-IMIDs (MS, AS, COPD, and PsO). Additionally, multi cohort-based networks of IBD studies were assessed. Furthermore, to explore potential interpretation of the signatures in other clinical settings, we examined the IBD studies with disease activity as well as FMT study.

Results: Cross-cohort validation of IMID case-control sub-cohorts of the discovery set at species-level showed that intra-cohort performance had significantly higher area under curve (AUC) compared to inter-cohort (W=3701, p-value<0.001), and among the inter-cohort, intra-disease had significantly higher AUC than inter-disease (W=23278, p-value<0.001). When the external IBD sub-cohorts were tested, the trained model of the IMID set showed the average AUC 0.818 (SD=0.089).

In individual signatures, there were several features commonly found to be highly scored in at least 5 IMIDs, including *Enterocloster bolteae* and probable pyridine nucleotide-disulfide oxidoreductase (K21739) in the case-side and *Faecalibacterium* sp. (CLG_10009380_s) and *Oscillibacter* sp. (MSSCM00948369_s) in the control-side. There were also disease or disease category-specific patterns such as *Gemmiger formicilis* and *Alistipes shahii* consistently found to be enriched in control-side in IBD but not in nonGI-IMIDs.

Furthermore, we checked the signatures obtained from our analysis in the other clinical settings such as IBD samples with disease activity scores as well as FMT study. For example, *Dysosmobacter welbionis* was negatively correlated with Harvey Bradshaw Index in 2 CD sub-cohorts (Spearman's rho=-0.5 and -0.26, p-value=0.009 and 0.039, respectively).

Conclusion: Our study analyzed multi-cohort gut metagenome data to identify consistent signatures across various IMIDs. Cross-cohort validation showed better intra-disease prediction compared to inter-disease, yet the performance of predictions between diseases was still comparable. Several microbial signatures were either shared or unique across IMIDs, with some showing potential clinical relevance in IBD.

Introduction: Gut microbiota in Crohn's disease (CD) exhibits considerable variability, with conflicting associations with disease severity and response to therapeutic intervention. We aimed to longitudinally investigate the dynamics of microbial composition in a cohort of patients with newly diagnosed, treatment-naïve Crohn's disease (ndCD) over a one-year period.

Aims & Methods: A prospective real-world study was conducted, enrolling patients with ndCD who were treatment-naïve. Treatment decisions were made by physicians with expertise in CD management. Key one-year clinical outcomes included corticosteroid-free clinical remission (CSFR) and biochemical remission (BR), defined as C-reactive protein levels <1mg/dL and fecal calprotectin levels <150ug/g. Paired stool samples were subjected to 16S rRNA gene sequencing (V4 region) at diagnosis and after one year, followed by analysis for microbial diversity and dysbiosis indices. A linear mixed-effect model was constructed to identify factors associated with microbial alterations and specific taxa driving these alterations, while controlling for confounding variables.

Results: Seventy-five patients completed the one-year follow-up (49.3% female, median age 27 years [IQR 22-38.5]); 45 (60%) received biologics (95.5% anti-tumor necrosis factor [TNF]). Rates of CSFR, BR, and combined CSFR-BR at one-year post-diagnosis were 64%, 56%, and 45.3%, respectively. Analysis of microbial composition revealed significant improvements in microbial indices among patients achieving all desired clinical outcomes, characterized by increased microbial diversity (Shannon index, $p=0.004$, $p=0.002$, $p=0.004$, respectively) and decreased dysbiosis (microbial dysbiosis index [MDI], $p=0.003$, $p=0.04$, $p=0.01$, respectively). Such improvements were not observed in patients failing to achieve CSFR, BR or combined CSFR-BR. Notably, patients treated with biologics, irrespective of outcome achievement, exhibited prominent shifts (improvement) in microbial composition (both indices $p<0.001$), whereas non-treated patients did not demonstrate significant changes (Shannon index, $p=0.53$; MDI, $p=0.81$).

Furthermore, microbial composition at baseline was more disrupted among patients treated with biologics compared to non-treated patients (Shannon index, $p=0.04$; MDI, $p=0.03$). The linear mixed model analysis confirmed a positive association between biologics and favorable changes in microbial indices (Shannon index, $p=0.02$; MDI, $p=0.04$), identifying an increase in 20 gut commensal taxa (considered beneficial) and a decrease in *Escherichia coli* among the biologics-treated subgroup. Conversely, no taxa exhibited significant alterations in the non-biologics treated subgroup.

Conclusion: In a real-world cohort of patients with treatment-naïve ndCD, clinical improvement over one year was associated with improvement in microbial composition. Treatment with anti-TNF agents was associated with improvement in microbial composition irrespective of clinical outcomes. These findings suggest that microbial composition reflects inflammatory activity and may be positively and independently modified by anti-TNF treatment.

Introduction: Gilbert's Syndrome (GS) is a benign polymorphism of the *UGT1A1* gene, leading to decreased enzyme activity in the liver and increased levels of unconjugated bilirubin in the blood, defined as mild hyperbilirubinemia (HBIL) with serum levels between 20 and 100 µM. Mild HBIL is associated with reduced inflammation, lower levels/numbers of reactive oxygen species (ROS), a lean phenotype, reduced risk for metabolic diseases, and lower cancer risk.

Despite the high prevalence of GS in healthy individuals (~5-12% worldwide) and its well-known clinical features, the effects of HBIL on the intestine, the primary site of bilirubin excretion, and its interactions with the gut microbiota remain unclear. We propose that an altered bilirubin metabolism in the liver affects microbe-host interactions in the colon.

Aims & Methods: Germ-free (GF) and specific-pathogen-free (SPF) C57BL/6N wildtype mice with induced HBIL and transgenic mice with the human *UGT1A1**28 polymorphism (TG) were investigated. Mice with induced HBIL received intraperitoneal bilirubin injections for 14 days. Bilirubin levels were analyzed in mouse serum and colon as well as *in-vitro* using the fluorescent protein UnaG, which specifically binds to unconjugated bilirubin. ROS and inducible nitric oxide (iNOS)-derivates were analyzed using Griess assay and gene expression analysis. Colonic microbiota was studied in TG and SPF mice using 16S rRNA gene sequencing. Colonic adenoma cell lines (ptk-6, Ht-29-mtx E12, and CaCo2) were stimulated with unconjugated bilirubin for 24 or 96 hours.

Results: The colonic mucosa of mice with induced HBIL exhibited higher levels of bilirubin than the control group, indicating the presence of 'intestinal HBIL' (HBIL = 12.34 nM/mg), Control = 0.5951 nM/mg; $p < 0.0001$). This was confirmed when colonic epithelial cells were treated with bilirubin *in vitro*, showing intracellular uptake of bilirubin, which could be led by organic anion transporting protein 1a1 (*Oatp1a1*), a potential candidate transporter for bilirubin that was upregulated in ptk-6 cells stimulated with bilirubin for 96 hours. HBIL mice showed an altered microbiota composition characterized by lower richness, distinct compositional clustering, and increased abundance of operational taxonomic units (OTUs) associated with gram-positive taxa (e.g., *Lachnospiraceae*) compared to wildtype mice. HBIL led to lower expression of iNOS and reduced levels of ROS-associated markers in the colon of mice. This was accompanied by higher expression of the aryl hydrogen receptor (*Ahr*), a bilirubin agonist, in the colon of HBIL and lower hepatic expression of *Ugt1a1*, reflecting GS conditions in HBIL mice.

Conclusion: The analysis of different murine models demonstrates that altered bilirubin metabolism along the liver-gut axis regulates the gut microbiota composition. These effects of intestinal HBIL may provide a new mechanistic explanation for the inverse association of GS with chronic disease risk.

GUT MICROBIOTA INFLUENCES COLORECTAL CANCER (CRC) PATIENTS' OUTCOME THROUGH THE METHYLATION OF PHLPP1 GENE

I. Sobhani¹, N. Brito^{2,3}, A. Amiot⁴, E. Bergsten¹, C. Charpy⁴, M. Chamailard³, D. Mestivier⁴, K. Khazaie⁵

Introduction: CRC is driven by changes in DNA such as genetic mutations or epigenetic modifications in the epithelium (colonocyte). Gut dysbiosis is a contributor to the alteration of gene function. However, the link between microbiota driven gene-specific alterations and its impact on clinical outcomes is yet unexplored. The Pleckstrin homology domain and leucine-rich repeat protein phosphatase 1 (PHLPP1) is a tumor suppressor gene that regulates signaling pathways in cell growth and survival, inhibits phosphorylation/kinase in PKC/Akt pathway, limits proliferation, inflammation, and trigger histone modification, and cell-activity mediated autophagy.

Aims & Methods: To understand the impact of microbiota on host DNA changes and outcomes, 96 CRC patients presenting with sporadic (n=64), Inflammatory bowel disease (IBD; n=20)- or the hereditary Lynch Syndrome (LS; n=13) were studied and surveyed. Human fresh stool (9 sporadic-

ic-CRC, 9 healthy controls) were orally transferred to germ-free mice. DNA mutation/methylation, cell proliferation, myeloid cell and lymphocyte infiltrates including CD8, Treg cells in the mice colonic epithelium were evaluated three months after human stool transfer and differences screened. Specimens from 96 CRC patients (n=13 LS, n=20 IBD and n=64 sporadic) were analyzed by human RNAseq and WES, and 16r sRNAseq; *in situ* metabolomic analysis and immunohistochemistry (IHC) were performed in human tumour tissues.

Inflammatory/immune cells were estimated using circumvolution approach based on RNAseq and quantified using IHC. Methylation of PHLPP1 gene promotor was determined in either mice colonic mucosa and human tissues by using bisulfite modified qPCR. For associated genes and pathways to the PHLPP1 gene expression, Gene Set Over-representation Analysis (ORA) and Gene Set Enrichment Analysis²⁴ (GSEA) were used according to t statistics and genes involved.

Bionformatics tools in link with patient's outcome up to 3 years follow from the baseline, were used. In a subset of 50 patients undergoing chemotherapy, abundances of bacteria candidates as suggested by 16sRNA analyses were measured using qPCR and associated to the related pathways.

Results: Stool transfer from CRC patients (vs controls) to mice resulted in the hypermethylation (not mutation) of PHLPP1, coinciding with the augmentation of aberrant crypt foci, inflammatory/immune cell infiltrate including FoxP3/RORgt+ cells within mice colonic mucosa and lower SCFA in the lumen. In patients' tumour tissues, intra-tumor Low (vs High, according to the median cutoff in the present series) PHLPP1 expression was significantly associated with a shorter survival, and a higher recurrence rate ($P = .01$). PHLPP1 hypermethylation of the promotor was more observed in CRC patients with Low PHLPP1 expression.

These patients, showed elevated levels of adherent virulent and reduced commensal bacteria taxa, a higher *in situ* metabolic activity in close to bacteria adherence and were more of IBD-CRC phenotype. Higher *E. Coli* and lower *Faecalibacterium Prautsnizii* (FP) as quantified by qPCR were observed in subset of patients who showed lower response to chemotherapy and in whome genes co-associated with PHLPP1 were involved in autophagy pathway.

Conclusion: Higher virulent/lower symbiotic bacteria unbalance influences CRC outcome through epigenetic down regulation of PHLPP1 an antioncogene and immunotolerance within tumour tissues. This bacteria unbalance enhances resistance to chemotherapy through alteration of autophagy. These suggest microbiota-associated failure of therapy is an epigenetic process that might be reversible.

Disclosure: Nothing to disclose.

Contact E-Mail Address: william7134@gmail.com

Introduction: Diarrhea is one of the most common adverse events of cancer therapies and, when severe, it may even cause the temporary suspension or the interruption of these drugs, limiting the treatment chances and potentially the survival of patients¹.

Moreover, immune-checkpoint inhibitors (ICI) are often associated to a more severe clinical picture of inflammatory condition (ICI-related colitis), which may require immunosuppressive treatments and hospitalization.²

An increasing body of evidence suggests that the manipulation of gut microbiome, mainly fecal microbiota transplantation (FMT), but also antibiotics and pre-probiotics, may represent a promising therapeutic strategy for diarrhea and colitis associated with cancer therapies, but these options are rarely applied into clinical practice.

Aims & Methods: Our aim is to evaluate whether an approach based on the modulation of gut microbiome can be an effective strategy for the treatment of diarrhea and colitis related to ICI treatment in cancer patients.

In this study, carried out from January 2023 to January 2024, we evaluated the efficacy of microbiome-modulating therapeutics (antibiotics, probiotics, FMT) in cancer patients referred to our Microbiome Clinic, under indication of their oncologists, for diarrhea and colitis related to ICI.

All patients underwent first a clinical evaluation to establish the severity of the symptoms and the oncological history, and then received a microbiome-modulating therapy.

All patients were followed up to at least 4 weeks after the prescription of the therapy. We collected the following data of patients: age, gender, type of cancer, oncological therapy and its suspension, severity of diarrhea (graded via CTCAE) and its onset since the start of the oncological therapy.

Results: Overall nineteen patients were enrolled in the study period (6 males, 13 females, mean age 54 years-old). Of them, 10 (53%) had Breast cancer, 3 (16%) Lung cancer, 2 (10%) Non-Melanoma Skin Cancer, 2 (10%) Kidney cancer, 1 (5%) Melanoma and 1 (5%) Cervix cancer. All the patients were treated with ICI (12 Pembrolizumab, 2 Atezolizumab, 1 Trastuzumab, 1 Nivolumab, 1 Mogamulizumab, 1 Cemiplimab, 1 Ipilimumab). Four patients had a G1 diarrhea (21%), seven (37%) G2, and eight (42%) G3. Twelve (63%) patients had to interrupt their immunotherapy due to diarrhea.

Multi-species probiotics were given in 10 (59%) patients, rifaximin in 6 (35%). Systemic steroids were necessary only in 10 patients (59%). At 4-week follow-up, 16 patients (94%) had a resolution of the diarrhea (G0), and 50% of the patients who had to interrupt their oncological therapy because of the diarrhea severity were then able to continue the treatment. Moreover, two patients, referred from another Centre (Pavia University) for ICI-related colitis refractory to steroids and biologics, were successfully treated with FMT, and were able to continue ICI.

Conclusion: An approach based on gut microbiome modulation can be an effective strategy to treat ICI-related diarrhea and colitis, and may potentially reduce the need for steroids. Our preliminary findings should be confirmed by more consolidated and well designed studies.

COMPARISON OF LONG-TERM OUTCOMES OF TRANSLUMINAL EUS- GUIDED BILIARY DRAINAGE VIA HEPATICOGASTROSTOMY VS. CHOLEDOCHODUODENOSTOMY FOR DISTAL MALIGNANT BILIARY OBSTRUCTION: A PROSPECTIVE STUDY

K. Amalou¹, M. Medkour¹, F. Bouaouina², H. Chetroub¹, K. Saidani¹, N. Benboudiaf¹

¹HCA, Gastroenterology, Algiers, Algeria, ²HCA, Anesthesiology, Algiers, Algeria

Contact E-Mail Address: amalou_kh@yahoo.fr

Introduction: Endoscopic ultrasound-guided biliary drainage (EUS-BD) can be performed entirely transgastrically (hepatogastrostomy/EUS-HG) or transduodenally (choledochoduodenostomy/EUS-CDS). It is a feasible and effective alternative for distal malignant biliary obstruction (MBO) in failed endoscopic retrograde cholangiopancreatography. However, the preferred technique for better outcomes is less evaluated.

Aims & Methods: The aims of this study were to compare efficacy and safety of both techniques and identify predictors of adverse events.

Consecutive jaundiced patients with distal malignant biliary obstruction who underwent EUS-BD were included. The primary outcome was the stent patency. The secondary outcomes were technical and clinical success, adverse events (AEs) of each technique, and independent risk factors for stent dysfunction.

Results: A total of 57 patients were divided into EUS-CDS ($n = 30$) and EUS-HGS ($n = 27$) groups. Among them, technical success was achieved in 89.32% of patients (EUS-CDS 93.3 %, EUS-HG 88.2%, $P=0.09$). Clinical success was attained in 84.5% of patients who underwent EUS-CDS group as compared to 80.1% of patients who underwent EUS-HG ($P=0.14$). The mean duration of stent patency for EUS-CDS was 230.3 days while that for EUS-HGS was 143.9 days ($p = 0.01$).

Adverse events occurred more commonly in the EUS-HG group (19.67% vs. 13.3%, $P=0.37$).

In addition, the only independent risk factor for stent dysfunction was systematic treatment after EUS-BD [hazard ratio and 95% confidence interval 0.238 (0.066–0.863), $p = 0.029$]. Length of hospital stay was significantly shorter in the CDS group (5.6 days vs. 12.7 days, $P<0.001$). The incidence of stent dysfunction of EUS-HGS was higher than EUS-CDS (35.1% versus 18.2%, 0.04), despite no significant differences even in late AEs.

Conclusion: In distal MBO, oth EUS-CDS and EUS-HG are effective and safe techniques for the treatment of distal biliary obstruction after failed ERCP. EUS-CDS may be better than EUS-HGS with longer stent patency, shorter hospital stay and fewer AEs. Furthermore, systematic treatment after EUS-BD is recommended for the improvement of stent patency.

Disclosure: Nothing to disclose.

Contact E-Mail Address: jorgevargasr@gmail.com

Introduction: Endoscopic ultrasound-guided hepaticogastrostomy (EUS-HGS) has emerged as a viable alternative for biliary drainage in patients with obstructive pancreatobiliary pathology in whom endoscopic retrograde cholangiography (ERCP) is not feasible.

Despite its effectiveness, however, this procedure is associated with a significant risk of complications. To carry out this procedure, the initial step is the puncture of the intrahepatic bile duct and the positioning of a guide wire; subsequently, the fistulous tract is dilated, and finally, a stent is placed, creating a bridge between the bile duct and the stomach.

Although this sequence is followed in most reported procedures, its technique has not yet been standardized. Therefore, this technique should be homogenized using dedicated devices with the aim of simplifying it as much as possible to reduce the risk of complications.

Aims & Methods: This study aimed to evaluate the feasibility and safety of a newly developed, dedicated, cautery-enhanced tubular stent for EUS-HGS created to simplify this procedure.

This multicenter, prospective study included 20 consecutive patients with malignant biliary obstruction who had failed ERCP due to tumor infiltration or altered anatomy.

A novel dedicated nitinol stent designed for EUS-HGS was used, featuring a cautery tip for tract creation, a 3 cm uncovered distal portion to prevent migration and a 7 cm silicone covered proximal portion with an anti-migratory distal cup to prevent bile leakage. (video 1 Hot Giobor v3.mp4) The technical and clinical success rates, procedure times, and adverse events were evaluated.

Results: Twenty patients underwent EUS-HGS using the dedicated stent, achieving 100% technical and clinical success rates. The mean procedure time was 16 min. Significant reductions in bilirubin levels were observed in all patients, with no reported severe adverse events or mortality.

Conclusion: Dedicated cautery-enhanced tubular stents for EUS-HGS could simplify the procedure and enhance its safety and efficacy, although further studies are required to validate these findings across broader patient populations and settings.

Contact E-Mail Address: marianoghr@gmail.com

Introduction: Despite the advances of recent years, the diagnosis and characterization of biliary strictures is challenging. Artificial intelligence applied to digital single-operator cholangioscopy (D-SOC) is expected to provide a significant increase in the diagnostic yield of indeterminate biliary strictures. Pilot studies using artificial intelligence (AI) algorithms applied to D-SOC have shown promising results.

This multicentric study aimed to validate a CNN model on a large dataset of D-SOC images, providing automatic detection of malignant biliary strictures, as well as their morphological characterization

Aims & Methods: Our group conducted an international study including D-SOC exams from 3 centers in Portugal (Centro Hospitalar Universitário de São João, Porto, Portugal, n=123), Spain (Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, n=18), and the United States of America (New York University Langone Hospital, New York, USA, n=23). Each frame was labelled as normal/benign findings or as a malignant lesion if histopathological evidence of biliary malignancy was available. Also, we evaluated the network's performance for detecting morphologic features, namely tumor vessels, papillary projections, nodules and masses. The image dataset was split for the constitution of training and validation datasets, with a ratio of 90% and 10%, respectively. The performance of the CNN was measured by calculating the area under the curve (AUC), sensitivity, specificity, and positive and negative predictive values (PPV and NPV, respectively).

Results: A total of 103,082 images from 164 D-SOC exams from the three centers were included (53,678 of malignant strictures and 49,404 of benign findings). The model had an overall accuracy of 94.1%, a sensitivity of 93.5%, a specificity of 94.8%, a positive predictive value of 95.1%, a negative predictive value of 93.1% and an AUROC of 0.96.

Our group evaluated the performance of the CNN for the detection of morphological characteristics associated with malignancy, including papillary projections, nodules, masses and tumor vessels. The accuracy for the detection of these features was 90.8%, 93.6%, 93.2% and 78.1%, respectively. The AUC values for each morphologic characteristic were determined to be 0.80 for tumor vessels, 0.91 for nodules, 0.95 for masses and papillary projections.

Conclusion: The potential of deep learning algorithms to impact the care

of patients with suspected biliary malignancy is vast. The authors have expanded this line of research with a multicentre study including patients from two continents, thus increasing the variability of the dataset.

This study assessed the performance of a CNN for detecting and differentiating malignant and benign biliary disorders using a large pool of D-SOC images. The excellent performance of this model lays the foundations for future exploration of AI technologies in this subset of patients, aiming to improve the clinical outcome of patients with suspected biliary malignancy.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is the most technically challenging procedure in endoscopic operations. Selective bile duct cannulation is the critical difficulty, which requires a combination of multiple endoscopic operations to align the knife, duodenal papilla and bile duct in vector direction. Poor endoscopic control, improper coordination of the endoscopists, and exposure to radiation are the challenges that ERCP is currently facing. The development of robotic-assisted ERCP can effectively solve a variety of clinical problems, which has important clinical significance for promoting robotic medicine and remote endoscopy.

Aims & Methods: We aim to develop a prototype robot (YunSRobot-ERCP system) that can integrate multiple endoscopic instruments in a single platform to achieve single-person operation. A randomized controlled animal study was conducted to explore the feasibility and efficacy of robotic-assisted ERCP when compared with conventional manual procedure. The robot system adopts master-slave and two-arm design, including an operating platform, duodenoscope manipulator arm and accessory manipulator arm. The endoscopist control the robot through the operating platform to complete the biliary intubation of beagle. A total of three ERCP physicians and 4 beagles participate in the animal experiment. Each ERCP physician performed one robotic-assisted and one manual ERCP bile duct cannulation on each beagle, totaling 24 procedures, which were randomized using a random number table.

We compared the location of duodenal papilla cannulation, time taken to successfully cannulate the bile ducts, cannulation success rate, and incidence of associated complications between manually and robotic-assisted group.

Results: The manual and robotic-assisted groups each involved 12 ERCP procedures. The percentages of time when the major duodenal papilla was in the desired position during cannulation in the manual and robotic-assisted groups were 77.25% and 95.74%, respectively. The robot-

ic-assisted group had significantly better performance in keeping the duodenal papilla in the desired position compared to the manual group ($p < 0.01$). In the manual and robotic-assisted groups, the time taken to successfully cannulate into the bile duct was 169.50 (106.25–207.25) s and 163.5 (126.50–210.75) s, respectively, with no significant difference ($P = 0.862$). The success rate of bile duct cannulation in the manual and robotic-assisted groups was 83.3%.

The number of attempts required to complete bile duct cannulation was 3.5 (2.00–4.00) in the manual group and 2.0 (1.25–3.00) in the robotic-assisted group per ERCP procedure. The robotic-assisted group required fewer attempts than the manual group, albeit with no significance ($P = 0.154$). Five duodenoscope dislocations occurred in the manual group and 0 in the robotic-assisted group, with no significant difference ($P = 0.07$). The manual and robotic-assisted groups showed no significant differences in the incidence of ERCP-associated adverse events, such as upper gastrointestinal mucosal edema and bleeding.

Conclusion: The animal study demonstrated that YunSRobot-ERCP robotic system can perform ERCP successfully, with a success rate of bile duct cannulation similar to that of the manual procedure. The robot performed superior in maintaining the stability of the duodenoscope. This study provides the possibility and research direction for robotic ERCP and remote operation.

Introduction: In more than 90% of cases, IgG4-related sclerosing cholangitis (IgG4-SC) is linked with autoimmune pancreatitis (AIP)¹, facilitating its diagnosis. Without AIP, differentiating IgG4-SC from malignant biliary obstruction is challenging, leading to unnecessary resections². Although diagnostic criteria for IgG4-SC were established in 2012³ and revised in 2020⁴, validation is lacking.

Aims & Methods: We retrospectively collected data from 17 Japanese high-volume centers on patients with isolated IgG4-SC. We excluded distal-type isolated IgG4-SC, previously characterized by Nakazawa, due to challenges in identifying distal intra-pancreatic biliary strictures without

pancreatic involvement. Diagnosis of isolated IgG4-SC was based on the 2012 and 2020 criteria, with evaluation of symptoms, serum markers, imaging, and prognosis.

Results: A total of 53 patients with isolated IgG4-SC were included in the study, categorized into two groups based on the primary location of the lesion: hilar type ($n = 40$) and extrahepatic type ($n = 13$). Ten patients with hilar-type lesions underwent unnecessary resection due to a lack of awareness regarding the possibility of IgG4-SC. Common findings of endoscopic ultrasound/intraductal ultrasound, such as symmetric mucosal lesions of the bile duct, were observed in both types. The revised 2020 criteria demonstrated utility in diagnosing extrahepatic lesions, not covered by the 2012 criteria.

While endoscopic biopsy could not reveal characteristic findings of isolated IgG4-SC, such as storiform fibrosis and obliterative phlebitis, it was useful in detecting infiltration of affected surfaces by IgG4-positive plasma cells.

The percentage of patients requiring a steroid trial decreased from 37.7% with the 2012 criteria to 7.6% with the revised 2020 criteria. The revised criteria improved diagnostic specificity from 58.5% to 88.7%.

Conclusion: Our validation of the revised 2020 criteria for diagnosing IgG4-SC holds the potential to mitigate unnecessary surgical interventions in patients with isolated IgG4-SC, classified into hilar and extrahepatic subtypes. These updated criteria can enhance the diagnostic accuracy of isolated IgG4-SC and facilitate the identification of this challenging-to-diagnose condition based on including the imaging findings without sufficient proof by endoscopic biliary forceps biopsy and dependence on a steroid trial.

Introduction: The phase 3 QUASAR maintenance study (NCT04033445) evaluated the efficacy and safety of guselkumab (GUS), a dual-acting IL-23p19 subunit inhibitor that potently neutralizes IL-23 and binds to CD64 (a receptor on cells that produce IL-23), in patients (pts) who achieved clinical response to 12 weeks of IV GUS. Here we present results for effects of GUS maintenance on histologic and combined histologic and endoscopic outcomes at Week 44.

Aims & Methods: At maintenance baseline, clinical responders following 12 weeks of GUS IV induction from the QUASAR Phase 2b and 3 induction studies were randomized 1:1:1 to GUS 200 mg SC q4w, GUS 100 mg SC q8w, or GUS withdrawal (PBO SC). Colonic biopsies were collected during endoscopy at maintenance baseline and Week 44 to evaluate treatment effect on histology measured using Geboes, Robarts, and Nancy Histological Index. Histologic improvement, histologic remission, the combination of histologic improvement and endoscopic improvement (histo-endoscopic mucosal improvement; HEMI), the combination of histologic remission and endoscopic improvement, and the combination of histologic remission and endoscopic normalization (remission) were evaluated at Week 44 (see Table for definitions).

Results: Of the 568 pts randomized (at induction baseline: mean age, 40.7yrs; mean UC disease duration, 7.8yrs; mean modified Mayo score, 6.9 [63.9% with severe disease]; Mayo endoscopy subscore of 3, 66.4%), 190 were receiving GUS 200 mg q4w, 188 receiving GUS 100 mg q8w, and 190 receiving PBO. Baseline characteristics were similar across treatment groups. Histologic activity at maintenance baseline was similar for the GUS 200 mg q4w, GUS 100 mg q8w, and PBO treatment groups (mean continuous Geboes total score: 6.7, 6.8, and 6.9, respectively). Improvements in histologic activity at Week 44 were observed in pts treated with GUS 200 mg q4w and GUS 100 mg q8w, while pts assigned to PBO worsened (mean change from maintenance baseline in continuous Geboes total score at Week 44: -1.0, -1.2, and 2.2, respectively [both nominal P<0.001]). At Week 44, a significantly greater proportion of pts treated with GUS 200 mg q4w and GUS 100 mg q8w achieved HEMI compared to PBO (47.9% and 43.6% vs 16.8%, respectively; both P<0.001). Greater proportions of pts in

both GUS treatment groups achieved other relevant endpoints at Week 44 compared to PBO-treated pts as presented in Table. Across biologic/JAK-inhibitor therapy history subpopulations, greater proportions of GUS-treated pts achieved the assessed endpoints compared to PBO.

	GUS Withdrawal (Placebo)	GUS 100 mg SC q8w	GUS 200 mg SC q4w
Primary analysis population, N	190	188	190
Histologic improvement, n (%) (Neutrophil infiltration in <5% of crypts, no crypt destruction, and no erosions, ulcerations or granulation tissue according to the Geboes grading system [ie, Geboes histologic score ≤3.1])	58 (30.5)	122 (64.9)	122 (64.2)
Adjusted treatment difference (95% CI)	-	33.6 (24.3, 42.9)	32.6 (23.3, 41.9)
Nominal p-value		P<0.001	P<0.001
Histologic remission, n (%) (Absence of neutrophils from the mucosa [both lamina propria and epithelium], no crypt destruction, and no erosions, ulcerations or granulation tissue according to the Geboes grading system [ie, Geboes histologic score ≤2 B.0]) ^a	51 (26.8)	111 (59.0)	115 (60.5)
Adjusted treatment difference (95% CI)	-	31.2 (21.9, 40.5)	32.6 (23.5, 41.8)
Nominal p-value		P<0.001	P<0.001
Histo-endoscopic mucosal improvement (HEMI), n (%) (Achieving a combination of histologic improvement and endoscopic improvement [Mayo endoscopy subscore of 0 or 1 with no friability])	32 (16.8)	82 (43.6)	91 (47.9)
Adjusted treatment difference (95% CI)	-	25.7 (17.1, 34.3)	29.6 (21.1, 38.0)
Multiplicity-controlled p-value		P<0.001	P<0.001
Histologic remission and endoscopic improvement, n (%) (Geboes histologic score ≤2 B.0 and endoscopic improvement)	30 (15.8)	78 (41.5)	89 (46.8)
Adjusted treatment difference (95% CI)	-	24.7 (16.2, 33.2)	29.6 (21.3, 38.0)
Nominal p-value		P<0.001	P<0.001
Histologic remission and endoscopic normalization (remission), n (%) (Geboes histologic score ≤2 B.0 and Mayo endoscopy subscore of 0)	27 (14.2)	59 (31.4)	62 (32.6)
Adjusted treatment difference (95% CI)	-	16.2 (8.2, 24.3)	16.9 (9.2, 24.7)
Nominal p-value		P<0.001	P<0.001

^a Results for histologic remission by alternative definitions using Robarts Histopathology Index (RHI ≤ 3, with subscores of 0 for lamina propria neutrophils and neutrophils in the epithelium and without ulcers or erosion) and Nancy Histological Index (NHI ≤ 1) were identical. Note: Patients who had a prohibited change in UC medication, an ostomy or colectomy, a dose adjustment (including sham dose adjustment), discontinued study agent due to lack of therapeutic effect or due to an AE of worsening of UC, or due to other reasons except for COVID-19 related reasons (excluding COVID-19 infection) or regional crisis in Russia and Ukraine prior to Week 44 were considered not to have achieved the endpoint. Patients who had an unevaluable biopsy (ie, a biopsy that was collected, but could not be assessed due to sample preparation or technical errors) or were missing the endoscopy subscore (if applicable) or any of the histology components pertaining to an endpoint at Week 44 were considered not to have achieved the endpoint. The adjusted treatment difference and confidence intervals were based on the Wald statistic with Cochran-Mantel-Haenszel (CMH) weight. The p-values were based on the CMH chi-square test, stratified by clinical remission status at maintenance baseline (Yes/No), and induction treatment (guselkumab 400 mg IV, guselkumab 200 mg IV, placebo IV crossover to guselkumab 200 mg IV).

Table. Summary of Histologic and Combined Histologic and Endoscopic Outcomes at Week 44.

Conclusion: In this phase 3 maintenance study, pts with UC treated with GUS 200 mg SC q4w or GUS 100 mg SC q8w experienced clinically meaningful improvements in histologic and combined histologic and endoscopic outcomes at Week 44 compared to PBO-treated pts.

Introduction: Patients with moderately to severely active ulcerative colitis (UC) have debilitating symptoms that may incur substantial negative effects on health-related quality of life (HRQoL). According to the STRIDE-II consensus, restoration of HRQoL is a desirable long-term treatment goal for patients with active UC.¹

In this post-hoc analysis, we evaluated the extent to which patients treated with upadacitinib (UPA) achieved normalisation of HRQoL after induction and maintenance treatment.

Aims & Methods: Data from the multicentre, double-blind, Phase 3 trials, U-ACHIEVE (NCT02819635) and U-ACCOMPLISH (NCT03653026), were analysed. During induction, patients were randomised 1:2 to oral placebo (PBO) or UPA 45 mg once daily (QD) for 8 weeks. Patients achieving a clinical response to UPA per Adapted Mayo score at Week 8 were re-randomised 1:1:1 to PBO, UPA 15 mg, or UPA 30 mg QD for 52 weeks of maintenance.

The proportion of patients achieving normalisation of each individual HRQoL outcome, per literature-based normative value thresholds, was assessed at Weeks 8 and 52: FACIT-Fatigue score; IBDQ score; WPAl-UC (overall work impairment, work time missed, impairment while working, activity impairment); SF-36 PCS; SF-36 MCS; EQ-5D-5L VAS; and EQ-5D-5L index.

A stringent composite score including these outcomes was also calculated to determine the proportion of patients who achieved normalisation of all individual HRQoL-related scores. Point estimates were calculated for all outcomes and treatment differences between UPA and PBO were compared using the Cochran-Mantel-Haenszel test.

Results: During induction, 660 patients were randomised to UPA 45 mg and 328 patients to PBO. In patients receiving UPA 45 mg vs PBO, more patients achieved normalisation of each individual HRQoL outcome at Week 8 of induction ($p < 0.001$; Table 1). Improvements were also observed at Week 52 of maintenance in patients receiving UPA 15 mg ($n = 148$) and 30 mg ($n = 154$), with more patients achieving normalisation of each HRQoL

outcome with both doses of UPA vs PBO ($p < 0.01$). More patients achieved normalisation of composite HRQoL scores at Weeks 8 (UPA 45 mg: 18.9%; PBO: 5.5%) and 52 (UPA 30 mg: 24.0%; UPA 15 mg: 22.3%; PBO: 8.7%) with all doses of UPA compared to PBO ($p < 0.001$).

For induction data, the Cochran-Mantel-Haenszel test was used to calculate the 95% CI for differences between treatment groups and was adjusted for strata: baseline corticosteroid use (yes or no), baseline Adapted Mayo score (≤ 7 or > 7) and bio-IR status (bio-IR or non-bio-IR).

For maintenance data, the Cochran-Mantel-Haenszel test was used to calculate the 95% CI for differences between treatment groups and was adjusted for strata: bio-IR status (bio-IR or non-bio-IR) at the baseline of the induction study, clinical remission status at Week 0 (yes or no), and corticosteroid use at Week 0 (yes or no).

Bio-IR, biologics inadequate response; CI, confidence interval; diff., difference; EQ-5D-5L, European Quality of Life 5 Dimensions 5 Levels; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HRQoL, health-related quality of life; IBDQ, Inflammatory Bowel Disease Questionnaire; imp., impairment; MCS, Mental Component Summary; PBO, placebo; PCS, Physical Component Summary; QD, once daily; SF-36, Short Form 36; UC, ulcerative colitis; UPA, upadacitinib; VAS, visual analogue scale; WPAI, Work Productivity and Activity Impairment Questionnaire.

Table 1. Proportion of patients with UC achieving normalisation of HRQoL outcomes after treatment.

Conclusion: UPA is more efficacious than PBO at achieving normalisation of patients' HRQoL, at induction and through Week 52 of maintenance. These results suggest that UPA may help patients with moderately to severely active UC achieve the long-term treatment goal of normalisation of HRQoL.

Introduction: Upadacitinib (UPA), an oral, reversible JAK inhibitor approved for the treatment of moderately to severely active ulcerative colitis (UC),^{1,2} has shown sustained efficacy and an acceptable safety profile in long-term studies of multiple autoimmune conditions.³⁻⁵

Aims & Methods: We report efficacy and safety of UPA after almost 3 years (yrs) of therapy in patients (pts) with moderately to severely active UC from the U-ACTIVATE (NCT03006068) study, consisting of 1 yr maintenance and around 2 yrs long-term extension (LTE). Pts aged 16–75 yrs with UC for ≥90 days prior to study entry, an Adapted Mayo score (AMS) of 5–9 and an endoscopic subscore of 2 or 3, were eligible for induction studies (U-ACCOMPLISH [NCT03653026]; U-ACHIEVE Induction [NCT02819635]) and randomised to placebo (PBO) or UPA 45 mg once daily (QD) for 8 weeks (wks).

Clinical responders were re-randomised to PBO, UPA 15 mg QD (UPA15) or UPA 30 mg QD (UPA30) for 52 wks (U-ACHIEVE Maintenance). Pts who completed 52-wks of maintenance were eligible to enter this LTE on their maintenance dose. Efficacy was evaluated by clinical remission (per AMS and Partial Mayo score), maintenance of clinical remission (per AMS), clinical response, endoscopic remission, endoscopic improvement and maintenance of endoscopic remission during the LTE at Wk 96 (endpoints are defined in the Table).

Safety was assessed by treatment-emergent adverse events (TEAEs), presented as exposure-adjusted event rates (EAERs; events per 100 pt yrs [E/100 PY]). Efficacy and safety analyses were based on data up to June 30, 2023 and analysed as observed without imputation for missing values.

Results: At Wk 96, approximately three-quarters of pts with UC treated with either UPA15 or UPA30 achieved clinical remission (per AMS) (Table). Of pts in clinical remission at Wk 0 of the LTE (per AMS), a similar proportion maintained this response with UPA15 and a slightly higher response rate was observed with UPA30 at Wk 96 of the LTE. Clinical outcomes and endoscopic improvement were observed in the majority of patients in both UPA groups.

Endoscopic remission was achieved by almost half of pts treated with UPA. Of endoscopic remitters at Wk 0 of the LTE study, more than half maintained remission status at Wk 96 of the LTE, with a slightly higher response rate observed with UPA30. For safety, 369 pts (UPA15, n=142; UPA30, n=227) with 789.4 PY (UPA15, 302.5 PY; UPA30, 486.9 PY) of expo-

sure were analysed. Rates of serious TEAEs and TEAEs leading to treatment discontinuation were similar across treatment groups. No deaths were reported in the UPA15 group; there was 1 TEAE leading to death (EAER: 0.2 E/100 PY) in a pt requiring prolonged hospitalisation for worsening COVID-19 infection in the UPA30 group (Table).

Efficacy endpoints at Week 96 n/N (%) [95% CI]	UPA 15 mg QD	UPA 30 mg QD
Clinical remission per Adapted Mayo score ^a	69/91 (75.8) [67.0, 84.6]	104/141 (73.8) [66.5, 81.0]
Clinical remission per Partial Mayo score ^a	83/92 (90.2) [84.1, 96.3]	123/143 (86.0) [80.3, 91.7]
Maintenance of clinical remission ^a	50/64 (78.1) [68.0, 88.3]	69/82 (84.1) [76.2, 92.1]
Clinical response per Adapted Mayo score ^a	89/91 (97.8) [94.8, 100.0]	136/141 (96.5) [93.4, 99.5]
Endoscopic improvement ^f	78/95 (82.1) [74.4, 89.8]	126/153 (82.4) [76.3, 88.4]
Endoscopic remission ^g	45/95 (47.4) [37.3, 57.4]	69/153 (45.1) [37.2, 53.0]
Maintenance of endoscopic remission ^h	20/31 (64.5) [47.7, 81.4]	37/51 (72.5) [60.3, 84.8]
TEAEs E (E/100 PY)	UPA 15 mg QD (n=142; PY=302.5)	UPA 30 mg QD (n=227; PY=486.9)
Any TEAEs ⁱ	699 (231.1)	1097 (225.3)
Serious TEAEs	32 (10.6)	60 (12.3)
TEAEs leading to discontinuation of study drug	15 (5.0)	17 (3.5)
TEAEs leading to death	0	1 ^j (0.2)

^aEfficacy and safety populations included induction responders (UPA 45 mg for 8 weeks) who completed 52 weeks of maintenance treatment and enrolled in this LTE analysis. Patients who were not in clinical remission could escalate their dose upon entry to this LTE.

^bAdapted Mayo score ≤2 with stool frequency subscore ≤1 and not greater than baseline of induction studies, RBS=0 and ES ≤1 without friability.

^cPartial Mayo score ≤2 with no subscore >1.

^dClinical remission per Adapted Mayo score at Week 96 in those who achieved clinical remission at Week 0 of the LTE study.

^eDecrease in Adapted Mayo score ≥2 points and ≥30% from baseline of induction studies, plus a decrease in RBS ≥1 or an absolute RBS ≤1.

^fES ≤1 without friability.

^gES=0.

^hPatients who achieved endoscopic remission at Week 96 among those who achieved endoscopic remission at Week 0 of the LTE study.

ⁱTEAEs are defined as events that begin either on or after the first dose of study drug in the LTE study, and within the earlier of the first dose change in the LTE study and the last dose of study drug in the LTE study plus 30 days.

^jFifty-seven-year-old male who experienced a suspected pulmonary thromboembolism event while hospitalised for worsening of COVID-19 infection and acute renal failure. Primary cause of death was pulmonary embolism. Risk factors included medical history of arterial hypertension, former cigarette smoker, concurrent COVID-19 infection and prolonged hospitalisation.

CI, confidence interval; E, events; ES, endoscopic subscore; LTE, long-term extension; PY, patient years; QD, once daily; RBS, rectal bleeding subscore; TEAE, treatment-emergent adverse event; UPA, upadacitinib.

Table. Summary of efficacy and safety^a (as observed)

Conclusion: Achievement of clinical and endoscopic endpoints at LTE Wk 96 demonstrates the continued benefit of almost 3 yrs of therapy with UPA. The long-term safety profile for UPA in pts with UC was consistent with previous analyses,^{1,2} with no new safety concerns identified in this ongoing LTE study.

Introduction: Filgotinib (FIL), a once-daily, oral, Janus kinase 1 preferential inhibitor, is approved for the treatment of ulcerative colitis (UC). FIL was effective in inducing and maintaining clinical remission and was well tolerated in the placebo-controlled phase 2b/3 SELECTION trial (NCT02914522).¹

Aims & Methods: The efficacy and safety of continued treatment with FIL 200 mg (FIL200) are being assessed in the long-term extension (LTE) study (SELECTIONLTE: NCT02914535). The study design of SELECTION has been published previously.¹ We now report the efficacy and safety of open-label FIL200 through up to 5 years of treatment: LTE week 192 in completers and LTE week 240 in induction non-responders. Completers were defined as patients who completed the SELECTION induction and maintenance studies, and non-responders were those without response at SELECTION week 10; all of whom entered the LTE study. A data cut-off of 23 March 2023 was used for this interim analysis. Proportions of patients who were in partial Mayo Clinic Score (pMCS) remission (pMCS ≤1) and Inflammatory Bowel Disease Questionnaire (IBDQ) remission (score ≥170) were reported both as observed cases and using non-responder imputation (NRI). Adverse events (AEs) and AEs of special interest (AESIs) were evaluated using exposure-adjusted incidence rates per 100 patient-years of exposure (PYE).

Results: This interim analysis included 148 completers and 372 non-responders. AEs and AESIs in patients treated with open-label FIL200 (2464.7 PYE) showed no new safety signals, and safety events were comparable to those seen in previous analyses. The proportions of patients who were in pMCS and IBDQ remission are shown in the *Table*. The proportions of patients who were in pMCS remission increased during SELECTION to reach 72.4% (FIL200, as observed) at week 58/LTE baseline and increased further during SELECTIONLTE (85.0% at LTE week 192) in completers. Proportions in pMCS remission increased more gradually over SELECTIONLTE, reaching 66.7% (FIL200–FIL200, as observed) at LTE week 240 in non-responders. Similar patterns were seen for IBDQ remission; 78.5% (FIL200, as observed) of completers were in IBDQ remission at week 58/LTE baseline, increasing to 84.8% by LTE week 192. In non-responders, increases in the proportions of patients who were in IBDQ remission were gradual, reaching 77.8% (FIL200–FIL200, as observed) at LTE week 240. NRI analyses showed similar but much more conservative results than the as observed analyses for both groups for both endpoints.

Conclusion: Filgotinib 200 mg was effective in maintaining symptomatic remission and health-related quality of life for up to 5 years. No new safety signals were identified, and rates of AEs under long-term exposure were comparable to those previously reported.^{1–4} Prolonged treatment with filgotinib is efficacious for the long-term management of UC, and together with its proven safety profile, results in an acceptable benefit–risk profile.

Introduction: Tofacitinib (TOFA) is a JAK inhibitor used for the treatment of rheumatologic diseases including rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis. The efficacy of TOFA in rheumatology led to big expectations on a potential benefit on ulcerative colitis (UC)-associated spondyloarthropathy (SpA), but very few data are currently available.

Aims & Methods: Real-world Effectiveness of Tofacitinib on Ulcerative Colitis Associated Spondyloarthropathy (RETUCAS) is a prospective, multicentre, observational study designed to assess the effectiveness of TOFA on UC associated SpA and promoted by the Italian Group for the study of Inflammatory Bowel Disease (IG-IBD). Patients with UC and an established diagnosis of active axial or peripheral SpA at baseline were included. Active SpA at baseline was defined with an Ankylosing Spondylitis Disease Activity Score (ASDAS)-CRP ≥ 1.3 in case of axial SpA, and with a disease activity score (DAS)28-CRP ≥ 2.6 in case of peripheral SpA.

The primary endpoint was the rate of patients achieving a steroid-free joint response (SFJR - defined by a decrease of ≥ 1.1 units of ASDAS-CRP for axial SpA, and a decrease of > 0.6 units of DAS28-CRP for peripheral SpA compared with baseline with no steroids use) at week 8 and 52.

Secondary endpoints were the clinical intestinal response (CIR) and the steroid-free clinical intestinal remission (SFCIR) assessed with the partial Mayo score.

Results: 44 patients were included (mean age: 43.8 ± 12.6 years; mean duration of disease: 14.2 ± 8.9 years; all but two were bio-experienced). Active axial SpA was reported in 4 patients (9.1%), active peripheral SpA

in 31 cases (70.5%), and mixed (axial + peripheral) SpA in 9 cases (20.5%). At baseline, mean ASDAS-CRP was 2.4 ± 0.7 , and DAS28-CRP was 3.5 ± 0.6 . At 8 weeks, SFJR was reported in 52.3% of patients, with a significant difference between patients with peripheral SpA only compared with the subgroup of patients with axial and mixed SpA (67.7% vs. 15.4%; $p=0.001$). At 52 weeks, SFJR was reported in 59.4% of patients (peripheral SpA only: 66.7% vs. axial and mixed SpA: 37.5%; $p=0.3$). CIR was reported in 59.1% of patients at 8 weeks, and in 75.0% of patients at 52 weeks, with SFCIR achieved by 34.1% at 8 weeks, and 56.2% at 52 weeks.

Three adverse events were reported: one case mild hypercholesterolemia, one case of mild elevation of transaminase levels, and one case of fever and malaise causing the withdrawal of TOFA after 3 days of administration.

Conclusion: This is the first prospective study designed specifically for the assessment of IBD-associated SpA and based on rheumatological scores. TOFA showed to be effective on UC-associated peripheral SpA, while more data are needed on axial SpA

Disclosure: The study was promoted by IG-IBD and received no funding.

Introduction: In the gut, intestinal epithelial cells form a structural barrier, delineating the intestinal lumen from the lamina propria¹. Within the lumen, microbes exert essential functions in maintaining gastrointestinal homeostasis and functionality². Regardless of commensal or pathogenic nature of the bacteria, their interaction with gut epithelium is inevitable. During ulcerative colitis (UC), both mucosal barrier and microbial composition are disturbed³. However, it is still unclear whether naturally occurring gut bacteria might influence the control or management of the protective lining of cells in the colon.

Aims & Methods: The aim of the study was to identify which faecal microbiota components remain unaltered during UC and assess the interplay of these bacteria with colonic epithelial cells.

The study was approved by the Kaunas Regional Biomedical Research Ethics Committee (protocol no. BE-2-31). Faecal microbiota was analysed by employing 16S rRNA-gene v1-v2 region sequencing on stool samples of active and quiescent UC patients (n=47) and non-IBD controls (n=25). Functional analysis was performed using colonic epithelial organoid-derived monolayers of UC patients (n=9) and non-IBD controls (n=8). Monolayers were co-cultured with *Escherichia coli* (ATCC 25922) and *Phocaeicola vulgatus* (ATCC 8482) bacteria type strains. The interplay between bacteria and colonic epithelial cells was assessed by analysing the expression of gene markers for epithelial barrier integrity (ZO1), pathogen recognition (TLR4) and stress induction (HSPA1A, HSPB1).

Results: First, 16S rRNA-gene sequencing revealed a persistent bacterial imbalance in both active and quiescent UC patients compared to non-IBD controls. Specifically, Chao1, Shannon, and Simpson α -diversity indices were significantly lower ($p_{\text{Wilcoxon}} < 0.05$) in both active and quiescent UC patient groups when compared to non-IBD controls. Microbial community clusters, assessed by Bray-Curtis dissimilarity index, also differed significantly between UC patients and non-IBD controls ($p_{\text{PERMANOVA}} < 0.05$). Subsequent co-occurrence and differential abundance analyses identified that in contrast to healthy individuals, UC patients exhibited statistical significance ($p_{\text{adj. Wilcoxon}} < 0.05$) in the relative abundance of 5 genera, including *Alistipes*, *Mediterraneibacter*, *Paraprevotella*, etc., while 35 genera were found to be present at comparable levels ($p_{\text{adj. Wilcoxon}} \geq 0.05$). Of them, the most abundant ones were *Phocaeicola*, *Collinsella*, *Roseburia*, *Holdemanella*, and *Bacteroides*.

Functional analysis, utilizing co-cultures of commensal bacteria and colonic epithelial cells of active UC patients and non-IBD controls, showed that both *E. coli* and *P. vulgatus* did not induce pathogen-pattern recognition and stress responses.

Interestingly, both species demonstrated potential to provoke diverse tight junction-related cellular reactivity (however, due to high variation in patient-to-patient responses, results did not reach statistical significance ($p_{\text{adj. Wilcoxon}} \geq 0.05$)).

More precisely, a contact with *E. coli* and *P. vulgatus* tended to increase the expression of ZO1 in non-IBD epithelial cells (FC=3.59 and FC=2.27, respectively) compared to untreated cells, while an opposite trend was observed in epithelial cells of UC patients (FC = 0.67 and FC = 0.75, respectively).

Conclusion: Diverse colonic epithelial cell responses to distinct commensal bacteria species imply the contribution of stably abundant gut microbiota to the impairment of mucosal barrier integrity during UC.

Introduction: The role of the gut microbiota in inflammatory bowel disease (IBD) pathogenesis is widely acknowledged, with numerous bacteria identified as contributing factors. Little however is known about the part viruses play – a likely major component in the structuring and functioning of the gut microbiota. Understanding how viruses interact with the gut microbiota and host cells in the context of IBD could facilitate innovative treatment approaches and personalized interventions.

Aims & Methods: We explore the colonic and upper intestinal virome in patients with IBD compared with general population (GP) controls. Faecal (colonic) and effluent (upper intestinal) derived shotgun metaviromes of 100 IBD individuals (UC = 50, CD = 50) and 50 IBD individuals with an ileostomy, respectively were compared to faecal derived metaviromes of 50 GP individuals. Metaviromes were generated using a combination of shotgun methods and viral particle enrichment, allowing for identification of both eukaryotic and prokaryotic, dsDNA, ssDNA and RNA viruses. Viral diversity, composition and prevalence were compared by calculating Shannon diversity, Bray-Curtis distances and performing logistic regression analyses. P-values were adjusted using false discovery rate (FDR) to correct for multiple testing, where relevant; FDR<0.05 was considered significant.

Results: Similar to bacterial diversity in IBD versus GP samples, we see a significantly lower viral diversity in CD and UC colonic samples compared with the GP, and an even lower diversity when comparing upper intestinal samples to colonic samples (FDR<0.05). Comparing viral populations between groups, we observe that, whilst there is evident interindividual variability within groups, distinct clustering between colonic and upper intestinal samples can be seen, with colonic IBD samples clustering slightly more towards upper intestinal samples.

When comparing viral group prevalences between GP and IBD colonic samples, 83 out of 260 viral groups present in IBD-UC samples are absent in the GP samples and 125 out of 302 viral groups present in the GP were absent in IBD-UC. For IBD-CD samples these numbers are 79 out of 248 and 133 out of 302, respectively. The top 3 viral groups that positively associated with IBD-UC samples are: one unknown phage group (predicted bacterial host: *Parasutterella* spp.), a group containing *Lactobacillus* phages (bacterial host: *Lactobacillus* spp.) and a group containing *Lactococcus* phages (bacterial host: primarily *Lactococcus* spp.). The top 3 viral groups that positively associated with IBD-CD samples are: the same unknown phage group as for IBD-UC, and two other unknown phage groups (predicted bacterial hosts: primarily *Enterocloster* & *Bacteroides* spp, respectively).

Conclusion: This first comprehensive description of the gut virome across multiple gastrointestinal sites shows specific alterations in IBD. Many viral groups differentially present in the IBD intestine infect bacteria often associated with gut health and significantly reduced in IBD patients. Dysregulated bile acid signaling has also been implicated in the pathogenesis of IBD, with bacterial dysbiosis being linked to its cause. In IBD populations, we observe phages with the host *E. boltea* – a bacteria increased in dysbiosis due to their potential to metabolise bile acids.

We speculate that alterations in the gut virome composition are key events that disrupt the equilibrium between gut microbiota and host, promoting a pro-inflammatory state and driving IBD pathogenesis. The next steps will be to investigate the mechanisms underlying these complex interactions.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel disease (IBD) is a chronic systemic condition of unknown etiology. Dysregulated T-cell responses play a fundamental role in perpetuating intestinal inflammation in IBD. Unconventional T cells are a diverse subset of T cells with innate and adaptive characteristics including: Gamma Delta T cells (GDT), mucosa-associated invariant T (MAIT) cells, and invariant natural killer T (iNKT) cells. As new studies emerge, unconventional T cells' role in IBD pathogenesis has been increasingly recognized, but their role in the pathogenesis and possible clinical application remains to be elucidated.

Aims & Methods: The aim of the study is to characterize the immune profile of IBD patients and controls in a large well-characterized cohort with focus on Unconventional T cells. We performed an in-depth, multidimensional flow cytometry analysis of unconventional T cells and plasma proteins from patients' samples collected from the IBD biobank in Norway. We used immunophenotyping from isolated PBMC to study both conventional T cells and unconventional T cells and evaluated their gut-homing

-a4 and b7 expression-, activation and senescence markers. A 65-plex Luminex assay was used to quantify soluble plasma proteins. We studied the variations of T cell profiles within the different disease phenotypes and their correlation with disease activity. A subset of patients was followed-up clinically for 6 (+/-2) years to evaluate the association with disease outcomes.

Statistical analysis was performed using GraphPad Prism (San Diego, CA). Two-tailed Mann-Whitney U test was used to compare two independent groups and ROC analysis was used for diagnostic accuracy; $p \leq 0.05$ was considered statistically significant. Ethical approvals were obtained and all patients gave written informed consent.

Results: A total of 184 individuals (106 F) were included: 149 IBD (84 UC and 65 CD) and 25 healthy controls. We found important quantitative and phenotypical differences in unconventional T cells and plasma protein in IBD and between UC and CD patients. Patients with IBD had a significant reduction in MAIT cells, and increase in GDT VD3+ and CD8+ cells ($p < 0.05$). MAIT cells from IBD patients had lower a4+ and b7+ expression than controls. ($p < 0.05$, $p < 0.001$). Interestingly, Macrophage Migration Inhibitor Factor (MIF) was significantly reduced in patients with UC but not in CD ($p < 0.0001$).

Patients with total colitis presented a significant increase in platelet count, MIG, IL-2R, and CD30 ($p < 0.001$, $p < 0.01$ and $p < 0.05$, respectively). CD patients with colonic affection (L2) had a significant increase in TNF-b, FGF-2, G-CSF compared with patients with ileal (L1) or ileocolonic (L3) CD ($p < 0.01$). Interestingly, MAIT cells were the only immune cells significantly reduced in patients with extraintestinal manifestations. The combination of 6 parameters: IL-4, IL-5, IL-8, MIG, CD30 and Eotaxin-3 showed a good diagnostic accuracy in ROC curves (CI:0.759-1.000; $p = 0.0005$) to distinguish patients with mucosal healing vs those with biochemical and clinical remission alone. A decrease in GDT VD2 cells was found in UC patients with worse outcomes ($p < 0.01$). CD patients with bad prognosis showed a significant increase in platelet counts and a decrease in: FABP2, CXCL10 and APRIL ($p < 0.05$).

Conclusion: These results demonstrate the potential of the characterization of Unconventional T cells and soluble plasma proteins as biomarkers in IBD and as markers of disease progression. Further investigation is warranted to elucidate the use of Unconventional T cells in precision medicine and as potential therapeutic targets in IBD.

Introduction:

The gut microbiome exerts a significant influence on the host's cellular energy metabolism during homeostasis and disease, notably due to the production of metabolites (1), such as polyamines (2).

Gut dysbiosis and bioenergetic alterations leading to metabolic shifts have been associated with altered cellular responses and are involved in intestinal disorders, such as inflammatory bowel disease (IBD) (3,4).

Cadaverine, a gut polyamine derived from L-lysine decarboxylation, has been previously proposed to be transported into mitochondrial inner compartments in basal and induced conditions (5).

On the other hand, it seems to be positively regulated in the gut of IBD patients (6). However, the biological significance in both contexts remains still unexplored.

Aims & Methods:

This study uncovers the potential immunometabolic role of cadaverine in vitro and during intestinal inflammation. For that, single-cell energetic metabolism by profiling translation inhibition (SCENITH), luminescence and flow cytometry-based assays, Seahorse real-time cell metabolic analysis, metabolomics, RNAseq, and proteomics were applied to explore the role of cadaverine on energy metabolism in purified cells. Antibiotic-induced gut microbiota perturbations and dextran sodium sulfate (DSS)-induced colitis were carried out to further investigate its effect in vivo.

Results: Here we demonstrate that cadaverine enhances adenosine triphosphate (ATP) levels in THP-1 monocytic cell line as well as in human monocytes and macrophages obtained from healthy donors. Those results were associated with increased glucose uptake and utilization as a metabolic fuel and with higher mitochondrial dependence as a metabolic pathway, particularly elevating basal and maximal oxidative phosphorylation (OXPHOS) rates. The effects of cadaverine on mitochondrial functions persisted even in the presence of lipopolysaccharide (LPS) that triggers aerobic glycolysis in monocytes/macrophages.

Interestingly, cadaverine presented immunomodulatory activity by increasing interleukin (IL)-10 levels and decreasing tumor necrosis factor (TNF)- α production in classical monocytes while triggering the polarization of macrophages to the M2 anti-inflammatory phenotype. Such immunomodulatory potential appears intricately dependent on mitochondrial respiration since this effect was blocked when OXPHOS was pharmaco-

logically inhibited. Omics analysis reveals that itaconate metabolism and Krebs cycle modulation may be associated with cadaverine immunometabolic activity. Oral administration of cadaverine in antibiotics-induced gut microbiota-depleted mice rescued from both small intestine and colon macrophage energy deficiency.

Furthermore, cadaverine also sustained OXPHOS and mitochondrial health features in those cells. As L-lysine decarboxylase genes are mostly expressed by gut Enterobacteriaceae, which in turn are augmented and suggested to be related to IBD, we specifically depleted this bacterial family with colistin in mice and induced colitis with DSS.

In this setting cadaverine administration ameliorates disease severity by polarizing colon macrophages towards the M2 phenotype and preserving the overall mitochondrial features, such as mass, mitochondrial membrane potential, and reactive oxygen species, to sustain ATP production by OXPHOS.

Conclusion: Such discoveries at the metabolic level hold promise for identifying novel therapeutic strategies that target cellular energy metabolism and the gut microbiota to modulate monocyte and macrophage responses in IBD.

Introduction: Patients with Crohn's disease (CD) and myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) exhibit elevated antibody responses against gut microbiota flagellins. However, flagellin-specific antibody repertoires and functional roles in the diseases remain incompletely understood. Bacterial flagellins can be categorized into three types depending on their interaction with toll-like receptor 5 (TLR5): (1) "stimulator" and (2) "silent" flagellins, binding TLR5 through a conserved

N-terminal motif, with only stimulators activating TLR5 due to a specific C-terminal domain; (3) “evader” flagellins of pathogens, which circumvent TLR5 activation via mutated N-terminal TLR5 binding motifs.

Here we studied the characteristics, epitope binding, and sequence (dis) similarity of anti-flagellin antibody responses in CD and ME/CFS.

Aims & Methods: Since conventional antibody profiling methods like enzyme-linked immunosorbent assays [ELISAs] do not allow for large-scale measurements of antibody repertoires, we leveraged phage-display immunoprecipitation sequencing (PhIP-Seq) to characterize 344,000 rationally selected peptide antigens in 256 patients with CD, 40 patients with ME/CFS and in two equally sized groups of age- and sex-matched healthy controls from population-based cohorts in the Netherlands and U.K., respectively. Different sequence alignment strategies were employed to compare flagellin peptide structures with observed antibody-bound flagellin peptide reactivity.

Results: Both patients with CD and ME/CFS exhibited elevated antibody responses against distinct regions of flagellin peptides compared to healthy individuals ($P < 0.001$). N-terminal binding to *Lachnospiraceae* flagellins was comparable in both diseases, while C-terminal binding was more prevalent in CD. N-terminal antibody-bound flagellin sequences were similar across CD and ME/CFS, resembling ‘stimulator’ and ‘silent’ flagellins more than evaders.

However, C-terminal antibody-bound flagellins showed higher resemblance to stimulator than to silent flagellins in CD, but not in ME/CFS. This group of antibody-bound flagellins was exclusively identified in a subset (10-20%) of patients with CD and characterized by its strong overrepresentation (exceeding 20-fold), underscoring its potential significance in distinguishing pathophysiological subtypes of CD.

Conclusion: Antibody binding to the N-terminal domain of stimulator and silent flagellins may impact TLR5 activation in both CD and ME/CFS patients. Furthermore, elevated antibody binding to the C-terminal domain of stimulator flagellins in CD may explain pathophysiological differences between diseases. Our results highlight the diagnostic potential of these antibody responses and their impact on innate/adaptive immunity balance.

Introduction: Optimal management after radical endoscopic resection (R0 ER) of high-risk (HR) T1 esophageal adenocarcinoma (EAC) is still a matter of debate due to conflicting reports on the risk of lymph node metastasis (LNM). In case of submucosal (sm) invasion, a/o poor differentiation, a/o lympho-vascular invasion (LVI), additional treatment is often still recommended. In this prospective international multicenter cohort study (PREFER, NCT03222635), we aim to evaluate the safety of a strict endoscopic follow-up (FU) strategy following R0 ER for T1b and HR-T1a EAC.

Aims & Methods: Patients treated with R0 ER of T1b EAC were included from July 2017 - July 2023, in 19 hospitals in Europe and Australia. Pa-

tients were defined as HR-T1b EAC in case of sm invasion $\geq 500\mu\text{m}$, a/o poor differentiation, a/o LVI. From July 2020 we also included HR-T1a EAC, with HR defined as presence of poor differentiation a/o LVI, as part of an ongoing prospective registry. To allow for appropriate FU we assessed outcomes for patients included up to July 2023, at which time inclusion for the prospective PREFER study was complete.

After R0 ER, patients underwent re-staging with endoscopic ultrasound (EUS) and CT/PET. If there were no signs of metastasis (cNOM0), patients were consented for strict endoscopic FU, with gastroscopy and EUS 3-monthly the first 2 years, 6-monthly during years 3 and 4, and at year 5. CT/PET was repeated after 1 year. Primary outcomes were 5-year disease-specific and overall survival; secondary outcomes were rates of distant metastasis, LNM, and local recurrence ineligible for endoscopic treatment.

Results: Per July 2023, 200 patients (166 male, median age 70 (IQR 63 - 76) years) were included, 157 T1b patients (n = 54 low-risk (LR) T1b and n = 103 HR-T1b) and 43 HR-T1a patients.

For the T1b group, median FU was 21 (IQR 12-38) months. Thus far, 11/157 patients (7%) have successfully completed the 5-year FU without signs of metastatic disease or intra-luminal tumor recurrence ineligible for endoscopic re-treatment. Distant metastases were diagnosed in 3/157 (2%, 95%CI 0 - 4) patients, all without signs of local recurrence or LNM: 1/3 underwent resection of a lung metastasis, with no signs of recurrence after 9 months; 1/3 had liver metastasis and started palliative systemic therapy 4 months ago; 1/3 had liver metastasis, declined further treatment and died. Locoregional LNM were diagnosed in 9/157 (6%, 95% CI 2 - 9). All were detected at a curable stage, but 1/9 declined further treatment and died from EAC; the other patients received appropriate treatment and are disease-free after median 26 (IQR 12 - 27) months post additional treatment. In total, 8/157 patients (5%, 95%CI 2 - 9) developed intra-luminal tumor recurrence ineligible for endoscopic re-treatment, 3/8 declined additional treatment and eventually died from EAC. Furthermore, 10/157 patients (6%) died during FU due to unrelated causes.

In the HR-T1a group, no recurrent disease was diagnosed after a median FU of 16 (IQR 12 - 23) months.

Total N=200	FU (months), Median (IQR)	Distant metastasis, N (% [95%CI])	FU until distant metastasis (months), Median (IQR)	Lymph node metastasis, N (% [95%CI])	FU until LNM (months), Median (IQR)	Intra-luminal tumor recurrence ineligible for ER*, N (% [95%CI])	FU until recurrence ineligible for ER*, (months), Median (IQR)	EAC- related death, N (% [95%CI])	Non-EAC- related death, N (% [95%CI])
High-risk T1b (n=103)	21 (12 - 36)	3 (3%[0 - 6])	29 (N/A)	7 (7%[2 - 12])	10 (3 - 13)	6 (6%[1 - 10])	6 (4 - 15)	4 (4%[0 - 8])	7 (7%[2 - 12])
Low-risk T1b (n=54)	22 (11 - 42)	0	-	2 (4%[0 - 9])	15 (N/A)	2 (4%[0 - 9])	8 (N/A)	0	3 (6%[0 - 12])
High-risk T1a (n=43)	16 (12 - 23)	0	-	0	-	0	-	0	0

*1 patient both had LNM and intra-luminal tumor recurrence

Conclusion: The preliminary findings of this first prospective study on HR-T1 EAC support a strict endoscopic FU strategy in select patients who underwent R0 ER with no signs of metastatic disease (cNOM0) at baseline.

Disclosure: Nothing to disclose.

Contact E-Mail Address: p.stougie@amsterdamumc.nl

Introduction: Current surveillance for low-risk Barrett's Esophagus (BE) patients is burdensome, cost-ineffective and dependent on subjective histological assessment of dysplasia with high inter-observer variability. This study aims to identify genomic features that can be identified in a clinically translatable targeted sequencing panel, enhancing the stratification of low-risk BE patients and enabling personalized surveillance strategies.

Aims & Methods: BE patients identified as progressors to early esophageal adenocarcinoma or non-progressors from a large community-based cohort, were matched for age, sex and BE segment length. DNA from baseline and prior non-dysplastic biopsies was sequenced using a targeted capture-based panel designed to detect mutations and copy number changes (CNV).

Detected mutations, homozygous deletions, and high-level amplifications were filtered for likely pathogenic events. We performed logistic regression, covariate analysis, and penalized mixed-effect models. A joint model for survival and mixed effects was implemented to analyze the data distributed over space and time.

Results: 331 baseline samples and 214 temporal samples, accounting for 105 progressors who progressed after a median 4 (IQR 2.4-7.2) years, and 115 non-progressors who had a median progression-free follow-up of 6 (IQR 4.3-7.3) years, were analyzed. *TP53* mutations strongly predict risk ($p < 0.0001$, Hazard Ratio (HR) = 3.84, 95% confidence interval (CI) 2.89-5.67) as does CNV 17p loss ($p < 0.0001$, HR = 4.41, 95% CI 2.29-8.52).

While there is significant overlap between *TP53* mutations and 17p loss, patients with both trended to progress faster. Chromosomal arm CNVs ($p = 0.0012$, HR = 1.32, 95% CI 1.14-1.52), amplifications ($p < 0.001$, HR = 2.89, 95% CI 1.57-5.31) and mutational burden ($p < 0.0001$, HR = 1.30, 95% CI 1.21-1.40) were also associated with progression risk. A combined model incorporating: —*TP53* mutations, 17p loss, and mutational burden—demonstrated a 57% sensitivity and 84% specificity and an AUC of 0.758. This model identified 60 of 105 progressors in non-dysplastic BE patients.

	Predicted non-Progressive	Predicted Progressive
True Non- Progressors	96	18
True Progressors	45	60

Table.

Conclusion: As expected, *TP53* was a pivotal risk factor in this spatial and time-dependent cohort, even in the absence of dysplasia. Two hits in *TP53* (mutation with 17p loss) suggested a trend toward near term progression, suggesting the possibility of more refined stratification. Prior studies focused on either mutations or CNVs for risk stratification.

We show the combination of both, detected in a clinically translatable assay, improves prognostic value, effectively identifying the majority of pro-

gressors among non-dysplastic BE patients while maintaining an acceptable false-positive rate. This approach has the potential to dramatically impact risk stratification and surveillance strategies in non-dysplastic BE patients.

Disclosure: Nothing to disclose.

Introduction: Barrett’s oesophagus endoscopic surveillance pathways exist to aid detection of early progression at the dysplastic phase. Performance in accordance with guidelines can be mixed, and rates of missed dysplasia are high(1). Barrett’s surveillance endoscopy is a complex skill and requires a broad outlook when considering behaviour change interventions. Behavioural theory can be used to target aspects which influence behaviour which are most likely to affect change when used in implementation studies and has been used in prior studies of colonic polyp detection(2).

Aims & Methods: In this study we aimed to explore using qualitative methodology and behavioural theory, factors which influence endoscopists behaviours to identify barriers and facilitators to the adherence of Barrett’s surveillance endoscopy guidelines which could be utilised in future implementation research to improve practice.

Semi-structured interviews were performed over video conferencing software between August 2021 and July 2022 with purposively sampled clinicians who perform endoscopic Barrett’s surveillance from across the UK who work in a range of hospital types. Framework qualitative analysis was used to identify modifiable factors in line with the Theoretical Domains Framework (TDF) and Capability, Opportunity Motivation - Behaviour (COM-B) model of behaviour change(3,4).

Results: Thematic saturation was achieved at 22 interviews consisting of 3 consultant surgeons, 9 consultant gastroenterologists, 6 clinical (nurse) endoscopists, 2 trainee gastroenterologists and 2 trainee surgeons. Themes were mapped into key themes of intrapersonal, interpersonal and organisational factors.

Key intrapersonal factors included the endoscopists’ knowledge of and recall of Barrett’s surveillance guidelines, their technical skills required to perform quality Barrett’s surveillance, the influence of a competing workload and their motivation to perform Barrett’s surveillance well. Interpersonal factors included having a motivated endoscopy team who are skilled in assisting endoscopic surveillance and who understand the importance of surveillance, endoscopists’ training both pre-certification and post certification and facilitating continued professional development for those in later career years.

Organisational factors included departments allowing adequate scheduling of procedure to allow time for lesion detection, the completing burden of other procedures and waiting lists and availability of equipment e.g. acetic acid.

From these themes, 21 barriers and facilitators were identified and mapped to behavioural interventions for use in future intervention studies - some examples are outlined in Table 1.

Barriers	Facilitators	TDF Domains	COM-B domains	Action	Level	Behaviour change wheel Intervention function
- Knowledge and recall of Barrett’s surveillance guidelines	- Barrett’s surveillance performed by those with an interest in the condition	Knowledge	Capability	- Local education sessions on guidelines	Intrapersonal	Training and education
		Skills	Reflective motivation	- Demonstrations of good practice by local experts/ UGI lead	Interpersonal	Restrictions
		Goals and intentions	Psychological capability	- Streamline Barrett’s surveillance procedures to those with an interest in UGI disease on dedicated endoscopy lists	Organisational	Enablement
- Motivation to perform Barrett’s surveillance well to find early lesions	- Motivation to perform Barrett’s surveillance well to find early lesions	Motivation	Social opportunity	- Departments engage in Barrett’s related research		Modelling
		Social and professional role		- Training in Barrett’s surveillance should include focus on tip control and lesion recognition in UGI endoscopy	Interpersonal	Persuasion
				-Improve access to UGI specialist trainers		
- Technical skills required to perform quality Barrett’s surveillance	- Increasing frequency of performing Barrett’s surveillance improves skills	Skills	Physical capability	-Credentialling in Barrett’s surveillance like Bowel cancer screening	Interpersonal	Training and education
		Knowledge	Automatic motivation			Modelling
				-Continue to maintain regular updates on Barrett’s surveillance guidelines to support endoscopists’ behaviour	Organisational	
- Lack of standardisation of Barrett’s audit and credentialling	- Guidelines providing a framework for behaviour and reassurance of quality of care being provided	Motivation	Reflective motivation	-Key performance indicators e.g. oesophageal withdrawal times, completion of Seattle protocol	Interpersonal	Education
		Behaviour regulation	Automatic motivation	-Audit Barrett’s practice, dysplasia detection and post endoscopy cancers	Organisational	Incentivisation
		Reinforcement	Psychological capability			Restrictions
- Negative emotion regarding completion of Barrett’s surveillance endoscopy		Emotions	Reflective motivation	-Reduce the burdensome aspects of surveillance – e.g. AI-assisted lesion recognition	Intrapersonal	Enablement
		Behaviour regulation	Automatic motivation	-Adequate scheduled time for procedures		Incentivisation
		Environmental context	Psychological capability	-Dedicated Barrett’s endoscopy lists ring-fenced away from other tasks	Organisational	Environmental restructuring
- Workload burden for endoscopists			Physical capability	-Wider issues of workload in the health service		Restrictions

Table 1: Outlining examples of barriers and facilitators to performing quality Barrett’s surveillance mapped to the Theoretical domains framework(TDF).

Conclusion: The findings of this study provide potential targets for intervention studies which may improve Barrett’s surveillance practice through facilitating behaviour change. Intra and interpersonal factors such as training and education are vital, but the real challenge may be the organisational shift from high turnover to a quality-centred approach for Barrett’s endoscopy. As a complex care intervention, clinician behaviour is one aspect in a multifaceted care pathway which can be improved.

Contact E-Mail Address: i.beaufort@antoniusziekenhuis.nl

Introduction: Different random biopsy techniques exist for Barrett Esophagus (BE) surveillance, of which the impact on histopathological quality is unclear. Therefore, we compared the double-biopsy (DB) versus single-biopsy (SB) method, and advance-and-close (A&C) versus turn-and-suction (T&S) technique in a multidesign study.

Aims & Methods: In a multicenter, factorial design trial, BE patients were randomly assigned to one of two biopsy methods (DB or SB) and techniques (A&C or T&S) in a 1:1:1:1 approach, stratified by BE length and hospital. Endpoints were biopsy size, defined as surface area in mm², and time required to obtain biopsies. Assessment of biopsy size was done in a blinded fashion. Data was analyzed with mixed effects regression analyses with a random intercept per patient including stratification factors as fixed effects.

We assumed no interaction between the co-primary comparisons. In a subsequent before-after study, the optimal biopsy method and technique found in the factorial trial was implemented in routine clinical practice. Biopsies before and after implementation were analyzed on biopsy size, using mixed effects regression analyses with a random intercept per patient including BE length as fixed effect.

Results: In the factorial trial, 107 patients were randomized and 1024 biopsies were assessed. Mean biopsy size for each randomization arm, that is, DB+A&C, DB+T&S, SB+A&C, SB+T&C was 2.77mm² (95%CI 2.44-3.09), 2.61 mm² (95%CI 2.29-2.93), 3.14 mm² (95%CI 2.81-3.46) and 3.54 mm² (95%CI 3.22-3.86), respectively (Table 1).

	Double-biopsy (DB)	Single-biopsy (SB)
Advance-and-close (A&C)	2.77 (2.44-3.09)	3.14 (2.81-3.46)
Turn-and-suction (T&S)	2.61 (2.29-2.93)	3.54 (3.22-3.86)

Table 1: Biopsy size in mm² per biopsy method and technique (95% CI).

Biopsy size increased with 25% from 2.68mm² (95%CI 2.45-2.92) with the DB method to 3.34mm² (95%CI 3.10-3.57) with the SB method (mean difference 0.65mm², [95% CI 0.34-0.97]; p<0.001). In contrast, average biopsy sizes were 2.95mm² (95% CI 2.72-3.19) and 3.08mm² (95%CI 2.85-3.31) using the A&C and T&S, respectively, translating into an increase of 4% using the T&S technique (mean difference 0.13mm², [95%CI -0.19-0.44]; p=0.44). The interaction term between the co-primary comparisons was not statistically significant (p=0.08).

Time required to obtain biopsies was comparable for biopsies obtained with the DB method and SB method (mean difference 2 seconds per biopsy, [95%CI -1-4]; p=0.26), while biopsy time was significantly longer when biopsies were taken with the T&S technique compared to the A&C technique (mean difference 7 seconds per biopsy, [95%CI 4-10]; p<0.001). A total of 46 patients (288 biopsies) and 44 patients (256 biopsies) were included before and after implementation of the SB method and the T&S technique, respectively.

Before implementation, 93/288 biopsies (32%) were obtained with the A&C technique and 163/288 biopsies (57%) were taken with the DB method. Mean biopsy size increased with 18% from 3.31mm² (95%CI 2.95-3.68) to 3.90mm² (95%CI 3.50-4.29) after implementation of the SB method and T&S technique (mean difference 0.58mm² (95%CI 0.07-1.09); p=0.03).

Mean biopsy size did not significantly increase when comparing biopsies before and after implementation (n=117 versus n=97) which were obtained by endoscopists already using the SB method and T&S technique before implementation (3.72mm² [95%CI 2.95-4.48] versus 3.79mm² [95%CI 2.97-4.62], mean difference 0.08mm² [95%CI -0.93-1.08]; p=0.88).

Conclusion: Biopsies in BE patients should be taken with the SB method to increase biopsy size. Implementation of SB-T&S in routine clinical practice resulted in significantly larger biopsies.

EFFICACY AND SAFETY OF CRYOBALLOON¹⁸⁰ ABLATION FOR THE TREATMENT OF DYSPLASTIC BARRETT ESOPHAGUS: PRELIMINARY RESULTS FROM A PROSPECTIVE MULTICENTER STUDY

K. Munters^{1,2}, C.N. Frederiks^{2,1}, A. Overwater^{2,1}, R.E. Pouw³, J.J. Bergman⁴, S. van Munster^{1,4}, B.L. Weusten^{2,5}

Contact E-Mail Address: k.munters-3@umcutrecht.nl

Introduction: Cryoballoon ablation is a relatively novel method which can be used for the eradication of dysplastic Barrett esophagus (BE). While the focal cryoballoon ablation system has shown to be efficacious for BE of limited extent, the cryoballoon¹⁸⁰ ablation system (CBAS¹⁸⁰) is developed to treat longer BE segments by semi-circumferential ablation over 3cm in a single step.

A prior first-in-human study demonstrated the feasibility of CBAS¹⁸⁰ treatment¹, yet the optimal dose needs to be determined. Therefore, in the current prospective multicenter study, we investigate CBAS¹⁸⁰ at lower dosages for patients with dysplastic BE. In addition, we report on the results of CBAS¹⁸⁰ followed by focal cryoballoon ablation (fCBA).

Aims & Methods: A total of 50 patients with ablation naïve BE (C≤3 and M≥1) will be enrolled in six Dutch Barrett expert centers. Treatment consists of a full circumferential ablation over 3 cm of length, using two semi-circumferential ablations at a dose of 1.2 mm/sec. Follow-up consisted of follow-up phone calls at days 1, 7 and 30, a symptom diary during 14 days, and a follow-up endoscopy after 3 months. Outcomes included:

- (1) technical success rate,
- (2) BE regression percentage at follow-up scored by an independent adjudication committee and the treating endoscopist,
- (3) incidence of adverse events,
- (4) post-procedural pain (on a scale of 0-10), and
- (5) post-procedural dysphagia (on a scale of 0-4).

Follow-up treatment consisted of fCBA treatments until complete eradication of visible BE was achieved, confirmed by biopsies from the neo-Z-line.

Results: So far, 25 patients (80% male; mean age 67) with a median BE length of C0M2 (p25-p75 C0-1M2-4) were included. Technical success rate was 92% (23/25). In two patients, treatment was technically unsuccessful due to unstable positioning of the balloon (n=1) or a device malfunction (n=1). Median procedure time was 14 (p25-p75 11-16) 4 minutes and median ablation time was 5 (p25-p75 3-5) minutes. All 23 successfully treated patients completed follow-up endoscopy at 3 months. Median BE regression was 90% (p25-p75 75%-100%) and 95% (p25-p75 75%-99%) as evaluated by the independent adjudication committee and the treating endoscopist, respectively.

Overall, CBAS¹⁸⁰ adverse event rate was 8% (2/23), with one patient developing an esophageal stricture (1/23; 4%) resolved after a single endoscopic dilation. Another patient (1/23; 4%) experienced post-procedural bleeding, resulting in re-endoscopy without intervention. The CBAS¹⁸⁰ procedure was well tolerated with low post-procedural pain (median 2 [p25-p75 1-4] at day 1 and 0 [p25-p75 0-1] at day 7) and dysphagia (44% and 30% of patients with score ≥1 at day 1 and 7) scores.

So far, 22/23 patients were treated with fCBA in the follow-up phase, of whom 4 are still under treatment. The remaining 18 patients achieved complete eradication of all visible BE after median 1 (p25-p75 1-3) fCBA treatments. Based on the histological assessment, a complete eradication of dysplasia and intestinal-metaplasia was achieved in all 18 patients. Two patients developed strictures requiring dilation (2 and 1 dilations, respectively) during the follow-up phase.

Conclusion: Based on these preliminary results, circumferential ablation with CBAS¹⁸⁰ at 1.2 mm/sec, followed by fCBA, emerges as an effective and safe procedure for dysplastic BE eradication in the hands of expert endoscopists. Further avenues for exploration should encompass the assessment of multiple CBAS¹⁸⁰ ablations stacked on top of each other in larger segments and the validation of outcomes in a larger patient cohort.

Introduction: Irritable bowel syndrome patients frequently suffer from comorbid mental (anxiety or depression) or somatic (fibromyalgia or chronic fatigue) conditions. In this pan-European project (the DISCOVERIE project), IBS patients with and without comorbidities were compared with disease controls and healthy controls, to further elucidate the effect of comorbid conditions in IBS on the disease burden.

Aims & Methods: We included participants from nine different European centers – IBS patients according to Rome IV criteria, disease controls (patients with comorbid conditions; i.e. fulfilling diagnostic criteria for anxiety, depression, fibromyalgia and/or chronic fatigue, but no IBS) and healthy controls. The participants were further divided into eight groups based on presence or absence of comorbidities: IBS with no/ mental/ somatic/ mental and somatic comorbidity, disease controls with mental/ somatic/ mental and somatic comorbidity, and healthy controls. The severity of IBS symptoms (IBS-SSS), depression (PHQ-9), anxiety (GAD-7), somatic symptoms (PHQ-15), fibromyalgia symptoms (FIQ) and general and mental fatigue (MFI) were compared between these groups.

Results: In total, 849 participants (median age 44 years) were included. A majority were females (76%), with the most pronounced female predominance (83%-86%) in the IBS groups with comorbidities. The most severe IBS symptoms were noted among IBS with both mental and somatic comorbidity and IBS with somatic comorbidity (Table 1).

In IBS, the severity of IBS symptoms increased gradually with increasing number of comorbidities (partial eta squared: 0.053, p<0.001), as did severity of anxiety, depression, somatic symptoms and general fatigue (partial eta squared: 0.214, 0.247, 0.240, 0.239, respectively, all p<0.001). The groups with both mental and somatic comorbidity had the highest levels of anxiety, depression and mental fatigue.

Somatic symptoms and general fatigue were most severe among IBS and disease controls with somatic comorbidity or both somatic and mental comorbidity. Fibromyalgia symptoms were most severe in IBS and disease controls with somatic comorbidity.

	IBS alone (N=268)	IBS comor- bid mental (N=173)	IBS somatic (N=48)	IBS multi- comorbid (N=124)	Disease control mental (N=58)	Disease control somatic (N=51)	Disease control mental + somatic (N=52)	Healthy controls (N=75)	P-value between all groups	p-value between IBS groups

Contact E-Mail Address: 602458052@qq.com

Introduction: Irritable bowel syndrome (IBS) is defined as a disorders of gut–brain interaction, which shows a high comorbidity tendency with anxiety and depression. Berberine has been suggested in previous studies to alleviate IBS-like symptoms, however, there is currently a lack of research investigating the clinical efficacy of berberine, its modulation of gut microbiota, and its influence on brain functional regulation in IBS patients with comorbid anxiety and depression.

Aims & Methods: We conducted a double-blind, randomized, placebo-controlled clinical trial to evaluate the therapeutic efficacy of berberine on clinical symptoms in patients with IBS comorbid depression and

(or) anxiety. Eligible participants with IBS based on Rome IV criteria and comorbid anxiety/depression based on HAMA/HAMD criteria were recruited. Participants were randomly assigned to receive berberine (300mg tid) or placebo for 8 weeks. Follow-up assessments occurred at 4 and 8 weeks. We collected stool samples from patients and performed resting-state functional magnetic resonance imaging (rs-fMRI) for patients and healthy controls (HCs) recruited at the same period at baseline and after 8 weeks of treatment. Fractional amplitude of low-frequency fluctuations (fALFF) was used to assess brain activation.

Results: 78 patients (40 berberine, 38 placebo) showed no significant baseline differences. Berberine had higher drug response rates at 4 weeks (61.86% vs. 32.26%, $p=0.027$) and 8 weeks (73.53% vs. 32.26%, $p=0.003$). Berberine also had higher drug efficacy rates for anxiety at 8 weeks (79.4% vs. 29.0%, $p<0.001$). Adverse reactions (constipation, nausea) were higher with berberine (35.00% vs. 13.16%, $p=0.025$) but not severe. Metagenomic sequencing revealed that, berberine decreased pathogenic bacteria (*Eubacterium*, *Faecalibacterium*, *Collinsella*, *Streptococcus*, *Lachnospira*) and increased beneficial bacteria (*Bacteroides uniformis* etc.). Correlations indicated associations between *Streptococcus*, *Eubacterium* and diarrhea and abdominal pain. Berberine suppressed flagella assembly and bacterial chemotaxis, accordingly reduced invasiveness by decreasing the abundance of *Eubacterium* and *Streptococcus*, and improved gastrointestinal symptoms. Also berberine may reduce the function of pyrimidine metabolism, one-carbon pool folate, and glycerophospholipid metabolism by suppressing the abundance of *Collinsella*, *Faecalibacterium* and enriching *Bacteroides uniformis*. Patients exhibited decreased activity in several brain regions compared to HC, while increasing activity in brain regions (cingulate gyrus, supplementary motor area, superior frontal gyrus, etc.) after berberine intake was shown. Placebo group showed limited activity increase. Activity in different brain regions negatively correlated with abdominal pain, anxiety scores.

Conclusion: Berberine significantly improves gastrointestinal symptoms and psychometric scale score in IBS patients comorbid depression and (or) anxiety. Berberine reduces the abundance of pathogenetic bacteria, suppresses bacterial chemotaxis, flagella assembly and accordingly decreases bacteria invasiveness, which correlate with symptom improvement. Berberine may affect metabolic pathways linked to anxiety and depression improvement. Following berberine intervention, the activity in these hypoactive brain regions significantly recovers. Moreover, berberine enhances the activity in brain regions related to the functionality of the whole-body action-cognition network and control network, which may serve as important neurobiological foundations for berberine's treatment of the gut-brain comorbidity.

Introduction: Studies on the prevalence of gastrointestinal (GI) red flags (RF) in the general population and among individuals with Rome IV disorders of gut-brain interaction (DGBI) in globally representative samples are scarce.

Aims & Methods: We aimed to describe the global prevalence of GI RF in the general population and in individuals meeting Rome IV criteria for DGBI. We analyzed data on participants across 26 countries who completed the Rome Foundation Global Epidemiology Study online survey, which included the Rome IV diagnostic questionnaire along with inquiries about 14 RF (hematemesis, hoarseness of voice, neck/throat pain, chest pain on exertion/related to heart problems, difficulty swallowing, hematochezia, melena, a major change in bowel movements, fever, unintentional weight loss, anemia/iron deficiency, first degree relative with GI cancer/inflammatory bowel disease/celiac disease). We assessed the global prevalence of RF and compared the prevalence in DGBI-positive (any DGBI [all RF] and anatomical DGBI groups [relevant RF for that anatomical region]) vs DGBI-negative participants without a history of organic GI disease using univariate logistic regression models. All analyses were stratified by age with cutoff at 50 years (y).

Results: Of 54,127 participants completing the internet survey, 58.9% reported at least one RF. A major change in bowel movements (frequency or consistency) was the most prevalent RF (16.5%), while hematemesis was the least prevalent (0.6%). Participants <50 y had a higher prevalence of RF compared to participants ≥50 y for any RF (63.1% vs 51.8%) and for all individual RF, except for a family history of GI cancer (more prevalent ≥50 y). Among 20,668 DGBI-positive participants, 72.8% reported any RF, with a higher prevalence in younger participants (Table). The prevalence of RF was highest in the anorectal DGBI group in participants <50 y, and in the esophageal DGBI group in participants ≥50 y (Table). The most prevalent RF was difficulty swallowing (30.1% <50 y; 30.5% ≥50 y) in esophageal DGBI, anemia/iron deficiency (22.8%) in gastroduodenal DGBI <50 y, a family history of GI cancer (17.2%) in gastroduodenal DGBI ≥50 y, and a major change in bowel movements in bowel (27.9% <50 y; 21.5% ≥50 y) and anorectal (38.4% <50 y; 29.5% ≥50 y) DGBI. In DGBI-positive vs DGBI-negative participants without organic GI disease, reporting any RF was positively associated with any DGBI and all anatomical DGBI groups (Table). Hematemesis was the RF most strongly associated with esophageal (OR 13, 95% CI 8.6-18 <50 y; OR 11, 95% CI 4.4-29 ≥50 y) and gastroduodenal (OR 12, 95% CI 8.4-16 <50 y; OR 11, 95% CI 4.5-26 ≥50 y) DGBI, although rare (0.8-3.2% in DGBI-positive participants). A major change in bowel movements was the RF most strongly associated with bowel DGBI (OR 3.3, 95% CI 3.1-3.5 <50 y; OR 3.5, 95% CI 3.1-3.8 ≥50y) and anorectal DGBI <50 y (OR 5.3, 95% CI 4.8-5.8), while hematochezia was the RF most strongly associated with anorectal DGBI ≥50 y (OR 6.1, 95% CI 5.2-7.3).

	Age <50 years			Age ≥50 years		
	Without DGBI n=17,995	DGBI ^a	OR 95% CI	Without DGBI n=11,370	DGBI ^b	OR 95% CI
Any RF ^c	50.7% (50.0, 51.5)	75.3% (74.5, 76.0)	3.0 (2.8, 3.1)	38.8% (37.9, 39.7)	67.5% (66.4, 68.7)	3.3 (3.1, 3.5)
Any esophageal RF ^d	36.9% (36.2, 37.6)	71.1% (69.1, 73.1)	4.2 (3.8, 4.7)	29.2% (28.4, 30.1)	65.6% (62.6, 68.5)	4.6 (4.0, 5.3)
Any gastroduodenal RF ^e	26.2% (25.5, 26.8)	53.4% (51.9, 55.0)	3.2 (3.0, 3.5)	20.6% (19.8, 21.3)	44.4% (41.8, 47.0)	3.1 (2.8, 3.5)
Any bowel RF ^f	38.3% (37.6, 39.0)	64.3% (63.4, 65.1)	2.9 (2.8, 3.0)	29.3% (28.5, 30.1)	54.9% (53.6, 56.3)	2.9 (2.8, 3.1)
Any anorectal RF ^f	34.1% (33.4, 34.8)	74.3% (72.6, 76.0)	5.6 (5.1, 6.1)	26.5% (25.7, 27.3)	61.6% (58.9, 64.2)	4.4 (4.0, 5.0)

^a Any DGBI, n=14174; esophageal DGBI, n=2066; gastroduodenal DGBI, n=4072; bowel DGBI, n=11803; anorectal DGBI, n=2622.

^b Any DGBI, n=6494; esophageal DGBI, n=1021; gastroduodenal DGBI, n=1438; bowel DGBI, n=5452; anorectal DGBI, n=1327.

^c Includes all RF listed in d-f.

^d Includes hematemesis, hoarseness of voice, neck/throat pain, chest pain on exertion/related to heart problems, difficulty swallowing, fever >38° C, unintentional weight loss >4.5 kg, anemia/iron deficiency, first degree relative with GI cancer.

^e Includes hematemesis, melena, fever >38° C, unintentional weight loss >4.5 kg, anemia/iron deficiency, first degree relative with GI cancer/celiac disease.

^f Includes hematochezia, melena, a major change in bowel movements (frequency or consistency), fever >38° C, unintentional weight loss >4.5 kg, anemia/iron deficiency, first degree relative with GI cancer/inflammatory bowel disease/celiac disease.

Table. Prevalence of red flags (RFs) in DGBI-positive participants vs DGBI-negative participants without organic GI disease.

Conclusion: GI RF are highly prevalent in the global general population with an even higher prevalence in individuals positive for a Rome IV DGBI. Given the substantial prevalence of RF observed in our study, especially among younger individuals, RF in general may not be as valuable at predicting serious underlying pathology as once thought. Further research is needed to validate the predictive utility of RF in the diagnostic approach to gastrointestinal symptoms and suspected DGBI in unselected population samples.

Disclosure: Nothing to disclose.

Introduction: Functional constipation (FC) occurs in 8.5% Chinese people, seriously affecting their quality of life and mental health. However, there is currently a lack of long-term effective treatment options.

As an oral guanylate cyclase-C (GC-C) agonist, plecanatide has been approved by the US FDA for the treatment of adult chronic idiopathic constipation (CIC) and irritable bowel syndrome with constipation (IBS-C), but

it has not yet been approved for use in constipated populations in China. Considering the potential differences in drug responses between races, and the higher proportion of FC than IBS-C in Chinese with constipation, the efficacy of plecanatide in the Chinese FC population is worth studying.

Aims & Methods: This study aimed to comprehensively assess the efficacy, safety, and pharmacokinetics of plecanatide during the treatment of Chinese FC patients. This phase III, randomized, double-blind, placebo-controlled, multicenter trial was performed in 40 hospitals of China. 648 patients with FC were assigned to the plecanatide or placebo group randomly with a ratio of 1:1 for a 12-week treatment and a 2-week follow-up. The primary efficacy endpoint was the durable overall complete spontaneous bowel movement (CSBM) response rate.

Treatment-emergent adverse event (TEAE) and treatment-related emergent adverse event (TRAEE) were collected. Concentration of plecanatide and its metabolite SP-338 were detected.

Results: After 12-week continuous administration, the durable overall complete CSBM response rate of the plecanatide and the placebo were 23.5% and 10.5% respectively ($p < 0.001$). Besides, all secondary efficacy endpoints showed statistically significant improvements compared with placebo. The incidence of TEAE and TRAEE was 55.7% vs 48.6%, and 13.9% vs 8.7% respectively, in the plecanatide group and placebo group.

The most common TRAEE was diarrhea, which occurred in 0.6% (placebo) and 4.3% (plecanatide) of patients. The concentrations of plecanatide and its metabolite SP-338 were below the lower limit of quantification (0.500 ng/ml) at all time points.

	Plecanatide	Placebo	P value
ITT population ^a	N=324	N=324	
Responders (%)	76 (23.5)	33 (10.2)	< 0.001
Non responders (%)	248 (76.5)	291 (89.8)	
PPS ^a	N=286	N=297	
Responders (%)	74 (25.9)	33 (11.1)	< 0.001
Non responders (%)	212 (74.1)	264 (88.9)	

Table 1: Comparison of durable overall CSBM response rate

^a: CMH Test

ITT: Intention-to-treat; PPS: per protocol set

Conclusion: Plecanatide had a significant efficacy for the treatment of Chinese FC patients, with a low rate of AEs and no systemic absorption. Plecanatide will be a good option in the management of Chinese FC patients.

Introduction: Real-time symptom assessment provides a detailed understanding of the dynamic interplay between gastrointestinal symptoms in irritable bowel syndrome (IBS) and potential triggers, including affect and environmental factors.

This study evaluates the association between abdominal pain and potential triggers over time in IBS patients with and without comorbidities, using the Experience Sampling Method (ESM) as a real-time, ecologically valid measurement method.

Aims & Methods: In this prospective, observational multicenter study, as part of the DISCOVERIE project, we included 215 Rome IV IBS patients (80% female; mean age 42.1) from six European countries, categorized into 103 IBS-alone, 67 IBS-mental (anxiety/depression), 16 IBS-somatic (fibromyalgia/chronic fatigue syndrome), and 29 IBS-multicomorbid patient subgroups. Participants scored abdominal pain and affect using an 11-point Numeric Rating Scale and environmental factors using ESM at up to ten random moments each day over seven consecutive days.

Linear mixed-effects models analyzed the associations between abdominal pain and these potential triggers, both concurrently and predictively (trigger scores lagged by one time point, maximum of 90 minutes), in each subgroup.

Results: ESM assessment completion rate was 63%. Regarding affect triggers, abdominal pain was significantly correlated with concurrent positive and negative affect in all IBS groups ($p < 0.02$), while significant lagged associations were only found within IBS-mental for positive affect ($p = 0.02$) and within IBS-alone and IBS-multicomorbid for negative affect ($p < 0.001$).

Regarding environmental triggers, abdominal pain was significantly associated with concurrent 'feeling comfortable in situation' within IBS-alone, IBS-mental and IBS-multicomorbid ($p < 0.001$), concurrent 'feeling of pleasantness of company' ($p = 0.01$) and being alone (versus with somebody, $p = 0.01$) within IBS-alone, and eating since the last ESM-assessment within IBS-alone ($p = 0.04$) and IBS-multicomorbid ($p = 0.002$).

No significant lagged associations or correlations with location, activity, alcohol consumption, and nicotine use were found.

Conclusion: Our results demonstrate that in IBS patients, real-time abdominal pain is significantly associated with environmental and affect triggers, with both positive and negative affect correlating with abdominal pain irrespective of mental comorbidities.

Moreover, fewer triggers predict abdominal pain over time, underscoring the importance of in-the-moment assessments. This study highlights the value of ESM in accurately identifying symptom triggers, thereby enhancing personalized healthcare in IBS.

Introduction: Several studies have shown that image enhancement technologies like NBI and BLI in expert hands can meet the PIVI criteria [1-6]. This has led to various calls for implementation of this technique in clinical practice. However, attempts at more widespread generalisation of optical diagnosis have failed due to the inability of general endoscopists to meet the established standards.

CAD-EYE (Fujifilm, Japan) is a novel AI driven optical diagnosis system (CADx) which has shown encouraging preliminary results in expert hands or in single centre studies.

Aims & Methods: To evaluate the diagnostic performance of AI (CAD-EYE) based optical diagnosis of colorectal polyps in the hands of both experts and non-experts and to explore the impact of AI based prediction on the learning curve of non-expert endoscopists.

A multicenter prospective observational study which compares the performance of CAD-EYE with that of the endoscopists, combined with monthly review meetings by all endoscopists involved in the study with the aim of group learning and improving the skills of optical diagnosis for non-expert endoscopists.

Results: Optical diagnosis (OD) was performed with high confidence by the endoscopists in 674/782 (86.2%) of polyps. High confidence OD was achieved in 91.5% polyps by expert endoscopists compared to 85.1% by non-expert endoscopists [$p < 0.05$].

The overall sensitivity, NPV and accuracy by all endoscopists were 84.4%, 74.1% and 86.2% respectively. CAD-EYE diagnosis was recorded in 672/782 (85.9%) of polyps. The overall sensitivity, NPV and accuracy were 83.0%, 72.8% and 85.9% respectively [$p > 0.05$].

Optical diagnosis was performed with high confidence by the endoscopist in 416/590 (84.9%) of diminutive polyps (≤ 5 mm). The overall sensitivity, NPV and accuracy were 84.6%, 74.5% and 84.9% respectively. CAD-EYE diagnosis was recorded in 413/590 (84.2%) of diminutive polyps. The overall sensitivity, NPV and accuracy was 83.4%, 73.2% and 84.2% respectively [$p > 0.05$].

273/590 diminutive polyps were located in the rectosigmoid. Endoscopist's sensitivity, NPV and accuracy was 93.1%, 92.6% and 91.9% respectively, compared to CAD-EYE whose sensitivity, NPV and accuracy were 93.7%, 92.4% and 92.9% respectively [$p > 0.05$].

The endoscopist's optical diagnosis-based post-polypectomy surveillance interval was calculated in all patients and compared with histology based surveillance and it achieved a 90.7% [CI 84.6-93.8] and 92.9% [CI 89.4-95.0] concordance with BSG and ESGE guidelines respectively; achieving the ASGE PIVI criterion. The post-polypectomy surveillance interval based on CAD-EYE diagnosis was calculated and compared with histology based surveillance and it achieved 91.9% [CI 88.7%-93.2 %] and 93.4 % [CI 90.2 %-96.8%] concordance with the BSG & ESGE guidelines; also achieving the ASGE PIVI criterion.

An improvement in the performance of non-experts during the study was noted with an improvement in accuracy from 63% for the first 50 polyps to 85% for the last 50 polyps, with an associated increase in sensitivity (65% and 82%), specificity (50% and 91%), NPV (55% and 79%) and also degree of confidence (65% and 90%) [$p < 0.05$ for all KPIs]

Conclusion: Our data proves that CAD-EYE based diagnosis can meet both PIVI criterion and help introduce both resect & discard and leave in-situ strategies even in the hands of non-experts.

Real time Optical diagnosis of polyps has the potential to transform clinical practice by reducing pathology & polypectomy costs, setting up surveillance intervals without waiting for histology, reducing morbidity and procedure time.

We have also demonstrated an improvement in performance of non-expert endoscopists over the course of the study. This is a novel finding and has not been shown in any study before and we feel that this is an important finding which can help inform the policy makers to invest in CADx.

Introduction: Although randomized controlled trials have shown that artificial intelligence (AI) for polyp detection improve adenoma detection rate (ADR) in colonoscopy, it is unknown how implementation of AI changes endoscopists' behavior on standard colonoscopy (colonoscopy without AI assistance). We aimed at answering this important clinical question.

Aims & Methods: We conducted a multicenter, observational study at four Polish endoscopy centers. These centers implemented AI tools for polyp detection in the end of 2021, after which colonoscopies were done either with or without AI assistance at endoscopists' discretion. We evaluated the change in the quality of all the diagnostic colonoscopies between September of 2021 and February of 2022, by comparing two different phases: 3 months before and after the AI implementation in clinical practice. The primary outcome measure was ADR of standard colonoscopy. To investigate the independent factors that affected ADR, multivariable logistic regression analysis was also done.

Results: A total of 1,460 patients underwent standard colonoscopy before and after the AI implementation (795 and 665, respectively; mean age 57.1±15.5 with female accounting for 58.6%). ADR of standard colonoscopy significantly decreased from 28.4% (226/795; 95% confidence interval [CI] 25.29- 31.56) to 22.1% (147/665; 95% CI 18.95 - 25.26; P=.006)

after the AI implementation, corresponding to a 6.3% absolute reduction (95%CI 6.2 - 6.5) and a 22.2% relative reduction (95% CI 21.8 - 22.7). In multivariable regression analysis showed that AI implementation in clinical practice (risk ratio 0.774; 95% CI 0.64-0.93), sex (risk ratio 1.33; 95% CI 1.14-1.54) and age (risk ratio 1.535; 95% CI 1.29-1.79) were the only independent factors that affected ADR.

Conclusion: Implementation of AI in clinical practice negatively affected the ADR during standard colonoscopy, raising a question of deskilling effect brought about by an advanced AI technology.

Introduction: Artificial Intelligence (AI) -based optical polyp diagnosis (CADx) allows for pathology prediction during colonoscopies to support resecting and discarding polyps. However, it is unclear if clinical use of such CADx modules should be as an autonomous decision-making device or rather to assist endoscopists in their decision-making. We therefore evaluated outcomes for CADx optical diagnosis when used autonomously versus as an assistive device for polyps up to 10mm.

Aims & Methods: We conducted a secondary analysis of a randomized non-inferiority trial in which 1-10mm polyps found in patients undergoing diagnostic, screening, and surveillance colonoscopies were randomized to undergo optical diagnosis using: 1) an Autonomous AI-based CADx diagnosis or 2) an AI-assisted endoscopist diagnosis (AI-H). Primary outcome was the accuracy of optical diagnosis in both arms with reference standard being the histological evaluation of the polyps. Secondary outcomes included the surveillance interval agreement based on USMSTF guidelines when using CADx (with pathology as a reference standard) as well as the proportion of misclassified polyps with advanced histology.

Results: A total of 223 and 227 polyps 1-10mm in size were found amongst 268 patients randomized to the autonomous AI group versus 229 patients to the AI-H group, respectively. Accuracy for optical diagnosis for cases with high-confidence diagnoses was 77.6% (95% confidence interval [CI], 71.5-82.9) in the autonomous AI group versus 74.0% (95%

CI, 67.8-79.6) in the AI-H group. When comparing surveillance interval agreement, autonomous AI-A did not exhibit superior agreement with USMSTF pathology-based recommendations compared to AI-H (88.5% [95% CI, 82.0-93.3] vs 83.4% [95% CI, 77.0-88.6]; $P = 0.213$), but did nearly reach the 90% PIVI recommendation benchmark to implement optical diagnosis. Prevalence of polyps with advanced histology (adenomas with villous component, high-grade dysplasia) and sessile serrated lesions was 11.2% (25/223 polyps) and 7.9% (18/227 polyps) in the autonomous AI and AI-H groups. The inability of CADx and endoscopists to specifically recognize these higher-risk lesions led to mismanagement of 3 out of 16 patients (18.8%) and 2 out of 16 patients (12.5%) with such lesions in the autonomous AI and AI-H groups, respectively.

Characteristics	Autonomous AI			AI-H		
	1-5mm	6-10mm	1-10mm	1-5mm	6-10mm	1-10mm
Polyps, N	158	65	223	155	72	227
Index Advanced Histology*, n (%)	11 (7.0)	14 (21.5)	25 (11.2)	7 (4.5)	11 (15.3)	18 (7.9)
Accuracy, % (95% CI)	77.8 (70.6-84.1)	76.9 (64.8-86.5)	77.6 (71.5-82.9)	75.5 (67.9-82.0)	70.8 (58.9-81.0)	74.0 (67.8-79.6)
Adenoma, %						
Sensitivity	85.0	100.0	89.1	91.7	91.3	91.5
Specificity	64.4	45.5	41.8	59.3	73.1	63.5

* Adenoma with villous component, high-grade dysplasia or sessile serrated lesion

Table. Diagnostic characteristics for high confidence polyp optical diagnosis.

Conclusion: In this study, autonomous use of CADx for optical diagnosis of polyps up to 10mm exhibited similar accuracy compared to its use as an assistive device. Autonomous AI did not achieve statistically significant different agreement with USMSTF guidelines-based surveillance interval assignment. Development of CADx advanced histology recognition and further evaluation of its use as an autonomous versus assistive device within multi-center studies is needed.

OP125

THE ARTIFICIAL INTELLIGENCE IMPLEMENTATION IN THE TRAINING OF YOUNG ENDOSCOPISTS - DOES IT INFLUENCE THE QUALITY OF FUTURE COLONOSCOPIES?

Z. Orzeszko¹, T. Gach¹, M. Szura¹

¹Jagiellonian University, Cracow, Poland

Contact E-Mail Address: zosia.orzeszko@icloud.com

Introduction: Colonoscopy is a widely accepted screening test for detecting colorectal cancer. Computer-aided detection (CADE) based on artificial intelligence (AI) may be the way forward to improve its quality. As AI becomes a common upgrade in endoscopic equipment, an increasing number of young endoscopists are trained in an AI environment. However, how AI will impact trainees' future endoscopy outcomes remains unclear.

Aims & Methods: The study aimed to evaluate quality indicators in the first 1000 colonoscopies performed by newly trained endoscopists, comparing those trained in an AI environment to those trained in a non-AI environment. A study included 6,000 patients over 18 years old who underwent a colonoscopy for various reasons. The procedures were carried out by six young endoscopists, of which three were trained without AI and three with the assistance of the AI-powered Olympus Endo-Aid CADE system. The study retrospectively evaluated the first 1,000 procedures

performed by each endoscopist after completing training. These procedures were performed without AI enhancement and relied entirely on the endoscopists' detection skills. Quality indicators were assessed in non-AI-training and AI-training groups. The morphology of detected polyps was assessed to determine the influence of AI during training on laterally spreading tumors (LST) detection.

Results: A total of 6,000 participants were included in the analysis. Withdrawal time (WT) was longer in the AI-training group (8 vs 9 min, $p < 0.05$). Adenoma detection rate (ADR; 30.3 vs. 35.5%, $p < 0.05$), advanced adenoma detection rate (AADR; 4.6 vs. 5.1%, $p < 0.05$), and adenoma per colonoscopy score (APC; 0.73 vs. 0.75, $p < 0.05$) were higher in the AI-training group. AI-assisted endoscopy training significantly improved LST-NG detection ($p < 0.05$) for lesions smaller than 20mm.

	non-AI-training	AI-training	p-value
WT, min	8 (5-15)	9 (6-16)	<0.05
ADR, %	30.3	35.5	<0.05
AADR, %	4.6	5.1	<0.05
APC	0.73	0.75	<0.05

Conclusion: Implementing CADE during endoscopy training can positively impact quality indicators in the first 1,000 cases. After AI-enhanced training, the detection of LST-NG may improve. The potential of artificial intelligence in endoscopy training requires further investigation through prospective randomized controlled trials.

Introduction: Guidelines indicate that optical diagnosis can be employed during endoscopy for a leave-in-situ or resect-and-discard strategy of diminutive polyps. Additionally, it aids in determining the appropriate techniques for polyp resection.

Aims & Methods: Our objective was to assess the accuracy and the clinical impact of real-life optical diagnosis during real-time colonoscopy conducted in the context of a CAdE trial.

We retrospectively compared optical diagnosis with histology results of 1608 polyps that were prospectively included in the CAD-ARTIPOD trial (NCT04442607). During CAD-ARTIPOD endoscopists (ADR 20-50%) provided optical diagnosis, polyps were resected, and histological examination was performed by two independent GI histopathologists.

Mismatch was defined as a difference in polyp type (hyperplastic (HP) vs tubular adenoma (TA) vs tubulovillous adenoma (TVA) vs sessile serrated lesion (SSL) vs pseudopolyp vs carcinoma vs no polyp) or a difference in grade of dysplasia (high grade vs low grade vs no dysplasia). Clinical impact on surveillance interval per patient was consecutively evaluated according to ESGE standards.

Results: On a total of 1608 resected and histologically assessed specimens of 946 patients, 1026 (63.8%) showed a match and 582 (36.2%) a mismatch between optical diagnosis and histology. The optical diagnosis was 552 (34.3%) HP, 904 (56.2%) TA, 3 (0.2%) TVA, 119 (7.4%) SSL, 11 (0.7%) carcinoma, 6 (0.4%) inflammatory pseudopolyp and 13 (0.8%) unknown histology. Mismatch was present in 254 (43.6%) HP, 225 (24.9%) TA, 77 (64.7%) SSL, 7 (63.6%) carcinoma and 5 (83.3%) pseudopolyps. Clinical consequences occurred for 48 (8.5%) polyps in as many patients (5.3%), with 12 polyps leading to a prolongation of the surveillance interval and 7 polyps overestimated as carcinomas not truly requiring further treatment. Twenty-nine (4.9%) of the optically misdiagnosed polyps led to a shortened surveillance interval (12 polyps with HGD and 17 as fifth TA)

and two (0.3%) required further surgical therapy. Of the 115 misdiagnosed hyperplastic polyps, 74 (64.4%) were left-sided and may have been left in situ when applying SODA criteria with correct optical diagnosis applied.

Conclusion: Even in the setting of a clinical trial with high detectors, where the focus was detection, rather than optical diagnosis, discordance between optical diagnosis and histology occurred in approximately one out of three polyps. The clinical impact was significant with alterations in clinical management for 8.5% of affected polyps, in 5.3% of patients. This underscores the importance of training in optical diagnoses and the potential role of artificial intelligence to assist in a resect and discard strategy.

Gastroenterolgy, Toronto, Canada

Contact E-Mail Address: r.klomberg@erasmusmc.nl

Introduction: Both exclusive enteral nutrition (EEN) and steroids are effective therapies to induce remission in children with Crohn's disease (CD), but comparative data accounting for disease location are scarce.

Aims & Methods: We aimed to compare the effectiveness of EEN and steroids induction treatment in isolated ileal pediatric CD using data from two large real-world data cohorts. Children (age 2-18 years) with newly-diagnosed CD with an isolated ileal disease phenotype prospectively enrolled in the multicenter Canadian CIDsCaNN or predominantly European PIBD-SETQuality inception cohorts, who received either EEN or systemic steroids induction treatment, were eligible for this study. Demographics and extensive clinical data were collected prior to treatment and longitudinally until the last follow-up.

Outcomes, including [sustained] steroid free remission ([S]SFR), normal CRP remission (NCR; defined as remission with CRP <0.5 mg/dl), and (delta) height and BMI z-scores were compared at 3 months and 1 year. Time-to-first-biologic and time-to-luminal-resection were determined by Kaplan Meier curves and compared between groups using the log-rank test.

Results: A total of 221 children (n=134 [61%] CIDsCaNN, n=87 [39%] PIBD-SETQuality) with Crohn's disease with an isolated ileal phenotype receiving EEN (n=158 [72%]) or steroids (n=63 [28%]) as induction treatment were eligible for analysis (median follow-up 868 days [IQR 539 – 1443]). Disease phenotype, clinical and biochemical disease activity indices as well as demographics and anthropometrics, were similar between treatment groups (Table 1) and between cohorts. At 1 year, rates of SSFR (33% vs. 38%; p=0.56) and NCR (53% vs. 44%; p=0.27) were comparable between EEN and steroids-treated patients. Linear growth was borderline reduced in the steroids treated group (median height Z-score -0.42 [IQR -1.21 - 0.12]) compared to the EEN treated group (0.02 [IQR -0.94 - 0.59; p=0.050]. Type of induction treatment did not affect time-to-first-biologic (p=0.84) or time-to-luminal-resection (p=0.11).

At 3 months, combined rates of SFR + NCR were higher in patients who received EEN (38/111 [34%]) compared to those who received steroids (9/47 [19%]; p=0.058), largely because of differences in steroid exposure (14/121 [12%] with EEN, 19/39 [48%] with steroids; p<0.001), and normal CRP (68/108 [57%] and 18/43 [42%] respectively, p=0.084). Only in 20/220 (9%) of patients (15/157 [10%] with EEN, 5/63 [8%] with steroids; p=0.71), an additional induction therapy agent (EEN, steroids, biological, surgery) was started within 30 days after the start of induction treatment.

Characteristics	EEN (N = 158)	CS (N = 63)	Total (N = 221)	p-value
Age in years, median (IQR)	13.6 (11.5 - 15.2)	13.8 (11.9 - 15.6)	13.8 (11.7 - 15.3)	0.47
Male sex, n (%)	90 (57)	41 (65)	131 (59)	0.27
Height z-score, median (IQR)	-0.06 (-0.84 - 0.62)	-0.11 (-1.10 - 0.65)	-0.07 (-0.93 - 0.61)	0.49
BMI z-score, median (IQR)	-0.81 (-1.60 - 0.23)	-0.60 (-1.46 - 0.36)	-0.69 (-1.58 - 0.26)	0.55
Upper gastrointestinal tract involvement, n (%)	N = 149	N = 57	N = 206

Introduction: Fatigue is a debilitating, multifactorial symptom experienced by many patients with Crohn's disease (CD).¹ Mirikizumab (MIRI), an anti-interleukin-23p19 antibody, demonstrated significant improvement in fatigue in patients with moderately to severely active CD in the Phase 2 AMAG² and Phase 3 VIVID-1³ studies.

Aims & Methods: This analysis examines the association of changes in clinical, endoscopic (endo) and selected patient-reported outcomes with changes in fatigue in MIRI-treated patients in the VIVID-1 study. Co primary and gated secondary outcomes, including comparisons with ustekinumab, have been presented elsewhere^{4,5} Adult patients (N=1065) with moderately to severely active CD were randomized 6:3:2 to MIRI, ustekinumab or placebo. MIRI was given every 4 weeks (W) as 900 mg intravenous at W0, W4, and W8, then 300 mg subcutaneous from W12 to W52. Fatigue was assessed via the validated Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) questionnaire (scale from 0-52, higher scores indicating less fatigue⁶ and at least 6-point increase identified as a clinically meaningful within-patient change). Achievement of ≥6-point increase in FACIT-F at W52 was reported among those with and without

clinical remission by Crohn's Disease Activity Index (CDAI), endo response, endo remission, and Urgency Numeric Rating Scale (NRS) ≤ 2 at W52. For stool frequency (SF), abdominal pain (AP), fecal calprotectin (FCP), and C-reactive protein (CRP), the association of the change from baseline (CFB) at W52 vs. the CFB in FACIT-F at W52 was assessed by the Pearson correlation coefficient.

Results: At W52, 50.9% (268/527) of MIRI-treated patients achieved FACIT-F ≥ 6 -point increase from baseline. Greater proportions of patients who achieved clinical and endo outcomes had ≥ 6 -point increase in FACIT-F ($p < 0.05$) vs. those who did not achieve the outcome (Table). There was weak/moderate correlation between CFB at W52 in AP, SF and log-transformed FCP and CRP, and the CFB in FACIT-F at W52 (Table).

A. W52 FACIT-F ≥ 6 -point Increase From BL by Outcome at W52 ^a , NRI	Outcome Achieved n/N (%) (95% CI) ^b	Outcome NOT Achieved n/N (%) (95% CI) ^b	Risk Difference (95% CI) ^b	p-Value ^c
Clinical remission by CDAI ^d	185/280 (66.1) (60.5-71.6)	83/247 (33.6) (27.7-39.5)	32.5 (24.4-40.6)	<0.0001
Endo response ^e	154/256 (60.2) (54.2-66.2)	114/271 (42.1) (36.2-47.9)	18.1 (9.7-26.5)	<0.0001
Endo remission ^f	59/96 (61.5) (51.7-71.2)	209/431 (48.5) (43.8-53.2)	13.0 (2.1-23.8)	0.0216
Urgency NRS ≤ 2 ^g	127/188 (67.6) (60.9-74.2)	127/311 (40.8) (35.4-46.3)	26.7 (18.1-35.4)	<0.0001
B. CFB in FACIT-F vs. CFB in Outcomes at W52	N	Pearson Correlation Coefficient	95% CI ^h	p-Value

Introduction: We recently described an interleukin(IL)-23-inducible pathogenic subset of CCR6⁺CXCR3⁺CCR5⁺ mucosal T helper (Th)17 cells (pTh17) infiltrating Crohn's disease (CD) inflamed mucosa and specifically activated in response to Adherent-Invasive Escherichia Coli. pTh17 cells are functionally and phenotypically distinct from CCR6⁺CXCR3⁺CCR5⁺ Th17 cells (cTh17) and from IL-12-induced CCR6⁺CXCR3⁺ Th1/17 subset. Here, we investigated pTh17 cells' recirculation into the bloodstream, localization into the intraepithelial lymphocyte (IEL) compartment, and in-vivo modulation by different biological therapies.

Aims & Methods: Adult patients with active CD initiating either vedolizumab as per clinical practice or ustekinumab and risankizumab during the SEQUENCE trial were prospectively recruited at Fondazione IRCCS Cà Granda, Ospedale Policlinico di Milano. In vedolizumab-treated patients, peripheral blood and intestinal biopsies were collected at baseline and at the end of induction. In ustekinumab- and risankizumab-treated patients, intestinal biopsies were collected outside study protocol assessments at baseline and week 24. Endoscopic response was defined as a greater than 50% decrease in the Simple Endoscopic Score from baseline. Peripheral blood mononuclear cells, lamina propria mononuclear cells (LPMC), and IEL were isolated and analyzed through flow cytometry.

Results: Overall, 34 CD patients were assessed. Demographic and baseline disease characteristics are summarized in Table 1. At baseline, as compared with cTh17, pTh17 cells: 1. are rarely found in the peripheral blood and express low levels of CCR9 and $\alpha 4\beta 7$, 2. express high levels of tissue-resident markers CD69⁺CD103⁺ in the mucosa, and 3. infiltrate the IEL layer upon binding of CD103 with E-cadherin. Baseline pTh17 cells

were upregulated in patients not achieving vedolizumab-induced endoscopic response. Upon vedolizumab treatment, a selective downregulation of mucosal cTh17 cells but not pTh17 was observed. Remarkably, risankizumab induced a specific downregulation of pTh17 cells, but not cTh17, in both LPMC and IEL layers. Conversely, ustekinumab reduced Th1/17 mucosal subsets, but not pTh17 cells (Figure 1).

Conclusion: pTh17 cells are largely unable to recirculate through the bloodstream, express markers of gut-tissue residency, and infiltrate the IEL compartment. IL-23 neutralization by risankizumab specifically downregulates mucosal pTh17 cells, as compared with vedolizumab and ustekinumab. Our immunologic results might provide mechanistic clues to vedolizumab latency effect in CD, and potentially explain early signs of risankizumab superiority over ustekinumab in the SEQUENCE study in terms of endoscopic response at 24 weeks.

Introduction: Upadacitinib (UPA), an oral, reversible and selective Januskinase-inhibitor (JAKi), was licensed for the treatment of seven immune-mediated inflammatory diseases, including moderate to severe ulcerative colitis (UC) (1). Real-word (RW) evidence on the effectiveness and safety of UPA in UC remains sparse (2). Here, we present clinical, biochemical, and sonographic data after 8 and 16 weeks of UPA induction in a large, multinational RW cohort of UC patients.

Aims & Methods: EUROPE is an ongoing, prospective, non-interventional, international multicentric study in patients with active UC selected for therapy with UPA. The study aims to analyse the predictive value of early disease improvements including sonographic parameters for the long-term outcome after 52 and 104 weeks. For this interim analysis, we report clinical, biochemical and sonographic results at baseline (BL), week 8 (8W), and 16W of 139 UC patients enrolled until January 2024. W2 results have been previously presented by Zeissig et al. at ECCO 2024 (P905). For 92 patients, sonographic BL data for the most affected bowel segment was available. The safety population included all 211 patients enrolled until data base lock. Because of lacking data on w52 no predictive value could be shown.

Results: Overall, 139 patients had a documented W16 visit until January 2024. Of these, 59.7% (n = 83) were male and .7%, n = 83) 54.0% (n = 75) had pancolitis. The median disease duration was 6.9 years (2.6–12.7) and a minority was fully vaccinated against herpes zoster at baseline (30.9%, n = 43). The majority of patients was bio-experienced (85.6%, n = 119) and about one third had been exposed to ≥ 3 biologicals (36.1%, n = 43/119). At BL, patients had a median bowel wall thickness (BWT) of 5.0 mm (4.0–6.2) in the sigmoid colon. It was the most affected segment in 70.7% of patients (n = 65/92). At BL, disease activity was high, reflected by a median partial Mayo score (incl. rectal bleeding (RB), stool frequency (SF), physician's global assessment (PGA) of 5.0 (4.0–7.0). After UPA induction, patients demonstrated high rates of symptomatic remission (SF≤1, RB=0) at 8W and 16W (65.5% (n = 91) and 69.1% (n = 96) vs. 26.5% (n = 23) at BL; both p < 0.001 vs. BL). BWT was ≤ 3mm (considered normalisation) in 63.0% (n = 58) and 60.9% (n = 56) at 8W and 16W (both p < 0.001 vs. BL with 10.9%, n = 10). Remission of biomarkers fecal calprotectin (fCal ≤ 250 µg/g) and CRP (< 5 mg/L) was observed in 59.0% (n = 82) and 60.4% (n = 84) at 8W and 16W (both p < 0.001 vs BL with 28.1%, n = 39). After 8W induction, 38.1% (n = 53) were still on 45mg UPA, while 37.4% (n = 52) had

switched to 30mg and 10.8% (n = 15) to 15mg maintenance dosing. This could potentially be confounded by visit time points. In total, 104 adverse events (AE), of which most were non-serious (7.1%, (n = 15) SAEs), were documented.

Conclusion: In this interim analysis of the EUROPE study, UPA induction treatment in UC provided relief of clinical symptoms and was associated with early sonographic and biochemical improvement.

Introduction: Histologic inflammation persists in up to 1/4 of patients (pts) with Crohn's Disease (CD) despite endoscopic mucosal healing. Responsiveness of histologic inflammation and of combined endoscopic-histologic endpoints to treatment are evolving measures of disease activity in CD. Mirikizumab (MIRI) increased histologic response (H-Res) and remission (H-Rem) relative to placebo (PBO) in the Phase 2 SERENITY trial.¹

Aims & Methods: To evaluate the impact of MIRI and ustekinumab (UST) on H-Res and H-Rem and combined endoscopic-histologic response (EH-Res) and remission (EH-Rem) in all pts, pts with prior biologic failure (BF), pts without prior BF in moderately to severely active CD, in the randomized, double-blind, double-dummy, treat-through Phase 3 VIVID-1 trial (NCT03926130). Two biopsy specimens from each of 5 intestinal segments (1 ileal and 4 colonic) were obtained from the edge of the ulcers, or the most inflamed mucosa from randomized pts at screening, and weeks (W)12, and 52. Criteria for H-Res were the absence of epithelial neutrophils and epithelial damage, erosions and ulceration or ≥50% decrease in

either the active Robarts Histopathology Index or the active Global Histologic Disease Activity Score. H-Rem was defined as complete absence of mucosal neutrophils (in epithelium and lamina propria), and no epithelial damage, erosions and ulcers; these criteria had to be met in all biopsy specimens. Endoscopic response was defined as ≥50% improvement from baseline in Simple Endoscopic Score for CD (SES-CD). Endoscopic remission was defined as SES-CD total score ≤4 and ≥2-point reduction from baseline and no subscore >1 in any individual variable.

Results: At W52, nominally significant differences between MIRI and UST were observed in achieving H-Res in all pts (58.2% vs 48.8%; p=.007 and in BF pts (56.5% vs 41.3%; p=.006). For EH-Res, differences of MIRI vs UST were numerically greater but not statistically significant in all pts (41.1% vs 34.4%; p=.063) but were nominally significant among BF pts (39.6% vs 27.8%; p=.023). While numerical differences between MIRI and UST were observed in H-Rem and EH-Rem in all pts (H-Rem: 30.2% vs 28.9%; p=.685; EH-Rem: 17.2% vs 14.8%; p=.363) and in BF pts (H-Rem: 24.3% vs 19.8%; p=.365; EH-Rem: 13.3% vs 8.7%; p=.237), no significant differences were observed in these endpoints (Table).

		MIRI	USTE	P	Difference (95%CI)
Histologic Response (%)	All patients	58.2	48.8	0.007	9.6 (2.6, 16.6)
	Without prior biologic failure	61.9	56.9	0.383	5.0 (-5.3, 15.3)
	With prior biologic failure	56.5	41.3	0.006	15.2 (4.7, 25.7)
Endoscopic-Histologic Response (%)	All active patients	41.1	34.4	0.063	6.8 (-0.3, 14.0)
	Without prior biologic failure	42.5	40.8	0.829	1.7 (-8.6, 12.0)
	With prior biologic failure	39.6	27.8	0.023	11.8 (2.0, 21.7)
Histologic Remission (%)	All patients	30.2	28.9	0.685	1.3 (-5.0, 7.7)
	Without prior biologic failure	33.3	34.6	0.822	-1.3 (-11.2, 8.6)
	With prior biologic failure	24.3	19.8	0.365	4.5 (-4.3, 13.2)
Endoscopic-Histologic Remission (% 95%CI)	All active patients	17.2	14.8	0.363	2.6 (-2.8, 7.9)
	Without prior biologic failure	20.9	20.8	>0.999	0.1 (-8.4, 8.6)
	With prior biologic failure	13.3	8.7	0.237	4.6 (-1.9, 11.1)

All active patients are patients with active histologic disease at baseline. Histologic response and histologic remission in all patients were prespecified, non-multiplicity-controlled endpoints. All analyses in patients without prior biologic failure, patients with biologic failure and combined endoscopic-histologic response and remission were analyzed post hoc. For achieving histologic response, the sum of five segments active RHI or active GHAS needed to be reduced by ≥50% from baseline.

CI=confidence interval; GHAS=Global Histologic Disease Activity Score; MIRI=mirikizumab; PBO=placebo; RHO=Robarts Histopathology Index; USTE=ustekinumab

Conclusion: Using strict definitions, all histology-based endpoints were achieved by MIRI versus PBO. For comparison versus UST, MIRI also showed nominal statistical difference for H-Res, which was prespecified and is considered the most sensitive to change, particularly driven by BF pts. The implication of these results on clinical endpoints and long-term outcomes, including hospitalization rates and surgeries, requires further evaluation.

Introduction: In pancreatic ductal adenocarcinoma (PDAC), the prognostic relevance of B cells remains controversial, and only when aggregated within tertiary lymphoid structures (TLS) have they been unanimously associated with extended survival. Our aim is to provide the first transcriptomic characterization of B cell subtypes and gain new insights into the immune-promoting role of TLS in PDAC.

Aims & Methods: We generated a comprehensive transcriptomic atlas of tumor-associated B cells in PDAC by integrating single cell technology with spatial transcriptomic approaches. Histological characterization of the B cell immune landscape was performed using a novel multiplexed immunohistochemistry panel in treatment-naïve PDAC patients. In addition, TLS assessment on routine H&E slides from two independent PDAC cohorts, comprising participants from the randomized controlled PREOPANC trial (n=44) and the PanGenEU study (n=66), were subjected to uni- and multivariate prognostic analyses, with associated bulk-RNAseq data utilized for additional validation.

Results: The presence of TLS was linked with an expansion of the B cell compartment and their differentiation into antibody-producing plasma cells. Using single nucleus (sn)RNAseq and spatial mapping, we uncovered that certain differentiated B cell subtypes including germinal center (GC) B cells and plasma cells, were exclusively identified in patients with late-stage TLS harbouring GCs. In addition, CD38+ CD138+ plasma cells were predominantly located forming clusters in stromal regions situated in close proximity to TLS.

Accordingly, the expression of antibody production and plasma cell markers was significantly heightened in patients with late-stage TLS, indicative of augmented adaptive immune responses. We further validated the prog-

nostic significance of GC formation within TLS in two independent PDAC cohorts (HR=0.45, 95%CI 0.27-0.77, P.adj.=0.034). Notably, in the PREOPANC cohort a positive TLS status was also associated with a favorable immune milieu enriched with antibody-presenting cells and B cell subsets, including plasma cells.

Conclusion: Our multiomic analysis unveils compelling evidence of selective B cell maturation and active adaptive immunity in PDAC patients harboring late-stage TLS. From a clinical perspective, TLSs emerge as robust prognosticators of survival in PDAC.

Overall, our findings provide novel insights into B cell biology and hold potential to refine immunotherapeutic strategies in this challenging tumor context.

Introduction: Approximately 10% of patients diagnosed with pancreatic ductal adenocarcinoma (PDAC) carry a pathogenic variant in a PDAC susceptibility gene. Current guidelines recommend offering germline cancer susceptibility testing for all individuals with PDAC regardless of family history.

Previous studies have shown moderate rates of uptake of gene testing, highlighting the need for efficient and accessible clinical pathways for delivering gene testing education and counseling.

We evaluated the uptake of gene testing when offered at the point-of-care by an oncology nurse specialist in an outpatient setting.

Aims & Methods: We undertook a retrospective chart review of PDAC patients treated at the Johns Hopkins Hospital between January 2021 and December 2023. Patients were educated about germline testing by an oncology nurse specialist during their initial clinic visit, and provided with instructional handouts, links to videos, instructions on kit ordering and given time to consider testing. “MyChart” reminders are sent as needed. Patients who desired testing were sent a saliva kit to their home that they had to send back to the testing lab.

Results were communicated by the oncology nurse to the patients, and those with pathogenic variants or variants of uncertain significance (VUS) are referred to formal genetic counseling.

Results: Of 1022 patients seen by the oncology and surgery teams, all but 2 were seen by oncology, 377 underwent surgery, 52% were male, 74.9% were White, 15.8% African American (AA), 6% were Asian, 3% were Hispanic, and 17.5% had a family history of pancreatic cancer. At diagnosis, median age was 67.1 +/- 10.6 years; 51.9% of cases had resectable-stage disease.

Among the 87.5% of patients offered gene testing, 77.6% completed testing. Completion rates among those offered testing increased from 72.4% (2021) to 78.5% (2022) and 82.2% (2023).

Factors significantly associated with reduced gene testing uptake includ-

ed African American patients, those that were single, had advanced-stage disease, did not receive chemotherapy and of older age at diagnosis (Table 1).

Among tested individuals, 55 (7.9%) involving PDAC susceptibility genes, with BRCA2, ATM and PALB2 being the most common. 50 out of these 55 patients (91%) were referred to genetic counseling, with 76% completing their counseling visit to date. Germline testing results led to a change in the treatment regimen in 23 of the 55 patients.

		Coefficient	Odds Ratio	95% Confidence Interval	P Value
Sex	Male vs Female	0.215	1.240	0.872-1.763	0.231
	White vs AA	-1.065	0.345	0.224- 0.531	<0.001
Race	White vs Asian	0.440	1.553	0.671- 3.596	0.304
	White vs Other	-1.508	0.221	0.083- 0.590	0.003
Ethnicity	Non-Hispanic Vs Hispanic	1.038	2.822	0.733- 10.863	0.131
Marital Status	Married vs Single	-0.755	0.471	0.295- 0.750	0.002
Stage at diagnosis	Resectable vs Metastatic	-0.5738	0.564	0.379-0.839	0.005
	Resectable vs Locally advanced	0.170	1.185	0.767-1.830	0.444
Age at diagnosis		-0.022	0.978	0.961- 0.996	0.015
Family History of PDAC	Yes vs No	-0.354	0.702	0.434- 1.136	0.149
Personal history of other cancers	Yes vs No	-0.036	0.965	0.629- 1.480	0.869
Received Chemotherapy	Yes vs No	-1.162	0.313	0.107- 0.910	0.033

Table 1: Multivariate analysis results for completion of germline genetic testing among offered patients.

Conclusion: The implementation of point-of-care encounters for cancer susceptibility gene testing by an oncology nurse specialist in the outpatient setting yielded a high uptake of testing. African American, older-age, single and advanced-stage disease individuals had lower rates of completing gene testing.

Disclosure: Nothing to disclose.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a systemic disease that resists almost any available therapies and is strikingly associated with thrombosis. We hypothesize that cell membrane of PDAC exhib-

its a high level of plasticity through exocytosis/endocytosis coupling-associated exosomes (or “extracellular vesicles”), leading to the cancer-related systemic effects, and reducing the biogenesis, release, and/or function of exosomes could offer a new therapeutic approach for PDAC.

Aims & Methods: We aimed to test whether pharmacological inhibition of exosomes might suppress the progression of PDAC. We first predicted the protein-protein interactions in our proteomics datasets with the focus on botulinum toxin A (BTX-A) and/or ivermectin (IVM) targets. We obtained PDAC cells from a genetically engineered C57BL/6 mouse model with KrasG12D/Pdx1-Cre for in vitro and in vivo tests.

We implanted the cells in 521 mice (C57BL/6) orthotopically (in the pancreas), subcutaneously, through hemi-spleen injection or tail vein injection, and treated the mice with BTX-A, IVM, gemcitabine plus paclitaxel (Gem/Pac) or their combinations.

Of note, BTX-A was given before the cell transplantation. In addition, we used PDAC mouse and human organoids. Measurements included survival rate, tumor size, growth of organoids, proteomics, exosomes, immunohistochemistry, electron microscopy, and bioinformatics.

Results: In response to orthotopical injection of PDAC cells, all 18 mice died within 12 days after receiving 1.0×10^5 cells and all 13 mice died within 18 days after receiving 2.25×10^5 cells due to thrombosis. Treatments with BTX-A and/or IVM in vitro suppressed the plasma membrane plasticity of PDAC cells (e.g., neurite-like outgrowth and expression of plasticity protein GAP43) in response to nerve growth factor or conditioned media of PDAC cells.

BTX-A in vitro exerted no effect on PDAC cell proliferation, but inhibited the SNARE protein complex signaling pathway, whereas IVM eliminated the formation of membrane microvilli (volume density 0.5% vs 10% saline) and inhibited cell proliferation, clathrin-mediated endocytic signaling and particularly Rab27a. BTX-A+IVM treated PDAC cells showed impaired formation and release of exosomes and down-regulation of proteins involved in exocytosis/endocytosis coupling and biogenesis of exosomes.

The exosomes of PDAC cells contained 301 proteins involved in axonal guidance signaling, clathrin-mediated endocytosis signaling, neuroinflammation signaling pathway, epithelial adherents junction signaling, EIF2 signaling and integrin signaling, and toxicities in neuro-immune, kidney, liver, and heart.

In vivo, treatment with IVM showed down-regulation of serum exosome proteins. Treatments with BTX-A, IVM or combination had no effects on the tumor size and the cell proliferation rate (Ki67 and DCLK1), but enhanced the inhibitory effects of Gem/Pac on tumors implanted in the pancreas, liver, lung or under the skin. Importantly, BTX-A and/or IVM increased median survivals of PDAC mice, i.e., 26 days without treatment vs. 21 days with Gem/Pac, 40 days with BTX-A, 89.5 days with IVM, and 90.5 days with BTX-A+IVM+Gem/Pac, and of mice with PDAC liver or lung metastasis (>135 days). IVM inhibited the growths of PDAC mouse organoids and human organoids which were derived from a PDAC patient at T2N2MO stage III without neoadjuvant therapy.

Conclusion: Inhibition of exosomes with IVM and/or BTX-A increased the survival rate in PDAC mice (probably by retardation of thrombosis) and the growth of human PDAC organoids, suggesting a translational potential.

Disclosure: Nothing to disclose.

Introduction: Recent studies using single-cell transcriptomic analysis have reported several distinct clusters of neoplastic epithelial cells and cancer-associated fibroblasts in the pancreatic cancer tumor microenvironment.

However, their molecular characteristics and biological significance have not been clearly elucidated due to intra- and inter-tumoral heterogeneity.

Aims & Methods: We performed single cell RNA sequencing using enriched epithelial cells and fibroblasts from 17 pancreatic cancer tissues. Then, to resolve the spatial information of heterogeneous cancer subclusters and cancer-associated niches in human pancreatic cancer tissues, we performed RNA in situ hybridization and spatial transcriptome analysis using 10X Visium technique in paired tumor tissues.

Results: We identified five distinct functional subclusters of pancreatic cancer cells and six distinct cancer-associated fibroblast subclusters. We deeply profiled their characteristics, and we found that these subclusters successfully deconvoluted most of the features suggested in bulk transcriptome analysis of pancreatic cancer.

Among those subclusters, we identified a novel cancer cell subcluster, Ep_VGLL1, showing intermediate characteristics between the extremities of basal-like and classical dichotomy, despite its prognostic value. Molecular features of Ep_VGLL1 suggest its transitional properties between basal-like and classical subtypes.

In the spatial transcriptome analysis, we constructed an adjacency network graph reflecting the neighborhood enrichment relationships across diverse cell types and draw a putative cancer progression axis from Ep_FXYD2, ADM population, to Ep_TRIM54, Ep_VGLL1, and Ep_KRT6A, supporting our model of pancreatic cancer cell dynamics.

In addition, we also discovered that the spatial distributions of Fb_LRRC15, representing the myCAF population, were highly correlated with pancreatic cancer cell distributions, whereas Fb_SFRP1, representing the iCAF population, were located distal to the cancer-associated niche.

Conclusion: This integrative analysis not only provides a comprehensive landscape of pancreatic cancer and fibroblast population, but also suggests a novel insight to the dynamic states of pancreatic cancer cells and unveils potential therapeutic targets.

Contact E-Mail Address: livia.archibugi@hotmail.it

Introduction: The Italian Registry of Families at Risk for Pancreatic Cancer (IRFARPC) is a surveillance program that enrolls individuals at increased risk (HRIs) as either mutation carriers (MC) of a pathogenic variant (PV) of a susceptibility gene or familial pancreatic cancer (FPC) individuals based on family history. It has been reported that FPC patients carry a lower risk of PC compared to MC, but their genetic background is often poorly evaluated.

Nonetheless FPC represent the larger part of subjects enrolled in surveillance protocols. In addition, PC predisposing genetic backgrounds can be shared with other malignant tumors that require a tailored surveillance program.

Aims & Methods: Our aim was to evaluate the prevalence of PV or variants of uncertain significance (VUS), in patients enrolled in IRFARPC. FPC patients enrolled in the IRFARPC registry at three forerunner centers (Verona, Milano, Rozzano) underwent buccal swabs in the context of the "PROPH-ITA" study funded by Italian Patients' Advocacy Groups ("Fondazione Nadia Valsecchi", "Associazione Oltre la Ricerca" and other individual initiatives), with germline evaluation of a panel of 41 genes. Genomic DNA was isolated from the biological samples for Whole Exon Sequencing. Considering scientific literature data and the main mutation databases, mutations defined as PV or VUS were reported in the genetic report, and subjects with a positive test were offered a genetic consultation.

Results: From December 2022 up to February 2024, a total of 270 FPC candidates participating to the IRFARPC were recruited and underwent buccal swab and genetic testing, of whom eighteen (6.6%) found carrying one or multiple PV: 6 CFTR, 5 ATM, 3 MUTYH, 1 CTSC, 1 TET2, 1 BRCA2, 1 PALB2. Ninety (33.3%) patients carried one or multiple VUS, mostly in the CFTR, APC, and ATM genes. All these one-hundred-eight patients (40%) accepted genetic counselling.

Conclusion: Genetic profiling of FPC patients in the context of the IRFARPC screening protocol retrieved a relatively small, yet not negligible, number of patients carrying a previously unknown PV and a large rate of

VUS. Further studies are needed to elucidate the relevance of VUS in this context and the association between mutational status and pancreatic and extrapancreatic findings during surveillance. In 2024, the PROPH-ITA study will be open to all IRFARPC centers.

Disclosure: Nothing to disclose.

Introduction: Antibiotic resistance in *Helicobacter pylori* (*H. pylori*) poses an increasing challenge for infection management. Genotypic antibiotic susceptibility testing (GAST) is proposed as cost-effective approach for successful treatment.

Aims & Methods: Aim of our study was to evaluate GAST for detecting clarithromycin and levofloxacin resistance in gastric aspirates from *H. pylori*-positive patients compared to conventional phenotypic AST (PAST). Patients undergoing upper GI endoscopy (UGE) between February 2022 and April 2023 were prospectively recruited. Real-time diagnosis of *H. pylori* was pursued during UGE through gastric juice analysis by Endofaster¹. In case of intraprocedural *H. pylori* detection, two types of gastric aspirates were collected: a) undiluted gastric juice (GJ) and b) water rinse aspirate (WR). The WR was obtained after complete removal of the GJ and instillation of 30 mL sterile saline solution against the wall of the stomach corpus. Furthermore, gastric biopsies were collected for histology and culture-based PAST by E-test. Sanger sequencing of the 23S rRNA and *gyrA* genes from *H. pylori* was performed using gastric aspirates to detect polymorphisms associated with resistance to macrolides and fluoroquinolones, respectively. The test accuracy of GJ-GAST and WR-GAST was determined using PAST as the gold standard. The McNemar test was used to compare sensitivities and specificities between GJ- and WR-GAST. The level of agreement among different AST was assessed by Cohen's κ -value.

Results: Seventy-two consecutive patients (29/43 male/female; mean age, 47.0 $\pm$ 13.5 years) tested *H. pylori*-positive during the UGE were included in the study. According to PAST the resistance rates were 15.3% (11/72) for clarithromycin and 18.1% (13/72) for levofloxacin. The diagnostic measures of GJ-GAST and WR-GAST for resistance detection, as well as their agreement with PAST are shown in Table 1. Overall, GAST and PAST results showed substantial agreement (κ -value ranging from 0.67 to 0.77) and a very high level of concordance (>93%) for detecting clarithromycin and levofloxacin resistance using both GJ and WR.

There were no significant differences in diagnostic performances between GJ- and WR-GAST ($p > 0.05$), as confirmed by an almost perfect agreement with a κ -value of 0.93 for both clarithromycin and levofloxacin. Additionally, molecular analysis, involving the inspection of Sanger chromatograms, enabled an increase in the detection of heteroresistance cases by 33% for clarithromycin and up to 50% for levofloxacin, compared to PAST.

	GJ-GAST		WR-GAST	
	Clarithromycin	Levofloxacin	Clarithromycin	Levofloxacin
Sensitivity	63.6% (30.8% - 89.1%)	69.2% (38.6% - 90.9%)	54.6% (23.4% - 83.3%)	66.7% (34.9% - 90.1%)
Specificity	100 % (94.0% - 100%)	98.3% (90.8% - 100%)	100% (94.1% - 100%)	100% (93.7% - 100%)
Accuracy	94.4% (86.2%-98.4%)	93.0% (84.3% - 97.7%)	93.1% (84.5% - 97.7%)	94.2% (85.8% - 98.4%)
Positive predictive value	100% (59.0% - 100%)	90.0% (56.0% - 98.5%)	100% (54.1% - 100%)	100% (63.1% - 100%)
Negative predictive value	93.8% (87.3% - 97.0%)	93.4% (86.3% - 97.0%)	92.4% (86.5% - 95.9%)	93.4% (86.5% - 96.9%)
Pairwise concordance	67/71 (93.1%)	66/71 (93.0%)	67/72 (93.0%)	66/70 (94.3%)
κ -value	0.75 (0.51 - 0.98)	0.74 (0.53 - 0.95)	0.67 (0.41 - 0.93)	0.77 (0.55 - 0.98)

Table 1. Diagnostic performances of GJ-GAST and WR-GAST for detection of clarithromycin and levofloxacin resistances, as compared to PAST. 95% confidence intervals are indicated in brackets.

Conclusion: Genotypic AST from gastric aspirates, following intraprocedural diagnosis of *H. pylori*, provides highly accurate results for detecting clarithromycin and levofloxacin resistances, comparable to conventional phenotypic AST. This novel method of GAST, performed using water rinse aspirates collected during UGE, is a valid and practical tool for tailoring eradication regimens.

Contact E-Mail Address: 2781829818@qq.com

Introduction: The NLRP3 inflammasome induced by *Helicobacter pylori* (*H. pylori*) infection serves as a crucial platform for the maturation and secretion of IL-1 β and IL-18, leading to pyroptosis, which thus exacerbates *H. pylori*-associated gastritis and accelerates its progression to gastric cancer. Inhibiting NLRP3 expression can attenuate the intensity of the inflammatory response and impede the progression of *H. pylori*-induced gastric mucosal lesions.

However, the post-transcriptional regulatory mechanisms governing NLRP3 in *H. pylori* infection remain unclear. Therefore, elucidating the molecular mechanisms underlying post-transcriptional regulation of NLRP3 could offer potential intervention strategies for *H. pylori*-related gastric mucosal diseases.

Aims & Methods: In the co-culture experiment of human gastric epithelial cells or mouse mononuclear macrophage and *H. pylori* in vitro, knock-down or overexpression of AUF1 was performed, and the effect of AUF1 on the activation of NLRP3 inflammasome was detected by Western blot assay and ELISA. Scanning or transmission electron microscopy, immunofluorescence (IF) assay, lactate dehydrogenase (LDH) release assays were used to detect the effect of AUF1 on pyroptosis.

Transcriptome analysis was used to explore the changes of inflammatory cytokine genes in gastric epithelial cells with *H. pylori* by AUF1 knockdown. RNA immunoprecipitation and RNA-pulldown assay were used to detect the interaction of AUF1 and NLRP3 mRNA. Immunohistochemical staining was used to detect the expression of AUF1, NLRP3, Caspase1 and GSDMD in gastric mucosa of *H. pylori*-infected patients. Exosomes from gastric juice of *H. pylori*-related gastric mucosal diseases were collected by ultracentrifugation and AUF1 expression was detected.

Results: The expression of AUF1 in gastric mucosa and gastric juice exosomes of *H. pylori*-infected patients with chronic superficial gastritis was significantly up-regulated, and gradually increased with the aggravation of inflammation. Transcriptome analysis of *H. pylori* infected gastric epithelial cells showed that inflammatory pathways were significantly inhibited and NLRP3 was the most significantly altered inflammatory gene after AUF1 knockdown.

After *H. pylori* infection, AUF1 knockdown can inhibit NLRP3 expression, NLRP3 inflammasome activation and the secretion of IL-1 β and IL18 both in gastric epithelial cells and macrophages.

On the contrary, overexpression of AUF1 promoted NLRP3 expression and inflammasome activation, while NLRP3 inhibitor MCC950 can counteract the activating effect of AUF1 overexpression on NLRP3 inflammasome.

Also, we confirmed that AUF1 promoted pyroptosis in *H. pylori*-infected gastric epithelial cells, and the treatment of MCC950 could relieve pyroptosis. Mechanically, we found that AUF1 can bind to the 3'UTR region of NLRP3 mRNA, thereby enhancing the stability of NLRP3 mRNA and upregulating the expression of NLRP3. In gastric mucosa tissues of *H. pylori*-infected patients, AUF1 expression was positively correlated with NLRP3, Caspase1 and GSDMD expression.

In addition, *H. pylori* CagA promotes the interaction between AUF1 and exportin CRM1, thus promoting the cytoplasmic redistribution of AUF1.

Conclusion: *H. pylori* infection promotes the cytoplasmic redistribution of AUF1 through CRM1 and AUF1 promotes NLRP3 inflammasomes activation by upregulating the expression of NLRP3.

Our findings identify AUF1 as a novel positive regulator of NLRP3 inflammasomes and suggest that dysregulation of AUF1 expression leads to an increased risk of *H. pylori*-gastritis.

HELICOBACTER PYLORI-RELATED GENES ARE NOT DETECTABLE IN GASTRIC MUCOSA OF PATIENTS WITH HISTOLOGICALLY HP NEGATIVE AUTOIMMUNE ATROPHIC GASTRITIS COMPLICATED WITH GASTRIC CANCER

G. Cozza¹, L. Belloni¹, S. Cingolani¹, M. Vavallo¹, L. Dottori¹, F.P. Schiavone¹, B. Annibale¹, E. Lahner¹

Introduction: Chronic atrophic gastritis (CAG) is primarily caused by *Helicobacter pylori* (Hp) infection but also by autoimmune phenomena giving rise to autoimmune atrophic gastritis (AAG), whose hallmark is corpus-restricted atrophy sparing the antrum (unlike Hp infection causing extensive CAG). AAG triggered by Hp has been proposed, but diagnosis of Hp in this condition is difficult. Hp infection is one of the main risk factors for gastric cancer (GC), while the role of AAG in the onset of GC is still debated.

Assessing the association of GC with AAG is thus challenging, as it requires the exclusion of Hp infection. Hence, investigating the presence of Hp-related genes in the gastric mucosa of histologically Hp negative AAG patients complicated by GC could be useful for accurately assessing the role of Hp in GC associated with AAG.

Aims & Methods: The aim was to assess the presence of Hp-related genes in corpus mucosa biopsies using Real-time and Digital PCR in AAG patients with GC and negative Hp at histology, along with Hp-positive and -negative controls.

Single-centre, experimental molecular biology study derived from 713 pts with histological diagnosis of CAG (2009-2022). Pts without corpus-restricted CAG (n=118) and with histological positivity for Hp (n=57) were excluded, resulting a source population of 538 AAG pts with negative Hp at histology. Out of these, 10 pts (80%F, age 69.5 (range 50-83) yrs) were diagnosed with gastric neoplastic lesions (GNL), including gastric cancer (GC) and high-grade intraepithelial neoplasia (HG-IEN). Real-time and Digital PCR were used to assess the presence of Hp-related genes in corpus mucosa biopsies of the 10 GNL-AAG pts and 2 Hp-positive non-atrophic gastritis pts (positive controls: 1 F, 1 M, age 39, 68 yrs) and 2 subjects with a healthy stomach (negative controls: 1 F, 1 M, age 22, 34 yrs).

DNA was extracted from formalin-fixed, paraffin-embedded (FFPE) tissue sections of corpus mucosa biopsies and Real-time and Digital PCR were performed using specific probes for UreA, UreC, and CagA Hp-related genes. 16sRNA and Beta2 microglobulin specific probes were used as amplification ctr of bacterial and human DNA. Real-Time PCR gives a semi-quantitative analysis, whereas Digital PCR measures the accurate copy numbers of Hp DNA.

Results: GNL were diagnosed in 3/10 pts at AAG diagnosis, while in 7 at follow-up (median 96, range 12-156 mos). GNL were frequently in the corpus (50%), less commonly at *incisura angularis* (30%) or antrum (20%), and consisted of 8 GC and 2 HG-IEN. None had family history of GC, all pts were parietal cell autoantibodies positive. ELISA Hp serology was negative in all 5/10 available sera. Hp-related genes were not detected in any of the GNL-AAG pts nor in negative controls, but UreA and UreC were found in both positive controls and CagA in one. 16sRNA gene was detected in GNL-AAG by Real-time(CT mean 26.0, SD 0.3) and Digital PCR (copies μ l mean 1397, SD 348) in similar amounts as in positive controls (mean CT 25.7, SD 0.9, mean copies/ μ l 4977.5, SD 2185.7), indicating the detectability of bacterial genes in the extracted DNA.

Conclusion: In FFPE corpus mucosa biopsies of pts with histologically Hp negative AAG and GC, specific Hp-related genes are detectable by nor Real-time neither Digital PCR. This result supports the idea that GC develop-

ment cannot be excluded *a priori* in primary, Hp negative AAG, suggesting that Hp-unrelated cancerogenetic mechanisms may be involved and regular surveillance should be considered in primary AAG.

A NOVEL *TLR4* MUTATION DEREGULATES INFLAMMATION DURING *HELICOBACTER PYLORI* INFECTION AND RELATED GASTRIC CARCINOGENESIS

E. Otaegui-Campos¹, I. Simovic¹, K. Vinasco Pacheco¹, L.D.W. Luu², N. Kaakoush³, N. Castaño Rodríguez¹

Introduction: While *Helicobacter pylori* infection is largely recognised in gastric cancer (GC) aetiology, only 1-3% of infected individuals will develop this inflammatory disease. Inheritable mutations in Toll-like receptor 4 (TLR4) deregulate responsiveness to *H. pylori* and may influence clinical outcomes. To date, *TLR4* mutations are often understudied in ethnically diverse populations with a high-risk of GC, yielding inconclusive findings and a limited understanding of their true biological relevance.

This study delineates the effect of the novel *TLR4* rs11536889 (G>C) mutation in the host response during *H. pylori*-related gastric carcinogenesis.

Aims & Methods: The relationship between the *TLR4* rs11536889 mutation, *H. pylori* infection and GC aetiology was evaluated in a multiethnic (Australian Caucasian, Colombian Mestizo, Han Chinese and Iranian) case-control study encompassing 315 GC cases, 372 gastric precancerous lesion cases and 1043 controls.

Local host transcriptomics of gastric biopsies and systemic inflammation of sera were interrogated and correlated with carriage of rs11536889. Inflammation and bacterial clearance were further examined in *H. pylori*-challenged *in vitro* models of CRISPR/Cas9-edited mutant gastric epithelial (AGS) and macrophage (THP-1) cell lines.

Results: Carriage of rs11536889 confers reduced susceptibility to *H. pylori* infection, meanwhile, it independently increases the risk of GC in high-risk populations but not the low-risk population. Transcriptomics of gastric tissue revealed rs11536889 carriage in high-risk patients modulated tumour suppression (*CPA6*, *KDM5D*, *TCL1A*), mucosal inflammation (*DEFB1*, *CXCL10*, *FAS*, *NLRP6*) and metabolism (*GLUT4*). In parallel, a systemic pro-inflammatory signature was consistent in high-risk individuals harbouring rs11536889, but was inversed in low-risk individuals. Interestingly, while both rs11536889-carrying human gastric epithelial and macrophage cell lines demonstrating augmented IL-8 and TNF- α expression, *H. pylori* clearance was ameliorated in mutant epithelial cells but impeded in macrophages.

Conclusion: This study offers appreciable insight into the genetic underlining of the host immune responses to *H. pylori* and related GC. These findings hint at a possible race-specific trend with carriage of rs11536889, which could confer the opposite phenotype outcomes between high- and low-risk populations worldwide.

Uncovering the clinical relevance of rs11536889 advances our efforts to establish effective and non-invasive biomarkers for global-scale GC screening programs, and posits TLR4 signalling as a potential target for immunotherapies to benefit high-risk patients.

Introduction: Endoscopic mucosal resection (EMR) is the mainstay of therapy for large colorectal polyps. A previous study has shown low complication and recurrence rates after EMR when performing margin and selective base ablation using hybrid argon plasma coagulation (h-APC). We were interested in evaluating the safety and efficacy of EMR with systematic complete margin, base and vessel ablation in a multicenter study.

Aims & Methods: Adults (18–89 years) undergoing EMR of large nonpedunculated colorectal polyps ≥ 20 mm were enrolled in a multicenter prospective study. After EMR completion and removal of all visible adenoma, patients received systematic h-APC ablation of the post-resection margin, the resection base, and of any visible vessels as the only prophylactic therapy for bleeding. Patients were contacted at 4 weeks to assess any adverse events. First surveillance colonoscopies were scheduled at 4–6 months.

The primary outcome was the rate of severe delayed bleeding within 4 weeks, defined as the need for hospitalization, transfusion, repeat endoscopy, embolization, or surgery.

Secondary outcomes were the rate of recurrence, defined as pathology confirmed adenoma or serrated recurrence at the EMR site at first surveillance, and other adverse events within 4 weeks, including abdominal pain, deep mural injury (using the Sydney Classification), perforation and post-polypectomy syndrome.

Continuous variables were compared using t-tests, and categorical variables were compared using chi-squared tests, with a $p < 0.05$ considered statistically significant.

Results: A total of 178 patients (mean age 67.3 y, 44.4% female) undergoing 190 EMRs were included. h-APC margin ablation was done in all cases, partial base ablation in 43/190 and complete base ablation in 127/190. 127 post-resection defects had visible base vessels, of which 122/127 underwent h-APC as prophylactic therapy to prevent delayed bleeding. The mean polyp size was 36.7 mm, with 77.1% being proximal to the splenic flexure, and 81.8% being adenomas.

The primary outcome, severe delayed bleeding, occurred in 1.7% ($n=3$). With regards to recurrence, 46.1% of patients ($n=83$) underwent a first surveillance colonoscopy at the time of writing, at a median of 4.0 months post-EMR, of which 1.2% (1/83) developed a local recurrence at the EMR resection site. Severe intraprocedural bleeding occurred in 0.6% ($n=1$). Post-procedural non-severe abdominal pain occurred in 3.4% ($n=6$), while no patients developed severe post-procedural abdominal pain. Perforation occurred in 0.6% ($n=1$). This was identified immediately after the procedure in a patient who received partial base ablation, and the defect was clipped. There was no deep mural injury seen during the procedure.

Post-polypectomy syndrome occurred in 1.6% of patients who underwent complete base ablation (2/122). Intraprocedural type 2 deep mural injury

occurred in 5.1% ($n=9$), with six out of nine being in the context of complete base ablation. Eight out of nine were clipped, and no patient with type 2 deep mural injury developed a perforation. There were no cases of deep mural injury type 3 to 5 identified intraprocedurally.

Conclusion: EMR with systematic h-APC ablation of the post-resection margin, base and visible vessels demonstrated to be safe and highly effective to treat large nonpedunculated colorectal polyps.

Introduction: EMR remains the primary therapeutic option for LNCP in western practice, but new procedures and techniques are increasingly employed. Large published series previously defined expected rates of, and risk factors for, residual/recurrent adenoma after endoscopic resection (ER). However, these may no longer be relevant.

Aims & Methods: We aimed to identify independent risk factors for recurrent/residual adenoma in a contemporary cohort of LNCP treated by ER compared to a historical cohort. Patients with LNCP treated by ER at a tertiary referral centre between January 2011 and September 2023 who had completed 6 month surveillance (SC1) were included.

Patients were divided into contemporary (January 2018 – September 2023) and historical (January 2011 – December 2017) cohorts. Post-ER scars were examined using with magnification chromoendoscopy and NBI/BLI.

Clinicopathological features significantly associated with recurrent/residual adenoma on univariate analysis were subjected to multiple logistic regression to identify independent risk factors.

Results: 1517 ER were performed over the study period of which 946 met the inclusion criteria and had undergone SC1: 483 in the contemporary cohort and 463 in the historical cohort. In the contemporary cohort 313 (65%) were treated using ESD compared to 117 (25%) in the historical cohort ($p < 0.001$).

En bloc resection was more frequently achieved in the contemporary cohort compared to the historical cohort (70% versus 33%, $p < 0.001$). Recurrent/residual adenoma at SC1 was detected in 2.5% in the contemporary cohort compared to 8.9% in the historical cohort ($p < 0.001$).

For the historical cohort, multivariate analysis revealed that previous failed attempt at resection (OR 2.80, 95% CI 1.14–6.88, $p = 0.02$); piecemeal resection (OR 5.21, 95% CI 1.18–23.02, $p = 0.03$) and involvement of $> 75\%$ of the circumference of the lumen (OR 5.80, 95% CI 2.07–16.25, $p < 0.001$) were

independently associated with recurrent/residual adenoma: However, for the contemporary cohort, only difficult access to the lesion (OR 4.24, 95% CI 1.21-14.78) was independently associated with recurrent residual adenoma at SC1.

Conclusion: Significant changes have taken place in ER practice over the last decade. This study demonstrates this has led to a marked alteration in previously established expected outcomes and risk factors for recurrence.

Furthermore, the increasing use of adjunctive measures and techniques such as ESD throughout the colorectum may help drive down recurrence rates with the advantage of producing high quality histopathological specimens and accurate diagnosis, leading to a reduction in surveillance requirements. These data should help define performance standards for advanced resection units as well as guide informed consent and decision making for patients.

RISK FACTORS FOR POSITIVE VERTICAL MARGINS IN ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR COLORECTAL PT1 CANCER

Y. Ebisawa¹, H. Chiba¹, M. Koga¹, A. Hayashi¹, M. Kobayashi¹, J. Arimoto¹, H. Kuwabara¹, M. Nakaoka¹

¹Omori Red Cross Hospital, Gastroenterology, Ota-ku, Japan

Contact E-Mail Address: you.ebisawa603@gmail.com

Introduction: For colorectal T1 cancers, factors such as invasion depth and vascular involvement vary the risk of recurrence and metastasis, often making diagnosis challenging based solely on endoscopic findings. The utility of ESD as a diagnostic treatment is being discussed to avoid excessive surgical procedures. In cases of positive vertical margins of T1 cancer, additional surgery is recommended regardless of risk factors. Accurate diagnosis and avoidance of overtreatment require negative vertical margins.

We retrospectively examined ESD for colorectal T1 cancers at our hospital and identify risk factors associated with positive vertical margins and safety of ESD for T1 cancer.

Aims & Methods: From April 2012 to December 2023, among the 1560 colorectal lesions treated with ESD at our hospital, those diagnosed with pT1 cancer were selected. These cases were divided into two groups: VM positive and VM negative, and their endoscopic findings and treatment outcomes were compared.

Results: Of the 708 early-stage colorectal cancer cases treated with ESD, 112 cases (15.8%) were diagnosed with pT1. Dividing these by VM status, there were 11 cases in the VM positive group and 101 cases in the VM negative group. The median age was 76 years (range 40-87) in the VM positive group and 73 years (range 44-92) in the VM negative group, with a male/female ratio of 8/3 in the VM positive group and 56/45 in the VM negative group.

The tumor locations were colon/rectum in 8/3 cases in the VM positive group and 66/35 cases in the VM negative group. The median tumor size was 22 mm (range 17-60 mm) in the VM positive group and 35 mm (range 15-141 mm) in the VM negative group. The macroscopic types were elevated/flat in 5/6 cases in the VM positive group and 46/55 cases in the VM negative group, and the invasion depths were pT1a/pT1b in 2/9 cases in the VM positive group and 45/59 cases in the VM negative group. The median operation time was 49 minutes (range 10-333) in the VM positive group

and 42 minutes (range 8-250) in the VM negative group.

An analysis of the endoscopic features associated with T1b or deeper, such as depression, expansion, and fold convergence, showed the following: indentation present/absent was 7/4 in the VM positive group and 19/82 in the VM negative group; fullness present/absent was 0/11 in the VM positive group and 17/84 in the VM negative group; fold convergence was not observed in any case.

In the univariate analysis of risk factor for VM positive, significant differences were observed for tumor size greater than 3 cm, vascular invasion, depression, and severe fibrosis.

However, in the multivariate analysis, severe fibrosis (OR 5.792, 95% CI: 1.364-24.589, p=0.017) and depression (OR 9.95, 95% CI: 2.335-42.403, p=0.02) were independent risk factors for VM positive. All cases in the VM positive group underwent additional surgical resection, with one case of local residual disease and two cases with N1 or higher metastases observed.

Conclusion: ESD for T1 cancer was performed safely. Colorectal cancer with depression or severe fibrosis is risk factors for VM positive in ESD. When depression is observed in preoperative findings, it is necessary to select an experienced physician and the treatment strategy. In cases of intraoperative findings of severe fibrosis, identification of the dissection line can be difficult, potentially leading to incomplete resection or an increased risk of complications. It is desirable to develop treatment strategies (traction/tunneling method, PAEM, LECS, etc.) that allow for safe en bloc resection of these difficult cases.

Introduction: Vedolizumab (VDZ) is efficacious to induce and maintain clinical remission in Crohn's disease (CD). However, prospective data about its efficacy including endoscopy in early CD are lacking.

Aims & Methods: We conducted a prospective multi-centre international (Belgium, the Netherlands and Hungary) open label trial comparing the efficacy and safety of VDZ therapy in patients with early or late moderate-severe active CD (Crohn's Disease Activity Index [CDAI] 220-450 and presence of ulcers at endoscopy).

Early CD was defined as diagnosis <2 years and treatment naïve or only treated with corticosteroids and/or immunomodulators; late CD was defined as diagnosis >2 years and previously treated with corticosteroids, immunomodulators and anti-tumor necrosis factor agents.

Patients received intravenous VDZ (300 mg) at weeks 0-2-6 and q8 weeks thereafter for a total of 52 weeks, with an extra infusion at w10 in the absence of a CDAI drop <70. Ileocolonoscopy was performed at baseline, w26 and w52 and all procedures were centrally read. The sample size was calculated for 1/3 early and 2/3 late CD.

An extremely strict primary composite endpoint was used: proportion of patients with clinical and endoscopic remission (CDAI≤150 and Simple Endoscopic Score for CD [SES-CD]≤4) at both w26 and w52.

Key secondary endpoints included the proportion of patients with absence of ulcers, proportion of patients with endoscopic response (SES-CD reduction ≥50%) at w26 and w52 and safety.

Results: We recruited 86 early and 174 late CD patients, of whom 52 early and 104 late CD patients completed w52 (insufficient clinical response and adverse events were the main reasons for early withdrawal). Baseline characteristics including disease activity parameters were similar across both groups (median total SES-CD 9 [6-17] and 12 [7-17], median CDAI 254.7 [235.7-287.2] and 259 [235.2-314.5] for early and late CD, respectively), apart from disease duration and age (median disease duration 0 [0-1] and 11 [5.5-15.5], median age 29.5 [23.8-45.3] and 36 [28-48] for early and late CD, respectively). The primary endpoint was reached in 31.4% vs. 8.6% (p=0.001; ITT) and 45.0% vs. 16.0% (p<0.001; per protocol [PP]) of patients with early vs. late CD (Table 1). All key secondary endpoints were also met in favour of patients with early CD (Table 1). Serious adverse events (SAEs) occurred in 4.7% of patients with early vs. 27% of pa-

tients with late CD (p<0.0001) and included infection (1.2 vs 7.5%) bowel obstruction (0 vs 2.3%), exacerbation of CD (2.3 vs 4%), abdominal pain (0 vs 1.7%) and malignancy (0 vs 1.7%).

		Early vs late CD (ITT)	Early vs late CD (PP)	P values (ITT/PP)
Primary composite endpoint				
Clinical and endoscopic remission ^A	w26 and w52	31.4% vs 8.6%	45.0 vs 16.0%	0.001*; <0.001*

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are chronic and progressive inflammatory bowel diseases (IBD), frequently associated with bowel damage and extraintestinal manifestations, and present a significant burden for patients.

Aims & Methods: The IBD-PODCAST was a descriptive non-interventional, cross-sectional study, which aimed to estimate the proportion of patients with CD and UC with Suboptimal Disease Control (SDC) in a real-world setting, across 103 sites in 10 countries. Criteria for SDC were largely based on STRIDE-II¹ and modified by an expert panel. The original cohort consisted of 2185 IBD patients. We previously reported that treatment modification opportunities were possible in 49% of CD and 61% of UC patients on advanced therapy².

The aim of this analysis was to evaluate treatment patterns and potential treatment modifications in patients on standard or escalated maintenance therapy with biologics according to summary of product characteristics (SmPC), at index date. Patients who were receiving induction phase regimen or concomitant multiple advanced therapies or were treated with lower dosages according to the label were excluded from this analysis. Patients whose therapy was escalated beyond SmPC indications (i.e., with shorter intervals of administration) were classified as "further escalated".

Results: A total of 796 CD and 549 UC patients treated with biologics (infliximab, adalimumab, ustekinumab and vedolizumab) were analyzed. Results are summarized in Table 1. Overall, 52% CD and 47% UC patients were in SDC. Among patients treated with adalimumab standard biweekly dose, 50% CD and 37% UC patients had the potential to modify therapy, while 70% CD and 50% UC patients were still in SDC despite dose escalation; concerning patients further escalated with adalimumab, 60% CD and 75% UC were in SDC.

Nearly half of the infliximab-treated-patients were still in SDC. In ustekinumab-treated group, 58% of CD patients treated every 12 weeks had SDC and were eligible for treatment modifications, while SDC was observed in 57% CD and 49% UC patients treated every 8 weeks and in 56% of CD and 82% of UC patients furtherly escalated.

Among vedolizumab-treated patients, 42% CD and 39% UC patients with intravenous (IV) maintenance every 8 weeks were in SDC and candidates for treatment modification; SDC was observed also in 65% CD and 35% UC patients treated every 4 weeks with IV Vedolizumab.

		Adalimumab		Infliximab**		Ustekinumab			Vedolizumab					
Treatment group and dosage at index date	80mg 40mg SC SC EOW	SC EOW or 40mg SC EOW	Further SC escalation*	5-10 mg/kg IV q8W**	Further IV escalation*	120mg SC q2W	90mg SC q12W	90mg SC q8W	Further SC escalation*	300mg IV q8W	300mg IV q6W	300mg IV q4W	108mg SC EOW	Further SC escalation*
Crohn's Disease (n= 796)	Sub-optimal Disease Control (n=412, 52%)	66 (50%)	37 (70%)	6 (60%)	106 (46%)	33 (54%)	7 (54%)	11 (58%)	67 (57%)	18 (56%)	35 (42%)	1 (17%)	22 (65%)	4 (57%)
	Optimal Disease Control (n=384, 48%)	65 (50%)	16 (30%)	4 (40%)	124 (54%)	28 (46%)	6 (46%)	8 (42%)	51 (43%)	14 (44%)	48 (58%)	5 (83%)	12 (35%)	3 (43%)
Ulcerative Colitis (n= 549)	Sub-optimal Disease Control (n=257, 47%)	18 (37%)	5 (50%)	3 (75%)	99 (55%)	14 (52%)	6 (46%)	3 (60%)	17 (49%)	9 (82%)	60 (39%)	3 (33%)	13 (35%)	6 (35%)
	Optimal Disease Control (n=292, 53%)	31 (63%)	5 (50%)	1 (25%)	80 (45%)	13 (48%)	7 (54%)	2 (40%)	18 (51%)	2 (18%)	92 (61%)	6 (67%)	24 (65%)	11 (65%)

*Further escalation = Patients whose therapy was escalated beyond SmPC indications (i.e., with shorter intervals of administration); ** The maintenance dose of IV IFX 5mg/kg q8W and IFX 10mg/kg q8W were not collected separately in the study and put together in this analysis;

TNF, Tumor Necrosis Factor; ADA, Adalimumab; IFX, Infliximab; qnW, very n Weeks; EOW, Every other Week, IV, Intravenous administration; SC, Subcutaneous administration

Table 1: treatment patterns in patients affected by UC and CD (total n = 1345).

Conclusion: This descriptive analysis showed suboptimally-controlled disease in nearly half of 1345 IBD patients treated with biologics. Moreover, almost half of patients whose therapy had already been escalated may still require treatment modification. These results further enhance the need for a targeted management strategy and additional therapeutic alternatives in IBD.

Contact E-Mail Address: s.schreiber@mucosa.de
Introduction: Dose escalation (DE) of intravenous infliximab is an option for inflammatory bowel disease (IBD) patients who lose response after induction therapy^{1,2}. DE of subcutaneous (SC) infliximab from 120 mg to 240 mg every 2 weeks (Q2W) showed restoring efficacy in the 54-week LIBERTY-UC and LIBERTY-CD studies, and safety profiles were generally comparable between patients with or without DE³. Both two studies included an extension phase through Week (W) 102, and we present post-hoc long-term efficacy and safety results of DE in patients who treated in extension phase in two studies.
Aims & Methods: Patients with moderately to severely active UC and CD were treated with 3 doses of infliximab IV 5mg/kg as induction therapy (Weeks 0, 2 and 6). Clinical responders at W10 were randomized (2:1) to receive either CT-P13 SC 120 mg or placebo Q2W as maintenance therapy up to W54. Patients who, in the opinion of the investigator, would benefit from continued treatment entered open-label extension study from W56 to W102 and received CT-P13 SC 120 mg regardless of previously assigned arm. From W22, the patients who met loss of response criteria were permitted to escalate the dose to CT-P13 SC 240 mg Q2W through W102 for both arms. The results from CT-P13 SC arm are analyzed.
Results: A total of 237 and 180 patients who were randomly assigned to CT-P13 SC 120 mg arm and treated in extension phase in UC and CD study, each. Among them, DE from CT-P13 SC 120 mg to CT-P13 SC 240 mg prior to W102 was more common in UC than CD (30.0% [71/237] vs 20.6% [37/180]). Patients showed improvement in terms of clinical remission at W102 (both CD and UC) or endoscopic response at W102 (CD) after DE.

Also, patients showed improvement in other efficacy endpoints after DE (Table 1). Compared to the first DE visit, patients who escalated the dose had a statistically significant reduction of more than half in mean modified Mayo score in UC (5.9 vs 2.1, P<0.0001) and mean CDAI score in CD (270.58 vs 76.31, P<0.0001) at W102.
The incidence rate of treatment-emergent adverse events (TEAEs) in the maintenance and extension phase of both studies was comparable between patients with and without DE (In UC, 84.7% [61/72] vs 78.1% [132/169], In CD, 86.8% [33/38] vs 79.7% [118/148]). Among these, TEAEs of infection were as follows; In UC, 40.3% (29/72) vs 43.2% (73/169), In CD, 55.3% (21/38) vs 42.6% (63/148).
The incidence rate of treatment-emergent serious adverse events in the maintenance and extension phase of both studies was also comparable between patients with and without DE (In UC, 12.5% [9/72] vs 10.1% [17/169], In CD, 13.2% [5/38] vs 10.8% [16/148]).

n = Number of patients achieving efficacy endpoints at Week 102 regardless of dose escalation; N* = Number of patients who were randomly assigned to CT-P13 SC 120 mg arm and treated in extension phase and have a SES-CD score of at least 6 (or at least 4 if isolated ileal disease) at Screening; n' = Number of patients achieving efficacy endpoints at Week 102 among dose-escalated patients; N** = Number of patients with dose escalation to CT-P13 SC 240 mg prior to Week 102 in CT-P13 SC 120 mg arm and treated in extension phase and have a SES-CD score of at least 6 (or at least 4 if isolated ileal disease) at Screening; N = Number of patients who were randomly assigned to CT-P13 SC 120 mg arm and treated in extension phase; N' = Number of patients with dose escalation to CT-P13 SC 240 mg prior to Week 102 in CT-P13 SC 120 mg arm and treated in extension phase.

- Clinical remission, defined as an absolute Crohn's disease activity index (CDAI) score of <150 points
- Endoscopic response at Week 102, defined as > 50% decrease in Simplified endoscopic activity score for Crohn's disease (SES-CD) score from the baseline value
- Clinical response, defined as a decrease in CDAI score of 100 points or more from the baseline value
- Corticosteroid-free remission, defined as being in clinical remission (by an absolute CDAI score of <150) in addition to not receiving any corticosteroids for at least 8 weeks prior to Week 102, among the patients who used oral corticosteroids at baseline
- Clinical remission, defined as an average worst daily abdominal pain (AP) score of ≤1 (using 4-point scale) and an average daily loose/watery stool frequency (SF) score of ≤3 (of Type 6 or Type 7 on BSFS) with no worsening in either average score compared with the baseline value.
- Endoscopic remission, defined as an absolute SES-CD score of ≤4 with no sub-score of >1
- Clinical remission, defined as modified Mayo score with stool frequency subscore of 0 or 1 point, rectal bleeding subscore 0 point, and endoscopic subscore 0 or 1 point
- Endoscopic-histologic mucosal improvement, defined as absolute endoscopic subscore of 0 or 1 point from modified Mayo score and an absolute Robarts Histopathology Index (RHI) score of 3 points or less with an accompanying lamina propria neutrophils and neutrophils in epithelium subscore of 0 point
- Clinical response, defined as decrease in modified Mayo score from baseline of at least 2 points and at least 30%, with an accompanying decrease in the rectal bleeding subscore of at least 1 point or an absolute rectal bleeding subscore of 0 or 1 point
- Corticosteroid-free remission, defined as being in clinical remission (by modified Mayo score) in addition to not requiring any treatment with corticosteroid for at least 8 weeks at Week 102, among the patients who used oral corticosteroids at baseline

Table 1. Summary of efficacy outcome in CT-P13 SC treated patients at Week 102.

Conclusion: DE of CT-P13 SC from 120 mg to 240 mg Q2W following IV induction in patients who initially respond but subsequently lose response, shows clinical efficacy over an extended observation period of 102 weeks.

Safety profiles were generally comparable between patients with or without DE, and no new safety concerns were found after DE as well in long term treatment.

Introduction: Anti-tumor necrosis factor (TNF)- α are the first target therapies approved for the treatment of steroid-dependent or -refractory ulcerative colitis (UC). Drugs with different mechanisms of action have recently entered the market, but data on the optimal management of UC after failure of first-line anti-TNF- α are lacking.

Aims & Methods: The PODIUM study is a multicentre, retrospective, observational study that aims to compare the real-life effectiveness and safety of second-line vedolizumab (VDZ), ustekinumab (UST) and tofacitinib (TOF) in patients with UC. Consecutive patients with UC who had failed at least one anti-TNF- α and were never exposed to other target therapies were enrolled from 12 centres across Europe.

Sociodemographic data, data on clinical activity and adverse events of interest (AEIs, defined as AE requiring temporary/permanent drug discontinuation or medical intervention) were retrospectively extracted from medical records, from the initiation of second-line therapy until one year of observation/drug discontinuation/last available follow-up.

The primary outcome was the cumulative probability of achieving steroid-free clinical remission (SFCR), defined as stool frequency=0-1 and rectal bleeding=0 and no concomitant steroids, over the first year of treatment; inverse probability of treatment weighting (IPTW), calculated as the inverse of the probability of receiving each drug (IPTW=1/Propensity Score), was applied to the primary outcome to account for imbalances in

cohorts' characteristics. We performed an interim analysis including all data collected up to March 15th 2024; data collection is still ongoing at the submission of this Abstract.

Results: Data on 303 patients (172 VDZ, 63 UST, 68 TOF) were included in the analysis. The main baseline characteristics are presented in Table 1. After IPTW, the cumulative probability of achieving SFCR during the first year was 51.0%, 59.1% and 64.1% for VDZ, UST and TOF, respectively; both UST and TOF were superior to VDZ at Log-rank test ($p<0.001$), with no differences between the two. At weighted logistic regression, female sex (adjusted Odds Ratio, aOR, 0.06, Confidence Interval, CI, 95% 0.41-0.73, $p<0.001$) and higher Charlson Comorbidity Index calculated without considering age (aOR 0.73, 95% CI 95% 0.60-0.88, $p=0.001$) were independently associated with a lower probability of achieving SFCR during the first year. Recorded AEs were 16 (4 infections) in the VDZ group (9.3% of VDZ-treated patients), 6 (1 infection) in the UST group (9.5% of UST-treated patients), and 15 (5 infections, including 1 Zoster reactivation) in the TOF group (22.1% of TOF-treated patients).

	VDZ	UST	TOF	p
N	172	63	68	
Sex (F), n (%)	66 (38.4)	31 (49.2)	34 (50.0)	$p<0.05$ (VDZ vs both)
Age, mean (SD)	45.2 (16.0)	48.43 (16.5)	38.7 (12.9)	$p<0.05$ (TOF vs both)
Disease duration, mean (SD)	8.16 (11.1)	11.1 (11.8)	7.4 (7.4)	$p<0.05$ (UST vs TOF)
Extent (E3), n (%)	107 (62.2)	35 (60.4)	38 (55.9)	$p=ns$
CCI without age, mean (SD)	0.4 (1.0)	0.8 (1.8)	0.2 (0.5)	$p<0.05$ (UST vs both)
Baseline steroids, n (%)	74 (43.0)	26 (41.2)	38 (55.8)	$p<0.05$ (TOF vs both)
Baseline clinical activity				
SF, mean (SD)	1.9 (1.0)	2.0 (1.0)	2.2 (0.8)	$p=ns$
RB, mean (SD)	1.0 (0.9)	0.9 (0.9)	1.0 (0.8)	$p=ns$
Baseline biochemical activity				
CRP (mg/dL), mean (SD)	15.4 (29.3)	21.2 (43.1)	15.7 (33.0)	$p=ns$
FCP (ug/g), mean (SD)	1611 (2627)	1111 (1466)	1331 (1684)	$p=ns$

Table 1.

Conclusion: This preliminary analysis suggests that both UST and TOF might have superior effectiveness, compared to VDZ, as second-line agents in patients with UC after anti-TNF- α . Confirmatory analysis with a larger sample size will be performed. A slightly higher rate of AEs was observed in the TOF group.

Disclosure: Giuseppe Privitera received consultancy fees from Alphasigma and Janssen. Introduction: Anti-TNF availability has been associated with a decrease or delay of the first intestinal resection in patients with Crohn's disease (CD). However, few studies have evaluated the impact of availability of biological therapies on the change in postoperative recurrence (POR) preventive strategies and the need for second intestinal resection.

Aims & Methods: Aims: To assess time trends in the management strategies in the postoperative setting after a first intestinal resection for CD and the rate of second surgeries through the last three decades.

Methods: Adult patients with CD who underwent a first ileocolic resection with ileocolic anastomosis between 1990 and 2020 and at least one year of clinical follow-up, were identified from the Spanish ENEIDA registry. Patients in whom ileocolic resection was due to cancer were excluded. Patients were grouped by date of surgery (before biologicals -BB- 1990-2000; early biological era -EB- 2000-2010; widespread biological era -WB- 2011-2020). Medical prevention of POR was defined as any immunomodulator or biological agent started within the first 6 months after the ileocolic resection and maintained for at least 3 months.

Medical treatment of POR was defined as any immunomodulator or biological agent started at least 6 months after the index surgery. Surgical POR was defined as the need for a second intestinal resection at least 6 months after the index surgery.

Results: A total of 5,084 patients were included (24% BB, 38% EB and 38% WB). Main characteristics of the whole cohort were as follows: 51% men, 39% active smokers at the first surgery, 40% penetrating and 40% stricturing behaviour and 25% perianal disease. 34% exposed to immunomodulators and 25% to biologicals before the first surgery.

Median disease duration at first surgery of 3 years (range, 0-46), median age at index surgery was 35 years (range, 9-89), median follow-up until second resection or last visit of 125 months (range 6-408). 55% followed medical prophylaxis (33% thiopurines, 10% biological monotherapy, 12% combotherapy). Surgical POR occurred in 17%.

A significant increase in medical prevention of POR with both thiopurines (BB 13%, EB 45%, WB 32%) and biological agents (BB 0%, EB 12%, WB 46%) was observed; moreover, an increasing proportion of patients started medical treatment with biologicals for POR (BB 35%, EB 48%, WB 43%) (P<0.001 for all comparisons).

The cumulative surgical POR-free survival was significantly higher in both EB and WB cohorts as compared to BB cohort at 3, 5 and 10 years (BB 96%, 91%, 82%; EB 97%, 95%, 89%; WB 97%, 96%, 90%; P=<0.001).

Conclusion: A significant increase in the use of medical prevention for POR after a first intestinal resection for CD was observed in the last two decades.

Moreover, almost half of the patients started biologicals to treat POR. These changes resulted in a significant decrease in the cumulative probability of a second intestinal resection in the long-term.

THE FUNGAL COMMUNITY IN THE LOWER GASTROINTESTINAL TRACT OF MONOZYGOTIC AND DIZYGOTIC TWINS

K. Lehr¹, R. Vilchez-Vargas¹, J. Skieceviciene², N. Hipler¹, C. Thon¹, A. Gecioniene², D. Schanze³, M. Zenker³, J. Kupcinskas^{4,2}, A. Link¹

Introduction: A wide range of relationships between the microbial community and various environmental or individual factors have been proposed. Monozygotic and dizygotic twins provide a unique model for assessing host-microbial interactions. The mycobiome has been increasingly implicated in the development of several diseases, but knowledge of the dynamics of the fungal community, particularly in twins, has not been addressed.
Aims & Methods: In this work, we investigated the fungal community in a twin cohort and explored its relationship with associated genetic and environmental factors through in-depth analysis. The twin cohort consisted of 106 well-characterised and systematically studied monozygotic and dizygotic pairs (212 stool samples). DNA was extracted and PCR reactions were performed to sequence the lower gastrointestinal microbiome and the mycobiome community. The bacterial community was characterised using the V1-V2 region of the 16 rRNA gene and the fungal community was analysed using the ITS1-ITS2 region.
Results: The fungal community, represented by the sum of all fungal sequences, showed a significantly higher heterogeneity than the bacterial community. Several individual and genetic factors, such as the zygotic status of the twins (monozygotic vs. dizygotic), as well as sex, mode of birth, breast-feeding as newborns or living in the same household, were independent of the total number of fungal sequences. The bacterial community was significantly more abundant than the fungal community, the most common representatives of which were *Candida* and *Geotrichum* with sometimes very high abundances. *Saccharomyces* was also common in the cohort, but only in low abundance, other fungi with a wider distribution were *Cladosporium* or *Penicillium*. The environmental and individual factors mentioned above were also correlated with the individual fungal genera, but there were no significant correlations found here either. The next step was to correlate the bacterial and fungal communities with each other, and strong negative correlations were found with certain bacteria such as *Prevotella*.
Conclusion: Genetic factors in twins are not associated with dynamics in the faecal fungal community and were the subject of high inter-individual variability. However, there is a strong association between bacterial and mycobial interaction, which requires further in-depth understanding of microbial interactions.
Disclosure: Nothing to disclose.

SIMBA CAPSULE CAPTURES SMALL INTESTINAL LUMINAL CONTENT FOR METAGENOMICS ANALYSIS AND MAPS SPATIAL DIFFERENCES ALONG THE GI TRACT AS VALIDATED BY MATCHED SALIVA, DUODENAL ENDOSCOPY AND FECES

G. Wang¹, C. Bundalovic-Torma¹, S. Bruehlmann¹, Y. Nasser², M. Woo³, C.N. Andrews²

Contact E-Mail Address: joseph@nimblesci.com
Introduction: The small intestine (SI) microbiome plays a crucial role in nutrient absorption and emerging evidence indicates that fecal microbiome is insufficient to represent SI microbiome. Ingestible sampling capsule technologies are emerging. However, potential contamination becomes a major limitation of these devices [1].
Aims & Methods: We previously reported the Small Intestinal MicroBiome Aspiration (SIMBA) capsules as effective means for sampling, sealing and preserving SI luminal contents for 16s rRNA sequencing analysis [2,3]. A subset of the DNA samples, including SI samples collected by SIMBA capsules (CAP) and the matched saliva (SAL), fecal (FEC) and duodenal endoscopic aspirate (ASP) and brush (BRU) samples, from 16 participants recruited for an observational clinical validation study [3] were sent for shotgun metagenomic sequencing. The aims are:
1) to compare the sampling performance of the capsule (CAP) compared to endoscopic aspirates (ASP) and 850 small intestine, large intestine and fecal samples from the Clinical Microbiomics data warehouse (PR-JEB28097), and;
2) to characterize samples from the 4 different sampling sites in terms of species composition and functional potential.
Results: 4/80 samples (1/16 SAL, 2/16 ASP, 0/16 BRU, 1/16 CAP and 0/16 FEC) failed library preparation and 76 samples were shotgun sequenced (average of 38.5 M read pairs / sample). Quality assessment showed that despite the low raw DNA yield of CAP samples, they retained a minimal level of host contamination, in comparison to ASP and BRU (mean 5.27 % vs. 93.09 - 96.44% of average total reads per sample). 3/14 ASP and all BRU samples have too few reads per sample mapping to genes, failed the rarefaction procedure and were excluded from analysis.

Site	Total (read pairs)	Host %	High Quality Non-Human (HQNH, %)	HQNH	Mapped to Gene Catalog
SAL	37.59 M	70.30	26.07	9.58 M	7.22 M
BRU	34.80 M	96.44	0.13	0.04 M	0.03 M
ASP	39.81 M	93.09	5.43	1.98 M	1.48 M
CAP	36.53 M	5.27	88.01	32.06 M	24.98 M
FEC	43.74 M	2.71	85.26	37.35 M	29.54 M

CAP samples shared majority of the species with ASP samples and a big fraction of CAP species detected in the terminal ileum samples. ASP and CAP sample composition was more similar to duodenum, jejunum and saliva and very different from large intestine and stool samples. Functional genomics further revealed GI regional-specific differences: In both ASP and CAP samples we detect a number of Gut Metabolic Modules for carbohydrate digestion and short-chain fatty acids. However, probiotic species, and species and genes involved in the bile acid metabolism were mainly prevalent in CAP and FEC samples and could not be detected in ASP samples.
Conclusion: CAP and ASP microbiome are compositionally similar despite of the high level of host contamination of ASP samples. CAP appears to be of better quality to reveal GI regional-specific functional potentials

than ASP. This analysis demonstrates the great potential for the SIMBA capsule for unveiling the SI microbiome.

Introduction: Diabetic gastroenteropathy is a condition that can cause debilitation symptoms such as vomiting, intense nausea, bloating, abdominal pain, constipation, diarrhea and faecal incontinence. These symptoms not only impact the patient's morbidity but also significantly reduce their quality of life.

The condition occurs due to damage to the nerves of the sympathetic, parasympathetic and enteric nerve systems. Treating the condition can be difficult since many available therapies have limited effectiveness or pose long-term safety concerns.

Consequently, this leaves the patients with few alternatives beyond general dietary advice, broad-spectrum antibiotics, or prokinetic laxatives. Faecal microbiota transplantation (FMT) involves transferring minimally processed faeces from a healthy donor to a recipient. This leads to the establishment of a donor-like microbiota in the recipient. By restoring the intestinal microbiota, FMT holds the potential for a safe and effective means to alleviate gastrointestinal symptoms and enhance the quality of life in patients with type 1 diabetes.

Aims & Methods: We conducted a pilot trial that was randomised, double-blinded and placebo-controlled. We enrolled adults who had type 1 diabetes and moderate to severe gastrointestinal symptoms. The patients

were randomly assigned to receive either encapsulated FMT or placebo in a 1:1 ratio. After six weeks, all patients received encapsulated FMT as a second intervention. Our primary endpoint was the occurrence of adverse events of severity grade 2 or higher, assessed by the Common Terminology Criteria for Adverse Events version 5.0 (CTCAE v5) during the initial intervention.

Secondary endpoints included assessing gastrointestinal symptoms and quality of life. The trial is registered with ClinicalTrials.gov, NCT04749030.

Results: From June 2021 to May 2023, we conducted a screening of 23 patients, out of which ten were randomly selected for FMT and ten for placebo. During the first intervention, we registered 26 adverse events of severity grade 2 or above. Out of these, four patients who received FMT reported seven adverse events, while five patients who received placebo group reported 19 adverse events. None of the adverse events related to the treatment were serious. The most commonly reported adverse events were diarrhea, bloating, and abdominal pain. Patients who received FMT experienced a significant reduction in their median Gastrointestinal Symptom Rating Scale – Irritable Bowel Syndrome (GSRS-IBS) score from 58 at baseline to 35, while patients receiving placebo had only a slight increase in the median score from 64 to 56 ($p=0.01$). The Irritable Bowel Syndrome Impact Scale (IBS-IS) score also improved from 108 to 140 points in the FMT group compared with an increase from 77 to 92 points in the group of patients receiving placebo ($p=0.02$). The Patient Assessment of Gastrointestinal Symptom Severity Index (PAGI-SYM) also showed improvement with patients who received FMT reducing their median score from 42 points at baseline to 25, while the score of patients receiving placebo was reduced from 47 to 41 ($p=0.03$).

Conclusion: This study is the first randomised trial of FMT for patients with type 1 diabetes and symptoms of severe diabetic gastroenteropathy. As far as we know, this study shows the most promising clinical effect of FMT beyond *C. difficile* infection.

This study demonstrates that FMT is safe and markedly improves clinical outcomes for patients with type 1 diabetes who suffer from debilitating bowel symptoms.

Disclosure: The study was funded by a Steno Diabetes Collaborative Grant. They had no influence on the design, analysis, or reporting of the study.

Introduction: Fecal microbiota transplantation (FMT) is the most effective therapy in the treatment of recurrent *Clostridioides difficile* infection (rCDI), and can be offered in fresh, frozen or lyophilized formulation with similar efficacy. Microbial engraftment is thought to be one of the mech-

anisms mediating its efficacy. However, the importance of microbes has been questioned by two small preliminary clinical studies that showed sterile fecal filtrate could prevent *C. difficile* recurrence.

Aims & Methods: Aims: 1) determine if lyophilized sterile fecal filtrate (LSFF) is non-inferior to lyophilized FMT (LFMT) in efficacy; 2) evaluate changes in patient reported health related quality of life (HRQOL); 3) understand patient preferences for different attributes of FMT.

Methods: This double-blind, non-inferiority (margin= 10%) study in 4 academic centers in Canada randomized rCDI patients with ≥ 3 CDI episodes to either LSFF or LFMT (1:1) between 2019 and 2023. Each treatment consisted of 15 oral capsules. Primary outcome was proportion of participants without CDI recurrence at 8 week. Secondary outcomes included 1) proportion of participants without CDI recurrence at week 24 weeks, 2) serious adverse events (mortality, hospitalization and infections related to treatments), and 3) minor adverse events (nausea, vomiting, abdominal pain and fever). Exploratory outcomes included changes in HRQOL and relative importance of different attributes of FMT.

Results: 137 participants were randomized (mean [SD] age, 61.2 [18.6] years; 89 women [65.4%]; mean CDI episodes 3.8) to LFMT group (66 participants) and LSFF (71 participants) group. In per-protocol analysis, prevention of rCDI 8 weeks after assigned treatment was achieved in 63.8% of participants in LSFF group and 86.9% in LFMT group (difference, -23.1%), resulting in trial termination. Serious adverse events were infrequent: 4 hospitalizations deemed not related and 1 hospitalization possibly related, and 1 death from COVID deemed not related to assigned treatment. Minor adverse events were self-limited and infrequent: nausea (6), vomiting (2), abdominal discomfort (15) and fever (2). Following treatment, participants had significant increases in EQ-5D-5L (n=99) VAS (median change: 10; p<0.001) and index value (median change: 0.04; p<0.001), and Cdiff32 (n=94) physical domain (median change: 16.07; p<0.001), mental domain (median change: 29.46; p<0.001), and social relationships domain (median change: 7.37; p<0.001). Work impairment decreased (n=21; median change: -10%; p<0.001) and activity impairment decreased (n=101; median change: -20%; p<0.001). Participants (n=103) indicated the 3 most important attributes of FMT were: treatment effectiveness, unknown risks of treatment and known risks of treatment.

		LFMT N (%)	LSFF N (%)
Total randomized		66 (48.2%)	71 (51.8%)
Sex	Female	42 (64.6%)	47 (66.2%)
Ethnicity	Caucasian	59 (89.4%)	69 (97.2%)
	Asian	5 (7.6%)	1 (1.4%)
History of inflammatory bowel disease (IBD)	Yes	6 (9.2%)	2 (2.8%)
Chronic Proton pump inhibitor use	Yes	12 (18.5%)	11 (15.5%)
Total # of episodes of RCDI prior to enrollment	Mean (SD)	3.6 (0.8)	3.9 (1.0)
# of ED visits or hospitalization prior to enrollment	Mean (SD)	1.5 (1.5)	1.4 (1.5)
Duration of rCDI prior to enrollment (interval between first CDI directed Rx till enrollment), in months	Mean (SD)	5.0 (2.9)	6.3 (2.6)

Table 1. Participant baseline characteristics.

Conclusion: Among adults with rCDI, LSFF was inferior to LFMT by oral capsules in preventing recurrent infection over 8 weeks. The result emphasizes the importance of microbes in mediating FMT efficacy. Preserving microbial viability in future development of microbial therapeutics is paramount.

Disclosure: None.

SAFETY AND TOLERABILITY OF MH002, A LIVE BIOTHERAPEUTIC PRODUCT, IN INFLAMMATORY BOWEL DISEASE: SUMMARY OF DATA FROM TWO PHASE 2 CLINICAL TRIALS

S. Vermeire¹, S. Danese², F. Magro³, S. Possemiers⁴, S. Bolca⁴, L. Haazen⁴
¹University Hospital Leuven, Dept. of Gastroenterology, Leuven, Belgium, ²Vita-Salute San Raffaele University - IRCCS San Raffaele Scientific Institute, Gastrointestinal immunopathology, Milan, Italy, ³Faculty of Medicine of the University of Porto, Porto, Portugal, ⁴MRM Health, Ghent, Belgium

Contact E-Mail Address: severine.vermeire@uzleuven.be

Introduction: Inflammatory bowel diseases (IBD) have an ongoing, unmet medical need for new medicinal products with a different mode of action and a favourable safety profile. MH002 is a live biotherapeutic product (LBP) consisting of 6 commensal bacteria and is entering phase 3 clinical development as a therapeutic treatment developed to restore dysbiosis and depletion of butyric acid producing-bacteria that are associated with IBD. The non-pathogenic nature of the MH002 strains and absence of systemic bioavailability are expected to result in a particularly favourable safety profile.

Aims & Methods: To assess the safety of MH002 in ulcerative colitis (UC) and pouchitis (PC).

Safety data from 45 UC patients randomized (2:1) to double-blind treatment with 400mg MH002 or placebo daily for up to 16 weeks (MH002-UC-201), and from 14 PC patients treated open label with 400mg MH002 daily for 8 weeks (MH002-PC-201) were collected prospectively, the primary endpoint being occurrence of treatment emergent adverse events (AEs). UC patients were on stable 5-ASA treatment with or without low-dose corticosteroid throughout the study. Concomitant and recent antibiotic use was prohibited in all, as was treatment with advanced therapies. Placebo-treated UC patients who did not have a clinical response after 8 weeks were switched to MH002 treatment for 8 weeks.

Results: A total of 52 patients were exposed to MH002 with a total of about 136 patient-months of exposure. At baseline, the mean (range) modified Mayo score in UC patients was 5.76 (4.0-8.0) and the modified mean (range) Pouchitis Disease Activity Index score in PC patients was 6.91 (5.3-9.3). In UC patients, 20% were on stable, low dose corticosteroid, none was in the PC study. In both studies, no deaths, no severe AEs, no related serious AEs were reported in MH002-treated subjects, and no discontinuation occurred for an AE in MH002-treated participants. In particular, no bacteremia or sepsis was reported. Most AEs were mild and unrelated. Numerically less patients experienced an AE with MH002 than with placebo in UC.

	MH002-UC-201		MH002-PC-201	Total
Nr (%) of subjects	MH002 (n=31)	Placebo (n=14)	MH002 (n=14)	MH002 (n=45)
with a severe Adverse Event (AE)	0	0	0	0
discontinuing for an AE	0	1 (7%)	0	0
with at least 1 AE	11 (35%)	8 (57%)	11 (79%)	22 (49%)
with a Serious AE (not related)	1 (3%)	1 (7%)	1 (7%)	2 (4%)
with a possibly related AE	1 (3%)	1 (7%)	3 (21%)	4 (9%)
with an AE of gastro-intestinal disorders	2 (6%)	4 (29%)	4 (29%)	6 (13%)

Possibly related AEs reported with MH002 included rash (UC) and abdominal pain, diarrhoea, flatulence and nausea (PC), while abdominal distension was reported with placebo (UC). Type 2 diabetes, arterial hypertension (MH002) and Clostridioides difficile infection (placebo) were the unrelated serious AEs that were reported. No clinically significant changes

were observed during physical examination, vital signs assessment and in routine laboratory safety analyses (biochemistry, hematology and urinalysis) with MH002 or placebo. Efficacy data showed positive trends for clinical and endoscopic improvement and have been reported previously.

Conclusion: MH002 was well tolerated and safe in the first-in-disease phase 2 clinical trials conducted in UC and PC. MH002 may exhibit a particularly favourable safety profile if these results are confirmed in larger, late-stage clinical studies.

INTESTINAL ADAPTATION IMPROVES SARCOPENIA IN SHORT BOWEL SYNDROME: RESULTS FROM A PROSPECTIVE STUDY (SARCO-SBS)

Introduction: Sarcopenia is highly prevalent in chronic gastrointestinal diseases, including short bowel syndrome (SBS, <2m of small bowel). While restoration of colonic continuity (RC) improves intestinal adaptation, the link with sarcopenia and underlying mechanisms are unknown.

Aims & Methods: We prospectively studied the presence of sarcopenia and the link with intestinal adaptation in SBS (1). Patients were prospectively included at 2 tertiary care centers (Belgium and France) from 2022 onwards. Sarcopenia and malnutrition were assessed before and 1 year after RC, using age- and gender-specific cut-offs (2,3). The primary outcome was the evolution of sarcopenia, defined as a reduced handgrip strength (HGS) and fat free mass index (FFMI, using bioimpedance analysis). Secondary outcomes were changes in body weight (BW) or composition, serum albumin levels and urinary metabolites. Subgroup analyses were performed based on gender, weaning off home-parenteral nutrition (HPN) and anatomy, i.e. presence of a jejuno-colonic (JC) or jejuno-ileocolonic (JIC) anastomosis. Untargeted urinary metabolomics was performed using liquid chromatography coupled with high-resolution mass spectrometry with metabolite identification as previously described (4). Comparisons were done using Wilcoxon tests with Benjamini-Hochberg (BH) correction for multiple testing and multivariate linear regression using Partial Least Squares-Discriminant Analysis (PLS-DA).

Results: In total, 112 patients (68 female, mean age 57 ±15.5 years, 74 SBS-JC and 38 SBS-JIC) were included. Proportions of sarcopenia were lower 1 year after RC (5% vs. 16%, p<0.05), with a significant increase in HGS (δ = 4.7kg, p=0.001) and albumin (δ = 5.6g/L, p<0.0001) in all patients. In contrast, proportions of malnutrition were similar 1 year after RC, with no significant change in BW, BMI or FFMI in all patients. Sarcopenia was more common in females vs. males at baseline (46% vs. 21%, p<0.01) but not at 1 year. Complete weaning off HPN was seen in 57 (51%) patients after 1 year and similar according to gender, but less frequent in SBS-JC vs. SBS-JIC patients (36% vs. 79%, p<0.0001). Despite these (baseline) differences, the decrease in sarcopenia after RC was significant in females (9% vs. 29%, p<0.05), in those without weaning (3% vs. 28%) and in SBS-JC patients (5% vs. 21%, both p=0.04). Urinary metabolites significantly associated with weaning off HPN (n= 31) and SBS-anatomy (n= 22) were mainly related to amino acid metabolism (top metabolites with adj. p-value <0.001 in the table).

Subgroup	Pathway	Metabolite	Fold change	Adj. p-value (BH)
Weaning vs. no-weaning	Proline	L-proline	3.55	0.0002
	Other	α -Hydroxyhippuric acid	8.06	0.0006
	Arginine	Methylhydantoin	2.67	0.0007
		Guanidineacetic acid	2.19	0.0008
	Alanine	N-Acetyl-alanine	1.94	0.0009
SBS-JIC vs. SBS-JC	Other	α -Hydroxyhippuric acid	8.13	0.0001
	Glycine	N,N-Dimethylglycine	2.2	0.0003

PLS models were built with significant separation based on weaning off HPN (Q2cum= 0.6, pQ2= 0.005) and SBS-anatomy (Q2cum= 0.5, pQ2= 0.005).

Conclusion: Intestinal adaptation after restoration of colonic continuity improves sarcopenia in SBS patients, even in those without weaning off HPN or unfavorable anatomy (no ileum). Differences in amino acid metabolism were found based on weaning or SBS-anatomy. The potential benefits of additional nutritional and/or physical interventions need to be studied as malnutrition was not yet reversed.

Introduction: SBS-IF is a severe organ failure with long-term parenteral support (PS) dependence. In the first years after extensive surgery, spontaneous structural (elongation of intestinal villi and crypts) and functional (incl. motility) intestinal changes occur, stimulating a more efficient nutrient and fluid absorption in the remnant bowel. GLP-2 analogs are hypothesized to boost intestinal adaptation resulting in increased intestinal absorption and reduced PS needs. Apraglutide (APRA) is a long-acting GLP-2 analog in development for SBS-IF. We investigated the effect of APRA at 52 weeks (W) on bowel morphology and motility based on magnetic resonance imaging (MRI).

Aims & Methods: STARS Nutrition is a 52-W multicenter, open-label, phase 2 study in adult SBS-IF-CiC pts receiving weekly subcutaneous APRA injections (5mg). We hypothesized that APRA treatment would lead to thickening of the intestinal mucosa, intestinal lengthening, reduced bowel dilatation and reduced intestinal motility. Therefore, MRI scans of the abdomen, incl. cine sequences, after oral intake of a manitol solution (600mL) were performed at baseline and at 4W, 24W and 48W of treatment. Morphology parameters were measured on static MRI

sequences; GI Quant software was used to quantify motility on cine MRI sequences. Data are presented as median (IQR). Nominal p-values are calculated using Wilcoxon matched-pairs signed rank tests with significance set at 0.05.

Results: Nine pts were included and comprise the full study population. While the numerically increased colon length failed to reach significance, small bowel length increased significantly from 29.7 to 40.7 cm (p=0.012) at 48W. Duodenal wall thickness increased by 0.8 (0.2;1.2) mm (p=0.020). There were no diameter changes in the small bowel nor colon. Changes in motility were evaluated using data from 7 pts, due to missing data. Over time, small bowel motility gradually reduced, albeit not significant. Motility in the proximal colon was significantly reduced at 48W. In the distal colon, decreased motility was observed at 4W and 24W, but returned to baseline level at 48W.

Conclusion: Using static and cine MRI sequences in pts with SBS-IF-CIC, STARS Nutrition shows that APRA treatment was associated with small bowel lengthening and increased duodenal wall thickness suggesting an intestinotrophic effect. Both effects may contribute to an increased surface area for absorption. The reduced motility, especially in the proximal colon may reduce transit time, allowing more time for absorption of nutrients, fluids and electrolytes; and reduced fecal output. Whether bowel lengthening results from a direct effect of APRA vs. changes in motility with passive elongation is subject of further investigation.

Introduction: In SBS-IF, patients (pts) depend on parenteral support (PS) to meet nutritional and/or fluid requirements. Apraglutide (APRA) is a long-acting novel GLP-2 analogue dosed once-weekly that stimulates intestinal adaptation, with the potential to reduce PS requirements. This phase 3 trial assessed the efficacy and safety of APRA vs placebo (PBO) in adult pts with SBS-IF.

Aims & Methods: In this phase 3 double-blind, PBO-controlled trial (NCT04627025) conducted in 73 centres and 18 countries, 164 pts were randomized 2:1 to once-weekly subcutaneous APRA (5 mg if pt ≥ 50 kg, 2.5 mg if pt < 50 kg) or PBO, stratified by intestinal anatomy (stoma or colon-in-continuity [CIC]).

The primary endpoint was relative change from baseline (BL) in weekly PS volume at Week (Wk) 24.

Key secondary endpoints at Wk 24 were reduction of additional ≥ 1 day/Wk off PS from BL, and in the stoma subgroup, relative change from BL in weekly PS volume.

Two other key secondary endpoints at Wk 48 in the CIC subgroup were reduction of ≥ 1 day/Wk off PS, and percentage of pts reaching total enteral autonomy. Wk 24 clinical responders were defined as proportion of pts with $\geq 20\%$ PS reduction at Wks 20 and 24. Adverse events (AEs) were collected.

Results: A total of 163 dosed pts (80 stoma; 83 CIC), 155 (95%) completed the study. BL demographics and mean BL weekly PS volume (APRA 13.1 L; PBO 12.9 L) were similar in both arms. At Wk 24, APRA-treated pts had a significantly larger reduction from BL in weekly PS volume vs PBO (APRA -25.5%; PBO -12.5%; $p=0.001$); both stoma and CIC subgroups demonstrated comparable treatment effects. In pts with stoma, the relative reduction from BL to Wk 24 in weekly PS volume in APRA pts vs PBO was statistically significant (-25.6% vs -7.8%; $p<0.001$) (Table 1). In pts with CIC, there was a numerical benefit in APRA that did not reach statistical significance (APRA -25.2%; PBO -17.6%; nominal $p=0.179$).

In the overall population, statistically significant PS reductions from BL were seen from Wk 8 onward. A significantly higher proportion of APRA pts achieved a reduction of ≥ 1 day/Wk off PS at Wk 24 (APRA 43.0%; PBO 27.5%; $p=0.040$). At Wk 48 in the CIC subgroup, 51.8% of APRA vs 44.4% of PBO-treated pts achieved ≥ 1 day/wk off PS ($p=0.348$), and enteral autonomy was reached in 7 of 56 (12.5%) APRA vs 2 of 27 (7.4%). APRA was well tolerated. Of 110 APRA-treated pts, only 4 (3.6%) discontinued APRA due to an AE, vs 1 of 53 (1.9%) PBO-treated pts.

Conclusion: APRA is the first once-weekly GLP-2 analogue to demonstrate efficacy in a phase 3 trial in SBS-IF. At Wk 24, APRA demonstrated significantly greater relative reductions in weekly PS volume from BL and a higher proportion of pts achieved an additional ≥ 1 day off PS, with comparable treatment effects in pts with stoma or CIC. APRA showed a favourable safety profile consistent with prior APRA studies in SBS-IF.

Endpoint	Population	Apraglutide (n=110)	Placebo (n=53)	APRA vs PBO Difference [LSM or % (95% CI)]	p-value
Primary Endpoint					
LSM or n (%)					
Relative % change from BL in actual PS weekly volume at Wk 24, Least Square Mean (LSM)	Overall	-25.5	-12.5	-13.0 (-20.9, -5.0)	0.001
Key Secondary Endpoints					
Percentage of subjects achieving a reduction of ≥ 1 day/wk off PS from BL at Wk 24, n (%) *	Overall	46 (43.0)	14 (27.5)	15.6 (0.7, 30.5)	0.040
Relative % change from BL in actual PS weekly volume at Wk 24, mean	Stoma (n=80)	-25.6	-7.8	-17.8 (-28.4, -7.3)	<0.001
Percentage of subjects achieving a reduction of ≥ 1 day/wk off PS from BL at Wk 48, n (%)	CIC (n=83)	29/56 (51.8)	12/27 (44.4)	7.3 (-16.4, 29.8)	0.348
Subjects reaching enteral autonomy at Wk 48, n (%)	CIC (n=83)	7/56 (12.5)	2/27 (7.4)	5.1 (-12.9, 18.5)	0.387
Other Secondary Endpoint					
Clinical responders at Week 24 ($\geq 20\%$ PS reduction at both Wks 20 and 24), n (%)	Overall	47 (42.7)	11 (20.8)	22.0 (7.7, 36.2)	0.003**

*n for the first key secondary is observed value and the percentage, difference in percentages and its p-value is based on results of multiple imputations. **nominal p-value.

APRA, apraglutide; BL, baseline; CI, confidence interval; LSM, least square mean; PBO, placebo; PS, parenteral support; SBS-IF, short bowel syndrome and intestinal failure.

DISCOVERY OF AN ORAL, LONG-ACTING GLUCAGON-LIKE PEPTIDE 2 AS BEST-IN-CLASS TREATMENT FOR SHORT BOWEL SYNDROME

H. Zou¹, X. Wu¹, R. Zhu¹, R. Wang¹, Y. Wang¹, J. Zhao¹, S. Jiang¹
¹Hangzhou Sciwind Biosciences, Beijing, China

Contact E-Mail Address: haixia.zou@sciwindbio.com

Introduction: Glucagon-like peptide 2 (GLP-2) is a gut secreted hormone in response to dietary nutrients. GLP-2 derivatives demonstrated therapeutic efficacy for Short Bowel Syndrome (SBS), a malabsorptive disease due to physical or functional loss of parts of the small intestine. However, injection administration may decrease patient compliance. The objective of this study is to discover an oral, long-acting and best-in-class GLP-2.

Aims & Methods: The objective of this study is to discover an oral, long-acting and best-in-class GLP-2. Following methods were applied in the discovery. Fatty acid conjugated peptides were designed and tested in CHO-K1 CRE reporter cells overexpressing human or rat GLP-2 receptor. 1037331 was selected, evaluated for small intestine growth (intestine weight and thickness coefficient as readout) by once daily injection for 5 days in SD rats, and tested in pharmacokinetic (PK) study in SD rats, minipigs and beagle dogs by subcutaneous injection. Finally 1037331 was formulated into pills (7 mg 1037331/pill) and assessed for oral absorption in beagle dogs by once daily dosage for 5 days. Apraglutide (VectiveBio), a GLP-2 analog in Phase 3 studies, was used as a comparator.

Results: Among the peptide tested, 1037331 activated both human and rat GLP-2 receptor more potently than apraglutide (EC₅₀ for 1037331 and apraglutide, respectively, human receptor: 0.68 nM vs 2.11 nM; rat receptor: 0.17 nM vs 1.07 nM). In SD rats, 10 nmol/kg 1037331 increased small intestine weight and thickness comparable to 250 nmol/kg apraglutide. In PK study, 1037331 showed longer half-lives resulting higher exposure by injection in all animal models (T_{1/2} for 1037331 and apraglutide, respectively, SD rat: 10.3 h vs 7.3 h; minipig: 22.4 vs 16.6 h; beagle dog: 54.8 h vs 17.7 h). In oral PK study, daily dosing leads to accumulation of 1037331 in circulation and C_{max} at 62.4 nM was achieved.

Conclusion: Overall, 1037331 demonstrated better in vitro and in vivo potencies, and better PK profiles than apraglutide. Most importantly, 1037331 with fatty acid conjugation showed oral bioavailability, which may improve patient compliance and convenience.

Disclosure: Nothing to disclose.

GLEPAGLUTIDE REDUCES NEED OF PARENTERAL SUPPORT OF FLUIDS, ELECTROLYTES, ENERGY AND MACRONUTRIENTS IN SHORT BOWEL SYNDROME PATIENTS: RESULTS FROM THE 52-WEEK OPEN-LABEL EASE SBS-4 STUDY

L. Pinar¹, T.SS Nielsen², L. Soldbro², M. Berner-Hansen^{2,3}, P.B. Jeppesen¹
¹Rigshospitalet, Department of Intestinal Failure and Liver Diseases, Copenhagen Ø, Denmark, ²Zealand Pharma, Copenhagen, Denmark, ³Bispebjerg Hospital, Digestive Disease Center, Copenhagen, Denmark

Contact E-Mail Address: ismail.pinar.01@regionh.dk

Introduction: Glepaglutide, a novel long-acting glucagon-like peptide-2 (GLP-2) analog, is currently in development for treatment of patients with short bowel syndrome (SBS) with intestinal failure (SBS-IF). GLP-2 facilitates intestinal adaptation, thereby enhancing intestinal absorptive

capacity in SBS patients. Employing metabolic balance studies including patients with SBS-IF and intestinal insufficiency, 24 weeks of treatment with glepaglutide has recently been reported to numerically increase wet weight absorption by 398 g/day and energy absorption by 1038 kJ/day, as measured by bomb calorimetry¹.

Here, the corresponding sustained effects of glepaglutide on the need for parenteral support (PS) in SBS-IF patients over 52-week treatment period are presented.

Aims & Methods: Patients received a once-weekly 10 mg subcutaneous injection of glepaglutide via a ready-to-use autoinjector. Prior to study visits, a 48-hour collection period at home was completed: Urine volumes were measured while adhering to a fixed drinking menu (individually determined before the first study visit).

Adjustments to PS volume were guided by a prespecified algorithm: PS volume reduction equaled seven times the difference between observed and baseline urine volumes, when observed urine volumes were ≥10% higher than baseline.

For the first 24 weeks, patients adhered to the fixed drinking menu; thereafter, beverage consumption was unrestricted intending to simulate usual living conditions. Changes from baseline to weeks 24 and 52 in PS volume and its content of electrolytes, energy and macronutrients were evaluated by post-hoc one-sample t-tests.

Results: 10 patients were included: mean age 55 years, 5 females, 8 with SBS-IF, 8 without colon-in-continuity (CIC). Mean baseline PS volume was 2.55 L/day (SD=1.72). Mean PS volume was decreased by -0.76 L/day at week 24 (p=0.0285), corresponding to a -25% reduction from baseline (see table). By week 52, mean PS volume reduction amounted to -0.80 L/day, a -30% reduction from baseline (p=0.0106).

PS sodium and potassium decreased at weeks 24 and 52. PS calcium and magnesium showed numerical reductions.

PS energy content decreased by -859 kJ/day (-37% reduction) at week 24 (p=0.0038) and remained stable and low until week 52.

PS carbohydrate content was reduced by -702 kJ/day at week 24 (-42% reduction) and remained consistently low until week 52. Protein content decreased by -151 kJ/day (-36%) at week 24. PS lipid content showed a numerical reduction at weeks 24 and 52. Body weight and urine volume remained constant throughout the study.

		Week 24	95% CI and p-value	Week 52	95% CI and p-value
Volume (L/day)		-0.76	[-1.41 ; -0.11], p=0.0285	-0.80	[-1.33 ; -0.26], p=0.0106
Electrolytes (mmol/day)	Sodium	-68.0	[-128.4 ; -7.5], p=0.0326	-57.2	[-112.2 ; -2.3], p=0.0436
	Potassium	-8.4	[-14.6 ; -2.3], p=0.0145	-8.8	[-17.3 ; -0.3], p=0.0437
	Magnesium	-0.8	[-2.6 ; 0.9], p=0.3084	-1.4	[-2.9 ; 0.1], p=0.0594
	Calcium	-1.0	[-2.1 ; 0.1], p=0.0727	-1.2	[-2.5 ; 0.2], p=0.0800
Energy (kJ/day)		-859	[-1337 ; -382], p=0.0038	-866	[-1441 ; -291], p=0.0103
Macronutrients (kJ/day)	Carbohydrate	-702	[-995 ; -409], p=0.0008	-645	[-1089 ; -201], p=0.0120
	Lipid	-6	[-229 ; 217], p=0.9508	-81	[-264 ; 103], p=0.3244
	Protein	-151	[-269 ; -34], p=0.0188	-140	[-302 ; 22], p=0.0795

Table: Mean changes from baseline in PS volume and its content of electrolytes, energy and macronutrients, with 95 % confidence intervals and p-values.

Conclusion: Glepaglutide induced clinically meaningful, sustained reduction in the PS need, including fluids, electrolytes, energy and macronutrients at 52 weeks in SBS patients with and without CIC.

These data are in alignment with glepaglutide-induced increases in intestinal absorptive capacity as demonstrated in state-of-art metabolic balance studies.

IMPACT OF USING THE ESGE GUIDELINE RISK-PROFILES FOR SURVEILLANCE AS OUTCOME PARAMETER IN A FIT-BASED COLORECTAL CANCER SCREENING PROGRAM

E. Rijnders¹, E. Toes-Zoutendijk², S. de Boer³, R. Schauwen⁴, M. Oudkerk Pool⁵, C. Verveer⁶, E. Dekker⁷, M. van Leerdam⁸, I. Nagtegaal⁹, M.C. Spaander¹⁰

Introduction: Recent guideline from the European Society of Gastrointestinal Endoscopy (ESGE) recommends the use of risk-profiles to determine surveillance colonoscopy after polypectomy.¹

These risk-profiles are potentially a better predictor for the development of colorectal cancer (CRC) incidence after polypectomy. CRC screening programs use advanced neoplasia as primary outcome parameter.² It might be more recognizable for doctors and policy makers to use the same outcome parameter.

However, by changing the outcome parameter from advanced neoplasia to high-/low-risk profiles in a FIT-based CRC screening program, the definition of what is considered a relevant lesions will change. Using risk-profiles as outcome parameter may impact both colonoscopy surveillance capacity and the positive predictive value (PPV) of finding a relevant lesions after a positive FIT.

Aims & Methods: Study aim: assessing the impact of applying the ESGE risk-profiles as outcome parameter of a FIT based CRC screening program on colonoscopy surveillance and PPV after a positive FIT.

Methods: We retrospectively analyzed all persons who had a positive FIT ($\geq 47\mu\text{g Hb/g feces}$) followed by a colonoscopy in the Dutch CRC screening program from 2019-2022. Colonoscopy and pathology reports were used to define the surveillance interval based on the old and new guideline.

The old guideline used a scoring table in which, adenoma count, location, villous type ($\geq 75\%$) or the presence of an adenoma or serrated polyp $\geq 10\text{mm}$ were used to determine a 3 or 5 year surveillance interval.² The new guideline defined a high-risk profile as either a high-risk adenoma or high-risk serrated polyp or ≥ 5 adenomas. A high-risk adenoma is an adenoma $\geq 10\text{mm}$ or with high-grade dysplasia. A high-risk serrated polyp is a serrated polyp $\geq 10\text{mm}$ or with any dysplasia.³ All persons with a high-risk profile receive surveillance in 3 years.

The old definition of the PPV was advanced neoplasia. Advanced neoplasia is defined as CRC or advanced adenoma (adenoma $\geq 10\text{mm}$ or high-grade dysplasia or $\geq 25\%$ villous type).³ The new definition of the PPV was CRC, high-risk adenoma or high-risk serrated polyps. A chi-squared test was used to determine significant differences between the old and new definition.

Results: 218,109 persons with a positive FIT underwent a colonoscopy between 2019-2022. Based on the old surveillance guideline, 51.2% of the persons would require colonoscopy surveillance. When applying high-risk profiles only 32.3% persons required surveillance. However, the number of persons referred for a 3-year surveillance interval was now doubled (Table 1). This is a result of 723 persons who first qualified for 10-year return to screening, and 34,451 persons who previously had a 5-year interval. In contrast, only 32 persons who initially had a 3-year interval will be advised to return to screening in 10 years, when risk-profiles are applied. The corresponding PPV for CRC, high-risk adenoma or high-risk serrated polyps was 34.4%, showing an increase of 1.7% ($p < 0.05$) compared to PPV based on advanced neoplasia.

	Treatment CRC		Surveillance 3- years		Surveillance 5-years		Return to screening in 10 years	
Old surveillance guideline	10,163	(4.7%)	35,004	(16.0%)	76,856	(35.2%)	96,086	(44.1%)
New surveillance guideline	10,163	(4.7%)	70,146	(32.3%)	x	x	137,800	(63.2%)

Table 1: surveillance count based on the old surveillance guideline and the new surveillance guideline.

Conclusion: This study shows that when the new ESGE surveillance guideline risk-profiles are applied as outcome parameter in FIT CRC screening, a total reduction of 18.9% of surveillance colonoscopies can be achieved although the number of persons in the 3-year surveillance interval will be doubled. A minor change in PPV can be expected.

Contact E-Mail Address: mogaraa2008@126.com

Introduction: The current screening and diagnostic methods for colorectal cancer (CRC) primarily involve tumor markers, imaging examinations, and endoscopic evaluations, which have inherent limitations. Therefore, it is imperative to explore novel diagnostic techniques for early-stage CRC to improve patient prognosis and survival rates. Recent studies have demonstrated the significant potential of circulating exosome-associated microRNAs (miRNAs) as biomarkers in CRC; however, these investigations are limited and predominantly focused on advanced tumors. Consequently, the differences in circulating exosomal miRNAs, among different stages of CRC within the classic developmental model of ‘normal mucosa, adenoma, early adenocarcinoma, advanced adenocarcinoma’, remain unknown.

Aims & Methods: Plasma exosomes were isolated from colorectal adenoma (CRA), early CRC (Tis-T1), advanced CRC (T2-T4), and healthy control (NC) groups (n=5 for each group) using ultracentrifugation. The miRNA expression profiles of plasma exosomes in the four groups were compared using miRNA microarray analysis to identify differentially expressed miRNAs in the three colorectal disease groups compared to the NC group. The results of miRNA microarray detection were validated by qRT-PCR to increase the sample size (n=30 for each group) and confirm the expression of characteristic miRNAs identified. Receiver operating characteristic curves were utilized to assess the diagnostic efficacy through area under curve (AUC).

Results: The extracted exosomes exhibited consistent morphology, size, and expression of protein markers that align with the fundamental characteristics of exosomes. Microarray analysis results revealed that both early and advanced CRC groups shared 31 up-regulated miRNAs and 34 down-regulated miRNAs compared to the CRA and NC groups. By intersecting with the GSE40247 dataset (CRC cell secreted exosome-derived microarray results), we identified five up-regulated miRNAs (miR-150-3p, miR-1224-5p, miR-1246, miR-1268a, and miR-1290). The expression levels of all five miRNAs showed a progressive increase with CRC advancement at different developmental stages. Notably, significant diagnostic potential was observed for miR-1224-5p, miR-1246, and miR 1290 in distinguishing patients with early CRC from NC (AUC 0.638 to 0.719).

All five identified miRNAs demonstrated relatively good diagnostic performance in discriminating patients with advanced CRC from NC (AUC 0.745 to 0.838), while none of them had clear diagnostic value in distinguishing early CRC patients from individuals with CRA (AUC 0.548 to 0.654). Logistic regression analysis was employed to construct a multi-panel diagnosis model based on three specific miRNAs: miR-1224 -5p, miR-1246, and miR-1290. The combined AUCs were found to be as follows: for discrimination between early CRC and NC groups, AUC=0.817 (P=0.0008); for discrimination between advanced CRC and NC groups, AUC=0.907 (P<0.0001); for discrimination between early CRC and CRA groups, AUC=0.754 (P=0.0035).

Conclusion: The miRNA expression profiles of plasma exosomes in early CRC patients exhibit similarities to those observed in advanced CRC patients. Specifically, the presence of miR-150-3p, miR-1224-5p, miR-1246, miR-1268a, and miR-1290 within plasma exosomes can serve as reliable indicators for the diagnosis of CRC. Importantly, a combination of miR-1224-5p, miR-1246, and miR-1290 shows promise for the early detection of CRC.

Contact E-Mail Address: anna.forsberg@ki.se

Introduction: We determined the impact of an increased two-stool FIT cutoff on colonoscopy positivity and relative sensitivity and specificity in the randomised controlled screening trial SCREESCO conducted in Sweden.

Aims & Methods: We performed a cross-sectional analysis of participants in the FIT arm that performed FIT between March 2014 and March 2020 within the study registered with ClinicalTrials.gov, NCT02078804, who had a fecal hemoglobin concentration of at least 10 µg/g in at least one of two stool samples and who underwent a colonoscopy (n=3841). For each increase in cutoff, we computed the positive predictive value (PPV), numbers needed to scope (NNS), sensitivity and specificity for finding colorectal cancer (CRC) and advanced neoplasia (AN; advanced adenoma or CRC) relative to cutoff 10 µg/g.

Results: The PPV for advanced neoplasia (colorectal cancer, or adenoma with high grade dysplasia or size >10mm or villous component) increased from 23.0% (95% CI: 22.3-23.6%) at cutoff 10 µg/g to 28.8% (95% CI: 27.8-29.7%) and 33.1% (95% CI: 31.9-34.4%) at cutoffs 20 and 40 µg/g respectively while the NNS to find a CRC (not shown in the table) correspondingly decreased from 41 to 27 and 19. The PPV for advanced neoplasia was higher in men than women at each cutoff, e.g. 31.5% (95% CI: 30.1-32.8%) in men and 25.6% (95% CI: 24.3-27.0%) in women at 20 µg/g. The relative sensitivity and relative specificity were similar in men and women at each cutoff.

Cutoff (µg/g)	N colonoscopies (%)	N with advanced neoplasia	PPV	NNS	relative sensitivity	95% CI	relative specificity	95% CI
10	3841 (100)	882	23	4.4	100		0	
20	2319 (60)	667	29	3.5	76	74-77	44	44-46
40	1428 (37)	473	33	3.0	54	52-55	68	67-69
60	1059 (28)	384	36	2.8	44	42-45	77	76-78
80	861 (22)	331	38	2.6	38	36-39	82	81-83
120	653 (17)	272	42	2.4	31	29-32	87	87-88
160	541 (14)	240	44	2.3	27	26-29	90	89-90

Number of colonoscopies, number with finding of advanced neoplasia (AN), positive predictive value (PPV), numbers needed to scope (NNS), relative sensitivity and relative specificity by FIT-cutoff (maximum of two stool samples).

The table shows the results for for advanced neoplasia with the number of colonoscopies and number of findings with AN for each cutoff. Furthermore for each cutoff the positive predictive value (PPV) and numbers needed to scope to find one AN is given. The relative sensitivity and specificity (each with 95% CI given) are calculated relative to the cutoff 10 µg/g.
Conclusion: The risk of advanced adenoma and colorectal cancer increased with increasing fecal hemoglobin concentration in both men and women, and a low cutoff around 20 to 40 µg/g for two-stool FIT allows detection and removal of many advanced adenomas and colorectal cancers. The findings suggest that a higher cutoff in women than in men could lead to comparable colonoscopy positivity for advanced adenomas and cancer.

Introduction: Tumor cells are known to express a unique isoform of the glycolytic enzyme pyruvate kinase, called pyruvate kinase isoenzyme type M2 (M2-PK). This study aims to evaluate the effectiveness of the M2-PK antigen rapid test, compared to the conventional fecal occult blood test (FOBT), for diagnosing colorectal neoplasms, including colorectal cancer (CRC) and advanced adenoma.

Aims & Methods: Participants screened by endoscopy in three South Korean referral hospitals (December 2020 - June 2023) were classified into three groups: CRC, advanced adenoma, and normal control. This study is parallel-design, [CYY1] comparing the fecal M2-PK antigen test (Sche-

bo® M2-PK Quick™ test, Biotech AG) to the FOBT for detecting CRC and advanced adenoma, using the normal control group as a reference. The study aimed to demonstrate the non-inferiority of the M2-PK antigen test for detecting CRC (non-inferiority margin: -15%) and its superiority in advanced adenoma group compared to FOBT.

Results: A total of 270 patients [CYY1] were analyzed. The sensitivity of CRC by M2-PK test was 0.88 and 0.75 in FOBT with margin difference of 0.13 [95% CI (0.02, 0.25), $p=0.01$]. In advanced adenoma group, sensitivity was 0.43 and 0.17, respectively. The M2-PK test showed a PPV of 0.73 (vs. 0.96 for FOBT) and an NPV of 0.82 (vs. 0.76 for FOBT) in the CRC group. For advanced adenoma, PPV and NPV were 0.51 (vs. 0.82 for FOBT) and 0.53 (vs. 0.55 for FOBT), respectively. The clinical specificity for colorectal neoplasms was 0.62 for the M2-PK test and 0.97 for FOBT.

Conclusion: The M2-PK antigen rapid test is non-inferior to FOBT for detecting CRC. While its sensitivity for advanced adenoma detection is higher than FOBT, further studies are needed to fully evaluate its role.

Disclosure: Nothing to disclose.

OP166

EFFECTIVENESS OF COLONOSCOPY ON EARLY ONSET COLORECTAL CANCER INCIDENCE AMONG PERSONS 40-49 YEARS

H.-S. Kim¹, S.-Y. Kim¹, H. Kim¹

¹Wonju Severance Christian Hospital, Internal Medicine, Wonju, South Korea

Contact E-Mail Address: hyskim@yonsei.ac.kr

Introduction: Recently, some guidelines recommend conducting colorectal cancer (CRC) screening at ages younger than 50 years. However, there are few data on the preventive effect of colonoscopy at ages 40-49 years at the population level.

Aims & Methods: In this study, the risk of CRC according to the presence or absence of CSP in their 40s was evaluated in a retrospective cohort design using a nationwide database. Using the Korean National Health Insurance System data between 2004 and 2006, we constructed 1:5 colonoscopy cohort (CsC) and non-colonoscopy cohort (NCsC) at ages 40-49 years and followed through 2014. A total of 2,940,792 subjects were enrolled and CRC risk was evaluated after propensity score matching between CsC and NCsC based on age, sex, smoking, metabolic syndrome (MetS) and potentially relevant variables related CRC risk.

Results: Among 490,132 CsC subjects and 2,450,660 NCsC subjects at baseline periods in 40-49 ages, 689 (0.14%) and 9,440 (0.39%) cases of CRC were found during 10 years follow up period, respectively. According to age group, cumulative CRC incidences in early 40's (40-44) were 0.10% in CsC and 0.25% in NCsC respectively. For late 40's (45-49), those were 0.17% in CsC group and 0.49% in NCsC group, respectively. Compared with NCsC, the adjusted hazard ratios (aHRs) for CRC development in CsC group were 0.42 (men, 95% CI: 0.35-0.50) and 0.37 (women, 95% CI: 0.30-0.47) in early 40's and 0.33 (men, 95% CI: 0.29-0.37) and 0.39 (women, 95% CI: 0.33-0.45) in late 40's.

Conclusion: Overall, colonoscopy in their 40s significantly lowered the risk of colorectal cancer development by 58-67%. This cancer prevention effect of colonoscopy was different according to age and gender, and it was most effective in men in their late 40s, suggesting the rationales for optimization of age and gender to start colonoscopy.

Introduction: Previous studies have demonstrated that infected pancreatic fluid collections are associated with worse clinical outcomes¹.

Aims & Methods: In light of the global rise in antibiotic resistance, this study investigates the impact of the spectrum of infecting microorganisms on the effectiveness of endosonography (EUS)-guided drainage for these conditions. Data on EUS-guided drainage of pancreatic fluid collections performed between 2018 and 2022 at three endoscopy units of Charité Berlin, regardless of the etiology, were reviewed and analyzed. The primary- endpoints were the duration of hospital stay and clinical success of the therapeutic EUS, defined as (1) the resolution of the collection to <50% within 1-3 months as observed in follow-up imaging and (2) clinical improvement. The secondary endpoints were the duration of ICU stay, mortality, and the total number of required interventions to achieve treatment success, including the initial intervention, removal and replacement of stents, and additional procedures, e.g., necrosectomy or therapy of complications during 12 months follow-up. The infection of the fluid collection was diagnosed based on microbiological evidence obtained from EUS-guided fine needle aspiration or positive blood culture, after excluding other sources of infection, along with clinical presentation and elevated inflammatory markers. The microorganisms were categorized based on microscopic appearance, Gram staining, and the number of germs in a collection. Patients with sterile necrotic collections undergoing the same therapeutic modality were used as a control group to compare the outcomes.

Results: A total of 102 patients (71.6% male, mean age 55.9±13.9 years) were included in the final analysis. In 91 of the 102 cases (89.2%), double pigtail plastic stents were utilized (46.1% were multiple), and in 38 (37.3%) patients, a transmural endoscopic necrosectomy was performed. In 29.5% of cases, penicillin; 18.2%, carbapenems; 13.6%, cephalosporins; 6.8%, metronidazole; 6.8%, vancomycin; and 18.2%, other antibiotics were administered. Compared to the control group, Gram-positive germs were associated with a significantly longer hospital stay (32 vs. 21 days, $p < 0.001$) and a greater need for ICU services (49 vs. 2 days, $p < 0.001$). Endoscopic therapy was less successful for *Candida glabrata* infections compared to those caused by *Candida albicans* (45.5% vs. 85.4%). While both were associated with a significantly prolonged hospital stay, infections with *Enterococcus faecium* (including 4 cases of vancomycin-resistant *Enterococcus faecium*, VRE) resulted in significantly higher mortality (29.4% vs. 4.5%, $p < 0.05$), and infections with *Enterococcus faecalis* were associated with significantly worse clinical outcomes as defined by the resolution of the collection in follow-up assessments (33.3% vs. 88%, $p < 0.05$). These correlations remained significant in the multivariate regression analysis, with *Enterococcus faecium* showing an odds ratio (OR) of 8.1 (95% CI: 1.4-47.4) for higher mortality.

	Number (%)	Hospital (days)	ICU (days)	Interventions (n)	Resolution (%)	Outcome (%)	Mortality (%)
Non-infected (control)	44 (43.1)	21 (1-71)	2 (1-60)	3 (1-8)	100 (14.3-100)	88	4.5
Infected	58 (56.9)	23 (1-243)*	15 (1-186)*	5 (2-21)*	81.4 (22.5-100)	75.8	12.1
Gram-positive	42 (41.2)	32 (1-243)**	49 (2-186)**	5 (2-21)*	70.8 (22.5-100)	69.6	14.3
Gram-negative	22 (21.6)	29.5 (7-243)*	49 (1-107)*	5 (2-11)*	100 (32.3-100)	76.9	13.6
Mixed infections	39 (38.2)	27.5 (1-243)*	49 (1-143)*	5 (2-21)*	81.2 (22.5-100)	73.9	12.8
Enterococcus faecium	17 (16.7)	34 (6-210)**	36 (3-186)*	6 (2-21)	83.5 (22.5-100)	62.5	29.4*
Enterococcus faecalis	6 (5.9)	93 (62-210)**	61.5 (7-92)*	8 (3-12)*	60.0 (32.3-69.2)*	33.3*	16.7
Candida albicans	18 (17.6)	20 (4-205)	9 (1-143)	3.5 (2-11)	85.4 (32.3-100)	76.9	5.9
Candida glabrata	7 (6.9)	34 (6-169)	16 (7-74)*	6.5 (2-20)	45.5 (22.5-83.8)*	50	28.6
Streptococcus spp.	13 (12.7)	10 (1-28)*	9	5 (3-5)*	78.9 (63.0-100)	100	0
Klebsiella pneumoniae	8 (7.8)	26 (12-107)	42 (9-92)	3 (2-6)	100 (32.3-100)	80	12.5
Escherichia coli	5 (4.9)	35 (7-107)	59 (1-92)	6	100 (32.3-100)	75	0
Others	22 (21.6)	47.5 (9-243)**	16 (2-143)*	5.5 (2-21)*	79.2 (32.3-100)	76.9	13.6

Compared to non-infected: *p <0.05, **p<0.001

Conclusion: The type of infecting organism significantly impacts clinical outcomes in patients undergoing EUS-guided drainage for infected peri-pancreatic fluid collections. *Enterococcus faecalis* and *faecium* infections were associated with poorer clinical outcomes, highlighting the need for targeted therapeutic strategies.

Introduction: Opioids used to manage severe pain in acute pancreatitis might exacerbate the disease through effects on gastrointestinal and immune functions. Methylnaltrexone, a peripherally acting μ -opioid receptor antagonist, may counteract these effects without changing analgesia.

Aims & Methods: This multicentre, double-blind, randomised, placebo-controlled, investigator-initiated trial included adult patients with predicted moderately severe or severe acute pancreatitis at four Danish pancreatitis referral centres. Patients having chronic pancreatitis, contraindications to methylnaltrexone, or renal insufficiency were excluded. Participants were randomised to receive 5 days of continuous intravenous methylnaltrexone (0.15mg/kg/day) or placebo added to the standard of care, including intravenous fluids, analgesics, and nutrition. The primary endpoint was the Pancreatitis Activity Scoring System score after 48 hours of treatment. Main secondary outcomes included pain questionnaire scores, use of opioids and laxatives, admission length, disease severity (revised Atlanta classification), and mortality.

Results: In total, 105 patients (54% males; median age 57 [IQR, 45-69]) were randomised to methylnaltrexone (n=51) or placebo (n=54). After 48 hours, the Pancreatitis Activity Scoring System score was 134.3 points in the methylnaltrexone group and 130.5 points in the placebo group (difference, 3.8 points [95% CI, -40.1 to 47.6]; $P=0.87$). At 48 hours, we found no differences between groups in pain severity (difference, 0.0 [95% CI, -0.8 to 0.9]; $P=0.94$), pain interference (difference, -0.3 [95% CI, -1.4 to 0.8]; $P=0.55$), and morphine equivalent doses (difference, 6.5 mg [95% CI, -2.1 to 15.2]; $P=0.14$). Compared to placebo, methylnaltrexone did not affect the median admission length (difference, -23 hours, [95% CI, -85 to 39]); $P=0.47$). Methylnaltrexone also did not affect the risk of laxative use (risk difference, -15% [95% CI, -34 to 2]; $P=0.10$), moderately severe or severe disease according to the Atlanta classification (risk difference, 8% [95% CI, -11 to 28]; $P=0.38$), 30-day mortality (risk difference, 6% [95% CI, -1 to 12]; $P=0.11$), or adverse events (risk difference, 10% [95% CI, -9 to 29]; $P=0.30$).

Conclusion: Methylnaltrexone treatment did not change the outcome of acute pancreatitis. Indirectly, the study supports that short-term opioid use is safe for pain control in acute pancreatitis.

Disclosure: Nothing to disclose.

Introduction: Although an increased risk of acute pancreatitis (AP) in inflammatory bowel disease (IBD) has been previously described, there are only small series, and data on clinical management are lacking.

We aimed to investigate the prevalence, etiology, and outcome of AP in IBD patients, including management, in a multicenter international study.

Aims & Methods: A two-step retrospective study was conducted involving 34 centers across Europe. The first step consisted of a survey questionnaire examining the number of AP (according to the Atlanta criteria) in adult IBD patients observed during a 10-year study period (2011-2020), and the second one in collecting data on IBD characteristics, onset of AP, etiology, clinical management, and outcome.

The study's primary aim was to estimate the prevalence of AP in IBD patients based on the total number of IBD patients observed in the study period indicated in the survey form.

Secondary aims included investigating the etiology of AP in IBD patients, the relationship between IBD medications and AP, the role of different imaging modalities in improving the diagnosis of pancreatic abnormalities, and the clinical outcome of AP. The study protocol has been disseminated through the ECCO (European Crohn's and Colitis Organization) platform after review and support by Clinical Research Committee.

Post-endoscopic intervention#	4 (1%)	2 (0.9%)	2 (1.2%)	
Others	15 (3.8%)	6 (2.7%)	9 (5.2%)	

Results: The expected prevalence of AP in IBD patients, according to the survey results, was 1.13% (780 out of 68989). However, the number of entered patients in the database was 501 (0.73%), but only 398 (0.58%) fulfilled the inclusion criteria. The mean age was 33.6± 14.3, 52% were female, 225 (56.5%) were CD, and 173 (46.4%) were UC. AP was clinically mild in most (86.9%) and, when imaging was performed (n=347, 86.7%), a normal pancreatic gland was described in 81 (23.3%), whereas edematous AP in 218 (62.8%).

The most frequent etiology was the drug-induced (220, 55.3%), due to azathioprine in 172 (77.8%), with AP occurring at 2 mg/kg dosage, after a median duration of 1 month.

Other causes included gallstones (59, 14.8%) and autoimmune (8.3%). In 54 (13.5%) AP was considered idiopathic. During a median follow-up of 67 months [IQR 34-96] from the index episode, 52 (13%) patients had AP recurrence, and 6 (1.5%) patients progressed to chronic pancreatitis.

According to a subgroup analysis by IBD type, CD patients were more often smokers, had a family history of IBD and/or pancreatic disease, extraintestinal manifestations (arthropathy), and a history of surgery, usually ileocecal resection. Ileal location with or without colonic involvement was present in 90.3%, with non-stricturing non-penetrating behavior in most (56%). Medications (66.7%) and gallstones (17.8%) were CD's most common AP etiologies.

In contrast, no risk factors for AP were found in UC patients, and extensive disease was described in 102 (59%). The etiology differed significantly from the CD group ($p < 0.0001$), since in addition to medication (40.5%), autoimmune pancreatitis was found in 13.9% and idiopathic AP in 22%.

Conclusion: PANDORA study established a 0.58% prevalence of AP in IBD patients, lower than expected. The AP is usually mild both clinically and radiologically. In 14% of cases no imaging is performed, in 23% pancreas is normal, suggesting that the real prevalence might be even lower. An ileal location in CD and extensive colitis in UC are usually reported and azathioprine seems the most common cause of AP in this setting, especially a few weeks after its introduction.

Disclosure: Nothing to disclose.

Introduction: Type 1 autoimmune pancreatitis (AIP) represents the most common manifestation of IgG4-related disease. Type 1 AIP responds well to glucocorticoids, but relapses are common requiring multiple treatment courses and ultimately leading to end-organ damage and treatment-related morbidity.

To date, scant reports exist on the long-term outcomes of these patients. Moreover, the role of maintenance treatment in preventing disease relapse is still debated.

Aims & Methods: We aimed to evaluate the long-term outcomes of a large European cohort of patients with type 1 AIP and to assess the role of maintenance treatment in preventing disease relapse. Patients with type 1 AIP fulfilling ICDC criteria were included in this multicentric retrospective study within the PrescrAIP framework involving 40 European university Hospital. Relapses were defined as new onset of either AIP related symptoms or radiological abnormalities after a successful induction of remission. Patients without either complete or partial remission were excluded.

The primary endpoint was time to relapse. Predictors of relapse were identified by multivariable logistic regression. A bootstrapping technique was performed to internally validate the model. Regression coefficients from the multivariable model were employed to develop a score for computing the risk of relapse for each patient. Patients were divided into four categories according to the score, from the lowest to highest risk of relapse.

Results: 477 patients were included in this analysis (325 male, 68%). Mean age at baseline was 59 (IQR 40-68). 60% of the patients presented with jaundice while 7% of the patient with acute pancreatitis. Other organs involvement was present in 238 patients (48%), being biliary involvement the most frequent one (40%). At baseline, diabetes mellitus and pancreatic exocrine insufficiency were present in 30% and 27% of patients, respectively. After a mean follow up of 32 months (IQR 13-68), 150 (31%) AIP relapses occurred. After accounting for confounders, biliary tree involvement (OR 1.62 95%CI 1.1-2.2), acute pancreatitis at baseline (OR 2.1 95%CI 1.1-4.2), narrowing of the main pancreatic duct (OR 1.6, 95%CI 1.1-2.1) were independently associated with relapse, while AIP presenting as a focal mass resulted in a protective factor (OR 0.65 95%CI 0.46-0.92). Increased serum IgG4 level (OR 1.2 95%CI 0.9-1.7) pointed to higher relapse rate without reaching statistical significance.

Notably, any maintenance treatment reduced the relapse rate after correcting for the above-mentioned risk factors (OR 0.51, 95%CI 0.37-0.72). There was no difference in term of relapse free survival between maintenance treatment with any anti-rheumatic drugs (azathioprine, methotrexate, mycophenolate) and low-dose GCs. Maintenance treatment reduced relapse rate only in patients with higher relapse risk. At the longest follow up, DM and PEI were recorded in 33% and 29% of the patients, respectively. Only one pancreatic cancer was detected.

Conclusion: Several disease features increase the risk of relapse in type 1 AIP. Any of the maintenance treatment reduce relapse rate in type 1 AIP. Patients showing multiple risk factors for relapse benefit the most from maintenance treatment. The development of a score predicting disease relapse enhances a personalized approach toward AIP treatment. In European AIP patients the development of pancreatic cancer during follow up appears rare.

Introduction: The WATERFALL randomized controlled trial¹ demonstrated that aggressive fluid resuscitation is associated with fluid overload without improving clinical outcomes compared to moderate fluid resuscitation. However, these fluid resuscitation regimens were administered up to 8 hours after disease diagnosis, and the effect of fluid resuscitation administered before recruitment in the emergency department (FRED) was not analyzed. We aimed to assess the effect of FRED on clinical and safety parameters among patients with acute pancreatitis who participated in the WATERFALL trial.

Aims & Methods: We conducted a post-hoc analysis of the WATERFALL clinical trial¹. FRED was the volume received until recruitment (up till 8 hours from diagnosis) and it was not determined by protocol in the trial but it was registered. Patients were categorized into two groups according to median FRED administered in the whole cohort: a) low volume group: patients who received $\leq$ median FRED before recruitment b) high volume group: patients who received $>$ median FRED before recruitment.

The primary efficacy outcome was the development of moderately severe or severe AP during admission. The main safety outcome was the development of fluid overload.

As secondary endpoints, we evaluated the influence of FRED in the development of severe AP, local complications, pancreatic or peripancreatic necrosis and its infection, systemic inflammatory syndrome (SIRS) at 24 hours, persistent SIRS (> 48 h), fluid overload symptoms, signs or imaging, intensive care unit (ICU) admission, death during admission and symptom intensity. Prediction of severity was calculated with the Bedside Index Severity in Acute Pancreatitis (BISAP) score, comorbidity with Charlson comorbidity score, and symptom intensity by Patient-Reported Outcome Scale in Acute Pancreatitis (PAN-PROMISE score).

We performed a univariate and multivariate analysis adjusted by possible confounding factors. Age, center, sex, BISAP ≥ 3 , gallstone etiology, urea and arm of treatment of the WATERFALL trial were included in the model (those which could potentially influence the administration of different volume rates of FRED and the ones with a p-value $< 0,1$ between both groups in the baseline characteristics bivariate analysis).

Results: 186 out of 249 patients of the WATERFALL trial were included for whom data on FRED was available. 93 of the patients were in the aggressive fluid resuscitation arm of treatment and 93 in the moderate fluid resuscitation arm of treatment. There were statistically significant differences amongst both groups in gallstone etiology and urea ($p < 0.05$). Median FRED was 700 mL. 94 (50,5%) of the cohort received low volume FRED (FRED ≤ 700 ml) and 92 patients (49,5%) received high volume FRED (FRED > 700 ml). There were no statistically significant differences in the main efficacy outcome with 20 patients (21,3%) with moderately severe to severe AP in low volume group and 18 (19,6%) in high volume group in the univariate or multivariate analysis with an adjusted Odds Ratio (IC 95%) of 0,85 (0,39-1,86) and $p = 0.68$.

No statistically significant differences were found regarding fluid overload, with 15 patients (16%) in low volume group and 9 patients (9.8%) in high volume group in the univariate or multivariate analysis with an adjusted Odds Ratio of 0.75 (0.27-2.10) and $p = 0.58$. Regarding secondary outcomes, we did not find statistically significant differences except for symptom intensity at recruitment. Higher intensity symptoms were associated to high volume FRED at recruitment with an adjusted Odds Ratio of 2.12 (1.12-4.01) and $p = 0.02$.

Conclusion: To conclude, high volume FRED is not linked to improved clinical outcomes in AP nor does it pose a higher risk of fluid overload.

Introduction: Intestinal fibrosis and strictures is one of the most challenging complications in patients with Crohn's disease (CD). There is an urgent medical need for non-invasive serological biomarkers for intestinal fibrosis, as magnetic resonance enterography (MRE) is not a feasible tool for repeated monitoring.

Here we wanted to investigate the role of the minor collagens; fibrillar type XI collagen and the Fibril-Associated Collagens with Interrupted Triple Helices (FACIT) type XVI collagen in relation to intestinal fibrosis. Therefore, we quantified the biomarkers PRO-C11 (formation of type XI collagen) and PRO-C16 (formation of type XVI collagen) in serum from pediatric CD (pCD).

Aims & Methods: We enrolled children with CD who underwent MRE in the ImageKids study. (ImageKids study: NCT01881490). Serum samples were collected at enrolment (n=203), and from healthy age- and gender-matched healthy subjects (HS) (n=82). The Nordic PFA biomarkers of tissue fibrosis PRO-C11 and PRO-C16 were measured. Intestinal fibrosis and stenosis were determined by MRE, and VAS score was applied to assess severity of intestinal fibrosis. Pearson-r correlation, students t-test and one-way-ANOVA with false discovery rate correction were applied for statistical analysis.

Results: The sample size of the different groups were as follows, no fibrosis [n=138]: VAS=0, mild fibrosis [n=55]: VAS=1-44, moderate/severe [n=17]: VAS>44). PRO-C11 (r=0.20, p=0.01) and PRO-C16 (r=0.20, p=0.01) correlated with the MRE VAS score. Both PRO-C11 (with fibrosis: median 26.4 ng/mL [IQR: 13.25-39.53 ng/mL]) and without fibrosis: median 20.6 ng/mL IQR 11.3-28.8 ng/mL) and PRO-C16 (with fibrosis: median 2990 ng/mL IQR: 2093-3884 ng/mL, and without fibrosis: median 2548 ng/mL [IQR: 1579-3286 ng/mL]) were significantly elevated in those with fibrosis compared to without fibrosis MRE-confirmed stenosis[AG1] [JHM2] (p<0.01). Serum PRO-C11 levels were significantly elevated in patients with moderate/severe intestinal fibrosis (median 32.2 ng/mL [IQR: 19.5-46.7 ng/mL]) as judged by VAS compared to patients with mild intestinal fibrosis (p<0.05, median 28.8 ng/mL [IQR: 12.6-37.3 ng/mL]), with no intestinal fibrosis (p<0.01) and HS (p<0.0001, median 8.3 ng/mL [IQR: 7.0-12.5 ng/mL]). PRO-C16 was significantly elevated in patients with moderate/severe intestinal fibrosis (median 3567 ng/mL [IQR: 2287-4608 ng/mL]) com-

pared to patients with mild intestinal fibrosis (p<0.05, (median 2791 ng/mL [IQR: 1970-3670 ng/mL]), with no intestinal fibrosis (p<0.001, (median 2548 ng/mL [IQR: 1579-3286 ng/mL]) and HS (p<0.0001, (median 1456 ng/mL [IQR: 1072-1804 ng/mL])).

Conclusion: Based on these biomarker data from the ImageKids study, PRO-C11 and PRO-C16 demonstrate potential as important non-invasive biomarkers reflecting intestinal fibrosis and stenosis.

BIOLOGIC DRUG AND ANTI-DRUG ANTIBODY MONITORING: TNF INHIBITORS, INFLIXIMAB, ADALIMUMAB, AND CERTOLIZUMAB PEGOL, IN 128,537 PATIENT SAMPLES

K.Y. Chun¹, J. Yang¹

¹Labcorp, Specialty Medicine, Calabasas, United States of America

Contact E-Mail Address: chunk@labcorp.com

Introduction: Serum assays to measure biologic drugs, especially TNF inhibitors, and their anti-drug antibodies (ADAb) are utilized to manage sub-optimal response and to proactively titrate doses and dosing intervals. Sensitive, drug-tolerant and high-resolution anti-drug antibody assays are an increasingly important tool necessary for detection and management of immunogenicity, especially when low-intermediate in titer and potentially reversible.¹

Aims & Methods: Serum samples from 72,819, 53,131, and 2587 patients were analyzed for infliximab (IFX), adalimumab (ADL), and certolizumab pegol (CTZ) drug (in µg/mL) and corresponding anti-drug antibodies (in ng/mL) as measured by drug-specific lab developed chemiluminescent immunoassays. Drug assays measure the free ADAb-unbound fraction of drug when serum ADAb are present. All ADAb assays detect total antibodies (including IgM & IgG subtypes), and their drug tolerance has been validated. Drug-specificity of ADABs is verified by a confirmatory test step. An extensive blinded method comparison of our IFX and Anti-IFX assays has been published.²

	IFX	ADL	CTZ
Therapeutic Target Drug Concentration (ug/mL) ³	5.0	7.5	20.0
Range of Drug Concentrations in ADAb-Negative Samples	n=50,325 0.4 to 593 µg/mL	n=37,653 0.6 to 74 µg/mL	n=837 1.0 to 138 µg/mL
Distribution of Drug Concentrations in Anti-Drug Ab-negative samples	25%: <5.0 µg/mL 27%: 5-10 µg/mL 21%: >20 µg/mL	45%: <7.5 µg/mL 37%: 7.5-12 µg/mL 14%: 13-20 µg/mL 4%: >20 µg/mL	40%: <20 µg/mL 32%: 20-39 µg/mL 28%: >40 µg/mL
Immunogenicity	n=22,494 31%	n=15,478 29%	n=1750 68%
Range of ADAb Titers	22 to 582,749 ng/mL	25 to 863,115 ng/mL	40 to 236,148 ng/mL
Anti-Drug Ab Titer Designation Cut-points (ng/mL)	Low: <200 High: >1000	Low: <100 High: >800	Low: <1000 High: >5000
Inverse Relationship Between Drug and Anti-Drug Ab Levels?	yes	yes	yes
Interpretive Comments for Anti-Drug Ab	Anti-drug antibody levels should be interpreted in the context of the concomitant free drug concentration at trough. Low titer anti-drug antibodies may be transient while high titers are likely to be more consequential. Some immunogenicity is reversible. Elimination of intermediate titer and some high titer anti-drug antibodies has been achieved with dose escalation and/or methotrexate or thiopurine. Non-neutralizing anti-pegol antibodies cannot be ruled out.		

Table 1. Analysis of Patient Samples for IFX, ADL, CTZ and Respective Anti-Drug Antibodies.

Results: Drug and ADAb results are summarized in Table 1. Immunogenicity rates were 31%, 29%, and 68% for IFX, ADL, and CTZ, respectively. ADAb-free samples were used to evaluate distribution of drug levels. Even in the absence of immunogenicity, many patients are subtherapeutic, 25%, 45% and 40%, for IFX, ADL, and CTZ, respectively, when using proposed therapeutic targets of 5 µg/mL for IFX, 7.5 for ADL, and 20 for CTZ.³ Therapeutic levels were observed in 27% for IFX, 37% for ADL and 32% for CTZ. Higher drug concentrations in the remaining samples may represent non-tough collected samples.

A wide range of immunogenicity titers was observed. Analyses of the inverse relationship between ADAb and drug led to determination of cut-points for low/high titer designations where in the setting of high ADAb, almost invariably, concomitant free drug is very low or nil. As a good rule, anti-drug antibodies should be interpreted in the context of the concomitant free drug trough concentration.

Conclusion: Here, we report concentrations of TNF-inhibitors used to treat IBD and their anti-drug antibodies in >128,000 patient samples. Though clinical histories and blood collection timing are not known, we observed that many patients may have insufficient drug levels. Immunogenicity to TNF inhibitors was frequent where a wide numeric range of ADAb was observed. Numeric ADAb antibody results should be interpreted with the help of titer designations by the laboratory because low to intermediate titers may be transient or reversible whereas high titers with nil or very low drug indicate refractory immunogenicity. High resolution ADAb assays have enabled the early detection and successful reversal of intermediate titers of Anti-IFX and Anti-ADL with dose escalation +/- co-immunomodulator.¹ Thus, biologic TDM aims to optimize drug efficacy and longevity by informing and expediting adjustments to medication.

Introduction: Inflammatory bowel diseases (IBD), encompassing ulcerative colitis (UC) and Crohn's disease (CD), are associated with increased risk of primary sclerosing cholangitis (PSC). However, population-level data for optimal screening strategies in incident IBD are lacking.

Aims & Methods: We aimed to determine the occurrence and predictors of PSC in patients with newly diagnosed IBD. Since May 1st, 2021, all adult and pediatric patients with incident IBD within a catchment area encompassing 20% of Denmark were enrolled in the prospective population-based Copenhagen IBD Inception Cohort.¹

All adult patients were invited for MRCP and blood tests (albumin, alanine aminotransferase (ALT), alkaline phosphatase (ALP), bilirubin, and INR) at IBD diagnosis. PSC-like lesions on MRCPs were evaluated by two experienced radiologists.

Multivariate Cox proportional hazard analyses adjusting for age, gender, smoking, and disease phenotype were performed (adjusted HR, aHR, 95% confidence interval).

Results: Between May 2021 and May 2023, 527 patients (UC: 326; CD: 201) were included, with 242 (74.2%) and 147 (73.1%) undergoing MRCP, respectively, within a median of 2.4 months (interquartile range (IQR) 1.3–4.9) of IBD diagnosis. No clinical differences were observed between patients who underwent MRCP and those who did not.

PSC-like lesions on MRCP were detected in 33 patients (8.5%), including 17 (7.0%) and 16 (10.9%) with UC and CD, respectively. Of those, 19 patients (4.9%), including 11 (4.5%) with UC and 8 (5.4%) with CD, had definite PSC. No difference was observed in the occurrence of PSC (p=0.37) or PSC-like lesions (p=0.08) in UC vs. CD, nor according to the phenotype of CD; however, PSC lesions in both intra- and extrahepatic bile ducts were more common in UC than in CD (46.2% vs. 6.3%, p=0.02). In addition, a larger proportion with PSC had extensive UC (62.5% vs. 27.1%, p=0.04) or were males (87.5% vs. 44.9%, p=0.03) compared to those without PSC.

Abnormal hepatobiliary biochemistry was found in 34 (14.0%) and 39 (26.5%, p<0.01) patients with UC and CD, respectively, with a higher prevalence observed in patients with definite PSC (9/19 (47.4%)) or PSC-like

lesions (8/14 (57.1%)) compared to those with normal MRCP (56/356 (15.7%), $p < 0.01$). Receiver operating characteristic analysis identified ALT ≥ 25 U/L and ALP ≥ 117 U/L to predict PSC best (accuracy and sensitivity: 0.65, specificity: 0.63, positive predictive value (PV): 0.96, and negative PV: 0.09).

During a follow-up of 2.1 years (IQR 1.6-2.6), PSC and PSC-like lesions were both independently associated with increased risk of intestinal resections (aHR 5.69, 1.13-28.54), biologics (aHR 2.00, 1.04-3.86), hospitalization (aHR 2.70, 1.02-7.12), and systemic steroids (aHR 2.45, 1.02-5.89) in CD but not in UC. Abnormal hepatobiliary biochemistry was associated with hospitalization (aHR 2.11, 1.12-4.00) and flare-up of CD (aHR 1.13, 1.02-1.96) as well as biologics in UC (aHR 2.49, 1.15-5.38). None of the PSC cases died, developed cancers, varices, or required liver transplantation within the follow-up period.

Conclusion: In this prospective population-based cohort, we found a considerable proportion (8.5%) to have undetected PSC or PSC-like lesions, despite normal hepatobiliary biochemistry in half of these cases. Notably, both definite PSC, PSC-like lesions, and abnormal hepatobiliary biochemistry had a negative impact on IBD prognosis. The results underscore the importance of systematic screening to mitigate the risk of overlooking PSC, thereby improving the management and outcomes of IBD.

Introduction: Intestinal ultrasound (IUS) is gaining increasing acceptance as a reliable tool for tight monitoring of ulcerative colitis (UC). Although several IUS scores have been proposed, none has been formally implemented into official recommendations of international scientific societies.

Aims & Methods: We aimed to compare an IUS score validated for Crohn's disease (CD), the International Bowel Ultrasound Segmental Activity Score (IBUS-SAS)¹, with other IUS scores specifically developed for UC, in terms of correlation with endoscopic activity.

Patients with UC ≥ 18 years old undergoing partial or full colonoscopy between April 2023 and January 2024 were prospectively included. Endoscopic evaluation of at least the sigmoid colon was mandatory for inclusion, and patients with proctitis (Montreal E1) were excluded. Endoscopic activity was scored with both the Mayo Endoscopic Subscore (MES) and the Ulcerative Colitis Endoscopic Index of Severity (UCEIS), and defined by MES ≥ 1 and UCEIS ≥ 2 .

Moderate endoscopic activity was determined by a MES = 2 or an UCEIS = 5-6, while severe activity was defined by a MES = 3 or an UCEIS ≥ 7 . IUS was performed within 4 weeks of endoscopy. The IBUS-SAS, the Milan Ultrasound Criteria (MUC)², the UC-IUS score³, the US Score from Parente et al.⁴, and the Hata index⁵ were included in the analysis.

Applicability of the Civitelli index⁶, an IUS score developed for pediatric patients, was also evaluated. The Spearman's rank coefficient [ρ] was used to perform correlations, while receiver operating characteristic (ROC) curves were compared with the Hanley & McNeil method.

Results: Collectively, 104 patients were included in the study. The majority of patients (61.5%) had extensive colitis (Montreal E3), with half of them having an active disease at endoscopy (54.8% using MES and 48.1% using UCEIS). IUS examination was performed at a median time of 8 days (IQR 2-15) after endoscopy.

All the investigated scores were significantly able to distinguish between the 3 grades of severity of colonic inflammation, using both MES and UCEIS as a reference, with the exception of the Parente's US Score for the severe endoscopic activity assessed with UCEIS [0 (IQR 0-1) for UCEIS < 7 vs 1 (IQR 0-1) for UCEIS ≥ 7 , $p = 0.09$]. The IBUS-SAS showed a strong correlation with endoscopic activity, both with MES ($\rho = 0.71$, $p < 0.01$) and UCEIS ($\rho = 0.73$, $p < 0.01$) assessments.

The Area Under the Curve (AUC) of IBUS-SAS to detect an endoscopic activity of at least moderate severity (MES ≥ 2 and UCEIS ≥ 5) was 0.85 and 0.90, respectively. The optimal cutoff to detect a MES ≥ 2 and UCEIS ≥ 5 was > 11 (sensitivity 75% and specificity 82%) and > 22 (sensitivity 92% and specificity 80%), respectively.

Both cut-offs showed progressive increase from mild to severe activity, with IBUS-SAS maintaining a consistently high AUC at different thresholds. Consistent with IBUS-SAS results, all the investigated UC-developed IUS scores correlated with both the MES and the UCEIS ($p < 0.01$). AUC values and relative comparisons between the AUC are detailed in Table 1.

A) AUC for MES ≥ 2	IBUS-SAS 0.85 (0.77-0.91)	Civitelli index 0.85 (0.76-0.91)	Hata index 0.77 (0.67-0.84)	US Score 0.74 (0.64-0.82)	UC-IUS 0.86 (0.78-0.92)	
MUC 0.85 (0.77-0.91)	0.99	0.92	0.03	< 0.01	0.55	
UC-IUS 0.86 (0.78-0.92)	0.45	0.55	0.02	< 0.01	0.62	Civitelli index 0.92 (0.83-0.95)
US Score 0.74 (0.64-0.82)	0.02	0.01	0.48		0.18	0.48 Hata index 0.87 (0.79-0.93)
Hata index 0.77 (0.67-0.84)	0.06	0.02		0.45	0.09	0.20 US Score 0.83 (0.75-0.90)
Civitelli index 0.85 (0.76-0.91)	0.93		0.09	0.30	0.95	0.50 UC-IUS 0.92 (0.85-0.96)
		0.92	0.05	0.24	0.98	0.59 MUC 0.92 (0.85-0.96)
		UC-IUS 0.92 (0.85-0.96)	US Score 0.83 (0.75-0.90)	Hata index 0.87 (0.79-0.93)	Civitelli index 0.92 (0.83-0.95)	IBUS-SAS 0.90 (0.83-0.95)
						B) AUC for UCEIs ≥ 5

Table 1. Relative comparisons between the AUC of each score to detect a MES ≥ 2 (A, top-right) and an UCEIS ≥ 5 (B, bottom-left) are reported.

Grey rows and columns: AUC values (with 95%CI).

White cells: *p*-values obtained via the Hanley and McNeil method (significant *p*-values are shown in bold).

Conclusion: In this study we provide a successful validation of 6 IUS scores for UC. The IBUS-SAS has an optimal performance in predicting endoscopic activity also in patients with UC, despite having been developed initially for CD.

OP176

A COHORT STUDY OF INFLAMMATORY BOWEL DISEASE CARE IN PREGNANCY IN A LARGE TERTIARY CENTRE

H. Mackenzie¹, S. McCartney¹, D. Nzelu², D. Williams², P. Harrow¹

¹University College London Hospitals NHS Foundation Trust, Department of Gastroenterology, London, United Kingdom,

²University College London Hospitals NHS Foundation Trust, Department of Obstetric Medicine, London, United Kingdom

Contact E-Mail Address: harry.mackenzie@nhs.net

Introduction: Treatment of IBD during pregnancy poses a clinical challenge. Myths and misconceptions abound. Numerous studies have shown active IBD is associated with adverse maternal and fetal outcomes. A growing field of new medication also creates challenges. We conducted a retrospective cohort study to report pregnancy outcomes and clinical practice in a large tertiary centre in the UK in 2023.

Aims & Methods: Tertiary care for pregnant patients with IBD is provided through a specialist joint gastroenterology-obstetrics service. Data was retrospectively extracted from the electronic health records of 50 women looked after between January 1st and July 1st 2023. We describe the patient population including IBD characteristics, treatments and disease activity during pregnancy and report obstetric outcomes.

Results: 50 unique pregnant women were included; 30 (60.0%) had Crohn's disease (CD) and 20 (60.0%) had Ulcerative Colitis (CD) with a median age of 34. Within the CD cohort, 4 (13.3%) had prior or active perianal disease. Vaginal delivery is relatively contraindicated in this cohort and all patients underwent C-section.

Overall, 22/50 (44.0%) patients were taking biologics, 6/50 (12.0%) on thiopurines, 14/50 (28.0%) on mesalazine only and 14/50 (28%) were on no IBD medication at the time of conception. Of those taking biologics, 3/22 (13.6%) discontinued in the third trimester while 19/22 (86.4%) continued biologics throughout pregnancy. This reflects a recent change in practice; only patients in remission with low risk of flare stopped biologic medication during pregnancy.¹

50% experienced an IBD flare during pregnancy. A flare was defined as a faecal calprotectin >250µg/g or exacerbation of symptoms requiring change in medical management.

A significant proportion (20/50, 40.0%) developed anaemia during pregnancy (Hb <116g/L). 6 (12%) developed anaemia according to pregnancy parameters (Hb <106g/L. 21 (42.0%) received iron supplementation. 11 (52.4%) received it exclusively orally, 3 (14.3%) exclusively intravenously and 5 (23.8%) received both. Oral iron was tolerated poorly.

Regarding obstetric outcomes; 48 (96.0%) had live singleton births, with 1 (2.00%) miscarriage and 1 (2.00%) elective termination following an abnormal anomaly scan; found at post-mortem to have Turner's syndrome. 35/48 (72.9%) women delivered in our hospital while 13/48 (18.1%) delivered in a local hospital.

1/48 (3.9%) baby was born prematurely (<37 weeks). Median birthweight was 3235g (2410g – 4280g). 2/48 (4.2%) were born with low birth weight (<2.5Kg), and 4/48 (8.3%) had fetal macrosomia (>4.0Kg). Median birthweight was lower in mothers who experienced flare (3210g) compared to those with no flare (3310g).

Incidence of gestational diabetes mellitus (GDM) (25.7%) was higher compared with the national average of 5%. Antenatal steroid use is associated with hyperglycaemia and GDM. Steroids were required to control disease flares in 6/48 (12.5%) women; 3 had prednisolone, 2 had budesonide and 1 buccal hydrocortisone. Only 1/6 (16.7%) exposed to steroids developed GDM.

Conclusion: IBD flares were common in pregnancy, which may reflect the complexity of patients referred to the tertiary service. Most patients continued biologic medication during pregnancy including the third

trimester. Obstetric and neonatal outcomes were similar to the general population. Anaemia was similar to and GDM was more common than the local population. Awareness and proactive management of these issues including continuing IBD medication is important to reduce the risk of associated complications.

Screening colonoscopy: How to save lives

10:00-11:00 / Lehar 1

OP177

THE IMPACT OF SCREENING COLONOSCOPY KEY PERFORMANCE INDICATORS ON THE RISK OF FUTURE COLORECTAL CANCER AND ADVANCED POLYPS

J. Parker¹, G. Greene², J. Torkington¹, S. Dolwani³

¹Cardiff and Vale University Health Board, Cardiff, United Kingdom, ²Welsh Cancer Intelligence and Surveillance Unit, Cardiff, United Kingdom, ³Cardiff University, Population Medicine, Cardiff, United Kingdom

Contact E-Mail Address: dolwanis@cardiff.ac.uk

Introduction: Polyp detection rates are considered surrogate indicators of colonoscopy quality. Current evidence suggests that improving these in low detectors may reduce the risk of post colonoscopy colorectal cancer (PCCRC). It is unclear whether an upper threshold exists above which this becomes less clinically meaningful.

The aim of this study was to assess the impact of KPIs in a high polyp detector group on the future risk of advanced polyps and colorectal cancer diagnoses within 3 years of screening colonoscopy. The PCCRC rate and number of interval cancers and advanced polyps detected were also described.

Aims & Methods: This was a retrospective cohort study of patients undergoing screening colonoscopy. Endpoints of advanced polyps or colorectal cancer and were identified by analysis of routine linked healthcare data through the Secure Anonymised Information Linkage (SAIL) databank. A multivariate cox regression analysis assessed the impact of colonoscopist performance indicators on outcomes of future diagnoses of advanced polyps or colorectal cancer.

Results: 5807 patients were included with a median follow-up of 60.1 months. There were 1.5% interval advanced polyps and 0.9% colorectal cancers identified with a median time to diagnosis of 19.8 and 39.2 months respectively. PCCRC rate was 3.8%. The median polyp detection rates were 62.2% with an adenoma detection rate of 50.9% amongst the colonoscopists. There was minimal variation in outcomes of advanced polyp or colorectal cancer diagnoses in these high detectors with no impact demonstrated of higher thresholds of the assessed key performance indicators on this.

Conclusion: It appears a threshold exists above which increasing performance indicators may not translate to better clinical outcomes. This is the first evidence assessing this in a group of high polyp detectors. The thresholds suggested may be utilised in endoscopy training, guiding surveillance recommendations, new technology and screening programmes.

OP178

ADENOMA DETECTION RATE LEVELS AND COLORECTAL CANCER RISK AFTER COLONOSCOPY

N. Pilonis¹, M. Bretthauer², M.F. Kaminski³, M. Kalager⁴, J. Regula⁵

¹The Maria Skłodowska-Curie Institute - Oncology Institute Warsaw, Poland, Department of Oncological Gastroenterology, Warsaw, Poland, ²University of Oslo, Department of Medicine, Gastrointestinal Endoscopy, Oslo, Norway, ³Maria Skłodowska-Curie Memorial Center and Institute of Oncology, Department of Gastroenterology, Warsaw, Poland, ⁴Oslo University Hospital, Oslo, Norway, ⁵Maria Skłodowska-Curie National Research Institute of Oncology and Centre of Postgraduate Medical Ed, Department of Gastroenterology, Warsaw, Poland

Contact E-Mail Address: nastazja@gmail.com

Introduction: Physician adenoma detection rate (ADR) is associated with colorectal cancer risk after screening colonoscopy (post-colonoscopy CRC). Quality assurance e.g., using computer-aided detection, are increasingly used to improve ADR. It is unknown if increasing ADR for physicians with already adequate performance is beneficial for CRC prevention.

Aims & Methods: To determine whether increasing ADR for physicians with already adequate performance reduces the risk of CRC incidence and mortality after screening colonoscopy. We analyzed 485,615 screening colonoscopies performed by 789 physicians in the Polish CRC screening program between 2000 and 2017 and used joinpoint regression analyses to identify trends between ADR levels and post-colonoscopy CRC incidence and mortality with follow-up until December 2022. We also compared CRC risk for individuals examined by physicians who did or did not improve performance by ADR levels

Results: During median follow-up of 10.2 years, we observed 1,873 CRCs and 474 CRC-related deaths. Median ADR was 21.8% (IQR 15.9-28.2%), maximum ADR was 63.0%. Joinpoint regression analyses showed strongest associations between ADR and CRC incidence for physicians with ADR's ≤26%, and weaker associations for physicians with ADR's >26%. Increasing ADR from the lowest level to a 26% threshold reduced post-colonoscopy CRC incidence by 42.7 per 100,000 person-years compared to 10.0 per 100,000 person-years for ADR increases from 26% to the maximum. For physicians with ADR of below 26% who increased ADR, post-colonoscopy CRC incidence was 31.8 (95%CI 29.5 to 34.3) per 100,000 person-years as compared to 40.7 (95%CI 37.8 to 43.8) for those who did not improve (Difference 8.9 per 100,000).

For physicians with ADR of above 26% who increased ADR, post-colonoscopy CRC incidence was 23.4 (95%CI 18.4 to 29.8) per 100,000 person-years as compared to 22.5 (95%CI 18.3 to 27.6) for those who did not improve (Difference 0.9 per 100,000). CRC mortality yielded similar results.

Conclusion: Higher ADRs are significantly associated with lower CRC risk, but associations are weak and may not be clinically relevant for patients examined by physicians with already adequate detection rates

WHICH PATIENTS REMAIN AT INCREASED RISK OF COLORECTAL CANCER AFTER FIRST SURVEILLANCE COLONOSCOPY AND NEED ONGOING SURVEILLANCE? A RETROSPECTIVE, COHORT ANALYSIS

E.C. Robbins¹, K. Wooldrage¹, A.J Cross¹

¹Imperial College London, Department of Surgery and Cancer, Cancer Screening and Prevention Research Group (CSPRG), London, United Kingdom

Contact E-Mail Address: e.robbs@imperial.ac.uk

Introduction: Patients deemed to remain at increased risk of colorectal cancer (CRC) following detection and removal of colorectal polyps are recommended to undergo surveillance by colonoscopy. Risk stratification to inform recommendations for the first surveillance colonoscopy, according to characteristics of baseline polyps, is well established.

However, the UK, European, and US post-polypectomy surveillance guidelines highlight the paucity of data to inform ongoing surveillance beyond the first surveillance colonoscopy.

Aims & Methods: Our aim was to identify which patient groups, defined by combinations of polyp findings at baseline and first surveillance, need ongoing surveillance and how many surveillance colonoscopies they might need. We performed a retrospective analysis of patients who underwent baseline colonoscopy with polypectomy at 17 UK hospitals, mostly from 2000 to 2010, and had ≥1 surveillance examinations. Cancer registration and death certificate data were collected through 2017. We examined patients in four groups defined by combinations of polyp findings at baseline and first surveillance: group 1 (low-risk findings at both baseline and first surveillance), group 2 (low-risk findings at baseline and high-risk findings at first surveillance), group 3 (high-risk findings at baseline and low-risk findings at first surveillance), and group 4 (high-risk findings at both baseline and first surveillance). High-risk findings included 2 premalignant polyps (PMPs: adenomas or serrated polyps) of which ≥1 was 'advanced' (adenoma ≥10mm or with high-grade dysplasia, or serrated polyp ≥10mm or with any dysplasia), ≥5 PMPs, or ≥1 non-pedunculated polyp ≥20mm, while all other findings were included as low-risk findings, as per the UK post-polypectomy surveillance guidelines. We examined CRC incidence after first surveillance, in the presence of a single surveillance examination, and after second surveillance, in the presence of ≥2 examinations. We compared incidence to that in the general population of England in 2007 using standardised incidence ratios (SIRs).

Results: After exclusions, 10,832 patients were available for analysis, of whom 6,746 (62%), 248 (2%), 3,437 (32%), and 401 (4%) were classified into group 1, 2, 3, and 4, respectively. Among each respective group, 3,581 (53%), 84 (34%), 1,478 (43%), and 119 (30%) had a single surveillance examination; remaining patients had ≥2 surveillance examinations. The median time from first surveillance to end of follow-up was 10.9 years, during which 158 patients were diagnosed with CRC. Compared to the general population, CRC incidence after first surveillance, with a single surveillance examination, was lower in group 1 (SIR 0.51, 95%CI 0.36-0.71), non-significantly different in group 2 (SIR 2.51, 95%CI 0.81-5.85) and group 3 (SIR 1.22, 95%CI 0.90-1.63), but higher in group 4 (SIR 2.84, 95%CI 1.30-5.39). After second surveillance, CRC incidence in group 4 was no longer higher than that in the general population (SIR 1.86, 95%CI 0.89-3.42).

Conclusion: In our cohort of patients undergoing post-polypectomy surveillance, high-risk polyp findings were uncommon at first surveillance, even among those with high-risk findings at baseline. Only those with high-risk findings at both baseline and first surveillance appear to have needed ongoing surveillance, with the second surveillance examination appearing sufficient to eliminate the excess CRC risk in these patients.

RETHINKING POST-COLONOSCOPY COLORECTAL CANCER RISK: ENDOSCOPIST PERFORMANCE VERSUS PRESENCE OF HIGH-RISK POLYPS

N.S. van Roermund^{1,2,3}, E. Dekker^{1,2,3}, M.E. van Leerdam^{4,5}, M.C. Spaander⁶, V.M.H. Coupé⁷, J.E. Ijspeert⁴

Introduction: At present, for the average risk population, colonoscopy surveillance intervals are based on previous detected and resected polyps in an individual. Although an inverse association between the endoscopist's adenoma detection rate (ADR) and the risk of developing post colonoscopy colorectal cancer (PCCRC) is widely recognized, performance measures of endoscopists are not taken into account when deciding on surveillance intervals.

This study aims to evaluate how the individual endoscopist's ADR compares to the presence of high-risk polyps when evaluating the risk of PC-CRC in the 3 years following a complete screening colonoscopy.

Aims & Methods: Data of all complete colonoscopies in which no CRC was found, performed within the Dutch fecal immunochemical test (FIT) based CRC population screening program between 2014 and 2020, were used for this study. Data were linked to the Dutch cancer registry. Individuals were categorized into having high-risk polyps or no/low risk polyps based on the 2020 ESGE post-polypectomy colonoscopy surveillance guideline. ADR was calculated per endoscopist. Risk of PCCRC, defined as any CRC diagnosed 6 months after the index colonoscopy, within 3 years was evaluated with shared frailty cox proportional hazard regression analysis in which ADR and presence of high-risk polyps were utilized as independent variables.

Secondary, endoscopists were categorized into three equal groups based on ADR (low/medium/high) to enable stratified analysis.

Results: In total 239.217 individuals were included of which 74.289 (31.1%) had high-risk polyps at baseline and 202 had PCCRC in the subsequent 3 years. Median ADR of the 441 endoscopists involved was 66.3% (IQR 61.4-69.9). Cumulative incidence of PCCRC was 2.66 (95%CI 2.21-3.11, table 1) per 10.000 person-years of follow-up in individuals with no or low-risk polyps and 2.54 (95%CI 1.92-3.15) in individuals with high-risk polyps. Presence of high-risk polyps was not associated with risk of PCCRC (HR 1.00; 95%CI 0.75-1.35), while ADR was associated (HR 0.94 per point increase in ADR; 95%CI 0.92-0.96).

The cumulative incidence of PCCRC was 3.68 (95%CI 2.74-4.62, table 1) per 10.000 person-years of follow-up for individuals with no or low-risk polyps that were treated by an endoscopist with low ADR, as compared to 1.69 (95%CI 0.89-2.50) for individuals with high-risk polyps treated by an endoscopist with high ADR (HR 2.11; 95%CI 1.21-3.65).

Individuals with high-risk polyps treated by an endoscopist with low ADR had the highest risk of PCCRC, while individuals with no or low-risk polyps treated by an endoscopist with high ADR had the lowest risk (HR 3.30; 95%CI 1.79-6.10).

	Overall	ADR Low	ADR high	
	PCCRC risk per 10.000 prs-y (95% CI)	PCCRC risk per 10.000 prs-y (95% CI)	PCCRC risk per 10.000 prs-y (95% CI)	HR* (95% CI)
No/low-risk polyp	2.66 (2.21-3.11)	3.68 (2.74-4.62)	1.16 (0.66-1.66)	3.17 (1.92-5.21)
High-risk polyp	2.54 (1.92-3.15)	4.18 (2.66-5.71)	1.69 (0.89-2.50)	2.11 (1.07-4.17)
	HR** (95% CI)	HR** (95% CI)	HR** (95% CI)	
	1.00 (0.75-1.35)	1.13 (0.73-1.77)	1.52 (0.80-2.89)	

Table 1: Cumulative incidence and stratified risk of ADR/presence of high-risk polyps on post colonoscopy colorectal cancer.

*= ADR high = reference, **= No or low-risk polyp = reference

Conclusion: We demonstrated that in the Dutch FIT-based CRC population screening program, the ADR of the endoscopist has a major impact on relative risk of PCCRC within 3 years after a complete colonoscopy, while the presence of high-risk polyps does not. This underscores the significant impact of quality of colonoscopy on the short-term development of PC-CRC and undermines the current surveillance guidelines that rely solely on polyp features.

Disclosure: Nothing to disclose.

PATIENT'S PER-PROCEDURAL COLONOSCOPY EXPERIENCE: HOW ACCURATE IS THE CLINICIAN'S ASSESSMENT?

Introduction: Per-procedural patient comfort is one of the key performance measures for colonoscopy [1]. In daily practice, patient comfort is generally reported by clinicians using rating scales such as the Gloucester Comfort Scale (GCS) [2]. However, despite the widespread use of the GCS, insights regarding the extent to which clinician-reported GCS scores really represent the patient's experience are lacking. Therefore, we aimed to assess the level of agreement between clinician-reported GCS scores and the level of patient-reported discomfort and pain.

Aims & Methods: Consecutive patients undergoing colonoscopy for any indication at two Dutch endoscopy clinics were invited to complete the Newcastle ENDOPREM™, a validated measure of patient experience of gastrointestinal endoscopy [3], within 48 hours after colonoscopy. Colonoscopies were performed by gastroenterologists or supervised gastroenterologists in training. Per-procedural comfort from the clinician's perspective is routinely reported by either the endoscopy nurse or endoscopist using the GCS (1 to 5 scale). Per-procedural experience from the patient's perspective was reported in terms of both the level of discomfort and pain on a 1 (no discomfort/pain) to 5 (worst discomfort/pain imaginable) scale. Moderate to high discomfort scores were defined as scores ≥ 3 . Levels of agreement between clinician- and patient-reported scores were assessed using Cohen's kappa statistic. Regression analyses were used to identify factors associated with moderate to high discomfort and pain scores.

Results: Of 579 invited patients, 243 (42%) returned a completed questionnaire and fulfilled the inclusion criteria (signed informed consent, no

deep sedation [4]). Percentual agreement between GCS and patient-reported scores is displayed in Table 1. A GCS score ≥ 3 was reported for 18 (7%) patients. Discomfort and pain scores ≥ 3 were reported by 53 (22%) and 60 (25%) patients respectively. For these patients, GCS underestimated discomfort and pain levels as reported by patients in almost all cases (discomfort: 49/53 [92%], pain: 54/60 [90%]). The level of agreement between GCS and discomfort scores was minimal (Cohen's κ : 0.34), agreement between GCS and pain scores was weak (Cohen's κ : 0.47). Levels of agreement were better for sedated patients (asleep but with response to verbal or tactile stimulation, n = 125) compared to patients who were awake or slightly drowsy (n = 116) for both discomfort (Cohen's κ : 0.45 vs. 0.20) and pain (Cohen's κ : 0.45 vs. 0.38). Based on multivariable regression analyses, female gender, age <55 years and high procedural difficulty (as defined by the endoscopist) were associated with moderate to high patient-reported discomfort and pain scores.

Moreover, where patients reported that they were anxious about discomfort and pain, anxious about procedure results, had a negative bowel preparation experience, felt unsafe, felt embarrassed or where procedures were longer than expected, moderate to high discomfort and pain scores were more common (all p<0.05).

	Matching GCS score and patient-reported score, n (%)	GCS score lower than patient-reported score, n (%)	GCS score higher than patient-reported score
Discomfort	119 (49%)	72 (30%)	52 (21%)
Pain	133 (55%)	71 (29%)	39 (16%)

Conclusion: Clinician-reported GCS scores, used to indicate per-procedural patient comfort, underreport discomfort and pain as reported by patients. A validated experience tool also allows the definition of patient factors that may be associated with greater patient reported discomfort and pain at colonoscopy. These findings support the use of patient-reported comfort scores for accurate monitoring of patients' experience.

LIPOFUSCINOSIS AS A NOVEL DISCRIMINATING FEATURE FOR DRUG-INDUCED LIVER INJURY VS. AUTOIMMUNE HEPATITIS

S. Weber¹, F. Erhardt¹, J. Neumann², J. Allgeier¹, D. Saka¹, N. Donga¹, C. Lange¹, A.L. Gerbes¹

²LMU Klinikum, Institute of Pathology, Munich, Germany

Contact E-Mail Address: Julian.Allgeier@med.uni-muenchen.de

Introduction: Differentiating drug-induced liver injury (DILI) from autoimmune hepatitis (AIH) is a challenge in clinical practice¹⁻³. Liver biopsy is recommended in unclear cases¹, however available studies comparing histopathological patterns between DILI and AIH have major limitations due to lack of control groups or limited sample sizes^{4,5}.

Aims & Methods: We aimed to further identify typical histopathological features of DILI in comparison to AIH. Clinical and histopathological data of well-characterized 136 DILI and 43 AIH patients from our prospective cohort on patients with acute liver injury and potential drug-related cause were analysed. Logistic regression was performed to identify models that could differentiate both entities and predict adverse outcome.

Results: We identified high overlaps regarding histological patterns between DILI and AIH, leading to a low overall agreement between clinical and histopathological diagnosis of only 48.9%. Interface hepatitis, plasma cell infiltration and portal-intralobular infiltration was favouring AIH over DILI, however relevant proportions of DILI patients also presented with those features (interface hepatitis: 69.8% vs. 44.1%, p=0.003, plasma cells: 72.1% vs. 46.3%, p=0.003, portal-intralobular infiltration 51.2% vs. 29.2%, p=0.005). Interestingly, lipofuscinosis showed the strongest association with DILI diagnosis on univariate analysis (odds ratio [OR] 1.33, 95% confidence interval [CI] 1.17-1.50). A model comprised of interface hepatitis, cholestasis, lipofuscinosis, portal-intralobular inflammation and steatosis could differentiate DILI from AIH with an accuracy of 77.7% and a sensitivity as high as 94.1% (specificity 25.6%). Multivariate analysis also identified lipofuscinosis as a highly discriminatory feature (OR 8.05, Table 1). Prediction of adverse outcome (defined as death or need for liver transplantation [LT]) in DILI and AIH patients using only histopathological patterns was possible with an accuracy of 88.7% (specificity 97.0%, sensitivity 48.1%). Severe necrosis and ductular proliferation were associated with poor outcome (OR 5.48 and OR 5.00, respectively) while presence of eosinophilic cells and lipofuscinosis (OR 0.36 and OR 0.163, respectively) lowered the risk for death or LT significantly.

Logistic regression models including histopathological parameters discriminating DILI vs. AIH.			
	OR	95 % CI	p
Interface hepatitis	0.453	0.209-0.982	0.045*
Cholestasis	1.986	0.925-4.267	0.079
Lipofuscinosis	8.050	1.019-63.617	0.048*
Portal-intralobular inflammation	0.471	0.222-1.000	0.050*
Steatosis	2.784	0.881-8.801	0.081

Logistic regression models including histopathological parameters discriminating DILI vs. AIH.

Conclusion: We here present the largest prospectively collected cohort of DILI and AIH patients for whom histopathological analysis was performed. Interestingly, DILI and AIH showed highly similar histological patterns, neither interface hepatitis nor plasma cell infiltration could specifically differentiate AIH from DILI patients.

However, lipofuscinosis was identified as a novel distinctive feature for DILI with a high discriminatory power. Moreover, a model combining histological features could differentiate both entities with high sensitivity. Histological analysis was especially helpful for predicting severe outcome in DILI and AIH patients showing higher specificity when compared to traditional risk scores predicting acute liver failure in DILI⁶.

Introduction: Chronic infection with the hepatitis D virus (HDV) may lead to rapid progression towards liver cirrhosis and portal hypertension. For this study, we characterized the cohort of Austrian HDV patients and their response to bulevirtide (BLV) treatment.

Aims & Methods: We included anti-HDV positive patients who visited one of six participating Austrian hepatology centers from 2020 onwards. At baseline (BL), demographic, clinical and laboratory data, endoscopy and imaging reports, liver stiffness measurement (LSM) and liver steatosis assessment (using controlled attenuation parameter, CAP) were recorded. If available, hepatic venous pressure gradient (HVPG) and histologic assessment of liver biopsies were included. In a subset of patients, single nucleotide polymorphisms (SNPs) in IL28B, PNPLA3, SERPINA1 and NTCP were assessed. Patients without BLV treatment were characterized at last contact. Patients who received treatment with BLV were evaluated for biochemical response (BR, defined by normalization of ALT), virological response (VR, negative HDV RNA PCR or ≥ 2 log decline in viral load), or combined response (CR, meeting both BR+VR) every 24 weeks (W24, W48, W72, W96).

Results: Overall, 84 anti-HDV positive patients were included (median age 45.5 years [IQR 37-56], 58.3% male, median BMI 25.0 [IQR 21.4-29.0]), of which 59 (70.2%) had detectable HDV RNA. Nine (10.7%) patients reported daily alcohol intake. Eleven (13.1%) patients were coinfecting with HIV and 17 (20.2%) had anti-HCV antibodies. A LSM ≥ 10 kPa was found in 36 (54.4% of 66) of patients and ≥ 25 kPa in 9 (13.6%).

Liver biopsy showed F4 fibrosis in 19 (52.8% of 36) of patients. Esophageal varices were found in 15/61 (15.4%) in endoscopy and 12/50 (19.4%) had signs of portal hypertension on imaging reports.

Median HVPG was 10 mmHg (IQR 6.75-15.5, n=28) and eleven (13.1%) patients were decompensated at baseline. Median MELD was 8 points (IQR 6-10). No polymorphisms were found regarding SERPINA1 or NTCP, while for PNPLA3 we found C/C n=15 (37.5%), C/G n=22 (55.0%) and G/G n=3 (7.5%); and for IL28B we found C/C n=17 [49.9%], C/T n=16 (43.2%) and T/T n=4 (10.8%).

Of 59 viremic patients, 50 were started on treatment with BLV (median treatment duration 17 [7.5-24] months). BR rates at W24, W48, and W96 were 27/46 (58.7%), 28/38 (73.7%), and 16/22 (72.7%). VR rates at M6, M12, and M24 were 15/46 (32.6%), 24/38 (63.2%), and 15/22 (68.2%). CR rates at M6, 12, and M24 were 10/46 (21.7%), 18/38 (47.4%), and 11/22 (50.0%). At W48 BLV treatment led to a decline of ALT ($p < 0.001$), HDV RNA ($p < 0.001$), and LSM ($p < 0.006$).

SNPs in either PNPLA3 or IL28B did not affect treatment outcomes. Ten patients who achieved clearance of HDV discontinued BLV, of which 4 relapsed and were restarted on BLV. Pegylated interferon alfa-2a was added to BLV treatment in 13 (26%) patients after a median of 10 (7-18) months. During follow-up, three (3.6%) patients – all without BLV treatment – were diagnosed with hepatocellular carcinoma and overall, five (6.0%) patients died, of which four deaths were liver-related.

Conclusion: Our Austrian HDV patient cohort showed a substantial burden of cirrhosis and signs of portal hypertension – still we observed high and steadily increasing rates of virologic and biochemical response to BLV treatment. Liver stiffness – as a surrogate of the risk for liver-related events – decreased significantly at W48.

Introduction: The current EASL and AASLD guidelines establish a risk of primary biliary cholangitis (PBC) development in patients with antimitochondrial antibodies (AMA) >1:40 and normal baseline alkaline phosphatase (ALP) of 16% after 5 years. However, this important data is based on a single retrospective study using questionnaires sent to responsible physicians, with only 66 patients.

Aims & Methods: Retrospective study of patients in our prospectively followed database with AMA >1:40 and normal baseline ALP. Analysis of the incidence of PBC development (elevated ALP on at least two occasions during follow-up along with elevated GGT) and associated risk factors. The date of the first AMA >1:40 was considered as the baseline. Patients with possible alternative causes of cholestasis, follow-up <2 years, and incomplete data were excluded.

Results: Since 2005, 559 patients were identified. 315 were excluded, mainly due to follow-up or incomplete data. In the 244 valid cases: mean age 64 years, 88.5% female, 10 visits, ALP 75.8 U/L, GGT 44.5 U/L, AMA titer 1:640, IgM 178 mg/dL. After a mean follow-up of 10.5 years, 84/244 developed PBC (34.4%; 95% CI: 28.8-40.6). Among them, 64/84 (76.2%) developed it in the first 3 years of follow-up. In the multivariate analysis using

Cox regression, baseline ALP values (>80 vs. ≤80 U/L; ULN 116), AST (≥34 vs. <34 U/L; ULN 34), and GGT (>40 vs. ≤40 U/L; ULN 40) were independently associated with the risk of PBC development, with an adjusted HR (95% CI) for age and gender of 2.45 (1.49-4.02, p<0.001), 1.97 (1.17-3.31, p=0.011), and 2.4 (1.28-4.51, p=0.006), respectively.

Conclusion: One-third of patients with AMA >1:40 and normal baseline ALP are susceptible to developing PBC after a 10-year follow-up. Baseline values of ALP, AST, and GGT are associated with this risk.

SERUM AUTOTAXIN AND FIBROBLAST GROWTH FACTOR-19 ARE BIOMARKERS OF LINERIXIBAT TREATMENT RESPONSE IN PATIENTS WITH CHOLESTATIC PRURITUS ASSOCIATED WITH PRIMARY BILIARY CHOLANGITIS

S. Mukherjee¹, L. Casillas¹, B. Swift², J. Fettiplace³, S. Das⁴, M.M. McLaughlin¹, A.E. Kremer⁵

Introduction: Cholestatic pruritus (itch) is common in primary biliary cholangitis (PBC) and is associated with significantly impaired quality of life. Lysophosphatidic acid (LPA) and bile acids may have a pathophysiological role in pruritus. Autotaxin (ATX) is the primary enzyme that produces LPA and is a surrogate for LPA levels. ATX activity correlates with itch intensity in PBC. Linerixibat is a minimally absorbed, small-molecule ileal bile acid transporter inhibitor that improves pruritus and reduces systemic bile acid levels, ATX, and fibroblast growth factor-19 (FGF-19), a downstream effector of farnesoid X receptor activation and regulator of bile acid biosynthesis.¹

Here, we analyze the association between itch response and changes in ATX and FGF-19 biomarker levels following linerixibat treatment.

Aims & Methods: The Phase 2b, placebo-controlled, dose-ranging GLIMMER study (NCT02966834) enrolled 147 adult patients with PBC and pruritus.¹ Patients were randomized to receive linerixibat or placebo for 12 weeks (Weeks 4-16).

Patients reported itch on a 0-10 numerical rating scale. As patient numbers were too low to analyze biomarkers in individual dose groups, the two twice daily (BID) dose groups, 40 and 90 mg BID, which showed a greater response in pharmacodynamic biomarkers compared to once daily dosing, were combined. Serum ATX and FGF-19 levels were compared post hoc in patients receiving linerixibat 40/90 mg BID or placebo, at baseline versus Week 16, in itch responders and non-responders.

Responder analysis from individual dose groups is not shown. Itch responders were defined as patients with a monthly itch score improvement of ≥2 at Week 16 compared with baseline.

Results: Patients treated with linerixibat 40/90 mg BID (n=45), or placebo (n=36) were included; baseline demographics have been reported previously.¹ Itch responders in the 40/90 mg BID group, but not in the placebo group, had greater reductions in serum ATX at Week 16 compared with baseline. In linerixibat-treated patients, ATX levels at Week 16 were reduced in itch responders compared to non-responders, and in comparison with placebo. Similarly, FGF-19 reduction was associated with itch response in patients receiving linerixibat 40/90mg BID compared with placebo.

Conclusion: Serum ATX and FGF-19 may function as biomarkers of itch response to linerixibat treatment. Reductions in these biomarkers are associated with clinical response in patients with PBC and pruritus.

Introduction: Metabolic dysfunction-associated steatotic liver disease (MASLD) can lead to fibrosis and cirrhosis. Assessment of fibrosis and steatosis via vibration-controlled transient elastography (VCTE) and controlled attenuation parameter (CAP) requires a dedicated device and time to obtain ≥ 10 reliable measurements.

Automated point shear wave elastography (Auto pSWE) allows for the collection of 15 ARFI based liver stiffness measurements (LSM) together with ultrasound derived fat fraction (UDFF) based steatosis assessment in a single acquisition.

Aims & Methods: This prospective study included patients who underwent liver biopsy - mostly during bariatric surgery - at the Vienna General hospital between 11/2021 and 12/2023. Paired Auto pSWE/UDFF and VCTE/CAP assessments of LSM and hepatic steatosis were performed within ± 90 days of liver biopsy.

Results: Among 134 patients (65% women, mean age: 42.6 $\pm$ 13.3 years) with a high prevalence of obesity (mean BMI: 42.7 $\pm$ 10.4), MASLD was the most common aetiology (88%). Median histologic fibrosis and steatosis

stages were F0 and S2. 68 (51%) and 36 (27%) patients had moderate steatosis ($\geq$ S2) and significant fibrosis ($\geq$ F2) on biopsy, respectively.

With Auto pSWE, 1x15 acquisitions were as accurate as using 5x15 acquisitions. Similarly, one UDFF measurement was as accurate as 5 UDFF measurements. Auto pSWE ($\geq$ F2, AUC=0.58; $\geq$ F3, AUC=0.96; F4, AUC=0.97) and VCTE ($\geq$ F2, AUC=0.60; F3, AUC=0.92; F4, AUC=0.93) showed moderate diagnostic accuracy for lower fibrosis stages and high diagnostic accuracy for higher fibrosis stages. There was no statistical difference between the diagnostic accuracy of UDFF ($\geq$ S1, AUC=0.79; $\geq$ S2, AUC=0.78; S3, AUC=0.67) and CAP ($\geq$ S1, AUC=0.80; $\geq$ S2, AUC=0.78; S3, AUC=0.66). The median time for a single VCTE measurement was 2.47 minutes (IQR 1.44-5.38), while a single composite acquisition of Auto pSWE/UDFF takes eight seconds and is integrated into standard ultrasound devices.

Conclusion: Auto pSWE and UDFF represent accurate non-invasive tests for liver fibrosis and steatosis assessment in MASLD patients, including those with severe obesity. Importantly, 15 individual LSM can be acquired using Auto pSWE simultaneously with UDFF in a single acquisition, saving valuable time without the need for a dedicated device.

Introduction: While biologic agents and small molecules have revolutionized inflammatory bowel disease (IBD) treatment, concerns persist regarding their usage in patients with a history of malignancy due to potential impact on cancer development or recurrence.

There remains a notable gap in understanding their utilization in this setting, especially concerning newer agents like ustekinumab, vedolizumab, and small molecules.

Aims & Methods: We aimed to study clinicians' views on using biologic therapy in IBD patients with extracolonic cancer, focusing on whether to continue or stop treatment and analysing factors influencing their decisions. We also aimed to describe clinical characteristics of this group of patients.

IBD patients under biologics or small molecules at the time of cancer diagnosis in ENEIDA registry, a prospectively maintained database from GETECCU, were included. Variables included demographic and clinical data, biologic drugs received, and start/discontinuation dates.

Additional information on oncologic history and IBD treatment changes after cancer diagnosis were collected directly from investigators. Main variable was the discontinuation of biologics/small molecules due to the diagnosis of cancer. Logistic regression analysis was used to identify factors associated with biologics/small molecules discontinuation due to cancer diagnosis.

Results: 1,386 patients with extra-colonic malignancies receiving biologics or small molecules were identified from ENEIDA registry. From this cohort, we identified 467 patients that were under biological treatment at the time of cancer diagnosis. Demographic and clinical characteristics revealed a median age at IBD diagnosis of 38 years, with 61% males. Crohn's disease accounted for 71% of cases. The most common cancer types were non-melanoma skin cancer (26%) and haematological neoplasms (14%), followed by nefrourotelial cancers, breast cancer, prostate cancer and melanoma. Vedolizumab, ustekinumab and small molecules represented 15% of the patient cohort, while anti-TNF were the most prevalent biologics at cancer diagnosis. Before cancer diagnosis, 40% patients had received previous biological drugs, while 60% were receiving their first biologic therapy.

Clinical decisions post-cancer diagnosis included discontinuing biological treatment (56%) and no changes in treatment (44%) as described in table 1. Multivariate analysis showed significant differences in discontinuing biologic therapy depending on neoplasm origin and type of biologic treatment. While patients with non-melanoma skin cancer were more likely to continue with biologic therapy after having an extracolonic cancer diagnosis, other types of cancer led clinicians to discontinue treatment more frequently (Table 2). We also observed that the probability of maintaining biological treatment was significantly higher in patients receiving ustekinumab and vedolizumab compared with anti-TNF agents. No significant differences were found based on the type of IBD, number of biologic treatments received before cancer diagnosis, sex and age at cancer diagnosis.

Biological treatment when diagnosed with cancer	No changes in biological treatment	Discontinuation of biological treatment
Anti-TNF agents	158 (39.8%)	239 (60.2%)
Ustekinumab	20 (66.7%)	10 (33.3%)
Vedolizumab	24 (68.6%)	11 (31.4%)
Type of extracolonic cancer		
Non melanoma skin cancer	105 (86.8%)	16 (13.2%)
Hematologic neoplasms	8 (12.3%)	57 (87.7%)
Nefro-urologic neoplasms	20 (43.5%)	26 (56.5%)
Breast cancer	7 (15.9%)	37 (84.1%)
Prostate cancer	9 (28.1%)	23 (71.9%)
Melanoma	4 (23.5%)	13 (76.5%)
Other cancers	51 (35.9%)	91 (56.3%)
Probability of discontinuation biological treatment	OR (95% CI)	
Depending on biological treatment		
Ustekinumab vs Anti-TNF	0.24 (0.10-0.60)	
Vedolizumab vs Anti-TNF	0.18 (0.08-0.41)	
Depending on cancer origin		
Hematologic neoplasms vs. non-melanoma skin cancer	59.9 (23.2-154.9)	
Breast cancer vs. non-melanoma skin cancer	33.1 (12.4-88.2)	
Melanoma vs. non-melanoma skin cancer	22.2 (6.1-80.8)	
Prostate cancer vs. non-melanoma skin cancer	18.7 (7.1-48.9)	
Other cancers vs. non-melanoma skin cancer	13.3 (7.0-25.3)	
Nefro-urologic neoplasms vs. non-melanoma skin cancer	11.1 (4.9-25.2)	

Table 1.

Conclusion: In real life, over 50% of IBD patients discontinue biologics/ small molecules when extracolonic cancer is diagnosed. The likelihood of treatment discontinuation is higher with anti-TNF agents than with more recently approved drugs (such as vedolizumab or ustekinumab). The type of cancer has great impact on the decision of treatment discontinuation. Management of IBD in patients diagnosed with cancer remains a challenge.

Disclosure: Nothing to disclose.

Introduction: Several histopathological features have been identified as risk factors for postoperative recurrence (POR) in Crohn's disease (CD) including active inflammation, submucosal plexitis and transmural inflammation.

Furthermore, granulomas and myenteric plexitis have been included as risk factor for POR in the current international guidelines. However, these factors have been identified in predominantly retrospective and older studies without adjustment for clinical risk factors.

Aims & Methods: This study aimed to assess the association between these histopathological features and early postoperative endoscopic recurrence in a large prospective, multicenter cohort study.

CD patients (≥16 years) scheduled for ileocolic (re-)resection (ICR) and those who underwent an ileocolonoscopy at 6 months following ICR were included. Primary outcome of the study was early postoperative endoscopic recurrence (ePOR)(modified Rutgeerts' score ≥ i2b at 6 months).

Proposed histopathological risk factors for postoperative recurrence were assessed in the ileal and colonic resection margins by expert pathologists blinded for clinical risk factors and outcome. Uni- and multivariable logistic regression was performed to explore the association of the histopathological features.

Results: In total, 293 patients (60% female; median age 33.3 years; primary resection 79%) underwent an ICR after a median disease duration of 5.2 (IQR 0.9–12.4). ePOR was observed in 37% of patients. At ICR, active smoking at surgery was reported in 22%. Isolated ileal location (64%) and stricturing disease (53%) were the most common disease location and behaviour at surgery. Postoperative prophylactic medication was initiated in 30% of patients (immunomodulator [IMM] 25%, anti-TNF agent with or without IMM 56%, vedolizumab 5% and ustekinumab 15%).

Active inflammation, transmural inflammation, myenteric plexitis, submucosal plexitis and granulomas were reported at the ileal resection margin in 29%, 9%, 14%, 16% and 4%.

At the colonic resection margin, the above mentioned parameters were reported in 9%, 2%, 7%, 8% and 3%. Univariate analyses identified associations for moderate to severe inflammation at the ileal (OR 2.3; 95%CI 1.3-4.0) and colonic resection margin (OR 3.7; 95%CI 1.3-10.3), submucosal plexitis at the ileal resection margin (OR 1.9; 95%CI 1.0-3.5) and transmural inflammation at the colonic resection margin (OR 10.7; 95%CI 1.3-90.5) (Table 1).

Length of resection specimen (in cm)	1.0 (1.0 - 1.0; 0.05)	1.0 (1.0 - 1.0; 0.41)
Postoperative prophylactic medication	0.4 (0.2 - 0.6; <0.01)	0.3 (0.2 - 0.7; <0.01)

Table 1.

Abbreviations. OR = odds ratio; aOR = adjusted odds ratio; REF = reference. * variables with a p-value <0.25 in univariable analysis were entered in multivariable analysis

In multivariable analysis, moderate to severe inflammation (aOR 4.6; 95%CI 1.1-19.5) at the colonic resection margin was associated with ePOR. No other histopathological features were significantly associated with ePOR in multivariable analysis. Active smoking was identified as risk

factor (aOR 2.8; 95%CI 1.4-5.6), whereas postoperative prophylactic medication (aOR 0.3; 95%CI 0.2-0.7) and ileocolic disease at time of surgery (aOR 0.3; 95%CI 0.2-0.7) were identified as protective factors.

Conclusion: In this study, a predictive value of histopathological features in ICR specimens of CD patients for early POR has not been confirmed, with the exception of moderate to severe inflammation at the colonic resection margin.

Therefore, there is a strong need for new biomarkers to adequately predict POR in patients with Crohn's disease.

Introduction: Pneumococcal vaccination is essential in IBD patients. However, its efficacy in patients on immunosuppressive or anti-TNF therapy is much lower than in the normal population (45% vs 80%). Vaccine regimen recommendations vary according to the degree of immunodepression.

The aim of our study was to identify an optimal vaccination strategy for immunocompromised IBD patients treated with anti-TNF, vedolizumab and/or IS.

Aims & Methods: This is a prospective, multicenter, randomized study comparing two vaccine regimens: intensified vaccine strategy (Prevenar13®/Prevenar13®/PSV-23® (or Pneumovax as a replacement for PSV-23) vs. normal strategy (Prevenar13®/PSV-23® (or Pneumovax as a replacement for PSV-23), (randomization 1: 1) on vaccine immunogenicity measured by antibody titer against at least 9 of the 13 pneumococcal serotypes contained in Prevenar13®.

Any patient with confirmed IBD under biotherapy (anti TNF with or without immunosuppressive drugs or Vedolizumab) and in clinical remission (HBI <4 for CD and partial Mayo Score <3 for UC) was included. Vaccination and vaccine monitoring were carried out by the vaccination center of each center, with adverse events reported at each visit (8 for 36 months of follow-up), and ELISA and OPA serotype assays systematically collected and clinical activity was reported by the gastroenterologist at the same time. Correlate of protection in adults using serology testing was classically defined as at least 9 out of 13. Serotypes > 1 µg/mL. For functional testing of antibodies using the Opsonophagocytic assays, we apply the well-defined 4 times increase of titer between pre and post-vaccination against at least 70% of serotypes. *ClinicalTrials.gov Identifier: NCT02255227*

Results: 51 patients in the normal vaccination arm and 53 in the intensified vaccination arm were included (mean age: 42.9 years, male: 63%, CD: 68%, active smoking: 21%, duration of IBD: 10.2 years, 98% IBD inactive). Around 88% of patients were under anti-TNF monotherapy (28% on combotherapy) and 12% under vedolizumab. Serology criteria for good responders at M5 were 57.5% for the intensified regimen vs 25.6% for the standard regimen (RR: 2.25 (1.26;4.00), $p = 0.003$). For OPA correlate of protection, vaccine response was significantly greater in the intensified arm at all-time points: M5 (96% vs. 89%), M12 (76 vs. 58%) and M36 (68% vs. 36.8%). In multivariate analysis, two factors reduced vaccine response: anti-TNF use (RR: 6.84; CI95: 1.01-46.1; $p=0.048$) and CD type (RR: 9.48; CI95: 2.74-32.8; $p:0.0004$).

The tolerability of the vaccine regimens was comparable throughout follow-up. In terms of IBD activity, percentage of clinical relapse was similar during follow-up (16.8% under the intensified regimen versus 25% under the normal regimen ($p:NS$)).

Conclusion: In IBD on biotherapy and/or IS, the intensified pneumococcal vaccine regimen (2 injections of Prevenar followed by one of Pneumo 23) is significantly more immunogenic than a standard regimen, especially when using functional correlate of protection. The duration of the response is also greater in this intensified arm.

Introduction: Resection rates for Crohn's disease (CD) have decreased over time, while re-resection rates have remained stable at about one-third in historic cohorts. Medical treatment has been shown to influence the course of the disease.

Aims & Methods: We aimed to assess the impact of disease burden categorization on medication use and risk factors. This cohort study encompassed all CD patients undergoing primary intestinal resection in Eastern Denmark from 2010 to 2020 (46% of the Danish population, $n=2,730,000$).

We isolated all patients with five years follow up and divided them into three groups based on post-operative disease burden: high (one or more resections after the initial resection), intermediate (recurrence without need for resection), and low (no recurrence within five years). Disease recurrence was defined based on colonoscopy (SES-CD ≥ 3 , Rutgeerts score

≥ 2), inflammation or stenosis on imaging (MRI, CTA, IUS), fecal calprotectin ≥ 250 mg/kg, starting corticosteroids or re-resection due to disease activity. Medication was classified by potency, with each patient assigned to only one category (no therapy<corticosteroids<immunomodulators<biologics). We used nonparametric statistics and the Kruskal-Wallis test to compare outcomes across groups.

Results: Primary resection was performed on 631 patients due to disease activity. Patients were categorized into burden groups: high burden ($n=59$), intermediate ($n=287$), and low ($n=170$). The median age at diagnosis was 28.2 years (range: 21.6-43.9), with no significant differences between the three disease burden groups ($p=0.069$). Age at primary resection differed across groups: 38 years (25-53) for high burden, 32 (24-45) for intermediate, and 36 (27-47) for low burden ($p=0.019$). Smoking rates were highest in the high burden group (47%) versus intermediate (37%) and low (27%) ($p=0.010$).

Pre-resection medical consumption was similar across the three burden groups ($p=0.2$). Postoperatively, the high burden group used more biologics (54%) compared to the low burden group (16%). Additionally, 57% of the low burden group remained recurrence-free and unmedicated for five years (Table 1).

In the high burden group, no patients received prophylactic biologics, compared to 8% in the intermediate and low burden groups ($p=0.001$). Disease location varied: colon resections were most common in the high burden group (31%), and small bowel disease, including ileocecal resections, predominated in the low burden group (47%) ($p<0.001$). Strictures were more common in the intermediate and low burden groups, while luminal disease was mostly seen in the high-risk group ($p=0.046$) (Table 1)

	High N = 59	Intermediate N = 287	Low N = 170	p-value
After resection, biological therapy	32 (54%)	108 (38%)	28 (16%)	<0.001
After resection, immunomodulators	8 (14%)	106 (37%)	45 (26%)	
After resection, no therapy	14 (24%)	56 (20%)	97 (57%)	
L1 ileal	20 (34%)	119 (41%)	80 (47%)	<0.001
L2 colonic	18 (31%)	19 (6.6%)	12 (7.1%)	
L3 ileocolonic	21 (36%)	149 (52%)	78 (46%)	
B1 non-stricturing, non-penetrating	19 (32%)	43 (15%)	23 (14%)	0.046
B2 stricturing	32 (54%)	179 (62%)	108 (64%)	
B3 penetrating	8 (14%)	64 (22%)	38 (22%)	

Table 1. Medical characteristics and Montreal classification.

Conclusion: High burden patients relied more on biologics, while half of the low burden patients stayed recurrence-free unmedicated for five years, suggesting tailored treatments could improve post-resection CD management.

Disclosure: Nothing to disclose.

LONG-TERM FOLLOW-UP OF PROTDILAT STUDY; LONG-PROTDILAT. SELF-EXPANDABLE METAL STENTS (SEMS) VERSUS ENDOSCOPIC BALLOON DILATION (EBD) FOR THE TREATMENT OF STRICTURES IN CROHN'S DISEASE: AN OPEN-LABEL, MULTICENTRE, RANDOMISED TRIAL

Introduction: The PROTDILAT study (Loras et al. Lancet Gastroenterol Hepatol. 2022) at 1-year follow-up showed greater efficacy of EBD vs SEMS for the treatment of short strictures in CD.

However, long term efficacy of endoscopic treatment is still debated, especially for EBD.

Aims & Methods: Aims: To assess the long-term evolution of patients included in PROTDILAT study.

1. Percentage of patients free of surgery;
2. Factors related to surgery;
3. Need for endoscopic retreatments;
4. Effectiveness related to the type of initial endoscopic treatment (EBD vs SEMS);
5. Complications related to endoscopic or surgical treatment.

Methods: Retrospective study based on PROTDILAT trial database (patients with CD, obstructive symptoms, with stenosis <10cm). Data on medical, endoscopic and surgical treatment and smoking habits were collected. The effectiveness of endoscopic treatment is defined by the percentage of patients free of surgery and endoscopic retreatment at the end of follow-up.

Results: Information available on 80/80 patients (39 SEMS, 41 EBD), 39 women, age (median): 45y (IQR: 38-55); median stricture length 3.4cm (IQR: 2-5.5), 42.5% being anastomotic. Thirty-one percent (25/80) of patients required surgical resection [(median time to surgery 30.61 months (6.35-55.24)). Factors associated to surgery: non-intensification of therapy (HR 0.26 (0.10-0.68)), treatment with EBD exclusively (HR 0.22 (0.08-0.58)) (with respect to treatment with EBD + SEMS) and number of stents (HR 2.31 (1.10-4.84)). Of the 55 patients free of surgery, during the entire follow-up (median 84 months (74.7-84.0)), a median of 2 endoscopic procedures (1-3) were performed: EBD in 45 cases (80.0%) and SEMS in 26 cases (46%). Thirty-eight-point seventy-five percent (31/80 patients) did not require neither surgery nor endoscopic retreatment during the follow-up. The long-term effectiveness of endoscopic treatment was 45% for SEMS and 57.6% for EBD (p=0.374). The complications related to endoscopic or surgical treatment were 8.75% (7/80) versus 36% (9/25) respectively (p=0.002). As for the severity of complications (AGREE/CLAVIEN-DINDO ≥ III), it was observed that surgical treatment presented more severe complications than endoscopic treatment (Endoscopic vs surgical treatment: 38% (3/8) vs 84% (10/12), p=0.011).

Conclusion: Endoscopic treatment (predominantly EBD) avoids surgery in most cases, requiring a low number of endoscopic treatments in the long-term. Patients at higher risk for surgery are those with a greater number of endoscopic treatments that include SEMS and EBD. On the contrary, protective factors are non-intensification of therapy and having been treated exclusively with EBD. Although there are no significant differences in the long effectiveness between SEMS and EBD, a trend for a better outcome is observed for EBD. To highlight a significant higher rate of complications observed in surgical treatment compared to endoscopic treatment.

Introduction: Mirikizumab is a humanized immunoglobulin G4 monoclonal antibody against the p19 subunit of interleukin-23, a key inflammatory mediator in ulcerative colitis (UC). Here we report efficacy and safety in pediatric patients with moderate to severe UC from the Phase 2 SHINE-1 study (NCT04004611) following 52 weeks of mirikizumab treatment.

Aims & Methods: Patients aged 2 to <18 years with active UC who had an inadequate response, loss of response, or intolerance to corticosteroids, immunosuppressants, or biologic therapies, or had corticosteroid-dependent colitis, were included in the study. Patients weighing >40 kg received an induction dose of 300 mg via intravenous infusion; patients weighing ≤40 kg received 5 or 10 mg/kg via intravenous infusion at weeks 0, 4, and 8. At week 12, patients were assessed for clinical response using the Modified Mayo Score. Responders entered the maintenance period and received subcutaneous doses of mirikizumab at 200 mg (>40 kg), 100 mg (>20 kg to ≤40 kg), or 50 mg (≤20 kg) once every 4 weeks, with the last patient visit at week 52.

Results: All patients (N=26) completed induction through week 12, and 73.1% (N=19) completed through week 52. At week 12, 69.2% (18/26) were Modified Mayo Score responders; at week 52, 55.6% (10/18) of responders were in clinical and endoscopic remission. Clinical response, remission, and endoscopic remission rates were consistent with LUCENT Phase 3 UC adult studies.

The safety profile of mirikizumab was consistent with the safety profile in LUCENT adults. Three serious adverse events (11.5%) were reported: non-infective appendicitis, UC flare, and pseudarthrosis. The UC flare resulted in study discontinuation.

Conclusion: Mirikizumab demonstrated an acceptable safety profile, and similar clinical response, clinical remission, and endoscopic remission compared to LUCENT adults. These results are the foundation of the pivotal Phase 3 pediatric SHINE-2 study.

Introduction: The efficacy of IL-23 blockade has implicated IL-23 in the pathogenesis of inflammatory bowel disease (IBD) and myeloid cells that express FcγRI (CD64) have been identified as the primary cellular source of IL-23 in inflamed IBD gut tissue [1, 2]. Guselkumab (GUS), risankizumab (RZB), and mirikizumab (MIRI) are monoclonal antibodies (mAbs) specifically directed against the IL-23p19 subunit. GUS is a fully human IgG1 mAb, RZB is a humanized IgG1 mAb, and MIRI is a humanized IgG4 mAb. Guselkumab has a native Fc domain while RZB and MIRI contain mutations in the Fc domain that diminish binding to FcγRs.

Aims & Methods: Here, we evaluated CD64 and IL-23 transcript expression in IBD patient gut biopsies, binding of GUS, RZB, and MIRI to IL-23 and CD64, and their potency for neutralization of recombinant or endogenous, locally produced, IL-23 in *in vitro* assays. *IL23A*, *IL12B*, and *FCGR1A* (CD64) expression was analyzed from bulk and single-cell RNA sequencing datasets. IL-23 binding affinity was evaluated using a kinetic exclusion assay. Binding of GUS, RZB, and MIRI to CD64 was assessed in cells with recombinant expression of CD64. Potency for inhibition of recombinant IL-23 was evaluated by impact on IL-23-induced phosphorylation of signal transducer and activator of transcription 3 (pSTAT3) in human peripheral blood mononuclear cells. Potency for inhibition of endogenous, locally produced IL-23 was determined in a co-culture of THP-1 (a CD64⁺ monocyte cell line activated to produce IL-23) and an IL-23 reporter cell line (measuring biologically active IL-23).

Results: Analysis of bulk and single cell RNA sequencing datasets showed that *FCGR1A*, *IL23A*, and *IL12B* were significantly increased in inflamed versus non-inflamed IBD gut biopsies, and that *IL23A* was predominantly expressed by *FCGR1A*-expressing myeloid cells. GUS, RZB, and MIRI displayed single-digit picomolar binding affinity for IL-23. GUS demonstrated binding to CD64, while no binding was observed for RZB or MIRI. GUS, RZB, and MIRI demonstrated comparable potency for inhibition of signaling by recombinant IL-23 in human PBMCs.

However, in a co-culture of IL-23–producing CD64⁺ THP-1 cells with an IL-23–responsive reporter cell line, GUS demonstrated enhanced potency compared to RZB and MIRI for inhibition of IL-23 signaling.

Conclusion: Our transcriptomic analysis supported previous observations of CD64⁺ myeloid cells as a key source of IL-23 production in inflamed IBD gut tissue. GUS binding to CD64 on IL-23–producing cells likely contributed to the enhanced functional potency of GUS compared to RZB and MIRI for inhibition of IL-23 signaling in the co-culture assay. These *in vitro* data support a hypothesis for optimal localization of GUS in inflamed tissues where CD64⁺ IL-23–producing myeloid cells are increased and in proximity to IL-23–responsive lymphoid cells, enabling GUS to more potentially neutralize IL-23 at its source of production.

Contact E-Mail Address: christopher.ma@ucalgary.ca

Introduction: Tumor necrosis factor–like cytokine 1A (TL1A) is a regulator of inflammation and fibrosis in inflammatory bowel disease. Tulisokibart, an anti-TL1A monoclonal antibody, demonstrated efficacy without clinically meaningful safety findings vs placebo after a 12-week induction

period in adults with moderately to severely active UC in the phase 2 ARTEMIS-UC study.¹ We report long-term efficacy and safety of tulisokibart among cohort 1 induction responders from the open-label extension (OLE) period of ARTEMIS-UC.

Aims & Methods: ARTEMIS-UC was a phase 2, multicenter, double-blind, placebo-controlled study of tulisokibart in patients with moderately to severely active UC. Cohort 1 enrolled patients regardless of genetic-based diagnostic test (Dx) status whereas cohort 2 enrolled only Dx-positive patients. Patients were randomized to receive intravenous (IV) tulisokibart 1000 mg on day 1 and 500 mg at weeks 2, 6, and 10 or placebo; after the 12-week induction period, all participants had the option to continue in the OLE period.

Participants were classified as induction responders (defined as reduction of ≥ 2 points and $\geq 30\%$ in modified Mayo score from baseline, accompanied by a reduction ≥ 1 in rectal bleeding subscore or absolute rectal bleeding subscore ≤ 1 at week 12) or induction nonresponders. Cohort 1 induction responders in the tulisokibart group were randomized (stratified by Dx status) to receive open-label IV tulisokibart 100 mg or 250 mg every 4 weeks at week 14 until week 170.

We report data from cohort 1 through week 50 of the OLE period: clinical and endoscopic efficacy outcomes and biomarkers through week 50 are reported for cohort 1 induction responders from the tulisokibart group whereas safety through week 50 are reported for cohort 1 induction responders from both the tulisokibart group and the placebo group. Descriptive statistics were used to summarize observed data.

Results: 47 of 68 tulisokibart-treated patients in cohort 1 were induction responders and were randomized to receive tulisokibart 250 mg (n = 25) or 100 mg (n = 22). Improvements in clinical, endoscopic, and biomarker outcomes observed with tulisokibart were generally maintained through week 50 in both dose groups (Table).

	Week 12 Tulisokibart Induction (n = 68)	Week 50 Tulisokibart 100 mg (n = 22)	Week 50 Tulisokibart 250 mg (n = 25)
Clinical remission, ^a %	26	32	48
Endoscopic improvement, ^b %	37	36	48
Clinical response, ^c %	66	59	68
Symptomatic remission, ^d %	19	23	32
Histologic-endoscopic mucosal improvement, ^e %	n = 65 31	n = 15 47	n = 20 50
High-sensitivity C-reactive protein fold change from baseline, geometric LS mean (95% CI)	n = 65 0.56 (0.48–0.66)	n = 17 0.51 (0.22–1.19)	n = 24 0.56 (0.26–1.19)
Fecal calprotectin fold change from baseline, geometric LS mean (95% CI)	n = 54 0.21 (0.16–0.27)	n = 13 0.28 (0.09–0.88)	n = 17 0.27 (0.10–0.77)

LS least squares; mMS, 3-component modified Mayo score.
^aClinical remission per mMS was defined as endoscopic subscore of 0 or 1, rectal bleeding subscore of 0, and stool frequency subscore of 0 or 1 and not greater than baseline.
^bEndoscopic improvement was defined as endoscopy subscore ≤ 1 with no friability.
^cClinical response per mMS was defined as reduction from baseline ≥ 2 points and $\geq 30\%$ in mMS, accompanied by a reduction ≥ 1 in rectal bleeding subscore or absolute rectal bleeding subscore ≤ 1 .
^dSymptomatic remission was defined as stool frequency subscore of 0 and rectal bleeding subscore of 0.
^eHistologic-endoscopic mucosal improvement was defined as Geboes score ≤ 3.1 and endoscopy subscore ≤ 1 .

Table. Clinical, endoscopic, and biomarker outcomes at week 12 in the cohort 1 tulisokibart group and at week 50 among cohort 1 induction responders in the tulisokibart group.

However, at week 50, a greater proportion of patients achieved clinical and endoscopic outcomes with tulisokibart 250 mg vs 100 mg. In the safety population, (tulisokibart 250 mg, n = 35; 100 mg, n = 30), through week 50, AEs occurred in 63% and 77% of patients receiving tulisokibart 250 mg

and 100 mg, respectively; most were mild to moderate in severity. Serious AEs occurred in 1 patient (3%) and two patients (7%) in the tulisokibart 250 mg and 100 mg groups, respectively.

Conclusion: At week 50, maintenance of treatment effect was generally observed in cohort 1 induction responders in the tulisokibart group. A trend for higher efficacy with tulisokibart 250 mg vs 100 mg maintenance treatment was observed at week 50. Tulisokibart was well tolerated with no identified safety signals. Larger trials are needed to confirm these findings.

Introduction: Obefazimod is an investigational, oral, once-daily, small molecule which enhances expression of microRNA-124 and is currently in phase 3 clinical trials for the treatment of patients with moderately to severely active ulcerative colitis (UC) [1]. Obefazimod demonstrated efficacy and safety in patients with UC at week-8 in a placebo-controlled, Phase 2b induction trial and in the subsequent open-label maintenance (OLM) study [2]. Here we present efficacy and safety among patients who did and those that did not achieve clinical response at week 8 of the double-blind induction trial.

Aims & Methods: Patients received placebo or obefazimod 25mg, 50mg or 100mg once daily (od) during the Phase 2b, induction trial and, irrespective of their clinical response, could enter the optional 96-week OLM study with obefazimod 50mg od. Patients were followed monthly for safety and efficacy. This analysis evaluates efficacy (at week 48) and safety (through week 96) among patients who achieved and those who did not achieve clinical response (decrease from baseline in the Modified Mayo score (MMS) ≥ 2 points and $\geq 30\%$ from baseline, plus a decrease in rectal bleeding sub-score (RBS) ≥ 1 or an absolute RBS ≤ 1) at week 8 of double-blind induction and continued treatment in the OLM.

Results: Among the 217 patients who participated in the OLM, 57% (124/217) achieved clinical response at week 8 of the induction trial (CR group), and 43% (93/217) did not (NCR group). Proportions of patients achieving efficacy endpoints were numerically higher within the CR group than those observed in NCR group. At week 48, 66% of CR patients and 40% of NCR patients achieved clinical remission; 86% of CR patients and 75% of NCR patients achieved clinical response; endoscopic improvement was achieved by 70% of CR patients and by 50% of NCR patients, and endoscopic remission was achieved by 38% of CR patients and 27% of NCR patients (Table 1). There was no significant difference in the safety profile between these two subpopulations.

Efficacy Endpoint, % (n)	Patients with clinical response at week 8 (N=124)	Patients with no clinical response at week 8 (N=93)
Clinical remission	66.1 (82)	39.8 (37)
Clinical response	86.3 (107)	75.3 (70)
Endoscopic improvement	70.2 (87)	49.5 (46)
Endoscopic remission	37.9 (47)	26.9 (25)

Table 1: Efficacy at week 48 of open-label maintenance study among clinical responders and non responders at week 8 of induction trial

Non-responder imputation (NRI) was used for missing efficacy data; clinical remission: stool frequency sub-score ≤ 1 , RBS = 0 and endoscopic sub-score ≤ 1 ; clinical response: decrease from baseline in the Modified Mayo score (MMS) ≥ 2 points and $\geq 30\%$ from baseline, plus a decrease in rectal bleeding sub-score (RBS) ≥ 1 or an absolute RBS ≤ 1 ; endoscopic improvement: endoscopic sub-score ≤ 1 ; endoscopic remission: endoscopic sub-score = 0

Conclusion: Substantial proportions of patients treated with obefazimod 50 mg od achieved clinical outcomes at week 48 of an open label maintenance study, irrespective of whether they achieved clinical response at week 8 of the prior induction trial. Patients achieving clinical response at week 8 of the induction trial consistently showed higher efficacy rates throughout the 48-week open-label maintenance trial. The safety profile remains consistent over time, regardless of treatment response at week 8.

Introduction: JAK inhibitors have become an efficacious oral treatment option to antibody-based therapies for ulcerative colitis (UC). However, they have received a black box warning by the FDA for causing serious systemic adverse events.

To increase safety, OST-122 is being developed as an orally administered, GI-targeted and non-systemic JAK3/TYK2 inhibitor for the local treatment of UC. In preclinical models and in healthy volunteers, OST-122 has demonstrated excellent safety and tolerability with minimal systemic exposure reducing the risk of causing serious systemic toxicities associated with current JAK inhibitors.

Here, we report the results of a phase 2a study in patients with UC on the safety, tolerability, pharmacokinetics and preliminary efficacy of OST-122.

Aims & Methods: In this randomized, double-blind trial, 37 adult patients with active UC were treated with oral OST-122 400 mg (n=28) or placebo (n=9) for 28 days. Eligibility criteria required a total Mayo Score TMS 5-10, endoscopic Mayo Score EMS ≥ 2 , inadequate/loss of response to conventional therapy (5-ASA, steroids, immunomodulators) or biologics (anti-TN- α , anti-integrin, anti-interleukin 12/23). Stable cotreatment with oral 5ASAs and corticosteroids was permitted.

To evaluate the safety and tolerability of OST-122, the number and severity of AEs, including changes in vital signs, safety laboratory values and ECGs, were analyzed. Plasma, tissue and stool samples were collected at various time points to examine the gut-restricted pharmacokinetic profile of the compound in UC patients. Preliminary efficacy was assessed through Mayo Clinical Scores including rectal bleeding (RB) and stool frequency (SF) along with clinical response and remission.

Results: During the 6-week observation period, no serious AEs nor treatment-related AEs leading to discontinuation were reported. Most AEs were tabulated as mild, followed by moderate, and the number of subjects reporting AEs were distributed equally in the placebo and OST-122 group (78% vs. 71%). There were no clinically relevant changes in vital signs, laboratory values or ECG parameters which raise any safety concerns.

Pharmacokinetic analysis indicated minimal plasma concentrations (C_{max} 0.92 ng/mL) and therapeutically relevant levels in colon tissue (15.5 $\mu\text{g/g}$ tissue) confirming a gut-restricted PK profile of OST-122.

Preliminary efficacy data after 28 days of treatment are summarized in the table below:

Outcome	400 mg OST-122 (n=28)	Placebo (n=9)	Δ
Rectal Bleeding			
Improvement of RB score by ≥ 1	63% (17/27)	33% (3/9)	33%
Stool Frequency			
Improvement of SF score by ≥ 1	52% (14/27)	33% (3/9)	19%
PRO-2 score (RB + SF)			
Improvement of PRO-2 by ≥ 2	48% (13/27)	11% (1/9)	37%
Clinical Response			
Decrease of TMS by ≥ 3 or $\geq 30\%$, plus improvement in RB by ≥ 1 and an absolute RB of 0 or 1	44% (12/27)	11% (1/9)	33%
Clinical Remission			
TMS ≤ 2 and no individual subscore >1 , plus RB of 0	22% (6/27)	0% (0/9)	22%

Table.

63% of patients taking OST-122 showed an improvement in rectal bleeding and 52% in stool frequency (vs 33% in the placebo group), and 48% had an improvement of ≥ 2 in PRO-2 (RB+SF, vs 11% Pbo). Clinical response was achieved by 44% (vs 11% Pbo) and 22% reached clinical remission (vs 0% Pbo). In addition, 16% of patients in the OST-122 group achieved both histological response and remission (vs 0% Pbo). A subgroup analysis showed that OST-122 was able to induce clinical response both in bio-naïve and bioexperienced patients. Confirmatory studies will be designed to determine dose and statistical significance.

Conclusion: GI-restricted OST-122 was well tolerated during the 4-week treatment. Its excellent safety profile, minimal systemic exposure and promising trends of clinical activity may provide a safer therapeutic option for a broad range of ulcerative colitis patients.

Introduction: Pancreas inflammation is frequently brought on by sustained intraductal pressure, which is mostly caused by gallstones or ERCP, a minimally invasive diagnostic technique. It has been demonstrated that in mice, this brief pressure reduces tight junction integrity through calcineurin. Another effector protein of intraluminal pressure is the mechanosensitive Ca²⁺ channel PIEZO1, which senses cell elongation, increases Ca²⁺ influx, and hence controls both epithelial cell division and apoptosis.

However, the development of treatment approaches that specifically target post-ERCP and gallstone-induced pancreatitis has been hampered in recent years due to challenges in *in vitro* modeling of pressure-related changes.

Aims & Methods: Therefore, our *aim* was to use apical-out organoids (hPOCs) generated from human pancreas to demonstrate the pressure-related disease processes *ex vivo*.

Pancreatic tissue samples were collected from 3 cadaver donors and used for establishment of hPOCs. Polarity switching of organoids was induced by Matrigel removal. Conventional and apical-out hPOCs were compared by RNA-sequencing and fluorescent live cell imaging. Gene expression changes in response of 1 µM PIEZO1 activator (YODA1) treatment were measured by qRT-PCR in apical-out hPOCs.

Results: Polarity switching reduced PIEZO1 expression, although decreasing intraluminal pressure and therefore cell elongation reduced expression of cytoskeletal and cell cycle related genes such as ACTB, VCL, LPXN, LMNA, and cyclin gene family members. In the same experiment, pro-inflammatory cytokines like CXCL1, CXCL2, CXCL3, and CXCL8 were found to be downregulated. We demonstrated that polarity switching resulted in enhanced Cl⁻ efflux via CFTR and ANO1 due to the absence of sustained intraluminal pressure maintained by basal secretion in the closed lumen of conventional organoids.

The production of pro-inflammatory cytokines in apical-out hPOCs was reversed upon pharmacological activation of PIEZO1 by YODA1, indicating that PIEZO1 is responsible for the development of the inflammation-like pre-stimulated phenotype of apical-in hPOCs.

Conclusion: Altogether, our results suggest that conventional organoid cultures, previously used as physiologically relevant models, may represent a pressure-induced inflammatory state by overexpressing elements of the epithelial innate immune response, while polarity switching of organoids may overcome the previous limitations and open new perspectives in modelling pressure-induced pancreatitis *in vitro*.

Disclosure: Nothing to disclose.

Contact E-Mail Address: joselarnoi@outlook.es

Introduction: The diagnosis of solid pancreatic tumours (SPT) is a clinical challenge and endoscopic ultrasound (EUS) is an essential tool in this setting. A new EUS-guided advanced imaging technique, detective flow imaging (DFI), has been developed to provide information on microvascularisation and low-velocity blood flow without the need for contrast agents.

Aims & Methods: The aim of our study was to evaluate DFI-EUS findings in SPT and compare them with those of contrast-enhanced harmonic EUS with Sonovue® (CEHEUS).

Methods: Prospective and descriptive study including patients with SPT who underwent EUS evaluation. The procedures were performed with a linear echoendoscope (Fujifilm 740UT) attached to the Arietta-850 ultrasound system. Lesions were graded according to the degree of vascularisation using DFI and CEHEUS. The final diagnosis was based on EUS sampling and long-term clinical and radiological follow-up when histology was not available.

Results: 106 patients (mean age 67.9 years [range 24-88 years], 48 males) were finally included. The mean lesion size was 28.4±16.2 mm. 46 (43.4%) tumours were located in the pancreatic head, 35 (33.0%) in the body, 1 (0.9%) in the neck, 19 (17.9%) in the tail and 5 (4.7%) in the uncinate process. 63 (59.4%) patients were diagnosed with adenocarcinoma, 30 (28.4%) with neuroendocrine tumour, 6 (5.6%) with inflammatory mass, 2 (1.9%) with pancreatic squamous cell carcinoma and lipoma, and 1 (1.2%) each with pancreatic necrosis, acinar carcinoma and accessory spleen. The vascular pattern of SPT evaluated by CEHEUS and EUS-DFI was concordant in 98.1% of cases.

All adenocarcinomas, pancreatic necrosis and pancreatic squamous cell carcinoma were hypovascular. Inflammatory masses were isovascular. Lipomas, accessory spleen and acinar carcinoma were hypervascular on both CEHEUS and EUS-FI. All 30 neuroendocrine tumours were hypervascular on CEHEUS and 28 (93.3%) on EUS-DFI.

Conclusion: DFI-EUS allows evaluation of the vascularisation pattern of pancreatic tumours with comparable accuracy to CEHEUS but without the need for contrast.

Disclosure: Julio Iglesias-Garcia: Advisor Fujifilm.

Introduction: In recent years, the detection of Branch Duct Intraductal Papillary Mucinous Neoplasms (BD-IPMN) has increased. The Association of Pancreatology (IAP) approved specific guidelines for their management in Fukuoka in 2017. The rates of malignant degeneration of these lesions remain unclear, raising concerns about the cost-effectiveness of the suggested surveillance strategies.

Aims & Methods: This study aimed to identify the rates of BD-IPMN malignant degeneration and their associated risk factors to propose a new, more cost-effective surveillance strategy. In this multicentric retrospective observational study, clinical and histopathological data of patients with IPMN were collected by four tertiary centers in Northern Italy. Multivariate Cox regression identified factors associated with a higher risk of malignant degeneration.

A segmentation analysis aimed to define new dimensional cut-offs for better risk stratification. Demographic and anamnestic data relating to the patient (age, gender, comorbidities based on the Age-Adjusted Charlson Comorbidity-Index (ACCI), imaging, endoscopic examinations, and surgical interventions), to IPMN (presence of Worrisome Features (WF) and High-Risk Stigmata (HRS) as defined by IAP), and surveillance costs were collected. Malignant degeneration was defined as the presence of high-grade dysplasia or invasive neoplasia.

Results: The study enrolled 333 patients, with a total of 1400 visits and a median follow-up of 4 years. IPMN developed malignant degeneration in 3.3% of cases. Cancer risk factors included the presence of HRS (HR 4.4, 95%CI 1.1-17.8, $p = 0.04$), of at least two WFs (HR 5.8, 95%CI 1.5-22.4, $p = 0.01$), and cyst size (HR 2.0, 95%CI 1.3-3.0, $p < 0.001$). The latter discriminated this risk (AUC 0.91, 95%CI 0.84-0.97), and two new cut-offs of 1.5 and 3.0 cm identified three dimensional categories with significantly different neoplastic potential (OR 6.6, 95%CI 1.7-25.4, $p = 0.007$, OR 9.8, 95%CI 1.1-89.7, $p = 0.04$).

Based on this, we proposed a new surveillance strategy that maintained diagnostic accuracy while reducing the cost per patient for a 3-year follow-up from 670.01 (407.33-1130.32) to 587.01 (347.10-930.28) euro, resulting in a total savings of 11% ($p = 0.001$).

Conclusion: IPMN malignant degeneration was infrequent. The presence of at least one WF, currently a cornerstone of guideline recommendations, did not independently associate with neoplastic risk, unlike HRS and the presence of at least two WFs. Implementing a follow-up strategy based on operatively identified dimensions (1.5 and 3 cm) could potentially enhance the cost-effectiveness of the 2017 Fukuoka IAP guidelines.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a devastating malignancy with a high mortality rate. While up to 25% of PDAC patients harbor mutations in genes involved in homologous recombination (HR) repair, targeted treatment with the PARP inhibitor (PARPi) olaparib is currently only approved in less than 5% of germline (g) *BRCA1/2* mutation carriers. Characterizing HR-deficient genotypes beyond g*BRCA1/2* that are susceptible to PARPi has potential to substantially broaden the eligible patient population, and defining the optimal inhibitor may further optimize treatment strategies to advance personalized medicine in PDAC.

Aims & Methods: Our previous preclinical work showed synthetic lethality of a multi-pronged DNA repair inhibition strategy using the PARPi olaparib, ATR inhibitor VE-822, and DNA-PK inhibitor CC-115 (termed PAD) in ATM deficiency¹. In the present study, we aimed to challenge the role of olaparib in our PAD combination and assess the regimen's efficacy across various HR-defective genotypes.

We assessed a spectrum of DNA-damaging agents and PARPi to identify the most potent inhibitor in HR-deficiency. Using *ATM*, *BRCA1*, *BRCA2* and *PALB2*-defective vs. HR-proficient murine PDAC cells, we systematically investigated the feasibility of expanding an optimized PAD regimen within defined HR-defective genotypes *in vitro* and *in vivo*.

Results: Here, we demonstrate a remarkable potency of the PARPi talazoparib in HR-deficient PDAC. Substituting olaparib, currently the only approved inhibitor in PDAC, with talazoparib in our PAD regimen enhanced its efficacy while maintaining comparable tolerability *in vivo*. Importantly, we demonstrate that PAD is an effective therapeutic regimen that can be extended to the most prevalent HR-defective genotypes in PDAC including *ATM*, *BRCA1*, *BRCA2* and *PALB2*.

Conclusion: Collectively, these data provide a strong rationale to implement the optimized regimen, talazoparib-based PAD, as a therapeutic concept tailored for the broad subgroup of HR-deficient PDAC patients.

CANCER-ASSOCIATED FIBROBLASTS REGULATE THE FORMATION OF MACROPHAGE EXTRACELLULAR TRAPS VIA CCL11/CCR5 AXIS TO RESIST IMMUNOTHERAPY IN PANCREATIC DUCTAL ADENOCARCINOMA

Z. Shi¹, Q. Zhou², K. Liu², Y. Jiang², S. Nie², Y. Yu², L. Wang², X. Zou², S. Shen², H. Li²

¹Clinical College of Nanjing Medical University, Nanjing, China,

²The Affiliated Hospital of Nanjing University Medical School, Nanjing, China

Contact E-Mail Address: cathyshizhao@163.com

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the most lethal malignancy with limited effective treatments options. PDAC remains resistant to immunotherapy due to its immunosuppressive tumor micro-environment and dense desmoplastic stroma, which are attributed to an abundance of cancer associated fibroblasts (CAFs) and infiltrating immunocytes. Macrophages release extracellular traps which are composed of a backbone of extracellular DNA fibers containing histones and cytotoxic proteases such as myeloperoxidase, elastase, and matrix metalloproteinase in order to exert local immunoregulation. However, the role of macrophages extracellular traps (METs) in PDAC is at present unclear.

Aims & Methods: METs expression was evaluated in human PDAC tissues using Immunofluorescence co-localization of citrullinated histone H3 (H3cit) and CD68. Patients cohorts were classified into METs-High and METs-Low groups based on their numbers of positive cells. The collagen deposition and infiltrating immune cell populations were detected by Immunohistochemistry in both human and mice PDAC tissues. Cytokine production in human serum was assayed using the Olink proteomic platform. The level of C-C motif chemokine ligand 11 (CCL11) and double-stranded DNA (dsDNA) in serum and conditioned medium were determined by ELISA. Pancreatic orthotopic transplantation tumors were constructed using panc02 cell line and organoids derived from KrasG12D/+; Trp53R172H/+; Pdx1Cre (KPC) mouse PDAC tissue. Western blot and q-PCR were utilized to validate the expression levels of CAFs and METs markers across different groups. T cell activation, macrophage phenotype and programmed death-ligand 1 (PD-L1) level in mouse pancreatic tumors were evaluated by flow cytometry.

Results: The METs level was elevated in PDAC compared to paracancerous tissues and it was significantly linked to poor patient survival, advanced tumor grade and stage, fewer infiltrating CD8+ T-cells, increased CD86+ macrophages, and increased α -SMA+ CAFs. CCL11, secreted by CAFs, was a key upstream signaling molecule for METs formation. Mechanistically, CCL11 binded to chemokine receptor 5 (CCR5) on the surface of macrophages and promoted PAD2 expression, facilitating MET formation. Maraviroc, a CCR5 inhibitor, effectively suppressed this process and increased the expression of PD-L1 and the infiltration of CD8+ T cells in PDAC tissue. In vivo, maraviroc effectively enhanced the anti-tumor effects of immunotherapy.

Conclusion: CAFs promoted the formation of METs via CCL11/CCR5 axis and further contributed to the formation of an immunosuppressive microenvironment in PDAC. Through the inhibition of METs formation by antagonizing CCR5 reshaped the immune microenvironment of PDAC and enhanced the sensitivity of immunotherapy.

Introduction: The integration of artificial intelligence (AI) during colonoscopy in patients with ulcerative colitis (UC) has garnered attention as an objective tool for predicting disease activity. Recently, we developed two types of AI-assisted software for assessing the inflammatory severity of UC: an AI-based white light endoscopy (WLE) system (EB-UC2 prototype; Cybernet Systems, Tokyo, Japan) and an AI-based Narrow-Band Imaging (NBI) system (EB-UC3). The AI-based WLE system is a fully automated video-based system that provides a three-class Mayo endoscopic subscore (MES) output (0, 1, and 2 or 3). The AI-based NBI system is a fully automated system that delivers a two-class predictive output (“Vascular active” or “Vascular healing”) of disease activity based on intramucosal vascular findings¹.

We are targeting the clinical implementation of these two systems and envisage their integration in real-world clinical practice, although the utility of integrating the two systems has not yet been investigated.

Aims & Methods: The aim of this study was to assess the usefulness of integrating the two AI systems in identifying patients with future clinical relapse among those with UC in clinical remission. This post hoc analysis included patients who achieved sustained corticosteroid-free remission (for 6 months) with a partial Mayo score ≤ 1 and underwent endoscopy using both AI systems between December 2021 and June 2022 at our institution. Patients were monitored in the outpatient clinic every 8 or 12 weeks for 12 months or until clinical relapse occurred. Clinical relapse was defined as a partial Mayo score > 2 .

Results: A total of 98 patients were enrolled in this analysis. Fifteen patients experienced a flare-up during the follow-up period. Patient background factors include gender: male 52.0%(51), median age 54 (IQR:64-44)years, disease type: pancolitis 51.2%(60), left-sided colitis 24.5%(24), and proctitis 14.3%(14).

The clinical relapse rate was significantly lower in patients achieving both AI-based MES=0-1 and “Vascular-healing” [3.2% (1/31)] compared to others [3.2% (1/31)] ($P < 0.01$). The AI-based NBI system was able to stratify the risk of relapse for patients assigned each MES by the AI-based WLE system: in patients with AI-based MES=2-3, the relapse rate was 0% (0/2) in AI-based vascular-healing and 53.8% (7/13) in AI-based vascular-active. In patients with AI-based MES=1, the relapse rate was 6.7% (1/15) and 18.6% (6/32) in AI-based vascular-healing and AI-based vascular-active, respectively. In patients with AI-based MES=0, the relapse rate was 0% (0/16) and 5% (1/20) in AI-based vascular-healing and AI-based vascular-active, respectively.

AI-based WLE output	AI-based NBI output		
	Vascular healing	Vascular active	Over all
MES=0	0% (0/16)	5.0% (1/20)	2.8% (1/36)
MES=1	6.7% (1/15)	18.6% (6/32)	14.9% (7/47)
MES=2-3	0% (0/2)	53.8% (7/13)	46.7% (7/15)
Over all	3.0% (1/33)	21.5% (14/65)	15.3% (15/98)

Table 1: The 12-month relapse rates following colonoscopy, according to the outputs from the AI-based white light endoscopy (WLE) system and the AI-based narrow band imaging (NBI) system.

Conclusion: The integrated use of AI-based WLE system for assessing MES and AI-based NBI system for diagnosing “vascular-healing” during colonoscopy effectively identifies patients with UC at high risk of relapse and thereby aiding in future disease management.

Introduction: Neoplasia detection in inflammatory bowel disease (IBD) poses a clinical challenge. We have previously reported the efficacy of a novel computer aided detection (CADE) algorithm for use in IBD (CADE-IBD) in images and videos. CADE-IBD is designed for use in high-definition white light endoscopy which may reduce operator variability which comes with chromoendoscopy. The added value of CADE-IBD is yet to be explored which this study aims to address.

Aims & Methods: Based on pilot data this study was powered as a superiority test, with 90% power for increased sensitivity of non-expert endoscopists with CADE-IBD compared to without CADE-IBD. 10 experienced and 11 less experienced endoscopists were asked to review short video clips of high definition white-light IBD endoscopy on a bespoke computer software designed by NEC Japan. The videos were watched once without CADE-IBD and then again with CADE-IBD when the videos were randomly redistributed to reduce recall bias. After each video the endoscopist was asked to select ‘polyp’, ‘no polyp’ or ‘uncertain’. If the endoscopist selected ‘polyp’ for a video they were asked to annotate the suspected abnormality.

Results: The study included 285 videos from IBD colon. 131 videos had lesions which showed a diverse range of size, morphology, histology and background mucosal inflammation. Videos were from all 3 major endoscopy processors (Pentax, Olympus and Fuji).

The standalone CADE-IBD sensitivity and specificity were 94.7% and 70.8% respectively. In comparison, experienced endoscopist sensitivity and specificity were 90.5% and 80.2% and less experienced endoscopists sensitivity and specificity of 73.7% and 82.1%. CADE-IBD sensitivity was significantly better than both experts and non-experts ($p < 0.05$).

With the addition of CADE-IBD, less experienced endoscopists sensitivity increased significantly to 89.2% ($p < 0.01$) and specificity remained similar at 81.0%. Experienced endoscopist sensitivity also improved with CADE-IBD to 93.4% which was again statistically significant ($p < 0.05$).

Sub-analysis was performed based on neoplastic or non-neoplastic histology, polypoid (Paris Is, Isp, Ip) and non-polypoid (Paris IIa/IIb/IIc) morphology and Mayo endoscopic sub-score for mucosal inflammation (Table 1).

	CADE-IBD sensitivity	Less experienced endoscopist sensitivity	Less experienced + CADE-IBD sensitivity	Experienced endoscopist sensitivity	Experienced + CADE-IBD sensitivity
Overall (n=131)	94.7%	73.7%	89.2%	90.5%	93.4%
Histology					
Neoplastic (n=62)	96.8%	72.6%	90.2%	92.1%	95.0%
Non-neoplastic (n=69)	92.8%	74.7%	88.4%	89.0%	92.0%
Morphology					
Polypoid (n=29)	100%	93.7%	98.1%	99.3%	99.7%
Non-polypoid (n=102)	93.1%	68.0%	86.7%	87.9%	91.7%
Mayo score					
0 (n=105)	95.2%	74.1%	90.9%	90.7%	93.7%
1 (n=21)	90.5%	68.4%	80.1%	89.5%	92.9%
2 (n=5)	100%	87.3%	92.7%	90.0%	90.0%

Table 1.

Conclusion: CADE-IBD has a standalone performance which is superior to both less experienced and experienced endoscopists. The addition of CADE-IBD significantly improved lesion detection regardless of experience. This superior performance was observed in neoplastic lesions, non-polypoid lesions and in the presence of mild background mucosal inflammation which is of high clinical importance. This calls for a head to head comparison of CADE-IBD with conventional surveillance techniques.

Contact E-Mail Address: bobby.lo@regionh.dk

Introduction: Endoscopic evaluation of disease severity remains the cornerstone of disease assessment in ulcerative colitis (UC). Endoscopic evaluation using scoring systems such as the Mayo Endoscopic Subscore (MES) is, however, subjective with interrater agreements typically ranging from a kappa of 0.4 to 0.7. Post-hoc analysis from clinical trials indicates that up to 30% of patients were incorrectly included due to misclassification of disease severity. Recent studies including our own using artificial intelligence (AI) to assess the MES have shown enhanced classification accuracy using only white light procedures¹.

Aims & Methods: In this study, we aimed to refine our AI model to assess disease severity using the Ulcerative Colitis Endoscopic Index of Severity (UCEIS).

We extracted 2000 images from recorded sigmoidoscopy/colonoscopy performed on UC patients at the Gastrounit, Copenhagen University Hospital Hvidovre, Denmark. Six IBD experts from The Digestive Disease Center, Copenhagen University Hospital Bispebjerg, scored each image according to the UCEIS and MES. The majority score from the six experts for each subscore (Bleeding, Erosions and Ulcers, Vascular Pattern) was considered the gold standard. In cases of tied scores, the higher score was selected, preferring a model that overestimates rather than underestimates disease severity. The final UCEIS score was the sum of the gold standards for each subscore.

A convolutional neural network was trained on 80% of the images, and then validated on the remaining 20%. The network performance was evaluated against gold standard and individual experts' scores.

Results: All six experts evaluated all 2000 images; the results are summarized in Table 1.

(linear) Kappa	Expert Mean	Min	Max	AI Model
Bleeding	0.62	0.44	0.73	0.78
Erosion and Ulcers	0.65	0.46	0.71	0.82
Vascular pattern	0.73	0.41	0.88	0.88
Total UCEIS	0.69	0.44	0.80	0.84
Total MES	0.68	0.50	0.77	0.87

Table 1: Comparative kappa scores from the leave-one-out analysis of experts and the model versus gold standard (majority score from all six experts) for each subscore and the total of the Ulcerative Colitis Endoscopic Index of Severity (UCEIS) and Mayo Endoscopic Subscore (MES).

The model surpassed the interrater reliability of expert IBD endoscopists in all subscores, showing particularly strong performance in the erosion and ulcers and vascular patterns subscores. The model's moderate performance in the "bleeding" subscore reflects the lower kappa scores among

experts, underscoring the challenges of visual assessments in this area. Notably, the model's performance on the MES was high, indicating significant overlap in the visual cues used for both UCEIS and MES scoring.

Conclusion: This study demonstrates the potential of using an AI model to enhance the accuracy of UC severity assessments with the UCEIS with results surpassing experts. The overlapping visual cues for MES and UCEIS suggest that the AI model can streamline training and application across different scoring systems, enhancing clinical practice efficiency.

We plan to validate the model on a new test set from another hospital to further evaluate its generalizability and effectiveness across various settings. This is essential for confirming its potential to significantly improve the consistency and precision of UC severity assessments.

Introduction: Capsule endoscopy (CE) is frequently employed as the first exam when mid-gastrointestinal bleeding is suspected, following normal upper and lower endoscopies. While its primary focus is on evaluating the small bowel, detection of vascular lesions both upstream and downstream could also hold clinical importance.

Aims & Methods: The aim of this study is to develop and test a Convolutional Neural Network (CNN)-based model for panendoscopic automatic detection of vascular lesions during CE. A retrospective study involving 2 centers was conducted, involving 1188 CE exams. A total of 152,312 frames were utilized, obtained from seven distinct types of CE devices, with 14,942 frames being classified as vascular lesions (angiectasias or varices) after triple validation. The data was divided in training/validation (90%) and test (10%) sets, using an exam-split design. A 5-fold cross-validation was conducted during training/validation set. The all process was iterated five times. The primary outcome measures were sensitivity, specificity, accuracy, area under the conventional receiver operating characteristic curve (AUC-ROC) and the precision-recall curve (AUC-PR), from the training/validation set.

Results: The model demonstrated a mean sensitivity and specificity of 87.5% (IC95% 81.5 – 93.6%) and 99.5% (IC95% 99.3 – 99.7%), respectively. Mean accuracy was 98.4% (IC95% 97.7 – 99.1%). Mean AUC-ROC value was 0.987 (IC95% 0.980 – 0.995), while AUC-PR value was 0.998 (IC95% 0.997 – 1.000).

Conclusion: This represents the first proof-of concept AI deep learning model developed for panendoscopic automatic detection of vascular lesions during CE. The CCN's high diagnostic performance in multibrand devices addresses a critical issue of technological interoperability, allowing it to be replicated in multiple technological settings.

Introduction: Recent evidence suggests a possible role of artificial intelligence in procedural quality measurement for endoscopic submucosal dissection by artificial intelligence¹. Precise frame by frame differentiation of operational phases may allow for a deeper understanding of the procedure and open a wide range of possibilities from automated documentation to concise training support.

Aims & Methods: In this study, we aimed to develop an algorithm for frame by frame procedural phase recognition during ESD. To this end, a dataset (27 ESDs, 2071546 single frames) was annotated for the operational supra-phases diagnostics, marking, needle injection, dissection and bleeding. Furthermore, the subphases scope manipulation, injection and application of electrical current were annotated where appropriate. A training-subset (17 ESDs, 898440 single frames) was used to train a video swin transformer with uniform frame sampling to detect the classes. The trained algorithm was evaluated internally (6 ESDs, 769523 single frames) and on a separate dataset (4 ESDs, 403583 single frames).

Results: Overall F1 Scores for internal validation and validation on the separate dataset were 83% and 90%, respectively. True positive rates for diagnostics, marking, needle-injection, dissection and bleeding were 100%, 100%, 96%, 97% and 93%, respectively. Overall F1 score over all supra-phases was 94%, overall accuracy was 93%. True positive rates for scope manipulation, injection and application of electrical current were 92%, 98% and 91%, respectively. Overall F1 score for subphases was 91%, overall accuracy was 97%.

Conclusion: The trained algorithm classified full length ESD videos on a frame by frame basis for concise surgical phases with high accuracy. Future research will focus on the development of intraprocedural quality measures, as well as automated reporting.

Introduction: Etrasimod is an investigational, oral, once-daily (QD), selective sphingosine 1-phosphate (S1P)_{1,4,5} receptor modulator in development to treat immune-mediated inflammatory disorders.

Aims & Methods: This analysis aimed to report the 52-week (wk) efficacy and safety data from the phase 2 VOYAGE study in adults with active eosinophilic oesophagitis (EoE). VOYAGE (NCT04682639) included a 24-wk randomised, double-blind, placebo (PBO)-controlled treatment period, followed by a 28-wk extension.

At Wk 24, patients (pts) continued on etrasimod 1 or 2 mg QD or were randomised from PBO to etrasimod 1 or 2 mg QD (data not shown) for 28 wks (investigator and pts remained blinded). The efficacy analyses presented include data from PBO-controlled and extension treatment period outcomes at Wk 52, with a focus on pts who received etrasimod in both periods (etrasimod 2 mg–2 mg and 1 mg–1 mg).

Efficacy endpoints included percentage change from baseline (BL) (%CFB) in oesophageal peak eosinophil count (PEC) at Wk 16 (primary endpoint), proportion of pts who achieved PEC <15 and ≤6 eosinophils/high power field (eos/HPF), and CFB in EoE-Histology Scoring System (EoE-HSS) grade and stage scores, EoE Endoscopic Reference Score (EREFS), Patient Global Impression of Severity (PGIS) and Dysphagia Symptom Questionnaire (DSQ; overall and by BL dilation history) at Wks 16, 24 and 52. Safety data are presented to Wk 52.

Results: 108 pts were randomised in the PBO-controlled period; 85 pts entered the extension period, with 30 and 31 pts maintaining etrasimod 2 and 1 mg QD, respectively. Treatment with etrasimod 2 mg resulted in a 46.1% decrease from BL in PEC (PBO-adjusted) at Wk 16 ($p=0.0103$) with the improvement maintained at Wk 24; improvements vs BL were seen at Wk 52 (Table). Other histological and endoscopic endpoints, including oe-

^aFull analysis set; includes all randomised pts who received at least one dose of study treatment.

^bEfficacy evaluable set; includes all randomised pts who received at least one dose of study treatment with an extension BL measurement and a Wk 52 measurement in the extension treatment period. The efficacy evaluable set can vary with endpoints since some pts may have the required data for some endpoints but not others.

^c%CFB (mean [SD] [median]) calculated for PEC, and CFB (least squares mean [SE]) calculated for EoE-HSS grade and stage, EREFS, PGIS and DSQ. All PBO-adjusted differences from PBO are expressed as least squares mean, except %CFB in PEC, which is expressed as the mean and median difference.

^dp values are from an analysis of covariance model for rank score of %CFB, including factors for treatment group, BL history of oesophageal dilation (Yes/No), concurrent PPI therapy (Yes/No), and BL eosinophil PEC (eos/HPF) as a covariate.

^eGrade and stage score range from 0–3 for each individual component of the EoE-HSS. Total scores are reported and are the ratio of observed component scores divided by the maximum possible score depending on the number of individual components that are present/evaluable.

^fp values are from a linear mixed effects model for change from BL, including factors for treatment group, visit, interaction of treatment-by-visit, BL history of oesophageal dilation (Yes/No), concurrent PPI therapy (Yes/No), and BL score as a covariate.

^gScore ranges from 0–9.

^hScore ranges from 0–4.

ⁱScore ranges from 0–84.

%CFB, percentage change from baseline; BL, baseline; DSQ, Dysphagia Symptom Questionnaire; EoE-HSS, Eosinophilic Oesophagitis-Histology Scoring System; eos, eosinophils; EREFS, Eosinophilic Oesophagitis Endoscopic Reference Score; HPF, high power field; N, number of pts in the treatment group; N1, number of pts in the efficacy evaluable set for the extension treatment period; N/A, not available; PBO, placebo; PEC, peak eosinophil count; PGIS, Patient Global Impression of Severity; PPI, proton pump inhibitor; pt, patient; QD, once daily; SD, standard deviation; SE, standard error; Wk, Week.

OP207 Table. Change from BL (CFB) in oesophageal PEC at Wk 16 (primary endpoint) and additional efficacy endpoints at Wks 24 and 52 in the VOYAGE study.

sophageal PEC <15 and ≤ 6 eos/HPF, EREFS and EoE-HSS, also showed statistically significant improvement at Wks 16 and 24, with improvements vs BL at Wk 52 in pts who received etrasimod 2 mg QD for the full study duration (Table, following page).

Statistically significant reductions in PGIS in the overall population and DSQ in pts without BL dilation history who received etrasimod 2 mg QD were observed at Wk 24 (-0.48 and -11.95, respectively; $p < 0.05$ for both parameters). PGIS and DSQ score improvements vs BL (overall population) were seen at Wk 52 in pts who received etrasimod 1 or 2 mg. In total, 16/30 (53.3%) and 19/31 (61.3%) pts reported treatment-emergent adverse events (TEAEs) in the 2 and 1 mg groups, respectively.

No TEAEs were considered serious or resulted in death. In the 2 mg etrasimod QD group, 2 pts discontinued treatment due to TEAEs of Alanine aminotransferase increased and Hypoglossal nerve paralysis; 1 pt in the 1 mg etrasimod QD group discontinued due to Dry eye and Dyspnoea.

Conclusion: PBO-adjusted improvements in histological and endoscopic features of EoE at Wks 16 and 24, and improvements in symptoms (PGIS and DSQ in pts without dilation) at Wk 24 in pts who received etrasimod 2 or 1 mg QD were also seen at 52 wks vs BL. The etrasimod safety profile appears consistent in pts with EoE and those in other indications.

Introduction: Eosinophilic esophagitis (EoE) is a chronic inflammatory disease of the esophagus with increasing incidence in all age groups^{1,2} and limited treatment options for pediatric patients. We evaluated the efficacy and safety of two doses of a novel budesonide oral suspension (BOS) for induction therapy of pediatric EoE in a phase 2/3 trial.

Aims & Methods: An initial 12-week randomized, double-blind (DB) induction phase enrolled 76 pediatric patients with active EoE aged 2-11 years (stratum I; n=35) and 12-17 years (stratum II; n=41). Patients were randomized to high-dose BOS (BOS-H: 0.5 mg (stratum I)/1 mg (stratum II) BOS, twice daily; n=26), low-dose BOS (BOS-L: 0.5 mg (stratum I)/1 mg (stratum II) BOS, once daily; n=26) or placebo (n=24). The composite primary endpoint was the proportion of patients with histologic remission plus clin-

ical response at week 12. Secondary endpoints included the proportion of patients with histologic remission, change in peak eosinophil counts, and the proportion of patients with clinical response. Patients who did not achieve the primary endpoint at week 12, who experienced a food impaction requiring endoscopic intervention or dilation, or with a lack of efficacy after week 8 were eligible for a subsequent open-label induction (OLI) phase. In this additional phase, 45 patients all received BOS-H for a further 12 weeks, after which the same endpoints were assessed.

Results: In the DB phase, the proportion of patients achieving the composite endpoint of histologic remission plus clinical response was significantly higher in both BOS treatment groups compared with placebo, with superior and clinically relevant results with high-dose versus low-dose BOS (Table). Both BOS doses demonstrated significantly superior benefits versus placebo on the secondary endpoints of histologic remission and peak eosinophil counts. However, no relevant differences were observed in clinical response between any groups. In the OLI phase, patients who received BOS-L or placebo in the DB phase achieved comparable rates of histologic remission and clinical response as the BOS-H group in the DB phase (Table).

Esophageal candidiasis was observed in 1 patient receiving BOS-H in the DB phase and 4 patients in the OLI phase. Decreased cortisol levels were recorded in 1 BOS-H patient, 1 placebo patient, and 1 OLI patient, with 1 case each of adrenal insufficiency and adrenal suppression in the OLI phase. Adrenal-related events were of mild severity. No bolus impactions requiring emergency endoscopy or serious adverse events related to BOS were reported.

	Double-Blind induction (DB, 12 weeks)			Open-Label Induction (OLI, 12 weeks)		
	BOS-H (n=26)	BOS-L (n=26)	Placebo (n=24)	BOS-H > BOS-H (n=8)	BOS-L > BOS-H (n=14)	Placebo > BOS-H (n=23)

¹Peak eosinophils < 16 eos/mm² hpf (i.e. < 5 eos/hpf); ²≥ 30% decrease on Pediatric EoE Symptom Severity Module, version 2.0 (PEESS v2.0) from baseline (DB baseline or OL baseline, respectively); ³DB baseline or OL baseline, respectively. * p-values shown depict comparison of treatment groups with placebo.
BOS: Budesonide oral suspension; BOS-H: High-dose BOS; BOS-L: Low-dose BOS; CI: Confidence interval; eos: Eosinophils; hpf: High-power field; LOCF: Last observation carried forward; SD: Standard deviation

Table. Efficacy endpoints (full analysis set).

Conclusion: BOS was safe and effective in inducing histologic remission associated with clinical response in pediatric patients with EoE. Superiority of BOS on the primary clinico-histologic endpoint and secondary histologic endpoints was demonstrated over placebo and for high-dose versus low-dose BOS. Clinical response rates were comparable among treatment groups. Treatment with high-dose BOS for a further 12 weeks led to improvement in patients not achieving remission in the DB phase. Adverse events were of mild or moderate severity.

Introduction: Eosinophilic esophagitis (EoE) is an increasingly prevalent esophageal disease resulting in dysphagia and food impaction. ESO-101 targets the esophageal mucosa by significantly increasing topical medication contact time through the slow release of mometasone furoate. This innovative application technology consists of a drug-loaded thin-film rolled up in a capsule that unravels and sticks to the esophageal mucosa when swallowed. The current proof-of-concept phase 2 study evaluated the efficacy and safety of ESO-101.

Aims & Methods: This randomized, double-blind, placebo-controlled trial (NCT04849390) investigated the safety and efficacy of ESO-101 in adult patients with EoE and dysphagia. Patients were randomized 2:1 to once-daily treatment with ESO-101 800 µg or placebo and treated for 4-weeks. The

primary endpoint was the absolute change in peak eosinophil count (eos/hpf) from baseline. Secondary endpoints were the change in EoE Endoscopic Reference Score (EREFS) and dysphagia symptoms measured by the 11-point numeric rating scale (NRS). Safety was also assessed.

Results: 59 patients were screened at 13 European study sites, 43 patients were randomized, and 40 (27 to ESO-101 and 13 to placebo) completed the trial. For all histological and endoscopic endpoints, ESO-101 led to a statistical improvement compared to placebo. The mean decrease in peak eosinophil count was 49.1 (± 88.4) eos/hpf with ESO-101, while counts increased by a mean of 6.6 (± 65.1) eos/hpf in the placebo group ($p=0.0318$). Mean EREFS decreased by 3.9 (± 2.6) with ESO-101 and there was no change with placebo (-0.1 [2.3]) ($p=0.0001$). A higher proportion of patients showed a histological response (<15 eos/hpf) with ESO-101 versus placebo (48% vs 0%; $p=0.0028$). There was also numerical improvement in the dysphagia severity score in the ESO-101 group (median improvement in the dysphagia severity of 4 scores [relative change: -71%]) compared to placebo (improvement in 3 scores [relative change: -57%]). No cases of oropharyngeal or esophageal candidiasis were observed (Table 1).

Outcome parameters ACESO study	ESO-101 (n=28)	Placebo (n=15)	p-value
Absolute change in peak eosinophil count CFB mean (SD)	-49.11 (88.42)	6.63 (65.11)	0.0318
Histological response < 15 eos/hpf (n [%])	13 (48.1)	0 (0.0)	0.0028

Table 1: Main Outcome Parameters ACESO Study.

SD= standard deviation; CFB=change from baseline;

EREFS=endoscopic reference score; IMP=investigational medicinal product

Conclusion: ESO-101 resulted in statistically significant histologic and endoscopic improvements compared with placebo, even with the 4-week treatment duration. ESO-101 was well tolerated. The ACESO study underscores the promise of topical drug delivery to the esophagus using the ESO-101 drug delivery system and provides a robust foundation for future ESO-101 development for EoE therapy.

Contact E-Mail Address: mirna.chehade@mssm.edu

Introduction: Eosinophilic esophagitis (EoE) is a chronic, type 2 inflammatory disease of the esophagus. Swallowed topical corticosteroids (STCs) are commonly used to treat EoE, however not all patients respond to STC treatment, and side effects may occur with long-term use. Dupilumab, a fully human monoclonal antibody that blocks drivers of type 2 inflammation, is approved for EoE in patients aged ≥ 1 year, weighing ≥ 15 kg in the US, and for adult and adolescent patients aged ≥ 12 years, weighing ≥ 40 kg in the EU.

We assessed the efficacy of dupilumab in children with EoE by baseline history of prior use of or prior inadequate response, intolerance, or contraindication to STCs in the Phase 3 EoE KIDS study (NCT04394351).

Aims & Methods: Eligible patients were aged 1 to <12 years with EoE unresponsive to proton pump inhibitors. This analysis includes patients randomized at Part A baseline to weight-tiered dupilumab higher-exposure (HE) or pooled placebo up to Week 16 (W16). Part B data were analyzed for patients who continued to receive dupilumab HE, and for patients who switched from exposure-matched placebo to dupilumab HE through to Week 52 (W52).

Patients were required to be withdrawn from STCs at least 8 weeks prior to study baseline. The study primary endpoint was the proportion of patients achieving peak eosinophil count (PEC) ≤ 6 eosinophils/high-power field (eos/hpf) at W16.

Secondary endpoints included the proportion of patients achieving PEC <15 eos/hpf, absolute change in the Endoscopic Reference Score (EREFS), EoE-Histologic Scoring System (EoE-HSS) grade/stage scores, and proportion of days with ≥ 1 EoE sign as assessed by the Pediatric EoE Sign/Symptom Questionnaire – Caregiver version (PESQ-C). Efficacy was assessed by prior use of or prior inadequate response, intolerance, or contraindication to STCs.

Results: Of the 102 patients who entered the study, most (80.4%) had a history of STC therapy, and 57.8% had a prior inadequate response, intolerance, or contraindication to STCs. Regardless of prior STC use, dupilumab HE improved the proportion of patients achieving ≤ 6 and <15 eos/hpf, and improved EREFS and EoE-HSS grade/stage scores at W16 versus placebo (Table). Up to W52, improvements continued or were maintained in patients continuing dupilumab HE, and improved in patients who switched from placebo to dupilumab HE regardless of prior STC use, although patient numbers were small in the subgroup without prior STC use (Table).

Similar improvements in PESQ-C with dupilumab HE were observed regardless of prior STC use (Table). Outcomes were similar in patients with/without prior inadequate response, intolerance, or contraindication to STCs.

Introduction: Current diagnostic reliance on invasive endoscopy for eosinophilic esophagitis (EoE) underscores the urgent need for non-invasive biomarkers. Plasma-derived-extracellular vesicles (pEVs) offer a promising solution (1) as they are known carriers of inflammation-related molecules and are involved in immunity (2).

Particularly, extracellular microRNAs exhibit numerous functions in inflammation (3) and their utilisation as a source of biomarkers in immunity is being exploited.

Aims & Methods: Here we aimed to evaluate the potential of plasma-EVs (pEVs) RNA cargo as biomarker for diagnosing and monitoring EoE. Plasma was withdrawn from EoE-patients (basal and post-treatment samples), and control subjects for isolation of circulating EVs using size exclusion chromatography and ultrafiltration. Plasma EVs were then characterised by electron microscopy and flow cytometry. Profiling small RNA content was performed through high-throughput RNA sequencing across a discovery cohort (26 EoE patients and 16 controls), and biomarker candidates were evaluated by RT-qPCR in a validation cohort (33 EoE-patients and 14 controls). Functional insights were analysed by identifying KEGG and GO terms, and the area under the ROC curve (AUC) was used for assessing the diagnostic potential of selected candidates.

Results: The overall profile of RNA cargo of pEVs was sufficient to discriminate control subjects from EoE patients as shown by principal component analysis. Notably, a shift in pEVs cargo was also observed in EoE patients before and after successful treatment, suggesting an impact of the inflammatory state in the small-RNA cargo of EVs. A total of 575 small RNAs were identified, with 32 displaying significant differential regulation and among which microRNAs and tRNA fragments (tRFs) were the most represented biotypes. Eight microRNAs distinguished controls from basal samples, while 4 served to differentiate basal from post-treatment cases based on diagnostic accuracy (AUC>0.75). Functional analysis of microRNAs upregulated in basal samples indicated that these RNAs target genes are involved in the regulation of inflammatory response, epithelial barrier, and eosinophil activity-related pathways. Then, we explored whether the combination of dysregulated microRNA pairs could improve diagnostic power, and highlighted two sets of microRNAs, miR10b-5p/miR221-3p (AUC=0.86) and miR15a-5p/miR30a-3p (AUC=0.90) as robust diagnostic and monitoring biomarkers, respectively. These combinations were further validated by RT-qPCR in an independent cohort with AUC values of 0.70 (CI 95% 0.54-0.87) for miR10b-5p/miR221-3p and 0.71 for miR15a-5p/miR30a-3p (CI 95% 0.58-0.84). Noteworthy, miR30a-3p appeared strongly upregulated in basal samples across discovery and validation cohorts.

Conclusion: We present, for the first time, the potential of different microRNAs derived from plasma-EVs as non-invasive biomarkers for EoE, which could significantly improve patient management by reducing dependency on invasive procedures. This work establishes a foundation for further research exploring the role of EVs in EoE.

Introduction: Severe fatigue, which has a large negative impact on quality of life, is often present in Crohn's disease (CD) and ulcerative colitis (UC), even in remission.¹

The Communicating Needs and Features of Inflammatory bowel disease (IBD) Experiences (CONFIDE) study explored patient and healthcare professional perspectives on the experiences and impact of CD/UC-related symptoms on patients in Europe (France, Germany, Italy, Spain, and UK), the United States (US), and Japan. These analyses focus on the experience and impact of fatigue among European and US patients with moderate-to-severe CD/UC.

Aims & Methods: Online, quantitative, cross-sectional surveys were conducted among patients with moderate-to-severe CD/UC, defined using criteria based on previous treatment, steroid use, and/or hospitalization. Fatigue over the past seven days was assessed using the 13-item Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) scale² (range: 0–52, higher scores indicate less fatigue; mean score in general population: 43/52³; scores <30/52 indicate severe fatigue⁴). The Manitoba IBD Index⁵ assesses disease activity based on patient-reported symptom persistence in the last six months (6-level scale:

- 1=constantly active,
- 2=often active,
- 3=sometimes active,
- 4=occasionally active,
- 5=rarely active, and
- 6=remission/absence of symptoms).

Disease was considered active if symptoms were experienced constantly to occasionally (responses 1–4), and inactive when infrequent/absent (responses 5/6). Patient-reported impact of CD/UC on energy levels was reported on a scale of 1–7, where 1=no impact and 7=high impact. Data are presented as descriptive statistics.

Results: A total of 547 European (55.4% male, mean age: 38.0 years) and 215 US (54.9% male, 40.9 years) patients with CD and 556 European (57.4% male, 38.9 years) and 200 US (61.5% male, 40.4 years) patients with UC completed the surveys.

Overall, 34.2% European and 35.8% US patients with CD, and 20.9% European and 27.5% US patients with UC reported currently (in the last month) experiencing fatigue. More than 80% of all patients indicated that CD/UC

negatively impacted their energy levels (scores 4–7): CD, Europe: 80.1%, US: 84.2%; UC, Europe: 81.1%, US: 88.0%. Mean (SD) FACIT-F scores were 27.4 (11.3) and 26.8 (10.8) for European and US patients with CD, and 29.4 (10.0) and 26.2 (11.3) for European and US patients with UC, respectively. Among patients currently experiencing fatigue, FACIT-F scores were 24.3 (10.8) and 26.1 (10.9) for European and US patients with CD, and 26.0 (10.6) and 24.5 (11.5) for European and US patients with UC. Among those currently experiencing fatigue, most patients with CD described their disease as active (Europe: 92.5%, US: 93.5%).

Similar results were observed among patients with UC (Europe: 92.2%, US: 98.1%). Among patients reporting ever experiencing fatigue (CD, Europe: 45.2%, US: 45.6%; UC, Europe: 30.6%, US: 40.0%), most reported experiencing fatigue at least once a week (CD, Europe: 67.5%, US: 79.6%; UC, Europe: 66.4%, US: 70.0%).

Conclusion: European and US patients with CD/UC reported severe fatigue (FACIT-F scores <30)⁴, indicating a major burden of fatigue, which is also clearly associated with patient-reported active disease. Both CD and UC negatively impact energy levels for the majority of patients. The findings of this study underscore the importance of active fatigue management in CD/UC to improve patients' overall quality of life.

Introduction: IBD remission is key for pregnancy outcomes. Previous studies have suggested a disease recurrence risk of approximately 30%

in patients in remission at conception, but this could be influenced by disease control in the periconceptional period and the discontinuation of treatments for IBD during pregnancy.

Aims & Methods: Aim: To provide updated data on the incidence of disease relapse during pregnancy in IBD patients and to identify predictive factors of relapse.

Methods: Pregnant patients with IBD from DUMBO registry were included. DUMBO is a prospective, observational, and multicentre registry, endorsed by GETECCU which enrolls pregnant women with IBD over 5 years in 70 centres in Spain. Relapse was defined based on the Crohn's Disease Activity Index and the Partial Mayo Score in Crohn's disease (CD) and ulcerative colitis (UC), respectively. Only patients in clinical remission at conception were considered for the relapse risk analysis (Cox-regression analysis). Only serious adverse events (SAE) were recorded.

Results: 1,033 patients were available in DUMBO registry, 56% had CD, 19% had previous surgery, 29% were exposed to thiopurines, 40% to biologics and 5.5% had active disease at conception. 830 patients had given birth (98% singleton), 69 had early termination (48 of them miscarriages), and 134 pregnancies were still ongoing.

The probability of having active disease at each trimester was higher in patients with active disease at conception than in those in remission [41% vs. 2% in the 1st trimester (TM), 18% vs. 2.6% in the 2nd TM, 14% vs. 2.7% in the 3rd TM; all p-values<0.001]. Seven patients underwent surgery due to IBD during pregnancy (3 abdominal and 4 perianal surgery); all of them were in remission at conception.

The proportion of patients with severe infections during pregnancy was higher in patients with active disease during pregnancy (2.8% vs. 0.8%, p<0.05); there were no differences in other SAE based on the activity.

A total of 73 out of 976 patients in remission at conception relapsed throughout pregnancy or puerperium (incidence rate of disease flare=11% per patient-year of follow-up); most cases from the 2nd TM of gestation. To have UC vs. CD (Hazard ratio=3, 95% confidence interval=1.8-5.3) was the only variable associated with the risk of relapse.

The proportion of patients who relapsed was similar among those who withdrew the biological treatment and those who maintained it (4% vs. 8%, p>0.05). Focusing on patients treated with biologics, the proportion of disease relapse based on biologics withdrawal and TM of withdrawal is summarised in Table 1.

Drug	N	Withdrawal	Relapse	p-value	Trimester of gestation	Relapse by trimester of withdrawal
Adalimumab, n (%)	159	Yes: 39 (25) No: 120 (75)	0 (0) 7 (6)	0.1	1TM: 9 (23); 2TM: 9 (23); 3TM: 20 (52)	None
Infliximab, n (%)	120	Yes: 27 (22.5) No: 93 (77.5)	1 (3.7) 7 (7.5)	0.4	1TM: 1(3.7); 2TM: 15 (56); 3TM: 9 (33)	One patient (6.6) discontinued in 2TM)
Certolizumab, n (%)	6	Yes: 1 (17) No: 5 (83)	0 (0) 3 (60)	0.2	2TM: 1 (100) 3TM: 2 (100)	None One patient (50%) discontinued in 3TM)
Golimumab, n (%)	3	Yes: 2 (67) No: 1 (33)	1 (50) 0 (0)	0.3		
Vedolizumab, n (%)	30	Yes: 6 (20) No: 24 (80)	0 (0) 5 (21)	0.2	1TM: 1(17); 2TM: 2 (33); 3TM: 2 (33)	None
Ustekinumab, n (%)	79	Yes: 18 (23) No: 61 (77)	2 (11) 3 (5)	0.3	1TM: 2 (11); 2TM: 13 (72); 3TM: 3 (17)	One patient of those who discontinued 1TM (50%) and one patient (7.7%) of those who discontinued 2TM

TM: trimester

Table 1.

Conclusion: The risk of having active disease during pregnancy was higher in patients with activity at conception. The risk of relapse in patients in remission at conception was lower than previously described. The risk of relapse was 3-fold higher in UC than in CD. Since most relapses occur from the second trimester of gestation onwards, and serious complications (including surgery) can occur also in patients in remission at conception, monitoring IBD during this period should be closely conducted

Contact E-Mail Address: jiangwei.sun@ki.se

Introduction: The co-occurrence of inflammatory bowel disease (IBD) and type 1 diabetes (T1D) has been linked to poor clinical outcomes. However, few longitudinal studies have explored their temporal relationships.

Aims & Methods: This study aimed to investigate the bidirectional association between IBD and T1D. In this nationwide cohort and case-control study, patients with biopsy-confirmed IBD were identified between 1987 and 2017. The cohort included 20,314 patients with IBD (≤ 28 years; Crohn's disease [CD, $n=7,277$], ulcerative colitis [UC, $n=10,112$], and IBD-unclassified [IBD-U, $n=2,925$]) and individually matched reference individuals from the general population ($n=99,200$). The case-control study enrolled 87,001 patients with IBD and 431,054 matched controls. We estimated adjusted hazard ratios (aHRs) of incident T1D by IBD status with flexible parametric survival models and adjusted odds ratios (aORs) of IBD by history of T1D with conditional logistic regression, with 95% confidence intervals (CIs). The familial factors from genetics and early environmental factors were additionally accounted for via sibling comparisons.

Results: In the cohort, during a median follow-up of 14 years, 116 patients with IBD and 353 reference individuals developed T1D. Patients with IBD had a higher incidence of T1D than reference individuals (incidence rate: 3.7 vs. 2.3 per 10,000 person-years; $aHR=1.58[95\%CI=1.27 \text{ to } 1.95]$). The HR was increased in patients with UC ($aHR=2.02[1.51 \text{ to } 2.70]$) but not in those with CD ($aHR=1.11[0.76 \text{ to } 1.64]$) or IBD-unclassified ($aHR=1.48[0.82 \text{ to } 2.69]$). In the case-control study, a total of 1,018 IBD patients and 3,496 controls had been diagnosed with T1D.

Compared with controls, patients with IBD tend to have higher odds of having previous T1D ($aOR=1.36[95\%CI=1.26 \text{ to } 1.46]$). Such positive association was observed in all IBD subtypes. Comparisons with siblings showed similar associations ($aHR=1.44 [0.97 \text{ to } 2.15]$ and $aOR=1.32 [1.18 \text{ to } 1.49]$).

Conclusion: Patients with IBD had a moderately increased incidence of developing T1D and higher odds of having a previous diagnosis of T1D. These findings demonstrate a bidirectional association between IBD and T1D independent of shared genetics and early environmental factors.

Contact E-Mail Address: re107@ic.ac.uk

Introduction: Infectious mononucleosis (IM) is a largely self-limiting syndrome mainly affecting adolescents and young adults but can present as a severe disease requiring hospitalisation. The infectious agent most commonly causing IM, Epstein-Barr virus (EBV), has been associated with the development of several immune-mediated and inflammatory diseases¹. Recent epidemiological studies have also identified a potential association with IM and inflammatory bowel disease (IBD)^{2,3}.

Aims & Methods: We therefore aimed to investigate the risk of IBD diagnosis following hospitalisation with IM using Danish nationwide registry data. We identified severe IM patients (those hospitalised with infectious mononucleosis) and matched these by sex-, age- and residence municipality to non-severe IM controls, from 1st January 1977 to 31st December 2021. We undertook Cox regression modelling to assess the hazards (HR) and 95% CI of IBD diagnosis, including Crohn's disease (CD) and ulcerative colitis (UC), following severe IM. Analyses were stratified by sex, age at, and calendar year of IM hospitalisation.

	Severe IM cases (N = 39,684)		Severe IM controls (N = 396,840)		Adjusted HR*	Adjusted HR 95% CI
	IBD events in severe IM (N)	IBD IR (per 1000 person years)	IBD events in controls (N)	IBD IR (per 1000 person years)		
Inflammatory Bowel Disease	496	0.67	3982	0.5	1.35	1.22-1.49
Crohn's Disease	203	0.27	1417	0.18	1.56	1.34-1.83
Ulcerative Colitis	293	0.40	2565	0.32	1.23	1.08-1.40

Abbreviations: IM; infectious mononucleosis, IR; incidence rate, HR; hazard ratio, 95% CI; 95% confidence interval. Severe IM cases include individuals hospitalised with IM between 1st January 1977 and 31st December 2021. Severe IM controls include individuals matched on sex, date of birth (within 6 months), and municipality of residence without an IM hospitalisation to severe IM cases; *adjusted for sex, age and municipality of residence as appropriate.

Table 1. Crude incidence rates and adjusted hazard ratios for IBD, CD and UC diagnosis in severe IM patients compared with severe IM controls.

Results: We identified 39,684 patients with severe IM who were sex-, age-, and municipality-matched to 396,840 non-severe IM controls. Severe IM was significantly associated with the development of IBD (HR: 1.35; 95% CI: 1.22-1.49) and this was seen particularly in CD (HR: 1.56; 95% CI: 1.34-1.83) and to lesser extent in UC (HR: 1.23; 95% CI: 1.08-1.40). Sex at severe IM diagnosis was not found to be a significant modifier to the risk of IBD diagnosis, with risk increased in both females (HR: 1.36; 95% CI: 1.20-1.55) and males (HR: 1.34; 95% CI: 1.17-1.54). Only those receiving a severe IM diagnosis at 10-16 years (HR: 1.42; 95% CI: 1.22-1.64) or 17-29 years (HR: 1.34; 95% CI: 1.15-1.56) had a significantly increased risk of IBD diagnosis. Finally, this increased risk remained present across calendar year of IM diagnosis, from 1977 to 2022.

Conclusion: This study demonstrated an association between IM hospitalisation and later IBD diagnosis, indicating an association between severe EBV disease and IBD development. Further exploration of the potential factors contributing to IBD susceptibility following EBV infection is warranted.

Contact E-Mail Address: soranbozorg@gmail.com

Introduction: Microscopic colitis (MC) is a chronic disabling inflammatory disease. Yet, the economic impact of MC is still largely unknown. In this nationwide study, we investigated societal costs, comprised of healthcare costs and productivity losses, in relation to MC diagnosis.

Aims & Methods: We identified 8,659 biopsy-verified patients diagnosed with MC between 2008 and 2017. Patients were followed from 4 years before diagnosis until either 4 years after diagnosis, emigration, death, or 2019 (end of follow-up), whichever came first. Each patient was compared to up to 5 general-population comparators matched on birthyear, sex, county of residence, and calendar year.

Using real-world data from Swedish national registers, we determined healthcare costs from prescribed medications, non-primary outpatient visits, and hospitalizations, while costs for productivity losses were derived from lost workdays due to sick leave or disability leave. All costs were adjusted for inflation and converted from Swedish currency, SEK, to USD (1 USD = 10.61 SEK).

Results: Patients with MC had 1.54 times higher societal costs than their general-population comparators already at 4 years before diagnosis, and the excess cost further increased during the years leading up to diagnosis. The excess cost of MC peaked during the year of diagnosis when patients with MC had 2.11 times the cost of comparators, corresponding to a mean annual excess cost of \$6,402 (adj. mean difference [95%CI]: \$6,460 [\$6,099; \$6,820]).

Although the mean cost of MC decreased after diagnosis, it did not return to pre-diagnostic levels. Instead, the cost of MC persisted at 1.85 times the costs of their comparators 4 years after diagnosis. The absolute excess cost of MC was also significantly higher 4 years after diagnosis compared with 4 years before diagnosis (\$4,654 vs \$2,926; P-value <0.05). Stratification by age, sex, and education level showed similar cost trajectories, with cost ratios peaking in the year of diagnosis and persisting at higher levels after diagnosis.

While work loss was the largest contributor to the absolute excess cost of MC both before and after diagnosis, the cost ratio (1.83) was lower than for other cost categories. Compared with the general population, the relative excess cost was highest for outpatient visits with a cost ratio of 3.00 during the year of diagnosis, followed by 2.54 for medications and 2.36 for hospitalizations.

Years in relation to diagnosis	Outpatient visits MC vs Control	Hospitalizations MC vs Control	Medications MC vs Control	Work loss MC vs Control	Total Cost MC vs Control	Crude Mean Difference ^A (95%CI)	Adjusted Mean Difference ^{A,B} (95%CI)	Cost Ratio ^C
-4	\$788 vs \$476	\$1,020 vs \$705	\$753 vs \$400	\$6,137 vs \$4,050	\$8,344 vs \$5,418	\$2,926 (\$2,460; \$3,392)	\$3,010 (\$2,547; \$3,474)	1.54
-3	\$991 vs \$598	\$1,434 vs \$871	\$843 vs \$418	\$6,066 vs \$4,026	\$9,333 vs \$5,914	\$3,412 (\$2,971; \$3,868)	\$3,482 (\$3,036; \$3,928)	1.58
-2	\$1,098 vs \$593	\$1,520 vs \$904	\$900 vs \$438	\$5,941 vs \$3,935	\$9,459 vs \$5,870	\$3,589 (\$3,177; \$4,002)	\$3,640 (\$3,229; \$4,050)	1.61

4	\$1,307 vs \$692	\$2,055 vs \$1,211	\$1,191 vs \$520	\$5,549 vs \$3,025	\$10,102 vs \$5,448	\$4,654 (\$4,268; \$5,040)	\$4,678 (\$4,293; \$5,063)	1.85

Table 1. Mean societal costs of patients with microscopic colitis (MC) and general-population comparators (control) in relation to year of diagnosis.

A: All mean differences had P-values <0.001.
B: Adjusted for age, sex, education level, and calendar year.
C: Cost of microscopic colitis as numerator and cost of general-population comparators as denominator (MC/Control).

Conclusion: Patients with MC have higher societal costs than the general population before diagnosis, and the excess costs increase and persist for several years after diagnosis. While excess costs may be multifactorial, improved disease control could provide opportunities to reduce the post-diagnostic cost of MC.

Introduction: There is significant interpersonal variation in management of gastric varices. In real life scenario both large esophageal and gastric varices coexist in a significant number of cases.

In patients presenting with variceal bleed, source of bleed whether esophageal or gastric varices is not clear in most patients. How aggressively to manage the large gastric varices in patients who had variceal bleed is not defined.

The aim of this study was to compare aggressive management of gastric varices with conservative management of gastric varices in patient with variceal bleed.

Aims & Methods: Consecutive patients with cirrhosis presenting with 1st episode of variceal bleed and having large gastric varices (Gastroesophageal varices (GOV)1, GOV2, Isolated gastric varices (IGV) 1) were randomized to receive aggressive (Group A, n=66) or conservative therapy (Group B, n=68) for gastric varices.

Aggressive group received glue injection for all types of gastric varies followed by band ligation of the oesophageal varies.

While group B patients were treated primarily with band ligation for oesophageal and GOV 1 varies and glue was used only those IGV or GOV 2 varies which revealed stigma of recent haemorrhage (SRH) (Table 1). Primary outcomes were variceal rebleed, rate of obliteration of varices or death at 1 year follow up.

Group A	Group B
Index endoscopy procedure	
Endoscopic cyanoacrylate (CYA) injection for all visible GOV1, GOV2 and IGV1, and EVL for esophageal varices	EVL for esophageal varices, GOV1 with SRH Endoscopic cyanoacrylate injection for: GOV2, IGV1 with SRH or; High risk* GOV 2, IGV1 with no SRH
Follow up endoscopy procedure	
Endoscopic cyanoacrylate (CYA) injection for all visible GOV1, GOV2 and IGV1, and EVL for esophageal varices	EVL for esophageal varices, GOV1 with SRH Endoscopic cyanoacrylate injection for: GOV2, IGV1 with SRH

Table 1: Endoscopic management on index and follow up endoscopy.
*High risk: size of varix (> 10mm) & red wale marks
Abbreviations: SRH, stigmata of recent haemorrhage;
EVL, Endoscopic variceal ligation; GOV, gastroesophageal varices;
IGV, Isolated gastric varices.

Results: There was no difference in the number of rebleed events among groups at 1 year (p=0.639).

Mortality due to variceal rebleed was comparable in both groups at 1 year (p=0.261), 6 months and 1 month. 1-year all-cause mortality was comparable in both groups.

The mean number of sessions required for obliteration of varices was lower in Group A than in Group B (1.24 ± 0.69 and 2.49 ± 1.38 respectively, p=0.01).

There was no significant difference between the two groups regarding the adverse events.

Conclusion: Aggressive approach to management of gastric varices using cyanoacrylate glue leads to early obliteration of varices but has similar rebleeding rates and survival benefit as compared to a more conservative approach.

Introduction: Patients with ischemic heart disease have a high risk to develop gastrointestinal bleeding because of antiplatelet therapy. It is argued that these patients might need a higher hemoglobin level for the oxygen demand when bleeding occurs [1-3].

There is little data about blood transfusion strategy for patients with ischemic heart disease complicated with acute upper gastrointestinal bleeding.

Aims & Methods: We designed a multicenter, prospective, randomized controlled trial to compare the outcomes of restrictive blood transfusion strategy with liberal blood transfusion strategy.

From 2019 June, we prospectively recruited 126 ischemic heart disease patients complicated with acute upper gastrointestinal bleeding. All of them were randomly assigned to restrictive blood transfusion group (blood transfusion when hemoglobin $\leq$ 80g/L) or liberal blood transfusion group (blood transfusion when hemoglobin $\leq$ 100g/L). The primary endpoint was 30 days rebleeding rate after randomization.

Results: There were 64 patients received restrictive blood transfusion, and 62 had liberal blood transfusion. The baseline characteristics, including sex, age, hemoglobin concentration, Glasgow-Blatchford score, endoscopic findings, types of ischemic heart disease, history of coronary angiography, use of proton pump inhibitor and hemostatic drugs were similar in the two groups. In an intention-to-treat (ITT) analysis, 13 (19.7%) of the restrictive blood transfusion group and 9 (14.3%) of the liberal blood transfusion group reached the primary endpoint (HR: 0.84, 95% CI: 0.56-1.25, $p=0.414$) (Table 1).

Treatment outcomes	Restrictive blood transfusion group n= 64	Liberal blood transfusion group n= 62	HR (95%CI)	p
30 days rebleeding, n (%)				
ITT analysis	13 (19.7%)	9 (14.3%)	0.84 (0.56- 1.25)	0.414
PP analysis	10 (20.8%)	5 (22.7%)	1.04 (0.70- 1.55)	0.858
30 days death, n (%)				
ITT analysis	2 (3.0%)	1 (1.6%)	0.76 (0.34- 1.73)	0.587
PP analysis	1 (2.1%)	1 (4.5%)	1.38 (0.34-5.58)	0.566
Major cardiovascular events, n (%)				
ITT analysis	12 (18.2%)	3 (4.8%)	0.52 (0.43- 0.81)	0.017
PP analysis	6 (12.5%)	2 (9.1%)	0.90 (0.58-1.40)	0.677

Table 1. Outcomes of both groups.

ITT, intention-to-treat; PP, per-protocol; HR, hazard ratio; CI, confidence interval

In a per-protocol (PP) analysis, 10 of 48 (20.8%) in the restrictive blood transfusion group compared 5 of 22 (22.7%) in the liberal blood transfusion group occurred rebleeding in 30 days after randomization (HR: 1.04, 95% CI: 0.70-1.55, $p=0.858$). The 30 days all-cause death were similar in the two groups (HR: 0.76, 95% CI: 0.34-1.73, $p=0.587$ in ITT analysis; HR: 1.38, 95% CI: 0.34-5.58, $p=0.566$ in PP analysis). The hospital stay length (8.95 $\pm$ 4.99 vs. 8.52 $\pm$ 4.68, days, in ITT analysis) were reduced in liberal blood transfusion group.

There was a reduction in 30-day major cardiovascular events in liberal blood transfusion group (HR: 0.52, 95% CI: 0.43-0.81, $p=0.017$ in ITT analysis; HR: 0.90, 95% CI: 0.58-1.40, $p=0.677$ in PP analysis). Of these, 6 (9.4%) patients in restrictive blood transfusion group had heart failure, 4 (6.3%) had myocardial infarction and 2 (3.1%) had both heart failure and myocardial infarction, while 2 (3.2%) patients in liberal blood transfusion group had heart failure and 1 (1.6%) had myocardial infarction.

Conclusion: In ischemic heart disease patients who occurred acute upper gastrointestinal bleeding, liberal blood transfusion reduced the hospital stay length, and the events of major cardiovascular events after bleeding. There was no significant difference in the 30-day rebleeding and 30-days all-cause death found between the restrictive and liberal blood transfusion groups.

Introduction: Gastrointestinal bleeds (GIBs) are associated with use of anticoagulants, such as Factor Xa inhibitors (FXai), and may result in significant morbidity and mortality.

The goal of this multicountry study was to explore the incidence and burden of GIBs following initial FXai use.

Aims & Methods: This retrospective observational cohort study involved analysis of electronic health records from new users of direct-acting oral anticoagulants (DOACs), specifically FXai, in Germany, the Netherlands, and the UK. Patients with a FXai prescription for a therapeutic indication (eg, venous thromboembolism, atrial fibrillation, non-mechanical cardiac-valve replacement) were included. Incidence rates of GIBs associated with FXai use and mortality after GIB were assessed and reported per 100 person years (PYR) with 95% confidence intervals.

Results: Among new FXai users (Germany, n=78,086; Netherlands, n=17,356; UK, n=212,378), 1583 GIBs were reported in Germany, 205 in the Netherlands, and 4683 in the UK (Table 1). Mean age across countries for patients experiencing a GIB ranged from 75 to 77 years and the proportion of female patients ranged from 42% to 62%. The most common FXai indication among patients with a GIB was atrial fibrillation (85% to 90%). The incidence of GIB at 1 year following FXai initiation was generally consistent across Germany (1.92 per 100 PYR), the Netherlands (1.27 per 100 PYR), and the UK (1.84 per 100 PYR; Table 1). Rates of upper GIBs were higher compared with rates of lower GIBs or unspecified location GIBs in Germany; in the UK and Netherlands, unspecified GIBs occurred at a higher rate than upper or lower GIBs. Rates of all-cause mortality declined from 3 months to 1 year following a GIB for Germany, the Netherlands, and the UK.

Conclusion: In this observational study, FXai-associated GIB incidence rates were similar across Germany, the Netherlands, and the UK. Rates of all-cause mortality after a GIB varied between countries and decreased over the first year for all countries.

Introduction: Proton pump inhibitors (PPI) may be over or underutilized in patients with acute gastrointestinal bleeding (AGIB). Further, the effects of their use on short- and long-term outcomes are not clear.

Aims & Methods: We examined utilization of PPI in patients with AGIB and its effect on short- and long-term rebleeding and mortality in a prospective study of patients admitted with AGIB to a tertiary referral center between Jan. 2013 and Aug. 2023. We determined intake of PPI on admission and on discharge, and intake of antithrombotics [antiplatelets (AP) only, anti-coagulants (AC) only or both AP and AC] on admission and on discharge. Univariate analysis was done to compare patients using PPI on admission or on discharge to patients not using PPI. Multivariate analysis was done to determine independent predictors of mortality and rebleeding.

Results: 846 patients with AGIB (462 had upper GIB) were admitted and followed-up for a median of 59 (29-88) months. 385 were admitted already taking PPI. 623 patients were discharged on PPI and 150 were discharged off PPI (73 patients died in hospital). 49% of patients admitted on PPI and 27% of patients discharged on PPI did not have a clear indication for their use. The overall PPI overutilization rate was 36%. 25% of patients discharged off PPI had at least one clear indication for their use.

Compared to patients admitted off PPI, those admitted on PPI were older (66 vs 70 years, $p<0.001$), had higher Charlson Comorbidity Index (CCI) (2.4 vs 3.2, $p<0.001$), were more likely to be on antithrombotics (56% vs 70%, $p<0.001$) and to require blood transfusion (54% vs 64%, $p=0.003$). They also had higher 1-month mortality (8% vs 16%, $p<0.001$). However, they had less stigmata of recent hemorrhage (SRH) (39% vs 30%, $p=0.022$) and were less likely to require endoscopic therapy (25% vs 15%, $p=0.002$). Compared to patients discharged off PPI, patients discharged on PPI were more likely to have had in-hospital re-bleeding (1.3% vs 5.3%, $p=0.036$) but had similar short- and long-term mortality (4.7% vs 2.9%, $p=0.301$ and 37% vs 44%, $p=0.122$, respectively).

On multivariate analysis, PPI on admission was not an independent predictor of 1-month mortality or re-bleeding [OR 1.46 (0.83, 2.57), $p=0.187$ and 0.91 (0.51, 1.59), $p=0.730$], respectively. Predictors of 1-month mortality were CCI [OR 1.13 (1.04, 1.22), $p=0.002$], severe bleeding [OR 2.48 (1.21, 5.10), $p=0.013$], blood transfusion [OR 2.72 (1.20, 6.15), $p=0.017$], and SRH [OR 2.53 (1.40, 4.59), $p=0.002$]. Predictors of 1-month re-bleeding were AC only on admission [OR 2.30 (1.20, 4.42), $p=0.012$], severe bleeding [OR 1.96 (1.03, 3.73), $p=0.041$], and SRH [OR 2.03 (1.16, 3.54), $p=0.013$]. PPI on discharge was not a predictor of long-term mortality or re-bleeding (table 1). Being on AC only on discharge was a predictor of long-term mortality, while being on AP only on discharge was protective against long-term re-bleeding (table 1).

	Variables	OR (95% CI)	p-value		Variables	OR (95% CI)	p-value
Long-term Mortality**	PPI on discharge	1.38 (0.85, 2.26)	0.194	Long-term Re-bleeding**	PPI on discharge	1.26 (0.76, 2.07)	0.375
	Age-related CCI	1.53 (1.41, 1.67)	<0.001		AP only on discharge	0.45 (0.28, 0.72)	0.001
	Blood transfusion	1.72 (1.18, 2.51)	0.005		AC only on discharge	0.91 (0.54, 1.56)	0.741
	AP only on discharge	0.85 (0.55, 1.32)	0.479		AP and AC on discharge	0.56 (0.29, 1.10)	0.095
	AC only on discharge	2.51 (1.45, 4.36)	0.001		Severe bleeding*	1.53 (1.03, 2.25)	0.034
	AP and AC on discharge	0.91 (0.50, 1.7)	0.749		SRH	1.78 (1.21, 2.64)	0.004

Table 1: Multivariate analysis showing predictors of long-term mortality and re-bleeding in patients with acute GIB. AP: antiplatelets; AC: anticoagulants; Hb: Hemoglobin level; CCI: Charlson Comorbidity Index; *Severe bleeding is defined as: Hb drop ≥ 2 units, blood transfusions ≥ 2 units, or systolic blood pressure on admission ≤ 100 mmHg. ** long term mortality and re-bleeding are defined as mortality or re-bleeding by the end of follow-up.

Conclusion: There is marked overutilization and underutilization of PPI in patients with GIB, without a significant effect on short- or long-term mortality or rebleeding. A PPI utilization stewardship program is needed to decrease health care costs and potential PPI related side effects.

Disclosure: Nothing to disclose.

Contact E-Mail Address: randataher12@gmail.com

Introduction: Asymptomatic patients with iron deficiency anemia (IDA) of indeterminate etiology are usually referred to bidirectional endoscopy evaluation. However, gastroscopy performance is questionable considering the low prevalence of gastric cancer in practice.

Aims & Methods: We conducted a retrospective, large cohort by reviewing electronic files of patients who underwent gastroscopy between 2005 and 2020. None had other active clinical symptoms than IDA. Asymptomatic patients referred routinely for gastroscopy before bariatric procedures served as controls.

Results: 6215 patients with IDA and 2010 controls were included. Female predominance was noted in both groups, IDA patients were significantly older (63.8 $\pm$ 17.3 vs. 40.6 $\pm$ 12.8; $P<0.001$), and significantly associated with severe gastritis (4.8% vs. 1%; $P<0.01$), gastric ulcer (2% vs. 0.5%; $P<0.01$), gastric cancer (1.4% vs. <0.01%; $P<0.01$), and gastric polyps (7% vs. 1.5%; $P<0.01$). The need for endoscopic intervention (1.9% vs. 0.1%; $P<0.01$) and biopsy performance (55% vs. 19%, $P<0.01$) were significantly higher among the IDA group. Overall, gastroscopy evaluation of IDA was significantly and independently associated with clinically significant findings (19.5% vs. 8.3%; OR 1.7, 95%CI=1.44-1.98; $P<0.001$). The highest yield of gastroscopy was documented among males (NNTI=13) and females

(NNTI=11) above 50, while the lowest was among young females in detecting clinically significant findings (NNTI=77), and upper GI malignancy (NNTI=1000).

Conclusion: Gastroscopy evaluation of asymptomatic patients with IDA is associated with an overall high yield of clinically significant findings detection, yet, among younger, colonoscopy performance first, rather than bi-directional endoscopic evaluation may be cost-effective.

Introduction: The implementation of the national bowel-screening program for colorectal cancer has had a significant impact on detecting early colorectal cancer (pT1 & pT2 carcinomas). In recent decades, there has been a shift towards minimally invasive approaches for treating T1 colon carcinomas (CC), favoring local resection techniques over major surgeries. It is unknown whether risk stratification could establish organ preservation in T2 CC.

Aims & Methods: We aimed to evaluate the incidence of lymph node metastases (LNMs) in patients with pT2 CC in the Netherlands and to develop a prediction model to estimate the risk of LNMs which could be helpful to compare the risk of LNMs against the age-specific adverse events associated with segmental surgery.

A retrospective nationwide cohort study was performed including all consecutive patients diagnosed with pT2 CC who underwent (completion) surgery between 2012 and 2020 in the Netherlands. Patients were identified by use of the Dutch ColoRectal Audit (DCRA).

Exclusion criteria were:

- 1) neoadjuvant therapy;
- 2) synchronous CRC;
- 3) hereditary predisposition
- 4) history of IBD; and,
- 5) non-adenocarcinoma.

Data obtained from the DCRA were linked to the Dutch Nationwide Pathology Databank (PALGA). A subgroup analysis was conducted on patients up to 70 years old, who were treated between 2018 and 2020, to examine the association between mismatch repair (MMR) status and the presence of LNMs.

Predictive factors for LNMs were evaluated with univariate- and multivariate logistic regression. Four machine learning (ML) models were developed and validated to predict LNM, including generalized linear modeling (GLM), GLM-Least Absolute Shrinkage and Selection Operator (GLM-LASSO), random forest (RF), and gradient boosting (XGB).

Results: In total 9,803 patients were included. The overall 30-day complication and mortality rates were 25.2% and 2.2%, respectively. In elderly patients (age ≥ 74), the complication and mortality rates increased to 30%, and 3.5%, respectively. LNMs were found in 1877 out of 9803 patients (19.1%). Younger age (OR 0.98, 95% CI 0.979 - 0.990), left-sided CC (OR 1.5, 95% CI 1.4-1.7), poor differentiation (1.7, 95% CI 1.4-2.2), and lymphovascular invasion (LVI) (OR 4.1, 95% CI 3.6-4.7) were independent risk factors for LNMs.

In the subgroup analysis, deficient MMR (dMMR) status was found to be associated with a significantly lower risk of LNMs (OR 0.3, 95% CI 0.2-0.5). GLM demonstrated the highest prediction accuracy, achieving AUCs of 0.67 for the full model and 0.68 for the model focusing on patients up to 70 years old.

The risk of LNMs in the lower-risk group (age ≥ 74 , right-sided CC, LVI absent, good/moderate tumor differentiation) was 10.7%. In the absence of other risk factors, patients with a dMMR carcinoma had a risk of LNMs of 6.1%.

		Right sided CC			Left sided CC			dMMR / pMMR
		Age ≥ 74	66 - < 74	Age < 66	Age ≥ 74	66 - < 74	Age < 66	
Good/ Moderate differentiation (G1-G2)	LVI -	10.7	12.6	14.1	15.6	18.2	20.2	6.1 / 17.2
	LVI +	33.2	37.5	40.6	43.4	48.1	51.4	19.3 / 43.1
Poor differentiation (G3)	LVI -	16.5	19.3	21.4	23.4	26.9	29.6	27.9 / 55.1
	LVI +	45.2	49.9	53.2	56.1	60.6	63.7	58.6 / 81.8
Complication rate		30.1	22.6	18	30.1	22.6	18	19.2
Mortality rate		3.5	1	0.5	3.5	1	0.5	0.7

Table. Predicted probability (%) of LNM in patients with T2 colon cancer.

Conclusion: The predicted probability of LNMs should be balanced against the risks associated with segmental colon surgery. The findings of this study could serve as valuable guidance for clinicians, enabling them to inform patients about these competing risks before making a shared decision.

RISK OF OCCULT LYMPH NODE METASTASIS IN PT2 RECTAL CANCER: A NATIONWIDE RETROSPECTIVE ANALYSIS

Introduction: Advances in transanal resection techniques have led to the increased use of surgical and endoscopic local excision (LE) as a diagnostic and potentially organ-sparing approach for early-stage (cT1-2N0) rectal cancer (RC). Current international guidelines recommend completion total mesorectal excision (TME) following LE for surgically fit patients with pT2 RC due to the 20-30% overall risk of lymph node metastasis (LNM). However, the risk of LNM is known to vary according to the presence of histological risk factors.

Therefore, omitting completion TME in selected patients with pT2 RC may constitute an oncologically safe alternative, provided there are no additional high-risk histological features other than muscularis propria invasion. The aim of this study was to determine the rate of LNM in patients with pT2 RC without additional histological risk factors.

Aims & Methods: Data from two large Dutch multicentre registries were analysed to evaluate the rate of LNM in patients with pT2 RC who underwent surgery between 2012 and 2020. In accordance with the clinical selection criteria for LE, only patients without suspected LNM on baseline imaging (cN0) were included in the study. Patients who received (neo)ad-

juvant (chemo)radiotherapy were excluded. Treatment strategies included primary TME, surgical LE followed by completion TME, or surgical LE followed by active surveillance with MRI for at least 24 months. Histological risk factors available in both registries were lymphovascular invasion (LVI) and poor tumour differentiation (PD).

Definitive LNM status was determined by histology after TME. Patients on active surveillance after LE were classified as LNM-negative if there was no evidence of LNM (cN0) on MRI during a minimum surveillance period of 24 months.

The primary study outcome was the rate of LNM in pT2 RC patients without LVI and PD. Secondary outcomes included the association between the two histological risk factors and the rate of LNM using univariable and multivariable analyses adjusted for age and sex.

Results: A total of 334 patients with pT2 RC met the inclusion criteria (mean age 69 years, 64% male). The majority of patients (262/334, 78%) underwent primary TME, while initial surgical LE was performed in 72/334 (22%). Within the LE group, subsequent TME surgery was performed in 59/72 (82%) patients, either as completion surgery (n=51) or as salvage surgery during the follow-up period (n=8). The remaining 13/72 (18%) patients underwent active surveillance for at least 24 months without suspicion of LNM on MRI during a median follow-up of 42 months (IQR 32-55).

The overall rate of LNM in the cohort was 17% (55/334). In the 266/334 (80%) patients without LVI and PD, the rate of LNM was 13% (34/266). The presence of either LVI alone or PD alone resulted in LNM rates of 31% (18/58) and 14% (1/7), respectively. When both LVI and PD were present, LNM occurred in 2 out of 3 cases. In our study, only LVI was identified as an independent predictor of LNM in multivariable analysis ($p < 0.001$; OR = 3.1, 95% CI 1.6-5.9).

Conclusion: In this large retrospective surgical cohort of patients with pT2 RC, the absence of LVI and PD was associated with a 13% risk of LNM. However, more detailed histological reassessment including risk factors such as tumour budding and perineural invasion may identify a subgroup of pT2 RC with an even lower risk of LNM. This may allow the omission of completion TME.

Disclosure: Nothing to disclose.

Introduction: Endoscopic intermuscular dissection (EID) was recently introduced as a novel resection technique for deep submucosal invasive rectal cancer (D-SMIC)¹. While short-term outcomes are promising, inter-

mediate- and long-term oncological safety has not yet been established. Therefore, we aimed to evaluate the 3-year oncological outcomes of EID for suspected rectal D-SMIC.

Aims & Methods: In this prospective cohort study, data of consecutive patients treated with EID for suspected rectal D-SMIC at two academic hospitals in the Netherlands between 2018 and 2022 were analyzed. Superficial submucosal invasive cancer (S-SMIC) was defined as Sm1 and D-SMIC as Sm2-3. Tumors were considered high-risk if they exhibited at least one of the following histological risk factors: high-grade tumor differentiation (G3), lymphovascular invasion, tumor budding grade 2-3, R1/Rx resection margins (<0.1 mm), or $\geq$ pT2 invasion. Patients with D-SMIC or $\geq$ pT2 invasion who did not undergo further treatment after EID, either due to the absence of additional risk factors or based on patient preference, underwent close surveillance. This surveillance involved biannual MRI and endoscopic scar inspection for 2 years, followed by annual MRI and endoscopy for 3 years. A complete colonoscopy was performed after 1 and 4 years. CEA blood levels were measured every six months for 5 years. Study outcomes included the 3-year locoregional recurrence rate (LRR), 3-year distant recurrence rate (DRR), 3-year salvageable recurrence rate (SRR) and 3-year rectal preservation rate. The 3-year estimates were calculated using the Kaplan-Meier method. Locoregional recurrence was defined as intramural cancer recurrence and/or mesorectal lymph node metastasis, while distant recurrences referred to other cancer recurrences. Salvageable recurrence was defined as cancer recurrence that could be treated with curative intent. Rectal preservation was defined as the absence of completion total mesorectal excision (TME) following EID or cancer recurrence.

Results: EID was initiated in 188 patients (median age 67 years, 33% female, 85% ASA I-II, median lesion size 25 mm) and successfully completed in 177 (94%). Histology showed non-invasive histology in 20 (11%), S-SMIC in 9 (5%), D-SMIC in 94 (53%) and $\geq$ pT2 in 53 (30%) cases. R0 resection rates within these groups were 100%, 100%, 93% and 58%, respectively. Among the 94 D-SMIC cases, 35 (37%) had no histological risk factors other than deep submucosal invasion. Out of the D-SMIC cases, 72/94 (77%) followed a rectal preserving strategy (64/72 close surveillance and 8/72 adjuvant chemoradiotherapy), while 22/94 (23%) underwent completion TME. The median follow-up period within the D-SMIC group was 30 months (IQR 18-48). At three years, the LRR was 5.9% (95%CI 0.0-11.5%) and the DRR was 1.1% (95%CI 0.0-3.4%). The 3-year SRR was 100% (95%CI 100-100%). One patient (1.1%) died of a non-CRC-related cause. Among the subgroup of 35 D-SMIC cases without additional histological risk factors, all of whom underwent close surveillance following EID, no recurrences occurred within the first three years of follow-up. Beyond this period, one locoregional recurrence (2.9%) occurred at 37 months and one distant recurrence (2.9%) at 51 months, both salvageable. Overall, the 3-year rectal preservation rate among all 188 patients who underwent EID for suspected rectal D-SMIC, was 64.6% (95%CI 58.0-71.9%).

Conclusion: EID for suspected rectal D-SMIC resulted in favorable 3-year rectal preservation rates and demonstrated excellent 3-year oncological outcomes for rectal D-SMIC without additional risk factors.

Introduction: Scar excision with endoscopic full-thickness resection (eFTR) offers a minimally invasive alternative to completion surgery after incomplete resection of low-risk T1 colorectal cancer (CRC). While this strategy has demonstrated promising technical and short-term results, long-term data on oncological safety are lacking.

Aims & Methods: Consecutive patients undergoing eFTR scar excision after incomplete resection of low-risk T1CRC were selected from the Dutch prospective eFTR registry. Incomplete resection was defined as indeterminate (Rx), tumour-positive (R1, <0.1mm) or <1mm tumour-free (R0) resection margins. Lesions were considered low-risk in absence of lymphovascular invasion, poor tumour differentiation and tumour budding grade 2-3 (if assessed). A retrospective analysis was conducted to evaluate the procedural outcomes, subsequent treatment after eFTR, and surveillance

data, including endoscopy, CEA and imaging studies, as outlined by local protocols. Study outcomes included the 3-year locoregional recurrence rate (LRR), distant recurrence rate (DRR), salvageable recurrence rate (SRR), overall survival (OS) and organ preservation rate. The 3-year estimates were calculated using the Kaplan-Meier method. Locoregional recurrence was defined as intramural cancer recurrence and/or locoregional lymph node metastasis. Other cancer recurrence was defined as distant recurrence. Salvageable recurrence was defined as cancer recurrence that could be treated with curative intent.

Results: Out of the 1341 procedures registered in the Dutch prospective eFTR registry between 2015 and 2023, 314 patients met the inclusion criteria (mean age 69 years, 62% male). Initial histology showed Rx/R1 margins in 260/314 (83%) and R0 <1mm in 54/314 (17%). Mean time from initial resection to eFTR was 2 months (SD 2). Macroscopic complete scar excision was achieved in 259/314 (83%) patients. At histology, 36/314 (12%) eFTR specimens had residual cancer (15 low-risk T1CRC, 21 high-risk T1CRC/≥T2CRC). Residual cancer was found in 26/143 (18%) patients after initial piecemeal resection versus 10/171 (6%) after en bloc resection. No residual cancer was found after R0 <1mm (0/54). The R0-resection rate for residual cancer was 25/36 (69%). After eFTR, 30/314 (10%) patients underwent completion surgery, of whom 9/30 (30%) had residual cancer. One patient received adjuvant chemoradiotherapy. Surveillance was initiated in the remaining 283/314 (90%) patients. In the surveillance-only group, 246/283 (87%) had at least one recorded follow-up visit, with a median follow-up time of 36 months (IQR 16-52). Of these, 17/246 (7%) had residual cancer in the eFTR specimen. The 3-year LRR, DRR, SRR and OS for this subgroup (n=17) were 13%, 0%, 100% and 94%, respectively. Of the 229/246 (93%) patients without residual cancer in the scar, 187/229 (82%) had no risk factors at initial histology, while the presence of risk factors could not be reliably assessed in 42/229 (18%). In the low-risk group (n=187), the 3-year LRR, DRR, SRR and OS were 1%, 1%, 99% and 98%, respectively. In the group with indeterminate risk factors (n=42), these were 7%, 3%, 97% and 92%. The overall 3-year organ preservation rate for all 314 eFTR procedures initiated was 87%.

Conclusion: In this analysis of a large Dutch prospective eFTR registry, the use of completion eFTR after incomplete resection of low-risk T1CRC demonstrated excellent 3-year oncological outcomes. However, caution should be exercised if the presence of histological risk factors cannot be adequately assessed. Further prospective studies with strict surveillance are warranted.

Introduction: According to the current guidelines, all patients with lymph node metastases after curative surgery for colon cancer (CC) are recommended to undergo adjuvant chemotherapy, regardless of the T-stage. However, a limited number of patients with pT1-2 CC were included in the trials that demonstrated a benefit of adjuvant chemotherapy for lymph node positive CC patients.

The aim of this study was to evaluate the value of adjuvant chemotherapy in patients with lymph node-positive pT1-2 CC.

Aims & Methods: A multicenter retrospective cohort study was conducted, including patients who underwent curative surgery for T1 or T2 CC between 2014 and 2015. Patients were originally identified through the Dutch ColoRectal Audit (DCRA), a prospective national registry of all patients undergoing surgery for primary colorectal cancer. Long-term oncological follow-up data from the original patient records were added to the DCRA data by surgical residents affiliated with the Dutch Snapshot Research Group (DSRG) from 61 participating hospitals. Patients were stratified by age (< 75 or ≥75 years).

Survival outcomes were compared with the Kaplan-Meier method and log-rank test. Cox proportional hazard models were used to determine risk factors associated with 5-year metastasis-free and overall survival (MFS/OS).

Results: Among the 2277 surgically treated pT1-2 CC patients, 370 (16.2%) were found to have lymph node metastases, with 262 (70.8%) of them receiving adjuvant chemotherapy (CT+). Patients who did not receive adjuvant chemotherapy (CT-) were significantly older, had a higher ASA score, and experienced more frequently a complicated postoperative course, compared to the CT+ group. Among the total cohort, the vast majority of patients (78.6%) received oxaliplatin-based chemotherapy (CAPOX) and 13% capecitabine monotherapy.

Among those under < 75 years old (n = 272), CAPOX was administered in 86.3% of cases, whereas in patients ≥ 75 (n = 97), capecitabine monotherapy was given in 42.9% and CAPOX in 38.1%. In younger patients (< 75), chemotherapy significantly improved OS (68.2% CT-group versus 91.8% in CT+ group, multivariate HR 0.3, 95% CI 0.1 - 0.6) and also had a favorable effect on MFS (83.7% in CT-group versus 91.6% in CT+ group, multivariate HR 0.5, 95% CI 0.2 - 1.09). In elderly patients (≥75 years old), the administration of adjuvant chemotherapy did not significantly affect the development of distant metastases (MFS of 81.7% in the CT- group versus

84.5% in the CT+ group, log rank p value 0.73, adjusted HR 1.2, 95% CI 0.4 – 3.8)), nor survival after correction for confounders (OS of 52.7% in the CT-group versus 77% in the CT+ group, age adjusted HR 0.6, 95% CI 0.2 – 1.5). The choice of chemotherapy regimen (CAPOX or capecitabine monotherapy) had no influence on MFS (HR 0.6, 95% CI 0.1 – 3.5) or OS (0.6, 95% CI 0.1 – 2.7).

	Age < 75 No CTx n = 53	Age < 75 CTx n = 219	p value	Age ≥ 75 No CTx n = 55	Age ≥ 75 CTx n = 42	p value
Follow-up (months), median [IQR]	53 [28-61]	64 [60-70]	<.001	49 [28-63]	59 [44-63]	0.11
Recurrent disease, n (%)	8 (15.1)	19 (8.7)	0.16	11 (20)	6 (14.3)	0.46
Loco regional recurrence only	1 (1.9)	2 (0.9)		3 (5.5)	0	
Distant metastases only	6 (11.3)	13 (5.9)		7 (12.7)	5 (11.9)	
Loco regional recurrence + distant metastases	1 (1.9)	4 (1.8)		1 (1.8)	1 (2.4)	
Unadjusted 5-Year Overall Survival (%)	68.2	91.8	<.001	52.7	77	0.02
Unadjusted 5-Year Metastasis Free Survival (%)	83.7	91.6	0.07	81.7	84.5	0.73

Conclusion: In the largest cohort of node-positive pT1-2 colon cancer patients currently available, no significant benefit of adjuvant chemotherapy in patients over 75 years of age could be demonstrated, irrespective of the regimen that is chosen.

Contact E-Mail Address: jybang213@gmail.com

Introduction: As outcomes in pancreatic cancer are stage dependent, high technical proficiency in EUS is required for early detection and accurate diagnosis of pancreatic lesions. We evaluated performance of artificial intelligence enhanced EUS (AI-EUS) to detect solid and cystic lesions in the pancreas.

Aims & Methods: An AI-EUS software was developed using convolutional neural network (CNN) model that included 32,713 linear-array EUS frames (training and testing phases) of normal, solid and >10mm cystic pancreatic lesions from 202 patients. A prospective, nonrandomized, comparative study was conducted in patients referred for pancreatic cancer screening and suspected solid or cystic lesions in pancreas. EUS findings were examined concurrently in real-time by two independent expert examiners, one using conventional EUS and another with AI-EUS. EUS procedures were projected to separate monitors with examiners blinded to alternate assessments. Main outcome was detection of solid pancreatic mass lesions. Secondary outcome was detection of pancreatic cysts.

Results: 180 patients were included (mean age 66.5 years [SD 14.5]; male 45.6%) between January to April 2024. There was 100% (95% CI, 94.6-100) concordance between conventional EUS and AI-EUS for detection of solid masses (n=67; mean size 32.7 mm [SD=16.7]) that were biopsy proven to be adenocarcinoma in 46, metastatic lesion 2, neuroendocrine tumor 7, lymphoma 1, solid pseudopapillary neoplasm 1, and benign disease in 10. Likewise, there was 100% (95% CI, 92.7-100) concordance for detection of normal pancreas (n=49). For pancreatic cysts (n=64; median size 22 mm [IQR 13-34.5]), as compared to AI, conventional EUS diagnosed more cysts (100 [95% CI 94.4-100] vs. 84.4% [95% CI 73.1-92.2], p=0.001), particularly those < 15 mm.

Conclusion: In this first human trial, performance of AI-EUS was comparable to conventional EUS for detection of solid pancreatic mass lesions. AI has potential to standardize technical performance at EUS which can further optimize clinical outcomes in pancreatic cancer. Additional refinements to CNN model incorporating Doppler techniques could improve detection of small pancreatic cysts.

Introduction: Accurate diagnosis of pancreatic lesions poses a considerable challenge due to the involvement of multiple examinations in the diagnostic process. Endoscopic ultrasound (EUS) stands out as a valuable tool enabling characterization and tissue sampling of both cystic and solid lesions, thereby influencing treatment decisions and follow-up strategies significantly. Pancreatic cystic neoplasms (PCNs) encompass mucinous (M-PCN) and non-mucinous lesions (NM-PCN), while pancreatic adenocarcinoma (P-ADC) remains the most prevalent cause of pancreatic solid lesions (PSL), trailed by pancreatic neuroendocrine tumors (P-NET). Despite the potential benefits of artificial intelligence, particularly deep learning algorithms, in EUS, research on the role of convolutional neural networks (CNNs) in pancreatic lesions is scarce.

Aims & Methods: This multicentric study aims to develop a CNN tailored for the detection and differentiation of PCNs (specifically M-PCN and NM-PCN) as well as PSLs (particularly P-ADC and P-NET). Our group developed a retrospective multicenter study based on patients submitted to EUS for pancreatic lesion characterization. A trinary CNN differentiated normal pancreas tissue from M-PCN and NM-PCN. A binary CNN distinguished P-ADC from P-NET. The total dataset was divided into a training and testing dataset (used for model's evaluation) in a 90/10% ratio. The model performance was evaluated through its sensitivity, specificity, positive and negative predictive values and accuracy. The Sci-kit learn v0.22.2 was used for statistical analysis of the model.

Results: A total of 378 videos of EUS performed for evaluation of pancreatic lesions during November 2017 and December 2023 in four reference centers (Hospital Universitario Puerta de Hierro Majadahonda, n=234; Centro Hospitalar Universitário São João, n=33; New York University Langone and Manhattan Hospital, n=60; Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, n=51) were used for development of the model. A total of 126.000 frames were extracted for development of CNN: 64.286 of P-ADC, 29.153 of P-NET, 4.858 of normal pancreas, 19.528 of M-PCN and 8.175 of NM-PCN.

Pancreatic Cystic Neoplasms

The trinary CNN was developed in order to distinguish between normal pancreas images and cystic lesions, differentiating M-PCN from NM-PCN. The deep learning model identified normal pancreas images with 98.6% sensitivity, 99.2% specificity and 99.1% accuracy. M-PCN were detected with 98.9% sensitivity, 99.1% specificity, a PPV of 99.4% and NPV of 98.3%, with a global accuracy of 99%. Finally, the testing dataset of our CNN revealed 99.3% sensitivity, 99.9% specificity, 99.9% PPV, 99.8% NPV and 99.8% accuracy for the diagnosis of NM-PCN.

Pancreatic Solid Lesions

The binary CNN was developed to differentiate between the two commoner PSL, namely P-ADC and P-NET. The testing dataset revealed 94.0% accuracy for the distinction between the lesions, with 98.7% and 83.7% sensitivities for P-ADC and PNET, respectively.

Conclusion: Our group developed a deep learning model capable of differentiating the main types of pancreatic solid lesions, as well as pancreatic cystic lesions, with high performance values. To our knowledge this is the first multicentric approach for the development of an AI algorithm designed to simultaneously characterize cystic and solid pancreatic lesions.. The development of deep learning models may help differentiate pancreatic lesions. Larger multicentric and prospective studies are needed for the validation and future clinical implementation of this technology.

Introduction: Patients with necrotizing pancreatitis are at risk of developing numerous complications as a consequence of their more severe disease course. Effective drainage strategies are essential for patients with symptomatic walled off necroses (WON). Here, most patients receive interventional-endoscopic drainage using Lumen apposing metal stents (LAMS)¹. However, LAMS-associated complications such as occlusion are still considered a relevant clinical problem. Occlusion rates ranging from 3,8% to 24,3% of all LAMS applied have been reported in literature^{1,2}. Thus far, few studies have identified factors, which could potentially affect LAMS occlusion rate such as preemptive placement of coaxial double pig-tails through the LAMS³. A recent study suggested a potential influence of Proton Pump Inhibitors (PPI) on LAMS occlusion and the rate of endoscopic necrosectomies⁴. However, the results of this study were contradictory.

Aims & Methods: We performed a European-wide distributed expert survey in combination with a European-wide multicentric retrospective cohort study. Data was acquired using the electronic case record form (eCRF) tool REDCap and analyzed using R Studio (V4.2.3). 75 interventional endoscopists participated in the expert survey and 882 patients with 956 LAMS implanted were included in the retrospective cohort study. The primary aim of the expert survey was to assess the clinical relevance of LAMS occlusion. The primary aim of the retrospective cohort study was to investigate the potential correlation of PPI intake and LAMS occlusion and the numbers of necrosectomies.

Results: We observed that in the majority of cases, patients included received PPIs (746 cases (79.3%) with versus 195 without PPIs (20.7%). Moreover, we observed that a relevant number of experts would discontinue PPIs upon LAMS implantation (n=18; 27%) – even though this is not resembled by the real-world data. By performing a multivariable logistic regression of various factors potentially affecting LAMS occlusion we show that concomitant continuous intake of PPIs significantly increases the LAMS occlusion rate (Odds Ratio (OR): 0.62; p-value 0.045). Moreover, our data reveals that patients who continuously receive PPIs exhibit a significantly higher rate of required endoscopic necrosectomies (mean continuous PPI intake: 4.13; mean no PPI intake: 2.99; p-value 0.006). In addition, we show that this effect is dose-dependent with a significantly higher ne-

crosectomy rate in patients who receive more than double the standard PPI dose in comparison to the standard dose of PPIs (p-value <0.001). For other complications such as relevant gastrointestinal bleeding (defined as with a need for blood transfusions or interventional measures) we did not observe any significant differences between the PPI and the Non-PPI group (bleeding: OR 1.37, p-value 0.3).

Conclusion: Our data suggests that concomitant PPI-intake could be disadvantageous in patients receiving LAMS. However, further studies are needed to investigate the mechanism behind the effects observed and to validate our findings prospectively.

Introduction: Acute pancreatitis (AP) is one of the most common gastrointestinal diseases necessitating acute hospitalisation. It is associated with notable morbidity and mortality, with a growing recognition of post-discharge mortality's importance. Nonetheless, comprehensive population-based studies in this regard are lacking.

Aims & Methods: In a Danish nationwide population-based cohort study, we aimed to investigate the post-discharge mortality risk in AP patients, including cause-specific mortality. We included all adults (>18 years) hospitalised with incident AP from January 1, 2002, through December 31, 2017. For each patient, we matched five individuals from the general population based on age and sex. The date of hospital discharge was used as the index date. Cox regression analysis was used to assess post-discharge mortality risk at 90 days, 1, 2, and 5 years. Models were adjusted for demographics, comorbidities and alcohol and smoking-related diseases. Furthermore, we examined the cause-specific mortality, including cardiovascular death, pancreatic ductal adenocarcinoma (PDAC), mortality from other cancers, and infection-related mortality, using Cox regression analysis.

Results: Among 28,763 adults with incident AP, 956 (3.3%) died in hospital. The 27,807 patients surviving the index AP event were matched with 139,035 comparison individuals (mean age 58.1 years, 51.1% men). The cumulative post-discharge mortality at 90 days was 5.02% for the AP cohort and 0.55% for the comparison cohort. The mortality risk was sig-

nificantly increased in AP patients at 90 days (adjusted hazard ratio [aHR] 7.62; 95% CI 6.86-8.45), 1 year (aHR 3.39; 95% CI 3.19-3.60), 2 years (aHR 2.47; 95% CI 2.36-2.60), and 5 years (aHR 1.85; 95% CI 1.79-1.92) post-discharge. Cause-specific mortality analysis revealed heightened risks of death from cardiovascular disease (90 days aHR 2.94; 95% CI 2.32-3.73), infectious disease (90 days aHR 11.67; 95% CI 6.78-20.07), PDAC (90 days aHR 73.08; 95% CI 22.58-236.54), and other cancers (90 days aHR 3.43; 95% CI 2.75-4.28) among AP patients when compared to the comparison group.

Conclusion: Patients discharged after an incident episode of AP are at increased risk of death compared to the general population. While PDAC presents the highest cause-specific mortality risk, cardiovascular and infectious mortality rates are also notably heightened post-discharge.

Introduction: There has been an ongoing debate over the appropriate timing of direct endoscopic necrosectomy (DEN) following the initial endoscopic ultrasound (EUS)-guided transmural drainage of walled-off necrosis (WON). We aimed to examine the superiority of immediate DEN over the drainage-oriented step-up approach in terms of the time to WON resolution.

Aims & Methods: This multicentre, open-label, superiority, randomised trial (WONDER-01) was implemented including patients who were scheduled to receive EUS-guided treatment of WON at 23 centres in Japan (1). Eligible patients were randomly assigned at a 1:1 ratio to receive either immediate DEN or the step-up approach. In both arms, a lumen-apposing metal stent was used as the first-choice stent for EUS-guided drainage. In the immediate DEN arm, DEN was initiated during (or within 72 hours of) the initial EUS-guided drainage session. In the step-up approach group, drainage-based step-up treatment with on-demand DEN was considered after clinical observation for 72-96 hours. The primary endpoint was time from the randomization to clinical success, which was defined as a decrease in a WON size to ≤ 3 cm and an improvement of inflammatory markers (i.e., body temperature, white blood cell count, and C-reactive protein). The secondary endpoints included technical success, procedure-related adverse events, and mortality. All efficacy and safety endpoints were analysed on an intention-to-treat basis. This study was registered with ClinicalTrials.gov (registration number, NCT05451901), and the recruitment and follow-up for the primary endpoint have been completed.

Results: Between July 2022 and December 2023, a total of 70 patients were enrolled (33 and 37 patients in the immediate DEN and step-up arms, respectively) with baseline characteristics being well-balanced between the arms. In an analysis of the primary endpoint, the immediate DEN was associated with a shorter time to clinical success compared to the step-up approach ($P < 0.001$) with median times of 31 days (95% confidence interval, 19-34 days) and 44 days (95% confidence interval, 38-52 days), respectively. As per the protocol, all patients in the immediate DEN arm received DEN compared to 46% in the step-up approach arm ($P < 0.001$), but the rates of procedure-related adverse events were compatible between the arms (24% vs. 22%, respectively; $P = 0.79$). No differences were noted between the immediate DEN and step-up approach arms in terms of the rates of technical success (100% vs. 98%, respectively; $P = 0.26$) and mortality (12% vs. 5.4%, respectively; $P = 0.31$).

Conclusion: In patients with symptomatic WON, immediate DEN following EUS-guided transmural drainage shortened the time to clinical success compared to the drainage-oriented step-up approach without increase in adverse outcomes. Immediate DEN can be a first-line treatment option for this patient population.

LONG-TERM HEALTH OUTCOMES IN OFFSPRING OF WOMEN WITH INFLAMMATORY BOWEL DISEASE: A NATIONWIDE POPULATION BASED STUDY

H. Shin¹, J.-S. Koo²

¹Korea University Ansan Hospital, Department of Internal Medicine, Gyeonggi, South Korea, ²Korea University College of Medicine, Department of Internal Medicine, Division Of Gastroenterology, Seoul, South Korea

Contact E-Mail Address: shg0715@nate.com

Introduction: Long-term health outcomes of children of mother with inflammatory bowel disease (IBD) are poorly understood. Therefore, this study aimed to evaluate the long-term impact of maternal IBD on disease in children, including IBD.

Aims & Methods: This nationwide retrospective study included women who delivered a singleton baby after 37 weeks between 2003 and 2004 in South Korea. Women gave birth to low birth weight babies were excluded from the study. We compared risk of diseases in offspring according to maternal IBD. Multivariate analysis was performed to estimate the hazard ratios (HRs) for the future disease risk.

Results: Among a total 542,780 woman who gave birth during study periods, 1,096 women with IBD and 541,684 non-IBD control were identified. In multivariate analysis, the offspring of IBD women frequently had lower respiratory infections (HR 1.124[1.018-1.242]), asthma (HR 1.209[1.065-1.372]), atopic dermatitis (HR 1.217[1.112-1.332]), allergic urticaria (HR 1.276[1.129-1.443])HRHR, and allergic rhinitis (HR 1.151[1.084-1.222]) than those of women without IBD. And the offspring of IBD mother had a higher risk of developing ulcerative colitis (UC) (HR 6.334[4.391-9.136]) and Crohn's disease (CD) (HR 2.325[1.463-3.694]) than others. Offspring of CD women were significantly associated with asthma (HR 1.244[1.048-1.476]), allergic rhinitis (HR 1.132[1.043-1.229]), and CD (HR 3.44[2.035-5.813]). The offspring of UC women had higher rates of pneumonia (HR 1.332[1.052-1.687]), gastroenteritis (HR 1.469[1.151-1.873]), juvenile arthritis (HR 2.872[1.194-6.909]), atopic dermatitis (HR 1.33[1.174-1.507]), allergic urticaria (HR 1.39[1.174-1.647]), allergic rhinitis (HR 1.158[1.063-1.261]), and UC (HR 11.776[8-17.336]).

Conclusion: Our results show that the offspring of IBD women have higher risk of developing allergic and autoimmune disorders including UC and CD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: zlata.chkolnaia@gmail.com

Introduction: Tumor necrosis factor inhibitors (anti-TNF) are associated with several adverse effects, including paradoxical reactions like psoriasis-like lesions and less common drug-induced sarcoidosis-like reactions. They present significant diagnostic and therapeutic challenges, as they require careful differential diagnosis and often necessitate the discontinuation of treatment. Initially described in patients with inflammatory rheumatic diseases, sarcoidosis-like lesions induced by anti-TNF therapy have been sparsely documented only through case reports in the context of Inflammatory Bowel Diseases (IBD).

Aims & Methods: This study aimed to comprehensively describe epidemiological, diagnostic and therapeutic features of sarcoidosis-like lesions in IBD patients treated anti-TNF therapy, along with patient outcomes. We conducted a nationwide observational case series across 59 institutions affiliated with the Groupe d'Etude Thérapeutique des Affections Inflammatoires du Tube Digestif (GETAID). The diagnosis of anti-TNF-induced sarcoidosis was based on typical clinical and radiological signs, histological evidence of non-necrotizing granuloma, exclusion of differential diagnoses, and a timeline consistent with drug exposure. Each case was reviewed by a pharmacovigilance expert to confirm drug causality.

Results: We identified 12 cases of sarcoidosis-like lesions during anti-TNF therapy, with an equal distribution of male and female and a median age of 39 years (range 25-55). Underlying conditions were Crohn's Disease (58.3%), Ulcerative Colitis (33.3%) and Inflammatory Bowel Disease Unclassified (8.3%). The median duration of IBD prior to diagnosis was 14 years (range 5-29).

The anti-TNF medications involved were infliximab (58.3%), adalimumab (33.3%) and golimumab (8.3%), with the majority of patients (75%) being first-time users of biotherapy.

6 patients had optimized treatment. The median time from anti-TNF initiation to diagnosis was 22.7 months (range 3-91).

The most commonly observed clinical manifestations were dyspnea (75%) and fever (58.3%). Affected organs included the lungs (100%), liver (16.7%), extrathoracic adenopathy (16.7%), spleen (16.7%), parotid gland (8.3%), and kidneys (8.3%). There was a case of Löfgren syndrome

and one of meningitis. Eight patients discontinued anti-TNF therapy and started oral steroids, resulting in complete resolution of symptoms in five cases and improvement in two. One patient with multivisceral sarcoidosis required azathioprine addition due to renal insufficiency. Anti-TNF discontinuation was the only intervention in 2 cases, giving clinical remission in both. In 2 other cases, resolution of symptoms was observed with addition of steroids without anti-TNF discontinuation. Median time from steroid initiation (daily dose of 30 or 60 mg) to clinical remission was 91 days (range 11-305).

After a median follow-up of 48 months (range 18-175), one case showed persistent sarcoidosis activity, while no relapses were noted in the others. Anti-TNF therapy was resumed in only one patient, without recurrence of granulomatous lesions. Of the 10 patients who discontinued anti-TNF, all needed a new line of treatment, which was mostly vedolizumab. At last follow-up, IBD activity was noted in 4 patients.

Conclusion: Sarcoidosis-like lesions represent a rare but significant adverse reaction to anti-TNF therapy in IBD patients. This diagnosis should be considered when patients present with persistent respiratory or systemic symptoms after ruling out mycobacterial infection. Management involves discontinuation of anti-TNF and introduction of steroids.

Introduction: Sphingosine 1-phosphate (S1P) receptor modulators have been associated with an increased risk of macular oedema.¹ Etrasimod is an oral, once-daily, selective S1P_{1,4,5} receptor modulator for the treatment of moderately to severely active ulcerative colitis (UC) and in development for the treatment of other immune-mediated inflammatory diseases.

Aims & Methods: We assessed the proportions and incidence rates (IRs; patients with events per 100 patient-years [PY] of exposure) of Macular oedema and Cystoid macular oedema in a comprehensive analysis of safety data from the etrasimod clinical programme. UC data were analysed in two cohorts: Placebo-controlled UC (completed phase [ph] 2 OASIS, ph 3 ELEVATE UC 52 and ELEVATE UC 12) and All UC (patients treated with etrasimod in the Placebo-controlled UC plus open-label extension [OLE] studies; completed ph 2 OASIS OLE and ongoing ph 3 ELEVATE UC and ES101002 OLE studies, both datacut at 31 Jan 2022). Data from completed ph 2 studies in Crohn's disease (CULTIVATE substudy A), and Placebo-controlled studies in eosinophilic oesophagitis (VOYAGE), alopecia areata and atopic dermatitis (ADVISE) were also analysed.

Results: Across the etrasimod UC clinical programme, 942 patients received ≥ 1 dose of etrasimod 2 mg once daily (QD), with 757.9 PY of exposure. In the Placebo-controlled UC cohort, Macular oedema was reported in two patients (0.3%; IR 0.70) receiving etrasimod 2 mg QD (one patient with long-term corticosteroid use in ELEVATE UC 52 and one patient with prior uveitis in ELEVATE UC 12, which was not considered clinically significant by the investigator) and one patient (0.3%; IR 0.84) receiving placebo

(ELEVATE UC 12). In the All UC cohort, one patient (0.1%; IR 0.13) receiving etrasimod 2 mg QD during the ELEVATE UC OLE reported two events of Cystoid macular oedema (Table). Four of five Macular oedema events began at Days 74–94, all were non-serious and only one event led to treatment discontinuation. No events of Macular oedema were reported in studies of etrasimod in other indications (Table).

Indication	Cohort/study	Treatment	Macular oedema		Cystoid macular oedema	
			n (%)	IR per 100 PY (95% CI)	n (%)	IR per 100 PY (95% CI)
UC	Placebo-controlled UC cohort ^a	Etrasimod 2 mg QD (N=577) ^b	2 (0.3) ^b	0.70 (0.00, 1.66)	0	0
		Placebo (N=314)	1 (0.3) ^c	0.84 (0.00, 2.50)	0	0
	All UC cohort ^c	Etrasimod 2 mg QD (N=942) ^b	2 (0.2) ^b	0.26 (0.00, 0.61)	1 (0.1) ^d	0.13 (0.00, 0.38)
Crohn's disease	CULTIVATE substudy A ^d	Etrasimod 2 or 3 mg QD (N=83)	0	N/A	0	N/A
Eosinophilic oesophagitis	VOYAGE ^e	Etrasimod 1 or 2 mg QD (N=80)	0	N/A	0	N/A
		Placebo (N=28)	0	N/A	0	N/A
Alopecia areata ^f		Etrasimod 2 or 3 mg QD (N=56)	0	N/A	0	N/A
		Placebo (N=23)	0	N/A	0	N/A
Atopic dermatitis	ADVISE ^g	Etrasimod 1 or 2 mg QD (N=94)	0	N/A	0	N/A
		Placebo (N=46)	0	N/A	0	N/A

Adverse events were coded according to the Medical Dictionary for Regulatory Activities, version 24.1, and reported by preferred term.

Reported events of Macular oedema or Cystoid macular oedema occurring before the available datacut (31 Jan 2022) were included.

Severity was classified by the investigators using the CTCAE v5.0. Grade 1 = mild, Grade 2 = moderate.

^aPlacebo-controlled UC cohort included: completed ph 2, 12-week induction OASIS (NCT02447302), ph 3, 52-week (12-week induction followed by 40-week maintenance period with treat-through design) ELEVATE UC 52 (NCT03945188), and ph 3, 12-week induction ELEVATE UC 12 (NCT03996369).

^bData are presented for patients receiving etrasimod 2 mg QD. There were no events of Macular oedema or Cystoid macular oedema reported in the etrasimod 1 mg QD group (N=52) in OASIS.

^cAll UC cohort included: Placebo-controlled UC cohort (patients in the etrasimod group only) plus patients treated with etrasimod in: completed ph 2, 34–40-week OASIS OLE (NCT02536404) and ongoing ELEVATE UC OLE (NCT03950232) and ES101002 OLE (NCT04176588), both datacut at 31 January 2022. IRs (per 100 PY) were calculated based on 2 mg etrasimod exposure only.

^dPh 2, 66-week (14-week induction period followed by 52-week extension period) CULTIVATE substudy A (NCT04173273).

^ePh 2, 24-week induction period VOYAGE study (NCT04682639).

^fPh 2, 24-week induction period study (NCT04556734).

^gPh 2, 12-week treatment period ADVISE study (NCT04162769).

^hOne patient with prior corticosteroid use receiving etrasimod 2 mg in ELEVATE UC 52 experienced non-serious, moderate Macular oedema on Day 74. This was considered by the investigator to be related to the study treatment, led to treatment discontinuation and resolved. One patient with prior uveitis receiving etrasimod 2 mg in ELEVATE UC 12 experienced non-serious, mild Macular oedema on Day 86, which was not resolved at the time of datacut and was not considered by the investigator to be related to the study treatment. One patient receiving placebo in ELEVATE UC 12 experienced non-serious, mild Macular oedema on Day 94. The event was resolving at the time of datacut.

ⁱOne patient receiving placebo in ELEVATE UC 52, then switching to etrasimod 2 mg in the ELEVATE UC OLE experienced two events of Cystoid macular oedema. The first began on Day 85 (first OLE etrasimod dose as Day 1), was not considered by the investigator to be related to the study treatment and resolved; the second began on Day 248, was considered to be related and the outcome was unknown at the time of datacut. Both events were non-serious, moderate and led to dose interruption.

CI, confidence interval; CTCAE, Common Terminology Criteria for Adverse Events; IR, incidence rate (patients with events per 100 PY); n, number of patients with Macular oedema or Cystoid macular oedema event; N, number of patients in treatment group; N/A, not available; OLE, open-label extension; ph, phase; PY, patient-years; QD, once daily; UC, ulcerative colitis.

Table. Incidence of Macular oedema and Cystoid macular oedema events in the etrasimod clinical programme.

Conclusion: The incidence of Macular oedema in patients treated with etrasimod in the clinical programme was low and generally comparable with placebo. These results are consistent with other S1P receptor modulators¹ and provide clinically relevant information on events of Macular oedema.

Introduction: Inflammatory bowel disease (IBD) that includes Ulcerative colitis (UC) and Crohn's disease (CD) may be associated with considerable changes in body composition, which include alterations in muscle and adipose tissue mass as well as osteopenia and osteoporosis which can have considerable impact on disease course and outcome.

Aims & Methods: Body composition and presence of sarcopenia were assessed in patients with UC and CD and their relationship with disease duration, location and severity was studied. This was a Single-Centre cross-sectional study conducted from January 2022 to June 2023.

Body composition analysis was performed using bioelectrical impedance (BIA) method and sarcopenia assessment was done with hand grip strength (HGS) using digital hand dynamometer and skeletal muscle index (SMI) at 3rd lumbar vertebral (L3) level using computed tomography (CT).

Results: A total of 132 patients (92 UC and 40 CD) were included. Mean age and sex in UC (37.33 ± 12.91 years, 46.7% males) and in CD (39.05 ± 15.05 years, 52.5% males). Mean duration of disease in UC and CD were 5.9 ± 5.28 years and 6.13 ± 4.33 years respectively. In UC group 41.3% patients had pancolitis and 37% had left sided colitis, among CD patients ileal (L1) and colonic disease (L3) was 37.5% each and 55% patients had inflammatory disease behavior.

In UC patients 33.7% had active disease and in CD 40% had active disease. In UC group, mean total body fat percentage was significantly lower with disease duration of 1-5 years compared to those with disease duration > 5 years (23.67 ± 8.52% vs 29.39 ± 7.14%, p=0.003) and mean visceral fat level was lower in those with active disease than in remission (3.26 ± 3.09 vs 6.49 ± 6.77, p=0.013). CD patients did not show any significant change in BMI, total body fat percentage, whole body skeletal muscle percentage with respect to disease duration, location, behavior and severity.

In UC group mean dominant HGS and L3-SMI were lower in active disease than remission (22.27 ± 8.72 kg vs 28.57 ± 9.1 kg, p=0.002 and 36.5 ± 13 cm²/m² vs 42.74 ± 13.92 cm²/m², p=0.02). Among CD patients no significant change in HGS and L3-SMI were observed. As per European consensus definition, prevalence of probable sarcopenia and sarcopenia in UC and CD were (26% and 9.4%) and (32.5% and 15%) respectively.

On comparison between UC and CD, SMI was significantly lower in CD patients (Table 1). When BIA method was used to measure low muscle mass, the prevalence of sarcopenia in UC and CD were 13.4% and 17.5%. Difference observed with the two methods of measurement of sarcopenia prevalence was not significant.

Parameters	UC(92)	CD(40)	P value
Body composition variables(mean)			
BMI (Kg/m ²)	21.91 ± 6.61	21.41 ± 5.55 kg/m	0.680
Body fat (%)	26.26 ± 8.42	24.45 ± 9.37	0.277
Whole body subcutaneous fat (%)	20.84 ± 7.29	19.17 ± 6.87	0.227
Whole Body Skeletal Muscle (%)	28.16 ± 5.62	27.55 ± 7.34	0.608
Visceral fat	5.52 ± 5.99	5.11 ± 5.196	0.679
Sarcopenia variables(mean)			
Dominant HGS (kg)	26.28 ± 9.4	25.96 ± 9	0.856
L3-CSA of muscles (cm ²)	108.08 ± 40.9	99.4 ± 28.08	
SMI (cm ² /m ²)	40.74 ± 15.18	37.11 ± 9.13	0.048
Probable sarcopenia and Sarcopenia	26% and 9.4%	32.5% and 15%	

Table 1- Body composition and sarcopenia variables in UC and CD

*CSA- cross-sectional area, BMI-Body mass index

Conclusion: Point prevalence of probable sarcopenia and sarcopenia was found to be 26% & 9.4% among UC and 32.5% and 15% patients with CD. CD patients had lower muscle mass as compared to UC patients. BIA showed good diagnostic accuracy compared to CT in assessing muscle mass. Both these methods can be considered complementary diagnostic tools in assessment of sarcopenia among patients with UC or CD.

COMPARISON BETWEEN THE CARDIO-METABOLIC RISK AND LIVER STEATOSIS AND FIBROSIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE AND RHEUMATOID ARTHRITIS – POTENTIAL IMPLICATIONS FOR THERAPEUTIC CHOICE

A. Bargas Bárbara¹, C. Moreira-Barbosa¹, A. Guedes¹, A.C. Bravo¹, J. Revés¹, L.M. Roque Ramos¹, C. Gouveia¹, C. Frias-Gomes¹, M. Canhoto¹, D. Raimundo², N. Gonçalves², S. Falcão², C. Palmela¹, M.L. Gloria¹, J. Torres¹

Contact E-Mail Address: bargasandre2@gmail.com

Introduction: Auto-inflammatory conditions like inflammatory bowel disease (IBD) and rheumatoid arthritis (RA) have a higher prevalence of liver fibrosis and cardiovascular risk (CVR), compared to the general population. This is relevant, given the potential metabolic and cardiovascular adverse effects of some drug classes.

Aims & Methods: Cross-sectional study of IBD and RA patients. Pregnancy or known cause of chronic liver disease were excluded. All patients underwent transient elastography, clinical and laboratorial assessment. International Physical Activity Questionnaire (IPAQ) classified activity as low, moderate, or high. Presence of steatosis and fibrosis was defined as Controlled Attenuated Parameter (CAP) measurement of >248 dB/m and Liver Stiffness Measurement (LSM) >8 kPa, respectively. For CVR, SCORE2 was calculated according to European Society of Cardiology (if >40 years).

Results: 130 patients were enrolled (79 with IBD and 51 with RA). Most RA patients (80%) have received treatment with methotrexate. Demographics and CVR factors are presented in table 1. RA patients were significantly older and had higher prevalence of CVR factors. Nonetheless, no differences in the median SCORE2 were found [4 (IQR 3-10) vs 8 (IQR 6-11), p=0.06]. 16% of IBD and 57% of RA patients had liver fibrosis (p<0.01); No differences were found in liver fibrosis between RA patients on methotrexate (70% vs 54%; p=0.35); 46% of IBD and 73% of RA patients had liver steatosis (p=0.006). RA had a higher risk of fibrosis (OR=5.16 (95%CI 1.8-14.7), p=0.004), even after adjustment for age, gender, body mass index, physical activity and CVR factors.

	IBD	RA	p
Male,%	51%	45%	0.54
Age, median,IQR	40, 30-54	64, 54-69	<0.001
Diabetes mellitus,%	5%	17%	0.027
Dyslipidemia,%	11%	39%	<0.001
thromboembolic diseases,%	6%	10%	0.48
Smoker/Previous smoker,%	38%	24%	0.46
Low IPAQ,(%)	87%	71%	0.93

Conclusion: In our cohort, more than half of the RA patients had undiagnosed liver fibrosis and RA appears to be to be an independent risk factor for this condition. Further research is warranted to elucidate the underlying pathophysiology and identify actionable risk factors for the development of these condition.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel disease (IBD) especially during flare periods, seems to be associated with an increased risk of thromboembolic and cardiovascular (CV) events[1]. After the results of the ORAL Surveillance study[2] enrolling patients with rheumatoid arthritis, several concerns have also been raised on the intrinsic risk of Janus kinase inhibitors (JAK-i), but population enrolled was predominantly >50 years old and had several CV risk factors.

Accordingly, regulatory agencies recommend that JAK-i should be used only if no suitable treatment alternatives are available in patients at increased CV risk for all indication[3]. However, the real prevalence of CV risk factors (CVRF) and the risk related to JAK-i seem to be lower for patients with Ulcerative Colitis (UC).

Aims & Methods: The aim of our study is to explore the prevalence of thromboembolic and CV risks factors in a large cohort of UC patients suitable for advanced therapies.

We conducted a single-center study including all consecutive adult patients with UC, who initiated advanced therapies from June 2020 to December 2023. To assess thrombosis and CV risks, an online questionnaire was administered, collecting following variables: BMI, smoking status, varicose vein (presence or previous surgery), personal or family history of (FHx) venous thromboembolism (VTE), presence of known genetic thrombophilic factors, active or previous cancer, admission to hospital in the last 6 months, leg or hip fractures or surgery in the last month, C reactive protein (CRP) serum levels, history of (h/o) abortion, ongoing treatment with estrogen or hormone replacement therapy (HRT), presence of heart failure, chronic kidney disease (CKD), chronic obstructive pulmonary disease, h/o acute myocardial infarction (AMI), hypertension, atrial fibril-

lation (AF), h/o stroke or TIA, diabetes, FHx CV disease and serum lipids levels. The International Physical Activity Questionnaire (IPAQ) was used to assess sedentary lifestyle.

Results: Out of 320 patients surveyed, 305 responded (95.3%): of whom 54% male, with a mean age was 45 years ($\pm$ SD 15.4) and a median disease duration of 7 years (IQR 2.9-16). Elderly patients ($\geq$ 60 years) were 21.3%. The average BMI was 23.9 ($\pm$ SD 14.1), with 34.8% being overweight and 8.5% obese. Active and former smokers accounted for 19.7% and 41.6% of the cohort, respectively; 54.1% were sedentary. Overall, 119 patients (39%) were biologic-naïve; 21.6% of patients started a JAK-i. Overall, 19% were recently hospitalized and in 86% of cases for IBD-related reasons. A genetic predisposition for thrombosis was identified in 4.6% of patients; varicose vein disease in 14.1%. CRP was high in 44.9% of patients. Of the female population 17.9% had h/o abortion, 7.1% were taking estrogen and 2.1% in HRT. Cumulatively only 27 patients (8.8%) had 4 thrombotic risk factors, 11 (3.6%) five, and 6 (2%) had $\geq$ 6.

Regarding CV risks, 15.1% of the population were hypertensive, 4.9% were diabetic, 4.3% had h/o AMI, 1.3% had h/o stroke or TIA, 2.3% had AF and 3.9% had CKD stage III. Total cholesterol values were available for 212 patients (69.5%), and 8% had cholesterol >240 mg/dl. The total cholesterol/HDL ratio was available for 171 patients (56.1%); 10.5% had values > 5 (medium risk). Overall, 92 (30.2%) had 1 CVRF, 17 (5.6%) had 2 CVRF, and 5 patients (1.65%) had more than 3 CVRF.

Conclusion: Our study confirms the prevalence of thrombotic and CV risk factors among patients affected by UC is quite low. Accordingly, the concerns regarding the use of JAK-i observed in rheumatological cohorts, may not be applicable for patients with UC.

Introduction: Thiopurine therapy is a cornerstone in the treatment of patients with inflammatory bowel disease (IBD).

Aims & Methods: We aimed to assess the effect of thiopurines on the risk of cancer in IBD according to drug exposure and age. Danish national registers were used to identify incident IBD patients, exposure to drugs and status of cancers, in 1996-2018. Cox regressions were used to:

- compare IBD to non-IBD reference individuals,
- analyse IBD according to drug exposure status, and;
- assess patients' cumulative drug exposure and the association to first reported cancer, excluding non-melanoma skin cancer.

Results: In total, 43,419 IBD patients were followed for a median of 8.2 years (IQR:3.7-14.2) after IBD diagnosis. Cancer was reported in 3,128 (7.2%) IBD patients. Both monotherapy and combination therapy were associated with developing cancer (aHR:1.36 (95%CI:1.17-1.58) and (aHR:2.48 (95%CI:1.64-3.76), respectively) compared to unexposed IBD patients. Among the elderly (>65 years), the risk was especially high in those receiving combination therapy.

In patients who discontinued thiopurines, the aHR returned to the level of unexposed patients (aHR:0.89 (95%CI:0.78-1.01)). The aHR was positively associated with cumulative thiopurine exposure and in patients with more than five years of exposure, reaching aHR of 1.36 (95%CI:1.14-1.61).

Conclusion: Thiopurines were associated with increased risk of cancer, especially when used in combination therapy in the elderly. The risk increased by 36% when patients were exposed to thiopurines for more than five years. Reassuringly, the risk returned to baseline after discontinuation of thiopurines.

This study suggests avoiding combination therapy in the elderly and not treating patients with thiopurines for longer than five years, regardless of age.

Disclosure: This study was funded by an unrestricted grant from Aage og Johanne Louis-Hansens Fond.

EMERGING ROLE OF IL-33 ACTIVATED CD73-EXPRESSING CELLS IN THE PROMOTION OF TUMORIGENESIS DURING COLITIS-ASSOCIATED COLORECTAL CANCER

Introduction: Colorectal cancer associated to chronic colitis (CAC) has a different pathogenesis compared to sporadic or familial colorectal cancer (CRC) and represents the major complication of inflammatory bowel disease (IBD). It is now well-established that IL-33 and its receptor, ST2, are important factors in the pathogenesis of IBD.

Emerging evidence also suggests its critical role in epithelial proliferation and the potential contribution to inflammation-driven tumorigenesis that can lead to CRC.

Aims & Methods: The aim of our study was to characterize the precise contribution of IL-33/ST2 axis in the azoxymethane (AOM)/dextran sodium sulfate (DSS) model of colitis-associated CRC.

C57/BL6 wild-type (WT), IL33^{-/-}, T1/St2^{-/-} and Nt5e^{-/-} mice were given a single dose of AOM (10 mg/kg) followed by two cycles of 3% DSS for 7d in drinking water. Vehicle-treated WT mice served as controls and were sacrificed at the same time points. Another group of WT followed the same protocol and received CD73 inhibitor i.p. treatment or vehicle.

Disease Activity Index (DAI), as well as endoscopic, stereomicroscopic and histological evaluations of colons were performed. IHC, immunofluorescence (IF), qPCR, and ELISA were done on full-thickness colons of WT for IL-33 and ST2 localization and identification, as well as mRNA and protein expression, respectively. RNA-Seq was performed on whole tissues from AOM/DSS treated WT, IL33^{-/-} and T1/St2^{-/-}. qPCR analysis was done on isolated polyps from WT, IL33^{-/-} and T1/St2^{-/-} for Nt5e (CD73) and adenosine pathway targets.

Results: IL33, Ilr1(ST2L), and Ilr1(sST2) mRNA transcripts, as well as IL-33 and total ST2 proteins were dramatically elevated in AOM/DSS-treated WT mice vs. controls. IHC and IF of treated WT mice revealed localization of IL-33 to the colonic epithelium and to cells within the polyp LP morphologically consistent with stromal and mast cells. Little to no staining for IL-33 was present in controls.

Using IF, IL-33 co-localized with sub-epithelial myofibroblast markers Actin and Vimentin, or with mast cell markers Tryptase and MCPT1. AOM/DSS treatment in IL33^{-/-} and T1/St2^{-/-} mice resulted in a significant decreased polyp number and size vs. WT, with colonoscopy revealing the development of protruding lesions with abnormal vascular patterns, suggesting tumorous lesions in WT mice, while all deficient mice showed their absence with a more impressive mucosal inflammation, likely due to reduced epithelial proliferation and repair caused by the deficiency of IL-33 signaling. RNA-Seq identified a significant reduction of Nt5e and adenosine pathway targets in IL33^{-/-} and T1/St2^{-/-} vs. WT. qPCR on isolated polyps confirmed this observation. AOM/DSS-treated Nt5e^{-/-} showed a significant decreased polyp number and size vs. controls. Therapeutic inhibition of CD73 produced similar results.

Conclusion: Our results suggest that the IL-33/ST2 axis promotestumor-igenesis in colitis-associated CRC through the activation of CD73. Further studies are underway to determine mechanisms of action that support these findings.

Introduction: Inflammatory bowel disease (IBD) is associated with a higher risk of developing colorectal cancer, according to the inflammation-dysplasia-cancer (IDC) sequence from inflammation to colitis-associated colorectal cancer (CAC).

Aims & Methods: The objective of this study was to identify and generate a transcriptomic signature and score, related to the IDC sequence, that could ultimately classify dysplasia and cancer in IBD. This is a national cohort study conducted across 7 Belgian tertiary centres within the Belgian Inflammatory Bowel Disease Research and Development (BIRD) Group. We retrospectively evaluated IBD patients diagnosed with low- or high-grade dysplasia (LGD or HGD) and/or CAC between January 1, 1990, and December 31, 2016. An exploratory and a validation cohort of lesions were analysed. RNA-seq was analysed in 134 formalin-fixed paraffin-embedded samples. We followed an ordinal logistic regression (olm) method to screen for significant IDC sequence-associated genes and computed a transcriptomic signature score.

Results: Principal component analysis and unsupervised clustering on 1% of the most variable genes showed an overall good clustering between the 4 lesion groups (Normal Mucosa, Inflamed Mucosa, LGD and HGD, and CAC). A gene signature was identified on 27 genes that correlated with the lesion groups in the exploratory cohort. Among these 27 genes, 23 were downregulated and 4 were upregulated. Based on these 27-genes expression, we built and validated a transcriptomic signature score to classify dysplasia and CAC in IBD patients. The overall accuracy of the transcriptomic signature score was 85.71 % in the exploratory cohort and 90.91% in the validation cohort. The most weighted gene in this transcriptomic signature was the long non-coding regulatory RNA KCNQ10T1, a gate keeper against genomic instability and transposon activation. We found a direct correlation in the expression of KCNQ10T1 and retrotransposable elements (RTEs) across the lesion groups of IDC sequence.

Conclusion: We have identified a transcriptomic 27 gene signature associated with the IDC sequence and uncovered some of the pivotal genes and underlying mechanisms in the progression of the IDC sequence. The tissue-based transcriptomic score generated here helps the classification of the lesions of the IDC sequence in patients with IBD but should be further evaluated for its prognostic value in prospective independent cohorts. The most discriminant top gene in this signature, the non-coding RNA KCNQ10T1, is consistent with the activation of RTEs that may be involved in the progression of the IDC sequence.

Introduction: Patients suffering from inflammatory bowel diseases (IBD) manifest an increased risk of developing colitis-associated colon cancer (CAC). Interleukin 22 (IL22) is a cytokine involved in the proliferation and survival of epithelial cells.

However, it also correlates with the development of tumoral lesions. IL22 is secreted by different immune cell types, including iNKT cells, tissue resident cells possessing cytotoxic properties in colorectal cancer (CRC). In IBD patients, though, iNKT cells perform both pro-inflammatory or tolerogenic functions in a microbiota-dependent fashion, opening questions on their functional role in CAC development.

Aims & Methods: Immune cell composition and iNKT cell phenotype of inflamed, non-tumor and cancerous tissue lesions of CAC (n=49), IBD (n=20) and sporadic CRC (n=38) patients were analysed in samples obtained from Policlinico Hospital, Milan, and IOV-IRCCS, Padua. High-dimensional single-cell flow cytometry, metagenomics, RNAseq, spatial immunophenotyping and transcriptomic (Cosmx, Nanostring), ex vivo and in vitro experiments were performed to evaluate the phenotype and function of human iNKT cells. Metabolomics was performed to identify microbial-derived molecules involved in iNKT cells activation. Mechanisms were dissected in CAC murine models, either iNKT proficient or deficient.

Results: An increased expression of IL22 and a higher NKT22 infiltration was observed in CAC tissues, as well as an enrichment of *Odoribacter*, a gram-negative bacteria implicated in tryptophan metabolism. Stimulation of iNKT cells with *Odoribacter*-derived metabolites induced Ahr-dependent IL22 production by iNKT cells. Metabolomic analyses revealed an increased presence of tryptophan metabolites in the *Odoribacter* supernatant, promoting NKT22 differentiation both in vitro and in vivo models.

Moreover, the administration of *Odoribacter* Supernatant or of the single purified metabolites were sufficient to increase tumorigenesis in CAC mouse models, but not in iNKT-deficient mice.

Spatial proteomics and transcriptomic analyses of human CAC tissues confirms the microbiota-dependent functional skewing of iNKT cells residing closely to cancer cells.

Conclusion: iNKT cells in CAC patients are the major IL22 producing cells and are induced by the recognition of microbiota-derived metabolites implicated in tryptophan metabolism and Aryl hydrocarbon receptor (AhR) stimulation. NKT22-microbiota interaction in CAC patients plays a potential crucial role in tumor development.

Disclosure: Nothing to disclose.

Introduction: FIT-based colorectal cancer screening programs have been severely hampered during COVID-19 pandemic and its aftermath. Both test distribution and post-FIT colonoscopies have seen a manifold decrease in number of performed procedures. It is well known that any delay in post-FIT+ colonoscopy results in an increase in advanced neoplasia and CRC. Since colonoscopy slots are limited, any means to risk-stratify subjects before post-FIT colonoscopy may result in timely diagnosis of CRC and advanced adenomas, but such tools are currently lacking.

Aim of our study was to develop and validate a simple scoring system to effectively sub-stratify CRC/advanced adenomas risks in FIT+ patients, based on the retrospective analysis of a large cohort of patients in a long-standing FIT based CRC screening program.

Aims & Methods: This was a retrospective analysis of prospectively collected data from a regional CRC screening program in Italy, from 2004 to 2019. Men and women aged 58 to 70 years were invited to undergo quantitative FIT (OC-sensor FIT) and subsequent colonoscopy if $\geq 20 \mu\text{g Hb/g}$ of feces (FIT+). Patients who underwent both FIT test with positive results and colonoscopy were included in the study.

A multivariable logistic regression analysis was performed to identify variables independently associated to CRC and advanced adenoma risks in the derivation cohort (2004-2015), and the discriminative performance of the model was tested on the validation cohort (2016-2019).

Results: Overall, 40,640 patients undergoing colonoscopy after a FIT+, were included. Prevalence of first-round FIT+ subjects was 58.5%. Median FIT was 52.4 mcg/g (IQR, 29.8-137.3). CRC was found in 2,164 (5.4%) subjects, high-risk adenomas in 12,218 (30.3%), and low-risk adenomas in 5,990 (14.9%).

Variables independently associated with CRC were age ≥ 70 years (OR 1.20, 95%CI 1.03-1.40), male sex (OR 1.23, 95%CI 1.11-1.37), FIT ≥ 50 mcg/g and < 200 mcg/g (OR 2.84, 95%CI 2.47-3.27), FIT ≥ 200 mcg/g (OR 6.91, 95%CI 5.99-7.98), and first round of FIT (OR 1.53, 95%CI 1.35-1.73). From these variables, a hierarchical approach based on marginal effect predicted probabilities was used to derive a clinically usable risk-stratification flow-chart.

The discriminative ability of the model was fair, as the AUROC was 0.65 (95%CI 0.65-0.66) in the derivation cohort and 0.63 (95%CI 0.62-0.64) in the validation cohort.

Conclusion: We show that the use of readily available clinical variables is effective in identifying FIT+ subjects at increased risk of CRC. This tool

could be integrated in FIT-based screening programs to maximize their effectiveness through the correct prioritization of colonoscopy resources.

Introduction: Bowel preparation is essential to high quality colonoscopy examination. Whether excellent bowel preparation can increase adenoma detection rate(ADR) comparing with good bowel preparation are still controversial.

Aims & Methods: A prospective, multi-center, observation study was designed to compare ADR between excellent and good bowel preparation based on BBPS in early CRC screening. Subjects aged 40 that received PEG bowel preparation were enrolled. Subject characteristics, bowel preparation quality and colonoscopy data were collected. BBPS score 8-9 was defined as excellent and 6-7 as good.

Primary endpoint was ADR. Secondary endpoints included polyp detection rate (PDR), advanced adenoma detection rate (AADR), and the detection rate of different diameter lesions (≤5mm, 6-9mm, ≥10mm).

Results: 1503 subjects (aged 40-75, ITT population) from 14 hospitals enrolled, 723 (48.1%) got excellent quality of bowel preparation, 707 (47.0%) got good quality of bowel preparation. ADR was significant higher in excellent quality group (35.8% vs 26.9%, P<0.001), especially in trans (13.0% vs 9.6%, P=0.036) and right colon (12.5% vs 8.2%, P=0.008),

numerical higher but no significant difference for left colon (23.5% vs 19.8%, P=0.089) . Excellent quality group had significant higher PDR (57.0% vs 45.1%, P<0.001), especially in left (44.7% vs 35.6%, P<0.001) and trans colon(18.9% vs 14.1%, P=0.015). numerical higher but no significant difference for right colon (16.0% vs 14.0%, P=0.280). AADR was also significant higher in excellent quality group (3.2% vs 1.4%, P=0.026) . ≤5mm lesions detection rate was significant higher in excellent quality group (47.6% vs 35.4%, P<0.001), no significant difference for the lesions of 6-9mm/≥10mm. PP set on analysis supported these result. Sex(female 53.9% vs male 47.1%, RR: 1.1, 95%CI[1.0-1.3], P<0.001), risk factors of inadequate bowel preparation (no 60.9% vs yes 42.8%, RR 1.4, 95%CI[1.3-1.6, P<0.001]), bowel preparation regiment (split dose 53.7% vs one dose 46.3%, RR1.1, 95%CI [1.1-1.2], P<0.001), PEG volume (4L 53.4% vs <4L 46.6%, RR 1.4, 95%CI[1.3-1.6], P<0.001), diet compliance (full compliance 52.2% vs other 44.26%, RR: 1.2, 95%CI[1.0, 1.4], P=0.015) as well as run-away time (2-5hour 53.8% vs other 46.2%, RR: 1.1, 95%CI[1.0, 1.3], P=0.017) were significant associated factors of excellent bowel preparation.

Item	Excellent N=723, n(%)	Good N=707, n(%)	Difference 95%CI,%	P-Value
Adenoma detection rate	259(35.8)	190(26.9)	8.9[4.0-13.8]	<0.001
Polyps detection rate	412(57.0)	319(45.1)	11.9[6.6-17.1]	<0.001
Advanced Adenoma detection rate	23(3.2)	10(1.4)	1.8[0.9-3.5]	0.026
≤5mm lesion detection rate	344(47.6)	250(35.4)	12.2[7.0-17.3]	<0.001
6-9mm lesion detection rate	123(17.0)	108(15.3)	1.7[-2.2-5.7]	0.372
>10mm lesion detection rate	45(6.2)	42(5.9)	0.3[-2.3-2.8]	0.823

Table 1. Lesion Detection Rate Comparing Between Excellent and Good Bowel Preparation (ITT population).

Conclusion: We should seek excellent bowel preparation due to higher ADR, PDR and AADR, especially for ≤5mm lesions. For male and populations with inadequate bowel preparation risk factors, enhance diet education, 4L PEG, split dose and right run-away time could help to get excellent bowel preparation.

Disclosure: Nothing to disclose.

Introduction: Colonoscopy is crucial for diagnosis, disease monitoring and colorectal cancer surveillance in patients with inflammatory bowel disease (IBD), which is a population at increased risk. Perfect bowel preparation (BP) is essential for high-quality monitoring, because an inadequate one lead to incomplete colonoscopy and higher rate of missing precancerous lesions. In contrast to general population, there is limited data on the most effective BP to use in an outpatient setting for IBD patients, especially after the introduction of 1L-PEG.

This study aims to compare the effectiveness of 1L-PEG and 2L-PEG in IBD undergoing outpatient colonoscopy and to identify any risk factors that lead to inadequate BP.

Aims & Methods: This is a cross-sectional, multicentric, retrospective study, including IBD patients aged ≥ 16 years, who underwent outpatient split-dose colonoscopy between Jan-2021 and Dec-2022. Patients at each center received a standard pamphlet with BP instruction, without any specific recommendations, and a list of available laxatives. Only Movi-prep® and Clensia® for 2L-PEG group, and Plenvu® for 1L-PEG group were included as they were recommended by all three centres, to avoid selection bias. Boston Bowel Preparation Scale (BBPS) was used to assess the adequacy of BP. Demographic, clinical and endoscopy data were collected and analyzed. A multivariable logistic regression model was used to compare 1L-PEG and 2L-PEG.

Results: 506 patients (F 42.9%, mean age 48.9 $\pm$ 15.2 years), 306 with ulcerative colitis and 200 with Crohn's disease (CD) were collected; 1L-PEG was used by 265 (52.4%) while the remaining 241 (47.6%) used 2L-PEG. Adequate BP was achieved in 440 (87.0%) and 1L-PEG was associated with a higher rate of adequate BP compared to 2L-PEG (238/265, 89.8% vs 202/241, 83.8%, $p=0.048$) and a higher BBPS score (median 8, IQR 7-9 vs 6, IQR 6-8, $p<0.001$). Male sex ($p=0.03$), previous ileal/colonic surgery ($p=0.01$) and stricturing CD ($p=0.01$) were associated with inadequate BP. No correlation was found between BP and maximum localization/ex-

tension of IBD, the use of advanced therapy, the presence of endoscopic activity, Mayo endoscopic score and the presence of CRC or pseudopolyps. At multivariable analysis, 1L-PEG was a predictor of adequate BP (OR=1.70, 95%CI 1.00-2.90, $p<0.05$); on the contrary, male sex (OR=0.51, 95%CI 0.29-0.90, $p=0.02$) and previous ileal/colonic surgery (OR=0.40, 95%CI 0.21-0.77, $p<0.01$) were confirmed as risk factors for inadequate BP.

Conclusion: These findings, from a large cohort of IBD patients, highlight the superiority of 1L-PEG compared to 2L-PEG in achieving adequate BP and suggests its routine use in an outpatient setting for IBD patients. Male patients, those with a history of ileal/colonic surgery and stricturing CD require careful attention and the implementation of adjuvant strategies.

Introduction: There are no randomised clinical trials evaluating the effect of endoscopic surveillance on the long-term incidence of colorectal cancer. In this context, it is relevant to know the preferences of the patients. The Polyprev study (NCT04967183) is a randomised clinical trial evaluating the impact of the incidence on colorectal cancer incidence of faecal occult blood surveillance versus endoscopic surveillance after resection of advanced lesions in screening programmes.

Aims & Methods: The aim of our study is to know the preferences of surveillance after resection of advanced lesions. Included patients were presented with a decision support tool using vignettes, presenting 8 scenarios based on estimated incidences of colorectal cancer, number of colonoscopies and associated complications. In each scenario, patient chose one of the following options: endoscopic surveillance, faecal occult blood surveillance or no surveillance. We conducted a descriptive analysis of the responses obtained in the questionnaires. Subsequently, we determined which variables were independently associated with a preference for endoscopic surveillance using a multivariate logistic regression.

Results: Out of the 1023 patients included, 521 subjects answered to the values and preferences questionnaire. The mean age was 57.89 (± 4.87) years, the percentage of women was 39.3% and the mean of resected adenomas was 3.07 (± 2.01) adenomas per patient. In the 8 scenarios, the preferred rate for endoscopic surveillance, faecal occult blood surveillance and no surveillance was 32.8 - 4.5%, 55.7 - 66.2% and 0.6 - 1.4%, respectively. The endoscopic surveillance was significantly associated with the female gender (OR: 1.27 95% CI: 1.11 - 1.44), the age (50 - 54 year OR: 1.25 95% CI: 1.07 - 1.47; 55 - 59 years OR: 1.47 95% CI: 1.26 - 1.72), the assignment to the colonoscopy branch (OR: 1.93 95% CI: 1.69 - 2.20) and the risk of colorectal cancer estimated by faecal occult blood surveillance (2% OR: 1.43 95% CI: 1.04 - 1.97; 2.5% OR 1.67 95% CI: 1.29 - 2.32).

Conclusion: Patients in the Polyprev study prefer to return to the colorectal cancer screening programme. Variables independently associated with endoscopic surveillance were sex, age, assigned study branch and estimated risk of colorectal cancer.

Introduction: Colonoscopy techniques is an independent factor of adenoma detection rate. However, the colonoscope insertion methods and cecal intubation time is often ignored compared with relevant technology or colonoscopy performance indicator in withdrawal stage. The effect of water exchange (WE) method characterized by water infusion with water removal primarily during insertion stage on colonoscopy has remained controversial.

We aimed to carry out a meta-analysis to systematically evaluate the relationship between WE and quality of colonoscopy compared with the conventional methods include air insufflation and carbon dioxide insufflation.

Aims & Methods: Aims: To evaluate the effect of water exchange method versus conventional methods including air insufflation and carbon dioxide insufflation method for the quality of colonoscopy.

Methods: We searched randomized controlled trials published up to October 2022 from PubMed, Web of Science, the Cochrane Library, CNKI, Wanfang, SinoMed databases. Two reviewers independently searched the literatures based on standards to extract the data and evaluate the quality. The primary outcomes were cecal intubation time and adenoma detection rate. The secondary outcomes included cecal intubation rate, quality of bowel preparation, pain score, number of abdominal compression, number of position change. Meta-analysis was conducted by RevMan5.4.1. The study protocol was registered in PROSPERO (CD42022327954).

Results: A total of 23 studies involving 10654 patients were included. Although cecal intubation time was prolonged in WE (MD=1.81, 95%CI: 1.28, 2.35; $P < 0.001$), WE had higher adenoma detection rate (OR=1.40, 95%CI: 1.26, 1.55; $P < 0.001$), cecal intubation rate (OR=1.62; 95%CI: 1.24, 2.10; $P < 0.001$) and quality of bowel preparation (MD=0.61; 95%CI: 0.42, 0.79; $P < 0.001$) compared with conventional colonoscopy. In addition, WE had significantly lower pain scores (MD=-1.07; 95%CI: -1.39, -0.76; $P < 0.001$), number of abdominal compression (OR=0.42; 95%CI: 0.29, 0.60; $P < 0.001$) and number of position change (OR=0.59; 95%CI: 0.42, 0.82; $P = 0.002$) than conventional colonoscopy.

Conclusion: Despite WE colonoscopy prolonged cecal intubation time, it could significantly increase adenoma detection rate, cecal intubation rate and quality of bowel preparation. And beyond that, WE reduced patient pain, the proportion of abdominal compression and position change. WE is a better choice for high-quality colonoscopy.

Disclosure: Nothing to disclose.

Introduction: Procedural sedation and analgesia (PSA) can be associated with respiratory depression that must be recognised rapidly and managed appropriately to avoid the risk of hypoxic brain damage, cardiac arrest, and death. Standard of care monitoring (SOCM) during PSA includes electrocardiogram, respiratory rate, blood pressure, and pulse oximetry but these do not reliably identify airway or respiratory compromise. Capnography can be used to measure exhaled carbon dioxide, providing real-time identification of airway obstruction and respiratory depression.

We aimed to measure the real-world impact of using capnography in addition to SOCM on patient safety during PSA for gastroenterology and bronchoscopy procedures.

Aims & Methods: A before-and-after, quality-improvement protocol was followed at four centres in Leuven, Ankara, Madrid, and Toronto using a specialised Microsoft Excel application for data collection. Collected adverse events were death, escalation of care, mild (75–90%; up to 60 seconds (s)) and severe (<75% or <90% for over 60 s) oxygen desaturation, prolonged apnoea (>60 s), bradycardia, tachycardia, airway obstruction, cardiovascular shock or collapse, and cardiac arrest. Data for SOCM were collected first, without modification to the centre's standard practice for PSA.

Then capnography was introduced, including staff training and a 2–4 week wash-in period, after which data collection commenced for capnography. Data were collected between 2017 and 2021 and combined by procedures into those using SOCM and those using SOCM plus capnography (capnography). Patients could have more than one procedure performed.

Results: Data were collected for 6,100 procedures (N=3,100 SOCM and N=3,000 capnography). Procedures were split as follows with 94.7% gastroenterology procedures: colonoscopy (n=2,773), gastroscopy (n=1,868), combined gastroscopy and colonoscopy (n=502), endoscopic ultrasound (n=362), bronchoscopy (n=326), endoscopic retrograde cholangiopancreatography (n=225), and others (n=44).

Total adverse events were decreased by 38.53% from 353 (SOCM) to 217 (capnography) events. The relative risk (RR) of at least one adverse event occurring per procedure with capnography versus (vs) SOCM was 0.68 (95% confidence interval: 0.57–0.81; 9.77% vs 6.63%).

Escalation of care was decreased when using capnography by RR 0.11 (0.01–0.91; 9 vs 1 events). Oxygen desaturation was decreased with RR 0.64 (0.52–0.79; 223 vs 139 events) for mild and RR 0.44 (0.24–0.82; 33 vs

14 events) for severe cases. Bradycardia and tachycardia were also reduced by RR 0.50 (0.28–0.89; 35 vs 17 events) and RR 0.14 (0.05–0.39; 30 vs 4 events), respectively. Prolonged apnoea was increased by RR 4.39 (1.48–13.04; 4 vs 17 events) when using capnography vs SOCM, potentially due to easier detection of apnoea using capnography. Airway obstruction and cardiovascular events were non-significantly different and no patient deaths were recorded.

Conclusion: In this, to date the largest real-world data set on PSA capnography monitoring, patient safety was found to be significantly improved in those procedures using capnography. Additional analyses, such as patient matching, are required to examine the potential influence of confounders on results.

COLORECTAL ADENOMA DETECTION RATE USING TEXTURE AND COLOR ENHANCEMENT IMAGING (TXI) VS WHITE LIGHT IMAGING WITH CHROMOENDOSCOPY: A PROPENSITY-SCORE MATCHING STUDY

O. Toyoshima¹, T. Nishizawa¹, S. Yoshida¹

¹Toyoshima Endoscopy Clinic, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: t@ichou.com

Introduction: Improving the adenoma detection rate (ADR) can contribute to reducing the incidence and mortality of post-colonoscopy colorectal cancer (PCCRC). Texture and color enhancement imaging (TXI) enhances subtle tissue textures, selectively brightens dark areas, and emphasizes the differences between red and white colors^{1,2}. Several studies have investigated the visibility and color differences of TXI in vitro and reported its superiority over WLI³⁻⁷.

However, A few studies have evaluated the ADR of colonoscopy with TXI, which is a novel image-enhancing technology. This study aims to compare the detection of colorectal polyps using TXI to that using white light imaging (WLI).

Aims & Methods: This study was conducted retrospectively in a single center using propensity-matched scoring based on the patients' baseline characteristics, such as age, sex, indication, bowel preparation, endoscopist, colonoscope type, and withdrawal time. This study compared the effectiveness of WLI and TXI in patients who underwent chromocolonoscopy with indigo carmine spraying.

The study determined the differences in the adenoma, including high-risk adenoma, and sessile serrated lesion (SSL) detection rates and the mean number of detected adenomas and SSLs per colonoscopy between the TXI and WLI groups. High-risk adenomas were defined as three or more adenomas, an adenoma ≥ 10 mm, an adenoma with a villous component, and an adenoma with high-grade dysplasia. The Wald test with logistic regression was used to analyze the *P* values.

Results: After propensity score matching, 1970 patients were enrolled into each imaging modality group. The mean patient age was 57.2 ± 12.5 years, and 44.5% of the cohort were men. The ADR was higher in the TXI group than in the WLI group (55.0% vs. 49.4%, odds ratio: 1.25). High-risk ADR were more common in the TXI group than in the WLI group (17.6% vs. 12.8%; OR: 1.45). The mean number of adenomas per colonoscopy (APC) was higher in the TXI group than in the WLI group (1.187 vs. 0.943, OR: 1.12). APC with a 0-II morphology according to the Paris classification (1.093 vs. 0.848, OR: 1.14) and APC of ≤ 6 mm (0.992 vs. 0.757, OR: 1.16) were higher in the TXI group than in the WLI group. The adenoma plus SSL

detection rate (ASDR) was higher in the TXI group than in the WLI group (58.8% vs. 53.2%, OR: 1.25). The mean number of adenomas plus SSLs per colonoscopy (ASPC) was greater in the TXI group than in the WLI group (1.287 vs. 1.025, OR: 1.13, *Table*).

	WLI	TXI	Odds ratio	95% CI	P value
ADR, %	49.4	55.0	1.25	1.10-1.42	<0.001
High-risk ADR, %	12.8	17.6	1.45	1.22-1.73	<0.001
APC, n	0.94	1.19	1.12	1.07-1.17	<0.001
APC, 0-II type, n	0.85	1.09	1.14	1.09-1.19	<0.001
APC, ≤ 6 mm, n	0.76	0.99	1.16	1.10-1.22	<0.001
ASDR, %	53.2	58.8	1.25	1.11-1.42	<0.001
ASPC, n	1.03	1.287	1.13	1.08-1.18	<0.001

Table. Polyp detection using TXI compared with WLI.

Conclusion: A randomized controlled trial⁸ and a cross-over study⁹ previously showed that the ADR of TXI was higher than that of WLI. In this study, we found that the ADR, high-risk ADR, APC, ASDR, and ASPC of TXI were higher than those of WLI after propensity-score matching of patients who underwent chromoendoscopy. TXI may help prevent PCCRC.

Contact E-Mail Address: hyung1125@naver.com

Introduction: Over the past two decades, there has been an increase in the incidence of rectal NET, which has in turn heightened the importance of optimizing its treatment and managing care after treatment. However, many cases of rectal NETs are removed by conventional EMR or even forceps polypectomy methods without being aware that it is NET which results in incomplete resection.

Currently, no strong clinical evidence is supported for the need of salvage treatment in case of incompletely resected rectal NETs.

Aims & Methods: In this study, we aimed to find the factors that can predict the presence of remnant tumor after incomplete resection performed for the treatment of rectal NET in order to appropriately select patients who may require additional resection. We retrospectively reviewed clinical data of patients who underwent salvage treatment for incompletely resected rectal NETs between January 2010 and November 2023 at 5 tertiary hospitals.

Results: A total of 190 patients were enrolled in the study. Of these, 109 patients (57.4%) had a positive resection margin, while 81 patients (42.6%) had an indeterminate resection margin. 128 (67.4%) patients had no remnant tumor and 62 (32.6%) patients had remnant tumor at salvage resection specimen. The presence of remnant tumor varied according to the initial resection method used: 38.1% (16/42) for cold forcep polypectomy, 70.6% (24/34) for cold snare polypectomy, and 29.9% (26/87) for conventional EMR.

Notably, no remnant tumors were found in patients who underwent modified EMR (n=21) or ESD (n=6) methods. Also, initial endoscopic resection performed by tertiary hospital expert showed significantly lower rate of remnant tumor compared to those performed by non-tertiary hospital expert with rate of 8.9% (4/45) and 40.9% (58/145) respectively.

Lastly, patients with endoscopically remnant tumor before salvage treatment showed significantly higher rate of remnant tumor compared to those with endoscopically no remnant tumor with rate of 63.5% (47/74) and 12.9% (15/116) respectively. In multivariate analysis, endoscopic resection performed by non-tertiary expert (OR, 3.887; p=0.045) and endoscopically remnant tumor (OR, 10.891; p<0.001) were significant risk factors for the presence of remnant tumor.

Conclusion: Follow-up rather than resection may be considered for patients with positive resection margin after modified EMR or ESD for rectal NET. Also, endoscopic resection done by non-tertiary hospital expert and endoscopically remnant tumor are significant risk factors for the need of salvage treatment.

THE PRESENCE OF SCARRING SIGNIFICANTLY IMPACTS BLINK DECISION MAKING IN LARGE NON-PEDUNCULATED COLORECTAL POLYPS BUT DOES NOT INTERFERE WITH CANCER DETECTION

L. Debels^{1,2}, P.J. Poortmans^{2,1}, S. Smeets¹, M.E. Argenziano¹, M. Montori¹, T. Tornai¹, L. Desomer³, D.J. Tate¹

Introduction: The detection of cancer within large non-pedunculated colorectal polyps (LNPCPs) is suboptimal in non-expert settings. Identification of 6 macroscopic (Blink) features (6BF) of deep submucosal invasive cancer (SMI) has shown significant improvement in the sensitivity of cancer detection by inexperienced endoscopists at the expense of decreased specificity.

This study investigates the impact of endoscopic resection scars, which can resemble deep SMI, on the accuracy of non-expert endoscopists using the 6BF evaluation system known as Blink Impression.

Aims & Methods: An online survey was disseminated containing 20 overview images of LNPCPs (1 image/polyp). Images (randomized) were shown before, and after a 2-minute educational video (the intervention) introducing the 6BF - fold deformation, extra redness, depression, chicken skin mucosa, ulceration and spontaneous bleeding.

Before and after the intervention participant Blink Impression was elicited (cancer/no cancer) and only after, the presence of the 6BF. Responses were analysed relative to histopathology (no vs superficial vs deep SMI) and expert opinion on the presence of the 6BF and endoscopic resection scars.

Results: 7/20 LNPCPs contained cancer (3 superficial, 4 deep SMI), 3 contained scars. 191 participants from 21 countries completed 3,755 observations. 129/191 (67.5%) participants were inexperienced. Expert-identified scarred LNPCPs contained median 1.0 (IQR 2.0) BF vs 1.0 (IQR 2.0) for no cancer, 2.0 (IQR 2.0) for superficial SMI and 3.0 (IQR 2.0) for deep SMI (all P<.001). Presence of ≥2 BF therefore reliably identifies cancer within LNPCPs but not scars. Fold deformation was the only BF identified more commonly amongst scarred LNPCPs (44.6%) vs no cancer (22.5%, P<.001) and vs superficial SMI (33.0%, P<.001), but similar to deep SMI (44.6%, P=1.000).

Depression, chicken skin mucosa and spontaneous bleeding were less commonly identified in scarred polyps (12.3%, 7.6% and 1.8%) than both no cancer (33.1%, 14.4% and 8.6%, all P<.001), superficially invasive (68.6%, 14.3% and 5.8%, all P<.001) or deeply invasive polyps (45.9%, 19.6% and 40.5%, all P<.001).

Extra redness and ulceration were identified with similar frequency to no cancer in scars (26.4% vs 26.8%, P=0.891 and 10.2% vs 9%, P=0.441 respectively), but less commonly than superficial (64.2%, P<.001 and 15.7%, P<.001) or deep SMI (60.2%, P<.001 and 24.7%, P<.001) (Table 1, next page).

Conclusion: The presence of ≥2BF reliably discriminates LNPCPs with cancer from non-cancer even in the presence of scarred lesions amongst non-expert endoscopists. Scarred LNPCPs exhibit fold deformation at a similar rate to LNPCPs with deep SMI but other BF are not present.

Introduction: Colon capsule endoscopy (CCE) may be recommended as a screening test for individuals under the age of 50 with low familial risk, diagnosed with irritable bowel syndrome (IBS) but lacking alarming symptoms and showing no fecal immunochemical test (FIT) positivity.

Aims & Methods: In the present study, our aim was to assess the efficacy, feasibility and acceptance of CCE in IBS patients with low risk of CRC, and our secondary aim was to assess polyp detection rates, transit times, cleanliness level and patient satisfaction. From April 2022 to April 2024, we conducted a prospective study at our institution involving 196 patients with IBS under the age of 50 (130 (66%) males, 66 (44%) females). We applied first in the literature, the recently developed colon capsule endoscopy technology of the Anx Robotics (USA) Navicam dual-camera CCE for this comprehensive assessment. The new first generation Navicam CCE measures 31mm in length and 11.6mm in diameter, weighing approximately 3 grams.

The two cameras operate at adaptive frame rate of 0.5 to 16 pic/sec, with adaptive focus of 0-30 mm, providing an image resolution of 480x480 pixels. The minimum battery time is 12h, and this is a fully functional panenteric capsule. Colonoscopy under anaesthesia was offered to all patients, and after detailed information and signing the consent form, they chose CCE as the first examination method.

We identified and addressed the incomplete cases, recorded capsule transit times, and calculated the polyp detection rates. If polyps were detected, patients underwent subsequent colonoscopy with Propofol sedation for polyp removal and histological analysis.

Results: Out of the total cases, 8.7% (n=17) were incomplete. The average colon and total transit time was 201.95 and 360.55 mins, respectively. Our study revealed a remarkable 14.8% (n=29) polyp detection rate (PDR) among the participants. PDR varied across age groups (18-30yo: 12.5%, 31-40yo: 14.04%, 41-50yo: 17.39%). Polyp sizes were categorized as <5mm (n=20), 5-7mm (n=6), and >7mm (n=3).

The majority of polyps were located in the sigmoid colon (n=12), followed by the unspecified left colon (n=10) and the right colon (n=7). Subsequent colonoscopy due to positive CCE performed in all patients and detected an additional 6 small polyps (<3mm). In 4 cases, colonoscopy yielded negative results. However, upon conducting a back-to-back colonoscopy all of the previously undetected polyps were eventually found. Histology results revealed one high-grade dysplastic polyp.

The average cleanliness level of the colon was assessed using the CCE Cleansing Score (CC-CLEAR). For the cecum, the right and left colon, the average scores were 5.5-7-8, respectively. Impressively, 95% of participants reported high tolerance, and 91% of respondents expressed a preference for CCCE as the next screening procedure too and colonoscopy only after a positive CCE result.

Conclusion: Navicam colon capsule endoscopy emerges as a useful and feasible screening tool, demonstrating unparalleled promise in detecting polyps among asymptomatic individuals. Its polyp detection rate, cost-effectiveness, patient-friendly nature, and agreement with colonoscopy findings position it as a potent complementary method for advancing colorectal screening in low CRC risk individuals.

Disclosure: Nothing to disclose.

COMPLICATIONS OF THE FIRST ENDOSONOGRAPHY-GUIDED DRAINAGE VS. FOLLOWING INTERVENTIONS IN PANCREATIC FLUID COLLECTIONS AND NECROSIS

M. Razpotnik¹, C. Jürgensen¹, M. Sigal¹, C. Makris¹, F.J. Körner¹, Ö. Celebi¹, T.M. Holtmann¹, A. Adler¹, F. Branchi², J. Buchkremer², F. Tacke¹, A. Wree¹

Contact E-Mail Address: marcel.razpotnik@gmail.com

Introduction: In general, it is recognized that there is a considerable risk of complications following early endotherapy in the development of pancreatic fluid collections. However, there is still limited information regarding the optimal timing for endosonography (EUS)-guided drainage once a well-defined wall has formed and the relative risk of complications in subsequent interventions.

Aims & Methods: Our study aims to examine the risk of the first EUS-guided drainage compared to the following interventions in pancreatic fluid collections and necrosis. Data on EUS-guided drainage of pancreatic fluid collections performed between 2018 and 2022 at three endoscopy units of Charité- Berlin, regardless of the etiology, were reviewed and analyzed. Adverse events were defined and graded according to the recommendations of the American Society of Gastrointestinal Endoscopy¹.

A severe event following an endoscopic procedure is defined as one that necessitates unplanned admission, prolongs hospital stay by > 10 nights, requires ICU admission for > 1 night, or results in surgery or permanent disability. The Cox proportional hazards regression model was used to examine the relationship between the timing of EUS-guided therapy and the occurrence of complications, adjusting for patient- and procedure-related (age, gender, body-mass index, comorbidities, etiology, size) covariates.

Results: In a cohort of 102 patients (72.5% male, mean age 57.0 ± 14.1 years), 202 procedures were performed, of which 71 (35.1%) were necrosectomies. The predominant etiology was fluid collection complicating pancreatic resection (31.4%), followed by alcohol-induced (22.5%) and biliary (18.6%) pancreatitis. Nearly half of the cases presented with necrotic particles on pre-interventional imaging and 85.3% had a fully definable wall. Adverse events were observed in 24 of the 202 (11.9%) procedures. Six were classified as severe and predominantly occurred during the initial session.

The most frequently reported adverse event was bleeding (4.5%), followed by abdominal pain (1.9%), infection (1.9%), and perforation (0.9%). Three patients died within 30 days after the intervention and were indirectly associated with iatrogenic-induced infection of previously sterile collection. In the Cox proportional hazards regression analysis, which was adjusted for confounding variables, the first intervention emerged as a significant predictor of complications, with a hazard ratio (HR) of 3.5 (95% CI 1.2-10.7). This finding suggests an increased risk of complications during the initial endotherapy session for pancreatic fluid collections.

Conversely, there was an association between the post-pancreatitis fluid collections and complications with an HR of 3.1 (95% CI 0.7- 14.0) compared to post-surgery collections but it did not reach statistical significance. The procedure's duration and the collection size were not associated with the risk of complications.

	1. Intervention	2. Intervention	3. Intervention	4. Intervention
Number	n=102	n=53	n=26	n=21
Time after symptoms (days)	32.1 ± 24.0	44.6 ± 24.7	46.6 ± 26.2	50.3 ± 20.6
Time of the procedure (min)	36.9 ± 16.3	46.9 ± 28.3	60.8 ± 26.7	64.6 ± 30.9
Necrosectomy (%)	5 (4.9%)	32 (60.4%)	18 (69.2%)	16 (76.2%)
Complications (%)	14 (13.7%)	5 (9.4%)	2 (7.7%)	3 (14.3%)
Complication severity				
Mild	7 (6.9%)	3 (5.7%)	2 (7.7%)	1 (4.8%)
Moderate	3 (2.9%)	1 (1.9%)	0	1 (4.8%)
Severe	4 (3.9%)	1 (1.9%)	0	1 (4.8%)

Conclusion: In the EUS-guided therapy of pancreatic fluid collections, the initial intervention emerged as a significant predictor of complications. While post-pancreatitis collections tend toward a higher complication rate compared to post-surgical collections, early intervention strategies require careful consideration to reduce risks.

Introduction: In our recent multicentre prospective study (AXIOMA), the effectiveness of lumen-apposing metal stents (LAMS) in endoscopic transluminal drainage of infected necrosis was comparable to that of double-pigtail plastic stents(1). The use of LAMS did not reduce the need for additional drainage procedures and resulted in similar patient outcomes compared to double-pigtails plastic stents. However, long-term follow-up data (>6 months) from prospective studies were still lacking for comparison of the stents.

Aims & Methods: We examined the long-term outcomes of patients with infected necrotizing pancreatitis enrolled in two prospective studies. Patients were treated with endoscopic transluminal drainage with LAMS (n=52) as part of a multicentre prospective cohort in 16 hospitals, or with double-pigtail plastic stents (n=48) as part of the endoscopic step-up arm of a randomized multicentre trial (TENSION) in 19 hospitals(2, 3). The protocol of both studies, including in- and exclusion criteria, were identical except for the type of transluminal stent.

The primary endpoint was the proportion of patients requiring additional endoscopic, percutaneous or surgical drainage procedures due to (recurrence of) symptomatic or infected (peri-)pancreatic collections. Secondary endpoints included the individual components of the primary endpoint, major complications, mortality, number of (pancreatitis-related) readmissions and interventions, length of hospital stay, pancreatic function and quality of life.

Results: The median follow-up period was 4 years. By the end of this period, 77 out of 100 patients were still alive. Among the 47 surviving patients treated with LAMS, 9 were lost to follow-up after the initial 6-month study. An additional percutaneous, endoscopic or surgical drainage or necrosectomy procedure was needed in 37 patients (77%) in the plastic stent group and 40 patients (77%) in the LAMS group (RR 1.002 95% CI 0.809-1.242). The median number of interventions did not differ during overall follow-up (2 [IQR, 1-5] vs 2 [IQR, 1.5-7.5], respectively, P = 0.66). Overall, there was no significant difference in mortality rates (12 patients (25%) vs. 11 (21%) respectively; RR 1.18 95% CI 0.576-2.42), and there was no difference in new mortality after the initial follow-up (3 patients (8%) vs. 6 (13%) respectively; RR 0.603 95% CI 0.16-2.254). No deaths during long-term follow-up were related to pancreatitis. The plastic stents group and LAMS group had a similar rate of pancreatitis-related readmissions (2 [IQR, 0-2] vs 1 [IQR, 0-3], P = 0.67) and associated length of hospital stay (9 [IQR, 0-20.75] vs 6 [IQR, 0-19.75], P = 0.58).

Conclusion: During the long-term follow-up of the AXIOMA study participants, we found no differences in mortality, major complications, readmissions or the need for additional interventions between double-pigtails plastic stents and LAMS. These long-term results are consistent with our prior findings, suggesting that double-pigtail plastic stents and LAMS have comparable clinical outcomes and adverse events in the endoscopic step-up approach for infected necrotizing pancreatitis.

Introduction: Even though numerous risk factors and methods for prevention of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) have been identified, it persists as the most prevalent complication. Administration of 100mg diclofenac prior to ERCP represents the most frequently used prophylaxis. Diclofenac is predominantly metabolized by various cytochrome P450 enzymes. The potential presence of single nucleotide polymorphisms (SNP) in these enzymes could cause interindividual variability in metabolism rates, which could affect serum plasma levels of diclofenac. Given the limited available research on this subject, the aim of this study was to investigate whether differences in presence of SNPs in the CYP-enzymes involved in diclofenac metabolism were associated with PEP.

Aims & Methods: This multicentre cohort study included patients above 18 years who underwent ERCP between 2012 and 2022. Upon inclusion, patients were divided into the PEP or control group. Real-time polymerase chain reactions were performed on buccal smear samples to identify gene variants involved in the diclofenac metabolism (e.g. CYP2C8*3). Secondary endpoints were validation of known and possibly yet unknown risk factors for PEP.

Results: In total, 103 patients were included in the PEP group and 245 in the control group. DNA amplification was possible in 91.5% of the genetic variants and revealed that heterozygous carriers of CYP2C8*3 variant were associated with a lower frequency of PEP (OR 0.2; 95% CI 0.0-0.8). Pancreatic duct cannulation (OR 3.0; 95% CI 1.4-6.6) and pre-cut sphincterotomy (OR 3.1; 95% CI 1.2-8.0) were both found as independent risk factors for PEP.

Conclusion: This study showed that heterozygous carriers of the CYP2C8*3 variant have a lower risk of developing PEP. To investigate gene variants affecting real-time diclofenac plasma levels, we have started a study in which we prospectively collect blood samples to enhance DNA quality and to analyze the existence of a correlation between PEP and reduced diclofenac levels. If this correlation is confirmed, further research is needed to investigate the optimal dosage of diclofenac in wild type CYP2C8 patients.

Introduction: There are limited molecular features to allow treatment personalization and outcome prediction of Pancreatic-Ductal-Adenocarcinoma (PDAC) patients. Two transcriptome subtypes have been identified: classical and basal-like. Classical PDACs show better prognosis and response to FOLFIRINOX, while basal-like display an opposite behaviour. This transcriptome-based classification is not straightforward and relies mainly on surgical series, with limited data on EUS-FNA samples. We have recently showed that the splicing factor QKI is a determinant of basal-like signature and that its evaluation together with GATA6 has strong prognostic capacity.

Aims & Methods: Our aim was to investigate transcriptome subtypes and gene expression of specific biomarkers on baseline EUS-FNA samples of PDAC patients and their association with prognosis and response to chemotherapy. 85 PDAC patients who underwent EUS at diagnosis were enrolled in a prospective study and FNA samples investigated by RNA-seq. PURIST score was applied to define subtypes, Differential Gene Expression DGE analysis was performed and the prognostic value of QKI and GATA6 expression was investigated. The outcomes were overall survival (OS) and progression-free survival (PFS) corrected for age and stage.

Results: RNA-seq was successful in 84/85 (98.8%) samples. According with PURIST, 4 patients were classified as basal-like (4.8%), 80 being classical. OS was lower in Basal-like vs classical patients (5.5 vs 13 months; p=0.01), with increased risk of death (HR 5.6; 95%CI: 1.5-20.9; p=0.01). PURIST score also correlated inversely with OS (r=-0.4; p=0.0002).

In 64 patients treated with first-line chemotherapy (FOLFIRINOX n=24; Abraxane-Gemcitabine, AG n=30; PAXG n=10) QKI expression correlated with OS (r=-0.36; p=0.0038). Among patients treated with FOLFIRINOX, median PFS was 7 months (IQR 2-9) in patients with a QKI/Gata6 ratio >1.13 and not reached in patients with ratio ≤1.13 (HR=5.1; 95%CI: 1.2-21.5); QKI/GATA6 ratio was not associated with PFS in patients treated with the other regimens.

At DGE analysis REG4 was the most enriched gene in patients with PFS >6 months; a cut-off for REG4 expression >111 was associated with response to AG (HR=0.2; 95%CI: 0.090-0.59; p=0.002).

Conclusion: Transcriptome analysis of EUS-FNA samples is feasible and allows stratification of PDAC patients in terms of prognosis and chemosensitivity. Few selected classifiers such as QKI, GATA6 and REG4 may be sufficient to predict response to certain treatments.

Introduction: Pancreatic cancer is characterized by tissue stiffness due to the high concentration of cancer-associated fibroblasts and extracellular matrix. Endoscopic ultrasound-guided tissue acquisition (EUS-TA) is performed to diagnose pancreatic cancer but yields false-negative results attributed to inadequate specimens. EUS-elastography is a real-time assessment method to pancreatic tissue stiffness.

Aims & Methods: This study aims to investigate the correlation between diagnostic yield and the number of needle passes based on the stiffness measured by elastography. Patients who underwent EUS-TA for pancreatic solid mass were enrolled. The number of needle passes during EUS-TA was determined based on macroscopic on-site evaluation. Tissue stiffness measurements were taken using EUS-elastography.

The primary study outcome was the diagnostic yield. The secondary outcome included the number of needle passes required for a diagnosis.

Results: A total of 652 patients were included. The average stiffness differed depending on the location of the tumor, and high-stiffness group had more malignant lesions.

Although the diagnostic yield was not significantly different between groups, the number of needle passes was significantly higher in the high-stiffness group (3.6 ± 1.0 vs. 3.2 ± 0.9 , $p < 0.001$).

Conclusion: The higher the stiffness of the pancreatic mass in EUS-elastography, the more needle passes are required to achieve a comparable diagnostic yield.

DRY SUCTION VERSUS WET SUCTION TECHNIQUE OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE BIOPSY FOR DIAGNOSIS OF SOLID PANCREATIC LESIONS: A MULTICENTER RANDOMIZED CONTROLLED NON-INFERIORITY TRIAL

S. Xu¹, J. Wang¹, J. Guo², F. Xie¹, Y. Meng³, P. Peng⁴, H. Hu⁵, Y. Huang⁵, S. Liu¹, M. Qin⁴, J. Yao³, Y. Li¹

Contact E-Mail Address: xushenglin16@163.com

Introduction: Endoscopic ultrasound-guided fine-needle aspiration/biopsy (EUS-FNA/B) has been widely used for the diagnosis of solid pancreatic lesion.

Studies have shown that the wet suction technique in EUS-FNA generates better histologic diagnostic accuracy and specimen quality than the dry suction technique.

However, conclusions of wet suction on the diagnostic accuracy of EUS-FNB are still controversial. Besides, the optimal number of passes for EUS-FNB has not been determined.

We aimed to design a multicenter randomized trial to compare the diagnostic accuracy of dry suction versus wet suction technique in solid pancreatic lesions using 22G Franseen needles and determine the optimal number of passes required for EUS-FNB without onsite cytopathologist.

Aims & Methods: This is a multi-center, open-label, randomized controlled and non-inferiority trial with two parallel groups. The patients with solid pancreatic lesion will undergo EUS-FNB using 22G Franseen needle in 4 tertiary hospitals in China and will be randomly assigned to the dry suction group and wet suction group in a ratio of 1:1.

The primary endpoint of this study is to compare the diagnostic accuracy of EUS-FNB for solid pancreatic lesions using the dry or wet suction technique.

Secondary endpoints include the optimal number of needle passes, sensitivity, specificity, specimen quality, time of the procedure, and rates of complications.

Results: Of the 195 patients undergoing EUS-FNB enrolled in the final analysis, 96 were randomized to the dry suction group and 99 to the wet suction group. The diagnostic accuracy was 98.95% and 98.98% in the dry and wet groups, respectively, with a 0.05% difference in accuracy between the study groups (two-sided 90% CI, -4.88% to 4.82%, $P=0.989$).

Diagnostic accuracy was shown to be non-inferior because the lower bound of the 90% confidence interval falls to the right of the non-inferiority margin. Compared to the wet group, no significant differences were seen in the sensitivity (98.80 % vs 98.77 %, $P = 1$) and specificity (100 % vs 100 %, $P = 1$) in the dry suction group.

The overall adverse event rate was 0.52 %, with 0 and 1.02 % in the dry and wet groups, respectively ($P = 1$). In terms of specimen quality, no significant differences were also seen in the two groups in sample adequacy (100 % vs 98.3 %, $P = 0.492$) and level of blood contamination ($P = 0.319$). In terms of puncture time in the dry group compared to the wet group, there was no statistically significant (18.82±8.21 min vs. 18.92±8.99 min, $P=0.952$), but the wet suction required more time to prepare the saline and the needle.

No significant improvement in diagnostic accuracy was seen with the 2nd needle compared to the 1st needle of EUS-FNB (97.41% vs 95.34% , $P=0.276$), and no significant improvement in diagnostic accuracy was seen with the 3rd shot compared to the 2nd shot of EUS-FNB (98.96% vs 97.41% , $P=0.446$).

Conclusion: The dry suction technique is non-inferior to the wet suction technique, while saving steps and time. In the absence of rapid on-site evaluation (ROSE), only 1 pass was required to reach the diagnostic accuracy ≥ 95% using EUS-FNB with Franseen needle.

Disclosure: Nothing to disclose.

Contact E-Mail Address: g.e.vanella@gmail.com

Introduction: Despite EUS-guided drainage (EUS-FCD) is the preferred modality for management of peripancreatic fluid collections (PFCs), factors predicting the need for step-up to additional procedures (including radiology, surgery or additional endoscopies) are retrospectively explored in studies restricted to Lumen Apposing Metal Stents (LAMS) or excluding pseudocysts and post-surgical collections, which might require a step-up as well.

Aims & Methods: All consecutive candidates to EUS-FCD with either LAMS or Double-pigtail Plastic Stents (DPPS) between 2020-2023 were included in a Prospective Registry of Therapeutic EUS (PROTECT). The role of baseline clinical and morphological factors, including the Quadrant / Necrosis / Infection (QNI) score, in predicting the need for any step-up to additional procedures was evaluated by stepwise logistic regression.

Results: Twenty-three post-surgical PFCs, 19 pseudocysts and 18 walled-off necrosis (WOPN) were included, 42% treated with LAMS and 58% with DPPS based on morphology. Clinical success was 92.9%, but 38% of patients required a step-up to necrosectomy (26.7%) or additional procedures.

Patients requiring step-up versus those sufficing drainage had a higher number of quadrants involved (OR=3.6 [1.5-8.4]), a more frequent paracolic extension (OR=6 [1.4-26]), a higher necrosis content ($\geq 30\%$, OR=7.2 [1.8-28.4]; $\geq 60\%$ OR=25.2 [4.2-153]) and were in the high-risk group according to the QNI score, with no difference in the diameter and rate of superinfection.

At multivariate analysis, being in the high-risk QNI group was the only independent predictor of step-up (OR=9.8 [2.9-32.9]). The score however was not able to stratify in analyses restricted to WOPN only or LAMS only. High-risk QNI patients presented also a longer hospital stay (17.5 [8-45] vs 4 [2-6.5], $p=0.001$), without any difference in ICU stay and nutritional support.

Conclusion: In this prospective series of consecutive non-selective PFCs undergoing EUS-FCD, QNI score was the only independent predictor of any need for step-up to additional procedures, and strongly correlated to the EUS-FCD allocation to LAMS versus DPPS, unravelling a potential additional utility.

NEED OF ENDOSCOPIC NECROSECTOMY IN WALLED-OFF PANCREATIC NECROSIS TREATED WITH LAMS: A PROSPECTIVE VALIDATION OF A PREDICTIVE CLINICAL INDEX

S. Bosso¹, G. Rizzatti¹, G. Tripodi¹, F. Borrelli de Andreis¹, F. Attili¹, A. Milani¹, A. Gasbarrini¹, C. Spada¹, A. Larghi¹

¹Policlinico Universitario A. Gemelli IRCSS, Rome, Italy

Contact E-Mail Address: silvia.bosso01@icatt.it

Introduction: The endoscopic ultrasound-guided drainage by means of Lumen-Apposing Metal Stent (LAMS) represents a minimally invasive treatment of Walled-Off Pancreatic Necrosis (WOPN). In order to achieve a complete healing of the lesion and depending on the amount of the necrosis, a subset of patients may benefit from a further endoscopic necrosectomy (EN).

Aims & Methods: An early identification of the subjects requiring EN may therefore represent a valuable clue in the clinical management of patients with WOPN.

In a first step of the study we retrospectively evaluated 53 patients ("training group") diagnosed with WOPN (16 females and 37 males, aged from 28 to 87) admitted to our Institution over the period 2013-2023. In 24 cases (45.3%) EN was required and then performed after LAMS placement. In this group, we identified a predictive Necrosectomy-index (NI), by means of a discriminant-function statistical analysis, taking into consideration only the individual variables showing a statistical difference (single tail $p < 0.10$, one-way variance analysis) between the patients requiring EN and the remaining subjects. Such a retrospectively-assessed NI is then able to provide an "a priori" identification of the subset of WOPN patients requiring necrosectomy.

Thereafter, NI predictive value and clinical reliability (global accuracy, predictive value and overall statistical significance) were prospectively tested in a separate set of patients with WOPN ("challenge group"), consisting of 53 patients (15 females and 38 males, aged from 23 to 85).

Results: In the "training" group, the retrospective analysis of our data allowed to calculate individual NI by means of the simple function:

$$NI = 336 - (PT\% * 1.26 + Hb \text{ (g/dL)} * 29.54 + PLT \text{ (kU/mm}^3\text{)} * 0.11 - 48.56 * EUS)$$

where EUS stands for the endoscopic US subjective rank of the collection features (0 = fluid; 1 = solid debris; 2 = purulent; 3 = necrosis $< 50\%$; 4 = necrosis $> 50\%$; 5 = completely necrotic).

The proposed NI provides an early discrimination of the subset of WOPN patients requiring EN after LAMS placement (identified by a positive NI) from those not requiring necrosectomy (NI lower than zero), the cut-off between the two groups being therefore represented by a NI = 0.

To increase the predictive ability of the model, the subjects with a NI close to 0 (between 3 and -3) may be considered as "undeterminable", being therefore addressed to EN on the basis of the clinical status, regardless of NI.

In the prospectively evaluated "challenge" group, NI showed a remarkable overall statistical significance ($p < 0.01$). The prospective statistical analysis allowed us to confirm NI clinical value (with a global accuracy of 73.3%, a 68.2% predictive value for positivity and a 78.3% for negativity respectively) in the early identification of WOPN patients requiring EN after LAMS placement. Three patients only (5.7%) showed a NI between 3 and -3, being therefore considered as "undeterminable".

Conclusion: Our data provided a prospective validation of the proposed Necrosectomy Index, confirming its reliable intrinsic predictive value. NI may therefore represent a powerful clinical tool in the patients with WOPN, providing an early identification of those requiring further endoscopic necrosectomy after LAMS placement.

Disclosure: Nothing to disclose.

VINEGAR INDUCED PANCREATIC JUICE COLLECTION VIA ENDOSCOPIC ULTRASOUND: OPERATING CONDITION EXPLORATION TOWARD MOLECULAR BIOMARKER DISCOVERY AND EARLY DIAGNOSIS OF PANCREATIC CANCER

W. Shi¹, Z. Yan¹, S. Zhang¹, Y. Zhang¹, Q. Jiang¹, Y. Feng¹, Q. Wang¹, X. Wu¹, A. Yang¹

¹Peking Union Medical College Hospital, Gastroenterology, Beijing, China

Contact E-Mail Address: ysfu_2005@126.com

Introduction: Early detection of pancreatic cancer (PDAC) in high-risk patients through molecular biomarkers in pancreatic juice (PJ) is promising but is limited by the lack of safe and effective methods for collecting PJ[1]. Traditional method via ERCP and pancreatic duct cannulation may bring additional risks[2], and intravenous injection of secretin is expensive, may cause complications and is not available in countries including China. Intraduodenal acid infusion can induce secretin release physiologically and is proved to facilitate pancreatic duct cannulation and decrease difficult pancreatic cannulation rate[3].

Thus we aim to investigate the feasibility and safety of PJ collection for molecular biomarker detection via endoscopic ultrasound (EUS) after injection of vinegar into duodenal bulb.

Aims & Methods: 20ml vinegar (5% acetic acid) or 20ml saline was injected into the duodenal bulb and PJ was collected via suction during EUS in patients suspected of having PDAC. The yield of cfDNA concentration, KRAS mutation load and PLA2G1B protein concentration (representing pancreatic source) was compared between vinegar-induced PJ and saline-control-induced PJ, as well as between 3 time periods of vinegar-stimulated PJ (0-5 vs. 5-10 vs. 10-15 minutes). Whole-exome sequencing (WES) was performed on genomic DNA extracts from exfoliated cells from vinegar-stimulated PJ.

Results: PJ from 19 patients diagnosed with PDAC were collected, of which 13 were in the vinegar group and 6 in the saline group. cfDNA concentration, KRAS mutation load and PLA2GB1 level are higher in the vinegar group than in the saline group ($p<0.01$). cfDNA concentration (ng/ μ L) at 5-10min timeframe was higher than 0-5min (82.59 ± 55.44 vs. 5.95 ± 4.60 , $p<0.05$), yet did not differ from 10-15min (75.06 ± 51.65 , $p=0.29$) in the vinegar group. KRAS mutation load (%) showed the same trend. However, PLA2G1B concentrations at 3 timeframes were not significantly different in the vinegar group. WES on genomic DNA extracted from PJ exfoliated cells was performed in 10 patients of the vinegar group, which revealed a large number of driver mutations (*PLEC*, *MUC16*, *BIRC6*, *HERC1*, *SYNE1*, etc.) and the expression of high-frequency mutated genes (*CSMD2*, *EPPK1*, *FSIP2*, *MUC17*, *AGMO*, etc.), some of which were common across different individuals. Furthermore, according to pathological result and clinical follow-up for more than 6 months, 8 patients were finally diagnosed of PDAC while 2 patients were diagnosed of pancreatitis (one with chronic pancreatitis and the other with autoimmune pancreatitis).

Of note, some mutations highly associated with PDAC were only observed in the malignant group, represented by *PTGER1*, *RHEB*, *IER3IP1*, *DLC1*, *GKN1*, *TNS3*, etc.

Conclusion: Vinegar-induced PJ collection via EUS is feasible and safe. We established that the optimal protocol is suction under EUS for 10 minutes after injection of 20ml vinegar into duodenal bulb for 2 minutes.

This resulted in the most favourable detection of molecular biomarkers including PJ cfDNA as well as exfoliated cells based on their yield, concentration and expression, which were helpful for precise diagnosis of PDAC. Further studies are needed to explore the potential of the collected PJ biomarkers in early detection and pathogenesis researches of PDAC and its precursor lesions.

Introduction: Patients with malignant distal biliary obstruction who are eligible for curative resection face the risk of complications from preoperative biliary drainage, especially pancreatitis. Endoscopic ultrasound guided choledochoduodenostomy (EUS-CDS) using a lumen apposing metal stent (LAMS) is a promising alternative for endoscopic retrograde cholangiopancreatography (ERCP) but data in patients undergoing pancreatoduodenectomy (PD) are limited. Therefore, in daily clinical practice multidisciplinary teams are reluctant to opt for EUS-CDS in patients with potentially resectable tumors.

Aims & Methods: Patients who underwent a PD between January 2020 and December 2022 after preoperative biliary drainage by EUS-CDS were included. Prospectively collected data from patients in the Dutch Pan-

creatic Cancer Audit were retrospectively analyzed. Primary endpoint was major postoperative complications, defined as Clavien-Dindo score ≥ 3 . Secondary endpoints included overall complications, pancreatic surgery specific complications (i.e. postoperative pancreatic fistula, delayed gastric emptying, hemorrhage, and chyle leakage), in-hospital mortality and hospital stay. A propensity score matching (1:3) analysis was performed using patient and tumor characteristics, neoadjuvant therapy, type of stent, and hospital volume. Surgeons who performed a PD in a patient who underwent pre-operative EUS-CDS were requested to fill-out a 5-questions survey directly after the surgical procedure.

Results: Overall, 937 patients after PD were included of which 42 patients underwent EUS-CDS pre-operatively and 895 patients ERCP. Major postoperative complications occurred in 8 patients (19%) in the EUS-CDS group and 292 patients (33%) in the ERCP group (RR 0.50; 95% CI, 0.23-1.07). No significant differences were observed in the secondary endpoints. Time between biliary drainage and surgery in patients without neoadjuvant therapy differed significantly between the EUS-CDS group (median 32 days [IQR 22-39.25]) and the ERCP group (median 41 days [IQR, 28-57]; $p=0.005$). Operative time was shorter in the EUS-CDS group (median 309 min [IQR 245.75-353] vs 349 min [IQR 281-425]; $p=0.002$). Results were similar after propensity-score matching.

The survey was completed on 29 resections after EUS-CDS. In the majority ($n=22$, 76%) there was no direct visualization of the stent during the PD. In most patients, the resection was not ($n=13$, 45%) or slightly ($n=8$, 28%) influenced by the EUS-CDS according to the surgeon. The stent did not hamper the creation of the hepaticojejunostomy.

Conclusion: This nationwide retrospective study found EUS-CDS to be safe without increase in (major) postoperative complications after PD as compared to ERCP. Moreover, surgeons did not encounter evident difficulties during most of the resections.

Introduction: The Updated Sydney System recommends reporting the severity of both glandular atrophy (GA) and intestinal metaplasia (IM) as two independent parameters. However, the OLGA system assesses both GA and IM together as part of the same entity which should be reported as an average severity. The OLGIM system is based on the IM severity recommended by the updated Sydney system.

Thus, the final OLGIM score can be estimated by any clinician. Currently, no system addresses the severity of both GA and IM as they are reported following the updated Sydney recommendation.

Aims & Methods: This study aimed to assess the utility of a new system, OLGIMA (Operative Link on Gastric IM and GA assessment), as a tool to identify patients at higher risk for GC in daily practice.

Consecutive diagnostic UGI endoscopies performed for any indications in patients older than 18 years old were recorded prospectively in 21 Spanish hospitals between April 2021 and July 2023. Protocolized gastric biopsies were taken according to the Updated Sydney consensus.

We excluded patients with dysplasia, any malignancy, suspicion of autoimmune chronic atrophic gastritis, and lack of histological data. The severity of both GA and IM was assessed in the antrum (including incisura) and corpus following the updated Sydney system.

After that, we considered the most advanced severity (none:0; mild:1; moderate:2; marked:3) provided for any of them in each of the two topographical areas.

Then, the OLGIMA staging was done according to the same methodology used by the OLGA and OLGIM systems.

Results: A total of 998 patients were included. The median age was 57 (IQR 46 - 67), and 64% were women. Hp infection was identified in 334 (35%) patients (19% active infection and 16% eradicated). GA was identified in 192 (19.2%) patients which was limited to the antrum in 113 (11.3%) cases and extensive in 79 (7.9%). IM was identified in 159 (15.9%) patients which was limited to the antrum in 114 (11.4%) cases and extensive in 45 (4.5%). According to IM severity, 27 (2.7%) patients were OLGIM III/IV. According to GA severity, 22 (2.2%) patients were significantly extensive. The OLGIM system would have missed 12 (1.2%) patients with GA at higher risk. Considering both criteria, we would have detected 39 (3.9%) patients at higher risk in total (17 OLGIM III-IV, 12 extensive significant GA, and 10 both OLGIM III-IV and extensive significant GA). The new OLGIMA system categorized all 39 (3.9%) patients, OLGIM III-IV and significantly extensive GA, in the high-risk group (OLGIMA III/IV).

Conclusion: The new OLGIMA system (based on the severity of IM and GA recommended by the updated Sydney system) was able to detect patients at higher risk including all cases of OLGIM III/IV and also with advanced GA. The OLGIMA staging is much simpler and it can be estimated by any clinician regardless of whether the biopsy from incisura was taken.

ANTITUMOR[A1] EFFECT[A2] OF TALAPORFIN PHOTO DYNAMIC THERAPY (PDT) COMBINED WITH DUAL IMMUNE CHECKPOINT INHIBITION

M. Tanaka¹, M. Sasaki¹, Y. Kojima¹, H. Nishie¹, H. Kataoka¹

¹Nagoya City University Graduate School of Medical Sciences, Departments of Gastroenterology and Metabolism, Nagoya, Japan

Contact E-Mail Address: mtanaka@med.nagoya-cu.ac.jp

Introduction: Photodynamic therapy (PDT) is a treatment method in which tumor tissues incorporated with a photosensitizer (PS) are irradiated with incident light at an appropriate wavelength, causing a photochemical reaction that releases free radicals, resulting in the necrosis of tumor cells via oxidative stress. The second-generation photosensitizer, talaporfin, is rapidly eliminated from the skin and requires a shorter sunshade period (two weeks). The "abscopal effect," where radiotherapy at one site leads to regression of metastatic tumors not irradiated, has been reported in PDT (1). Studies on the synergistic effect of the abscopal effect in combination with immune checkpoint inhibitors (ICIs) have been reported in radiotherapy and other related fields. PDT induces not only a direct cytotoxic effect but also enhances tumor immunity (2). Therefore, we hypothesized that the addition of ICIs to PDT would regulate the immune system and promote the cancer immunity cycle, leading to the effective inhibition of tumor growth at both irradiated and non-irradiated sites. CTLA-4 and PD-1 inhibit T-cell activation through distinct and potentially synergistic mechanisms (3). In this study, we investigated the therapeutic efficacy of combining talaporfin PDT (TS-PDT) with dual ICIs (targeting PD-L1 and targeting CTLA-4).

Aims & Methods:

1. To analyze the cell death mechanism induced by TS-PDT, we performed an apoptosis/necrosis assay and stained the cells with annexin V-fluorescein isothiocyanate and propidium iodide for flow cytometric analysis.
2. Furthermore, we measured CRT translocation after TS-PDT using immunofluorescence staining. We also measured the supernatant concentration of HMGB1 in the culture medium treated with TS-PDT to evaluate the release of HMGB1.
3. We assessed the in vivo efficacy of Talaporfin PDT, ICIs, and their combination using a xenograft tumor model.
4. For immunohistochemical analysis, we examined the expression of CD4, CD8, and PD-L1.
5. IFN- γ , perforin 1 and granzyme B mRNA expression levels in tumors were measured by qRT-PCR.

Results:

1. The percentage of cells undergoing apoptosis and necrosis was higher in the TS-PDT group than in the untreated group. The mean fluorescence intensity of active caspase-3, a marker of apoptosis, was higher in the TS-PDT-treated cells than in the untreated cells.
2. Translocation of CRT from the nucleus to the cytoplasm was induced by TS-PDT. HMGB1 levels in the supernatant increased after TS-PDT.
3. The combination exhibited significantly greater tumor growth inhibition than either agent alone in a xenograft tumor model.
4. In non-irradiated tumors, the expression levels of CD4, CD8, and PD-L1 were elevated in the TS-PDT group. Combination of TS-PDT and ICIs reduced PD-L1 expression.
5. In the tumors on the non-irradiated side, combination therapy tended to induce IFN- γ , perforin 1, and granzyme B

Conclusion: Our results demonstrate that TS-PDT not only induces a direct cytotoxic effect on tumor cells but also enhances anti-tumor immunity and exhibits synergism with dual ICIs. Therefore, these findings suggest that a combination of TS-PDT and dual ICI antibodies may be a promising approach for the development of anti-tumor therapeutics.

Introduction: Malignant oesophageal strictures can cause airway compromise and fistula formation¹. Combined oesophageal and airway stenting is a potential treatment yet no guidelines exist². This study aims to describe the outcomes of same-session oesophageal and airway endoscopic stenting for malignant strictures and propose an algorithm for intervention.

Aims & Methods: A retrospective study on patients undergoing same-session gastroenterology (GI) and respiratory endoscopy at University College London Hospital, 2019-2023. All procedures were with anaesthetic-led propofol sedation. Endoscopic decision making was based on preprocedure multidisciplinary team meeting (MDM) and intra-procedure clinical assessment. Data collected included malignancy type, luminal narrowing, complications, and mortality.

Results: 26 patients were identified. Mean age was 63 years. Cancer type was oesophageal (81%) or lung (19%). The most common referral indication was dysphagia (42%); airway compromise was often seen on imaging (65%). Stent insertion was oesophageal only (35%), airway only (19%) and dual (27%) (Table 1).

Characteristic	Dual Intervention (N=7)	Oesophageal Intervention alone (N=9)	Airway Intervention alone (N=5)	No Intervention (N=5)
Procedure time, mins	87 (66, 152)	41 (36, 43)	64 (55, 66)	39 (28, 86)
Procedural Airway				
None	6 (86)	8 (89)	3 (60)	3 (60)
Endotracheal tube	0	1 (11)	1 (20)	0
Rigid Bronchoscopy	1 (14)	0	1 (20)	2 (40)
Fistula at endoscopy	4 (57)	3 (33)	3 (60)	2 (40)
Oesophageal narrowing:				
<50%	1 (14)	3 (33)	2 (40)	0
>50%	5 (71)	5 (56)	2 (40)	4 (80)
Not reported	1 (14)	1 (11)	1 (20)	1 (20)
Airway narrowing:				
0-25%	0	7 (78)	0	1 (20)
25-50%	0	2 (22)	0	1 (20)
50-75%	1 (14)	0	0	0
75-100%	6 (86)	0	5 (100)	3 (60) [†]
Location of airway narrowing:				
Not documented	0	3 (33)	0	0
Trachea	3 (43)	4 (44)	0	1 (20)
Left main/lower lobe	3 (43)	1 (11)	3	2 (40)
Right main/lower lobe	0	1 (11)	1	0
Multiple locations	1 (14)	0	1	2 (40)
Type of airway stent:				
Self-expanding metal	6 (86)	0	4 (80)	0
Silicone stent*	1 (14)	0	1 (20)	0
Post Procedure Complications:				
Oesophago-airway fistula	1 (14)	1 (11)	2 (40)	0
Airway stent migration	0	3 (33)	0	0
Airway stent obstruction	1 (14)	0	1 (20)	0
Significant bleeding	0	0	0	0
Respiratory failure	1 (20)	0	1 (20)	0
Repeat procedure	3 (43)	7 (78)	1 (20)	2 (40)

Table 1: Procedure and intervention details for same-session procedures.

Data is presented as N (%) or median (IQR). *Silicone stent includes the placement of one straight bronchial stent and one tracheal Y-stent. [†]two of three patients with no intervention despite significant airway stenosis had multiple locations of airway involvement and stent placement was not feasible.

Airway stenting was common (80%) if airway stenosis was >50%. No airway stenting occurred if stenosis was <50%. After oesophageal stenting, repeat bronchoscopy showed increased airway stenosis in 4 patients (25%). The only intraoperative complication was one oesophageal perforation. New tracheoesophageal fistula was the most common post-intervention complication (15%). Median time from malignancy diagnosis to death was 7.9 weeks.

Conclusion: We present the first algorithm (Figure 1) for endoscopic stenting in patients with malignant oesophageal stricture and airway involvement. We suggest upper GI and respiratory MDM to plan same-session endoscopy with decision-making framed by patient-centred goals given their poor prognosis.

Introduction: Gastric squamous cell carcinoma (GSCC) is an aggressive rare histological subtype accounting for 0.04-0.5% only of all gastric tumors. Due to its scarcity, there are very few case reports in the literature and data are limited to institutional case series with significant variations. Thus, no recommendations for GSCC were published by the European Society of Medical Oncology or the National Comprehensive Cancer Network societies.

Aims & Methods: The aim of this study is to provide the literature with an updated evidence about this rare type for better understanding for its nature and establish a proper management strategy. Data were extracted from the Surveillance, Epidemiology and End Results (SEER) database for 784 patients diagnosed with primary GSCC with sequence 0 or 1 from 2000 to 2020. Patients were selected based on microscopic confirmation for the diagnosis. We used a rate session to calculate the age-adjusted trends as Percent Chance (PC) and Annual Percent Change (APC). We subdivided the patients according to the treatment modality into medical therapy, partial gastrectomy and total gastrectomy group, then followed by smaller subgroups (primary therapy and surgery with systemic therapy). We used a survival session to calculate the relative survival. SPSS version 23 was used for data analysis, Kaplan-Meier and Log-Rank test for survival analysis. The results were considered significant when $P < 0.05$.

Results: GSCC had 2000-2020 PC of -13.3 [APC= -0.5, 95% CI (-1.6: 0.6), $P > 0.05$]. African-Americans had increased rate compared to Caucasians (RR=2.32, 95%CI: 1.96-2.73, $P < 0.0001$). The overall 3-year and 5-year relative survival of GSCC were 21.7% and 17.4%. Out of 502 patients, 341(68.1%) received medical treatment only, 43(8.6%) had partial gastrectomy and 117(23.3%) had total gastrectomy with 5-year relative survival of 10.4%, 38.1% and 44.6% respectively; $P < 0.0001$. Adjuvant chemoradiotherapy had similar 5-year survival compared to surgery with no systemic therapy while both had improved survival compared to surgical

management with systemic chemotherapy only (43.4%, 51.5% and 22.9% respectively; $P = 0.07$). Among the group who received systemic therapy only, primary chemoradiotherapy had improved 5-year relative survival compared to primary chemotherapy and primary radiotherapy (16.3%, 8.1% and 0.0%; $P < 0.0001$).

Conclusion: GSCC is an aggressive malignancy with poor survival outcome. GSCC rates have decreased over the past 20 years. However, the rate in African-Americans is two folds greater to develop GSCC compared to Caucasians. Total gastrectomy had significant improved survival compared to partial gastrectomy and the medical treatment.

These results highlights total gastrectomy as the modality of choice for primary GSCC. As adjuvant chemoradiotherapy had no significant benefit over surgery with no systemic therapy, we discourage the use of systemic therapy to avoid serious systemic side effects related to the systemic treatment for better quality of life after the surgical management.

Introduction: Biomarkers associated with the progression from gastric intestinal metaplasia (GIM) to gastric adenocarcinoma (GA) could provide valuable insights into identifying patients with increased risk for GA. Currently, the discovery of effective GA biomarkers poses a challenge due to the complexity of predictive and actionable value. Rarely can tumorigenesis be attributed solely to an individual molecule, as GA arises from the complex interplay of various intrinsic and environmental factors and collective interactions among multiple molecules.

Aims & Methods: The aim of this study was to identify potential biomarkers for the GIM-to-GA progression and potential drug repurposing for GIM. Sixty-four surgical biopsies were collected from 16 patients (4 tissue biopsies per patient) at St. Olav's Hospital, Norway. Transcriptome datasets of

GIM, GA, and normal tissues were compared within the same stomachs. Computational platform ScType was used for cell-type identification based on given scRNA-seq data and a comprehensive cell marker database. Ingenuity pathway analysis, Pagerank centrality, GO and MSigDB enrichments, CopyKat, aneuploid analysis, docking analysis, pathology and immunohistochemistry (IHC) were used for data and pathway mining, protein-protein interaction (PPI), and molecular structure-based drug repurposing.

Results: GIM displayed 110 canonical pathways that exhibited a negative correlation with GA. Wnt/ β -catenin, ERK/MAPK, mTOR, neuregulin, and BRCA1 pathways were activated in both GIM and GA. Conversely, pathways such as HIPPO, p53, toll-like receptor, aryl hydrocarbon receptor, LPS/IL-1-mediated inhibition of RXR function, and eIF2 were inactivated in GIM but activated in GA. GIM exhibited elevated gene expression compared to GA in tumor microenvironment-related cells. Particularly, RBP2 expression and goblet cell-related gene expression were found to be restricted in GIM, but not in GA. Chromosome instability occurred mainly in GA cells with high rates of gain or loss of chromosomes 1, 7, 12, 21 (gain), and 5, 7, 8, X (loss). CD44 IHC expression was expanded from the basal part of mucosa in normal and GIM stomachs to the upper part of the mucosa in GA stomachs. PPI analysis of 865 GIM-related proteins showed seven network nodes (i.e., drug targets) including epidermal growth factor receptor (EGFR), SRC (proto-oncogene tyrosine-protein kinase), paxillin (PXN), Jun proto-oncogene (JUN), breast cancer type 1 susceptibility protein (BRCA1), tumor protein P53 (TP53 or p53), mouse double minute 2 homolog (MDM2), and CD44. These network node proteins were also shown in The Human Protein Atlas and IHC, with the exception of SRC in GA. Computational drug repurposing of approved and investigational drugs/compounds (e.g., as found on www.clinicaltrials.gov) identified the following drugs as effective for GIM: dasatinib with or without erlotinib, nilotinib, afatinib on SRC, SM1-71 on SRC, JNJ-26483327 on EGFR, Afatinib on EGFR, ingenol mebutate on protein kinase C (PKC) family, amoxapine, benoxaprofen, avobenzon, amlexanox, alprazolam, praziquantel, ibuprofen piconol, tranilast, and restoril.

Conclusion: The druggable protein network associated with GIM progression toward GA was identified. The distinct phenotypic patterns between GIM and GA might challenge the notion that GIM serves as the primary precancerous lesion in GA tumorigenesis rather than shares a common cause with tissue-resident stem cells. Further validation of the druggable protein network is needed for the development of a cost-effective surveillance program and preventive treatment of the GIM-to-GA progression.

Introduction: Small bowel cancers are rare, accounting for less than 5% of gastrointestinal cancers, but their incidence is increasing. Small bowel adenocarcinoma (SBA) accounts for one-third of small bowel cancers, and due to its rarity, scarce data exist on its molecular and clinicopathological features. According to the stem cell hypothesis, only a very small number of cancer cells in a tumor have the ability to promote its growth and development. Lgr5 is known as a Wnt/ β -catenin target gene, marking normal stem cells in various tissues, including the small and large intestine. Lgr5

expression has been shown to correlate with poor prognosis in colorectal cancer. However, the clinicopathological significance of Lgr5 expression in SBA remains unclear.

Aims & Methods: Aims: To explore the localisation of Lgr5 in human SBA tissue and draw comparisons and determine the relationship between their expression and clinicopathological factors and Wnt/ β -catenin signaling pathway-related genomic alterations and proteins.

Methods: We examined 50 surgical resections from patients with primary SBA for immunohistochemical analyses of Lgr5, cyclin D1, c-Myc, and β -catenin expression. DNA mismatch repair (MMR) status was defined by immunostaining for all MMR proteins; MLH1, MSH2, MLH6, and PMS2. A comparative investigation was then performed with the clinicopathological data of patients (sex, age, localisation, histological type, depth of invasion, lymph node metastasis, distant metastasis, and clinical stage) and cancer specific survival. In addition, genomic profiling was performed on 31 patients using targeted next-generation sequencing. Correlation between the positive rate for each protein and prognosis was determined by the Kaplan-Meier method and multivariate analysis using the Cox regression.

Results: The average observation period was 53 months (median, 48; range, 4–110 months), and 18 patients died during the analysis. The primary localisation of the tumor was the duodenum (n=20), jejunum (n=25), and ileum (n=5). Forty-one cases were well differentiated; 5, poorly differentiated; and 4, mucinous adenocarcinoma. In terms of TNM classification, 25 cases were stage I; 16, stage II; 12 stage III; and 16, stage IV. Lgr5 expression was observed in 38% of SBA patients and correlated with lymph node metastasis, distal metastasis, and advancing TNM stage. Lgr5 expression was not associated with DNA mismatch repair status. Lgr5 expression was significantly associated with reduced membranous β -catenin staining, which correspond to an activation of the Wnt/ β -catenin pathway in cancer cells. CTNNB1 mutations (N=3) were found in only Lgr5 positive SBA patients, although the difference was not significant (P=0.090). APC mutations (N=5) were not associated with Lgr5 expression. Lgr5 expression, lymph node metastasis, and distant metastasis were significantly associated with worse cancer specific survival. In multivariate analysis for cancer specific survival, lymph node metastasis and Lgr5 expression retained independent prognostic significance.

Conclusion: Lgr5 expression is associated with an activation of the Wnt/ β -catenin pathway and worse cancer specific survival independent of lymph node metastasis in SBA.

Disclosure: Nothing to disclose.

SIZE, BUT NOT THE NUMBER OF POSITIVE LYMPH NODES IS ASSOCIATED WITH WORSE OVERALL SURVIVAL IN PATIENTS WITH SMALL BOWEL NEUROENDOCRINE TUMOURS

B. Timmermans^{1,2}, R. Srirajaskanthan¹, C. Mestre – Alagarda³, A. Wasif⁴, M. Abildtrup⁴, S. Brown¹, D. Clement¹

Introduction: Until recently lymph node metastases (LNM) in small bowel neuroendocrine tumours (SB-NETs) were classified as absent (N0) or present (N1). However, the American Joint Committee on Cancer (AJCC) updated the classification to N0, N1 < 12 positive LNM and, N2 as $\geq$ 12 positive LNM and/or a large mesenteric mass (> 2 cm) (1). All patients will

be offered the same surveillance strategy with 6-monthly cross-sectional imaging. This updated N-classification has not been explored in a real-life cohort of patients with SB-NETs.

Aims & Methods: Aim to describe the prevalence of N1 and N2 LMN in a cohort of patients with SB-NETs and to explore its association with recurrence-free survival (RFS) and overall survival (OS).

A retrospective study was performed in a single NET expert centre King's College Hospital. All patients with curative resection of an SB-NET in the absence of metastases between January 2010 and December 2022 and a histology report available were included. All histology reports were reviewed and reclassified according to the new AJCC N-classification. Additional demographic data were collected from patient records. Recurrence-free survival was calculated from the date of the histology report to the date of documentation of disease recurrence in the multidisciplinary tumour board. Overall survival was calculated from the date of the histology report until the date of death due to any cause. Kaplan-Meier curves were plotted, log-rank test and uni- and multivariate Cox regression analysis were performed.

Results: A total of 112 patients, 52% male with a median age 63.5 years (IQR 55 – 72 year) were included. Sixty-seven patients (60%) had N1 disease and 45 patients (40%) had N2 disease. Within the N2 group, 35 patients (79%) had a large mesenteric mass, 7 patients (17%) had ≥ 12 positive LMN and 2 patients met both criteria (4%). The median mesenteric mass size in the N2 group was 30mm (IQR 25 – 40mm). Three quarters of patients had grade 1 disease and 27 patients (24%) had grade 2 disease. Recurrence occurred in 35 patients (31.5%), of which 18 (26.9%) belonged to the N1-group, while 17 (38.6%) were patients with N2. No significant difference (p-value 0.291) was found in the median time to recurrence, which was 83 months in N1-staged patients versus 61 months in N2-staged patients. There was no significant difference (p-value 0.155) in the median overall survival time between the N1-staged patients (134 months), compared to the N2-staged patients (106 months). Patients with a large mesenteric mass had a significantly (p-value 0.006) shorter overall survival of 102 months compared to the patients with a smaller or no mesenteric mass, median not reached. In multivariate analysis a larger mesenteric mass points towards an association with worse overall survival HR 3.71 (0.93 – 14.83), p-value 0.06.

Conclusion: For patients with small bowel NETs, N1 or N2 lymph node metastases do not affect recurrence-free survival or overall survival. However, a larger mesenteric mass is associated with a significantly shorter overall survival. These data could help develop more patient-tailored surveillance strategies, especially for patients with a larger mesenteric mass who could benefit from more frequent surveillance. Future research in a prospective, multi-center setting could help to clarify better the role of N1 and N2 LNM on recurrence-free and overall survival.

Introduction: The molecular and clinicopathological features of primary small bowel adenocarcinoma (SBA) are not as fully understood as are those of colorectal cancer and gastric cancer because SBA is relatively rare. According to the stem cell hypothesis, only a very small number of cancer cells in a tumor have the ability to promote its growth and development. CD44 and CD44 variant isoforms are known as stem cell markers of colorectal cancer. CD44 upregulation has been shown associated with cancer progression, invasion, and metastasis. In addition, CD44 plays an important role in epithelial-mesenchymal transition. However, the clinicopathological significance of CD44 and CD44 isoforms expression in SBA remains unclear.

Aims & Methods: To explore the localisation and clinicopathological significance of CD44 and CD44 variant isoforms in SBA.

We performed immunohistochemical analysis of CD44, CD44v, CD44v9, β -catenin and E-cadherin using formalin-fixed paraffin-embedded tissue specimens obtained from 50 cases of SBA. For E-cadherin and β -catenin, cases showing membranous staining equivalent to that of normal small intestinal epithelial cells in $> 75\%$ of cancer cells were considered preserved expression and otherwise considered reduced expression. A comparative investigation was then performed with the clinicopathological data of patients (sex, age, localisation, histological type, depth of invasion, lymph node metastasis, distal metastasis and clinical stage) and cancer-specific survival. The average age of the patients was 64 years old (median 68; range, 32–84 years old). Correlation between the positive rate for each protein and prognosis was determined by the Kaplan-Meier method and multivariate analysis using the Cox regression.

Results: The average observation period was 53 months (median, 48; range, 4–110 months), and 18 patients died during the analysis. The primary localisation of the tumor was the duodenum (n=20), jejunum (n=25), and ileum (n=5). Forty-one cases were well differentiated; 5, poorly differentiated; and 4, mucinous adenocarcinoma. In terms of TNM classification, 14 cases were stage I; 13, stage II; 10, stage III; and 13, stage IV. The positive rates for each protein were CD44, 54%; CD44v6, 50%; and CD44v9, 52%. CD44 and CD44 isoforms were significantly associated with lymph node metastasis and distal metastasis. There was a mutual interrelationship between CD44, CD44v6 and CD44v9 expression. CD44 and CD44v6 immunostaining significantly correlated with abnormal reduced membranous β -catenin staining. CD44 and CD44v9 immunostaining significantly correlated with reduced membranous E-cadherin staining. Factors showing a significant correlation with cancer-specific survival in univariate analysis included lymph node metastasis, distant metastasis, CD44, CD44v6, and CD44v9. In multivariate analysis performed by introducing lymph node metastasis and CD44, CD44v6, and CD44v9 expression in the Cox proportional hazards model, both lymph node status (hazard ratio: 18.5) and CD44 expression (hazard ratio: 7.5) retained independent prognostic significance.

Conclusion: These results suggest that CD44 and CD44 variant isoforms expression are associated with epithelial-mesenchymal transition and could be prognostic factors independent of lymph node metastasis in SBA.

Disclosure: Nothing to disclose.

Introduction: A recent prospective, multicenter pilot study demonstrated that a radical endoscopic resection (ER) of a high-risk T1 esophageal adenocarcinoma (EAC) followed by sentinel node navigated surgery (SNNS) might be feasible without impairment of the esophageal and gastric function at three months.¹ In the current study, we present the follow-up data of this new, esophageal preserving treatment strategy.

Aims & Methods: Ten patients underwent SNNS in two tertiary hospitals after radical ER of a high-risk T1 EAC (i.e. deep submucosal invasion [$\geq 500\mu\text{m}$], poor differentiation, and/or lymphovascular invasion) without the clinical presence of lymph node or distant metastases at baseline (i.e. cN0M0). SNNS consisted of endoscopic injection of a hybrid tracer around the ER scar followed by preoperative imaging the day before surgery. The next day, sentinel nodes were identified and subsequently resected during thoracoscopy and laparoscopy.

Follow-up after SNNS involved three-monthly upper endoscopy supplemented with endoscopic ultrasound (EUS) during 24 months. During each procedure, the esophagus was assessed for new visible lesions, while any suspicious lymph nodes were evaluated with fine-needle aspiration (FNA). Additional ablation therapy for any residual Barrett esophagus (BE) could be initiated at the discretion of the treating endoscopist.

Complementary to strict endoscopic surveillance, radiological follow-up (i.e. CT thorax/abdomen or PET/CT) was performed at 12 months after the initial ER to evaluate for distant metastases. Endpoints were the incidence of new visible lesions, metastases, mortality, and gastroesophageal functional disorders during follow-up.

Results: A median of 3 (range 1-6) sentinel nodes were identified and resected in the included patients (10 male, median age 69). Two patients (20%) were found to have a metastasis in one of the resected sentinel nodes. Since none of these patients had signs of residual disease upon restaging directly after SNNS, both patients were kept under endoscopic and radiologic follow-up after discussion in a multidisciplinary meeting, considering patient's older age (n=1) and patient's preference (n=1). After median 23 (range 12-28) months of follow-up, none of the 10 patients (0%) were diagnosed with lymph node or distant metastases related to esophageal cancer.

One patient (10%) however died as a result of a second primary tumor with distant metastases at 12 months after SNNS. In two patients (20%), FNA (median 2 [range 1-2] sessions) was performed during EUS to assess suspicious lymph nodes, without signs of esophageal malignancy. Three patients (30%) developed a new visible lesion in median C1M4 (range C0-9M1-11) residual BE, which were all amenable for ER with histopathology

revealing low-grade dysplasia (n=1), high-grade dysplasia (n=1) and moderately differentiated T1m2 EAC with no lymphovascular invasion (n=1). None of the patients (0%) developed functional gastroesophageal disorders during follow-up.

Four patients (40%) underwent additional radiofrequency ablation (median 3 [range 2-4] sessions) of whom two patients had a new visible lesion prior to the initiation of ablation therapy.

Conclusion: Based on these long-term results demonstrating a low risk of metastasized disease, SNNS appears to be a feasible and safe instrument to tailor the extent of lymphadenectomy in patients with high-risk T1 EAC who underwent a prior radical ER. The exact position of this new strategy in the treatment algorithm for high-risk T1 esophageal cancer needs to be studied in future research.

CLINICOPATHOLOGICAL SIGNIFICANCE OF WNT/B-CATENIN SIGNALING PATHWAY-RELATED GENES AND PROTEINS IN SPORADIC SMALL BOWEL ADENOCARCINOMA

R. Inoue¹, A. Tatsuguchi¹, T. Yamada², Y. Shimazu¹, H. Machida¹, R. Hamakubo¹, A. Hoshimoto¹, T. Nishimoto¹, J. Omori¹, N. Akimoto¹, S. Tanaka¹, S. Fujimori¹, K. Iwakiri¹

Introduction: Background: Small bowel cancers are rare, accounting for less than 5% of gastrointestinal cancers, but their incidence is increasing. Small bowel adenocarcinoma (SBA) accounts for one-third of small bowel cancers, and due to its rarity, scarce data exist on its molecular and clinicopathological features. The genomic profiling of SBA has been shown to be distinct from colorectal cancer and gastric cancer through comprehensive analysis of genomic alterations. The low incidence of APC mutations in SBA suggests that the adenoma-carcinoma sequence is not the main carcinogenic mechanism.

However, the extent to which the Wnt β -catenin signaling pathway, which is important in the adenoma-carcinoma sequence, is involved in the process of carcinogenesis in SBA remains controversial.

Aims & Methods: Aims: We examined the clinicopathological significance of gene mutations involved in the Wnt/ β -catenin pathway and their downstream target gene products in SBA.

Methods: Immunostaining for β -catenin, Cyclin D1, c-Myc, E-cadherin and p53 was performed in 69 surgical resections from patients with primary SBA. Genomic alterations were analyzed by targeted next-generation sequencing in 32 cases out of the 69 cases. For cyclin D1 and c-Myc, cases showing nuclear staining in $\geq 10\%$ of cancer cells were considered positive. For E-cadherin and β catenin, cases showing membranous staining equivalent to that of normal small intestinal epithelial cells in $> 75\%$ of cancer cells were considered preserved expression and otherwise considered reduced expression.

Results: Results: Patients included 49 men and 20 women, ranging in age from 32 to 84 years (mean 65 years; median 68 years). At the time of analysis, 21 patients had died. The overall 5-year survival rate was 64%. The median follow-up duration for the entire series was 36 months (mean 51.4 months; range, 5-124 months). The primary localisation of the tumor was the duodenum (n=36), jejunum (n=28), and ileum (n=5). Fifty-five cases were well differentiated; 9, poorly differentiated; and 5, mucinous adenocarcinoma. In terms of TNM classification, 25 cases were stage I; 16, stage II; 12 stage III; and 16, stage IV. Reduced membranous β -catenin staining pattern, which correspond to an activation of the Wnt/ β -catenin pathway in cancer cells was observed in 39% of the cases. Cyclin D1 and c-Myc was positive in cancer cells in 58% and 30% of cases, respectively. A significant positive relationship was observed between aberrant β -catenin and cyclin D1. The Wnt pathway-associated gene mutations in SBA were APC in 18.8% and CTNNB1 in 12.5% of the cases, and no cases exhibited both of them. Concurrent reduced β -catenin immunostaining was observed in 4/4 CTNNB1 and 2/6 APC mutation cases, respectively. Reduced β -catenin immunostaining correlated significantly with lymph node metastasis and distant metastasis, and thereby advanced TNM stage. Furthermore, a combined reduced E-cadherin and β -catenin expression was associated with worse prognosis, independent of lymph node metastasis by Cox regression multivariate analysis.

Conclusion: Conclusion: Wnt-related genomic alterations including APC and CTNNB1 were only found in a third of cases examined. The above results suggest that the Wnt/ β -catenin pathway is involved in carcinogenesis and cancer progression in SBA, although to a lesser extent than in colorectal cancer.

Disclosure: Nothing to disclose.

Introduction: Potential Coeliac Disease (PCD) is defined by the presence of positive CD serology, anti-endomysial antibodies (EmA) and anti-tissue transglutaminase (anti-tTG), positive genetic predisposition (HLA-DQ2/DQ8), and absence of atrophy (Marsh ≥ 3) at duodenal histology in patients on a gluten containing diet (GCD).

Currently, there is no established consensus on the management of patients with PCD, particularly regarding treatment and follow-up. Literature on PCD remains limited, especially in adults, including mostly retrospective studies with small cohorts and short follow-up often without a second endoscopic sampling.

Aims & Methods: The aim of our study is to describe the presentation and outcome, including the rate of progression to biopsy-proven CD, in a cohort of adult PCD patients.

This is a retrospective single-center study including all adult PCD patients (>16 years old) referred to our Celiac Disease Clinic between January 2006 and March 2024. All patients with positive anti-tTG and at least one esophagogastroduodenoscopy (EGD) with duodenal biopsy were included. Presenting manifestations, serology and HLA-DQ genotyping, endoscopy and histology as well as outcome were recorded.

Results: A total of 34 PCD patients (mean age at presentation 33.1 $\pm$ 14.3 years, 75% female) were included in the study. The median follow-up time from first presentation (T0) was 4 years (IQR 1-6).

Out of the 34 patients, 24 were tested for CD due to the presence of symptoms (most frequently abdominal pain, dyspepsia and diarrhea), while the rest were tested in the context of CD screening for positive family history. At T0, the median anti-tTG IgA titre was 2.5 times higher than the upper limit of normal (ULN) and EMA were positive in 27 out of 34 patients. All patients had Marsh 0-1 at duodenal histology performed within 12 months from the first positive tTG-test. The majority of patients (75%, 24/34) had at least a second EGD with duodenal biopsies. At follow-up, 8 (24%) patients were diagnosed with CD confirmed histologically (Marsh ≥ 3); CD diagnosis occurred after 2.95 $\pm$ 2.84 years from T0. In the remaining PCD patients, 20 patients (59%) kept following a GCD while continuing clinical and endoscopic follow-up. Specifically, 60% of them (followed for 3.79 $\pm$ 2.71 years), had at least another follow-up duodenal biopsy still confirming absence of atrophy with either spontaneous resolution or reduction of presenting symptoms while on a GCD. Conversely, 6 patients decided to start a gluten-free diet (GFD), despite the absence of villous atrophy at duodenal biopsies which was confirmed on a second duodenal histology in 4 out of 6 of them. In these patients, the GFD led to symptoms improvement in 83% of patients.

Conclusion: In our cohort, 24% of PCD patients develop celiac disease within almost 3 years (2.95 $\pm$ 2.84 years) from the first presentation. Most patients (59%) upon PCD diagnosis preferred staying on a GCD while being regularly followed with serology and endoscopy. Among those who

decided to start a GFD despite CD not being histologically confirmed, symptoms improvement occurred in 83% (5/6), confirming that a trial of GFD in symptomatic patients could be proposed.

Introduction: Among patients with celiac disease (CeD), following a gluten-free diet after diagnosis is expected to reduce symptom burden. Using a large US claims database, we compared symptoms in individuals with CeD pre- and post-diagnosis with those in matched individuals without CeD to evaluate the burden of CeD.

Aims & Methods: This case-control study was conducted among individuals of all ages enrolled in MarketScan from 2002 to 2023. CeD diagnosis (index date) was defined as ≥ 1 inpatient or ≥ 2 outpatient International Classification of Diseases (ICD)-9/-10 diagnostic codes; controls were matched (1:5 ratio) for age, sex, region, and diagnosis year. All individuals had continuous medical and pharmacy enrolment for 2 years pre- and post-index. Core CeD symptoms (abdominal pain, diarrhoea, joint pain, bloating, fatigue, and nausea) were defined as ≥ 1 inpatient or ≥ 2 outpatient ICD-9/-10 codes during each 2-year period. Unadjusted odds ratios (ORs) and 95% confidence intervals (95% CIs) were estimated by logistic regression comparing CeD cases versus controls.

Results: During the 21 years of data coverage, we identified 39 814 patients with CeD and 198 961 matched individuals without CeD with similar age and sex distribution (mean age 41.6 years [standard deviation 20.1]; 70.5% female). The burden of CeD symptoms pre-diagnosis was significantly higher among patients with CeD versus controls, particularly for diarrhoea, bloating, and abdominal pain. The pre-diagnosis OR (95% CI) for abdominal pain was 5.37 (5.22, 5.52), joint pain 1.87 (1.81, 1.93), diarrhoea 11.64 (11.10, 12.20), bloating 8.64 (7.86, 9.51), fatigue 3.63 (3.48, 3.79), and nausea 5.78 (5.36, 6.24). As expected, symptom burden decreased post-diagnosis, however all symptoms (except joint pain) had an approximately twofold greater burden compared with controls, 2 years post-diagnosis: OR (95% CI) abdominal pain 2.43 (2.57, 2.30), joint pain 1.61 (1.51, 1.71), diarrhoea 2.47 (2.21, 2.76), bloating 2.47 (1.86, 3.27), fatigue 2.17 (1.98, 2.38), and nausea 2.24 (1.83, 2.74). When we evaluated symptoms only among individuals with CeD, on average symptom persistence 2 years after diagnosis occurred in 29.7% of patients while an average of 6.3% had new-onset symptoms (most commonly abdominal pain; 17.0%).

Conclusion: Claims databases were able to capture CeD symptom burden and demonstrated that patients with CeD continue to experience symptoms (including new-onset) post-diagnosis. Although a gluten-free diet might control some symptoms, there is still considerable remaining burden and some unresolved symptoms (e.g. joint pain and fatigue) or new-onset symptoms.

Introduction: Accurate and timely identification and treatment of celiac disease (CeD) by clinicians is increasingly recognized to be an important issue. This study aimed to identify educational needs of healthcare providers (HCPs) in diagnosing and managing CeD by surveying HCPs across Europe (EU) and the United States (US).

Aims & Methods: A survey focused on practices, knowledge, experience, and attitudes towards CeD was conducted among gastroenterology (GI) physicians (EU and US), nurse practitioners (NPs), and physician associates (PAs); primary care physicians (PCPs), NPs, and PAs; and dietitians (US only) who see patients with CeD. The survey used a simulated patient case for decision-making context and was distributed from August to September 2023.

Results: Respondents included 378 HCPs (75 EU, 303 US); most were physicians in group practices, with significant representation from community settings. After reviewing the case, most GIs (76%-88%) included CeD in their top 3 differential diagnosis versus 65% of PCPs. 83% of PCPs recommended starting a gluten-free diet (GFD) before endoscopy vs 36%-37% for GIs. Most dietitians were comfortable providing dietary guidance for CeD but the majority would also recommend initiation of a GFD prior to endoscopy. 87%-93% of GIs would order an endoscopy to confirm diagnosis, but many are not obtaining a guideline-recommended number of biopsies, particularly from the distal duodenum.

Conclusion: This study highlights a significant need for targeted interventions to enhance the identification and evidence-based diagnosis of CeD across various healthcare specialties. In particular, the practice of initiating a GFD prior to diagnosis should be addressed.

Disclosure: NC, SC, AS, MA and DL are employees and shareholders of Takeda.

Contact E-Mail Address: jostein.ibsen@gmail.com

Introduction: Diagnosis of coeliac disease (CeD) rests on clinical signs, serology (IgA against transglutaminase 2 (IgA-TG2), alternatively IgG to deamidated gliadin peptides (IgG-DGP)) and mucosal damage in duodenal biopsies [1, 2]. Mucosal pathology is often classified according to the modified Marsh criteria [3].

A gluten free diet leads to clinical, serological and mucosal improvement and rapid immunological improvement as well as mucosal healing after 1 year after rigid follow-up [4].

However, we previously reported that only ½ of treated patients in a community-based setting reached mucosal healing one year after diagnosis [5]. We here report recent results.

Aims & Methods: Patients with suspected CeD were referred from general practice to secondary care endoscopy service at Oslo University Hospital; no tertiary referral patients are reported here. All patients gave written, informed consent. Serology was repeated at the day of endoscopy. Diagnosis of CeD was given for patients with combination of positive serology and definite mucosal damage (Marsh 3a-c). Exceptions to this was agreed in selected cases after careful clinical evaluation. All participants who received the CeD diagnosis were referred to one individual consultation with a clinical dietician and to a follow-up endoscopy after 12 months. Patients with CeD in Norway receives a monthly reimbursement of approximately EUR 66 pr month to cover their additional costs for a gluten-free diet.

Results: In total 138 of the 214 eligible participants were diagnosed with CeD between 2018 and 2021. Among these, 6 patients had negative (<4 U/L) IgA-TG2, 29 a negative (<20 U/L) IgG-DGP and only 2 were seronegative for both markers. Correlation between levels of IgA-TG2 and IgG-DGP were calculated with Pearson (assuming normal distribution) showing a correlation coefficient (r) = 0.4893, p -verdi = 0.0000112, i.e. a significant moderate positive correlation. Spearman's rank correlation coefficient (r_s) = 0.52095, p -verdi = 0.00002301 showed significant strong positive correlation (assuming not normal distribution). Within the CeD group, 63 were diagnosed with a Marsh 3C, 44 with Marsh 3B, 22 with Marsh 3A, and 9 with Marsh 1 or 2. One hundred and four patients came to the 1-year control. Eighty had achieved mucosal healing (Marsh 0 or 1), while 19 showed improvement but still showed mucosal damage (Marsh 3). Nine of the patients who did not achieve mucosal healing were followed up for an additional year where 6 achieved recovery. Thus, only 3 could be classified as non-responsive CeD. No data are available for those who did not return to repeated endoscopy.

Conclusion: Simultaneous testing of both IgA-TG2 and IgG-DGP renders very few patients truly seronegative, as only 2 of 139 new CeD patients were negative for both. Wide ranges were seen for both IgA-TG2 and IgG-DGP. We now investigate factors in serum leading to predominant IgA-TG2 vs IgG-DGP responses using multi-plex inflammation panel analysis. One year after the diagnosis, and with the mentioned follow-up system, the prognosis for mucosal healing is achieved in 77% of patients and better than often anticipated.

Introduction: Several studies have proposed a non-biopsy serological diagnosis of celiac disease (CeD) based on the sequential detection of anti-tissue transglutaminase (tTG) IgA and follow-up with anti-endomysial IgA as a confirmatory test or, more recently, using one test, the tTG IgA at cut-off values ≥ 10 UNL in both children and adults.

However, while the non-biopsy strategy was well received by pediatricians, gastroenterologists still raise concerns about adopting such a strategy for diagnosing CeD in adults, especially in a non-expert setting.

Aims & Methods: The study aimed to assess the performance and clinical utility of the concurrent detection of two autoantibodies targeting two independent antigens, tTG and deamidated gliadin peptides (DGP), as an effective alternative approach for a non-biopsy diagnosis of CeD in adults with high pre-test probability.

This prospective, multicenter, binational study collected consecutive patients with a high pre-test probability for CeD. Between 2018 and 2020, adults were enrolled at four Italian and one Argentinian centers. Patients underwent evaluation for serology and duodenal biopsy at local centers. Serology was also blindly analyzed by a central laboratory (Werfen, San

Diego, USA) for tTG IgA and DGP IgG by Aptiva Particle Multi-Analyte Technology (PMAT) assays. CeD diagnosis required histological confirmation of Marsh 3 damage.

Results: 181 adult patients with suspected CeD were enrolled (134 with histological diagnosis of CeD and 47 not histologically confirmed as CeD). The sensitivities of tTG IgA and DGP IgG were 98.5 and 93.3%, respectively. Patients positive for both tTG IgA and DGP IgG (double positive) were predictive of CeD in 92.5% of patients at >1x upper limit of normal (ULN). Double positivity for tTG IgA and DGP IgG, both at >10x ULN, had a 100% positive predictive value for the presence of Marsh 3 histology.

Conclusion: The presence of both tTG IgA and DGP IgG at concentrations >10x ULN was 100% predictive of CeD. Incorporating DGP IgG alongside tTG IgA in a single-step approach can be considered a valid confirmatory strategy for definitive non-biopsy diagnosis of CeD, particularly for patients with high pretest probability, even in non-expert settings.

PERSISTENT VILLOUS ATROPHY IN CELIAC DISEASE: RISK STRATIFICATION AND LONG-TERM OUTCOMES

R. Saidani¹, H. Dabbebi², D. Cherif², H. Yacoub², H. Hassine², H. Kchir², N. Maamouri²

¹La Rabta Hospital, Tunis, Tunisia, ²La Rabta Hospital, Gastroenterology B, Tunis, Tunisia

Contact E-Mail Address: raouia.saidani@etudiant-fmt.utm.tn

Introduction: Celiac disease (CD) is an autoimmune disorder triggered by gluten ingestion, leading to intestinal villous atrophy. While a gluten-free diet (GFD) is the mainstay of treatment, some patients exhibit persistent villous atrophy (pVA) on follow-up biopsies.

This raises concerns about the long-term health consequences of pVA in CD patients adhering to GFD.

Aims & Methods: Objectives: To evaluate the association between pVA and long-term outcomes in CD patients.

To assess the performance of a scoring system identifying patients at high risk of pVA.

Methods: We conducted a retrospective analysis including all the patients diagnosed with CD between 2014 and 2020, who underwent follow-up duodenal biopsies. Patients were categorized as having pVA or not based on the Marsh classification ($\geq 3a$).

We considered as complications of CD malignant and premalignant conditions arising in the abdomen, including refractory CD, ulcerative jejuno-ileitis, abdominal lymphomas and small bowel carcinomas.

In particular, persistence of malabsorption symptoms and VA despite a strict GFD for at least 12 months in the absence of lymphoma, malignancies and non-coeliac enteropathies allowed the diagnosis of refractory CD (RCD).

Additionally, we applied the 5-point scoring system to predict pVA risk, incorporating the following factors:

- Age at diagnosis ≥ 45 years
- Classical pattern of celiac disease (CCD)
- Lack of clinical response to GFD
- Poor GFD adherence

Each of the first three factors was assigned a point score and the fourth item was assigned two points score, with higher scores indicating a greater risk of pVA.

Results: We collected 151 patients with CD. Approximately 24.5% of patients had pVA. Patients with pVA exhibited a significantly higher risk of complications (HR 7.61, 95% CI 3.18 to 17.64, $p < 0.001$). Overall, during follow-up, 9 patients (5.96%) developed a complication (three refractory CD, one B-cell lymphoma, three persistence of malabsorption symptoms and two ulcerative jejuno-ileitis). Over these 9, 7 patients had a pVA.

While most patients adhered to GFD, 35.1% still had persistent VA at follow-up.

Up to 29.72% of patients with persistent villous atrophy do not have ongoing symptoms.

The 5-point scoring system stratified patients by risk of pVA into

- Low risk (0-1 points): 4.1% pVA prevalence (3 patients out of 73).
- Intermediate risk (2 points): 20% pVA prevalence (9 patients out of 45).
- High risk (3-5 points): 75.75% pVA prevalence (25 patients out of 33).

Conclusion: This study demonstrates that persistent villous atrophy in CD patients following GFD is associated with increased risk of complications. It also shows the effectiveness of the 5-point scoring system, in stratifying CD patients by risk of pVA. The system accurately identified high-risk patients with a significantly higher prevalence of pVA. It can also help identify these individuals who, despite a lack of current symptoms, may still be at higher risk for future complications so it can be used in clinical practice to personalized follow-up modalities.

Introduction: Little is known about the association of (CeD) with chronic liver diseases (CLD) and major adverse liver outcomes (MALO).

Aims & Methods: To investigate the long-term risk of CLD in patients with CeD. In a Swedish nationwide histopathology cohort, patients with biopsy-confirmed CeD were identified between 1969 and 2017 (n=48,033). Each patient was matched with up to five general population reference individuals (n=231,940) by sex, birth year, calendar year, and county of residence and followed-up until 31 December 2021. We used Cox proportional hazard regression to estimate the adjusted hazard ratio (aHR) of incident overall and specific CLD (i.e., viral hepatitis, metabolic

dysfunction-associated steatotic liver disease [MASLD], alcohol-related liver disease [ALD], and autoimmune liver disease) and major adverse liver outcomes (composite endpoint for compensated or decompensated cirrhosis, hepatocellular carcinoma, liver transplant, and liver-related death), along with 95% confidence intervals (CIs). Outcomes were identified from the National Patient Register using relevant ICD-codes. Familial risk factors were additionally accounted for by comparison with CeD-free full siblings (n=53,003).

Results: During a median follow-up of 16.0 years, there were 646 incident CLD in patients with CeD and 1,567 in reference individuals (incidence rate [IR]: 79.1 vs. 39.4 per 100,000 person-years). Compared with reference individuals, patients with CeD had higher hazards of overall CLD (aHR=1.84, 95%CI=1.67 to 2.02). The hazards of overall CLD remained significantly increased ≥ 15 years after CeD diagnosis, leading to one extra CLD case per 214 patients with CeD until then. The hazards elevation was primarily driven by MASLD (aHR=2.35 [1.90 to 2.91]), ALD (aHR=1.35 [1.08 to 1.68]), and autoimmune liver disease (aHR=4.36 [3.67 to 5.18]), but not by viral hepatitis (Table 1). There were 646 incident MALO cases in patients with CeD and 1567 in reference individuals over the follow-up period. Both absolute and relative risks of MALO were higher in patients with CeD than reference individuals (IR: 65.6 vs. 41.6; aHR=1.44 [1.31 to 1.59]). Our main findings were confirmed in the sibling comparison (aHR=1.81 [1.57 to 2.09] for overall CLD and 1.33 [1.14 to 1.56] for MALO) and were robust in sensitivity analyses.

	Including first three years of follow-up			Excluding first three years of follow-up		
	No. of events (IR, per 100,000 person-years)		HR (95%CI) *	No. of events (IR, per 100,000 person-years)		HR (95%CI) *
	Patients	References		Patients	References	
Any CLD	646 (79.1)	1567 (39.4)	1.84 (1.67 to 2.02)	505 (62.0)	1365 (34.4)	1.65 (1.49 to 1.83)
Viral hepatitis	134 (16.3)	731 (18.3)	0.88 (0.73 to 1.07)	103 (12.6)	606 (15.2)	0.81 (0.66 to 1.00)
MASLD	142 (17.7)	262 (6.7)	2.35 (1.90 to 2.91)	113 (14.2)	239 (6.1)	2.05 (1.63 to 2.59)
ALD	109 (13.3)	364 (9.1)	1.35 (1.08 to 1.68)	88 (10.7)	332 (8.3)	1.21 (0.95 to 1.54)
Autoimmune liver disease	291 (35.5)	266 (6.7)	4.36 (3.67 to 5.18)	221 (27.0)	234 (5.9)	3.75 (3.10 to 4.54)
MALO	538 (65.6)	1660 (41.6)	1.44 (1.31 to 1.59)	426 (52.0)	1472 (37.0)	1.29 (1.15 to 1.44)

ALD: alcohol-related liver disease; CeD: celiac disease; CI: confidence interval; CLD: chronic liver disease; HR: hazard ratio; IR: incidence rate; MALO: major adverse liver outcomes; MASLD: metabolic dysfunction-associated steatotic liver disease;

* Conditioned on matching variables (birth year, sex, county of residence, and calendar year) and further adjusted for country of birth, educational attainment, number of healthcare visits before the index date, and history of autoimmune diseases.

Table 1 Incident CLD and MALO in patients with CeD and their matched reference individuals, including or excluding the first three years of follow-up.

Conclusion: Patients with CeD had higher hazards of overall CLD and MALO for more than 15 years after diagnosis. However, absolute risks were low. The increased hazards of CLD were driven by MASLD, ALD, and autoimmune liver disease. Our findings support diagnostic work-up and regular follow-up for possible CLDs in patients with CeD who had elevated liver enzymes.

Introduction: According to literature data, the occurrence of hepatic steatosis is more common in patients with celiac disease than in the general population. The reasons behind this include malabsorption, proinflammatory processes, as well as weight gain and unfavorable metabolic changes on a gluten-free diet.

Aims & Methods: In our prospective multicenter, case-control study (ARCTIC study), we examined the occurrence of hepatic steatosis determined by ultrasound (US), body composition parameters, and blood lipid levels in patients with celiac disease who had been on a gluten-free diet for at least 1 year. We investigated the proportion of celiac patients with and without steatosis, and compared the data of celiac patients with and without steatosis.

Patients from three university centers with celiac disease participated in the study. Body composition analysis was performed using an Inbody 770 device, measuring parameters such as BMI, waist-hip ratio, Inbody score, Skeletal muscle mass (SMM), Percent body fat (PBF), and Visceral fat area (VFA). Blood lipids including total cholesterol, LDL, and triglyceride levels were measured. Hepatic steatosis was assessed by US using the Hamaguchi score and the NAFLD-LFS score. If either score was positive, the patient was classified into the steatosis group. Fischer's exact test was used for categorical variables, and Welch Two Sample t-test was used to assess continuous variables. A p-value less than 0.05 was considered statistically significant.

Results: 97 patients with celiac disease and 47 control individuals were included. Hepatic steatosis was described in 13.8% of control subjects and 35% of celiac patients (p=0.012). In celiac patients, steatosis developed in 31% with normal BMI. The occurrence of hepatic steatosis in celiac patients showed a significant association with BMI (p<0.001), waist circumference (p<0.001), hip circumference (p<0.001), percent body fat (p=0.037), visceral fat area (p=0.006), and triglyceride levels (p=0.006). However, there was no significant difference in waist/hip ratio (p=0.56), Skeletal Muscle Mass (p=0.164), Inbody score (p=0.31), LDL (p=0.80), and total cholesterol level (p=0.73). The adherence to a gluten-free diet did not influence hepatic steatosis (p=0.60). Among celiac disease patients with hepatic steatosis, 83% met the Metabolic Dysfunction-Associated Liver Disease (MASLD) criteria.

Conclusion: The occurrence of hepatic steatosis is substantial in celiac patients on a gluten-free diet, even in those with normal BMI. Increased attention should be paid to its examination and monitoring during care, weight control, dietary and lifestyle counseling, as well as timely recogni-

tion and prevention of cardiovascular and metabolic diseases.

Contact E-Mail Address: sonal.ghura@takeda.com

Introduction: There is a need to reliably measure celiac disease (CeD) symptom severity in clinical trials. The Celiac Disease Symptom Diary 2.1[®] (CDSD 2.1[®]) is a daily diary that assesses five core symptoms of CeD (abdominal pain, bloating, diarrhoea, nausea and tiredness) and was developed following FDA guidelines for fit-for-purpose patient-reported outcome measures (PROMs). The objective of this study was to psychometrically validate the CDSD 2.1[®].

Aims & Methods: Psychometric properties of the CDSD 2.1[®] were evaluated using data from a 12-week US observational study (NCT05309330) in patients with CeD maintaining a gluten-free diet. Participants completed the CDSD 2.1[®] daily and other symptom severity PROMs at specified timepoints to evaluate validity, reliability and responsiveness. The average CDSD 2.1[®] weekly severity scores did not include tiredness in order to focus on GI-related symptoms.

Results: Overall, 480 participants (338 adults, 142 adolescents) completed the study. Weekly average gastrointestinal (GI; abdominal pain, bloating, nausea, diarrhoea) CDSD 2.1[®] scores demonstrated high internal consistency reliability (Cronbach's alpha, Week 0 = 0.77). Convergent validity was confirmed by moderate-to-strong correlations between weekly average GI CDSD 2.1[®] scores and Gastrointestinal Symptom Rating Scale

(GSRS) domains at Week 0 and Celiac Symptom Index (CSI) scores at Week 3 ($r = 0.48-0.73$; $p \leq 0.05$). Known-groups validity was supported with significant differences in weekly average GI CDSD 2.1[®] scores observed by Patient Global Impression of Severity (PGIS) groups ($p < 0.001$). Test-retest reliability of GI CDSD 2.1[®] scores was demonstrated among stable patients on the PGIS (intraclass correlation coefficient = 0.89). Responsiveness was established as weekly average GI CDSD 2.1[®] change scores followed the expected pattern among PGIS change groups.

Conclusion: This study demonstrates that CDSD 2.1[®] is a valid, reliable and responsive PROM of CeD GI symptom severity that could be used to construct endpoints in clinical trials for CeD therapies.

Introduction: Irritable bowel syndrome (IBS) is a disorder of brain-gut interaction often accompanied by psychiatric and/or somatic comorbidities. Intestinal barrier dysfunction has long been hypothesised to be a key player in IBS pathophysiology. However, it is unknown how psychiatric and somatic comorbidities affect intestinal barrier dysfunction. This study aims to assess intestinal barrier function in a large multicentric cohort of adult IBS patients with and without psychiatric/somatic comorbidities.

Aims & Methods: IBS patients (Rome IV) with (N=197) and without (N=171) comorbidities, and healthy volunteers (N=23), were included in six European hospitals. Intestinal permeability (IP) was assessed *in vivo* with the lactulose-mannitol-sucralose test (LMS) and *ex vivo* in colonic biopsies using Ussing chambers. Sugar concentrations in the urine were assessed through HPLC-ELSD and GC-MS. The L/M ratio after 2 hours was used as an estimation of the small intestinal permeability, and the %S excreted and the S/M ratio from 2 to 24 hours, for colonic permeability. Colonic biopsies were collected from 17 controls and 18 IBS patients and mounted in Ussing chambers to measure the paracellular permeability to FITC-dextran (4 kDa).

Results: When compared with healthy controls, L/M ratio did not differ in IBS patients with (p=0.33) or without comorbidities (p=0.44). Moreover, the %S excreted and S/M were not altered in IBS patients with (respectively p=0.3 and p=0.09) and without (p=0.14, p=0.1) comorbidities. Interestingly, when comparing results from IBS patients among recruiting hospitals in different parts of Europe, significant differences were found in L/M ratio (p<0.0001), %S (p<0.0001), and S/M ratio (p<0.0001). Lastly, paracellular permeability assessed *ex vivo* in colonic biopsies was not different between IBS patients and controls (p=0.46).

Conclusion: These results suggest that psychiatric and somatic comorbidities do not alter small intestinal and colonic permeability in IBS patients. Interestingly, our results highlight a strong variability between IBS patients from different countries, which may be explained by lifestyle, environmental, and genetic factors. Further investigations are needed to better understand these findings.

CLINICAL CHARACTERISTICS OF PATIENTS WITH DYSSYNERGIC DEFECATION AND THE VALUE OF CURRENT HIGH-RESOLUTION MANOMETRY PARAMETERS IN ITS DIAGNOSIS

C. Rodríguez Carrillo¹, M. Aparicio Cabezudo², R. Sánchez del Hoyo³, C. Ciriza de Los Rios²

¹Hospital Clinico San Carlos, Gastroenterology and Hepathology, Madrid, Spain, ²Hospital Clinico San Carlos, Neurogastroenterology and Motility, Madrid, Spain, ³Hospital Clinico San Carlos, Research Methodological Support Unit and Preventive Department, Madrid, Spain

Contact E-Mail Address: clararc31@gmail.com

Introduction: Functional defecation disorders are causes of obstructive defecation due to alteration in the coordination of abdominal contraction and anal relaxation. Four manometric patterns of dyssynergic defecation (DD) have been described, such that in type I and III there is an alteration of anal relaxation with adequate rectal propulsion, and in types II and IV rectal propulsion fails.

According to the Rome IV criteria, the diagnosis of DD requires confirmation with two tests of anorectal function, with the most commonly used being high-resolution anorectal manometry (HRAM) and the balloon expulsion test (BET). Within the manometric parameters, the rectoanal gradient (RAG) appears to be the most useful.

Aims & Methods: To evaluate the clinical characteristics of patients according to patterns of DD defecation and to establish the cutoff point of the RAG and relaxation percentage (RP) that allows predicting balloon expulsion or not.

A total of 960 high-resolution anorectal manometries (HRAMs) performed from January 2021 to April 2024 were reviewed, including 337 patients with DD (35%). Prior to performing the HRAM, epidemiological and clinical data of the patients were collected. Although retrospectively reviewed, all data were prospectively collected. HRAM was performed with solid-state catheters (Medtronic). For BET a balloon (Matla Systems S.L) was filled with 50 mL of water was used under conditions of privacy while sitting on a toilet. Values of 60 seconds or less were considered normal.

Results: Included were 337 patients with a mean age of 61.7 ± 13.9 years. Among them, 226 (67.1%) were female. The diagnosis of DD was confirmed with an altered BET in 96 (28.5%) of the patients. In the remaining cases, the diagnosis of DD was inconclusive.

	Types I-III (N= 240)	Types II-IV (N=97)	P value
Confirmed DD (HRAM and abnormal BET)	58 (24,2%)	38 (39,2%)	0.006
Gender (female vs male)	148 (61,7%)	78 (80,4%)	0.001
Age (years)	63,85 ± 13,1	56,36 ± 14,6	0.000
BMI (kg/m ²)	26,42 ± 4,4	24,41 ± 4,7	0.000
Anal surgery	54 (22,6%)	11 (11,3%)	0.018
Comorbidities			0.006
No comorbidity	64 (26,7%)	24 (24,7%)	
Neurologic/Psychiatric	42 (17,5%)	32 (33%)	
Others	134 (55,8%)	41 (42,2%)	
Drugs			0.206
No drugs	35 (14,7%)	17 (17,5%)	
Inhibit motility (opioid, anticholinergic, psychotropic)	42 (25,8%)	24 (41,4%)	
Others	121 (74,2%)	34 (58,6%)	
Structural alterations (rectocele, cystocele, prolapse, etc)	102 (42,7%)	52 (53,6%)	0.068
Bristol			0.572
1, 2	61 (26,3%)	26 (27,7%)	
3, 4	103 (44,4%)	36 (38,3%)	
5, 6, 7	68 (29,3%)	32 (34%)	

Table 1.

The epidemiological and clinical characteristics are described in table 1. The presence of associated structural causes was observed in all groups: 102 cases (42.7%) in types I-III; and 52 patients (53.6%) in types II-IV. The frequency for rectal hyposensitivity was 47.5%, and it was similar in both groups: 112 cases (46,6%) in types I-III, and in 48 cases (49,5%) in types II-IV.

The Area Under the Curve (AUC) for RAG was 0.738 (95% CI 0.682 - 0.794), identifying a cut-off value for RAG of -34.1 with an estimated sensitivity of 81.3% and specificity of 57.3% (figure 1). The AUC for RP was 0.544 with a cutoff point of 5.5% (95% CI 0.476 - 0.611), demonstrating low sensitivity (62,5%) and specificity (52,7%) (figure 2).

Conclusion: The frequency of DD diagnosed by HRAM is high (35% in our series), being more common in women. The high coexistence of structural causes, which can give a false manometric pattern of DD, is noteworthy. In types II and IV (rectal propulsion disorders), the diagnosis was confirmed by the failure to expel the balloon more frequently than in types I and III. Rectal hyposensitivity is very frequent in these patients.

So far, the Rectoanal Gradient (RAG) is the best parameter of HRAM to evaluate DD. A value below -34 mmHg allows reasonably discriminating whether patients will expel the balloon or not.

HOME BIOFEEDBACK TRAINING WITH LOCAL SPHINCTER STIMULATION FOR FECAL INCONTINENCE: A FEASIBILITY STUDY

P. Liptak¹, M. Vojtko¹, J. Hoferica¹, M. Ďuriček¹, P. Banovcin¹

¹University Hospital in Martin, Clinic of Internal Medicine-Gastroenterology, Jessenius Faculty of Medicine in Martin, Comenius University, Martin, Slovakia

Contact E-Mail Address: liptak@jfm.uniba.sk

Introduction: Fecal incontinence is a diagnosis represented by recurrent uncontrolled passage of fecal material for at least 3 months. Although there are no sufficient data, based on large-community studies, FI is relatively common, with prevalence up to 7% of population worldwide. The therapy of fecal incontinence should be specifically tailored to each individual symptom presentation of the patients. One of the treatment options for incontinence is biofeedback training.

As office biofeedback is often time consuming and comes with substantially high cost there is an emerging trend of home biofeedback administration. However, only few studies considering this new approach were published so far and without consideration of commercially available biofeedback devices. Also, there are no relevant data published regarding the efficacy of commercially available devices.

Aims & Methods: The aim of this study is to evaluate the feasibility and efficacy of commercially available biofeedback devices. We performed a prospective single center study on patients with fecal incontinence (age>18 years). The duration of the training was 12 weeks, with training twice (2) daily for 5-6 days a week. Two types of biofeedback devices were used, both with the application of local electric stimulation of sphincters during the training.

Parameters for device one were: Frequency: 40 Hz; Impulse Width: 0.2 s; Ramp up time: 1s; Work out time: 6s; Rest: 15s; Training duration: 20min. Parameters for the second device: Continual stimulation with 35 Hz, 0.33 impulse width followed by workout: Frequency: 30 Hz; Impulse Width: 0.25 s; Ramp up time: 0.3s; Work out time: 5s; Ramp down time: 0.3s; Rest 5 s. Training duration: 6+20 min. 3D anorectal manometry was performed according to the IAPWG protocol at the initiation visit and at the control visit. Clinical evaluation was performed by self-reporting Wexner score for fecal incontinence at both visits.

Results: Twenty-seven patients (27) were randomly assigned either to device No. 1 or No.2. Two patients did not attend the control visit for unknown reasons and one patient stop the study because of adverse event (pain in rectum and worsening of the incontinence). Two patients did finish the study but did not attend the planned clinical control in the pre-defined date due to travel reasons and thus were excluded from the evaluation. Thus, twenty-two patients (22) were considered for the final evaluation. Average increase of sphincter rest medium pressure was 11.45% and average increase of maximum sphincter pressure was 26.1%. The absolute pooled average of the cohort for maximum voluntary pressure was significantly higher after the therapy compared to basal values (135.82 mmHg vs. 110.13 mmHg, p<0.05). This was not observed in the case of rest pressure (54.88 mmHg vs. 57.72 mmHg). The average improvement of Wexner score was 1.7 points and was statistically significant (p<0.05).

Conclusion: To our current knowledge this is a first study evaluating commercially available home biofeedback devices for fecal incontinence and one of few for home biofeedback devices in the defecation disorders generally. Here presented data shows the feasibility and safety of the home biofeedback device for the treatment of fecal incontinence as there was only one mild adverse event recorded. Efficacy is shown by significant improvement of the maximum voluntary sphincter pressure. Based on these results a randomized, double-blind study will be performed to further explore and evaluate the efficacy of the different devices.

Disclosure: Nothing to disclose.

Introduction: Gastrointestinal involvement is universal among patients with systemic sclerosis (SSc). Small intestinal dysfunction manifests with non-specific gastrointestinal symptoms (abdominal pain, distension, nausea, or vomiting), along with objective signs such as malnutrition, small intestinal bacterial overgrowth, and, in severe cases, chronic intestinal pseudo-obstruction. The pathogenesis of small intestinal dysmotility in SSc has been proposed to follow a sequential progression, beginning with neuropathy, progressing to myopathic damage, and ultimately culminating in fibrosis. Currently, there are no diagnostic techniques available to differentiate between stages of small intestinal involvement.

Aims & Methods: Aim: To assess the discriminative potential of high-resolution jejunal manometry in categorizing small intestinal dysmotility among patients with SSc.

Prospective study evaluating small intestinal motility in consecutive patients with SSc and digestive symptoms between January 2018 and July 2023 and healthy volunteers as controls. A 35-channel high-resolution manometry catheter was trans-nasally inserted into the jejunum under fluoroscopic radiological guidance. Small intestinal motility was continuously recorded for 5 h; 3 h fasting and 2 hours during continuous nutrient perfusion at 2 kcal/min. Tracings were analyzed by conventional qualitative

tive analysis (identifying neuropathic and myopathic motility patterns) and by quantitative analysis of high-resolution parameters (measuring a motility index (MI) that integrates contractile frequency and amplitude over time, and manually counting the number of propagated contractile fronts)

Results: Twenty patients (52 ± 10 years, 95% women) with SSc and 18 healthy subjects (HS) (27 ± 6 years, 78% women) were included. By conventional visual analysis, 6 (30%) patients exhibited abnormal small intestinal motility patterns indicative of neuropathic involvement (uncoordinated bursts n=3 and postprandial minute-rhythm n=3), and 7 (35%) patients showed diminished contractile activity during fasting and after nutrient infusion (mean amplitude <20mmHg), indicative of myopathic involvement. The remaining 7 (35%) patients had apparently normal small intestinal motility.

Quantitative analysis of high-resolution parameters detected additional abnormalities in patients with SSc compared to healthy controls (table 1). A significant decrease in fasting (phase II) propagated fronts was observed in all subgroups, including those with apparently normal motility by conventional analysis. The postprandial response to nutrient infusion was reduced in 15 of 20 patients with SSc. All patients with myopathic involvement had a null response to nutrient infusion. Patients with neuropathic patterns and those with apparently normal motility by conventional analysis also exhibited a poor postprandial response, which was similarly reduced in both groups.

	Healthy controls (n=18)	Patients with systemic sclerosis		
		Apparently normal motility (n=7)	Neuropathic involvement (n=6)	Myopathic involvement (n=7)
Fasting phase II MI (Log mmHg. contractions)	7.1 ± 0.2	6.9 ± 0.4	7.6 ± 0.7	4.7 ± 0.3*
Phase II propagated contractile fronts (n/3hrs)	24.3 ± 2.7	10.1 ± 3.1*	10.3 ± 5.5*	0.6 ± 0.4*
Postprandial MI (Log mmHg. contractions)	9.8 ± 0.2	8.4 ± 0.8	9.1 ± 0.5	4.4 ± 0.5*
MI increase after nutrient infusion (Log mmHg. contractions)	41% ± 5%	21% ± 8%*	23% ± 11%*	-6% ± 12%*

Table 1: Results from quantitative analysis of high-resolution jejunal manometry

*p<0.05 by Mann-Whitney U test compared to healthy controls.

Conclusion: High-resolution jejunal manometry detects abnormalities in fasting and postprandial small intestinal motility in patients with systemic sclerosis, even at early stages of intestinal involvement, when neuropathic and myopathic patterns are not evident.

PREVALENCE OF BOWEL, BLADDER AND SEXUAL DYSFUNCTION SYMPTOMS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

C. Dell'Oro¹, L. Hicks^{1,2}, E.V. Carrington^{1,2}

¹Imperial College, Department of Surgery and Cancer, London, United Kingdom, ²Imperial College NHS Trust, Gastroenterology and Hepatology, London, United Kingdom

Contact E-Mail Address: chiara.delloro20@imperial.ac.uk

Introduction: Bowel, bladder and sexual dysfunction symptoms in patients with Inflammatory Bowel Disease (IBD) are common. Treatment with biofeedback, medication, neuromodulation or surgery can improve

quality of life. Unfortunately, few patients proactively report symptoms for reasons including: embarrassment, lack of awareness of associations / treatment options or concerns about consultation time.

Aims & Methods: Between February-April 2024, patients with IBD attending infusion units and outpatient clinics at a tertiary hospital in the United Kingdom were asked to complete the validated ICIQ-IBD (International Consultation on Incontinence Questionnaire for IBD patients), and the ICIQ-MLUTS / ICIQ-FLUTS (Male / Female Lower Urinary Tract Symptoms) questionnaire, which assesses bowel, bladder and sexual dysfunction symptom frequency and impact on quality of life (QoL) using a 5 point scale of never-always. Presence of symptoms was defined as those rated more than 'never'. Regular symptoms were those occurring 'most of the time' or 'always'. Patients were asked to rate QoL, bowel and sexual symptoms during both remission and relapse. Patients with unclassified IBD, microscopic colitis, stomas and J-pouches were excluded.

Results: One hundred and sixteen patients received the questionnaire. Sixteen were excluded on clinical grounds and 30 due to incomplete questionnaire data leaving 70 for analysis. Thirty-three (47%) were female, 38 (54%) had Crohn's disease (CD) and 32 (46%) ulcerative colitis (UC). All patients were on biologics (96%) and/or JAK inhibitors (7%). Median age was 36 (range 20-77). Faecal urgency was the most commonly reported symptom, with 55 (79%) reporting symptoms during relapse and 45 (64%) during remission. Regular symptoms during remission were present in 9 (13%). Faecal incontinence (FI) was reported in 51 (73%) during relapse and 30 (43%) during remission. Regular FI symptoms were present in 6 (9%) during remission. Of those patients reporting to be sexually active (n=57), sexual dysfunction was common, reported in 41 (72%) during relapse and 25 (44%) during remission. Urinary incontinence (UI) was reported in 12 (17%) patients, with 10 (14%) patients reporting the presence of both UI and FI. Even during remission, patients commonly reported a bowel-control related QoL impact, with 31/70 (44%) reporting disruption to family, 36/70 (51%) to social and 38/67 (57%) to working life. Forty-three out of 70 (61%) patients worried about getting to a toilet in time and 24/54 (44%) reported feeling less attractive to their partner.

		Symptoms ^A		Regular symptoms ^B	
		Remission	Relapse	Remission	Relapse
Bowel ^C	Faecal urgency	45 (64%)	55 (79%)	9 (13%)	40 (57%)
	Faecal incontinence	30 (43%)	51 (73%)	6 (9%)	20 (30%)
	Anorectal pain	32 (46%)	43 (61%)	6 (9%)	19 (27%)
	Constipation	41 (59%)	26 (37%)	3 (4%)	3 (4%)
Sexual ^D	Sexual dysfunction ^E	25 (44%)	41 (72%)	4 (7%)	27 (47%)
Bladder ^F	Urinary incontinence	12 (17%)		2 (3%)	

Table 1: Bowel, sexual and bladder symptom frequency

N = 70

^A Symptoms reported more than 'never'

^B Symptoms reported 'most of the time' or 'always'

^{C&D} assessed using the ICIQ-IBD

^E patients reporting 'not applicable' excluded (n = 57)

^F assessed using the ICIQ-M/FLUTS

Conclusion: Bowel, bladder and sexual dysfunction symptoms are common in IBD patients and negatively impact QoL. Even during remission, symptoms are more common than in the background population and interfere with QoL. An appreciation of the prevalence of these symptoms with proactive screening may facilitate triage to pelvic floor services for targeted care.

Disclosure: Nothing to disclose.

ACUTE MUCOSAL REACTIONS FOLLOWING FOOD ADMINISTRATION IN IRRITABLE BOWEL SYNDROME ARE ASSOCIATED WITH MAST CELL ACTIVATION EX VIVO IN A SUBGROUP OF PATIENTS

L. Balsiger¹, K. Raymenants^{1,2}, C. Van de Bruaene¹, J. Schol¹, L. Juvyns¹, K. Routhiaux¹, J. Toth¹, R. Farré¹, T. Vanuytsel^{1,2}, J. Tack^{1,2}

Introduction: Irritable bowel syndrome (IBS) is a prevalent disorder of gut-brain interaction characterized by abdominal pain and altered bowel movements. While the pathophysiology underlying IBS is incompletely understood, local allergic reactions to foods are a candidate mechanism. Confocal laser endomicroscopy (CLE) has shown acute alterations of the duodenal epithelium in IBS within minutes of local food administration and these findings have been used to identify foods contributing to IBS symptoms. However, the mechanisms and relevance of the observed alterations remain elusive.

Aims & Methods: Aim: To visualize the effect of local food administration on the duodenal mucosa using CLE and assess whether visible changes are associated with altered permeability or markers of mast cell activation ex vivo.

Methods: Non-constipated Rome IV IBS patients with negative serum specific IgE for tested foods underwent baseline gastroscopy (EGD) and CLE performed during a second EGD. Duodenal mucosa was visualized using CLE at baseline and after luminal administration of foods (egg white, soy, milk, wheat, lyophilized fish and shellfish, and nuts solutions sequentially applied in a random order) through the working channel. Altered mucosa was defined as leakage of fluorescein into the lumen and presence of particles (previously termed “cell shedding”). Serum samples were taken at index endoscopy and 30 minutes after acute mucosal alterations. Biopsies were taken at index EGD and after visualized alterations to measure transepithelial electrical resistance (TEER) in Ussing chambers and tryptase levels in biopsy supernatants. Data are reported as mean ± SEM or median and IQR as appropriate.

Results: 45 CLE exams were carried out in 28 patients (age 35±2 y, 93%^f, BMI 24±1 kg/m², mean IBS symptom severity score 320±20).

At baseline, mucosal alterations were present in 9% of exams (n=4), whereas all other exams (n=41) demonstrated alterations after food administration. The highest rate of acute alterations was observed after fish/shellfish mix (50%; 10 altered / 20 exposed). The rate of observed alterations per food is presented in the table. TEER was not altered after observed alterations vs baseline (25±0.8 Ωxcm² vs 25±1 Ωxcm²). Serum tryptase was not altered after food exposure vs baseline (ratio after/before = 0.9, IQR= 0.8-1.1, n=13). Tryptase release from biopsies increased after exposure compared to baseline in 5/9 (56%) of patients after one hour and in 13/19 (68%) patients after 24h. Overall, the average tryptase release of the tissue was 1.48-fold increased after food exposure compared to baseline in the first hour after exposure (IQR = 0.3-2.1, n=9) and 1.29-fold following 24h incubation (IQR = 0.9-2.1, n = 19).

Food	Exposed	Altered n(%)	Food	Exposed	Altered n(%)
Fish/Shellfish mix	20	10 (50%)	Egg	21	6 (29%)
Milk	21	10 (48%)	Wheat	18	5 (28%)
Nuts	19	6 (32%)	Soy	15	4 (27%)

Conclusion: In this group of IBS patients, we found a high rate of acute food-induced mucosal alterations as visualized with CLE. Ex vivo permeability was unaltered after observed alterations vs. baseline. Systemic

tryptase remained unchanged after acute alterations compared to baseline whereas tryptase release from biopsies was increased following food exposure compared to baseline in more than half of patients.

Disclosure: Nothing to disclose.

Introduction: Chronic Intestinal Pseudo-Obstruction (CIPO) is a rare disease characterized by a severe impairment of intestinal propulsive activity resulting in a clinical picture mimicking a mechanical intestinal obstruction despite the absence of any physical obstruction. Velusetrag (VEL) is a highly selective oral 5-hydroxytryptamine type 4 receptor (5-HT₄R) agonist that enhances peristalsis, stimulates intestinal secretion and inhibits gastrointestinal visceral sensitivity via acetylcholine and calcitonin gene-related peptide released from motor and sensory neurons, respectively. This phase II, multicenter, double-blind, placebo-controlled, 2 treatments, 4 periods, multi-crossover (N-of-1) trial investigates the efficacy and safety of VEL in CIPO patients.

Aims & Methods: Seventeen patients with idiopathic or secondary (to primary neurodegenerative disorders) CIPO with at least 30% of their daily caloric intake from oral nutrition were treated for 4 periods of 4 weeks each with either VEL 15 mg once daily or placebo (PLA), with a washout period of 2 weeks between treatment periods. Each cycle with two periods assigned to either VEL or PLA is considered as a pair of observations. Analysis was performed on the evaluable pairs (i.e., evaluation available both for VEL and PLA within cycle). Each subject could be evaluated twice, once for each cycle, thus, each subject could contribute to 0, 1 or 2 observations for each treatment. The present analysis was performed on 15 patients, assessed as responders or naïve to 5-HT₄R agonists. The number of pseudo-obstructive episodes and stool type (Bristol stool scale) were assessed during the entire study.

Results: A 50% reduction in the number of pseudo-obstructive episodes in VEL (n=4) vs PLA (n=8) was detected in 30 evaluable pairs of observations. During VEL treatment, pseudo-obstructive episodes occurred once in 2 patients and twice in 1 patient; during PLA treatment 7 patients experienced 1 episode and 1 during wash-out period after PLA. Complete normalization of constipation was observed only with VEL. In 23 evaluable pairs, all 4 observations with constipation on VEL at pre-treatment had normal stools at end of treatment (from Bristol stool type 1-2 to 3-4); additionally, observations with normal stools increased from 3 (pre-treatment) to 6 (end of treatment). In contrast, all 3 observations with constipation on PLA at pre-treatment remained constipated at end of treatment and other 2 observations with diarrhea at pre-treatment shifted to consti-

pation at the end of treatment (Tab. 1). These results did not reach statistical significance due to limited sample size. The number of subjects with treatment emergent adverse events was similar between VEL and PLA. No cardiovascular adverse reactions or serious treatment emergent adverse events were observed in both treatment groups.

Conclusion: A VEL prokinetic effect was confirmed by a decreased number of pseudo-obstructive episodes and a normalization of constipation, two main clinical features of CIPO. VEL was also well-tolerated and safe, with no serious drug-related adverse event reported.

EFFECT OF INTERMITTENT COLONIC EXOPERISTALSIS ON PEOPLE TAKING CONSTIPATION-INDUCING MEDICATION. MEDICAL DEVICE USE AT HOME WITHOUT PATIENT SUPERVISION

I. Herrero-Fresneda¹, D. McClurg²

¹USMIMA S.L., Scientific & Medical Dpt., Esplugues Llobregat, Barcelona, Spain, ²Glasgow Caledonian University, Glasgow, United Kingdom

Contact E-Mail Address: ihf@mowoot.com

Introduction: Opioids and many other chronic medications are risk factors for constipation [1]. Lifestyle changes and second-line treatment with laxatives are not enough to solve the problem [2]. Indeed, most laxative agents show limited efficacy for chronic use, especially in people under concomitant medication, in addition to potential adverse effects [3]. Intermittent colonic exoperistalsis (ICE) administered with the MOWOOT medical device, is a non-invasive, non-drug solution for chronic constipation. It has been developed to facilitate natural bowel movements and

reduce the burden of laxatives, enemas, and other invasive approaches. ICE has been proven safe and effective in a previous multicentric clinical trial [4].

Aims & Methods: The aim of the present study was to assess the effect of ICE treatment on those people included in the previous clinical trial [4] who were under constipation-inducing medication (CIM).

The patients under CIM were identified by searching the clinical trial data base for concomitant medication. A medication was considered as constipation-inducing (CIM) when its medical leaflet indicated constipation as secondary adverse event occurring with a frequency >10%.

The ICE device was used daily for 20 minutes over 4 weeks at home without the direct supervision of a medical professional.

The difference after ICE-treatment (V2) respect to baseline (V1) was assessed for the number of complete bowel movements/week (CBM/w; primary outcome), the constipation symptoms (KESS score [5]), and the quality of life (PACQoL [6]).

Results: Out of the total 92 participants [4], there were n=42 under CIM, which include opioids (n=6; 14.29%), antidepressants (n= 29; 69.05%), antipsychotics (n=3; 7.14%), anticonvulsants (n=2; 4.76%), antihypertensives (n=13; 30.95%), and other CIM (n=9; 21.43%). Most people were women (78.57%), aged 53'86 (10.16) yr, with BMI: 27,68 (5,25). The rest of the sample not taking CIM were also mostly women (82.61%), aged 49.64 (13.12) yr, with BMI: 24.23 (4.83).

All the constipation-related assessed parameters significantly improved after ICE treatment, both in people taking CIM or not (Table). The number of CMB/w in the CIM sample after 4 weeks of ICE treatment increased to 7.1 (5.4), while participants not taking CIM increased to 5.9(3.3). Although this difference between groups did not reach statistical significance (Table), the clinical impact was notable for people taking CIM who achieved the goal of a daily deposition. The symptoms of chronic constipation and the quality of life were similarly ameliorated in both CIM and no-CIM groups.

	CIM	V2-V1 mean (SD)	*P _{V2-V1}	**P _{Yes vs No}
Compleat Bowel Movements/week	Yes	2.4 (3.1)	<0.0001	0.0517
	No	1.3 (2.1)	0.0002	
KESS score	Yes	-3.6 (5.3)	0.0001	0.6402
	No	-4.2 (4.8)	<0.0001	
PAC-QoL	Yes	-0.6 (0.7)	<0.0001	0.3360
	No	-0.7 (0.8)	<0.0001	

KESS (0 to 39) & PAC-QoL (0 to 4): the lower value, the better result. The Wilcoxon test (*paired, **unpaired) was used. Statistical significance reached at P<0.05.

Conclusion: The results favour the use of intermittent colonic exoperistalsis (ICE) with the MOWOOT medical device to treat constipation at home, without direct supervision of a medical professional, in people under constipation-inducing medication. As a non-invasive and non-drug solution, ICE would offer important advantages over the current standard of care (laxatives, enemas...) to CIM patients and the healthcare system.

DISORDERS OF GUT-BRAIN INTERACTION IN PATIENTS WITH CELIAC DISEASE ADHERING TO GLUTEN-FREE DIET: A PROSPECTIVE 10-YEAR STUDY

L. Colecchia¹, F. Candia², A. Gobbato¹, A. Di Biase², S. Crestani², G. Cammarata², V. Boarino³, E. Dajti¹, F. Ravaoli¹, M.R. Barbaro¹, C. Cremon⁴, G. Barbara¹, A. Colecchia², L. Iughetti², G. Marasco¹

¹University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy, ²University of Modena and Reggio Emilia, Modena, Italy, ³Modena Hospital, Gastroenterology and Digestive Endoscopy Unit, Modena, Italy, ⁴IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Contact E-Mail Address: giovannimarasco89@gmail.com

Introduction: Patients with celiac disease (CD) can present persistence or de-novo occurrence of gastrointestinal (GI) symptoms later in life even following a strict gluten-free diet (GFD). Indeed, GFD can alter the gut microbiota inducing dysbiosis that with time may lead to the development of disorders gut-brain interaction (DGBI).

Aims & Methods: In this prospective study, we evaluated the rate of irritable bowel syndrome (IBS), functional dyspepsia (FD), anxiety, and depression over a follow-up period of more than 10 years in a population of patients with CD following GFD.

Patients with CD diagnosed between 2004 to 2014 at the University Hospital in Modena, Italy were re-evaluated to assess the presence of DGBI. Rome-IV (pediatric modules if patients were younger than 17 years old), gastrointestinal symptoms rating scale (GSRS) and hospital anxiety and depression scale (HADS) questionnaires were administered along with the evaluation of the last blood examinations. The rates of IBS, FD, anxiety, and depression were then assessed. Univariate and multivariate analyses were performed to investigate the presence of factors associated with IBS and FD.

	No IBS 130 (85.53%)	IBS 22 (14.47%)	No FD 141 (92.76%)	FD 11 (7.24%)	Multivariate (IBS) OR (95% CI)	P-value	Multivariate (FD) OR (95%CI)	p- value
Age at diagnosis (months)	62 (35-97)	79 (49-116)	62 (35-97)	84 (49-121)				
Follow-up (months)	151 (123- 177)	177 (152- 189)	152 (123- 179)	179 (154-225)	1,142 (1,023 - 1,275)	0,018		
Gender (Male)	41 (32.28%)	3 (13.64%)	42 (30.43%)	2 (18.18%)				
Depression (HADS)	9 (6.92%)	4 (18.18%)	9 (6.92%)	2 (18.18%)				
Anxiety (HADS)	28 (21.54%)	14 (63.64%)	35 (24.82%)	7 (63.64%)	6,595 (2,441 - 17,815)	< 0,001	5.045 (1.322 - 19.248)	0.018
BMI percentile	33 (8-74)	44 (10-71)	33 (8-67)	44 (21-95)				
Diarrhea	6 (4.72%)	2 (9.09%)	8 (5.8%)	0				
Constipation	6 (4.72%)	2 (9.09%)	8 (5.8%)	0				
Abdominal pain	40 (31.5%)	8 (36.36%)	42 (30.43%)	6 (54.55%)				

Results: We contacted 197 patients out of 340 from our original pediatric cohort. Patients who were not strictly adhering to GFD (25 patients) and who did not complete the questionnaires (20 patients) were excluded

from the study. The median follow-up time was 154 months (inter-quartile range 125-180). The rate of IBS was 14.47% (22/152) which increased to 22.3% (21/94) considering only the adult population (Table 1 panel A). Patients were then subclassified in IBS-C (5/22, 22.7%), IBS-M (6/22, 27.3%) and IBS-D (10/22, 45.5%). The overall rate of FD was 7.24% (11/152) (Table 1 panel B) and up to 11.7% (11/94) in the adult population and none in the pediatric one.

We found that postprandial distress syndrome (PDS) was present in 7.89% (12/152) of the population and epigastric pain syndrome (EPS) in 5.26% (8/152). Significantly higher rates of anxiety were found in patients developing IBS and FD (Table 1 and 2).

Univariate and multivariate analyses showed that a longer follow-up time was significantly correlated with a higher rate of IBS and that anxiety was correlated with both IBS and FD diagnosis (Table 1).

Conclusion: Over more than 10 years from the initial diagnosis of CD, we found a higher rate of IBS and FD than the one reported for the general population. In our cohort, DGBIs are correlated with higher levels of anxiety and longer follow-up time.

ARTIFICIAL INTELLIGENCE AS A TRANSFORMING FACTOR IN MOTILITY DISORDERS – AUTOMATIC DETECTION OF MOTILITY PATTERNS IN HIGH-RESOLUTION ANORECTAL MANOMETRY

F. Mendes¹, M.J. Mascarenhas Saraiva¹, J. Mota¹, T. Ribeiro¹, P. Cardoso¹, M. Martins¹, M.J. Almeida¹, J. Cordeiro², J. Ferreira², G. Macedo¹, C. Santander³

¹Centro Hospitalar Universitário São João, Department of Gastroenterology, Porto, Portugal, ²Faculdade de Engenharia da Universidade do Porto, Porto, Portugal, ³Hospital Universitario de la Princesa, Madrid, Spain

Contact E-Mail Address: francisco.cnm@gmail.com

Introduction: Anorectal functional disorders are common in clinical practice, impacting the life of over 5% of the world population. High-resolution anorectal manometry (HR-ARM) is considered the gold standard for evaluating anorectal functional disorders. However, progress is hindered by the limited accessibility of the procedure, which is not available across all centers, and by the complexity of the data analysis involved. The London Protocol and Classification were developed as a standardized method for anorectal motility patterns classification. Artificial intelligence models have increasingly been developed in medical areas with a strong imaging component and Gastroenterology is not an exception. However, when it comes to functional anorectal disorders it remains uncharted territory, with only a few research articles published.

This study aims to develop and validate an AI model for the identification and differentiation of disorders of anal tone and contractility during HR-ARM, based on the London Classification.

Aims & Methods: A dataset of 701 HR-ARM exams from a tertiary center was used for developing and testing of multiple machine learning (ML) algorithms. All HR-ARM procedures were performed with Solar™ GI High-Resolution Anorectal Manometry HRAM single use Water Perfused Catheters Cathethers (Laborie™, Enschede, The Netherlands). Classification of anorectal motility disorders was based on the London Classification.

The training dataset had 80% of the total exams, with the remaining 20% being used for the testing dataset. The testing dataset was used for the models' evaluation through its accuracy, f1-weight score, sensitivity, specificity, positive and negative predictive values and area under the receiving-operating characteristic curve.

Results: After models' fine tuning, LGBM Classifier had the best performance, with a mean accuracy of 87.0% and a F1 weight score of 85.0% for identifying disorders of anal tone and contractility. Different ML models excelled in distinguishing specific disorders of anal tone and contractility, with mean accuracy over 90.0%. LGBMClassifier identified anal hypotension with normal contractility with a F1 weight score of 91.0%. On the other hand, AdaBoostClassifier had a F1 weight score of 97.0% for combined anal hypotension and hypocontractility. Anal normotension with hypoco- ntractility was detected with 90.0% F1 weight score by LGBM Classifier. Finally, DecisionTreeClassifier excelled in the detection of anal hyperten- sion, with a F1 weight score of 97.0%.

Conclusion: This is the first worldwide study proving the accuracy of ML models for differentiation of motility patterns in HR-ARM, based on London Classification. The evaluation of disorders of anal tone and con- tractility with HR-ARM is an indirect measure of the internal and external anal sphincter function and accurate identification of these disorders is of utmost importance for guiding clinical practice. Artificial intelligence has the potential to enhance accessibility to HR-ARM by facilitating the evaluation of the data and, perhaps, making it more cost-efficient. Finally, interoperability, a key point of interest, can be achieved using AI models.

AFFORDABLE ENDOSCOPIC VACUUM THERAPY FOR COLORECTAL ANASTOMOTIC LEAKS: A COMPREHENSIVE COMPARATIVE ANALYSIS OF MANUAL AND COMMERCIAL KITS

L. Correia Gomes¹, M. Rajão Saraiva¹, A. Bestetti²,
D. Conceição¹, J. Cortez-Pinto³, I. Rosa¹,

Contact E-Mail Address: luisfilipe.gomes@outlook.com

Introduction: Colorectal surgery for oncological diseases has progressed significantly, yet anastomotic leaks (AL) remain a daunting challenge, with an incidence rate of up to 10%. AL not only entails reintervention but also leads to increased costs, discharge delays, and elevated morbidity and mortality risks. Endoscopic vacuum therapy (EVT) has emerged as a preferred minimally invasive approach, offering favorable outcomes. However, despite its recognized effectiveness, widespread EVT adoption remains limited, one of the limitations is cost. Manual EVT kits present a cost-effective alternative, particularly beneficial in resource-limited set- tings, however there's a lack of comparative studies between both kits.

Aims & Methods: Our study aims to address these gaps by comparing the efficacy and safety of manual and commercial EVT kits.

Retrospective multicenter study from October 2017 to December 2023, all patients undergoing EVT for colorectal and ileo-anal AL. The analysis covered patients' demographics, surgery type, number of EVT sessions, their efficacy and safety.

Patients displaying indications of rectal defects after colorectal surgery underwent diagnostic assessment using endoscopic exam and CT scan. EVT initiation depended on identifying leakage or defect as the primary in- fection focus. Two self-manufactured EVT options (polyurethane or open pore) and one commercial (Endo-sponge®) were available, chosen based on leak characteristics. Clinical success was defined as successful sepsis control (clinically and analytical) and closure of the leak, either endo- scopically and radiologic. Technical success involved successful vacuum device positioning.

Results: 35 patients underwent EVT for colorectal and ileo-anal anasto- motic leaks following various surgical procedures. Average age was 53.63 years with 62.9% males. The interval from surgery to EVT placement aver- aged 235.9 days, on average, 6.97 sponge exchanges were performed with treatment duration of 31 days. Leak sizes ranged from 0.5 to 12 cm. Stoma reversal was possible in nearly half of the patients (48.6%), with 65.7% achieving long-term gastrointestinal tract preservation.

Manual EVT: 17 patients were included, average age of 56 years and leaks ranging from 2 to 5cm (mean: 3,55cm). The mean time from surgery to treatment initiation was 343.24 days, with an average of 4.59 EVT ses- sions over 29.65 days to successfully close the defect. Technical success was achieved in all patients, with clinical success rate of 94.1%. 41.7% of patients successfully underwent ostomy reversal, and 70.59% maintained long-term intestinal continuity.

Commercial EVT: 18 patients, average age was 51 years and leaks rang- ing from 2 to 12cm (mean: 6,47cm). The mean duration from surgery to treatment initiation was 134.56 days, with an average of 9.22 EVT sessions over 32.89 days to successfully close the defect. Technical success was

achieved in all patients, with clinical success rate of 83.3%. 61.11% of patients had stoma reversal all maintained long-term intestinal continuity. Statistical analysis showed no significant differences between the two groups in patient demographics, clinical success ($p = 0.603$), stoma reversal ($p = 0.857$) or long-term intestinal preservation ($p = 0.349$). Adverse events were comparable between the groups.

Conclusion: Our data demonstrate that EVT is an extremely safe and highly effective therapy for managing colorectal leaks, whether using commercial or manual kits. EVT can be feasibly implemented in resource-limited settings without compromising treatment outcomes.

ENDOSCOPIC MANAGEMENT OF STRICTURES AND LEAKS FOLLOWING COLORECTAL SURGERY: A SYSTEMATIC REVIEW

G. Chlorakis¹, T.K. Nikolouzakakis², A. Augoustaki¹, V. Valatas¹, E. Kalaitzakakis¹

¹University Hospital of Heraklion, Gastroenterology Clinic, Heraklion, Greece, ²University Hospital of Heraklion, General Surgery, Heraklion, Greece

Contact E-Mail Address: giwrgosw92@hotmail.gr

Introduction: Leaks and strictures on the anastomotic site of the lower gastrointestinal tract increase morbidity and mortality of colorectal surgery. Multiple endoscopic methods have been described to treat anastomotic leaks, namely, endoscopic vacuum-assisted therapy, over-the-scope clips and sealants (fibrin glue and cyanoacrylate). As for anastomotic strictures, lumen apposing metal stents, self-expandable metal stents, balloon dilatation, intralesional steroid injection and endoscopic stricturotomy have all been proposed.

Aims & Methods: We aimed to report the indications and the overall clinical efficacy of endoscopic therapies applied for anastomotic leaks and/or strictures following colorectal surgery. The Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) 2020 guidelines were followed and a literature search was performed by two independent reviewers using relevant search terms in the databases PubMed and Scopus. A total of 14 studies were found and 21 additional reports were obtained from their references, overall, containing 992 patients.

Results: The overall clinical success rate of all endoscopic methods to treat leaks and strictures was 78.3%. For the treatment of leaks in 572 patients 83.4% long-term success was achieved. In 68 patients over-the-scope clips reached 67.2% symptom relief, in 473 patients the endoscopic

vacuum therapy had 86.3% success rate and in 31 individuals sealants reached 79.8% efficacy. A sum of 420 cases with strictures were identified. Clinical success was reported at 72.3% for this group. A total of 101 cases with strictures were managed with self-expanding metal stents and 54.7% experienced clinical improvement. The introduction of lumen apposing metal stents for the treatment of strictures in 19 patients produced 92.4% clinical efficacy. Migration rate for fully covered stents was 46.1% and for lumen apposing metal stents 9.1%. Balloon dilatation was applied in 182 patients reporting clinical improvement in 94% of cases and in 71 cases the strictures were treated with endoscopic stricturotomy, leading to symptom relief in 41% of patients. Forty-four patients had anastomotic strictures with concomitant leaks and were managed with self-expanding metal stents reaching clinical success in 82.1% of cases. Major complications, namely bleeding or perforation, were recorded in 2.4% and the highest rate (7.2%) was reported for stricturotomy.

Conclusion: Patients with anastomotic colorectal strictures should be treated with balloon dilation initially. Self-expandable metal stent deployment, either fully-covered or uncovered or lumen-apposing metal stents, can be used in refractory cases, with the latest expressing lower rates of migration. Colorectal anastomotic leaks with concomitant cavity can be treated with endoscopic vacuum therapy and avoid re-surgery. In the case of no cavity, sealants represent an appropriate alternative method. Strictures with leaks should be considered for treatment with fully-covered metal stent deployment. Stricturotomy is associated with high rates of complications and it is not recommended unless the technique is modified appropriately to guarantee safety.

Introduction: Recent evidence suggests that Computer-Aided Detection (CADE) systems, when used alongside mucosal-exposure devices, may enhance adenoma detection during colonoscopy. This study evaluates whether the integration of CADe with the GEYE balloon, an endoscope with a reusable on-demand inflatable balloon at the tip, enhances adenoma detection in a fecal immunochemical test (FIT)-based colorectal cancer screening program.

Aims & Methods: Subjects aged 50-74 who tested FIT-positive as part of a national colorectal cancer (CRC) screening program, were randomized to undergo colonoscopy with either CADe alone (CADEYE, Fujifilm Co., Tokyo, Japan) or CADe combined with the GEYE balloon (G-EYE 760R, Fujifilm Co., Tokyo, Japan), performed by accredited endoscopists. The primary outcome measures included the rate of "high-risk" individuals, who need intensive surveillance, as defined by the ESGE criteria (≥ 5 low risk adenoma, at least one adenoma with high-risk features, any serrated polyp ≥ 10 mm or with dysplasia) and the adenoma detection rate (ADR). Based on prior research, the study was intended to include 600 subjects.

Variables	CADE, n (%)	CADE+G-EYE	p-value
Rate of „high risk” subjects	61/229 (26.3%)	45/216 (20.8%)	0.19
ADR	139/229 (60.7%)	117/216 (54.2%)	0.19
PDR	154/229 (67.2%)	136/216 (63.0%)	0.39
SSLDR	6/229 (2.6%)	6/216 (2.7%)	0.91
APC	1.46 $\pm$ 1.86	1.41 $\pm$ 1.99	0.79

Results: From May 2023 to April 2024 (ongoing), 479 subjects were randomized; 34 were subsequently excluded due to incomplete examination (4), inadequate preparation (12), or malfunctioning of the G-EYE balloon or CADe (18). The remaining 445 subjects were enrolled in the study (median (IQR) age 61 y/o (58-66); 216 men). Of them 229 and 216 underwent CADe colonoscopy and CADe+GEYE colonoscopy, respectively. No significant differences were observed between the two groups in terms of patient characteristics, cleansing levels, insertion times, overall withdrawal times, or inspection durations. At interim analysis, the rate of "high-risk" individuals post-colonoscopy was 26.3% (95% CI: 20.9-32.4%) with CADe and 20.8% (95% CI: 15.4-26.3%) with CADe+GEYE. The ADR was 60.7%

(95% CI: 54.4-67%) for CADe and 54.2% (95% CI: 47.5-60.8%) for CADe+GEYE, respectively. Secondary outcomes, including Polyp Detection Rate (PDR), Sessile Serrated Lesion Detection Rate (SSLDR), and Adenoma Per Colonoscopy (APC), showed no significant differences.

Conclusion: Data suggest that adding GEYE to CADe does not significantly increase the adenoma detection. Although the data are still not definitive, we can hypothesize that a "ceiling effect" due to the high detection rate of lesions with CADe have marginalized the impact of mucosal-exposure device.

Introduction: Computer-Aided polyp Detection (CADE) systems based on artificial intelligence (AI) can increase the detection rate of colonic lesions. PolyDeep is a CADe that has demonstrated its ability to detect lesions.

Aims & Methods: The aim of the study is to evaluate its performance in the context of expert endoscopists in a population-based colorectal cancer screening programme. PolyDeep Advance 2 (NCT05512793) is a multicentric randomised clinical trial with a tandem colonoscopy design. The primary endpoint of this study is to determine and compare whether PolyDeep-assisted colonoscopy reduces the Adenoma Miss Rate (AMR). The secondary outcomes are to determine and compare the serrated lesion miss rate, the polyp miss rate including adenomas and serrated lesions in this category, the advanced lesion miss rate (adenomas and serrated lesions) and the small or diminutive lesion miss rate. We included patients referred for colonoscopy with a positive faecal immunochemical test result, or who required surveillance after resection of advanced adenomas. All baseline, patient, procedure and lesion characteristics were compared using chi-squared and t-Student tests.

Results: Between May 2023 and November 2023 we included 260 patients who were randomised to first colonoscopy with PolyDeep (130) or first colonoscopy without PolyDeep (130). We excluded 16 patients due to lack of double cecal intubation (15) or poor bowel preparation (1). Baseline characteristics of the 244 patients (124 first PolyDeep-assisted colonoscopy, 120 first non-assisted colonoscopy) were equivalent (male: 62.3%,

years of age: 62.3 ± 6.5, FIT positive: 66.0%, mean Boston Bowel Preparation Scale: 7.5 ± 1.3, first withdrawal time: 13:47 ± 08:34 min, second withdrawal time: 07:52 ± 03:39 min, detection rate of colonic lesions: 77.0%, mean number of colorectal lesions per colonoscopy: 3.0 ± 4.3). We detected 727 colonic lesions (66.4% adenomas, 23.8% serrated lesions, 6.1% other histologies, 3.7% non-retrieved lesions). We found no statistically significant differences in the miss rates between groups (Table).

	PolyDeep-assisted colonoscopy	Non-assisted colonoscopy	p
Adenoma Miss Rate	21.6%	17.0%	0.2
Serrated Lesion Miss Rate	23.4%	24.0%	0.9
Polyp Miss Rate	22.0%	19.0%	0.2
Advanced Lesion Miss Rate	10.9%	10.4%	0.9
Small lesion Miss Rate	23.4%	21.0%	0.5
Diminutive lesion Miss Rate	25.5%	21.6%	0.3

Conclusion: In colonoscopies performed by experienced endoscopists, PolyDeep does not reduce the AMR.

Disclosure: Nothing to disclose.

Introduction: The benefit of computer-assisted detection systems (CADE) has been evaluated in several randomized controlled trials (RCTs) showing improved adenoma detection rate (ADR) and polyp detection rates (PDR) (1-3). However, the generalizability of these studies is questioned as these studies are performed in highly controlled setting and thus not representing a real-world clinical setting (4). It is also believed that the increase in ADR by CADe-assisted colonoscopy is mainly observed in lower detector endoscopists (5, 6).

We aimed to evaluate the effect of CADe-assisted colonoscopy on ADR in an actual clinical setting in a high-volume, non-tertiary endoscopy centre with high detector endoscopists.

Aims & Methods: A single-centre, observational study was conducted on all patients undergoing colonoscopy due to symptoms of colorectal cancer (CRC), screening colonoscopies for CRC, post-polypectomy surveillance, or colonoscopy due to positive results from a fecal immunochemical test in an Australian hospital between March 2023 to October 2023. Colonoscopies were performed by 19 experienced endoscopists using the validated CADe system that allows for real-time image analysis (GI Genius, Cosmo IMD Ireland). Historical procedural data regarding colonoscopies were obtained up to 10 months before the start of the study and were compared to the CADe-assisted colonoscopies in a 2:1 fashion. The primary outcome of the study was the ADR. Data were analyzed using logistic mixed effects models with random intercepts for patient and endoscopist, expressed as Odds ratio (OR) with a 95% confidence interval (CI).

Results: A total of 7798 colonoscopies were performed for 7460 patients during the timeframe, including 2813 colonoscopies using CADe and 4985 standard colonoscopies. The ADR in the CADe-assisted colonoscopy group

was 52% compared to 46% in the standard colonoscopy group. There was a significant difference in ADR (OR 1.22, 95% CI 1.09 - 1.36, p<0.001) and PDR (OR 1.22, 95% CI 1.09 - 1.37, p<0.001) between CADe-assisted colonoscopy and standard colonoscopy respectively, adjusted for age, bowel preparation quality, withdrawal time and sex.

	Standard colonoscopy n=4985	CADe-assisted colonoscopy n=2813	OR (95% CI)
ADR (%)	2318/4985 (46%)	1455/2813 (52%)	1.22, 1.09 - 1.36
PDR (%)	2865/4985 (57%)	1769/2813 (63%)	1.22, 1.09 - 1.37
Advanced ADR (%)	536/4985 (11%)	343/2813 (12%)	
Serrated lesion detection rate (%)	1107/4985 (22%)	667/2813 (24%)	
Mean number of adenomas per colonoscopy	2.0 (1.0-3.0)	2.0 (1.0-3.0)	
Polyps per colonoscopy	1.0 (0.0-3.0)	2.0 (1.0-4.0)	

Table 1 Adenoma detection and polyp detection rate of the CADe-assisted colonoscopy group compared to the standard colonoscopy group. Data are number (%) and median (IQR).

Conclusion: In this real-time, observational study, CADe-assisted colonoscopy significantly improves the adenoma detection rate and polyp detection rate. Our study shows that the implementation of CADe-assisted colonoscopies in daily practice is useful, even in high-detector endoscopists.

EFFECT OF COLON ENDOSCOPIC RESECTION ON ALL-CAUSE MORTALITY AMONG HEALTH CHECK-UP POPULATION OLDER THAN 80 YEARS WITH EARLY COLORECTAL LESIONS IN KOREA : A NATIONWIDE POPULATION-BASED LONG-TERM FOLLOW-UP STUDY IN KOREA

Y.I. Choi¹, C.K. Lee¹, J.W. Choi¹, S.Y. Won¹, Y.S. Cho¹, B.K. Park¹

¹National Health Insurance Service Ilsan Hospital, Department of Gastroenterology and Hepatology, Goyang, South Korea

Contact E-Mail Address: cys7like@hanmail.net

Introduction: Even colon endoscopic resection (ER: endoscopic mucosal resection, endoscopic polypectomy, and endoscopic submucosal dissection) has been an effective tool for treating early colorectal lesions, there is limited data on efficacy (colorectal cancer (CRC) related mortality, and all causes mortality), and safety profiles of ER among extremely elderly patients (≥ 80 years) who have early colorectal lesions which needs ER.

Aims & Methods: This study investigated the efficacy, and safety profiles of colon ER among extremely elderly patients (>80 years) detection of early colorectal lesions after Fecal occult blood test (FOBT) positive results as Korean national Free-CRC screening process. We designed a nested case-control study using data from Korean National health insurance data (NHIS), and National health check-up data from 2009 to 2021. Among patients (≥ 80 year) with FOBT positive, and following confirmative test (colonoscopy) results as with early colorectal lesions >8 mm sized which needs ER, according to whether or not performed ER within 1 year, case ($n =$), and control ($n =$) groups were divided. Efficacy profiles were defined as CRC related, and all causes mortality. After adjusting for confounding variables, multivariable analysis was performed to analyze the effect of colonoscopy guided ER on the risk CRC related, and all-causes mortality. Safety profiles were defined as ER related perforation, bleeding, aspiration pneumonia, and cardiovascular attack events which need admission within 1 month after ER. For comparing the risk of ER among extremely elderly patients (≥ 80 years), 75-79 year of elderly patients who performed ER (with same including criteria except for age) were used as control group.

Results: We identified total of 7000 patients (≥ 80 years) with early colorectal lesions which needs ER. Among them, total of 700 case of patients undergone Colonoscopy guided ER within 1 years, others were not undergone following ER nor operation. During more than 5 year of follow up periods, total of 300 case (incidence rate: 00) and 250 case of CRC and mortality were defined in case, and control group, respectively.

Colonoscopy guided ER was statistically significantly reduced CRC related death (HR, 95%CI;), and all causes of mortality (HR, 95%CI;) even after adjusting for confounding variables.

Safety profiles for colonoscopy guided ER of extremely elderly patients group (≥ 80 years) showed no statistically higher complication risk after ER as compared to those of 75-79 years group.

Conclusion: For extremely elderly patients (≥ 80 year), colon ER after early colorectal lesions detection is associated with reduced CRC related mortality, and all causes mortality with reasonable safety profiles. Therefore, physicians should keep in mind that not refrain from performing colon ER solely based on the patients advanced age. Instead of relying on rigid age cut off, physicians still should be with cautious comparing risk, and benefit of CFS for extremely old patients.

COMPARATIVE RESULTS OF HIGH-RISK T1 COLORECTAL MALIGNANT POLYPS AFTER ENDOSCOPIC RESECTION – A PARADIGM SHIFT IN THERAPEUTIC DECISION-MAKING?

S. Bragança¹, J. Tinoco², M. Cardoso¹, D. Horta¹, M.N. Costa¹, L.C.C. Lourenço¹

Introduction: Patients with T1 stage colorectal cancer (CRC) according to TNM classification can undergo endoscopic resection (ER) with curative intent. However, in the presence of high-risk recurrence characteristics, additional surgery may be proposed, which is associated with considerable morbidity, especially those involving rectum. Additionally, it is not yet established that surgery prevents the risk of distant recurrence of CRC.

Aims & Methods: We aim to compare the outcomes of high-risk T1 CRC patients who remained under surveillance versus those who underwent additional surgery. Unicentric, retrospective cohort study, including left colon high-risk T1 CRC patients who underwent to ER, between January 2015 and December 2020. After ER, the patients were included in one of the two groups: surveillance (clinical, laboratory, imaging, endoscopic) versus surgery with lymphadenectomy. The decision regarding follow-up (surveillance vs surgery) was based on the histological characteristics of the malignant polyp, the patient's age, surgical and anesthetic risk (patient's comorbidities), and the patient's willing. Minimum follow-up period was 3 years after the initial colonoscopy for ER (baseline). Primary outcome: recurrence or death at 36 months.

Results: Among the 109 included T1 CRC patients, 70 were deemed high-risk for recurrence and had a median follow-up of 73 months (IQR=55.93), either in the surveillance group (SvG, $n=20$) or the surgery+lymphadenectomy group (SG, $n=50$). Older age or history of cerebrovascular/cardiovascular disease was associated with a higher propensity for surveillance only (propensity score). The endoscopic resection technique used was mostly conventional mucosectomy (97%). The incidence of complications related to ER was 1.4% (1 patient, colonic perforation). In the SG, 51% of the patient were submitted to surgery involving rectum and colorectal anastomosis. The incidence of complications directed related to surgery with lymphadenectomy was 20% (10 patients; 3 Anastomotic dehiscence; 1 lower gastrointestinal haemorrhage related to colorectal anastomotic; 5 wound infection ; 1 colorectal anastomotic stenosis). In SG, 84% ($n=42$) showed no evidence of CRC in the specimen (pT0N0). From baseline to 36 months, no patient in SvG experienced recurrence, while 1 patient in SG

did. During this period, 2 patients in SvG and 2 in SG died, all from causes unrelated to CRC. There was no significant difference in recurrence and mortality between the two groups (p-value >0.05). Additionally, within SG, there was no difference in recurrence and mortality between the subgroup of patients with pT0N0 versus non-pT0N0 disease (p-value > 0.05).

Conclusion: Our study suggests that high-risk T1 CRC patients undergoing ER may not benefit from additional surgery with lymphadenectomy, which, if confirmed in further studies, represents a paradigm shift in therapeutic decision-making based on current evidence.

Introduction: Clinically significant delayed bleeding (CSDB) is the most frequent complication after colorectal endoscopic submucosal dissection (ESD). The Limoges Bleeding Score was recently developed to identify patients at risk of CSDB after colorectal ESD. The efficacy of prophylactic clipping to prevent bleeding has been a topic of ongoing debate.

Aims & Methods: This study aimed to evaluate the real effectiveness of complete clip closure in preventing CSDB after colorectal ESD.

We performed a retrospective analysis of data prospectively collected from ten-centers between 2017 and 2023. Specifically, pre- and periprocedural data were collected prospectively, while post-procedural data,

including the evaluation of CSDB, was retrospectively assessed. All epithelial colorectal lesions treated by ESD were included. The patients were allocated into the closure and non-closure groups which were compared before and after propensity-score matching based on risk factors of the Limoges Bleeding Score (age > 75 yrs, size > 50 mm, ASA III-IV, location in rectum and anticoagulant/antiplatelet). We further analyzed post-ESD CSDB in the subgroups of patients on anticoagulants and with high risk of bleeding (5 to 8 points according to Limoges score).

Results: A total of 3431 patients were included, 1236 in the closure group and 1985 in non-closure group. The propensity score matching based on risk factors of the Limoges Bleeding Score created 1064 matches pairs. The rate of CSDB was not significantly different between the two groups (closure group 7.04% vs non-closure group 6.8%; $p = 0.85$), nor after propensity score matching (closure group 7.47% vs non-closure group 6.11%; $p = 0.38$). The subgroup analysis including patients on anticoagulants (165 patients in closure group vs 251 in non-closure group) and those identified at high-risk by Limoges score (181 in each group), found no significant difference of CSDB between the groups ($p = 0.31$ and $p = 0.16$, respectively).

Conclusion: In our population, prophylactic clipping after colorectal ESD did not significantly reduce the incidence of CSDB. These findings were confirmed even when the analysis was restricted to high-risk patients. Considering the technical challenges of complete clip closure, it could be reserved for selected clinical scenarios.

Introduction: Endoscopic Mucosal Resection (EMR) with Margin Thermal Ablation by Snare-tip Soft Coagulation (MTA) is effective to treat Large (>20mm) Non-Pedunculated Colorectal Polyps (LNPCP) with recurrence in large studies at <2%. Non-lifting LNCP (NL-LNPCP) account for approximately 10% of LNCP and are well managed by EMR with adjunctive Cold-forceps Avulsion with adjuvant Snare-Tip soft coagulation (CAST) for non-lifting areas, however recurrence occurs in >10%. We sought to evaluate the effect of MTA on NL-LNPCPs treated by EMR and CAST.

Aims & Methods: Prospective observational data on consecutive patients with NL-LNPCPs treated by EMR and CAST at a single tertiary center was evaluated. Two cohorts were established: the pre-MTA period (January 2012-June 2017) and the MTA period, (July 2017-October 2023). The primary outcome was the comparison of recurrence rates between the two groups at first surveillance colonoscopy at 6 months (SC1).

Results: From January 2012 to October 2023, 298 NL-LNPCPs in 298 patients (median age 69.1 years, interquartile range [IQR] 61.5-76.7 years, 43.4% male) underwent EMR and CAST (median size 36.0mm, IQR 24.7-54.2mm): 72 lesions pre-MTA and 226 with MTA. The MTA cohort had a higher rate of NL-LNPCP in complex locations (ileocecal valve, ano-rectal junction, appendiceal orifice) (18.6% vs 5.6%, $p=0.02$), granular lesions (61.9% vs 41.7%, $p=0.01$), and lesions with submucosal fibrosis (87.2% vs 72.2%, $p=0.05$). No differences were observed in procedural time. At SC1, recurrence was lower in the MTA cohort compared to the pre-MTA cohort (2.7% vs 9.7%, $p<.001$). Deep mural injury type III-V (4.4% vs 4.2%, $p=.93$) and post-procedural bleeding (5.3 vs 4.2%, $p=.94$) was similar between the MTA and pre-MTA cohort respectively. There was one case of delayed perforation in the pre-MTA group.

	EMR + CAST overall cohort n=298	EMR + CAST with no STSC margins n=72	EMR + CAST with STSC margins n=226	P value
Age, median (IQR) (years)	69.1 (61.5-76.7)	68.8 (61.0-76.6)	69.3 (59.5-79.1)	.76
Size of NL-LSL, median (IQR) (mm)	36.0 (24.7-54.2)	35.8 (26.7-44.9)	36.8 (23.5-50.1)	.59
Complex location (ileocecal valve, anorectal junction, appendiceal orifice) (n,%)	46 (15.4)	4 (5.6)	42 (18.6)	.02
Morphology, (n,%)				.01
Granular	170 (57.0)	30 (41.7)	140 (61.9)	
Non-Granular	101 (33.9)	31 (43.0)	70 (31.1)	
Mixed	13 (4.4)	3 (4.2)	10 (4.4)	
Consistent with SSL	4 (1.3)	3 (4.2)	1 (0.4)	
Unable to be classified	10 (3.4)	5 (6.9)	5 (2.2)	
Procedure duration, median (IQR) (min)	44.2 (23.8-64.7)	39.8 (17.8-61.8)	45.6 (21.6-69.6)	.38
Submucosal fibrosis (n,%)	249 (83.6)	52 (72.2)	197 (87.2)	.05
Delayed bleeding (n,%)	15 (5.0)	3 (4.2)	12 (5.3)	.94
Delayed perforation (n,%)	1 (0.3%)	1 (1.4)	0 (0)	.09
Recurrence at first follow-up (n,%)	13/216 (4.4)	7/66 (9.7)	6/150 (2.7)	<.001

Conclusion: The implementation of MTA significantly reduced recurrence at SC1 for NL-LNPCP treated by EMR with CAST. The refinement of CAST and addition of MTA in recent years has enabled the treatment of more complex lesions with greater effectiveness without compromising safety.

Introduction: Positive circumferential resection margin (CRM) after total mesorectal excision (TME) predicts higher local and systemic recurrence rates, affecting overall survival in rectal cancer patients. Although predictive factors for positive CRM have been identified for open, laparoscopic, and transanal TME, these may differ for robot-assisted TME (R-TME).

Aims & Methods: This study aimed to assess the incidence of positive CRM and to identify preoperative risk factors associated with this outcome following R-TME. An international multicenter retrospective study included patients receiving R-TME between January 2013 and January 2022 in participating Dutch, English, and French centers. Endpoints were the incidence of and predictive factors for positive CRM.

Univariate and multivariate logistic regressions were performed, and factors associated with positive CRM were then assessed by formulating a predictive model.

Results: Of 1390 patients undergoing R-TME, the incidence of positive CRM was 6.0% (83 cases). Multivariate analysis revealed significant associations between positive CRM and tumors located up to 1 cm from the anorectal junction, cT4 tumors, cN+ tumors, and non-sphincter-saving surgery (odds ratios of 1.91, 3.04, 1.84, and 2.02, respectively). The predictive model exhibited satisfactory discrimination (area under the receiver-operating characteristic curve 0.71) and predicted a 37% risk of positive CRM when all identified risk factors were present.

Conclusion: Preoperative tumor- and procedure-related factors, rather than patient-related factors, significantly influenced CRM involvement after R-TME. The proposed predictive model allows preoperative calculation of the risk of positive CRM, offering valuable insights for optimizing patient selection and tailoring treatment approaches to enhance oncological outcomes.

Introduction: Individuals with alcohol use disorder (AUD) are at high risk of liver disease. Despite international clinical practice guidelines recommend screening for liver fibrosis in at risk populations, information regarding fibrosis prevalence, predictive factors and screening strategies in patients with AUD is scarce. Recently, a novel score (LiverRisk score) has been developed to predict liver fibrosis and liver-related outcomes in the general population.

Aims & Methods: We conducted a screening program for liver disease in subjects who attended the Addiction Unit of the Hospital Clínic of Barcelona between 2019 and 2022. Data regarding socio-economic status, medical history and alcohol consumption were recorded. Blood tests and transient elastography (TE) were performed in all patients. The main aim of the study was to analyze the prevalence of significant liver fibrosis in patients with AUD.

The secondary objectives were to analyze the prevalence of advanced chronic liver disease in this population, identify the factors associated with the presence of significant liver fibrosis in patients with AUD and to evaluate the diagnostic accuracy of non-invasive liver fibrosis tests (Fibrosis-4 [FIB-4], NAFLD fibrosis score [NFS], Fatty Liver Index [FLI], AST to Platelet Ratio Index [APRI] and LiverRisk score) using TE as the Gold Standard. Significant liver fibrosis was defined as a liver stiffness (LS) value ≥ 8 kPa measured by TE. Advanced liver fibrosis was defined as a LS ≥ 15 kPa.

Results: Out of 334 total patients, 40 had significant liver fibrosis (prevalence of 12%). Out of the 40 patients with significant liver fibrosis, 19 (48%) had advanced chronic liver disease.

Multiple factors were associated with the presence of significant fibrosis in univariate analysis; however, on multivariate analysis BMI ($p=.04$) and GGT levels ($p=.001$) were confirmed as the only independent predictors. Regarding non-invasive tests, the LiverRisk score was the test with the best diagnostic performance for detecting significant liver fibrosis, with an area under the receiver operating characteristic (AUROC) of 0'854. All other tests had similar diagnostic performance, with AUROC of 0'799 (NFS), 0'798 (FIB-4), 0'797 (FLI) and 0'784 (APRI).

Conclusion: The prevalence of significant liver fibrosis (TE > 8 kPa) in population with at-risk alcohol consumption is high. BMI and GGT are the main factors associated with the presence of liver fibrosis and could be useful for selecting patients with higher risk. The most accurate serological test to assess liver fibrosis in our cohort is the LiverRisk score. These results demonstrate the usefulness of a screening program for early detection of liver disease in patients with AUD and support the implementation of screening programs in this population.

Introduction: The recommended treatment for severe complications of portal hypertension (PH) is transjugular intrahepatic portosystemic shunt (TIPS) implantation. Despite alcohol-related liver disease (ALD) representing the most frequent cause of advanced chronic liver disease (ACLD) and PH, literature on the effects of ongoing alcohol use (AU) after TIPS placement currently remains scarce.

Aims & Methods: The study population consisted of patients with ALD-related ACLD who had undergone TIPS implantation at two Viennese tertiary care centers (pooled cohort from the prospective AUTIPS study, NCT03409263: 01/2017–11/2022; and a retrospective cohort: 09/2000–09/2019). Through the electronic patient management system, individual demographic, laboratory, and clinical data were retrieved. AU after TIPS placement was investigated according to clinical documentation, serum ethanol quantification if available, and patients' reporting.

Results: Overall, the study population consisted of 276 patients (median follow-up 29 [IQR 54] months), 196 (71.0%) of which had received TIPS for refractory ascites while in 80 (29.0%) the indication for TIPS implantation had been variceal hemorrhage. The median age was 56 (IQR 13) years and 215 (77.9%) of the patients were men. At the time of the TIPS insertion, the median MELD was 11 (IQR 9) and 38 (13.8%) individuals were classified as Child-Pugh C. AU after TIPS placement was documented in 85 (30.8%) study participants. Baseline characteristics at TIPS implantation were similar in patients with and without post-TIPS AU, specifically regarding the prevalence of ascites ($p=0.51$), variceal hemorrhage ($p=0.87$), and hepatic encephalopathy ($p=0.87$).

Bacterial infections were more frequently detected among patients with ongoing AU (log-rank $p=0.002$). Importantly, patients with ongoing AU showed a higher incidence of acute-on-chronic liver failure (ACLF; log-rank $p<0.001$) and higher overall mortality (log-rank $p=0.005$; including liver-related death [log-rank $p<0.001$]).

Furthermore, cumulative incidence of ACLF ($p=0.014$) and liver-related death ($p=0.004$) were significantly higher in patients with ongoing AU. Of note, ongoing AU was independently associated with ACLF (aSHR: 1.66; 95%CI: 1.13–2.44; $p=0.010$) and liver-related death (aSHR: 2.09; 95%CI: 1.32–3.33; $p=0.002$) in multivariable competing risks regression analysis adjusted for age, MELD, and portal pressure gradient after TIPS implantation.

Conclusion: AU represents an independent risk factor for outcome deterioration after TIPS placement. These findings emphasize the paramount role of psychiatric care and harm reduction measures in addition to hepatological optimization after TIPS implantation.

THE PREVALENCE OF DYSGEUSIA IN PATIENTS WITH ADVANCED CHRONIC LIVER DISEASE (ACLD): RELATIONSHIP WITH THE LIVER-DISEASE PROGRESSION STATUS, AND IMPACT ON “MALNUTRITION-SARCOPENIA-FRAILITY TRIANGLE” (THE PREDYCI STUDY)

M. Dallio¹, M. Romeo¹, F. Di Nardo¹, C. Napolitano¹, M. Cipullo¹, A. Coppola¹, G. Iadanza¹, P. Vaia¹, S. Olivieri¹, A. Federico¹

¹University of Campania “Luigi Vanvitelli”, Department of Precision Medicine, Hepatogastroenterology Division, Naples, Italy

Contact E-Mail Address: marcello.dallio@gmail.com

Introduction: Malnutrition, sarcopenia, and frailty constitute the three vertices of a nutrition-status-determined physio-pathological triangle constantly featuring and dramatically burdening the prognosis of advanced chronic liver disease (ACLD) patients.

Dysgeusia is defined by a distortion of the sense of taste whose prevalence, relationship with the progression of the disease, and the direct contribution to malnutrition (and consequently, sarcopenia-frailty) in ACLD have never been systematically explored.

Aims & Methods: This observational study aimed to explore the prevalence of dysgeusia in a cohort of ACLD patients and evaluate the impact of this disorder on appetite levels and nutritional status (malnutrition, sarcopenia, and frailty), as well as to prospectively estimate the repercussions of dysgeusia-induced impaired nutritional status on liver-related events (LREs) occurrence. For this purpose, 40 controls, 50 chronic-liver disease-affected individuals staging initial-mild fibrosis (<F3), and 150 ACLD patients of various etiologies were enrolled. Anthropometrical, biochemical, clinical, and nutritional [European Prospective Investigation into Cancer and Nutrition (EPIC) questionnaire] data were collected. The opportunely modified Chemotherapy-induced Taste Alteration Scale (CITAS) questionnaire was used to assess the dysgeusia. Child-Pugh (CP) and Liver Frailty Index (LFI) calculations, Liver Stiffness Measurement (LSM), and Bioelectrical Impedance Analysis (BIA) were performed. Skeletal Muscle Mass (SMM) index (SMMI) ($\text{SMM}/\text{height}^2 < 7 \text{ kg}/\text{m}^2$ (male) and $< 5.7 \text{ kg}/\text{m}^2$ (female) defined sarcopenia. ACLD patients were 3 years followed up semiannually and LREs (including ascites, hepatic encephalopathy, and bleeding) were collected.

Results: The prevalence of dysgeusia was significantly higher in ACLD (68%) in comparison to <F3 (8%) individuals and controls (5%) and in decompensated ACLD (dACLD) than compensated (cACLD) (54% vs 6%) patients (all $p < 0.0001$). In line, CITAS-dysgeusia severity positively correlated with CP ($R: 0.81$), as well as with the levels of appetite impairment ($R: 0.93$) (both $p < 0.0001$). Logistic regression analysis, appropriately weighted for factors notoriously impacting food intake in ACLD patients (low-sodium diet, drugs/supplements taken, physical activity frequency, occurrence of encephalopathy and ascites episodes in the previous 2 weeks), revealed the level of impairment of the appetite as a factor significantly associated with dysgeusia [$\text{HR}: 2.12$; $p: 0.02$]. Compared to no-dysgeusia-affected dACLD ($p: 0.03$), dysgeusia-affected dACLD patients (dys-dACLD) showed a decreased daily protein intake, reduced Free Fat Mass % ($p < 0.0001$), and SMMI ($p < 0.0001$; $p: 0.04$), in contrast with increased LFI ($p < 0.0001$). Consis-

tently, dys-dACLD patients showed a higher prevalence (59% vs 39%) of sarcopenia ($p: 0.0002$). The Kaplan-Meier Log-Rank Test analysis on LREs occurrence showed $\text{HR}: 3.53$ [95% C.I.: 1.58-4.92] for dys-dACLD individuals.

Conclusion: The prevalence of dysgeusia, increasing in parallel to the worsening of liver disease, promoted sarcopenia-frailty pictures, negatively influencing ACLD patients' outcomes.

Introduction: Globally, rates of acute-on-chronic liver failure (ACLF) and hepatic decompensation necessitating hospitalisation are rising¹ and patients frequently have barriers to healthcare engagement including substance abuse, psychosocial stressors, and limited health literacy^{2,3}. Previous chronic disease management (CDM) programs have had variable impact on re-admission rates^{4,5}.

LivR Well is a 28-day, multidisciplinary, ambulatory intervention targeting the critical period after hospitalisation.

Aims & Methods: A randomised controlled study was conducted at an Australian, non-liver transplant hospital from February 2022 to March 2024. Patients with acute hepatic decompensation were recruited from inpatient admissions or outpatient clinic and randomised to LivR Well, or standard care in a 1:1 ratio. The control group received a hepatology consultation within 4 weeks of discharge and then at clinician discretion. The intervention group received a hepatology consultation weekly and allied health consultations as required from physiotherapist, dietitian, pharmacist, social worker, and/or addiction medicine specialist, coordinated by a hepatology clinical nurse consultant.

Follow up was to week 12. Quality of life instruments were performed at baseline, week 6 and week 12. The primary outcome was 30-day re-admission. Secondary outcomes were 28-day mortality, patient reported outcomes, and change in liver disease severity.

Results: Eighty nine patients were recruited with a combined median age of 56 years (IQR: 47-65), a median baseline Model for End-Stage Liver Disease-Sodium (MELD-Na) score 19.5 (IQR: 16-23), median Child-Pugh score 10 (IQR: 8-11), 71.1% were male, and 26.7% had ACLF. The primary liver disease aetiologies were alcohol (74.4%) and metabolic dysfunction-associated fatty liver disease (16.7%). There were no differences in baseline characteristics or median index admission length of stay (LOS) between intervention and control groups.

There was no difference in readmission rates in LivR Well vs. control group at 30 days (Incidence Rate Ratio 1.28, 95%CI 0.50-3.45, $p=0.58$), 90 days (IRR 1.0, 95%CI 0.56-1.81, $p=0.99$), or 6 months (IRR 0.99, 95% CI 0.63-1.55, $p=0.95$). The median MELD-Na improved in both groups. Attrition was similar in control and LivR Well (17.5% vs. 16.3%, $p=0.59$), with half those in LivR Well never commencing the program.

	Total (n=90)	Control (n=40)	Intervention (n=49)	p-value
Total mortality, n(%)	19 (21)	8(20)	11 (22)	0.43
Time to death, median (IQR)	117 (57-245)	115 (50-242)	203 (57-262)	0.30
MELD-Na, median (IQR)	Baseline 19.5 (16-23)	20(16-23)	18 (16-22)	0.30
	28-day 15 (9-21)	14 (11-21)	15(9-20)	0.94
EQ-5D VAS, median (IQR)	Baseline 54 (35-70)	60 (45-67)	50 (35-70)	0.03
	Week 12 77 (40-85)	77 (50-88)	76 (35-85)	0.66

There was no difference in mortality rate with a total 19 deaths over follow up, at a median days post randomisation of 115 (IQR: 50-242) and 203 (IQR: 57-462) respectively ($p=0.30$), and 28-day mortality was 0%. Health-related quality of life measured with the Chronic Liver Disease Questionnaire overall score and a self-reported visual analogue scale improved from baseline in both groups.

Conclusion: A multidisciplinary, ambulatory intervention did not reduce 30-day re-admission rates in patients admitted with hepatic decompensation. In a population with challenging healthcare engagement reflected in dropout rates, improvements in liver disease severity and quality of life were observed but not attributable to the intervention. Additionally, no deaths within 28-days, and a trend towards longer time to death may reflect medium-long term benefits of this unique program not yet captured.

MAS1 DEFICIENCY PROTECTS AGAINST ACUTE LIVER FAILURE BY SUPPRESSING THE FXR/S1P/RAF-DEPENDENT NETOSIS IN MICE

B. Yang¹, J. Li¹, C. Yang¹

¹Tongji University, School of Medicine, Tongji hospital, Division of Gastroenterology and Hepatology, Shanghai, China

Contact E-Mail Address: cqyang@tongji.edu.cn

Introduction: Mas is a newly discovered G protein-coupled receptor that plays a critical role in inflammatory responses. The gut-liver axis regulated neutrophilic inflammation is crucial in acute liver failure (ALF); however, the underlying mechanisms remain poorly understood.

Aims & Methods: The aim of this study is to investigate Mas signaling and neutrophilic inflammation in ALF, and to elucidate its underlying mechanisms. The 8-10 week-old male *Mas1^{-/-}*, *Vil1^{cre}Mas1^{fl/fl}*, and wild-type control mice were subjected to intraperitoneal challenge with D-galactosamine/lipopolysaccharide (D/L) for *in vivo* analysis of the gut-liver axis-dependent formation of neutrophil extracellular traps (NET), utilizing pharmacological compounds and genetic tools. Age-matched mice received injections of phosphate-buffered saline as vehicle controls.

Results: The hepatic expression of Mas was significantly upregulated in ALF patients and mice models. The knockout of the *Mas1* gene in both systemic and intestinal epithelial cells significantly alleviated D/L-induced NETosis and hepatotoxicity in mice. The involvement of gut microbiota in the attenuated hepatotoxicity of *Mas1^{-/-}*-D/L mice was confirmed through antibiotic experiments. The co-housed experiments between *Mas1^{-/-}* and WT mice have demonstrated that *Mas1^{-/-}* may confer protection by reducing the intestinal abundance of *Eubacterium* sp. and inhibiting deoxycholic acid (DCA) production. This was accompanied by hepatic activation of farnesoid X receptor (FXR) signaling and suppression of downstream sphingosine-1-phosphate (S1P)-dependent NETosis. As revealed by single-cell transcriptomics, the downregulation of NETosis in *Mas1^{-/-}*-D/L mice was found to be dependent on the senescence of *Cldn1⁺CD177⁺* neutrophils and the activation of Raf signaling.

Conclusion: *Mas1^{-/-}* significantly protects mice from D/L-induced hepatotoxicity by suppressing the FXR/S1P/Raf-dependent NETosis, thereby suggesting Mas as a promising therapeutic target for ALF.

Disclosure: Nothing to disclose.

Introduction: Esophageal and gastric variceal bleeding is a life-risk complication of portal hypertension, with a high mortality. Recently, the number of patients with unexplained portal hypertension is gradually increasing¹. Non-cirrhotic portal hypertension caused by pre-hepatic/post-hepatic causes can also cause esophageal and gastric varices, of which the clinical diagnosis and treatment are still difficult². Oxaliplatin (Op) is a first-line drug in chemotherapy regimens for many kinds of cancers³, while the incidence of portal hypertension (PH)-related symptoms during follow-up of Op-treated patients without prior liver disease is increasing⁴. Chronic liver damage and portal hypertension caused by platinum-based drugs have an insidious onset and almost half of them are diagnosed due to the emergency treatment for esophageal and gastric variceal bleeding, which is highly dangerous and affects the long-term survival of patients⁵. To date, oxaliplatin-related PH studies are mainly clinical reports, and the underlying mechanisms are unclear.

Aims & Methods: We aimed to explore the pathology, mechanisms and key molecular players and potential pharmacological prevention of Op-induced PH. Gene expression profiles related to Op treated vs normal human livers were obtained from the GEO database, to identify key mol-

ecules and pathways via differentially expressed genes (DEG). OP-induce PH was induced in rats and liver transcriptome profiles were compared with the human samples, and key signatures confirmed by PCR. Since main Op-induced signatures were due to hepatocytes, human hepatocytes LO2 were treated with Op, and molecular responses measured in these cultures and in cultures of primary human liver sinusoidal endothelial cells (HHSEC) exposed to LO2-conditioned media.

Results: Totally, 19 Op-treated and 5 Op-treated rats were analyzed with 5 and 3 controls, respectively. Liver samples from Op-treated patients showed apparent hepatic sinusoidal dilatation. PH was induced by a 6-week Op treatment in rats, with sinusoidal endothelial activation and perivenous monocyte-macrophage infiltration, while a classical sinusoidal obstructive syndrome was missing. Hyaluronan synthase 2 (HAS2) and prominently the ERK pathway were upregulated after Op treatment in both rats and patients. Op-treated LO2-hepatocytes showed the activation of ERK pathway, and the up-regulation of HAS2; Co-culture of HHSEC and Op-treated LO2-hepatocytes showed that mediators released from LO2 cells induced HHSEC activation: up-regulated von Willebrand and tissue factor, increased migration, and activation of the ERK pathway. Notably, HHSEC migration was also increased after hyaluronic acid (HA) treatment, confirming an important role of HAS2 in Op-induced pathology.

Conclusion: Activation of the MAPK/ERK cascade is central to Op-induced PH. This pathway is implicated in the upregulation of HAS2 in hepatocytes, which releases HA, which activates sinusoidal endothelial cells, resulting in LSEC damage and subsequent portal hypertension.

Introduction: Copeptin is a stable surrogate biomarker for the activation of the arginine vasopressin (AVP) system [1] as occurs in patients with cirrhosis and clinically significant portal hypertension (CSPH). Specifically, CSPH-induced haemodynamic alterations characterized by reduced peripheral vascular resistance and splanchnic hyperemia cause subsequent AVP system activation [2]. We aimed to evaluate serum copeptin levels (i) in different stages of cirrhosis and (ii) their prognostic value for clinical events in a cohort of stable outpatients with cirrhosis.

Aims & Methods: Stable outpatients with cirrhosis undergoing hepatic venous pressure gradient (HVPG) measurements and available copeptin levels were included; while patients with liver transplantation, malignancy, vascular liver disease, transjugular intrahepatic portosystemic shunt, heart failure and infection were excluded. Patients were stratified into 6 subgroups (S0-S5) for their clinical stage of cirrhosis, with S0-S2 representing compensated cirrhosis (S0: subclinical portal hypertension (PH) with an HVPG of 6-9 mmHg, S1: CSPH without varices, S2: CSPH with varices) and S3-S5 decompensated cirrhosis (S3: history of variceal bleeding, S4: non-bleeding decompensation, S5: further decompensation). Competing risk regression models were used to evaluate the association between copeptin levels and the risk of acute on chronic liver failure (ACLF) and liver-related death (LRD). Liver transplantation was considered as a competing event. Our previously established serum copeptin cut-off at >11.4 pmol/L [3] was used to stratify the patients into a high vs. low AVP system activation group.

Results: In total, 475 patients (S0: n=49, S1: n=53, S2: n=75, S3: n=22, S4: n=156, S5: n=120) with male predominance (72.6%; median age: 57.1 years) were included. Median follow-up time was 26.4 months. Median copeptin levels significantly increased throughout the substages of ACLD (from S0: 7.5 pmol/L to S5: 14.3 pmol/L; p<0.001). Patients with ascites had significantly higher copeptin levels (11.3 pmol/L vs. 7.2 pmol/L in non-ascites patients; p<0.001).

Serum copeptin correlated significantly with C-reactive protein (p=0.281; p<0.001) and interleukin-6 levels (p=0.416; p<0.001) in patients with decompensated cirrhosis.

AVP system activation (i.e., Copeptin high >11.4 pmol/L) was found in n=194/475 (40.8%) patients. Patients with high-Copeptin had a significantly higher median MELD-Na (15 vs. low-Copeptin: 12; p<0.001) as well as significantly lower median mean arterial pressure (97 mmHg vs. low-Copeptin: 101 mmHg; p=0.027). The cumulative incidence of ACLF and LRD was significantly higher in patients with high-Copeptin at 1 year (ACLF: 24.1% vs. 4.0%; LRD: 21.9% vs. 4.0%), 2 years (ACLF: 32.0% vs. 7.2%; LRD: 26.7% vs. 6.3%) and 3 years (ACLF: 34.4% vs. 11.6%; LRD: 29.9% vs. 11.2%) of follow-up (p<0.001 for ACLF and LRD).

In competing risk regression adjusted for age, Child Turcotte Pugh score, creatinine, sodium and HVPG, higher levels of copeptin were independently predictive of ACLF (adjusted subdistribution hazard ratio [asHR] per pmol/L: 1.01; 95% confidence interval [95%CI]: 1.00-1.01; $p=0.014$), as well as LRD (asHR: 1.01; 95%CI: 1.00-1.01; $p=0.024$).

Conclusion: In ACLD, copeptin levels are upregulated with increasing disease severity suggesting progressive AVP system activation, associated with hemodynamic dysregulation and systemic inflammation. High-Copeptin represents an independent risk factor for ACLF and LRD development.

Introduction: The Baveno Consensus Workshops recommend gastroscopy for advanced chronic liver disease (CLD) patients to detect varices, with Grade 2 or 3 varices advised to receive prophylactic treatment using non-selective beta blockers (NSBB) or band ligation [1-2].

Western Health (WH) is a tertiary health service serving a population of 1.2 million, primarily in socioeconomically disadvantaged Melbourne suburbs with a high density of non-English speaking background (NESB) immigrants with low health literacy [3-4]. This demographic presents challenges such as poor health service engagement, impacting guideline adherence and patient management.

Aims & Methods: The objective of this study is to evaluate adherence to the Baveno criteria for variceal management among CLD patients at WH. We retrospectively collected data from the electronic medical records of all CLD patients admitted to WH in 2021. We documented demographics, presenting complaints, underlying liver disease, adherence to varices screening and treatment. Univariate and multivariable logistic regression assessed predictors of liver-related mortality, which is defined as death resulting directly from a CLD complication at a 2-year follow-up.

Results: Our study included 275 CLD patients (mean age 60 years, SD 13; 64% male), 142 (52%) were born in Australia and 116 (42 %) were immigrants from NESB. The leading causes of CLD were alcohol-related (62%, $n=169$), metabolic liver disease (20 %, $n=56$), Hepatitis C (15 %, $n=42$) and B (4 %, $n=10$). Cirrhosis developed in 92 % ($n=253$) of patients, with 30 % ($n=75$) classified as Child-Pugh score A, 40 % ($n=102$) as B, and 30% ($n=76$)

as C. Ascites (23.3%, $n=64$), hepatic encephalopathy (16%, $n=44$), and variceal bleeding (9.5%, $n=27$) were the common presenting complaints. 245 patients met BAVENO criteria for variceal screening, 77.6% ($n=190$) underwent gastroscopy, revealing Grade 1 varices in 33.6% ($n=43$) and Grade 2 or 3 varices in 36.7% ($n=47$). Follow-up gastroscopy was scheduled for 56.7% ($n=21$) without initial varices and 75.6% ($n=31$) with Grade 1 varices. Among those with Grade 2 or 3 varices, 80.9% ($n=38$) underwent variceal banding, with 94.7% ($n=36$) receiving follow-up gastroscopy. However, only 19.1% ($n=9$) were prescribed NSBB. Of the 27 variceal bleeding cases, 21 warranted varices screening, yet only 11 had prior gastroscopy. Within these, 6 patients had Grade 1 and 1 had Grade 2 varices. The Grade 2 varices were ligated but NSBB was not initiated.

Univariate regression showed correlation between reduced liver-related mortality and variceal screening (OR 0.42, 95% CI 0.22-0.81, $p=0.01$) as independent variable, confirmed by multivariate logistic regression, after adjusting for confounders like age and Child-Pugh scores. Intriguingly, among unscreened patients, the most common cause of death is infection ($n=10$, 16.1%), only 4 had variceal bleeding with no resulting deaths. This is possibly due to selection bias as high-risk patients with prior varices bleeding history were more likely to be connected to the service.

Conclusion: Our study shows that variceal screening reduces liver-related mortality, yet it also reveals deficiencies in the current clinical approach to screening and treating varices at WH. These deficiencies may arise from various challenges, including communication barriers such as language constraints or time limitations in outpatient clinics, as well as patient factors such as limited health literacy resulting in poor compliance. Efforts should be directed towards improving the uptake of varices surveillance and enhancing the utilization of NSBB among patients.

SPLEEN STIFFNESS BY SHEAR-WAVE ELASTOGRAPHY AS AN INDICATOR OF PORTAL HYPERTENSION AND RESPONSE TO PREEMPTIVE TIPS PLACEMENT: A PROSPECTIVE STUDY

D. Feijó¹, C. Borges Chaves¹, D. Perdigoto¹, B. Rato², P. Donato², P. Narra Figueiredo¹

¹ULS Coimbra, Gastroenterology, Coimbra, Portugal, ²ULS Coimbra, Radiology, Coimbra, Portugal

Contact E-Mail Address: diogofeijo96@gmail.com

Introduction: Portal hypertension (PH) is a significant complication of advanced chronic liver disease (ACLD), often leading to acute variceal bleeding (VB), a life-threatening emergency. Preemptive transjugular intrahepatic portosystemic shunt (pTIPS) has become a critical intervention in managing PH-related complications, specifically in reducing the risk

of re-bleeding. The hepatic venous pressure gradient (HVPG) is the gold standard for assessing PH severity, but its invasive nature necessitates the exploration of non-invasive alternatives.

Aims & Methods: This study aimed to investigate the role of spleen stiffness, measured through shear-wave elastography (SWE), as a non-invasive predictor of PH severity and its correlation with HVPG in ACLD patients undergoing pTIPS after acute VB. We conducted a prospective study correlating spleen stiffness, measured by shear-wave elastography (SWE), with HVPG in ACLD patients (Child-Pugh class C<14 or B>7 with active bleeding) undergoing pTIPS placement following acute VB. Eleven patients with pre- and post-TIPS spleen stiffness measurements were included.

Results: Spleen stiffness was positively correlated with both pre-TIPS HVPG (Spearman's coefficient $r=0.527$; $p=0.145$) and post-TIPS HVPG ($r=0.719$; $p<0.05$). Furthermore, spleen stiffness significantly decreased after p-TIPS placement (pre-pTIPS: 36.42 [IQR 6.06] vs. post-pTIPS: 28.94 [IQR 7.80]; $p<0.05$), while the decrease in liver stiffness measurement was not statistically significant.

Conclusion: The results of this prospective study indicate that spleen stiffness, as measured by SWE, offers a valuable non-invasive method for assessing portal hypertension severity in patients with ACLD. We found a positive correlation between spleen stiffness and both pre- and post-TIPS HVPG. Additionally, significant reductions in spleen stiffness post-TIPS suggest that this metric can serve as a useful tool for monitoring patient response to pTIPS and potentially predicting outcomes. These findings highlight the importance of incorporating spleen stiffness measurement into the clinical management of patients with PH undergoing pTIPS, providing clinicians with an additional tool for assessing treatment efficacy and guiding patient care. Further research with larger cohorts is recommended to confirm these results and establish spleen stiffness as a reliable non-invasive alternative for PH assessment.

Disclosure: Nothing to disclose.

EARLY PREDICTION OF CORTICOSTEROID RESPONSE AND MORTALITY IN PATIENTS WITH SEVERE ALCOHOLIC HEPATITIS

H.-O. Minea¹, A.M. Singeap¹, C.M. Muzica¹, S. Zenovia¹, C. Sfarti¹, I. Girleanu¹, S. Chiriac¹, R. Stafie¹, A. Rotaru¹, R. Nastasa¹, S. Ermina¹, S. Juncu¹, C. Stanciu¹, A.-V. Trifan¹

¹University of Medicine and Pharmacy Gr.T.Popa/Institute of Gastroenterology and Hepatology Iasi, Gastroenterology, Iasi, Romania

Contact E-Mail Address: horia.minea@yahoo.com

Introduction: Alcoholic hepatitis (AH) represents a medical challenge, from moderate to life-threatening episodes, with high mortality. This study aimed to compare prognostic scales to evaluate early response to corticosteroids and prediction to 28 days and 90 days mortality in patients with severe AH.

Aims & Methods: We performed a retrospective study that included patients with severe AH (Maddrey/MDF score ≥ 32) admitted to a tertiary center. Clinical and paraclinical data were collected on the response to corticosteroid administration and were assessed based on Lille scores (from days four and seven) and neutrophil to lymphocyte ratio (NLR) calculated on admission. MELD (Model for End-Stage Liver Disease), MELD-Na, MELD 3.0, ABIC (age-bilirubin-INR-creatinine), Maddrey and Glasgow scale scores were used to predict survival at 28 and 90 days, respectively. AH.

Results: Out of 310 patients enrolled with severe AH, 59% received corticosteroids, achieving a response rate of 75.4%. Lille score on day four presents a better performance than NLR in early anticipation of a response to

corticotherapy ($R^2=0.824$ versus $R^2=0.233$, $p<0.001$). Predictive factors for non-response were identified: presence of cirrhosis (OR= 2.11, $p<0.001$), MELD scores exceeding 30 (OR=2.42, $p<0.001$), hypoalbuminemia (<2.8 g/dl) (OR=2.46, $p<0.001$), and increased serum creatinine (OR=1.5, $p<0.001$). Non-responders have a five times higher risk of developing infections compared to responders (OR=6.74, versus OR=1.34, $p<0.001$). Among the prognostic scores, MELD 3.0 score proved superior efficacy for 28 days (AUC=0.734) and 90 days mortality (AUC=0.777) compared to alternative scoring systems.

Conclusion: An improvement in risk stratification based on the implementation of therapeutic response evaluation scores and mortality prediction, represent tools with applicability for adjusting the treatment scheme and prioritizing patients who require liver transplantation.

DECIPHERING THE REGULATORY ROLE OF LONG NON-CODING RNA IN PANCREATIC DEVELOPMENT AND DIABETES

S. Heller¹, S. Merz¹, C. Julier², A. Kleger¹

Introduction: Gene regulatory networks play a vital role in pancreatic development and function. However, pathomechanisms associated with the non-coding genome are just starting to be discovered. Our recent work demonstrated that mutations in the *ONECUT1* gene are responsible for a new neonatal diabetes syndrome in homozygous patients, whereas heterozygous carriers develop early-onset diabetes. Stage-specific characterization of *in vitro* differentiated human embryonic stem cells (hESC) revealed that *ONECUT1* plays an important role in transcriptional regulation during pancreatic progenitor formation and the initiation of the endocrine developmental program.

Nonetheless, the complex regulation is only partly uncovered. While investigating the *ONECUT1* locus, we found a variant most strongly associated with T2D (rs2440374). This variant is located within the lncRNA RP11-209K10.2 (further lncRNA-RP11), 11 kbp distant to *ONECUT1*. GTEx Portal database shows decreased lncRNA-RP11 expression in the pancreas in the presence of the T2D-associated allele.

Also, this SNP disrupts a binding motif for transcription factor NKX2.2 essential for endocrine pancreas development and pancreatic islet-cell fate. Since promoters of lncRNAs can also act as enhancer elements stimulating the regulation of neighboring genes, we hypothesize that the lncRNA-RP11 locus plays an important role in regulating *ONECUT1* and that disturbance of this transcriptional network promotes diabetes onset.

Aims & Methods: After deletion of lncRNA-RP11, hESC were differentiated into the pancreatic endocrine lineage followed by characterization of the developmental stages.

Results: Although differentiation of pancreatic progenitors is not impaired by the loss of the regulatory region, stem cell-derived islets further generated from these progenitors exhibit reduced number and function of beta-cells supporting an involvement during pancreas differentiation. The transcript of lncRNA-RP11 with main localization in the nucleus follows similar stage-specific dynamics as *ONECUT1* allowing for several modes of action.

Conclusion: Next, a comprehensive mechanistic characterization will provide insights into the exact function of lncRNA-RP11 in pancreatic endocrine development and pathophysiology. Thus, identifying novel molecular mechanisms involved in diabetes will improve our understanding of the transcriptional landscape and lay the groundwork for personalized diabetes treatment.

Introduction: Individuals with the Dutch founder *CDKN2A*/p16-Leiden pathogenic variant (PV) have an increased lifetime risk of melanoma (70%) and pancreatic cancer (20%). Consequently, skin surveillance is offered from the age of 12 to those with a confirmed or suspected PV, while pancreatic cancer surveillance is exclusively offered to confirmed carriers from the age of 40. It is unknown whether the *CDKN2A* PV impacts quality of life (QoL). Therefore, we aimed to assess QoL and psychological distress in individuals from affected families.

Aims & Methods: This cross-sectional study included confirmed carriers and those with a 50% risk of the *CDKN2A* PV (at-risk carriers) undergoing cancer surveillance. Individuals ≥ 18 years were identified from the skin and pancreatic cancer surveillance programs at the Leiden University Medical Center and invited for a one-time, validated self-report questionnaire, including the 12-Item Short Form Health Survey (SF-12), Hospital Anxiety and Depression Scale (HADS), and Cancer Worry Scale (CWS).

Scale	Scale range / threshold	Skin surveillance group (N = 59)	Pancreatic surveillance group (N = 188)	General population
		Mean (±SD) % > threshold	Mean (±SD) % > threshold	Mean (±SD) % > threshold
Health-related QoL				
SF-12 PCS	Range 0-100	54.7 (6.6)**	50.4 (8.1)**	51.7 ¹ / 48.1 [‡]
SF-12 MCS	Range 0-100	46.9 (10.1)	51.4 (8.8)	48.0 ¹ / 51.0 [‡]
General and cancer-related distress				
HADS - anxiety	Range 0-21 Abnormal threshold ≥ 11	4.7 (3.7) 6 (10%)	4.0 (3.6)** 11 (6%)	5.1 (3.6) [§] -
HADS - depression	Range 0-21 Abnormal threshold ≥ 11	2.8 (3.1) 2 (3%)	2.7 (2.8)* 3 (2%)	3.4 (3.3) [§] -
CWS - melanoma-related worries	Range 8-32 Abnormal threshold ≥ 14	12.7 (3.2) 26 (44%)	13.4 (3.9) 76 (40%)	-
CWS - pancreatic-related worries	Range 8-32 Abnormal threshold ≥ 14	11.4 (3.0) 10 (17%)	13.6 (3.9) 84 (45%)	-

Table 1. Descriptive statistics and summary of group comparisons for psychological variables

**P<0.01. *P<0.05. SF-12, 12-item Short Form Health Survey; PCS, Physical Component Scale; MCS, Mental Component Scale; HADS, Hospital Anxiety and Depression Scale; cancer worries measured by the adapted Cancer Worry Scale (CWS). Scores of the SF-12 ranged from 0-100, with higher scores indicating better health. The HADS cut-off score was ≥ 11 , indicating a clinically significant anxiety or depressive disorder. The CWS cut-off score was ≥ 14 , indicating increased cancer-related distress. ¹ age-matched QoL norm scores from Dutch general population with skin surveillance group. [‡] age-matched QoL norm scores from Dutch general population with pancreatic surveillance group. [§] HADS scores were compared with 199 individuals from the general Dutch population. ²

Results: A total of 537 individuals were screened for eligibility, of whom 59/249 (24%) individuals under skin surveillance (skin surveillance group) and 188/288 (65%) individuals under combined pancreatic cancer and skin surveillance (pancreatic cancer surveillance group) responded. In both surveillance groups, health-related QoL and general distress levels were within the general population norms (Table 1). However, more than 40% of all study participants reported melanoma-related distress. Pancreatic cancer-related distress was experienced by 45% of the pancreatic surveillance group. Determinants of cancer-related distress were a first-degree relative with melanoma or pancreatic cancer, increased cancer risk perception, and poor general health perception. Over 80% of the participants felt that the benefits of cancer surveillance outweigh the disadvantages.

Conclusion: In conclusion, confirmed and at-risk carriers of the *CDKN2A* PV experienced similar levels of QoL and general distress compared with the general population. However, cancer-related worry was substantial in this population. These findings can help identify individuals who may benefit from psychological support.

Introduction: Pancreatic cancer is a highly fatal disease with a 5-year survival rate of approximately 10%. Pancreatic ductal adenocarcinoma (PDAC) is characterized by abundant collagen deposition in the tumor stroma. However, the precise impact of this phenomenon on PDAC remains unclear.

Aims & Methods: This study aimed to clarify the interactive relationship between tumor stromal collagen and its molecular characteristics, immune characteristics, and tumor progression in human PDAC. The goal is to elucidate the mechanism of fibrosis in PDAC. A comprehensive examination was performed using a molecular pathological epidemiology database on 169 cases with resected PDAC.

Among 234 patients who underwent pancreatectomy surgery between April 2008 and March 2017 at Kobe University, 169 conventional PDAC patients were analyzed. Patients with special type pancreatic cancers, with stage IV PDAC, who underwent preoperative radiation, and without available FFPE samples were excluded. The following information was collected retrospectively about these patients: age, gender, body mass index, family history, blood test results, surgical pathology specimen, and treatment course.

We quantified the amount of tumor stromal collagen by digitally processing EVG-stained whole-section slides. Gene alterations (KRAS, TP53, *CDKN2A/p16*, and *SMAD4*), immune parameters (CD4+ tumor-infiltrating

lymphocytes [TILs], CD8+ TILs, FOXP3+ TILs, and tertiary lymphoid structures), and marker of cancer-associated fibroblasts such as α SMA were evaluated by immunohistochemistry, next-generation sequencing, and droplet digital PCR.

Results: Multivariate logistic regression analysis revealed that low stromal collagen levels were linked to poor differentiation ($P=0.008$) and *CDKN2A/p16* alteration ($P=0.03$) of PDAC. Additionally, low stromal collagen levels were found to be an independent poor prognostic factor. The overall survival of such patients was significantly shorter (22.1 months vs. 38.0 months, $P=0.001$).

Regarding those who underwent chemotherapy, low amounts of stromal collagen were linked to poor prognosis in the S-1 ($P=0.005$) and gemcitabine ($P=0.007$) treatment groups. Furthermore, they were linked to low levels of CD4+ tumor-infiltrating lymphocytes (TILs) ($P=0.046$), CD8+ TILs ($P=0.09$), and tertiary lymphoid structures ($P=0.001$).

The mechanism by which fibrosis is associated with prognosis is not well-defined. The components of tumor microenvironment are diverse, including cancer cells, fibroblasts, immunocompetent cells, and extracellular matrix. Thus, we explored comprehensively the factors and mechanisms that define fibrosis with Spatial Transcriptome. Gene expression analysis was performed using two sets of four cases with different amounts of stromal collagen. The gene expression could be classified into 7 clusters. The cancer cells in the low amounts group consisted of one cluster and those in the high amounts group consisted of two clusters on the hand. Enrichment analysis on the distinctive cluster in the high amounts group revealed that it was genes that activated the TGF β pathway.

Conclusion: The amount of tumor stromal collagen varies in tumor characteristics, prognosis, and response to postoperative chemotherapy in PDAC, and may affect the modulation of the tumor immune microenvironment. We found that there is a group of genes that are characteristically expressed in PDAC with high amounts of stromal collagen and a good prognosis. Further studies will be conducted to elucidate the mechanisms that regulate fibrosis.

Disclosure: Nothing to disclose.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the seventh leading cause of cancer related death worldwide, with a progressive increasing incidence¹ and 5 years overall survival (OS) of 12.5% irrespective of the disease stage². Given the tumor biological aggressiveness and the limited response to chemotherapy, it arises the need to develop preclinical study models able to understand the underlying mechanism of tumor progression and chemoresistance³. These models need to be easily generable, reproducible, representative of the entire population affected by PDAC and to have the ability of mimicking the cancer behavior. Patients derived organoids (PDOs) are models of epithelial cells with self-regeneration and self-organization abilities able to behave and mimic the tumors of origin⁴. Liquid biopsy has also gained importance in tailoring the treatment for oncological patients, although the role of bile as biological fluid in patients affected by biliopancreatic malignancies is still uncertain.

Aims & Methods: We performed a prospective observational study aiming to evaluate the feasibility to create tridimensional PDOs from fine needle biopsy (FNB) samples of patients affected by PDAC and to correlate PDOs with native cancer histology. The secondary endpoint of our study was to assess the feasibility of using bile as biological fluid for cell free DNA (cfDNA) and to investigate the landscape of cfDNA in bile and plasma of patients affected by PDAC.

Patients with strong suspicion or recent diagnosis of PDAC and concomitant jaundice were included. Each patient underwent EUS guided FNB (EUS-FNB) for histological diagnosis and organoid collection was performed. By the time of biliary drainage, bile and plasma were collected for DNA extraction and analysis.

Results: From June 2023 to September 2023, 36 patients with neoplastic jaundice were evaluated. Eighteen patients with final diagnosis of PDAC have been included in the study. Eighteen underwent biliary drainage with collection of bile and plasma. Sixteen underwent EUS-FNB for organoid collection.

Mean tumor size was 33.7±9.6 mm. Tumor was located in the head of pancreas in 94.4% of cases. Nine patients (50%) were metastatic by the time of diagnosis, eight patients (44%) had locally advanced disease and only one patient was considered resectable. Tissue acquisition was performed using FNB needles. Organoids establishment rate was successful in 100% of cases. No EUS-FNB related adverse events were observed.

At a quality concordance pathological analysis between PDAC and PDOs, morphological similarities have been observed in all cases (100%). Cellular morphology and nuclei atypia were the most consistent similarities. Organoids showed a glandular over expression compared to native PDAC. Extracted cfDNA was significantly higher in bile supernatant than in plasma (2.9 ng/ml vs 19.8 ng/ml p=0.0001). No significant differences were found for plasma and bile cfDNA among disease stages. Higher level of bile cfDNA in locally advanced disease and a trend of higher level of plasma cfDNA in metastatic stage. Bile cfDNA showed longer DNA fragment compared to plasma.

Conclusion: Organoids establishment is feasible and safe with a single passage of EUS-FNB. PDOs maintain the morphological architecture of native cancer, although the absence of dense stromal reaction leads to a remarkable organoids ability to create glandular structures. Qualitative and quantitative composition of ctDNA is superior in bile rather than in plasma, making this fluid an important tool for NGS analysis and a better comprehension of tumor mutations.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease with the lowest 5-year survival rate of all cancers due to late diagnosis and lack of effective treatment. One of the challenges of developing molecular diagnosis and molecular targeted therapy for PDAC is the “mismatch” between research models and patients.

Aims & Methods: This study aimed i) to identify common proteins among different research models and patients and accordingly ii) to identify potential hub proteins and signaling pathways involved in the PDAC pathogenesis by using proteomics-based system modeling of multimodal datasets derived from multiple research models and patients. Mouse PDAC cells (derived from a genetically engineered mouse model with KrasG12D/Pdx1-Cre), PDAC orthotopically tumors in C57B/L6 mice (n=5), mouse PDAC spheroids, mouse pancreatic organoids, mouse PDAC organoids, normal mouse pancreatic tissues (n=5), human PDAC tumor tissue samples from treatment-naïve (n=20), neoadjuvant chemotherapy (n=22), and human PDAC organoids were included. Mass spectrometry-based proteomics, Rstudio, Cytoscape 3.10 and pathway enrichment analysis (using ingenuity pathways analysis, including human PDAC transcriptomic in addition) were used.

Results: In the comparison of PDAC models and patients, shared proteins were identified as follows: 60% between the mouse PDAC cells and the mouse PDAC spheroids, 78% between the mouse PDAC cells and the mouse PDAC tissue, 56% between the mouse PDAC spheroids and the mouse PDAC tissue, 66% between the mouse PDAC cells and the mouse PDAC organoids, 54% between the mouse PDAC spheroids and the mouse PDAC organoids, 38% between the mouse PDAC and the human PDAC tissues, 31% between the human PDAC tumor and the human PDAC organoids, and 60% between the mouse and the human PDAC organoids. A total of 1,367 common proteins were identified within all the PDAC models. Among these proteins ACTB, HSP90AA1, HSPA8, HSP90AB1, HSPA4, EEF2, RPS3, RPS20 and GAPDH were the top 10 hub proteins (with >300 node connections). Upon comparison of all eight models, eight proteins were identified as unique to PDAC, namely FAHD1, ARSA, NEK9, SERPINB9, LAMTOR2, SNRPG, TMED3, and RAB1A. There was a correlation in terms of z-score regarding signaling pathways between the mouse PDAC and human PDAC ($p < 0.001$), particularly in activations of nerve growth factor signaling, integrin signaling, and neuregulin signaling. Central hub proteins commonly found in the mouse models included vinculin (membrane-cytoskeletal protein) as one of the high connectivity nodes and β -catenin

and probable ubiquitin carboxyl-terminal hydrolase FAF-X (involved in axonal growth and neuronal cell migration) as high centrality nodes. In patients, central hub proteins that were dysregulated after chemotherapy included 14-3-3 protein zeta/delta (encoded by YWHAZ gene), β -catenin and SRC. Among the 47 proteins that were associated with altered metabolism after the chemotherapy in patients, CD44, CTNND1, APOA1, PARVA, and SCRBS1 were nodes with low degrees, and desmosomes (DSP, KP3, PPL, PRTN3, thrombospondin-2 (THBS2), and DMBT1 were the most down-regulated proteins without nodes, and APOA1, caveolin-1 (encoded by CAV1), LRP1 were the most up-regulated proteins with nodes.

Conclusion: The system modeling identified the common proteins among the research models and patients and the hub proteins and signaling pathways, suggesting the potential translational targets of PDAC.

Introduction: Pancreatic cancer is a highly lethal disease, commonly characterized by aggressiveness and a unique tumor microenvironment, where mutant KRAS signaling stands as a hallmark event in its pathophysiology.

Aims & Methods: To deepen our understanding of KRAS-dependent signaling, stem cell-derived pancreatic ductal-like organoids (PDLOs) were induced by oncogenic KRAS expression, followed by time-resolved single-cell RNA- and bulk ATAC-sequencing. This unique precancerous state model facilitated a comprehensive characterization of early oncogenic events at cellular resolution.

Results: Specifically, mutated KRAS triggers two distinct gene signature programs: extracellular matrix remodeling and inflammation-related signaling. Correlation with published datasets underscored relevance of these distinct gene signatures in advanced cancer states within human patients. Various co-culture systems showed that KRAS^{G12D}-expressing PDLOs could induce cancer-associated fibroblast (CAF) activation while simultaneously shielding KRAS-activated, yet non-cancerous, organoids from T cell infiltration *in vitro*. Furthermore, *in silico* approaches were employed to reconstruct a virtual pancreatic cancer space, demonstrating that our PDLOs transcriptomically bridge healthy and malignant duct, while also unveiling the KRAS driven pathways mediating CAF reprogramming and T cell shielding preceding cancer onset.

Conclusion: In summary, our human PDLO model enables us to explore the transition from normal to cancerous states, overcoming gaps in our understanding of tumor development and tumor niche preparation.

ALDH1A3/AP-1 AXIS FOSTERS AN ONCOGENIC ENHANCER NETWORK IN PANCREATIC CANCER

S. Nie¹, H. Li¹, Y. Yu¹, Y. Lv¹, L. Wang¹, X. Zou¹, B. Kong², S. Shen¹
¹Affiliated Drum Tower Hospital of Nanjing University, Department of Gastroenterology, Nanjing, China, ²University Hospital of Heidelberg, Department of General, Visceral and Transplantation Surgery, Heidelberg, Germany

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a histopathologically defined tumour entity with a devastating prognosis. We previously defined a highly aggressive PDAC subtype labelled by ALDH1A3 (aldehyde dehydrogenase 1 family member A3) expression, partially overlapping with defined molecular subtypes with unfavourable prognosis. ALDH1A3 is a known enzyme catalyzing multiple metabolic processes in nuclear, which could further provide intermediate metabolites (i.e. acetyl coenzyme A and S-adenosyl methionine) for histone modification and affect chromatin accessibility.

Aims & Methods: In this study, we aim to examine the relationship between ALDH1A3 and pancreatic cancer malignancy, focusing to its influence on transcriptional subtype determination. ATAC-seq (assay for transposase-accessible chromatin using sequencing), CUT&Tag (cleavage under targets and tagmentation), RNA-seq, and several other assays were performed to evaluate the impact of ALDH1A3 on enhancer reprogramming and transcriptional subtyping. Pancreas-specific Aldh1a3 inhibition or overexpression was studied in mouse models, and the results were validated using human samples.

Results: A consistent overexpression of ALDH1A3 was observed in aggressive PDAC subtypes. Mechanistically, ALDH1A3 orchestrated the AP-1-dependent enhancer landscape in a dose-dependent manner, potentiating oncogenic MAPK (mitogen-activated protein kinase) signalling. Using an integrative multi-omics approach, we identified the pivotal role of RUNX2 (runt-related transcription factor 2)- a transcription factor downstream of the ALDH1A3/AP-1 axis. RUNX2 formed a functional complex with BRD4 (bromodomain containing 4), enabling the discernment of acetylated chromatin and DNA sequences, and thereby activation of an oncogenic enhancer network, which underpins oncogenic MAPK signalling.

Conclusion: These findings elucidate the integral crosstalk among an ALDH1A3-mediated oncogenic enhancer network and signal transduction pathways in aggressive PDAC subtypes, providing a molecular framework for targeted and personalized therapeutic intervention.

Introduction: By 2030, pancreatic ductal adenocarcinoma (PDAC) is predicted to become the second leading cause of cancer-related death. Due to its resistance to conventional therapies and heterogeneous mutational landscape, molecular stratification and the development of targeted

therapeutic options are essential for improving survival of PDAC patients. Previous work from our group investigated loss-of-function mouse models for the ATM serine/threonine kinase causing homologous recombination deficiency (HRD) in PDAC. Specifically, ATM loss was reported to accelerate tumorigenesis, support metastatic burden, and coincide with oncogenic programs, including epithelial-mesenchymal transition (EMT). Interestingly, ATM-deficient tumors accumulated EZH2, suggesting that ATM status contributes to rewiring the epigenetic landscape of pancreatic tumors, subsequently supporting oncogenic features.

Aims & Methods: To investigate whether and how EZH2 impacts ATM-deficient PDAC pathogenesis, we generated conditional double ATM and EZH2 knockouts in *Kras*^{G12D/+}; *Ptf1a*^{Cre/+} mice. *In vitro* approaches were conducted using primary cell lines isolated from murine endpoint tumors. Additionally, CRISPR/Cas9 strategy was implemented on ATM-deficient cell lines to decipher the ATM-EZH2 molecular axis.

Results: Double-null mice showed extended mouse survival and decreased undifferentiated malignant cell features. Strikingly, interrogation of publicly available human datasets (TCGA, PanCancer Atlas) revealed a significant extended progression-free survival of *ATM*^{neg} *EZH2*^{neg} PDAC patients compared to *ATM*^{neg} *EZH2*^{pos} PDAC cases. Furthermore, we identified the histone-methyltransferase EZH2 as a direct ATM substrate impacting the mesenchymal phenotype of ATM-depleted tumors. Interestingly, RNA-seq analysis of ATM-deficient pancreatic cancer cells revealed upregulation of a transcriptomic program associated with cell differentiation upon EZH2 depletion by CRISPR/Cas9 strategy. In line, EZH2 depletion restored differentiated tumor features *ex vivo*. Further *in vitro* investigations revealed that ATM status significantly impacts EZH2 activity via a post-translational regulation axis, leading to a fostered tumor supporting EZH2 activity during pancreatic carcinogenesis. Specifically, the ATM kinase activity results in EZH2 ubiquitination and degradation by promoting Cullin1 E3-ubiquitin ligase recruitment. Finally, we demonstrated that a combinatorial therapy involving a potent EZH2 inhibitor promotes genomic instability and exacerbates the cytotoxic effects of PARP interference in ATM-deficient HRD PDAC.

Conclusion: Overall, we show that ATM deficiency significantly impacts EZH2 epigenetic functions and highlight the molecular stratification according to ATM status prior to pharmacological EZH2 interference in PDAC therapies as a valuable approach to target ATM-deficient HRD tumors.

Disclosure: Nothing to disclose.

AGR2 ACTS THROUGH MULTIPLE MECHANISMS TO RESTRUCTURE THE IMMUNE MICROENVIRONMENT OF PANCREATIC DUCTAL ADENOCARCINOMA BY IMPACTING THE IGF1 SIGNALING PATHWAY

H. Li¹, S. Zhou¹, S. Shen¹, Z. Shi¹, Q. Zhou¹, X. Wang¹, Y. Yu¹, S. Nie¹, Y. Lv¹, L. Wang¹, X. Zou¹, B. Kong¹

¹Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Gastroenterology, Nanjing, China

Contact E-Mail Address: 13405443939@163.com

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has a poor prognosis, with a five-year survival rate of only about 10%, primarily attributed to the desmoplastic stroma and the immunosuppressive microenvironment. The regulatory mechanism of anterior gradient 2 (AGR2) as an oncogene in the tumor microenvironment remains unclear.

Aims & Methods: The purpose of this study was to investigate the mechanism by which AGR2 regulates the tumor microenvironment and its role in the malignant progression of PDAC. ELISA and immunohistochemistry (IHC) were utilized to assess the expression of AGR2 in the serum and tumor tissues of PDAC patients. Different truncated forms of AGR2 cDNA

were employed to restrict the subcellular distribution of AGR2 to assess its impact on tumor cells and the tumor microenvironment. AGR2 knockout and overexpressing transgenic mice with spontaneous pancreatic cancer were utilized to assess the influence of AGR2 on the tumorigenesis and tumor progression of PDAC. AGR2 monoclonal neutralizing antibody was developed to validate the therapeutic efficacy of targeting AGR2 in PDAC.

Results: We find that AGR2, exclusively produced by neoplastic cells, was highly expressed in both precursor lesions and overt cancer cells, contributing to PDAC tumorigenesis and progression. AGR2 was activated by IGF1 signal from cancer-associated fibroblasts (CAFs) and secrete outside the tumor cells which further induces IGF1 expression, transforming fibroblasts into an inflammatory CAFs (iCAFs) phenotype through a positive feedback loop. At the same time, the intracellular AGR2 promoted the maturation and cell surface transport of IGF1R to provide receptors for IGF1 signaling. Combining a monoclonal neutralizing antibody against AGR2 with an IGF1R inhibitor had a synergistic effect in restructuring the tumour microenvironment and disrupting the immunosuppressive state, exerting an anti-tumour effect.

Conclusion: AGR2 promotes the interaction between tumor cells and CAFs by amplifying the IGF1 signaling pathway, further enhancing the immunosuppressive signals emitted by iCAFs. Targeting AGR2 as a potential PDAC treatment method may improve immune infiltration in the tumor microenvironment and attenuate malignant progression of PDAC.

Disclosure: The authors declare no potential conflicts of interest.

Introduction: Esophagogastric junction contractile integral (EGJ-CI) is a metric of EGJ barrier function on high-resolution manometry (HRM), which may be limited by measurement discrepancies and unclear clinical utility. Mean EGJ basal pressure is a novel, simple HRM metric assessing barrier function. We compared their performance to predict conclusive gastroesophageal reflux disease (GERD).

Aims & Methods: Consecutive patients (Nov 2022-Oct 2023) undergoing combined HRM and 24 hour pH-impedance testing OFF antisecretory therapy (except for Barrett's patients) for known or suspected GERD were eligible, all with prior upper endoscopy. Mean (between end-expiration and end-inspiration) basal EGJ pressure, referenced to mean intragastric pressure, was calculated manually using the isobaric contour tool. EGJ-CI was calculated using the smart box tool, with the isobaric contour set 2 mmHg above intragastric pressure, over three respiratory cycles and normalized for its duration. On pH-impedance testing, Lyon classification 2.0 was applied. Conclusive GERD was defined as acid exposure time (AET) >6% or histologically confirmed Barrett's. Mann-Whitney U and Kruskal-Wallis test, with Bonferroni correction, were used. ROC curves were plotted.

Results: 125 patients were included (mean age 51.6 ± 16.5 years, 60% males). Upon applying Lyon 2.0 classification, 45 (36%) patients had conclusive GERD (25 Barrett's), 7 (6%) borderline GERD, 16 (13%) reflux hypersensitivity (RH), while 57 (45%) had functional symptoms. Patients with conclusive GERD, on HRM, had a significantly lower mean basal EGJ pressure (11.0 vs 18.5 mmHg; p<0.001) than patients without conclusive GERD, while EGJ-CI was not statistically different (26.1 vs 35.1 mmHg·cm; p=0.101). Mean basal EGJ pressure was significantly different across Lyon v2.0 subgroups (median values in GERD: 11, borderline GERD: 16, RH: 19, FH: 20 mmHg; p<0.001), while EGJ-CI did not differ (p=0.283). Mean basal EGJ pressure (AUROC: 0.73, 95%CI 0.64-0.82) showed greater predictive performance of conclusive GERD than EGJ-CI (AUROC: 0.59, 95%CI 0.49-0.69). The optimal cut-off of 13 mmHg had 72% sensitivity and 62% specificity; a cut-off of 9.5 mmHg had 86% sensitivity, while a cut-off of 23.5 mmHg had 91% specificity.

	GERD	Borderline GERD	Reflux Hypersensitivity	Functional	p-value
N	45	7	16	57	
Mean EGJ basal pressure, mmHg, median (IQR)	11 (9-17)	16 (11-19)	20 (14-24)	20 (12-30)	<0.001
EGJ-CI, mmHg·cm, median (IQR)	26 (13-51)	25 (12-37)	41 (25-52)	37 (15-67)	0.283
DCI, mmHg·cm·s, median (IQR)	466 (227-959)	723 (401-997)	1270 (504-2074)	1160 (675-2172)	<0.001
LES total length, mm, median (IQR)	2.8 (2.6-3.1)	3.0 (2.9-3.1)	3.3 (2.9-3.6)	3.1 (2.8-3.5)	0.037
EGJ morphology					
Type I (%)	20 (44)	5 (72)	9 (56)	44 (77)	
Type II (%)	8 (18)	1 (14)	6 (38)	8 (14)	
Type III (%)	17 (38)	1 (14)	1 (6)	4 (7)	

p-values for Kruskal-Wallis test

Conclusion: Mean EGJ basal pressure is a simple HRM metric to predict conclusive GERD, well differentiating GERD phenotypes, with greater performance than EGJ-CI. This metric could be preferred over EGJ-CI as a useful adjunctive measure to support GERD diagnosis.

Disclosure: Nothing to disclose.

A COMPARISON OF TWO WIRELESS PH RECORDING SYSTEMS - AN ANALYSIS OF THE ATTACHMENT DURATION AND PATIENT TOLERABILITY

R.-L. Rusu¹, D.-M. Borrow¹, J. Jafari¹, G.P. Sui¹, S.S. Zeki¹, J.M. Dunn¹, T. Wong¹

¹Guy's and St Thomas' NHS Foundation Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: radu75ro@yahoo.com

Introduction: Prolonged wireless pH monitoring is the preferred diagnostic tool in unproven GERD when available.¹ The Bravo system is better tolerated and increases the diagnostic yield compared to 24-hour transnasal catheter studies.^{2, 3} A novel system, Alpha, uses a stitch rather than a pin to attach the capsule to the esophageal wall. It stores data temporarily inside the capsule before transmission to the recorder and has been introduced in the United States and worldwide. We aim to compare the two systems with respect to the duration of attachment and patient tolerability.

Aims & Methods: We aim to compare the two systems with respect to the duration of attachment and patient tolerability. Three hundred and ninety-nine patients who underwent prolonged wireless pH monitoring at a regional esophageal center from November 2020 to October 2022 were prospectively studied. The clinical indications for wireless pH studies were set out in published guidelines, and patients followed the same standard procedures. The total capsule retention time and duration of artifacts were measured in minutes. A complete day was defined as more than 20 hours of attachment. Patients completed a previously validated tolerability questionnaire, which included symptoms graded on a Likert scale.³

Results: Two hundred and two symptomatic patients (mean age 47 (18-82) years, 65% F) underwent wireless Alpha, and 197 patients (mean age 48 (18-81) years, 72% F) underwent wireless Bravo catheter-free pH monitoring. Capsule attachment for 96, 72, and 48 hour studies were obtained in 184 (91%), 11 (5.4%), and 3 (1.5%) patients who received Alpha studies, respectively, and in 149 (75.6%), 22 (11%) and 16 (8%) patients who received Bravo studies. No complications occurred with either method (capsule retention, bleeding, perforation). The total capsule retention time was longer in patients receiving the Alpha system when compared to the Bravo system (mean 5560 minutes vs 5194 minutes, $p < 0.00001$). The Bravo system recordings had more artifacts than Alpha (mean 272 minutes vs 133 minutes, $p < 0.00001$). In patients who achieved a 96-hour study, there were no significant differences in patient tolerability and acceptance between the two systems across all domains (table 1). One hundred and fifteen out of 126 (91%) would recommend Alpha, and 83 out of 91 (91%) patients would recommend Bravo to another patient ($p=0.7$).

Question	n	Alpha 96 hours	n	Bravo 96 hours	p value
Overall experience of the system	127	3.62	89	3.89	0.08
Chest pain	130	3.4	94	3.37	0.7
Swallowing difficulty	130	3.33	94	3.62	0.1
Eating feel different	130	3.27	93	3.36	0.6
Restriction daily activities	128	3.7	93	4.01	0.1
Throat discomfort	130	3.32	94	3.35	0.9

Table 1.

Values are presented as n, number of patients; Alpha and Bravo mean scores.

Conclusion: Both wireless pH monitoring systems had excellent tolerability and low capsule detachment rates before 96 hours. The Alpha system had a lower premature detachment rate, lower artifacts and similar tolerability when compared with the Bravo system.

²Policlinico San Donato, San Donato Milanese, Italy, ³University of Padua, Division of Gastroenterology, Department Of Surgery, Oncology And Gastroenterology, Padua, Italy

Contact E-Mail Address: nicola.debortoli@unipi.it

Introduction: High resolution manometry (HRM) currently has a marginal role in the diagnosis of gastroesophageal reflux disease (GERD) except for the correct placement of pH-impedance (MII-pH) probes. However, a Manometric Score for Gerd Probability (i.e., the Milan Score) has been recently developed to predict a diagnosis of GERD based on HRM findings prior to pH monitoring studies.

Aims & Methods: In this study, we performed the external validation of the Milan Score in a high-volume tertiary referral center. HRM and MII-pH tracings of consecutive patients reporting GERD symptoms between 2019-2022 were retrospectively reviewed. Clinical, MII-pH, and HRM data were recorded for all patients. Patients with achalasia, body mass index $> 35 \text{ Kg/m}^2$, previous esophageal surgery, paraesophageal hiatal hernia, eosinophilic esophagitis and scleroderma were excluded. To calculate the Milan Score score, data on diagnosis of ineffective esophageal motility (IEM) according to Chicago Classification v4.0, esophagogastric junction contractile integral (EGJ-CI), EGJ morphology (i.e., type I, II or III), intraesophageal pressure (IEP) during reference ID and straight-leg raise (SLR) pressures were collected. A SLR maneuver was considered positive if $> 11 \text{ mmHg}$. The Milan Score was calculated using the nomogram published in the Milan Score paper (United European Gastroenterology Journal 2024 [1]). Wilcoxon rank sum test, Pearson's chi-squared test and Fisher's exact test were used for comparison. ROC curve analysis was used to calculate the diagnostic accuracy (AUC) of the MSGP score.

Results: Of the 86 included patients, 36 (41.8%) had conclusive GERD based on acid exposure time (AET) $> 6\%$, while 50 (58.2%) had AET $< 6\%$. Patients with AET $> 6\%$ and AET $< 6\%$ were comparable in terms of age, weight, regurgitation, chest pain, dysphagia, erosive esophagitis, and HRM diagnosis. Patients with AET $> 6\%$ more frequently had heartburn ($p=0.009$), EGJ type 3, MNBI $< 1500 \text{ Ohms}$ ($p < 0.001$) and positive symptoms index and symptoms association probability ($p=0.007$). The median Milan Score was 78 (IQR, 54-132) in patients with AET $< 6\%$ and 164 (IQR, 125-198) in patients with AET $> 6\%$ group. Based on ROC curve analysis,

a Milan Score higher than 103 was associated with a diagnosis of conclusive GERD (i.e., AET>6%) with AUC of 0.78, with 70% specificity and 80% sensitivity.

Conclusion: The Milan Score has good performance in the diagnosis of GERD upon HRM recording, prior to MII-pH in patients reporting GERD symptoms. The Milan Score proved external validity and can be used as a screening test for GERD in patients undergoing HRM.

Characteristic	AET ≤6%, n = 50 (58%)	AET >6%, n = 36 (42%)	p-value
Ineffective esophageal motility	5 / 50 (10%)	5 / 35 (14%)	0.24
SLR >11mmHg	13/50 (26.0%)	26/36 (72.2%)	<0.001
EGJ-Contractile Index (CI)	42 (28, 55)	27 (13, 42)	0.015
Positive SI/SAP	2 / 50 (4.0%)	9 / 36 (25%)	
EGJ type			0.005
1	26 / 50 (52%)	14 / 36 (39%)	
2	20 / 50 (40%)	9 / 36 (25%)	
3	4 / 50 (8.0%)	13 / 36 (36%)	
Total Milan Score	78 (54, 132)	164 (125, 198)	<0.001

LYON 2.0 OPTIMIZES THE COST-EFFECTIVE EVALUATION AND MANAGEMENT ALGORITHM FOR HEARTBURN ACROSS GENERAL GASTROENTEROLOGY: COST-EFFECTIVENESS ANALYSIS

E. Shah¹, CP. Gyawali², W. Chan³

¹University of Michigan, Division of Gastroenterology, Ann Arbor, United States of America, ²Washington University School Of Medicine, St Louis, Mo, Division Of Gastroenterology, St Louis, United States of America, ³Brigham and Women's Hospital, Boston, United States of America

Contact E-Mail Address: ershah@med.umich.edu

Introduction: Heartburn is the most common symptom leading to gastroenterology referral. The Lyon 2.0 consensus advocates up-front OFF-PPI ambulatory pH testing in unproven GERD when erosive esophagitis is absent, followed by ON-PPI pH-impedance testing when PPI therapy fails in proven GERD. Due to cost concerns with routine diagnostic testing and since wireless pH testing is not widely available in parts of the world, most patients receive rotating, prolonged courses of PPIs for persistent symptoms.

We performed an economic analysis to compare evaluation/management strategies for heartburn in routine practice.

Aims & Methods: We developed a Markov model to compare routine care strategies for patients with heartburn and no alarm features:

- (1) Reassurance alone;
- (2) EGD with PPI optimization;
- (3) EGD with a PPI discontinuation trial when erosive esophagitis is absent; EGD with OFF-PPI
- (4) wireless pH testing or
- (5) pH-impedance testing to phenotype care based on physiology;
- (6) EGD with OFF-PPI wireless pH testing followed by ON-PPI pH-impedance testing when needed following Lyon 2.0.

Definitions to interpret diagnostic tests and treatment recommendations were extracted from practice guidelines. Model inputs were extracted from appropriate US cost databases and from systematic reviews, clinical trials, and national observational studies that considered diagnostics and clinical outcomes. We used a one-year time horizon and a willingness-to-pay threshold of \$100,000/quality-adjusted-life-year (QALY) gained.

Results: Reassurance alone (Strategy 1) cost \$3,936/year to insurers due to repeated diagnostics and visits, and \$2,976/year to patients due to out-of-pocket expenses and impaired work productivity. EGD with a trial of PPI optimization (Strategy 2) or discontinuation (Strategy 3) was more expensive and less effective than strategies that involved up-front pH testing, because EGD-only strategies exclude erosive esophagitis but do not optimize treatment. Up-front wireless pH (Strategy 4) or pH-impedance (Strategy 5) monitoring defining GERD were similarly cost-effective. The most cost-effective strategy was to follow Lyon 2.0 (Strategy 6), resulting in \$2,542 annual savings to patients, \$2,311 annual savings to insurers, and health gains of +0.07 QALY or 23 more healthy days per year. Findings were similar from insurer and patient perspectives.

Strategy	Total cost (\$USD per year)	Total effectiveness (quality-adjusted life years [QALY] gained per year)	Incremental cost	Incremental effectiveness	Incremental cost-effectiveness ratio or ICER (\$/QALY-gained)
Reassurance alone	\$3,936 to insurers \$2,976 to patients	0.89	Reference	Reference	Reference
EGD with PPI optimization trial	\$2,865 to insurers \$1,417 to patients	0.92	\$1,071 saved to insurers \$1,559 saved to patients	+0.03	Dominates reassurance alone
EGD with PPI discontinuation trial for non-erosive findings	\$3,706 to insurers \$1,770 to patients	0.95	\$230 saved to insurers \$1,206 saved to patients	+0.06	Dominates reassurance alone
EGD with up-front OFF-PPI 96hr wireless pH testing	\$1,695 to insurers \$638 to patients	0.95	\$2,241 saved to insurers \$2,338 saved to patients	+0.06	Dominates EGD-only strategies
EGD with up-front OFF-PPI 24hr pH/impedance testing	\$1,652 to insurers \$1,028 to patients	0.95	\$2,284 saved to insurers \$1,948 saved to patients	+0.06	Dominates EGD-only strategies
Lyon 2.0	\$1,625 to insurers \$434 to patients	0.96	\$2,311 saved to insurers \$2,542 saved to patients	+0.07	Dominates all strategies

Table. Cost-effectiveness of routine strategies to manage heartburn in general gastroenterology from insurer and patient perspectives. Strategies 1-5 are updated from our previous report (doi 10.1016/j.cgh.2023.08.026) to reflect availability of Lyon 2.0.

Conclusion: By matching patients to the appropriate therapeutic targets based on diagnostics and PPI response, Lyon 2.0 optimizes the cost-effective care pathway for heartburn in general gastroenterology. Since wireless pH and pH-impedance monitoring are equivalent strategies, availability of technique and local expertise should dictate choice for evaluation of heartburn. Our findings advocate the need for access to, coverage for, and usage of diagnostic testing and broad adoption of the Lyon 2.0 consensus.

EFFICACY AND SAFETY OF FEXUPRAZAN IN PATIENTS WITH EROSIVE ESOPHAGITIS AND MODERATE SEVERITY OF MAJOR SYMPTOMS: POOLED ANALYSIS OF TWO RANDOMIZED CONTROL TRIALS IN SOUTH KOREA AND CHINA

G.H. Kim¹, Y. Xiao², H. Lee³, M.H. Park³, H. Park³, S. Moon³, D.H. Kim³, S.J. Park³, J.H. Chae³, O.Y. Lee⁴

Contact E-Mail Address: 2210467@daewoong.co.kr

Introduction: Fexuprazan, a novel potassium-competitive acid blocker (P-CAB), is currently recognized as a successful alternative to proton pump inhibitors (PPIs) for acid-related disorders. However, its experience in the global market remains limited.

Aims & Methods: This study aimed to integrate two randomized phase 3 studies (NCT03736369 in South Korea and NCT05813561 in China) investigating the efficacy and safety of fexuprazan in subjects with erosive esophagitis (EE) across Asian populations, especially those with at least moderate severity of major symptoms (≥ 2 days of heartburn or acid regurgitation at baseline). The Cochran-Mantel-Haenszel method was used to assess the efficacy of fexuprazan 40 mg and esomeprazole 40 mg in treating EE and relieving major symptoms, whereas the Wilcoxon signed-rank test evaluated safety by testing changes in gastrin levels within each treatment group.

Results: Of the 595 randomized subjects, 513 (256 in the fexuprazan group and 257 in the esomeprazole group) were included in the efficacy analysis set (per-protocol set, PPS). In the PPS, the healing rates of EE in the fexuprazan and esomeprazole groups at weeks 4 and 8 were 86.90% and 84.00% (95% confidence interval [CI] = -2.80, 9.23) and 98.05% and 98.44% (95% CI = -2.30, 2.02), respectively. In the subgroup analysis of patients with at least a moderate severity of major symptoms (205 in the fexuprazan group and 197 in the esomeprazole group), the healing rates of EE did not differ between the two groups (week 4, 85.57% vs. 83.33% [95% CI = -4.70, 9.28]; week 8, 97.56% vs. 97.97% [95% CI = -2.84, 2.61]). However, the proportion of subjects without symptoms in the first 3 days in both full day and nighttime in the fexuprazan group was significantly higher than that in the esomeprazole group (20.44% vs. 11.90%, $p = 0.0212$ and 32.04% vs. 22.02%, $p = 0.0387$, respectively). In the safety set, serum gastrin levels at the final visit significantly increased by 87.23 pg/ml and 61.99 pg/ml from baseline serum gastrin levels in both fexuprazan and esomeprazole groups, respectively. However, the mean gastrin levels at the final visit in both groups did not increase to the clinically significant levels (121.89 pg/ml vs. 96.40 pg/ml, respectively). None of the observed increases in gastrin levels resulted in discontinuation of the study, and no significant safety risks were identified in either group.

Conclusion: The efficacy of fexuprazan in treating EE was not inferior to that of esomeprazole in Asian populations. In subjects with at least a moderate severity of major symptoms, symptom relief in the fexuprazan group was higher in the first 3 days, regardless of full-day or nighttime. In terms of safety, serum gastrin level was tolerable in both groups, and no serious adverse events occurred in the fexuprazan group.

Disclosure: Nothing to disclose.

CLINICAL RESULTS OF 158 PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE TREATED BY A NOVEL IMPLANTABLE DEVICE: TWO-YEAR FOLLOW-UP

M. Elshafei¹, T. Lehmann²

¹Krankenhaus Nordwest, Klinik für Allgemein-, Viszeral- und Minimal Invasive Chirurgie, Frankfurt, Germany, ²Klinikum Friedrichshafen, Department of Visceral Surgery, Friedrichshafen, Germany

Contact E-Mail Address: elshafei.moustafa@gmail.com

Introduction: Standard-of-care treatments for gastroesophageal reflux disease (GERD) include proton pump inhibitor (PPI)-based medical management and conventional antireflux surgery (i.e., Nissen fundoplication). However, these modalities are associated with a significant burden of unmet needs, such as irresponsiveness and postoperative adverse events (AEs), respectively. This study presents the results of 158 patients managed with RefluxStop in Germany.

Aims & Methods: One-hundred fifty-eight reflux patients were treated with RefluxStop between July 2021 and November 2023. Clinical endpoints included GERD Health-Related Quality of Life (GERD-HRQL), postoperative AEs, and change in PPI use.

Results: Baseline characteristics are shown in Table 1. Median GERD-HRQL score improved by 90.9% from a baseline of 22 (IQR 19-31.5) to 2 (IQR 0-2) at 20 $\pm$ 7-month follow-up ($p < .001$). A 96.3% reduction in PPI use was also observed; baseline PPI use in 96.5% of $n = 113$ decreased to 3.6% of $n = 110$ at follow-up. All cases of preoperative dysphagia ($n = 18$) resolved after surgery. New-onset dysphagia occurred in five patients (3.2%) post-operatively but did not require esophageal dilation. Hiatal hernia recurred in 1.3% ($n = 2$) of patients and was managed with device repositioning. Device penetration and migration occurred in 1.3% ($n = 2$) of patients due to excessively tight suturing of the fundic pouch in which the device was invaginated. One of these patients was later treated by Toupet fundoplication.

Characteristic	Observation
Age, mean (SD)	49.3 (13.3) years
Sex	Male 51.3%; female 48.7%
Body mass index, mean (SD)	27.1 (4.5) kg/m ²
Large hiatal hernia (>3 cm)	22.2%
Esophagitis	44.3%
Barrett's esophagus	10.1%

Table 1 Baseline characteristics.

Conclusion: This report demonstrates the promising clinical effectiveness of RefluxStop as a novel treatment principle in management of GERD. Additional evaluation is necessary to enhance the evidence supporting this new antireflux procedure.

Disclosure: The authors disclose travel grants and speaking honoraria from Implantica (Zug, Switzerland).

OUR ONE YEAR EXPERIENCE OF ANTI-REFLUX MUCOSAL ABLATION AS A MINIMALLY INVASIVE TREATMENT FOR PPI DEPENDENT OR REFRACTORY GASTROESOPHAGEAL REFLUX DISEASE PATIENTS. A RETROSPECTIVE STUDY FROM A HIGH PREVALENCE COUNTRY IN THE MIDDLE EAST

A.H. Raina¹, K. Elsayed¹

¹Burjeel Hospital, Gastroenterology and Hepatology, Abu Dhabi, United Arab Emirates

Contact E-Mail Address: hameedraina49@gmail.com

Introduction: Gastroesophageal reflux disease (GERD) is found in 8.7 to 33.1% of the population in middle east. Proton Pump Inhibitor (PPI) is the most common modality of treatment used. Surgical intervention is less commonly accepted by the patients in this region of the world. Anit reflux Mucosal Ablation (ARMA) is a novel minimally invasive endoscopic therapy for it.

Aims & Methods: The study aimed to find out the safety and efficacy of ARMA in GERD in this part of the world.

Patients and Methods:

All Proton Pump Inhibitor (PPI) dependent or refractory GERD patients who presented to our hospital from April 2022 to August 2023 who consented were recruited. Retrospective analysis of a prospectively maintained data was used. GERDq questionnaire was used for diagnosing and treatment success of the GERD. The same was confirmed with OGD and pH metry tests. Argon Plasma Coagulation (APC) with 1.6-1.8 L/min flow rate and 70-100 watts voltage were used for ablation. Repeat OGD and pH metry tests were performed after 3, 6 and 12 months. Clinical success was defined as a > 50% reduction in a validated GERDq questionnaire or daily stoppage of PPI use. Objective success was defined by normalization of Total Acid Exposure time and DeMeester score and no significant esophagitis on OGD.

Age, median (range), years	35.5 (18-75)	ARMA Performed n(%)	P value
Sex		Technical success n (%)	51/51(100%)

PPI use n(%)	60	Off PPI use n(%) at 12 months	39/51(76.47%) P=0.0001
		Occasional PPI use n(%)	12/51 (37.25%)
PreARMA Mean GERDq question-naire score	29.3± 3.8	Post ARMA Median GREDq Questionnaire score	13.4± 2.1 P<0.001

Table.

Results: Total of 60 patients with definitive GERD on OGD or pH tests were recruited. Among them 51 patients underwent ARMA. There was 100 % (51/51) technical success rate. Mean procedure time was 36.4± 5.8 minutes. Clinical success rates at 3 and 6 and 12 months post-ARMA were 82.35% (42/51) and 80.39% (41/51), and 76.47 % (39/51), respectively. The mean GERD-health-related quality of life score improved from mean of 29.3± 3.8 to 13.4± 2.1 at 3 -12 months ($P < 0.01$). Median DeMeester score decreased from 21.6 to 4.9 in 88.23% (45/51) ($P = 0.003$) in 3-12 Months. Multivariate analysis showed Hill's grade I to II and PPI depend GERD as predictors of success.

Adverse events in the form of stricture (3.92%), Severe pain requiring three days of analgesics (3.92%) and Esophageal Mucosal burn injury (1.96%) were seen. All were managed endoscopically. 76.47% of the patients were completely off PPI at 12 months compared to 0% pre ARMA procedure($p=0.0.001$).

Conclusion: ARMA was safe and effective endoscopic modality of treatment for GERD. Majority of the patients who underwent ARMA were off PPI at one year. PPI dependent GERD and Hill's grade I to II were predictors of success of ARMA. Large prospective randomized studies are required to further substantiate these findings.

Introduction: The safety profile of proton pump inhibitors (PPIs) is considered excellent; however, concerns regarding the potential side effects linked to prolonged usage are emerging.

Aims & Methods: This work focused on assessing the risk of *Clostridioides difficile* infection (CDI) in patients undergoing treatment with PPIs compared to non-users, in the context of randomized controlled trials (RCTs). The study protocol was prospectively registered on PROSPERO (CRD42023403322). The systematic search was conducted on March 2nd, 2023 across three medical databases (PubMed, Embase, and CENTRAL). We included all RCTs that reported the rates of CDI in adults receiving treatment with PPIs compared to non-users (placebo, other medications). Risk ratio (RR) with its corresponding 95% confidence interval (CI) was used as an effect size measure using a random effects model.

Heterogeneity was described using Higgins and Thompson's I² statistics. The risk of bias was estimated using the Revised Cochrane Risk-of-bias Tool for Randomized Trials (RoB 2).

Results: We identified and analysed seven RCTs investigating the rates of CDI in individuals receiving treatment with PPIs compared to placebo, which included 25.118 patients. No significant difference was observed regarding the risk of acquiring CDI between the two study groups (32/12.561 vs. 33/12.557; RR: 0.94, 95% CI: 0.55; 1.59, I²=0%). Four RCTs compared subjects receiving PPIs to H₂-receptor blockers, totalling 27.254 patients. Similarly, the pooled analysis found no significant difference regarding the risk of developing CDI between the two study groups (43/13.658 vs. 59/13.598; RR: 0.72, 95% CI: 0.49; 1.07, I²=0%). We would like to highlight the fact that the overall number of events in the included studies were low. Additional subgroup analyses were intended based on patient population, treatment duration, and follow-up time; however, there was insufficient data available for conducting meta-analytical calculations.

Conclusion: Previous works that reported associations between PPI use and adverse effects have been derived from observational data only. It is known that these types of studies cannot definitely establish causality and are highly susceptible to bias, such as confounding by indication and protopathic bias. Based on data derived from RCTs only, treatment with PPIs does not seem to increase the risk of acquiring CDI, both when compared to placebo and to other acid-suppressive medications.

Introduction: The optimal timing of endoscopy in acute upper gastrointestinal bleeding (AUGIB) management remains debated. We assessed time to endoscopy's impact on rebleeding and mortality based on patient characteristics and pre-endoscopic factors.

Aims & Methods: Data from 3,001 patients with AUGIB undergoing endoscopy within 48 hrs of referral from the prospective multicentre UK 2022 audit were analysed. Patients were categorised into 0-12 hrs, 12-24 hrs, and 24-48 hrs groups based on the time to endoscopy from referral. Regression analyses, adjusting for age, admission status (inpatient vs new admission), vital signs, symptoms, comorbidities, laboratory parameters, red blood cell transfusion, and pre-endoscopic management, assessed the association between endoscopy timing and rebleeding and mortality.

Results: Patients undergoing endoscopy within 0-12 hrs were younger, more likely to be haemodynamically unstable, and had a higher median Glasgow Blatchford Score (GBS) compared to those undergoing endoscopy in the 12-24 and 24-48 hrs groups. Despite a higher proportion receiving endotherapy (41% for the 0-12 hrs group, 28% for the 12-24 hrs group, and 17% for the 24-48 hrs group; p<0.001), the 0-12 hrs group had the highest rates of rebleeding (16%) and mortality (10%), compared to 9% rebleeding and 6% mortality in the 12-24 hrs group, and 7% rebleeding and 5% mortality in the 24-48 hrs group (p<0.001). The median length of stay was longer for the 0-12 hrs and the 24-48 hrs groups at 5 days, compared to 4 days in the 12-24 hrs group (p < 0.001). (see table)

Characteristic	0-12 hrs, N = 1,366	12-24 hrs, N = 944	24-48 hrs, N = 691	p-value*
Age	67 (52, 79)	69 (55, 80)	71 (56, 81)	0.001
Hemodynamically unstable	653 (50%)	377 (42%)	270 (41%)	<0.001
GBS	10.0 (7.0, 13.0)	9.0 (6.0, 12.0)	8.0 (5.0, 11.0)	<0.001
Pre-endoscopy peak blood lactate	2.20 (1.40, 3.90)	1.80 (1.20, 2.80)	1.80 (1.30, 2.90)	<0.001
Stigmata of recent bleed	642 (47%)	259 (28%)	121 (18%)	<0.001
Endo therapy	563 (41%)	224 (24%)	114 (17%)	<0.001
Death	136 (10%)	60 (6.4%)	35 (5.1%)	<0.001
Rebleeding	196 (16%)	74 (8.9%)	41 (6.7%)	<0.001
Length of stay	5 (3, 10)	4 (2, 8)	5 (3, 10)	<0.001

Table: Patient characteristics in relation to time of endoscopy (n=3001)

*Between the group comparison

Regression analysis indicated that, compared to the 12–24-hrs group, the 0–12 hrs group had higher odds of rebleeding (OR 1.91, 95% CI 1.38–2.69, $p < 0.001$), after adjusting for confounding variables. However, the 24–48 hrs group exhibited comparable odds of rebleeding (OR 0.93, 95% CI 0.60–1.45, $p < 0.001$) compared to the 12–24-hrs group. Regression analysis for mortality showed the 0–12 hrs group had higher odds of mortality compared to the 12–24 hrs group (OR 1.59, 95% CI 1.09–2.34, $p = 0.001$), while the 24–48 hrs group had similar odds of death (OR 0.74, 95% CI 0.43–1.23, $p = 0.001$).

Conclusion: The findings suggest a complex relationship between the timing of endoscopy and clinical outcomes in patients with AUGIB. Earlier endoscopy (0–12 hrs) may be associated with a higher risk of rebleeding, mortality and resource utilisation, while later endoscopy (24–48 hrs) may not be associated with increased adverse outcomes, but may lead to a longer hospital stay. Despite the initial severity of illness, early endoscopy may not translate to improved patient outcomes in AUGIB management. These results highlight the need for individualised management when determining the optimal timing of endoscopy in AUGIB.

COMPARISON OF GASTRIC ULCER CASES IN PATIENTS TAKING WARFARIN OR DOACS

Y. Shimada¹, H. Nago¹, M. Yamaguchi¹, Y. Terai¹, R. Om¹, Y. Kita¹, Y. Ikeda¹, S. Sato¹, A. Murata¹, S. Sato¹, A. Nagahara², T. Genda¹
¹Juntendo University Shizuoka Hospital, Gastroenterology and Hepatology, Izunokuni-city, Japan, ²Juntendo University School of Medicine, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: yshimada@juntendo.ac.jp

Introduction: In Japan, more than ten years have passed since direct oral anticoagulants (DOACs) was released in 2011. The differences between DOACs and warfarin (VKA) have gradually become clearer, and many studies have been reported regarding the differences in gastrointestinal bleeding risk⁽¹⁾⁽²⁾⁽³⁾. However, there are few reports that examine the prevalence of gastric mucosal injury or ulcers rather than the risk of bleeding.

Aims & Methods: The aim of this study is to reveal the clinical features about patients with gastric ulcer taking anticoagulants (DOACs or VKA). This study is a retrospective cross-sectional study conducted in a single hospital. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and December 2022. We focused on subjects who took anticoagulants (DOACs or VKA), and compared the prevalence of gastric ulcer between subjects taking DOAC and those taking VKA. Subjects taking anticoagulants were limited to those taking that anticoagulant as the only anti-thrombotic agents. This study was conducted separately for subjects taking antacids (P-CAB or PPI) and those not taking antacids (NO P-CAB, NO PPI and NO H2RA). Statistical analyses were performed by Fisher's exact test.

Results: Of the 8,602 subjects analyzed, 522 subjects were taking anticoagulants, of which 103 were taking VKA (76 men, 27 women, mean age 73.1±12.0 years) and 297 were taking DOACs (205 men, 92 women, mean age 74.9±8.7 years). Among subjects taking DOACs, 33 subjects received Dabigatran, 93 received Edoxaban, 87 received Rivaroxaban, and 84 received Apixaban. The prevalence of gastric ulcer in subjects taking antacids was 6.7% (4/60) on VKA and 2.9% (5/170) on DOACs ($p=0.24$). The prevalence of gastric ulcer in subjects not taking antacids was 23.1% (9/39) on VKA and 5.4% (6/111) on DOACs ($p=0.004$).

Conclusion: Without concomitant use of antacids, subjects taking DOACs had a statistically significantly lower prevalence of gastric ulcers than

those taking warfarin. These results suggest that DOACs are gentler on the gastric mucosa and user friendly than warfarin.

Introduction: Peptic ulcer is the most common cause of upper gastrointestinal bleeding (UGB), accounting for about 50 percent of cases. Several scoring systems have been developed for the early and accurate assessment of patients with UGB to predict clinical outcomes, assisting in the management of patients. The Glasgow-Blatchford score (GBS) is currently recommended for risk stratification of UGB in the emergency department, helping triage patients to in-hospital or ambulatory management. GBS includes hemoglobin, urea, heart rate, systolic blood pressure, co-morbidity and symptoms like syncope and melena.

Aims & Methods: Aim: To compare GBS in patients with bleeding peptic ulcer (BPU) infected and non-infected by Helicobacter pylori (HP).

Methods: We conducted a prospective observational study from September 2019 to March 2002, 48 patients with BPU were prospectively evaluated in a tertiary hospital. During emergency endoscopy, two gastric mucosal biopsy samples (one from corpus and one from the antrum) were collected for polymerase chain reaction (PCR) and invasive rapid urease test (RUT). Two hours later, all underwent carbon-13 urea breath test (13C-UBT). Patients were considered HP infected when two or more tests were positive. The clinical data were obtained from the patients' records immediately before the endoscopy. The Qui-square test and Fisher were used to compare the groups. Written informed consent was obtained from all patients. The study protocol was approved by the local ethical committee.

Results: Mean age was 61.7±17.3 years, 25 (52.1%) presented with melena. Gastric ulcers were the major cause of acute bleeding in 39 (81.3%) and duodenal in 9 (18.8%) patients. Data about blood transfusion (BT), Rockall Score (RS) and presence of blood in the stomach are represented in table 1. GBS was significantly lower in HP positive patients (n=19) compared to HP negative (n=25): 9.1±3.3 e 11.5±3.1, $p = 0.0441$.

Variable	Total (n=48)	HP negative (n=26)	HP positive (n=22)	p-value
Age	61.7±17.3	64.8±15.	58.9±18.8	0.4624
Melena	25 (52.1%)	13 (50%)	12 (54.5%)	1.000
Gastric ulcer	39 (81.3%)	23 (88.5%)	16 (72.7%)	0.2669
BT.*	16 (33.3%)	10 (38.5%)	6 (27.3%)	0.4126
Associated diseases	27 (56.3%)	15 (57.5%)	12(54.5%)	0.8267
Complete RS*	4.0±2.0	4.4±2.0	3.6±1.8	0.726
Blood in the stomach	4.0 (8.3%)	1 (3.8%)	3(13.6%)	0.3202
GBS*	10.5±3.4 (n=25)	11.5±3.1 (n=19)	9.1±3 (n=44)	0.0441

Table 1. Comparison between H.pylori negative and positive groups

* BT: blood transfusion, RS: Rockall score, GBS: Glasgow Blatchford score.

Conclusion: H pylori positive patients showed less comorbidities and lower GBS in the BPU scenario. HP negative patients need more severe clinical conditions to bleed than those HP positive. HP is a pathogenic factor by itself, suggesting that GBS might be underestimated in this population. A score using HP presence could be better to predict prognostic in the episode of bleeding peptic ulcer.

Introduction: Antithrombotic drugs (AT) pose an increased risk of upper gastrointestinal bleeding (UGIB), and their discontinuation carries the risk of thromboembolic events, presenting a challenge for clinicians (1,2). Clinical practice guidelines advocate for a restrictive approach, recommending non-discontinuation and/or early reintroduction based on the drug and its indication (3).

Despite available literature, controversy persists regarding the outcomes of patients with UGIB on antithrombotic therapy, both in the short and long term, as well as the potential impact of drug discontinuation (4,5).

Aims & Methods: Aim: To determine the impact of ATs on in-hospital and delayed outcomes. Also, to determine whether suspension and resumption influenced delayed outcomes.

Methods: Prospective registry analysis of UGIB patients between 2013-2021. Anticoagulants and antiplatelets were classified as AT drugs. Outcomes examined included in-hospital mortality and delayed-6 months cardiovascular, bleeding and mortality events.

Results: 1345 patients were included, with 21.7% on anticoagulants and 19.1% on antiplatelets. Patients on ATs were older (73 vs. 59 years; p<0.0001) and had a higher rate of comorbidities, has longer delay of endoscopic performance (11±11h vs. 9.6±8h; p=0.027), with gastric erosions being more usual (14.2% vs. 9.1%; p=0.006). Table shows main outcomes.

	Non-AT (n=839)	AT (n=506)	P	Aspirin (n=195)	Thienopyridine (n=29)	Double anti- aggregating (n=24)	VKA (n=179)	NACO (n=49)
Endoscopy therapy	48.3%	38.5%	0.001	75 (38.5%)	12 (41.4%)	7 (29.2%)	62 (34.6%)	20 (40.8%)
Rescue therapy	6.1%	3.8%	0.083	8 (4.1%)	17 (58.6%)	0	4 (2.2%)	1 (2%)
Rebleeding	10.5%	9.7%	0.702	20 (10.3%)	1 (3.4%)	18 (75%)	12 (6.7%)	4 (8.2%)
Transfusion	56.3%	66.2%	0.000	127 (65.1%)	17 (58.6%)	0	115 (64.2%)	41 (83.7%)
In-hospital mortality	12%	8%	0.028	14 (7.2%)	0	1 (4.2%)	13 (7.3%)	1 (2%)
Delayed cardiovascular event	3.4%	13.7%	0.000	18 (9.2%)	5 (17.2%)	1 (4.2%)	31 (17.3%)	12 (24.5%)
Delayed hemorrhagic event	12.9%	22.9%	0.000	43 (22.1%)	5 (17.2%)	6 (25%)	41 (22.9%)	12 (24.5%)
Delayed mortality	6%	9.4%	0.034	17 (8.7%)	2 (6.9%)	2 (8.3%)	19 (10.6%)	4 (8.2%)

AT suspension <72h was associated with increased in-hospital mortality (14.9% vs. 2.3%; p=0.001), especially <24h (20.9% vs. 2.6%; p<0.0001).

Delayed mortality was higher in patients on ATs who suspended them more than 7 days (17% vs. 8.7%; p= 0.033), with no differences when last <72h. Suspension/reintroduction have no effect on other delayed outcomes.

Multivariate analysis identified ASA≥3 (HR 12.20; 95%CI 3.69-56.92; p<0.001), disseminated malignancy (HR 4.73; 95%CI 1.92-11.42; p=0.001) and rebleeding (HR 19.25; 95%CI 9.07-43.04) as independent risk factors for in-hospital mortality, with AT therapy (HR 0.27; 95%CI 0.13-0.55; p<0.001), NSAIDs (HR 0.26; 95%CI 0.07-0.75; p=0.023), endoscopic therapy (HR 0.49; 95%CI 0.24-0.96; p=0.040) and hemoglobin levels being protective factors HR 0.80; 95%CI 0.69-0.93; p=0.004).

Logistic regression analysis for delayed mortality showed that age (HR 1.04; 95%CI 1.02-1.07; p=0.001), disseminated malignancy (HR 3.49; 95%CI 1.81-7.86; p=0.004), esophageal varices HR 3.34; 95%CI 1.62-6.64; p=0.001), ischemic heart disease (HR 2.44; 95%CI 1.10-5.19; p=0.023) and a being an inpatient (HR 1.92; 95%CI 1.00-3.98; p=0.042) were independent risk factors for the outcome.

Conclusion: Despite increased comorbidities and older age, patients with AUGIB on ATs had lower in-hospital mortality, with no differences in other relevant outcomes. In fact, our results suggest that AT treatment provides a survival benefit, possibly related to a higher risk of bleeding in milder lesions.

Regarding delayed mortality, it was higher in patients on AT, determined by the comorbidity leading to their prescription.

Interestingly, early resumption of AT was associated with higher in-hospital mortality, while reintroduction after 7 days increased delayed one.

Introduction: Upper gastrointestinal bleeding (UGIB) continues to pose a significant threat to patients presenting at the emergency department, especially if the patients present with hemodynamic instability. There are still some uncertainties in the guidelines about the stepwise assessment and management for those patients before undergoing endoscopy.

Aims & Methods: Our study aims to report practice patterns to better understand the pre-endoscopic assessment for patients presenting with acute UGIB. This is an international online survey that included a prospective two-phase data collection. The distribution was conducted from April 2023 to November 2023. The target population was active physicians with clinical practices focusing on the management of patients with UGIB. Study data were collected and managed using Research Electronic Data Capture (REDCap), an electronic data collection tool. The survey included four main sections (demographics and clinical practice, definition of hemodynamic instability, pre-endoscopy assessment, and optimal time for endoscopy) with a total of 33 relevant questions. The survey was endorsed by several national and international gastroenterology societies. The primary analysis was a descriptive assessment of individual survey response items in different domains. Descriptive statistics were reported as proportions. Secondary analysis evaluated differences in survey responses according to the years of clinical experience, type of practice location, and the estimated number of UGIB patients presented annually.

Results: In total, 533 clinicians completed our survey from 50 countries. Over half of the respondents work at university-based hospitals (54.6%) and have over 100 UGIB patients hospitalized annually (67.7%). In terms of clinical experience, 55.7% reported less than 10 years and 44.3% with more than 10 years. In 29.1% of the hospitals, there was no specific protocol or guideline for the initial assessment of patients with suspected UGIB, and in 44.7%, there were no emergency on-call interventional radiology services for such cases. Among the respondents, 39.6% do not use any risk stratification scores at the time of patient presentation. Both 0.9% saline

(40.9%) and balanced crystalloid fluid (39.5%) were almost equally chosen as initial fluid resuscitation. However, the rate of fluid resuscitation was dependent on the hemodynamic status of 40.2% of the answers. In 40.7% of the answers, clinicians do not use any major hemorrhagic protocol for patients with severe ongoing bleeding and at risk of exsanguination. Prokinetics were generally little or never used prior to endoscopy in patients with UGIB (34.3%) or even in those with known gastric emptying problems (27.6%). The most chosen optimal time for endoscopy was within 24 hours for stable patients with non-variceal bleeding and within 12 hours for variceal bleeding. If patients were unstable but responding to resuscitation, the most chosen time was within 6 hours regardless of the source of bleeding and within 2 hours for those with persistent hemodynamic instability.

Conclusion: Adherence to international gastroenterology guidelines is low. There is a significant variability in different assessment approaches among respondents. Based on our data, the optimal time for endoscopy seems to be dependent on the hemodynamic status of patients with acute UGIB in both variceal and non-variceal bleeding. Our study highlights opportunities for improving consistency in reporting data and identifies potential areas for research.

Introduction: A global surge in anticoagulant use raises concerns about managing acute upper gastrointestinal bleeding (AUGIB) in affected patients.

Aims & Methods: This study presents findings from a large UK multicenter study of AUGIB in patients on anticoagulants. A prospective multicenter observational study included adults (>16 years) from 152 UK hospitals with AUGIB between 3 May- 2 Jul, 2022.

Results: Of 5101 AUGIB cases enrolled, 31%(1566) were on anticoagulants – 10%(n=159) warfarin, 58%(n=912) direct oral anticoagulants (DOACs), and 34%(n=530) heparin (prophylactic dose – 76%, therapeutic dose – 18%, and bridging therapy – 2%). The median age was 78 yrs (IQR 68-85), with 58% being new admissions. Anticoagulants were discontinued post-AUGIB in 87%. The major hemorrhage protocol activated for 4%. Transfusion rates were: 59% packed red blood cells, 7% prothrombin complex concentrate (PCC), 5% fresh frozen plasma, 3% platelets, 0.8% cryoprecipitate, and 0.3% fibrinogen. For DOACs (n=912) a reversal agent was needed for 6% (46% - andexanet alfa and 54% -PCC). Glasgow-Blatchford score (GBS) categorized patients into: 3% low-risk(GBS 0-1), 16% medi-

um-risk(2-6), 33% higher-risk(7-11), and 34% very high-risk(≥ 12). Inpatient endoscopy was performed in 85%(n=1335). Time to endoscopy from presentation was: 0-6 hrs 5%, 6-24 hrs 32%, 24-48 hrs 25%, and >48 hrs 24%. Bleeding etiologies identified (n=798) included: peptic ulceration (49%), esophagitis (26%), varices (8%), portal hypertensive gastropathy (4%), malignancy (7%), and other (27%). Stigmata of recent bleeding observed in 29% (390/1335) of cases, leading to endotherapy in 25% (328/1335). Anticoagulants resumed while in-patient for 46% (613/1335) – 19% within 24 hrs, 14% 24-48 hrs, 9% 48-72 hrs, and 41% >72 hrs after the index endoscopy. 10% (136/1335) had evidence of further in-patient bleeding after the index endoscopy. Overall, 10%(160/1566) had >1 endoscopy, 1% (16) underwent surgery, and 2.8% (44) had interventional radiology. Median length of stay was 7 days (IQR 4-13), with in-patient mortality at 13%(211). A multivariable logistic regression revealed delayed endoscopy (>48 hrs) was associated with reduced rebleeding odds (OR:0.19,95%CI:0.04-0.99), while early endoscopy (0-6 hrs) was linked to higher rebleeding odds (OR:1.81,95%CI:0.44-7.46). Importantly, stigmata of recent bleeding on endoscopy significantly elevated rebleeding odds (OR:4.88,95%CI:1.75-13.64), emphasizing its prognostic relevance in AUGIB.

Conclusion: A third of AUGIB patients in this multi-center UK study were on anticoagulants at the time of presentation. Real-world evidence underscores the importance of appropriate resuscitation and careful restarting of the anticoagulants based on the indication. Further development of predictive models to guide the time to restart different anticoagulants is needed.

Contact E-Mail Address: eliomikhael7@gmail.com

Introduction: Gastrointestinal bleeding is a common presentation in the emergency department, or a complication of a hospital stay, in which red blood cells (RBC) transfusion is often needed (1).

Aims & Methods: The aim of this paper is to create a clinical score to predict the need of transfusion in a patient presenting for gastrointestinal bleeding. This is a retrospective observational study, including all patients that presented for gastrointestinal bleed or that developed bleeding in-hospital, from January 2018 till December 2023. Patients that were under 18 years old and patients with portal hypertension related bleeding were excluded from analysis. Demographic data (gender, age), past medical history, history of gastrointestinal bleeding, and chronic medication were collected. Data from the hospitalization that were included were vital signs at presentation, initial laboratory results, endoscopic exams or other work-up performed, need of transfusion of packed red blood cells (RBC), platelets, or fresh frozen plasma, length of hospitalization, recurrence, length of follow-up, and mortality.

Results: In total, 279 patients were included for analysis, with a mean age of 67.5 ± 16.7 years old. There were 166 (59.5%) males and 113 (40.5%) females. Mean length of hospitalization was 6.6 days. Recurrence occurred in 33 patients (11.8%) during a mean follow-up of 368.7 days, 7 (21.2%) of which occurred during initial hospitalization. Death occurred in 23 (8.2%) patients, in average 276.7 days after index bleeding. In our population, 153 (54.8%) patients needed transfusion of packed RBC, with an average of 3.4 packed RBCs per patient. Average hemoglobin at presentation is of 10.0g/dL.

A multivariate analysis was performed. Variables that were independently associated with the need of packed RBC transfusion were included in a predictive model. The APICA score was constructed using these variables: Anticoagulation agent (multiplied by 50), antiPlatelet agent (multiplied by 50), In-hospital bleed (multiplied by 500), Coronary artery disease (multiplied by 20), and Age. The score had an AUC of 0.749 with a p-value less than 0.001. In comparison, the Glasgow-Blatchford score had an AUC of 0.805 (p<0.001) and the Oakland bleeding score had an AUC of 0.879 (p<0.001). The table below represents the sensitivity, specificity, negative predictive value, and positive predictive value for different cut-offs of the APICA score.

	APICA Score		
	≥ 108	≥ 118	≥ 129
Sensitivity	76.4%	71.9%	60.1%
Specificity	61.1%	67.4%	76.2%
Negative predictive value	68.1%	66.4%	61.5%
Positive predictive value	70.5%	72.8%	75.6%

Conclusion: The APICA score is a good clinical predictive model for the need of packed RBC transfusion for gastrointestinal bleeding with an AUC of 0.749. Unlike existing scores for gastrointestinal bleeding, it does not require hemoglobin levels, therefore sparing time for transfusion preparation. Prospective studies are required to further assess the benefits of this model and to validate it.

Introduction: In patients with upper gastrointestinal bleeding (UGIB), the European Society of Gastrointestinal Endoscopy (ESGE) recommends adopting the following definitions regarding the timing of upper GI endoscopy: urgent (6-12h), early (≤ 24 h), and delayed (>24 h) (1). There is no consensus definition of emergent endoscopy, but previous publications use the timeline of <6h (2).

Early endoscopy is associated with better outcomes, and guidelines suggest that it should be performed within this time frame (1).

Last ESGE guideline about variceal bleeding (VB) suggests performing urgent endoscopy in this context (3). This is based on a meta-analysis showing lower overall mortality when endoscopy was performed <12h compared to >12h (4). Surprisingly, ESGE concludes that the optimal timing in this setting is controversial due to a lack of high-level evidence. In fact, except for this study, all the others examining this aspect show that performing endoscopy before 12h does not provide benefits (5,6).

Aims & Methods: We aim to compare whether urgent endoscopy (6-12h) provides benefits to VB and explore predictors for mortality.

Methods: Retrospective analysis of a prospective registry of UGIB patients admitted to 'Virgen de las Nieves University Hospital' (2013-2020). VB was

defined as that coming from gastric or esophageal varices. Endoscopy timings were defined according to ESGE: emergent (<6h), urgent (6-12h), early (≤24h) and delayed (>24h) (1).

Main outcomes were in-hospital (endoscopy therapy, transfusion, re-bleeding, misbalance of chronic condition, hospital stay, and mortality) and delayed-6 months (bleeding, cardiovascular events, mortality). Statistical analysis was performed using SPSS.

Results: 1459 UGIB patients were collected, 216 with VB.

Statistical differences in main outcomes are shown in Table 1 (each letter in the subscript denotes column proportions that do not differ significantly from each other). No differences were found for the other outcomes.

Timing (% patients)	<6h (39.7%)	6-12h (28.8%)	12-24h (17.4%)	24h (2.7%)	p
Endoscopy therapy	85.1% _a	63.5% _b	65.8% _b	66.7% _b	0.014
Misbalance of chronic condition	48.3% _a	30.2% _b	23.7% _b	50% _a	0.026
Rebleeding	22.1% _a	7.9% _b	7.9% _b	16.7% _a	0.037
In-hospital mortality	27.4% _a	13.6% _b	11.1% _b	50% _a	0.025

We also compared basal characteristics and found differences in MAP(ASH) score≥2 (92.3% vs. 66.7% vs. 77.4% vs. 75%; p=0.003) and GBS≥12 (69% vs. 44.4% vs. 52.6% vs. 83.3%; p=0.011).

Independent risk factors for in-hospital mortality were MAP(ASH)≥2 (1.26, 95% CI 1.03-1.54), misbalance of chronic condition (OR 9.92, 95% CI 3.56-27.61, p=0.000), and rebleeding (OR 3.95, 95% CI 1.45-10.79, p=0.007). The timing of endoscopy performing was not an independent prognostic factor for mortality.

We also conducted subgroup analysis to assess whether performing endoscopy before 12h provides benefits in other UGIB patients, without finding differences for patients with non-variceal bleeding or in those at higher risk of poor outcomes (GBS≥12, MAP(ASH)≥2, ASA≥3).

Conclusion: Our study highlights, in line with the majority of available ones (5,6), that endoscopy before 12h does not provide a benefit in patients with VB. This necessitates a reconsideration of the ESGE recommendation. Patients with endoscopy performed before 6 or after 24h have poor outcomes. However, multivariate analysis shows that the timing of endoscopy is not an independent prognostic factor for mortality. On the other hand, the decompensation of basal chronic disease and the severity of bleeding (determined by MAP(ASH) and rebleeding) are the determinants of patient outcomes.

Introduction: Optimal timing of endoscopy in patients with acute variceal bleeding (AVB) remains unclear. Studies in patients with peptic ulcer bleeding (PUB) have indicated that urgent endoscopy <6 hours from presentation may be associated with worsened patient outcome. We aimed to analyse the association between timing of endoscopy and mortality in AVB.

Aims & Methods: Prospective multicenter cohort study based on data from the 2022UK Audit on Acute upper gastrointestinal bleeding. The association between timing of endoscopy and in-hospital mortality was evaluated using logistic regression analyses with adjustment for differences in patients' characteristics and severity of bleeding.

Results: We included 401 AVB patients. Mean age was 58 years, 65% were males, 75% had known cirrhosis at time of presentation, mean Child-Pugh score was 8.2, 31% had other comorbidities, 13% had ongoing bleeding at time of endoscopy, 78% were treated with terlipressin, 75% were treated with antibiotics, and 12.6% died during hospital admission. Mortality rates were 22%, 17%, 11%, and 11% for patients undergoing endoscopy in the periods <6, <12, 6-24 and >24 hours from presentation. Patients undergoing endoscopy < 6 hours had lower blood pressure, higher heart rate, lower haemoglobin, and higher peak-lactate levels than patients undergoing later endoscopy (see table). However, even haemodynamically stable patients with systolic blood pressure above 100mmHg had high mortality rates (16%) when performing urgent endoscopy < 6 hours. When adjusting for differences in patients' characteristics, and severity of bleeding, we did not find any association between timing of endoscopy and mortality (Odds ratio (95% confidence interval): 1.01 (0.99-1.03); p=0.17).

Characteristics	<6hrs (n=60)	6-24hrs (n=181)	>24hrs (n=160)	P
Age (mean, 95%CI)	56 (34-78)	58 (37-77)	58 (36-83)	NS
Child Pugh score (mean, 95%CI)	8.4 (6-12)	8.2 (5-12)	8.2 (5-11)	NS
SBP (mean, 95%CI)	106 (69-140)	118 (85-160)	120 (90-156)	<0.001
Heart Rate (mean, 95%CI)	101 (66-142)	99 (67-134)	94 (64-131)	0.008
Hemoglobin (mean, 95%CI)	83 (40-122)	87 (52-127)	93 (57-128)	0.014
Peak blood lactate (mean, 95%CI)	5.8 (1.4-14)	5.0 (1.0-13)	3.3 (1.0-9.2)	<0.001
Oesophageal varices	55 (92)	166 (92)	144 (90)	NS
Treatment with EDS, SBT or TIPS	9 (15%)	11 (6%)	11 (7%)	NS
Mortality (overall)	13 (21.7)	20 (11.2)	17 (10.8)	NS

Table: Patient characteristics in relation to time of endoscopy (n=401).

Reported values represent n(%) unless otherwise stated.

CI: Confidence Interval; EDS: Ella Danis Stent; NS: Not Significant; SBP: Systolic Blood Pressure; SBT: Sengstaken-Blakemore Tube; TIPS: Transjugular Intrahepatic Portosystemic Shunt

Conclusion: AVB is associated with significant mortality, in particular in patients undergoing urgent endoscopy <6 hours from presentation, which may be explained by more severe bleeding. When taking differences in patients characteristics and severity of bleeding into consideration, endoscopy within 6-12 hours appears to be associated with similar outcomes to endoscopy undertaken 6-24 hours from presentation, despite less time to patient optimization before endoscopy. Thus, the association between timing of endoscopy and outcome may differ between patients with AVB and patients with PUB.

Disclosure: No conflicts of interest.

Introduction: Even though gastric varices (GV) are less frequently encountered than oesophageal varices, they are associated with severe bleeding¹. Novel endoscopic ultrasound (EUS)-guided therapeutics approaches have emerged from GV recent classification based on afferent and efferent hemodynamics^{2,3}.

Aims & Methods: We aim to target the feeder vessel or afferent component displaying a novel therapeutic approach comprising a combined application of cyanoacrylate (CYA) and coils. This approach is intended to address the vascular pathology of GV with enhanced precision and efficacy. A single-centre, prospective registry was conducted from Jul/2015-Oct/2023. Enrolled patients included adults ≥18 years old considered for primary or secondary prophylaxis of gastro-oesophageal varices (GOV) II and isolated GV (IGV) I. First, the location of the feeder's vessel was determined by angiography using a 10 ml water-soluble contrast. Subsequently, using a FNA needle, coils were EUS-guided deployed (10-20 mm coiled diameter, 14-20 cm straight lengths, 0.035 inches diameter), followed by CYA injection (2-Octyl-CYA). The number of deployed coils and injected CYA was documented. Outcomes were technical success, immediate disappearance, complete obliteration, recurrence rate, recurrence-free survival (RFS) and recurrence management.

Results: Over eight years, 167 patients underwent EUS-guided coils and CYA: 49.7% females, a median age of 63 years, and 19% alcohol-related cirrhosis. Child-Pugh B and C were estimated in 65.9% and 18% of patients, respectively. The most common previous therapies included B-blockers (32.3%), band ligation (26.9%), and CYA (21.0%). GV treatment was intended as secondary prophylaxis in 88.6%. More than one feeder vessel was targeted in 38.9%. In 67.7% of cases up to three coils were required, with a median injection of 3.6 ml of CYA. A 100% technical success was achieved. Among the 167 patients, 15 experienced recurrences (8.9%), with a median RFS of 4.9 months. When comparing non-recurrence vs recurrence patients, immediate disappearance was noticed in 69.7% vs 40.0% with white light endoscopy ($p=0.039$) and complete obliteration in 90.1% vs 73.3% during EUS ($p=0.072$), respectively. Immediate disappearance was a significant predictive factor for non-recurrence (OR 0.29; IC 95% 0.09 –

0.85; $p=.026$), with a 95% positive predictive value. All recurrences were managed with EUS-guided coils and CYA (9/15) and clips and CYA (6/15), with a 12/15 non-recurrence rate (Table 1). On multivariate analysis, a lower recurrence was associated with previous B-blockers therapy (OR 0.18; 95% CI 0.02 to 0.78; $p=.045$), while a previous CYA attempt represented a high-risk factor for recurrence (OR 10.2; 95% CI 1.08 to 110; $p=.044$).

	n=15	
Re-intervention procedure, n (%)	Coils + CYA	9 (60.0)
	Clips + CYA	6 (40.0)
Re-intervention-free survival (months), median (IQR)		4.9 (3.10 - 12.5)
Recurrence post-re-intervention, n (%)	No recurrence	12 (80.0)
	Reappearance	3 (20.0)
	Re-bleeding	-
Post-reintervention procedure, n (%)	Coils alone	-
	Coils + CYA	3/3 (100.0)
	Clips + CYA	-

Table 1. Management and follow-up in patients with recurrence. IQR, interquartile range.

Conclusion: EUS-guided coils and CYA in feeder vessels have shown high technical success and low recurrence rate in treating IGV I and GOV II. CYA attempts should be misadvised in GV. Non-immediate disappearance requires shorter follow-ups to assess for early recurrence.

Introduction: CYP2E1 is one of the main members of cytochromes P450 superfamily, which is expressed in numerous tissues, including intestines. Overactivity of intestinal CYP2E1 leads to the loss of intestinal wall integrity and contributes to the development of the leaky-gut syndrome (LGS) which is observed in inflammatory bowel diseases (IBD). Moreover, activity of CYP2E1 may contribute to the severity of inflammation due to the production of reactive oxygen species.

Aims & Methods: The main aim of the study was to evaluate the therapeutic effects of selective CYP2E1 inhibitors in *in vitro* and *in vivo* models of intestinal hyperpermeability and inflammation. We used 1) Allyl methyl sulfide, 2) Diallyl ether (DE), and 3) Thiophene (T).

First we used MTT test to assess the cytotoxicity of CYP2E1 inhibitors in Caco-2 cells. Then, we measured the permeability of Caco-2 monolayer exposed to fructose; alone or after pretreatment with CYP2E1 inhibitors, with the use of transepithelial electrical resistance (TEER). Finally, we evaluated the effect of CYP2E1 inhibitors on cellular inflammatory response to the cocktail of IFN γ , TNF α , IL-1 β , and LPS.

In the *in vivo* part of the study we used three mouse models of intestinal inflammation and disrupted permeability. Acute colitis was induced by the addition of 3% dextran sulfate sodium (DSS) to drinking water for 5 days. Chronic colitis was induced by treatment with 2% DSS in drinking water followed by 4 days of water without DSS. Fructose-induced intestinal hyperpermeability was induced through free access to water containing 30% fructose solution for 8 weeks. In all models, DE was administered orally (*p.o.*) or rectally (*i.c.*) at a dose of 10 mg/kg body weight.

After each *in vivo* experiment, we performed macroscopic assessment of mouse colon, determination of tissue myeloperoxidase activity, measurement of intestinal permeability with FITC-dextran method, and analysis of mRNA expression of the following genes: occludin, ZO-1, CLDN-1, TNF α , IL-1 β , IL-6, CYP2E1.

Results: We did not see cytotoxicity of CYP2E1 inhibitors in Caco-2 cells. Further research showed that monolayers of cells pretreated with DE and T were significantly resistant to the increase in its permeability induced by fructose. Moreover, DE completely prevented the cellular inflammatory response as indicated by low IL-6 secretion. These results allowed us to choose DE for the *in vivo* phase.

In the first *in vivo* experiment, we assessed the effect of DE administered *p.o.* and *i.c.* on acute intestinal inflammation induced by DSS. DE treatment (*p.o.*) significantly prevented DSS-induced increase in TNF α and CYP2E1 expression. DE administered *i.c.* once daily significantly prevented from the decrease in colon length caused by DSS.

Then, we modeled chronic intestinal inflammation induced by DSS. DE was administered *p.o.* and *i.c.*. DE *p.o.* and *i.c.* significantly prevented DSS-induced increase in macroscopic intestinal damage. Additionally, DE *p.o.* significantly increased ZO-1 expression compared to the DSS group. In the fourth experiment, we assessed the effect of DE administered *p.o.* and *i.c.* on the gut permeability in the model of LGS induced by high doses of fructose. DE *p.o.* significantly reduced intestinal permeability compared to the fructose group.

Conclusion: Our experiments show, that CYP2E1 selective inhibitors display beneficial properties. Further studies on these substances may bring additional opportunities to develop novel therapeutics for IBD and LGS.

MELANIN NANOPARTICLES AMELIORATES COLITIS IN MICE BY
REDUCING OXIDATIVE STRESS

吴^{1,2}, J. Sun², S. Chen², Z. Qiang²

Introduction: Oxidative stress disruption are involved in the occurrence and development of inflammatory bowel disease (IBD). Previous reports have shown that melanin nanoparticles (MNPs) have the function of regulating oxidative stress. The aim of this study is to explore the preventive effect of MNPs on DSS-induced colitis in mice and its mechanism.

Aims & Methods: In this study, C57BL/6 wild-type mice were divided into 7 groups according to whether induced colitis by DSS, whether prophylactic application of MNPs or mesalazine, and different administration method. Mice were randomly assigned to control group, DSS group, MNPs gavage (MNPs-ig+DSS), MNPs enema (MNPs-en+DSS), MNPs enema + gavage (MNPs-bo+DSS), MSL gavage (MSL-ig+DSS), and MSL gavage + enema group (MSL-bo+DSS). The effect of MNPs on DSS-mice was evaluated by clinical manifestation, length of colon, pathological scores of colon tissues, and the level of inflammatory cytokines. The distribution and expression of intestinal mucosal junction proteins Occludin (OCC) and ZO-1 were detected to evaluate the effect of MNPs on colon mucosal barrier. In addition, the abundance and species distribution of intestinal microbiota were determined by 16S rRNA sequencing in each group. In the mechanism exploration part, the level of superoxide dismutase (SOD) and malondialdehyde (MDA) were used to evaluate the activity of reactive oxygen species (ROS) in mouse colon tissue, and the expression of ROS-related NLRP3/NF- κ B signaling pathway-related proteins was further detected. In addition, this study verified the effect of MNPs on liver and kidney through the evaluation of organ morphology and function.

Results: C57BL/6 wild-type mice showed weight loss, colon shortening, increase of DAI and intestinal pathological scores, accompanied by increased levels of intestinal inflammatory cytokines TNF- α , IL-1 β and IL-6 and decreased levels of IL-10 in colon tissue, which can be prevented by the application of MNPs to a certain extent. MNPs can help protected the integrity of the intestinal mucosal barrier, which is manifested by the restoration of the distribution and expression of tight junction proteins ZO-1 and Occludin. However, 16S rRNA sequencing failed to show a significant regulatory effect of MNPs on the intestinal microbiota. MNPs can significantly reduce the level of colonic SOD and increase the level of MDA induced by DSS, and this effect was related to the inhibition of the activation of NLRP3 inflammasome and the expression of downstream NF- κ B inflammatory signaling pathway proteins. Finally, MNPs had no effect on the morphology and function of liver and kidney.

Conclusion: MNPs can improve colitis and regulate mucosal barrier function in mice, which may be related to reduced oxidative stress and inhibited activation of NLRP3 inflammasome and downstream NF- κ B inflammatory signaling pathway. Our findings suggest the potential value of MNPs as a treatment for IBD.

Contact E-Mail Address: kaline.arnauts@kuleuven.be

Introduction: GLPG3970, a potent and selective small molecule salt-inducible kinase (SIK) 2/3 inhibitor, exhibits a dual mechanism modulating both pro-inflammatory and immunoregulatory pathways that holds potential as a novel therapeutic option for inflammatory bowel disease.^{1,2} Oral administration of GLPG3970 in colitis mouse models reduced disease activity scores, inhibited pro-inflammatory cytokine release and improved histological endpoints including protection of goblet cell health and MUC2 expression.^{2,3}

Mechanistic investigations demonstrated a broad immunomodulatory activity on colonic immune cell types. It remains unclear whether SIK2/SIK3 inhibition exerts a direct therapeutic activity on intestinal epithelial cell types or if these effects result indirectly from modulating pro-inflammatory and immunoregulatory mechanisms.³

Aims & Methods: We aimed to unravel the activity of SIK2/SIK3 inhibition using GLPG3970 in ulcerative colitis (UC) patient-derived epithelial cells focusing on SIK target engagement markers, inflammation and mucus production. Differentiated intestinal organoids from patients with UC were exposed to vehicle control, GLPG3970 (3 μ M and 20 μ M) or PGE2 (20 μ M; positive control) for 24 hours (gene expression) or 48 hours (immunohistochemistry). Gene expression was evaluated in organoid cultures derived from five patients with UC, with or without 24 hours of pro-inflammatory stimulation (using a mix of 100 ng/mL TNF α , 20 ng/mL IL-1 β and 1 μ g/mL flagellin)⁴ prior to 24 hours of exposure in combination with the compound, and measured by RT-qPCR compared with vehicle control (Friedman, Dunn's multiple comparison). Immunohistochemistry was performed for MUC2, DAPI, CK14 (n = 3 patients, minimum 10 images/condition, 3 replicates). Randomized images were analysed by Imaris Software by sectioning regions of interest (two-way ANOVA, Dunnett's multiple comparison).

Results: Upon GLPG3970 exposure, UC patient-derived organoids showed transcriptional upregulation of SIK target engagement markers such as the CREB¹ activation genes *NR4A1*, *NR4A2* and *NR4A3*. There was no effect with GLPG3970 on gene expression of inflammatory markers in colon epithelial cells, in the presence or absence of inflammatory stimulation, except for *IL-1 β* and *IL-8* upregulation after 24 hours of GLPG3970 exposure. Genes related to mucus production were upregulated in both non-inflamed (*MUC5AC*, 20 μ M, $p < 0.01$; *AGR2*, 20 μ M, $p < 0.05$) and inflamed conditions (*MUC2*, 20 μ M, $p < 0.01$; *MUC5AC*, 3 μ M and 20 μ M, $p < 0.01$) at the highest GLPG3970 concentration tested. Immunohistochemistry confirmed increased MUC2 secretion (secreted MUC2 surface $\times$ secreted MUC2 intensity) after 48 hours of GLPG3970 stimulation (3 μ M, $p < 0.05$; 20 μ M, $p < 0.01$); however, no significant increase was measured in absolute goblet cell number or goblet surface intensity compared with vehicle control.

Conclusion: SIK2/SIK3 inhibition by GLPG3970 showed a significant up-regulation of target engagement markers as measured by the CREB activation genes *NR4A1/2/3* in UC patient-derived colon epithelial cells, whereas

no direct downregulation of inflammatory markers was observed. Exposure of UC patient-derived colonic organoids to GLPG3970 20 μ M resulted in a signature of enhanced mucus secretion, both in the presence and absence of inflammation. Overall, these data indicate a direct impact of SIK2/SIK3 inhibition in intestinal epithelial cells with potential benefit in promoting barrier reinforcement via goblet cell mucus production in patients with active UC.

Introduction: Maintaining the mucus layer is crucial in the innate immune system, and MUC2 is a significant component of the mucus layer in the intestinal tract. Urolithin A (Uro A) is a gut microbiota-derived metabolite from ellagic acid, commonly found in pomegranates and raspberries.

Recently, it has been described that the administration of Uro A enhances barrier function via the tight junction. However, the intestinal protective effect via mucin production has yet to be elucidated.

Aims & Methods: This study aimed to elucidate the effect of Uro A on mucin synthesis in the colon and to investigate the underlying molecular mechanisms. First, in vivo experiments were performed using wild-type mice (C57BL/6), NF-E2-related factor 2 (Nrf2) deficient mice, and wild-type mice treated with an aryl hydrocarbon receptor (AhR) antagonist. After Uro A administration, gut microbiota composition was analyzed, and short-chain fatty acid concentration was also measured. Next, in vitro assays using mucin-producing cells (LS174T) were conducted to assess mucin production upon Uro A treatment.

Results: The thickness of the MUC2-positive mucus layer in the Uro A group was significantly increased compared with that in the control group ($p < 0.01$). MUC2 protein levels in the colonic mucosal epithelium were significantly higher in the Uro A group than in the control group ($p = 0.041$). In Nrf2 deficient mice, Uro A treatment did not increase MUC2 protein levels in the colonic epithelium ($p = 0.309$). Similarly, in mice treated intraperitoneally with an AhR antagonist, MUC2 protein levels did not increase in the colonic epithelium after treatment with Uro A ($p = 0.222$). In experiments using Fluorescein isothiocyanate- Dextran, Uro A administration suppressed the mucosal permeability. Meanwhile, Uro A administration did not significantly upregulate tight junction protein expression in the epithelium. Hence, increased intestinal mucus appears to suppress leaky gut by a mechanism distinct from upregulating tight junction protein. After the treatment with Uro A, short-chain fatty acid-producing bacteria such as family *S24_7*, and genus *Ruminococcus* significantly increased. In addition, the propionic acid concentrations in stools were significantly increased after UroA administration. The treatment of Uro A was also beneficial for dextran sulfate sodium (DSS)-induced colitis in the mice model. The Uro A group showed a marked reduction in the disease activity index (DAI) after DSS administration ($p = 0.033$), and in the control group, the intestinal length was significantly shortened ($p = 0.018$). Hematoxylin and eosin staining of tissue sections showed that inflammatory cell infiltration and destruction of gland duct structures were mild in the Uro A group. In vitro data using LS174T cells demonstrated that the MUC2 mRNA level and the MUC2 protein levels in LS174T cells significantly increased after Uro A administration ($p = 0.02$ and $p < 0.01$, respectively). Fluorescence immunostaining showed that the strength of MUC2 fluorescence in LS174T cells after treatment with Uro A was significantly higher than that in the control group. In addition, MUC2 fluorescence expression did not increase after treatment with an Nrf 2 inhibitor. Similarly, MUC2 fluorescence did not increase after treatment with AhR antagonist.

Conclusion: Uro A promoted the up-regulation of MUC2 synthesis through the AhR and Nrf2 pathway, leading to the enhancement of the mucosal barrier function and the inhibition of the development of murine colitis. These findings involve alternating the intestinal microbiota and SCFA.

A NOVEL ROLE FOR FREE FATTY ACID RECEPTOR 3 IN MODULATING INFLAMMATORY SIGNATURE OF MACROPHAGES IN IBD

C. O'Mahony¹, J. Toman¹, A. Amamou¹, S. Ghosh¹
¹APC Microbiome, College of Medicine, Cork, Ireland

Contact E-Mail Address: 121126891@umail.ucc.ie

Introduction: As many as 40% of IBD patients do not respond to targeted therapies¹. Enhancing the efficacy of these therapies is a key priority, and defective host-microbe interplay is often thought to underpin a proportion of mechanistic therapeutic failure. Interactions of macrophages with the microbial-derived SCFAs (Butyrate, Propionate and Acetate) in particular; may be critical for disease remission. Therefore, we examined the manner that macrophages interacted with, and changed their behaviour according to exposure to SCFAs in order to identify new therapeutic targets.

Aims & Methods: This study aimed to explore phenotypic changes of macrophages upon sensing of SCFAs in the context of IBD. We hypothesised that SCFAs would alter the inflammatory signature of macrophages, and that de-orphanized transmembrane G-protein receptor Free-fatty acid receptor 3 (FFA3) expressed by immune cells in GI tract would be critical for this process, and furthermore that effective sensing of SCFAs would be necessary for shaping macrophage phenotype. THP-1 and monocyte-derived macrophage models were developed for exploring inflammatory signatures in the presence of 1mM or 4mM of each SCFA (Butyrate/Propionate/Acetate). By using a pharmacological activator of FFA3 (AR420626) we aimed to identify whether this receptor play an important role in directing macrophage phenotype. Secretion of (type-I Interferon) IFN-I and pro-inflammatory cytokines were measured using ELISA. Expression of Interferon-stimulated genes (ISGs) was quantified using RT-PCR. Subsequent experiments aimed to validate our findings with a knock-down model of FFA3.

Results: We demonstrated that polarisation of macrophages with LPS & IFN- γ rapidly led to the induction of type-I interferon responses and release of pro-inflammatory cytokines. This heightened secretion of IFN-I was almost entirely muted in the presence of butyrate and propionate (1mM and 4mM). As IFN-I drives the expression of ISGs through activation of IFNAR1-JAK/STAT axis, we quantified expression of the ISGs MX1 and IFIT1 as an indirect measure of bioactive IFN. Induction of MX1 and IFIT1, were strongly repressed by butyrate and propionate. Based on these observations, we determined that these responses to both SCFAs were being mediated by FFA3. Intriguingly, our results were closely mimicked by pharmacological intervention with AR420626 in a dose-dependent manner (10 – 50 μ M), suggesting that IFN-I secretion could be attenuated through activation of FFA3. Introducing a knock-down to our model, we validated our findings, and macrophages displayed impaired sensing of SCFA in the absence of FFA3.

Conclusion: We identified that macrophages reduce IFN-I release in the presence of butyrate and propionate, which is partly mediated through FFA3, and FFA3 ligands may be helpful for dampening inflammation in the gut mucosa in IBD.

CANNABIDIOL, WHEN COMBINED WITH OLSALAZINE, OFFERS A NOVEL TREATMENT APPROACH FOR ULCERATIVE COLITIS

D. Thapa¹, L. Warne^{1,2}, M. Patil¹, R. Carlessi¹, M. Falasca³

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease (IBD) characterized primarily by colon inflammation, significantly impacting quality of life. Current treatment options, including aminosalicylates such as olsalazine, often result in adverse effects and reduced efficacy over time, providing symptomatic relief rather than a cure. This underscores the urgent need for new, effective therapies.

The endocannabinoidome, the body's endogenous lipid signalling system comprising cannabinoid receptors, endogenous ligands, and metabolic enzymes, is emerging as a novel target for treating various inflammatory and metabolic disorders, including IBD (1).

Cannabidiol (CBD), a non-psychoactive compound found in Cannabis, exhibits anti-inflammatory and analgesic properties, including in IBD, through modulation of the endocannabinoidome. However, the clinical efficacy of CBD in IBD remains uncertain despite numerous trials (2).

Aims & Methods: This study aims to investigate the efficacy of CBD in combination with a sub-therapeutic dose of a clinically used drug for ulcerative colitis, olsalazine, in a refined and translationally relevant murine acute and chronic colitis model (3).

For induction of the acute colitis model, female BALB/c mice, aged 8-10 weeks, were challenged with 4% dextran sodium sulfate (DSS) in drinking water for 7 days, followed by 3 days of normal water. For the chronic model, 2% DSS was administered for 7 days, followed by 1% DSS for 10 days and again 2% for another 7 days. CBD (10, 30, and 60 mg/kg), and olsalazine (50 mg/kg) were administered intraperitoneally or orally once a day from day 1 to day 11 in the acute model whereas in the chronic model, these drugs were administered from days 1 to 10 and days 18 to 24. For the combination treatments, 50 mg/kg olsalazine was combined with 10 mg/kg CBD and delivered orally in both acute and chronic models.

Daily monitoring, including body weight, stool consistency, and occult blood/rectal bleeding, was recorded to calculate the disease activity index (DAI) score.

On endpoints (day 11 or day 24), whole blood was collected, and mice were euthanized to assess inflammation in different organs including the colon, spleen, kidneys, and liver. The tissues were flash frozen in liquid nitrogen and stored at -80°C. Frozen tissues were used to measure cytokines and chemokines using multiplex assays and neutrophils using myeloperoxidase (MPO) activity assays.

Results: Mice challenged with DSS in both acute and chronic models exhibited increased DAI scores, decreased colon length, increased cytokines and chemokines expression, increased MPO activity, and increased liver, spleen, and kidney weight. CBD treatment at 60 mg/kg, but not at 10 and 30 mg/kg, significantly reduced acute colitis as demonstrated by decreased DAI scores, decreased MPO activity and cytokines and chemokines expression, and increased colon length. Administration of olsalazine alone at 50 mg/kg orally did not produce any beneficial effects, but when combined with 10 mg/kg of CBD, there was a significant reduction in all colitis markers in both acute and chronic models.

Conclusion: While using CBD alone for treating colitis is ineffective, and high doses of olsalazine used in the clinics often come with adverse effects and lose effectiveness over time, our data show that combining low doses

of CBD and olsalazine significantly reduces colitis without adverse effects. Therefore, the low-dose combination of CBD and olsalazine offers a promising novel treatment for ulcerative colitis.

SINGLE-CELL TRANSCRIPTOMIC ANALYSIS REVEALS INSIGHTS INTO THE MECHANISM OF ACTION OF GRANULOCYTE-MONOCYTE APHERESIS WITH ADACOLUMN®

D. Kioroglou¹, J.L. Cabriada Nuño², U.M. Marigorta¹,

I. Rodríguez-Lago²

¹CIC bioGUNE, Bilbao, Spain, ²Hospital Universitario de Galdakao, Gastroenterology, Bilbao, Spain

Contact E-Mail Address: iago.r.lago@gmail.com

Introduction: Granulocyte-monocyte apheresis (GMA) with Adacolumn® is a non-pharmacological treatment approved for the management of ulcerative colitis (UC), especially in steroid-dependent cases. The precise mechanism of action and immunological changes associated with GMA are still not fully understood. Gene expression analysis at the single-cell level (through scRNA-Seq) has emerged as a key tool to characterize drug responses at the molecular level.

Aims & Methods: We used scRNA-Seq to investigate the transcriptomic effects and immune cell population alterations induced by GMA. We generated scRNA-Seq from peripheral blood mononuclear cells (PBMC) of six ulcerative colitis (UC) patients undergoing GMA treatment.

Our analyses focused on gene expression profiles obtained at three key timepoints, namely

- i) immediately before the start of the first session,
- ii) immediately after the end of the first session (and hence, with a 2-hour gap from the first timepoint), and
- iii) after 5 sessions of GMA treatment. We examined a total of 12 samples, including three patients with data available for all three timepoints. The analytical pipeline comprised standard steps in scRNA-Seq, including quality control, filtering and integration by cell-type annotation, differential gene expression analysis and pathway enrichment profiling.

Results: We report three main results. First, we observed alterations in cell types directly impacted by GMA treatment in UC patients, including expansions of IFN γ -producing plasmacytoid dendritic cells (pDC) and subtype composition changes in central components of the innate system such as Natural Killers. Second, our analysis of short-term effects within the first session highlights significant changes in non-classical monocytes, including upregulation of pathways associated with hypoxia and glycolysis. Finally, evaluation after 5 sessions of treatment unveiled more widespread changes affecting various regulatory pathways and extending across cell types. In particular, we detect alterations in T cell populations, including upregulation of key pathways in response to inflammation in regulatory T cells.

Conclusion: For the first time, we have generated 12 single-cell transcriptomic profiles to characterize the effects of GMA treatment on peripheral blood of UC patients. Our analyses reveal significant alterations in gene regulation and cell type composition among patients undergoing GMA treatment, observed both in the short-term after the first 2-hour session and over the course of 5 sessions. By examining three key timepoints, we provide insights into the longitudinal changes and molecular mechanisms underlying the response to GMA treatment.

Disclosure: Nothing to disclose.

Contact E-Mail Address: l.mulders@amsterdamumc.nl

Introduction: Perianal fistulas occur in up to 30% of patients with Crohn's disease (pCD) and frequently require a combined medical and surgical treatment approach. Hyperbaric Oxygen Therapy (HBOT) has previously shown benefit in treatment-refractory pCD.

Aims & Methods: In this pilot study, we aim to assess the feasibility of surgical fistula closure 4 weeks after HBOT, and efficacy of combining surgical closure and 8 weeks HBOT.

Patients with complex pCD refractory to at least 6 months of anti-TNF therapy were included in this study. All patients received a seton prior to starting treatment with 40 sessions (8 weeks) of HBOT (each lasting 110 minutes, with 5-minute air breaks) with 100% oxygen at 2.4 atmosphere. At week 4 the seton was removed, and surgical closure of the internal fistula opening was attempted. All patients continued stable dose of medical treatment during the study. Response was assessed by the fistula drainage assessment (FDA) and the perianal disease activity index (PDAI) at week 9, 26 and 52, and by pelvic MRI at week 9 and 26. MRI response was defined as a decrease of 2 points in MAGNIFI-CD score, MRI remission as a MAGNIFI-CD ≤6. (Serious) Adverse Events (AE) were reported for 52 weeks. Univariate logistical regression was used to explore potential variates associated with PDAI response (≤4) at week 26.

Age (years), mean (95%CI)	30.5 (23.7 – 27.3)
Female, n (%)	9 (90)
Crohn's disease duration (years), median [IQR]	9.0 [1.8 – 14.5]
Perianal disease duration (years), median [IQR]	3.5 [1.8 – 7.3]
Proctitis at baseline, n (%)	2 (20)
Internal fistula openings, n (%)	1: 7 (70) 2: 3 (30)
Primary fistula location, n (%)	anterior: 3 (30) lateral: 3 (30) posterior: 4 (40)
Fistula tracts, mean (95%CI)	3.5 (2.8 – 6.3)
Previous fistula surgeries, mean (95%CI)	4.1 (2.5 – 5.7)
Perianal fistula classification (Geldof et al.; class 1 – 4b), n (%)	2a: 3 (30) 2b: 1 (10) 2c-i: 1 (10) 2c-ii: 5 (50)

Table 1. Patient and fistula characteristics (n=10).

Results: Ten patients completed treatment and were analyzed (Table 1). All patients completed HBOT and underwent a technically successful surgical procedure at week 4. No proctitis was encountered at week 4 during examination under anesthesia. PDAI response was achieved by 30%, 60%, 58% at week 9, 26 and 52, respectively. FDA response/remission was achieved in 50%/20%, 80%/40% and 80%/50% of patients at week 9, 26 and 52, respectively. MRI response/remission was achieved in 60%/10% and 60%/20% of patients at week 9 and 26, respectively. No significant parameters were associated with PDAI response at week 26 in univariate logistical regression. (S)AEs included one patient with a potential oxygen toxicity seizure without long term effects, and one patient reported claustrophobia, no new AEs were reported.

Conclusion: HBOT is feasible in combination with surgical therapy in patients with complex pCD refractory to anti-TNF therapy. Patients had long-lasting benefit of the combined treatment approach. Further translational data are currently analyzed to clarify mechanisms of action and to explore potential biomarkers for therapy response.

DEVELOPMENT AND CHARACTERIZATION OF SPY003, A NOVEL EXTENDED HALF-LIFE MONOCLONAL ANTIBODY DRUG CANDIDATE TARGETING IL-23 FOR THE TREATMENT OF IBD

B. Kang¹, M. Alam¹, J. Milligan¹, S. Oliveira¹, J. Friedman², D. Nguyen², A. Spencer², J. Oh¹, H. Shaheen¹
¹Paragon Therapeutics, Waltham, United States of America, ²Spyre Therapeutics, Waltham, United States of America

Contact E-Mail Address: andy.spencer@spyre.com

Introduction: The cytokine IL-23 is secreted by activated macrophage and dendritic cells (DC) and promotes the expansion and/or activity of Th17 cells, CD8+ T cells, macrophages, and DCs. Its pathogenic role in IBD is suggested by genetic association and has been confirmed in clinical trials demonstrating IL-23 antagonism as an effective and safe treatment for Crohn's disease (CD) and ulcerative colitis (UC). SPY003 is a novel, extended half-life humanized IgG1 monoclonal antibody (mAb) that binds IL-23 with high affinity and specificity and potentially inhibits IL-23-mediated signaling.

Aims & Methods: SPY003 was evaluated in multiple *in vitro* and *ex vivo* assays compared to risankizumab (RIS) and guselkumab (GUS). Binding affinity to IL-23 was determined by surface plasmon resonance (SPR) and kinetic exclusion assays (KinExA). Antagonism of IL-23 signaling was measured via a STAT3 reporter cell line and phospho-STAT3 ELISA. SPY003-induced reduction of IL-17 secretion in response to human IL-23 was assessed in mouse splenocytes and human peripheral blood mononuclear

cells (PBMC). The binding epitope of SPY003 to IL-23 was determined using cryogenic electron microscopy. Half-life extension was measured via pharmacokinetic analysis in cynomolgus monkeys given a single bolus of SPY003 by intravenous and/or subcutaneous (SC) administration.

Results: SPY003 binds specifically to IL-23 with picomolar affinity. It inhibits STAT3 activity and phosphorylation with IC_{50} values $< 1nM$, as well as IL-17 secretion in IL-23-stimulated mouse splenocytes and human PBMC. IL-23 binding potency and IC_{50} values for IL-23 antagonism are comparable to those of RIS and GUS. Cryo-EM demonstrates the binding epitope of SPY003 within IL-23. The half-life of SPY003 is significantly extended in cynomolgus monkeys compared to both RIS and GUS. Based on allometric scaling of the clearance of SPY003 observed in this study, predictive simulations of SPY003 PK in humans suggest that Q3M-Q6M+ SC dosing will achieve therapeutic exposures in patients across a wide range of body weights and albumin concentrations.

Conclusion: SPY003 exhibits high selectivity and affinity for IL-23 and potentially inhibits downstream cellular signaling. With an extended half-life in NHP, SPY003 demonstrates therapeutic potential for effective and safe treatment of CD and UC with the potential advantage of twice a year SC dosing. Further preclinical and clinical studies are warranted to demonstrate this potential.

UNVEILING THE STRONG SAFETY PROFILE AND HIGH TARGET ENGAGEMENT OF OPM-101, A FIRST-IN-CLASS ORALLY AVAILABLE RIPK2 INHIBITOR, IN A PHASE 1 CLINICAL TRIAL IN HEALTHY VOLUNTEERS

L. Peyrin-Biroulet¹, B. Robin², J. Hoflack², P. Genne²

¹Nancy University Hospital, Nancy, France, ²Oncodesign Precision Medicine, Dijon, France

Contact E-Mail Address: peyrinbiroulet@gmail.com

Introduction: Oncodesign Precision Medicine (OPM) has designed and developed OPM-101, an orally available macrocyclic small synthetic molecule with high affinity and specificity for binding and inhibiting RIPK2. The NOD2/RIPK2 pathway is a key driver of inflammatory bowel disease (IBD) as its hyperactivation results in an over production of proinflammatory cytokine, including tumor necrosis factor (TNF)- α , which plays an essential role in initiating and perpetuating inflammation and tissue damage in the intestine. Targeting RIPK2 has emerged as a promising therapeutic strategy for reducing inflammation, disease progression, and normalizing proinflammatory cytokines generation in IBD. Blocking RIPK2 pathway could become a possible therapeutic strategy for severe steroid refractory or dependent IBD patients. The main objective of this phase 1 study was to assess the safety and tolerability of OPM-101 in healthy volunteers.

Aims & Methods: The safety, pharmacokinetic (PK), and pharmacodynamic (PD) properties of OPM-101 were determined in a Single Ascending Dose (SAD) part of the study in male and female healthy volunteers. A single dose (5-1,000 mg) was administered to male healthy volunteers and a dose of 150 mg in female volunteers. A group of male volunteers received two single doses of 150 mg in fasted and in fed conditions a week apart. OPM-101 safety and tolerability were monitored throughout the study considering the following parameters: physical examination, any adverse events, clinical laboratory values, safety and 12-lead ECG, cardiac echography, Holter monitors, vital signs, and digestive tolerability. Blood samples were collected at pre-defined timepoints to determine the PK parameters and to assess the target engagement. Target engagement was determined *ex vivo* on whole blood samples by the percentage of in-

hibition of the L18-MDP-induced TNF α production. L18-MDP is a specific activator of the NOD2 pathway.

Results: In the SAD part of the study, 72 healthy volunteers were randomized in 9 cohorts. Volunteers were randomized 3:1 between OPM-101 (n=6) and placebo (n=2) in each cohort. The overall safety profile of OPM-101 was very good with only 8.3% of participants reporting a total of eight treatment-related TEAE (6 mild and 2 moderate).

OPM-101 is orally bioavailable, rapidly absorbed (T_{max} is between 2-4h), with a long terminal half-life of 12-15h. Female volunteers tended to have higher exposure than male volunteers receiving the same dose. When OPM-101 was administered after intake of a high fat breakfast, the exposure was twice that observed in fasted conditions, and variability of absorption was lower. The target engagement, observed with doses as low as 60 mg, was $>80\%$ over 24h and showed an immunomodulatory property inducing normalization of TNF α levels.

Conclusion: Following a single administration in both male and female healthy volunteers, OPM-101 exhibited a highly favorable safety profile. Its pharmacokinetic properties are well-suited for oral administration, demonstrating rapid target engagement after a single oral dose leading to an immunomodulation. This phase 1 study unveils OPM-101 as a potent RIPK2 inhibitor paving the way for groundbreaking therapeutic advancements in inflammatory colitis.

Introduction: Esophageal varices can lead to morbidity and mortality in patients with chronic liver diseases. There is a debate about the frequency of endoscopic variceal band ligation sessions needed for the eradication of esophageal varices.

Aims & Methods: We aimed to explore the optimal interval for endoscopic variceal band ligation sessions needed to obliterate esophageal varices. This study enrolled 374 patients with liver cirrhosis indicated for endoscopic variceal band ligation. After the first variceal band ligation, patients were randomly assigned to one of four groups regarding the interval of subsequent band ligation sessions:

Group 1 (subsequent band ligation every week),

Group 2 (subsequent band ligation every two weeks),

Group 3 (subsequent band ligation every three weeks), and;

Group 4 (subsequent band ligation every four weeks).

Patients were followed up till the point of eradicating esophageal varices with reporting of complications in the form of bleeding or post-banding ulcers.

Results: The studied groups had insignificant variations in terms of the mean number of sessions needed to eradicate varices completely and the mean number of subsequent band ligation sessions. Post-banding ulcers were highly incident in Group 1 (52.9%), followed by Group 2 (22.8%), Group 3 (8.0%), and Group 4 (2.7%), with a statistically significant difference between the studied groups ($p < 0.001$). The incidence of bleeding after the first band ligation session was only reported in Group 2 (1.3%). Patients with higher number of sessions needed to obliterate esophageal varices (sessions) were associated with lower hemoglobin (9.75 ± 1.60 vs.

10.48 ± 2.19 ; $p = 0.003$), lower INR (1.26 ± 0.24 vs. 1.35 ± 0.31 ; $p = 0.009$), and larger spleen diameter (15.52 ± 3.58 vs. 14.65 ± 3.31 ; $p = 0.011$) when compared with patients needed lower number of sessions to obliterate esophageal varices.

Conclusion: The four-week interval of elective variceal band ligation sessions is effective in achieving complete esophageal varices eradication with a lower rate of complications.

IDENTIFICATION OF SUBPHENOTYPES OF SEPTIC PATIENTS WITH LIVER CIRRHOSIS

J. Lin¹, J. Zhu¹, R. Li²

¹First affiliated hospital of Soochow university, Department of Gastroenterology, Suzhou, China, ²Soochow University, Suzhou, China

Contact E-Mail Address: jxlin@stu.suda.edu.cn

Introduction: Septic patients with liver cirrhosis exhibits considerable heterogeneity.

Aims & Methods: The objective of current study was to identify subphenotypes of liver cirrhosis with sepsis among intensive care unit (ICU) patients. A retrospective study was performed based on the Medical Information Mart for Intensive Care (MIMIC-IV 2.0) database. Using unsupervised clustering, we identified distinctive subphenotypes based on 37 clinical variables obtained on admission. Primary outcomes were 28-day mortality. Cox regression was applied to quantify the risk associated with each subphenotype concerning clinical outcomes. A machine learning (ML) prediction model was developed and made available online, capable of identifying these subphenotypes from fundamental clinical variables.

Results: Our study enrolled a total of 1087 septic patients with liver cirrhosis, revealing two unique subphenotypes via k-means clustering algorithm. Subphenotype 1 was assigned to 719 patients (66%) and subphenotype 2 to 368 patients (34%). The subphenotype 2 was characterized by higher levels of hepatic injury, higher SOFA scores (average SOFA scores were 12.5), and worse clinical outcomes (28-day mortality, 49%). Subphenotype 2 showed significantly increased risk of 28-day mortality compared to Subphenotype 1 (hazard ratio [HR] = 2.14 [95%CI 1.69 – 2.71], $p < 0.001$). The ML model integrated seven variables could predict subphenotypes accurately.

Conclusion: This study differentiated and stratified subphenotypes among septic patients with liver cirrhosis, laying a foundation for more personalized therapeutic strategies. The predictive ML model developed has the potential to bolster clinical decision-making pertaining to these patients within the ICU setting.

Introduction: This study revisits the management and outcomes of acute upper gastrointestinal bleeding (AUGIB) in cirrhotic patients across the United Kingdom, allowing comparisons with the last UK wide audit undertaken in 2007.¹

Aims & Methods: Focusing on cirrhotic patients with variceal bleeding, we analyze patient profiles, investigations, treatments, and outcomes, drawing comparisons with the 2007 study. A prospective multi-center observational study of adults (>16 years) presenting to 152 UK hospitals with AUGIB between 3 May - 2 Jul 2022.

Results: 744/5101 (15%) presenting with AUGIB had known cirrhosis (Child-Pugh categories: A:1%, B: 47%, C: 11%).with median age of 59yrs (IQR 49.7-69). 73%(547/744) were new admissions. Glasgow-Blatchford score(GBS), stratified patients into, 22% medium-risk(GBS 2-6),47% high-risk(7-11),and 30% very high-risk(≥12). For pre-endoscopy management: 58%(433) received proton pump inhibitors (PPI), 50%(371) terlipressin/vasopressor and 44%(326) antibiotics.

An endoscopy was performed for 91%(679/744). Time to endoscopy from presentation was: 0-12 hrs in 25%, 12-24 hrs in 25%, & 24-48 hrs in 21%. 45% (307/679) were identified to have varices (91% - oesophageal, 15% - gastric and 2% - duodenal) and 33%(224/679) had non-variceal findings. Median age of patients with varices (n=307) was 57 yrs (IQR 49-68). Stigmata of recent bleed were noted for 72%(222) - 45% blood in the upper GI tract and 65% high risk markings on varices and endotherapy was applied for 78%(241). Variceal therapy applied in 70%(214 - 93% banding, 12% injection therapy), Danis stent 2%(5) and Sengstaken tube 6%(14). 18% (55) had evidence of further in-patient bleeding after index endoscopy. During inpatient stay, 26%(81) needed >1 endoscopy, and 2%(6) underwent transjugular intrahepatic portosystemic shunt(TIPSS). 67%(206) were transfused ≥1 packed red blood cells, 17%(53) platelets and 22%(68) fresh frozen plasma for AUGIB. Median length of stay was 7days (IQR 5-11) and in-hospital mortality was 13%(40).

Comparisons with the 2007 audit for patients with varices revealed an increased average age (58yrs vs 54.5 yrs), increased pre-endoscopic use of PPI (62% vs 50%),vasopressors (70% vs 57%) and antibiotics (61% vs 27%). There was a significant increase in those receiving endotherapy (78% vs 64%) and undergoing TIPSS (2% vs .8%), along with a lower likelihood of further in-patient bleeding after an index endoscopy (18% vs 26%), and numerically lower in-hospital mortality (13% vs 15.2%).Comparisons with the 2007 audit are presented in table 1.

Outcome	2007 (n=526)	2022 (n=307)	p value
Mean age	54.5 yrs	57.7 yrs	-
Pre-endoscopy treatment			
Proton pump inhibitors	57%	62%	<0.05
Terlipressin/ vasopressor	57%	70%	<0.05
Antibiotics	27%	61%	<0.05
Endoscopy outcomes			
Stigmata of recent bleed	65%	72%	<0.05
Endotherapy	64%	78%	<0.05
Further bleeding	26%	18%	<0.05
TIPSS	0.8%	2%	<0.05
Transfusion >1 unit			
Packed red cells	73%	67%	<0.05
Fresh frozen plasma	35%	22%	<0.05
Platelets	14%	17%	0.26
Median LOS	9 days (IQR 5-21)	7 days (IQR 5-11)	-
In-hospital mortality	15.2%	13%	0.32

Table 1: Comparative analysis with 2007 audit of main outcomes for variceal bleeds.

Conclusion: Compared with 2007 patients presenting with variceal haemorrhage were more likely to receive optimal treatment, had reduced length of stay, reduced rebleeding and a trend towards reduced mortality. Our data suggests that further improvements in pre-endoscopic management and provision of TIPSS are required.

USE OF PROTON PUMP INHIBITORS IN PATIENTS WITH LIVER CIRRHOSIS AND ANTICOAGULANT THERAPY, A RETROSPECTIVE STUDY

R. Eftimie Spitz¹, T. Surdea-Blaga²

¹University of Medicine and Pharmacy “Iuliu Hatieganu” Cluj-Napoca, Snd Department of Internal Medicine, Cluj-Napoca, Romania, ²University of Medicine and Pharmacy “Iuliu Hatieganu” Cluj-Napoca, 2nd Medical Department, Cluj-Napoca, Romania

Introduction: Proton Pump Inhibitors (PPIs) are commonly prescribed for gastrointestinal disorders. Several studies have reported an overprescription of PPIs in patients with liver cirrhosis^{1,2}, yet their use in these patients increases the risk of spontaneous bacterial peritonitis and mortality rates. HAS-BLED score is a tool used to evaluate bleeding risk in individuals on chronic anticoagulation therapy, and cardiologists use it to prescribe PPIs in patients on anticoagulants, to reduce the risk of gastrointestinal bleeding³.

Aims & Methods: This study aimed to assess the appropriateness of PPI prescriptions in patients with liver cirrhosis and anticoagulant treatment. A secondary objective was to investigate whether the guidelines for administering PPIs based on a patient's HAS-BLED score align with the indications for PPI prescription recommended in established gastroenterological guidelines.

This study was retrospective. From January 2022 to December 2023, we included consecutive cirrhotic patients who had anticoagulant treatment for various indications (atrial fibrillation, deep vein thrombosis, pulmonary embolism). All patients were counted only once, even if hospitalized multiple times. To establish the validity of PPI prescription, we used the current guidelines⁴⁻⁷. Anticoagulant treatment alone, is not a valid indication for PPI prescription in patients with liver cirrhosis, in the absence of concomitant antiplatelet treatment⁴. HAS-BLED scores were calculated⁸, and patients with a score ≥ 4 were considered at high risk for bleeding.

We looked for an association between high HAS-BLED score and PPI prescription, and whether these prescriptions were aligned with the current gastroenterological guidelines.

Results: We found 577 hospitalizations for cirrhosis, among these, 61 patients (mean age 71.3 years old $\pm$ 8.88, 46 males) were under chronic anti-coagulant treatment. We identified 32 patients on PPIs during the hospital stay. Fourteen (43.7%) had no valid indication, but 5 had a high HAS-BLED score. The remaining patients (n=18) were prescribed PPIs for the following reasons: gastritis (n=10), antiplatelet with high risks (n=3), NSAID and corticosteroid (n=2), peptic ulcer disease (n=2), gastroesophageal reflux disease (n=1). In our cohort, 27 (44.3%) patients had a high HAS-BLED score. Among these patients, 18 were on PPI. In the patients with low HAS-BLED (n=34), 14 were on PPIs, and 9 of them didn't have a valid indication based on current gastroenterological guidelines. We computed the Chi2 statistic to assess the association between PPI prescription and a high HAS-BLED score: the chi-square statistic yielded 3.921 (p=0.048). A similar association was observed at discharge: the chi-square statistic was 3.994 (p=0.046). No association was observed between HAS-BLED score and inappropriate PPI prescription (Chi2 = 0.147, p = 0.7).

		Low HAS-BLED score	High HAS-BLED score
During hospitalization	PPI	14	18
	No PPI	29	9
At discharge	PPI	7	12
	No PPI	27	15

Conclusion: In our cohort of patients with liver cirrhosis, over 50% were prescribed PPIs during their hospital stay, with 43.7% lacking a valid indication. An association was observed between the HAS-BLED score and the prescription of PPIs; however, only a portion of the non-valid indications can be attributed to the high HAS-BLED score.

HEPATIC EXTRACELLULAR VESICLES-INDUCED CGAS-STING SIGNALING PROMOTES SKELETAL MUSCLE INFLAMMATION AND ATROPHY IN CIRRHOSIS

Y. 彭¹, X. Fan¹, L. Yang²
¹West China Hospital, Sichuan University, Division of Gastroenterology & Hepatology, Chengdu, China, ²West China Hospital of Sichuan University, Gastroenterology, Chengdu, China

Contact E-Mail Address: 2023224020021@stu.scu.edu.cn

Introduction: Sarcopenia, an important component of malnutrition, is linked to poor prognosis in cirrhotic patients. Recent studies have indicated that chronic muscle inflammation plays a pivotal role in the progression of sarcopenia, although the mechanism underlying the association between cirrhosis and chronic muscle inflammation remains poorly understood. Therefore, this study aimed to elucidate the specific mechanism by which hepatic-derived extracellular vesicles (EVs) promote proinflammatory responses in muscle macrophages via circulation, leading to the advancement of muscle inflammation during cirrhosis.

Aims & Methods: Liver fibrosis was induced by carbon tetrachloride injection and bile duct ligation. EVs from cirrhotic liver were isolated and characterized. Proteomics was utilized to identify functional mitochondrial components in EVs. Lastly, we conducted a cross-sectional study on patients with cirrhosis to validate these findings.

Results: Treatment of EVs from cirrhotic liver promoted inflammation in macrophages and muscle inflammation progression via activating the STING pathway. The Sting inhibitor in cirrhotic mice abolished the role of cirrhotic-derived EVs in muscle inflammation. In addition, hepatic-specific deletion of *Rab27a* and the inhibitor of EV—GW4869, significantly alleviated cirrhosis-induced muscle inflammation progression in cirrhotic mice. The proteomics results showed that mitochondrial proteins and mtDNA were enriched in EVs from cirrhotic liver. Furthermore, mitochondrial damage in hepatocytes caused by mitochondrial membrane potential decline led to mitochondrial DNA leakage, which caused macrophage inflammation through the STING pathway. Moreover, EVs from peripheral veins and hepatic veins who underwent transjugular intrahepatic portosystemic shunt in patients with cirrhosis and EV-mtDNA expression were associated with the severity of cirrhosis.

Conclusion: Hepatocyte-derived EVs promote inflammation in macrophages in muscle and facilitate muscle inflammation progression via the mtDNA-cGAS-STING signaling pathway. Reducing EV secretions in cirrhotic liver or targeting STING may be potential therapeutic approaches to slow the progression of cirrhosis-driven muscle inflammation.

ENDOSCOPIC CYANOACRYLATE INJECTION IMPROVES THE EFFICACY OF ENDOSCOPIC MANAGEMENT OF ESOPHAGEAL VARICEAL BLEEDING IN GOV TYPE I

X. Huang¹, L. Wu¹, S. Chen¹

¹Zhongshan Hospital, Fudan University, Endoscopy Center and Endoscopy Research Institute, Shanghai, China

Contact E-Mail Address: huangxiaoquan1010@aliyun.com

Introduction: The European Society of Gastrointestinal Endoscopy Guideline (ESGE) suggests endoscopic variceal ligation for treating acute esophageal variceal hemorrhage, and either endoscopic cyanoacrylate injection or EVL for GOV1-specific bleeding. However, some experts propose treating GOV1 similarly to esophageal varices since varices along the lesser curvature share a similar natural history.

Thus, data on endoscopic obstruction of gastric varices in GOV1 patients with esophageal variceal bleeding are limited. The efficacy of EVL for esophageal varices combined with cyanoacrylate injection for gastric varices in GOV1 appears promising.

Aims & Methods: In this multi-center retrospective cohort study, we aimed to access the efficacy of blocking gastric varices in the managing bleeding from esophageal varices in patients with GOV1. Cirrhotic patients experiencing bleeding from esophageal varices and having GOV I gastric varices in four centers were screened. All included patients were followed up for 180 days, or until death.

Results: A total of 93 cirrhotic patients with GOV I and bleeding esophageal varices were included. Among them, 58 patients underwent endoscopic cyanoacrylate injection (ECI) for gastric varices in addition to treatment for esophageal varices (EV) treatment, while the remaining 35 patients received treatment for EV only. Kaplan-Meier analysis demonstrated that the cumulative 180-day rebleeding rate was significantly lower in the ECI plus EV treatment group (7.9%) compared to the EV treatment group (30.7%) ($p=0.0031$). The cumulative incidence of 180-day mortality rate was 1.9% in the ECI plus EV treatment group and 23.9% in the EV treatment group ($p=0.0010$). Multivariable Cox regression analysis revealed that concomitant ECI treatment was an independent protective factor against for 180-day rebleeding and overall mortality.

Conclusion: In conclusion, obstruction of gastric varices in addition to endoscopic treatment for bleeding from esophageal varices in patients with GOV 1 proved superior to endoscopic treatment alone for esophageal variceal bleeding.

Introduction: The gut-liver axis, the anatomical and physiological connection between the gut and liver, is hypothesized to contribute to the development of portal vein thrombosis (PVT) in patients with end-stage liver disease (ESLD). It has been proposed that the portal vein in patients with ESLD is an inflammatory vascular bed due to the translocation of endotoxins and proinflammatory cytokines from the gut.

We hypothesized that a pro-inflammatory gut microbiome in ESLD patients, and elevated levels of the gut microbiota-derived metabolite trimethylamine N-oxide (TMAO) which is an established driver of thrombosis, may contribute to the development of PVT.

Aims & Methods: In this cross-sectional study we investigated whether differences in gut microbiome diversity, bacterial species, metabolic pathway abundances, and TMAO blood levels are associated with presence of PVT in ESLD patients. Fecal samples, serum samples and data from patients with ESLD, as well as living kidney transplant donors ('healthy controls'), were collected from the TransplantLines Biobank and Cohort Study (NCT02811835). PVT was defined as presence of a thrombus in the portal vein assessed by either radiology or during surgery within a year prior to or after fecal sample collection.

We analyzed the fecal samples using Shotgun Metagenomic Sequencing to assess and compare microbiome diversity, microbial taxonomy, and metabolic pathways abundances. TMAO levels were measured in serum samples using a Vantera® Clinical Analyzer (LabCorp, Morrisville, NC, USA).

Results: A total of 102 ESLD patients, of which 23 had PVT, and 246 healthy controls were included. We found no significant difference in microbiome diversity between patients with PVT (median Shannon Diversity Index (SDI): 2.08), and without PVT (median SDI: 1.84; $P=0.18$). Both ESLD groups had lower microbiome diversity compared to healthy controls (median SDI: 2.55; both $P<0.05$). A Beta Diversity Analysis confirmed that the gut microbiome of ESLD patients was markedly distinct from that of healthy controls.

After false discovery rate correction, *Bacteroides fragilis* and three species from the family Clostridiales were increased in abundance in ESLD patients with PVT compared to those without PVT. No altered metabolic pathways abundances were observed between both ESLD groups.

Overall, altered abundances of 29% ($n=49$) and 51% ($n=86$) bacterial species, and 18% ($n=96$) and 35% ($n=191$) metabolic pathways were observed between patients with and without PVT, respectively, when compared to healthy controls. TMAO levels were higher in both ESLD patients

with (3.30µm) and without PVT (3.00µm) compared to healthy controls (2.70µm) (P = 0.13 and P = 0.84 respectively), with a trend towards higher levels in patients with PVT (P = 0.19).

Conclusion: Although we observed a profound difference in gut microbiota composition between patients with ESLD and healthy controls, our analysis revealed minimal differences in the gut microbiome composition between ESLD patients with or without PVT. These results indicate that a gut microbiome-derived pro-inflammatory state was not associated with the presence of PVT in these patients.

Disclosure: Nothing to disclose.

Introduction: Fontan Procedure (FP) is a palliative surgical intervention designed to address congenital heart defects involving a single functioning ventricle. Fontan-Associated Liver Disease (FALD) refers to liver damage linked with hemodynamic shifts occurring in patients more than 10 years post-surgery. This condition encompasses structural alterations, liver lesions, and the onset of portal hypertension. Its progression can be categorized into three functional phases. The duration elapsed since the FP stands out as a significant predictor of FALD.

Aims & Methods: 1. To describe clinical, analytical, imaging and elastographic characteristics of a group of patients with FALD.

2. To correlate time since FP, type of procedure, and single ventricle morphology with stages 2 or 3 FALD related clinical events (ascites, esophageal varices, hepatic nodules, hepatocellular carcinoma-HCC) and with analytical variables.

Single-centre retrospective observational study of patients followed for FALD between 2020-2023 in the hepatology department. All patients were evaluated with abdominal ultrasound ± hepatic MRI and elastography. Upper endoscopy was performed in cases with thrombocytopenia <150,000 or elastographic values >20 kPa.

Results: Fifty-five patients, 51% men with a mean age of 27.75 ± 8.5 years were included. Median time since FP was 19 years. Stage 2 or 3 FALD was observed in 78.2% of patients. Median laboratory values were total bilirubin 0.98 mg/dL; albumin 4.8 g/dL; platelets 179,000/µL; INR 1.06. Median elastographic value was 18.3 kPa. Imaging findings compatible with cirrhosis were observed in 54.5% of patients. Hepatic lesions in MRI were found in 46.3% of patients (37% were focal nodular hyperplasia), but no HCC was detected. Esophageal varices were described in 20% of patients, but no bleeding was recorded. Ascites was the only form of hepatic decompensation (7.3% of patients). Time since FP was associated with thrombocytopenia, imaging findings of cirrhosis, portal hypertension findings on imaging or endoscopy; stage 2 or 3 FALD as well as FP failure (defined as functional deterioration which requires cardiac transplant evaluation) and death (p-value <0.05). No statistically significant associa-

tions were found between type of FP or single ventricle morphology and stage 2 or 3 FALD. Biological markers such as CA 125 and proBNP were associated with failure of the FP and development of ascites, respectively.

Conclusion: FALD comprises a group of hepatic alterations that require follow-up according to the functional stage. Time since FP is considered the main predictor of severe presentations. Although over half of our patients had signs of cirrhosis on imaging, a low rate of hepatic complications was observed, even in patients with a FP of over 20 years.

Introduction: Anticoagulation is one of the treatment options for patients with liver vascular disease. Given the potential severity of recurrent thrombosis and the high frequency of pro-thrombotic states in these patients, long-term anticoagulation may be necessary, but there are very few data on direct oral anticoagulants (DOACs) in this context. The aim of this study is to report our experience of the tolerability of DOACs and vitamin K antagonist (VKA).

Aims & Methods: This is a prospective, descriptive, preliminary, mono-centre study of patients with liver vascular disease who were treated with DOACs or vitamin K antagonists and who experienced an adverse event as a result of this therapy. Curative anticoagulation treatment with Rivaroxaban 20 mg or VKAs was initiated in patients at high risk of thrombosis or with DOACs 15 mg in patients at low risk. The aim of this study is to report our experience of the tolerability of DOACs and vitamin K antagonist (VKA).

Results: Out of a total of 142 patients followed for liver vascular disease, 62% of patients were on anticoagulation (n=88), 17% of them had undesirable effects to anticoagulants (n=15), including 10 patients on DOACs (27%) and 5 cases on VKA (10%). The mean age was 48.56 years, with a M/F sex ratio of 0.8%.

Concerning patients on AOD, 20% were being monitored for porto-sinosoidal vascular disease (n=2), 50% for portal cavernoma (n=5) and the remaining 30% for Budd-Chiari syndrome (n=3). The associated conditions were protein S and C deficiency in all patients, one of whom was also taking oestrogenic oral contraception (10%), and another hyperhomocysteinemia due to celiac disease (10%). All patients had preserved liver function. Average time to onset: 1 month. The following events occurred: 50% metrorrhagia (n=5); 40% had, in addition to metrorrhagia, haematemesis and gingivorrhagia (n=4), and 10% rectorrhagia. There was 1 death due to massive haemorrhagic shock caused by rupture of oesophageal varices.

Among patients on VKAs, one patient (20%) was being followed up for porto-sinosoidal vascular disease due to protein C and S deficiency, 2 patients were being followed up for portal cavernoma (40%), one due to coeliac disease and the other due to chronic myeloid leukaemia and 2 patients were being followed up for chronic portal thrombosis due to primary myelofibrosis and antiphospholipid syndrome, and another for chronic

portal thrombosis due to antiphospholipid syndrome. Average time to onset: 4 months. The following events occurred: 40% haematemesis (n=2); 40% each of gingivorrhagia and epistaxis (n=2) and 20% rectal bleeding. In terms of treatment, maintenance of the same treatment was envisaged in 40% with close clinical and biological monitoring, temporary cessation of treatment pending the completion of the necessary investigations in 13% (n=2), and switch to a VKA in 34% (n=5).

Conclusion: DOACs are associated with numerous adverse events, some of which are very severe and may lead to death. In our series, 27% of patients on DOACs had adverse events compared with 10% of patients on VKAs. This shows that VKAs could be an effective and safe alternative in patients with thrombosis even at low risk compared with DOACs. These results need to be confirmed by large prospective studies.

Disclosure: Nothing to disclose.

Introduction: According to the International Consensus Diagnostic Criteria (ICDC), histological evaluation is crucial in diagnosing autoimmune pancreatitis (AIP). However, it is challenging to obtain pre-operatively using standard fine needle aspiration (FNA). In the last decade, endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB), particularly new-generation needles with end-cutting design, has been demonstrated to outperform FNA in pancreatic solid lesions. More recently, their role in AIP definition has been evaluated with promising results. We aimed to assess the utility of EUS-FNB end-cutting needles in enhancing ICDC diagnostic levels in suspected AIP patients and in defining the specific AIP subtype.

Aims & Methods: Adult patients with suspected focal or diffuse AIP, classified as probable type 1, type 2, or NOS AIP according to ICDC, were prospectively and competitively enrolled in four different Centers. Definitive AIP, previously diagnosed AIP, and patients who had steroid administration within three months were excluded. All patients underwent EUS-FNB with a 22-gauge end-cutting needle. The capability of EUS-FNB in enhancing ICDC diagnostic level, the detection rates of level 1 or 2 of histologic criterion, the diagnostic accuracy of FNB in this setting, and the malignancy rate were calculated.

Histological parameters (ICDC) on FNB samples of AIP patients	Type 1 N=26	Type 2 N=12
Periductal lymphoplasmacytic infiltrate	23 (88.4%)	4 (33.3%)
Storiform fibrosis	23 (88.4%)	4 (33.3%)
Obliterative phlebitis	9 (34.6%)	0
IgG4+ cells	23 (88.4%)	1* (8.3%)
Granulocytic and lymphoplasmacytic acinar infiltrate	0	10 (83.3%)
GELs	0	7 (49%)
Level 1	19 (73.1%)	6 (50%)
Level 1+2	22 (84.6%)	11 (91.6%)

*<10 HPF

Results: A total of 52 suspected AIP were enrolled (75% male, mean age 57.9 ± 17.3), 50 with focal/segmental appearance and 2 with diffuse pancreatic involvement. The ultimate diagnosis was AIP in 39 (75%) patients (including 26 (50%) type 1 AIP, 12 (23.1%) type 2 and 1 (1.9%) type NOS) and malignancy in 7 (13.5%) (including 3 adenocarcinomas, 2 lymphomas, 1 neuroendocrine tumor and 1 metastasis). Chronic pancreatitis was diagnosed in the remaining 6 (11.5%) patients, with no recurrence or malignancy onset during a mean follow-up of 14 months (range 12-48). EUS-FNB improved the diagnostic level of AIP in 36 out of 39 (92.3%) patients with a final diagnosis of AIP, 29 (74.3%) definitive, and 7 (17.9%) probable, according to ICDC. Three patients received a final AIP diagnosis after a steroid trial (respectively, one type 1, one type 2 with subsequent IBD

diagnosis, and one type NOS). The rate of level 1 in type 1 and type 2 AIP was 73.1% and 50%, respectively. The level 1 or 2 rates in type 1 and type 2 AIP were 84.6% and 91.6%, respectively. The overall diagnostic accuracy of EUS-FNB was 94.2% [95% CI 84.1–98.8]. Two mild pancreatitis (3.8%) occurred after EUS-FNB in focal type 1 AIP located in the head.

Conclusion: EUS-FNB using end-cutting needles can enhance the existing diagnostic criteria, mainly in atypical and focal presentations, ruling out malignancy and defining the specific subtype in a relevant percentage of cases with an optimal accuracy (94.2%) and good safety.

Disclosure: Nothing to disclose.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) remains the procedure with the highest complication rate underscoring the importance of high-quality training. Despite existing guidelines, real-world data regarding training conditions remain limited. This Pan-European survey aims to explore the perceptions surrounding ERCP training.

Aims & Methods: A survey was distributed through the friends of the Young United European Gastroenterologists (UEG) Talent Group network. Inclusion criteria were physicians working in a UEG member state and regularly performing ERCP. Likert-scales as well as single- and multiple-choice questions were utilized.

Results: 649 of 1035 respondents from 35 countries were eligible for analysis. 228 were identified as trainees, 225 as trainers, and 196 regularly performed ERCP without being in either category. The mean age was 43 years with 72.0%, 27.6%, and 0.3% identifying as male, female, and non-bina-

ry, respectively. 73% of all participants agreed that a structured training regimen is desirable. However, 64% of participants reported not having such a structured program at their institution (71% of trainees and 55% of trainers). Likewise, 80% of participants did not have a mandatory self-assessment before training initiation.

Majority of trainees (73%) and trainers (81%) favored that training should be concentrated within centers meeting certain quality metrics. For this, 64% of all participants indicated that a threshold of 200 annual ERCPs should be used. Using this threshold revealed that 32% of trainees pursued training in centers with <200 annual ERCPs and that a low annual caseload of <50 was more frequent at lower volume centers vs. higher volume centers (86% vs. 63%, respectively). Furthermore, 71% of trainees performed <50 ERCPs/year in stark contrast to 95% of trainers performing >50 ERCPs/year. While 27% of trainees in higher volume centers were female, all trainees in lower volume centers were of female gender.

Conclusion: The first Pan-European survey investigating ERCP training conditions revealed that structured training and concentration of training efforts within European centers meeting specific quality metrics are desirable but exposed the low availability of structured training programs and that around 30% of trainees are practicing at lower volume centers. These data could be interpreted as motivation to further standardize ERCP training conditions and ultimately improve patient care throughout Europe.

Introduction: Indeterminate biliary duct strictures (IBDS) pose a diagnostic dilemma, and digital single-operator cholangioscopy (d-SOC) has improved diagnostic accuracy by enabling targeted intra-ductal biopsies (1-3). There is no consensus on the optimal biopsy strategy, but data suggests that at least four single biopsies yields adequate specimen samples for pathological examination (4). Considering the desmoplastic character of cholangiocarcinoma obtaining larger and deeper samples may have a higher diagnostic yield.

The aim of this study was to compare the diagnostic yield of d-SOC guided single standard biopsies to those obtained via bite-on-bite-biopsy (BBB) technique in patients with IBDS.

Aims & Methods: This international, multi-center, prospective cohort study included patients with a diagnosis of IBDS who underwent d-SOC from November 2020 to August 2022 at fourteen European tertiary referral centers (Dutch Trial Register: NL9649). IBDS was defined as a bile duct stricture of indeterminate nature after previous laboratory work-up, imaging or endoscopic retrograde cholangiography with or without brush-cytology of fluoroscopy guided intra-ductal biopsies.

During d-SOC, in every patient sampling of the stricture(s) was performed by firstly obtaining at least 4 single biopsies, and secondly obtaining at least 1 BBB. Definitive diagnosis was established on pathology outcomes (biopsies or surgical resection specimens) and clinical follow-up of at least one year. Primary outcome was the accuracy of both biopsy techniques.

Results: Eighty-nine patients were included (62% male, median age: 66 years), 52 of whom had a hilar and 37 a distal stricture. Single and BBB biopsies were technically successful and with sufficient tissue for diagnosis in 82 (92.1%, median number of biopsies = 4) and 78 (87.6%, median number of BBB biopsies = 2), respectively. These biopsies confirmed malignancy in 31/82 and 29/78 of cases, respectively. Comparing the two biopsy techniques, these techniques yielded different results in 4/78 patients (5.1%).

In 82 (92.1%) patients follow-up was complete and malignancy was confirmed in 51 (62.2%) patients, resulting in an overall sensitivity, specificity and accuracy of 60.8%, 100% and 75.6% of both techniques combined. For both sampling techniques, sensitivity and accuracy decreased significantly if a stent was placed at a prior ERC (n = 37, 41.6%) or whenever prior intra-ductal tissue acquisition had been performed (n = 41, 46.1%). The number of BBB did not affect sensitivity or accuracy. No adverse events related to d-SOC guided biopsies were noted.

Conclusion: In this prospective study, BBB did not outperform at least four random single biopsies of IBDS. Prior manipulation of the IBDS, by stent placement or prior tissue acquisition, is associated with a decreased yield.

Introduction: Among the diagnostic methods for EHCC, cell brush is the conventional method for EHCC diagnosis, but the sensitivity of cell brush and routine biopsy is low. The sensitivity and accuracy of EHCC diagnosis can be improved by single oral choledochoscopy. Radiofrequency ablation is a common and effective treatment for unresectable EHCC, providing local tumor control. Single oral choledochoscopy combined with radiofrequency ablation can improve the positive rate of pathological diagnosis.

Aims & Methods: To investigate the feasibility and safety of treating non-resectable extrahepatic cholangiocarcinoma (EHCC) with single resection combined with radiofrequency ablation (RFA).

A total of 149 patients with suspected extrahepatic cholangiocarcinoma treated in Hangzhou First People's Hospital from January 2013 to January 2023 were reviewed. According to the treatment process, 114 patients were eventually included and divided into two groups (n=48 cases): Single oral choledochoscopy was performed by ERCP and the lesion tissue was biopsied under direct vision. Intraoperative rapid pathologic examination was performed on the same stage RFA for the patients who were pathologically identified as malignant tumors. Regular times group (n = 66): first by endoscopic retrograde pancreatic angiography (endoscopic retrograde cholangiopancreatography, ERCP) + cells brush or a single biopsy samples by mouth choledochoscope examination, pathological results to obtain positive line of ERCP + RFA again; The operation success rate, postoperative liver function recovery, average ERCP number, postoperative adverse event incidence, length of hospitalization and cost were compared between the two groups.

Results: 1. Patients in both groups successfully completed the RFA, the operation success rate was 100% (114/114).

2. There was no significant difference in the overall incidence of postoperative adverse events between the two groups [39.58% (19/48) vs. 39.40% (26/66), $\chi^2=0.00$, $P=0.984$].

3. There was no significant difference in the proportion of patients with total bilirubin improvement between the two groups [41.67% (20/48) vs. 42.42% (28/66), $\chi^2=0.32$, $P=0.750$].

4. The average number of ERCP in the same group was significantly lower than that in the conventional group, and the difference was statistically significant (1.00±0.00 times/person vs. 2.64±0.49 times/person, $t=0.77$, $P<0.001$).

5. The average length of hospital stay in the same group was significantly longer than that in the conventional group, with statistical significance (8.40±3.63 days vs. 17.47±9.82 days, $t=6.21$, $P<0.001$).

6. The average hospitalization cost in the same group was significantly higher than that in the conventional group, and the difference was statistically significant (27718.31±9142.02 yuan versus 49112.76±16153.14 yuan, $t=7.38$, $P<0.001$).

Conclusion: Single oral choledochoscopy combined with biopsy and RFA in the diagnosis and treatment of unresectable EHCC can reduce the number of operations and does not increase the incidence of postoperative adverse events, which is a safe and effective method with a high cost-benefit ratio.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is associated with increased technical difficulty and can potentially contribute to prolonged procedural duration and excess exposure to ionizing radiation.

Aims & Methods: The purpose of the present study was to present descriptive information about fluoroscopy during ERCP from a large reference center and to investigate possible determinants of the radiation dose or fluoroscopy duration during ERCP. We examined a prospectively collected single-center database of adult patients undergoing ERCP between 09/2021 and 12/2023 in a tertiary greek public hospital. Detailed information concerning patient, endoscopist and procedural parameters including ERCP indication, degree of difficulty of ERCP (defined using the Schutz score), types of interventions and fluoroscopy were recorded retrospectively. Non parametric statistical methods were used (Mann-Whitney U-test and Kruskal-Wallis test) for the analysis.

Results: In total, data of 1051 ERCPs were collected at first, while 1028 ERCPs with complete information for fluoroscopy duration and radiation

dose were included (mean patient age 72.20 ± 14.02 years, 49.1% men) in the analysis. The mean procedure time was 34.22 ± 14.9 minutes, carried out by three different endoscopists ($n_1=321$, 31.4%, $n_2=338$, 33%, $n_3=363$, 35.6%). The majority of ERCPs were performed for treatment of choledocholithiasis (64.5%) and were classified as of intermediate difficulty according to Schutz scoring system [Schutz score 2 ($n=523$, 53.4%)]. Fluoroscopy was used in 1010 ERCPs (98.2%) and the median fluoroscopy duration was 2.4 minutes (IQR=2.6 min) and the median radiation dose was $1031.6 \mu\text{Gym}^2$ (IQR= $1237.5 \mu\text{Gym}^2$). ERCPs performed with an indication of biliary tract neoplasm (e.g. cholangiocarcinoma, liver metastases) were associated with prolonged fluoroscopy duration [5.05min (IQR=6.35 min), $p=0.008$] and increased radiation dose [$2372.75 \mu\text{Gym}^2$ (IQR= $2462.68 \mu\text{Gym}^2$), $p=0.003$] in comparison to the rest of the indications including choledocholithiasis, pancreatic neoplasm, obstructive jaundice and other indications. ERCP difficulty was also related with increased radiation; ERCPs with Schutz score ≥ 3 were associated with increased radiation dose and fluoroscopy duration compared with ERCP procedures evaluated as Schutz score ≤ 2 [3.3min (IQR=3.9 min) vs. 2.1min (IQR=2.15 min), $p<0.001$ and $1280.8 \mu\text{Gym}^2$ (IQR= $1836.8 \mu\text{Gym}^2$) vs. $937.6 \mu\text{Gym}^2$ (IQR= $820.25 \mu\text{Gym}^2$), $p<0.001$ respectively]. There was no significant difference of the fluoroscopy duration ($p=0.495$) and radiation dose ($p=0.950$) among the three performing endoscopists.

Conclusion: Increased difficulty of ERCP and the indication of biliary tract neoplasm were related to higher radiation dose and prolonged fluoroscopy duration. These factors could be utilized to predict ERCP procedures related to increased radiation exposure and may contribute to adoption of appropriate radiation reduction methods.

Introduction: The introduction of lumen-apposing metal stents (LAMs) has revolutionized the field of therapeutic endoscopic ultrasound (EUS). In the last decade, its utilization for off-label indications has markedly increased, particularly among patients with surgically altered anatomy to establish access in the excluded segment of the gastrointestinal tract. Indications for anastomosis creation include EUS-directed transgastric endoscopic retrograde cholangiopancreatography (EDGE), EUS-directed transgastric intervention (EDGEI), or endoscopic reversal of Roux-en-Y gastric bypass (RYGB) for specific indications (see below).

Aims & Methods: This study aims to evaluate the effectiveness and safety of LAMS in patients with surgically altered anatomy for EDGE, EDGEI, and reversal of RYGB. We collected data on all LAMS procedures conducted in patients with surgically altered anatomy, between October 2019 and February 2024 at the University Hospital of Ghent.

We used our prospective LAMS database and retrieved missing data from retrospective analysis of the medical patient records. The main outcome data of interest were technical success, clinical success, and adverse events. Technical success was defined as a successful placement of LAMS in the desired position. Clinical success was defined as either successful endoscopic access to the intended excluded gastrointestinal segment or achievement of the intended therapeutic goal when RYGB reversal was necessary. Adverse events were classified according to the AGREE criteria.

Results: A total of 73 LAMS procedures were performed: 70 cases of EUS-guided gastro-gastrostomy in patients with RYGB and 3 cases of EUS-guided gastro-enterostomy in patients with hepaticojejunostomy. Indications for LAMS procedures included 55 (75.3%) cases of EDGE, 13 (17.8%) cases of EDGI (such as gastroduodenoscopy and EUS), and 5 (6.8%) cases of RYGB reversal. Reversal of RYGB was required for one cachectic patient due to metastatic cholangiocarcinoma, three patients with hyperinsulinemic hypoglycemia, and one patient with therapy-resistant small intestinal bacterial overgrowth (SIBO).

The overall technical and clinical success rates were very high at 97.3% and 95.9%, respectively. Adverse events were observed in 11 out of 73 (15.1%) cases, including 7 (9.6%) minor events (AGREE score < 3) and 4 (5.5%) major events (AGREE score ≥ 3). Major events included stent migration (N=1), persistent fistula (N=2), and respiratory desaturation (N=1). All events could be successfully managed, and there were no procedure-related deaths. In 69.9% of cases, our method involved a dual-step approach, strategically implemented to await fistula maturation and reduce the risk of perforation. The median LAMS dwell time was 38 days (range 7, 431). LAMS was removed in 72.6% of the cases. Loss of LAMS patency occurred in 1 out of 73 (1.4%) cases and was endoscopically managed.

Conclusion: In conclusion, our study demonstrates that EUS-GG and EUS-GE offer an effective and safe approach to create anastomoses between gastrointestinal (GI) segments when performed by experts. With high technical (97.3%) and clinical (95.9%) success rates, LAMS proves beneficial for accessing excluded GI segments and reversing RYGB. Adverse events (15.1%) were mostly minor and manageable, with no procedure-related mortality. The extended patency duration and low re-intervention rate highlight LAMS as a minimally invasive and durable option in therapeutic endoscopic ultrasound procedures. Further prospective studies are required.

Disclosure: Nothing to disclose.

Introduction: Endoluminal radiofrequency ablation (RFA) is a palliative treatment option for patients suffering from malignant biliary obstruction.

Aims & Methods: We aimed to conduct a meta-analysis to evaluate the impact of RFA on stent patency, patient survival, and adverse events. Major databases were searched from inception until November 2023 for patients who underwent stenting with or without RFA for extra-hepatic malignant biliary obstruction.

A random effects model was employed for analysis and results conveyed using risk ratio (RR) and mean difference (MD) with 95% confidence interval (CI).

Results: Nine RCTs involving 750 subjects (n=374 RFA plus stent vs n=376 stent only) diagnosed with malignant biliary obstruction were included. Overall, there was no difference in stent patency between both groups (MD = 26 days [95% CI -2.63 – 54.85]; I²=53%, P=0.07), however, RFA showed improved overall survival (MD = 1.64 months [95% CI 0.21 – 3.07]; I²=100%, P=0.02).

Subgroup analysis showed that patients with cholangiocarcinoma experienced an overall survival benefit with RFA (MD = 4.86 months [95% CI 4.61 – 5.07]; I²=0%, P<0.001), however, stent patency was unaffected (P=0.08). Subgroup analysis comparing plastic versus uncovered metal stents showed no difference in stent patency (P=0.63), however, plastic stents were associated with improved survival (MD = 2.05 months [95% CI 0.60 – 3.50]; I²=91%, P=0.002). An increased incidence of cholecystitis was noted with RFA versus stenting only (5% vs 0.2%, respectively).

Conclusion: Combining endoluminal RFA and stenting may improve overall survival in patients with malignant biliary obstruction. RFA did not impact stent patency significantly.

Disclosure: Nothing to disclose.

Introduction: Lumen-apposing metal stents (LAMS) provide a conduit to access lumens close to the gastrointestinal tract to perform various interventions. While outcomes of LAMS placement in native anatomy have been reported, data on LAMS placement in surgically altered anatomy (SAA) is sparse.

Aims & Methods: We aim to assess technical, clinical, and safety outcomes of LAMS placement in patients with SAA for different indications. This was an international multicenter retrospective observational study at 25 tertiary-care centers through November 2023. Consecutive patients with SAA who underwent LAMS placement under endoscopic ultrasound guidance were included. Primary outcome was technical success defined as correct placement of LAMS. Secondary outcomes were clinical success and safety.

Results: 255 patients with SAA (118 males; average age 61 ± 15 years) underwent LAMS placement. Surgical anatomy included total gastrectomy (n=3; 1.2%) subtotal gastrectomy (n=8; 3.1%), billroth I (n=19; 7.5%) billroth II (n=23; 9.0%), sleeve gastrectomy (n=16; 6.3%), pancreaticoduodenectomy (n=72; 28.2%), total pancreatectomy (n=3; 1.2%), roux-en-y gastric bypass (n=106; 41.6%), partial gastrectomy with roux-en-y (n=3; 1.2%); esophagectomy with partial gastrectomy (n=2; 0.8%). Indications were malignant biliary obstruction (n=32; 12.5%), cholecystitis (n=12; 4.7%), drainage of peri-pancreatic fluid collections (n=46; 18.0%); EUS-guided creation of enteric anastomoses (n=74; 29.0%); endoscopic ultrasound-directed transgastric ERCP (EDGE) (n=82; 32.2%); others (n=9; 3.5%). Both technical and clinical success ranged between 50% to 100%. Overall adverse event rate was 10.6% (n=27/255).

Conclusion: This study shows that placement of LAMS is associated with varying technical and clinical success rates in patients with SAA. The rate of adverse events is noteworthy, and thus, these procedures should be performed by expert endoscopists at tertiary centers.

Contact E-Mail Address: jgornals@bellvitgehospital.cat
Introduction: EUS-guided biliary rendezvous (RV) is an EUS-assisted technique described as a rescue method in cases of failed biliary cannulation via endoscopic retrograde cholangiography (ERC). Current literature remains unclear regarding its current role.
Aims & Methods: Aim: to evaluate the efficacy and safety of biliary EUS-RV (benign vs malignant) and compare outcomes with EUS-guided transmural drainage (TMD) in malignant biliary obstruction. Methods: Retrospective observational study with prospective consecutive inclusion in a specific database from a tertiary-center. All patients that underwent a EUS-assisted ERC between October-2010 and November-2022 for failed ERC were included. A comparison analysis between benign vs. malignant disorders was performed. The outcomes of the EUS-RV malignant group were compared with an EUS-TMD group. Main outcomes were technical/overall success and adverse events (AEs).
Results: A total of 69 patients who underwent EUS-RV procedures, with benign and malignant pathologies (n=40 vs n=29), were included. Technical/overall success and related-AEs were 79.7% (95%CI, 68.3-88.4)/74% (95%CI, 61-83.7) and 24% (95%CI, 15.1-36.5), respectively. Failed cases were mainly related with guidewire manipulation. Seven failed RV were successfully rescued by EUS-TMD. On multivariable analysis, EUS-RV and malignant pathology was associated with a greater failure rate (technical success: OR,0.21; 95%CI,0.05-0.72; p=0.017), and higher AEs rate (OR,3.46; 95%CI,1.13-11.5; p=0.034). Also, the EUS-TMD group had greater technical success (OR,16.96; 95%CI,4.69-81.62; p<0.001) and overall success (OR, 3.09; 95%CI,1.18-8.16; p<0.026) with a lower AEs rate (OR,0.30; 95%CI,0.11-0.78; p=0.014) than EUS-RV in malignant disorders.

EUS-guided assisted ERC: benign vs malignant						
		No	Yes	OR [95%CI]	P value	N
Overall technical success, n (%):	Benign	4 (10.0)	36 (90.0)	Ref.	Ref.	69
	Malignant	10 (34.5)	19 (65.5)	0.21 [0.05-0.72]	0.017	
Overall success, n (%):	Benign	7 (17.5)	33 (82.5)	Ref.	Ref.	69
	Malignant	11 (37.9)	18 (62.1)	0.35 [0.11-1.03]	0.067	
Overall adverse events rate, n (%):	Benign	34 (85.0)	6 (15.0)	Ref.	Ref.	69
	Malignant	18 (62.1)	11 (37.9)	3.46 [1.13-11.54]	0.036	

Table 1: Comparison of clinical outcomes between groups.

Conclusion: EUS-RV is a demanding technique with better outcomes in benign than in malignant disorders. Comparison of the EUS-TMD group on malignant disorders showed worse outcomes with EUS-RV. Therefore, EUS-RV might be reserved basically for benign cases.

Introduction: Radiation exposure to patients and staff is unavoidable during endoscopic retrograde cholangiopancreatography (ERCP). International and contemporary Diagnostic Reference Levels (DRL, 75th centile) range from a Dose Area Product (DAP) of 3-40 Gy.cm², and fluoroscopy time (FT) over 3 minutes per ERCP¹. Effective doses for patients and high-volume practitioners can approach acceptable annual safety limits. Our group reports a baseline DAP DRL of 2.81 Gy.cm² from 1857 ERCP over 5 years, the lowest reported for a large series. Dose determinants include fluoroscopy settings, patient/C-arm positioning and patterns of fluoroscopy use². Along the lines of the ALARA principle, we evaluated the implementation of a protocol to optimize these factors. Our study is the first to standardize a language for ERCP fluoroscopy between endoscopist and radiographer.
Aims & Methods: Along the lines of the ALARA principle, we evaluated the implementation of a protocol to optimize these determinant factors. Our study is the first to standardize a language for ERCP fluoroscopy between endoscopist and radiographer. Endoscopists and radiographers developed a protocol from their collective best practices. Radiographers applied the lowest dose and frame rate settings. Patient positioning was optimized relative to the C-arm. Endoscopists were asked to minimize low-yield images and preference intermittent fluoroscopy. Commands were standardized to streamline communication between endoscopists and radiographers. The protocol was implemented using verbal and written cues in the ERCP suite. The primary outcome was the effect of the protocol on Air Kerma, DAP and FT compared to the baseline, pre-intervention cohort. The same mobile under-couch C-arm was used, and comparisons were made between the amongst the same core group of surgeon-endoscopists.
Results: The protocol was implemented over 10 months over 274 successful ERCPs. There was a 75% reduction in median Air Kerma (5.27mGy to 1.33mGy, p<0.0001) and DAP (1.35 Gy.cm² to 0.33 Gy.cm², p<0.0001). The DAP DRL we report is the world's lowest, at 0.79 Gy.cm². Median FT improved by 41% (42s to 24s, p<0.0001); the FT DRL under protocol conditions was 38s. Sizeable reductions in dose were seen in the upper quartile of cases. Multivariate analysis of the pre-intervention group identified sphincteroplasty, malignancy and certain endoscopists negatively influence DAP and FT (p<0.001). Use of our protocol minimized the effects of these variables on radiation doses at multiple linear regression. Temporal analysis showed that the protocol was effective from first implementation, but there were ongoing improvements in reducing the radiation used in the more complex, higher-dose cases.
Conclusion: We demonstrate that a protocol to modify the endoscopist and radiographer behavior is easy to adopt, and results in sizeable percentage improvements from an already low-dose baseline. Thus, we de-

scribe the lowest reported doses at ERCP. Such a protocol can be applied to any ERCP environment to achieve similar dose improvement, which will reduce the radiation-risks for patients and staff.

Introduction: Patients with an ileostomy are at increased risk of dehydration and sodium depletion.

Aims & Methods: We aimed to investigate if protein type or protein hydrolysis affects absorption from oral rehydration solutions (ORS) in patients with an ileostomy.

This was a randomised, double-blinded, active comparator-controlled 3x3 crossover intervention study. We developed three ORS with whey protein isolate, caseinate or whey protein hydrolysate. The ORS contained 40-48 g protein/L, 34-45 mmol sodium/L and had an osmolality of 248-270 mOsm/kg. The patients ingested 500 mL/d during three 4-week periods with a >2-week washout.

The primary outcome was wet-weight ileostomy output.

Results: Thirteen patients were included in the analyses. Wet-weight ileostomy output did not change and there was no difference between interventions (p=0.38). A series of statistically significant improvements were observed following intake of whey protein isolate ORS, including decreased faecal losses of energy (-365 kJ/d, 95% confidence interval (CI), -643 to -87, p=0.012), magnesium (-4.0 mmol/d, 95%CI, -7.4 to -0.7, p=0.020), plasma aldosterone (-4,674 pmol/L 95%CI, -8,536 to -812, p=0.019), and increased eGFR (2.8 mL/min/1.73m², 95%CI, 0.3 to 5.4, p=0.03).

Conclusion: Ingestion of 500 mL/d of three protein-based iso-osmolar solutions resulted in unchanged and comparable ileostomy outputs in patients with an ileostomy. Following whey protein isolate ORS, we observed discrete improvements in a series of absorption proxies in both faeces and blood. The protein-based ORS were safe and well-tolerated. Future studies are warranted to explore if different compositions or doses of protein-based ORS can improve absorption in patients with an ileostomy.

Introduction: Short bowel syndrome (SBS) is the most common cause of intestinal failure (IF) in children and is generally managed using parenteral nutrition and/or intravenous fluids (PN/IV). Long-term PN/IV can cause potentially life-threatening complications. Patients may receive teduglutide (TED) to encourage adaptation of the remaining intestine and to reduce dependence on PN/IV. Short-term studies have shown that TED is effective and has an acceptable safety profile in children and adults with SBS-associated IF (SBS-IF). However, assessment of long-term treatment with TED in paediatric patients with SBS-IF is limited.

Aims & Methods: We report real-world long-term safety and effectiveness data of TED from a paediatric cohort enrolled in the prospective, multinational SBS Registry (NCT01990040; EUPAS7973). Data were analysed cumulatively for up to 6 years between enrolment and interim data cut-off (June 23, 2014 to June 30, 2023). Patients were categorised based on whether they received TED (ever-treated; received ≥ 1 dose of TED 0.05 mg/kg/day [median]) or never received TED (never-treated; received PN/IV for ≥ 6 months before study entry). Safety endpoints included: occurrence of colorectal cancer in patients with any remnant colon; other malignancy; colorectal polyps; and adverse events (AEs). Effectiveness endpoints included clinical response ($\geq 20\%$ reduction in PN/IV volume from baseline) and change from baseline in volume of PN/IV (per weight [L/kg]) and number of days/week receiving PN/IV.

Results: In total, 398 paediatric patients were enrolled: 266 never-treated, 132 ever-treated (per-protocol set, n=397; 266 never-treated, 131 ever-treated). Patients had a mean (standard deviation [SD]) age of 5.4 (4.01) years (ever-treated 6.8 [4.12] years; never-treated 4.8 [3.80] years) and the majority were male (63.7%; ever-treated 68.7%; never-treated 61.3%). The median (range) length of exposure in ever-treated patients was 29.0 (1.15–106.61) months.

No new cases of colorectal cancer or new/worsening colorectal polyps were reported between baseline and interim cut-off. New/worsening malignancies were reported for one never-treated patient. A greater proportion of ever-treated patients reported AEs (87.0% vs 74.4%) and serious AEs (SAEs; 72.5% vs 59.0%) than never-treated patients. AEs and SAEs related to TED were reported in 15.3% and 6.1% of ever-treated patients, respectively. There were no allergic or hypersensitivity reactions to TED. The most common TED-related AEs were vomiting (3.8%) and abdominal pain (2.3%). Fatal events were recorded for one ever-treated and three never-treated patients.

A greater proportion of ever-treated patients had achieved a clinical response (year 1, 18/30, 60.0%; year 3, 11/17, 64.7%) than never-treated patients (year 1, 23/100, 23.0%; year 3, 17/82, 20.7%). Ever-treated pa-

tients had a greater mean (SD) reduction from baseline in PN/IV volume (L/kg; ever-treated: year 1, -39.4% [35.97], n=19; year 3, -61.6% [23.64]; n=7; never-treated: year 1, -21.1% [50.70], n=80; year 3, -34.4% [36.83], n=49) and number of days/week receiving PN/IV (ever-treated: year 1, -1.6 [2.16], n=30; year 3, -1.5 [1.77], n=17; never-treated: year 1, -1.0 [2.22], n=100; year 3, -0.6 [1.51]; n=82) than never-treated patients.

Conclusion: This 6-year interim analysis of real-world data from a large cohort of paediatric patients with SBS-IF supports that the safety profile of TED is consistent with the previous 5-year follow-up and suggests that TED improves intestinal adaptation in paediatric patients with SBS-IF over a 3-year period.

Introduction: Diet plays a pivotal role in inflammatory bowel disease (IBD) as it is postulated to mediate inflammation in the gut. Certain foods dysregulate the immune system by altering the intestinal mucosal layer, contributing to microbial dysbiosis¹.

There is emerging evidence that specific dietary interventions may promote remission in mild to moderate IBD. However, few studies investigate the role of specific diet patterns in the development of IBD.

Aims & Methods: We aim to describe the nutritional profile in multi-ethnic Asian patients with IBD and compare them to healthy controls. We also aim to demonstrate association of certain diet patterns with increased risk of IBD, by analysis of inflammatory proteins.

The study cohort was sequentially recruited from a single tertiary centre comprising 145 patients with IBD (58.6% Ulcerative colitis (UC) and 41.4% Crohn's disease (CD)), and 112 healthy control, who are individuals undergoing screening colonoscopy with no colonic pathology.

A semi-quantitative validated food frequency questionnaire² was administered and nutrients and food group intakes were calculated for patients in g/day. Unsupervised analysis of the nutrient and food group data was done through principal component analysis (PCA).

Multivariate linear regression was used to identify nutrients and food groups associated with IBD subtypes while adjusting for age, gender, BMI, and race. Serum protein profiling was performed using the *Olink* Target 96 Inflammation assay, and spearman correlation was used to associate serum cytokines with nutrient and food groups.

Results: Dietary composition of IBD patients differ significantly from the control as demonstrated by PCA, with discrepancy between PC1 ($p<0.0001$) and PC2 ($p=0.0063$) axes which account for 17.9% and 13.0% of the total dietary composition variance. There is no significant difference between UC and CD subgroups.

Participants with IBD were younger ($46.9(\pm 14.2)$ in UC, $44.7(\pm 15.9)$ in CD, $p<0.01$), with greater representation of males (72.6% amongst UC, 66.7% amongst CD, $p=0.03$), and lower proportion of Chinese (50.6% amongst UC, 56.7% amongst CD, $p<0.01$) as compared to controls. Adjusting for differences in age, gender and ethnicity, sweetened beverages and white bread were dietary elements significantly associated with UC and CD respectively, whereby both groups had increased intake of sweetened beverages and savory bread. (Table 1)

Using paired serum samples and dietary outputs, 39 significant cytokine-dietary elements were identified. Of note, increased consumption of sweetened beverages and fruit juice was associated with increased expression of matrix metalloproteinase-1 (MMP-10) ($p<0.01$) and reduced expression of interleukin-22 (IL-22) ($p=0.03$). MMP-10³ regulates the pro-inflammatory cytokines in IBD patients. Conversely, IL-22⁴ promotes mucosal healing, and hence reduced expression may worsen IBD.

White bread intake has also been associated with multiple inflammatory proteins including OSM⁵ ($p=0.03$), EN-RAGE⁶ ($p=0.03$), FGF-23 ($p<0.01$) and IL-17A ($p=0.04$), shown from previous studies to be proinflammatory in IBD.

	Nutrient type	Estimate	Standard error	Statistic	p-value	Adjusted p-value
UC	Sweetened beverage	0.233	0.0561	4.15	<0.0001	0.0006
	Savory bread	0.0783	0.0362	2.16	0.0316	0.1420
	Tea	0.148	0.0604	2.45	0.0151	0.0844
	Carbohydrate/day	0.0211	0.00897	2.36	0.0192	0.0950
	Other seafood	0.0772	0.0383	2.01	0.0451	0.1800
CD	Sweetened beverage	0.148	0.0613	2.41	0.0168	0.0896
	Savory bread	0.0843	0.0396	2.13	0.0343	0.1480
	White bread	0.154	0.0442	3.49	0.0006	0.0059
	White porridge	0.110	0.0472	2.33	0.0203	0.0968

Conclusion: Our study shows a unique dietary profile for patients with and without IBD. There is a direct correlation of certain foods with increased expression of inflammatory proteins in patients with IBD. This suggests dietary profile in patients may affect IBD activity. Further studies may elucidate new nutritional therapy for IBD patients.

Introduction: Exclusive enteral nutrition (EEN) is the first-line therapy for pediatric Crohn's disease (CD) and has been shown to impact the gut microbiome. However, the evidence for EEN-mediated functional changes in the gut microbiome as an underlying cause of therapeutic efficacy is still lacking.

Aims & Methods: Our aim is to assess the protective mechanisms of EEN through its impact on the modification of gut microbiome signatures in pediatric CD. We established a prospective pediatric IBD cohort (N=78) and longitudinally followed 20 treatment-naïve Crohn's disease patients undergoing EEN therapy for 6-8 weeks. Changes of fecal microbiota and metabolites was characterized using integrated multi-omics analysis with profiling data from 16S rRNA amplicon sequencing and untargeted mass spectrometry. To validate the functional changes of diet-exposed fecal microbiota on gut inflammation, we established a combined approach using gut chemostat cultures and microbiota transfer into germ-free *IL10^{-/-}* mice. Metagenomic analysis was applied to identify specific strain signatures associated with the protective effects of EEN in the pediatric cohort and the colonized mice.

Results: Treatment-naïve CD patients (18/20) achieved clinical remission in response to EEN therapy (90%) of which 8 experienced recurrent CD activity within 1 year. Integrated multi-omics analysis identified network clusters from individually variable microbiome and metabolomic profiles, with *Lachnospiraceae* and medium chain fatty acids as protective features. Exposure of fecal microbiota from selected Crohn's disease patients to EEN-like and fiber-repleted diets in the gut chemostat model, followed by the subsequent transfer of their conditioned microbiota into germfree *IL10^{-/-}* mice, prevented or induced IBD-like inflammation, respectively. Metagenomic analysis of 54 selectively colonized mice identified highly individualized strain signatures in the gnotobiotic mouse model, contrary to the more universal metabolite profiles discriminating inflamed from non-inflamed mice. Furthermore, differentially abundant species in humanized mice showed individual patterns associated with EEN and EEN cessation in the CD patient cohort, confirming the highly personalized strain-level dynamics in patients.

Conclusion: These findings demonstrate that EEN therapy mediates protective changes in individually variant microbiome profiles, leading towards personalized patient-to-patient species and strain signatures. Most importantly, we provide evidence that EEN creates explicit functional changes in temporally and individually variable microbiomes of Crohn's disease patients.

Introduction: β -casein, a major protein in cow's milk, is divided into the A1 and A2 type variants. Digestion of A1 β -casein yields the peptide β -casomorphin-7 which could cause gastrointestinal (GI) discomfort but A2 milk containing only A2 β -casein might be beneficial than A1/A2 (regular) milk.

Aims & Methods: The aim of this study was to evaluate the differences in GI discomfort after ingestion of A2 milk and A1/A2 milk. A randomized, double-blind, cross-over human trial was performed in 40 subjects who experienced GI discomfort following milk consumption. For each intervention period, either A2 milk first (A2→A1/A2) or A1/A2 milk was first consumed for 2 weeks (A1/A2→A2) following a 2-week washout period. GI Symptom Rating Scale (GSRS) scores, questionnaire for digestive symptoms, and laboratory tests including fecal calprotectin were evaluated. For symptom analysis generalized estimating equations (GEE) gamma model was used.

Results: A2 milk increased bloating ($P=0.041$) and loose stools ($P=0.026$) compared to A1/A2 milk in GSRS. However, A2 milk caused less abdominal pain ($P=0.050$), fecal urgency ($P<0.001$) and borborygmus ($P=0.007$) compared to A1/A2 milk in questionnaire for digestive symptoms. In addition, fecal calprotectin also decreased or less increased after consumption of A2 milk compared to A1/A2 milk ($P=0.030$), and this change was more pronounced in males ($P=0.005$) than in females. There were no significant adverse reactions during the trial.

		A2 milk		^a P-value	A1/A2 milk		^a P-value	^b P-value
		Before	After		Before	After		
Period 1	Abdominal pain	2.00 ± 0.71	1.00 ± 0.00	1.000	1.00 ± 0.00	1.00 ± 0.00	1.000	0.050*
	Fecal urgency	2.50 ± 0.35	1.00 ± 0.00	0.813	1.00 ± 0.00	1.50 ± 0.31	0.375	< 0.001***
Period 2	Borborygmus	1.00 ± 0.00	1.25 ± 0.22	0.500	1.00 ± 0.00	2.00 ± 0.00	0.750	0.007**

Per protocol analysis.
Period 1, the consumption period for the first intervention milk; Period 2, the consumption period for the second intervention milk.
P-values were calculated using ^aWilcoxon signed rank test or Generalized estimating equation (gamma distribution). * $P<0.05$, ** $P<0.01$, *** $P<0.001$.
Values are presented as LS mean ± SE.

Conclusion: A2 milk alleviated digestive discomfort in Koreans following A2 milk consumption (ClinicalTrials.gov NCT06252636 and CRIS KCT0009301).

Disclosure: Nothing to disclose.

Introduction: Ultra-Processed Foods (UPFs) have been associated with chronic diseases such as cancer, obesity and inflammatory bowel diseases (IBD). A typical feature of UPFs is the presence of Advanced Glycation End products (AGEs), including Carboxy-Methyl Lysine (CML), due to thermal treatments.

Aims & Methods: We studied to what extent different cooking methods affect cardiometabolic and inflammatory markers through differential dietary AGE intake.

In a randomized cross-over pilot trial, healthy participants sequentially consumed a diet prepared with cooking methods that generate either low or high amounts of AGEs. Recipes during both periods contained identical ingredients, but simply differed in their cooking methods (grilling and baking vs. steaming and raw foods). Daily food logs were kept using photo documentation and the smartphone application FatSecret during the one-week run-in (baseline diet) and the subsequent two-week intervention periods. Estimated AGEs levels were calculated based on the previously published database of Uribarri et al.¹ Anthropometric measurements and biological samples were taken at baseline and after each intervention period. Blood samples were collected for routine tests, Lipopolysaccharide-Binding Protein (LBP) ELISAs, serum proteomics (Olink Target 96 Inflammation and Cardiometabolic panels), and direct measurement of serum AGEs. Faecal calprotectin, 16S rRNA sequencing, and short chain fatty acids (SCFA) measurements were performed on stool samples. Small intestinal permeability was measured according to a 2-hour Lactulose Mannitol Ratio (LMR) protocol.

Results: Twenty healthy participants with a median age (IQR) of 28 (23.5-38) years, and a median BMI of 23.0 (20.9-25.4) kg/m² were included. The average estimated intake of CML during the high-AGEs diet was comparable to baseline (20,480.5 vs. 19,545 kU CML/day, Wilcoxon signed rank test, p>0.1), but significantly higher than during the low-AGEs period (10,590 kU CML/day, Wilcoxon signed rank test, p=3.8 x 10⁻⁶). Metabolically, total cholesterol values increased (paired Wilcoxon signed rank test, p=0.04) when changing from a low-to-high AGEs diet. After applying a linear mixed model per protein, eukaryotic initiation factor 4E-binding protein (4E-BP1), increased significantly after consumption of the low-AGEs diet (adjusted p=0.03). The gut microbiota composition was largely unaffected

by the diets, as was faecal calprotectin. Importantly, faecal butyrate concentrations increased after the high-AGEs study period in the low-to-high AGEs group (paired Wilcoxon signed rank test, p=0.04). The LMR was increased throughout the study in the high-to-low AGEs group, but not in the low-to-high AGEs group. Serum LBP showed no difference.

Conclusion: By conducting the first randomized cross-over cooking methods trial that focusses on both intestinal and systemic endpoints at a proteomic, gut microbiome and permeability level, we found that cooking methods generating different AGE levels have a differential impact on human and gut microbial metabolism. More specifically, we show a beneficial effect of the low-AGEs diet on lipid profiles and the serum protein 4E-BP1, a protein known to affect lifespan, metabolism, and cancer development. In contrast, the high-AGEs diet was associated with increased faecal butyrate levels, a SCFA that is studied for its beneficial and anti-inflammatory luminal properties. These results are instructive for diet-based interventions in the prevention and treatment of chronic diseases, including the metabolic syndrome and IBD.

Introduction: SBS-IF is a severe organ failure with long-term parenteral support (PS) dependence. GLP-2 stimulates intestinal adaptation resulting in increased absorptive capacity. Apraglutide (APRA) is a novel, long-acting GLP-2 analog in development for SBS-IF. This study investigated the safety and efficacy of APRA in patients with SBS-IF and CiC.

Aims & Methods: STARS Nutrition is a 52-Week (W) multicenter, open-label, phase 2 study in 9 adult SBS-IF-CiC patients (pts) receiving weekly subcutaneous APRA injections (5mg). 72-h metabolic balance studies (MBS) were performed at baseline (BL), 4W and 48W; with stable PS at BL and 4W. During MBS, oral fluid intake was kept constant by adhering to an individual predefined drinking menu. Duplicates of meals and fluids (wet weight intake) were collected as well as urine and feces (fecal wet weight output). Pts were advised to keep oral food intake at 4W similar to BL, but not at 48W to explore the effect of APRA on spontaneous dietary intake.

Safety was the primary endpoint. Secondary endpoints included changes in wet weight, energy and macronutrient absorption at 4W and 48W. Data are presented as mean (95% CI) unless specified otherwise. Nominal p-values are calculated using paired T-tests with significance set at 0.05.

Results: Small bowel length was 19 (range 0-50) cm and median estimated residual colon was 79 (range 43-100) %. At BL, pts received a PS volume of 10 (range 4-21) L/W. APRA had an acceptable safety profile. At 4W, fecal output reduced significantly by 253 (68 – 437) g/day (p=0.013); resulting in a trend to increased wet weight absorption of 256 (-9 – 520) g/day (p=0.057) while energy absorption remained unaltered. At 48W, pts significantly increased their overall wet weight intake (p=0.047), carbohydrate (p=0.042) and nitrogen intake (p=0.024) resulting in a significantly increased energy intake (p=0.027). Fecal wet weight output remained constant despite the increased oral intake. There was a significant increase in wet weight absorption by 316 (21 – 611) g/day (p=0.039), energy absorption by 1134 (58 – 2210) kJ/day (p=0.041) and carbohydrate absorption by 56.1 (8.8 – 94.3) g/day (p= 0.024). Urine output and body weight remained stable throughout the study.

Conclusion: The STARS Nutrition MBS findings confirm the role of the colon in energetic recovery of carbohydrates and maintenance of the fluid balance in SBS-IF-CiC. In pts with SBS-IF-CiC, APRA treatment resulted in an early reduced fecal output and improved wet weight absorption. After 48 weeks, oral intake was increased despite stable fecal output, leading to increased energy and carbohydrate absorption.

Introduction: Intestinal transplantation (ITx) is the only cure for patients with irreversible intestinal failure and complications of parenteral nutrition, however, 5-year graft survival is only ~50%. We currently do not know why graft failure is highly prevalent and hypothesize that disturbed repopulation of recipient cells in the graft is associated with this imbalance leading to rejection. So far, answering this question has been hampered by technical limitations and limited patient numbers.

Aims & Methods: We performed single-cell mRNA sequencing of 28 longitudinally sampled ileal graft biopsies of three transplanted patients from surgery up to six months post-transplantation, obtained through the TransplantLines Biobank. Using their differential genetic background, we identified 90,282 donor and recipient cells in the graft and characterized their composition and function during clinical follow-up and rejection.

Results: We found no consistent repopulation of recipient immune cells over time, nor disturbance of repopulation upon rejection. T cells in the graft were predominantly of donor origin (59% of donor immune cells) and myeloid cells originated from the recipient (16% of recipient immune cells). Induction therapy using anti-thymocyte globulin did achieve less than 50% T cell depletion in the graft. Instead, apoptotic pathways in epithelial cells during moderate rejection preceded pathology-defined mass rejection, indicating potential prognostic information in the transcriptomic profiles.

Conclusion: In conclusion, this is the first longitudinal study of the ITx graft at single-cell level. We see that molecular profiles precede histologic signs of mass rejection, which may be a useful biomarker for treatment intensification. Unexpectedly, we find no consistent repopulation of recipient immune cells and a variable response to drugs.

Introduction: SBS-IF is a severe organ failure with long-term parenteral support (PS) dependence. GLP-2 stimulates intestinal adaptation resulting in increased absorptive capacity. Apraglutide (APRA) is a novel long-acting GLP-2 analog in development for SBS-IF. This multicenter, open-label, phase 2 study in SBS-IF-CiC aims to investigate the safety and clinical efficacy of APRA at 52 weeks (W).

Aims & Methods: STARS Nutrition is a 52W open-label study in 9 adult SBS-IF-CiC pts receiving once-weekly subcutaneous APRA injections (5 mg). Metabolic balance studies were performed at baseline and 4W with stable PS, followed by a 48-W PS adjustment period. During monthly 48-hour fluid balance assessments, oral fluid intake was kept constant by adhering to an individual predefined drinking menu while measuring urine volume. PS was reduced according to an algorithm if an increase in mean daily urinary output of $\geq 10\%$ was observed. As part of patient-reported outcomes (PRO), Patient Global Impression of Change (PGIC) v2.0 (5-point verbal response scale from 2= much better to -2= much worse) was used to assess overall change in pts' status since APRA use. Safety was the primary endpoint. Secondary endpoints included changes in weekly PS volume, energy content, and PS days, proportion of clinical responders ($\geq 20\%$ PS reduction) and changes in PGIC at 52W. Data are presented as mean (95% CI) unless otherwise specified. Nominal p-values are calculated using paired T-tests with significance set at 0.05.

Results: APRA had an acceptable safety profile. All pts experienced ≥ 1 adverse event (AE); a total of 127 AEs were reported. Three pts experienced serious AEs. APRA was interrupted for 1 week in one pt with acute cholangitis and restarted successfully to trial completion. Absolute weekly PS volume decreased significantly by -4702 (-6539 to -2865) mL/week representing a 52% reduction from baseline ($p=0.0004$). Accordingly, PS energy content significantly decreased by -3510 (-4991 to -2029) kcal/week ($p=0.0006$). All pts qualified as clinical responders. Seven pts (78%) achieved ≥ 1 day off PS of whom two pts (22%) reached enteral autono-

my. Pts gained an additional 2.1 (0.7–3.6) days off per week. Total body and lean body weight; and daily urine output remained stable despite PS reductions. All pts experienced a subjective improvement of their general condition based on the PGIC: eight pts reported a score of 2 (much better) and one pt reported a score of 1 (little better).

Conclusion: STARS Nutrition prospectively shows evidence for clinical benefit of a long-acting GLP-2 analog in SBS-IF-CiC. APRA has an acceptable safety profile and is associated with significant reductions in PS needs in pts with SBS-IF-CiC resulting in days without PS and subjective improvement based on PRO.

Introduction: CD is a chronic progressive disease associated with bowel damage and disability and with a globally increasing prevalence. Contemporary reports on the clinical presentation, disease outcomes, and treatment choices in newly diagnosed patients across Europe are important to inform physicians.

Aims & Methods: To describe the clinical characteristics in a contemporary European cohort of recently diagnosed CD patients. The Crohn's Disease Cohort (CROCO) is an ongoing multicentre, European, prospective cohort study of recently diagnosed CD patients (within 12 months following diagnosis) intended to characterize bowel damage progression and disability. Herin, we report on the characteristics of CD-patients at inclusion in the study.

Results: Between Aug/21-April/24, 316 patients (58% male, 47% smoker or ex-smokers) with a median age at diagnosis of 34.4 (IQR 24.8; 49.6), were recruited from 17 centres. The median delay between symptoms onset and diagnosis was 6.5 months (IQR 2; 17.5); median disease duration at the time of inclusion was 3.9 months (IQR 1.6; 7.6); Ileal involvement (L1/L3) was reported in 86%. Overall, 15% had perianal disease and 28% had extra-intestinal manifestations, the most frequent being arthritis/arthralgia. One-third (32%) had evidence of either stricturing (B2) (17%) or penetrating (B3) (15%) phenotype; 7% had an intestinal-related surgery, and 2% perianal surgery. Fifty-nine (21%) patients had at least one CD-related hospitalization. Median faecal calprotectin was 236µg/g (IQR 75; 731) and median C-reactive protein was 4mg/L (IQR 1.2; 11). Regarding the therapies received from diagnosis to inclusion, 54% of the patients had received systemic steroids, 18% 5ASA, 10% IM monotherapy, and 43% started biological therapy (126 anti-TNF, 6 anti-IL 12/23 and 3 anti-integrin).

Conclusion: In this prospective cohort of newly diagnosed CD-patients, more than one-third of the patients presented with a complicated phenotype despite a short delay between onset of symptoms and diagnosis. Steroids remain frequently used, however early and effective therapy was started in approximately in 40% of patients, highlighting the changing paradigm in CD treatment.

Introduction: Patients with inflammatory bowel diseases (IBD) exhibit distinct shifts in circulating metabolite levels that have been associated with clinical disease activity and disease phenotype. However, there are limited data on the impact of metabolomic changes on disease progression in IBD. In this study, we aimed to understand the association of circulating metabolite levels and related pathways with the risk of disease progression in patients with IBD. Furthermore, we aimed to predict disease progression in these patients using both clinical and metabolomic features.

Aims & Methods: We conducted an observational cohort study using the Mount Sinai Crohn's and Colitis Registry (MSCCR). Patients were prospectively enrolled with baseline questionnaires and biospecimens that were then linked to longitudinal electronic health record data. A total of 1,456 serum metabolites were measured in 277 patients with UC and 375 patients with CD using untargeted metabolomics. Disease progression was defined as any new steroid or biological prescriptions, IBD-related hospitalizations, or surgery. Multivariable Cox proportional hazards regression (CoxPH) models, adjusted for age, sex, smoking, biologic use, and surgery were used to explore metabolite associations with risk of disease progression. Metabolite set enrichment analysis (MSEA) was performed to identify underlying metabolic pathways associated with disease progression. Prediction analyses were performed using L1-regularized CoxPH models with Random Survival Forests (RSF), and applied using different preceding feature selection approaches. Clinical parameters and metabolites were used as input features individually and in combination. Models were evaluated using Harrell's C-index, the Brier Score, and the area under the curve (AUC) at 3-years follow-up time.

Results: During a median of 2-year follow-up (IQR 0.3-5.1 years), 375 patients (57.5%) had a disease progression event. Among CD, 151 metabolites significantly correlated with the composite outcome (FDR<0.1). Of these, 81 (53.6%) were linked to higher risk, mainly enriched in amino acids, purine, and pyrimidine metabolism, fibrinogen cleavage peptides,

and bile acid pathways. Additionally, 70 (46.4%) metabolites associated with lower risk with enrichment in fatty acid metabolism, steroid biosynthesis, histidine, tryptophan, and antioxidant pathways. In CD, aspartate metabolism was most significantly associated with increased risk and linoleic metabolism with decreased risk. In UC, 84 metabolites were significantly associated with disease progression (FDR<0.1), with 29 (34.5%) associated with increased and 55 (65.5%) with decreased risk. Metabolic pathways linked to higher risk were sphingolipid, benzoate, hydrogen sulfide, polyamine, and tyrosine metabolism, while protective metabolites were enriched in branched-chain amino acid (BCAA), steroid biosynthesis, histidine, and phenylalanine pathways. In UC, sphingolipid metabolism was prominently associated with increased risk and BCAA metabolism with decreased risk. The combination of metabolomic and clinical features best predicted disease progression in both CD and UC, with 20 and 25 features robustly selected, respectively.

Conclusion: Specific metabolites and metabolic pathways are associated with risk of disease progression in patients with IBD, highlighting potential prognostic metabolite biomarkers and pathways that may be important in modulating risk of disease progression. Metabolomic features improve overall model performance when predicting disease progression in IBD, with distinct metabolites showing high predictive value.

Introduction: Acute severe ulcerative colitis (ASUC) is a serious, potentially life-threatening condition. Hospital admission and prompt medical therapy with intravenous steroids is crucial, but rescue medical therapy is frequently needed, and surgery is often required.

Aims & Methods: Our aim was to assess the adherence to main diagnostic and management recommendations within the MASC multinational study. MASC was a prospective, multinational cohort study, including all consecutive patients hospitalized for ASUC between February 2019-January 2020. The primary outcome was surgery during the first 90 days after admission. We used descriptive statistics to determine the proportion of patients fulfilling each diagnostic and treatment recommendation according to ECCO and AGA.

Results: A total of 823 patients from 123 centers in 32 countries in five continents were included (median age 39 years [IQR, 28-54], 56% male, 64% non-smokers; Table 1). Most cases (74%) had a previous diagnosis of ulcerative colitis, and around half (48%) with prior ASUC episodes. Upon admission, they were under 5-ASA therapy (60%), thiopurines (14%), or biologics (21%). They were mostly admitted to the Gastroenterology ward (74%). During the initial assessment, 112 patients (15%) did not have stool culture or C. difficile testing, and CMV was evaluated in 50% of cases. Endoscopic assessment was performed in 66% of patients, mainly by flexible rectosigmoidoscopy (74%).

Patient characteristics	Frequency N=823
Age at ASUC diagnosis, median (IQR)	39 years (28-54)
Gender, male, n (%)	463 (56%)
Smoking history, never, n (%)	528 (64%)
Previous UC diagnosis, n (%)	613 (74%)
Disease extension, n (%)	
E1	54 (7%)
E2	298 (36%)
E3	428 (52%)
Previous episodes of ASUC, n (%)	297 (48%)
Ward of admission, Gastroenterology, n (%)	612 (74%)
Treatment upon admission, n (%)	
Oral steroids	37 (6%)
Oral mesalazine	367 (60%)
Thiopurines	85 (14%)
Methotrexate	8 (1.3%)
Anti-TNF	100 (16%)
Vedolizumab	31 (5%)
Tofacitinib	17 (3%)
Calcineurin inhibitors	5 (1%)

Regarding treatment, 3.4% of patients received exclusive parenteral nutrition, 70% low molecular weight heparin, and 42% prophylactic antibiotics. Steroids were started after a median of 0 days (IQR, 0-1), mostly with methylprednisolone or hydrocortisone (64%), 26% with other steroids, and 7% were managed without steroids. Infliximab was started in 159 patients (19%) after a median of 6 days (IQR, 4-8) after starting steroids, with 27% after >7 days. Most of the patients (93%) had some type of tuberculosis screening done prior to infliximab. Twenty-eight patients (3.4%) started cyclosporine. Thirty-two patients (4%) received other rescue therapy different from infliximab or cyclosporin. Colectomy was performed in 25 patients (3%).

Conclusion: The diagnostic and medical management of ASUC remains heterogeneous and different from current recommendations. This context demands more evidence and consensus on the best management of ASUC.

Disclosure: Nothing to disclose.

IMPACT OF ADVANCED THERAPY ON BOWEL URGENCY IN INFLAMMATORY BOWEL DISEASE: A MULTICENTER STUDY

F. D’Amico¹, O.M. Nardone², A. Bruno¹, M. Allocca¹, A. Zilli¹, F. Furfaro¹, T.L. Parigi¹, F. Ungaro³, I. Faggiani¹, A. La Mantia⁴, G. Calabrese², G. Fiorino⁵, L. Peyrin-Biroulet⁶, L. Massimino³, F. Castiglione², S. Danese¹

Contact E-Mail Address: damico_ferdinando@libero.it
Introduction: Bowel urgency (BU) is a common symptom in patients with inflammatory bowel disease (IBD). More than 80% of patients with ulcerative colitis (UC) and more than 60% of patients with Crohn’s disease (CD) experience BU during their life. Although BU negatively impacts the quality of life and psychosocial status, currently it is an overlooked symp-

tom. Furthermore, there is little evidence of the effectiveness of available advanced therapies on BU.

Aims & Methods: We aimed to evaluate the impact of different advanced therapies for IBD in improving BU. This was a retrospective cohort study conducted at two third-level centers (IRCCS San Raffaele hospital and university of Naples Federico II) between April 2023 and April 2024. All consecutive patients with confirmed diagnosis of CD or UC who started an advanced therapy (any biological drug or small molecule) with available data regarding BU at baseline (before starting an advanced therapy) and after induction therapy were eligible. BU was assessed using the numeric rating scale urgency score (NRS-us), a validated tool for quantifying BU in IBD. BU was defined as ≥3 in NRS-us. All available clinical (partial Mayo score for UC and Harvey-Bradshaw Index (HBI) for CD), biochemical (fecal calprotectin (FC) and C-reactive protein (CRP)), endoscopic (Mayo endoscopic score or SES-CD score) and intestinal ultrasound data were collected before and after the induction of an advanced therapy. Patients with history of bowel surgery or radiotherapy were excluded. The primary endpoint was BU improvement, defined as an NRS-us ≤3 or a score reduction of at least 2 points. A logistic regression multivariate analysis was performed to identify any correlation between socio-demographic factors, disease features, and treatment at baseline and changes in NRS-us. Analyses were subjected to correction using the false discovery rate (FDR) method.

Results: In total, 159 patients were included (89 male (56%) with a median age of 36 years and a median BMI of 22,1, 104 (65,4%) UC) (Table 1). Patients were treated with infliximab (24,5%), adalimumab (24,5%), ustekinumab (22,6%), vedolizumab (13,2%), upadacitinib (9,4%), tofacitinib (3,1%), filgotinib (1,3%), golimumab (0,6%) risankizumab (0,6%). A small proportion of patients underwent concomitant steroid (8,8%) or immunosuppressant therapy (12,6%). At baseline the median NRS-us was 7. Approximately half of the patients (81, 50,9%) experienced BU improvement after induction with a mean reduction of NRS-us of 2,3 ± 2,9. In the multivariate analysis, improvement in BU was associated with clinical remission (FDR=0.009 for CD and FDR=0.01 for UC), normalization of fecal calprotectin (FDR=0.001) and CRP (FDR=0.008), and normalization of bowel wall thickness to IUS (FDR=0.0006). No statistically significant difference in obtaining an improvement in BU was identified between the different drugs investigated.

	Number (%)
Male	89/159 (56)
Median age (years)	36
UC diagnosis	104 (64)
Median BMI at baseline	22,1
Disease duration (months)	63,4
Median NRS urgency score at baseline	7
Median fecal calprotectin at baseline	500 µg/g
Median C-reactive protein at baseline	10 mg/dL

Conclusion: The available advanced therapies improve bowel urgency after the induction phase. Improvement in BU is associated with clinical, biochemical, and ultrasound remission.

Disclosure: Nothing to disclose.

Introduction: Therapeutic goals and clinical guidelines in Crohn's disease (CD) have evolved to include endoscopic outcomes being a key prognostic parameter in disease management. STRIDE-II guidelines comprise of clinical and patient-reported outcome remission, along with biomarker normalization and endoscopic healing. While available publications have correlated achievement of endoscopic response with long-term outcomes, few if any have adjusted for clinical remission status. Moreover, most of the data comes from patients treated with immunomodulators and/or TNFs. The objective of this analysis was to assess the impact of endoscopic response at the end of maintenance and long-term outcomes while adjusting for clinical remission status at maintenance.

Aims & Methods: Data from two randomized clinical trials (GALAXI-1, NCT03466411 and IM-UNITI, NCT01369355) were pooled to assess the impact of endoscopic response at 1 year on long-term patient relevant outcomes including clinical response, clinical remission, quality of life as assessed by the Inflammatory Bowel Disease Questionnaire (IBDQ), and risk for hospitalizations/surgeries. This post-hoc analysis assessed endoscopic response at the end of maintenance (~48 weeks) and patient relevant outcomes in the long-term extension (LTE) duration (~96 weeks). Patients without LTE outcome data and placebo treated patients were excluded. Multivariate analyses with trial as a random effect were conducted and adjusted for treatment arm during maintenance, clinical remission status at end of maintenance (EOM), and endoscopic response at EOM.

Results: A total of 461 patients had available endoscopy and clinical remission status at EOM (IM-UNITI, N=177; GALAXI-1, N=284). The number of patients with available LTE outcomes ranged from 290 (IBDQ remission) to 383 (clinical remission/clinical response). Endoscopic response at EOM was significantly associated with higher odds of LTE clinical remission and IBDQ remission with ORs of 1.91 and 1.99 respectively, with corresponding p values below 0.05. Endoscopic response at EOM was also associated with lower odds of LTE C-reactive Protein abnormality (OR=0.46, p<0.005), a marker of inflammation and disease activity. Lastly, a greater percentage of patients without endoscopic response at EOM experienced hospitalizations/surgeries though the difference was not significant due to low event counts (16% versus 9%, p=0.1237).

Conclusion: This analysis uses clinical data from robust trials and adjusted for patients' clinical remission status at the end of maintenance to isolate the benefit of endoscopic response in predicting long-term outcomes. Endoscopic response is significantly associated with more patients reaching clinical remission and better quality of life. Further investigation in large datasets with longer follow-up is needed to better understand whether measures of endoscopic improvement are also good surrogates for reductions in hospitalizations and surgeries.

Introduction: Vedolizumab (VDZ) is a gut-selective anti-lymphocyte trafficking drug indicated for the treatment of CD and UC [1] administered by intravenous (IV) infusion at Weeks 0, 2, and 6 followed by IV infusions every 8 weeks (Q8W) or subcutaneous injections every 2 weeks [2,3]. For IV treated patients who experience a suboptimal or loss of response (LOR), dose escalation to every four-week infusions (Q4W) may recapture response to treatment [4] but there is a lack of large-scale real-world data describing outcomes of dose-escalated patients [5].

Aims & Methods: Patients with moderately to severely active UC or CD were prospectively followed in a patient support program in Canada from 2015 to 2023. Harvey-Bradshaw Index (HBI, CD) and Partial Mayo Scores (PMS, UC) were assessed 2, 6, and 14 weeks after treatment initiation to understand VDZ induction effectiveness. HBI or PMS were assessed 12 weeks post dose Q4W escalation to understand the effectiveness of dose escalation in the presence of suboptimal or LOR.

Results are presented for patients who dose escalated to Q4W from Q8W maintenance (Q8W > Q4W), initiated Q4W at week 14 (w14>Q4W), or at week 10 (w10>Q4W). Remission was defined as HBI <5, or PMS <3. Response was defined as achieving remission or an HBI decrease of ≥3 points from baseline, or a PMS decrease of ≥2 points and ≥25% from baseline.

Results: 1056 CD (45% bio-naïve) patients and 1959 UC patients (71% bio-naïve) were eligible for this study. The median follow up was 18 months (range 3-61). The median age was 48 years (range: 18-92), and 44 years (range:18-89) for CD and UC patients respectively. 60% of CD patients and 51% of UC patients were female. For CD patients the median baseline HBI score was 10 (range 8-40), and for UC patients the median baseline PMS score was 6 (range 5-20).

Disease duration prior to VDZ was longer in bio-experienced patients compared to bio-naïve; CD (Medians: 14 vs 4 years) and UC (Medians: 6 vs 4 years). To further characterise the patient cohort induction effectiveness is reported. For CD patients, remission and response were 25% and 56% at 2 weeks, 34% and 66% at 6 weeks and 40% and 68% at 14 weeks.

For UC patients, remission and response were 32% and 64% at 2 weeks, 48% and 78% at 6 weeks and 55% and 81% at 14 weeks. In CD, 39% (183 of 473) of bio-naïve patients and 52% (302 of 583) of bio-experienced patients dose-escalated to Q4W within the first two years. In UC, 37% (520 of 1399) of bio-naïve patients and 49% (275 of 560) of bio-experienced patients dose-escalated to Q4W within the first two years. At Q4W dose escalation, 319 CD patients (110 bio-naïve, 209 bio-experienced) and 514 UC patients (334 bio-naïve, 180 bio-experienced) were not in HBI or PMS remission. For these patients, remission and response 12-weeks post dose escalation to Q4W are presented in table 1.

Conclusion: IBD patients experienced clinically meaningful remission and response rates following induction with IV VDZ. For those that have a suboptimal or LOR this study demonstrates the real-world effectiveness of dose escalating VDZ to Q4W in Canadian patients with IBD to complement previous clinical trials, and real-world studies.

THE CHOICE OF FIRST-LINE BIOLOGICAL THERAPIES IS HIGHLY IMPACTING THE EVOLUTION OF ULCERATIVE COLITIS AND CANNOT BE RESCUED BY LATER TREATMENTS: RESULTS FROM THE APPETISER STUDY

D. M'Baye¹, B. Pereira¹, A. Buisson¹

¹CHU Estaing Clermont-Ferrand, IBD Unit, Clermont-ferrand, France

Contact E-Mail Address: a_buisson@hotmail.fr

Introduction: Therapeutic sequencing is a burning question in patients with ulcerative colitis (UC) requiring an advanced therapy. Whether starting with a less effective but safer and more convenient drug is a loss of chance for UC patients or can be rescued by later treatments is key point.

Aims & Methods: In the APPETISER study, we compared the effectiveness of two strategies based on the choice of the first biologic owing to either the drug efficacy in network meta-analyses and randomized controlled trials (vedolizumab or infliximab) or better acceptability (full subcutaneous therapy: adalimumab and golimumab) to induce and maintain steroid-free clinical remission during the first 24 months.

We collected real-world data from an IBD referral center including all consecutive UC patients ≥ 18 years-old who started a first line of biologic for active UC with follow-up > 6 months. Prior colectomy or severe acute colitis were excluded. Patients were included in either effectiveness-based sequencing (EBS) if they started with infliximab or vedolizumab, or in acceptability-based sequencing (ABS) if they received adalimumab or golimumab as first-line biologic.

The primary endpoint was remission defined according to PRO2 (PRO2-remission) as the absence of bleeding, normalization of transit (Mayo stool frequency subscore = 0) and no steroid. PRO2-remission was defined as a binary criterion each month (the statistical unit being the month and not the patient).

The secondary endpoints concerned the analysis by patient and were CFREM (partial Mayo score ≤ 2 without steroid) at week 12 and 52, endoscopic remission (CFREM + score Endoscopic Mayo ≤ 1) at week 12, time to drug discontinuation and time to colectomy.

All comparisons were adjusted using propensity scores on potential confounders. Analysis by month was performed using mixed models to account for repeated data.

Results: Overall, 130 patients were included including 60 patients in the EBS group (IFX= 50 and VDZ= 10) and 70 in the ABS group (ADA= 48 and GLM= 22).

The populations had similar characteristics at baseline apart from concomitant immunosuppressant more frequent in EBS group (55.9% vs 21.7%). 2nd line treatment was started in 26.7% of patients in EBS group (ADA in 48.8%, VDZ 25.5% and ustekinumab 18.8%) and 87.1% of patients in ABS group (IFX in 54.1%, VDZ 31.1%).

After adjustment, the rate of CFREM was significantly higher in EBS arm than in ABS arm at week 12 (70.8% vs 33.0%, p < 0.001) and week 52 (72.8% vs 42.1%, p = 0.017). The rate of endoscopic remission at W12 was 22.1% and 10.0% in EBS and ABS arms, respectively (p = 0.086).

For the primary endpoint, 3350 months were analyzed (1180 in EBS arm and 1175 in ABS arm). The percentage of months spent in PRO2-CFREM in the first 24 months (primary endpoint) was greater in EBS arm than in ABS arm (74.2% vs 46.6%; p<0.001). The percentage of months spent in CFREM was higher in the IV arm in the first 6 months (60.4% vs 18.9%), and was not rescued later: between M7 and M12 (73.1% vs 38.6%), M13 and M18 (79.9% vs 57.0%) or M19 and M24 (83.3% vs 64.6%) (p < 0.001 for all comparisons).

Regarding long-term data, EBS group had a lower risk to first-line biologic discontinuation (aHR=6.5 [2.8-15.3], p < 0.001) and a clear trend for lower risk of colectomy (aHR=4.5 [0.9-22.3], p = 0.068).

Conclusion: Our data highlight that the choice of first-line biological therapies is highly impacting the evolution of ulcerative colitis and cannot be rescued by later treatments. Thus, the results of the APPETISER study advocate for the use of the most effective therapeutic option as first line of biologic.

Introduction: As a first-line biotherapy, vedolizumab showed superior efficacy compared to adalimumab in the VARSITY trial, which, combined with a favorable safety profile, should position it in a privileged position in bionave patients with ulcerative colitis (UC). However, a proportion of

patients have an insufficient response and/or intolerance, resulting in the need for a 2nd line of advanced therapy. To date, there are no data on the efficacy of biotherapies and small molecules in the 2nd line treatment of UC, after vedolizumab has failed. The objective of our study was to compare the efficacy of anti-TNFs, ustekinumab and JAKi in 2nd line in UC, after prior exposure to vedolizumab.

Aims & Methods: We conducted a retrospective multicenter study in 27 French and Belgian GETAID centers. All UC patients treated with vedolizumab in the first-line setting who received a second-line of anti-TNFs, ustekinumab and JAKi were retrospectively included. The primary outcome was corticoid-free remission at induction (week 14) defined by a clinical partial Mayo score of 2 or less, with no subscore greater than 1, in patients still receiving 2nd line therapy. The response was defined as a decrease in partial Mayo score of at least 30%. We also assessed the persistence rate of second-line treatments using the Kaplan-Meier method.

Results: 203 patients were included with a median follow-up of 5 months (IQR: 3.0-11.0). Of the 203 patients, 123 (60.6%), 64 (31.5%) and 16 (7.9%) were treated with anti-TNF, ustekinumab and JAKi in the second-line setting. The median duration of disease progression was 39 months prior to the introduction of the second line (IQR 15-137.0). Vedolizumab was discontinued in 109 patients for primary failure (53.7%), 81 patients for secondary failure (34.9%), and 14 patients for adverse reaction (7.4%).

At week 14, 31/95 (32.6%) patients on infliximab, 7/27 (25.9%) on SC anti-TNF, 20/63 (31.7%) on ustekinumab and 7/16 (43.8%) treated with JAKi achieved corticosteroid-free remission. Remission rates were 37.9% for patients on infliximab, 33.3% on SC anti-TNF, 50% on JAKi, and 38.1% on ustekinumab. Response rates were 51.6%, 40.8%, 52.4%, and 62.5%, respectively, for the infliximab, anti-TNF SC, ustekinumab and JAKi groups. At 1-year, overall treatment persistence was 41.9% [IC 95% 34.7-50.6%]. Treatment persistence was 45.2% [35.0-58.4] in patients treated with infliximab, 43.3% [27.8-67.5] for anti-TNF SC, 40.4% [28.2-58.0] in the Ustekinumab group and 18.8% [5.5-64.3] for the JAKi.

Second-line therapy was discontinued in 37 patients (34.9%) for primary failure, 53 (50%) for secondary failure and 16 (15.1%) for adverse reaction. The overall adverse reaction rate was 31/203 (15.3%), of which 16 resulted in discontinuation (15.1%). In patients on infliximab, the overall rate was 19/96 (19.8%), and infliximab was discontinued in 10 patients (10.4%) due to adverse reactions. With JAKi, the overall rate was 1/16 (6.3%) with no cases of herpes zoster or thrombo-embolic events. Finally, in the 64 patients treated with ustekinumab, only 5 side effects especially arthralgias were reported (7.8%).

Conclusion: This is the largest real-world study of the efficacy of second-line treatments after vedolizumab in UC. Corticosteroid-free remission rates at induction appeared to be similar between the different treatment groups. About forty percent of patients remained on second-line treatment at one year. Discontinuation of second-line treatment was predominantly related to primary or secondary failures. Efficacy at induction appeared to be similar between the different treatment groups.

Disclosure: Nothing to disclose.

Introduction: After first anti-TNF α (aTNF) failure in ulcerative colitis (UC), switching to a different mechanism of action (MoA) could decrease the rates of failure and discontinuation compared to a second aTNF and with a better safety profile.

Aims & Methods: We performed a retrospective and multicenter study (6 Andalusian sites). Patients diagnosed of UC who had failed a first biological therapy with an aTNF and started a second-line biological therapy with another aTNF or a different MoA such as ustekinumab (UST), vedolizumab (VDZ), tofacitinib and filgobinib (JAK) were included. The aim of our study was to evaluate the long-term durability of a different MoA compared to a second aTNF after a first-line therapy failure with aTNF.

Results: 185 patients with UC were included. There were no significant differences between both groups in terms of age, sex, extension of disease, extraintestinal manifestations or IMIDs, smoking habit or HLA-DQA1*05. The only significant difference was disease duration (9 years MoA vs 12 years in second aTNF, $p=0.02$). 80 patients received a different MoA (37 VDZ, 24 UST, 19 JAK) and 105 a second aTNF (34 IFX, 60 ADA, 11 golimumab). Duration of first aTNF, although non-significant ($p=0.06$), tended to be shorter in the MoA group (7 months vs 12 months in aTNF group). The most frequent cause of suspension of first aTNF in the MoA group was primary failure (46% vs 31%, $p=0.02$) and in the second aTNF group was secondary failure (51% vs 35%, $p=0.02$). The follow-up mean was 22.4 months in the group of a different MoA and 23.3 months in the second aTNF group. 60% of patients discontinued the second-line biological treatment, 64% with aTNF vs 35% with a different MoA. Durability of therapies in the group of different MoA was significantly longer compared with second aTNF (50% vs 31.4%, $p=0.036$) (figure 1). UST showed the best durability (66.7%), followed by JAK (63.2%), IFX (52.9%), VDZ (32.4%), ADA (21.7%) and golimumab (18.2%), with significant differences ($p=0.03$). Reasons for discontinuation were primary failure in 29.7% (63.6% second aTNF vs 36.4% different MoA), secondary failure in 25.9% (64.5% second aTNF vs 35.5% different MoA) and intolerance or adverse events in 6.4% (66.6% second aTNF vs 34.4% different MoA). Adverse events were reported in 12 patients, 8 with aTNF and 4 with other MoA (2 vs 0 infusion reactions, 1 vs 1 mild infections, 2 vs 1 respiratory adverse effects, 1 vs 1 cutaneous reactions, 1 vs 0 musculoskeletal effects, 1 vs 1 neoplasia).

Conclusion: Our study shows that after a first aTNF failure in UC, a switch to a biological therapy with a different MoA achieves longer survival compared to switching to a second aTNF, with less primary and secondary failure.

Disclosure: Nothing to disclose.

Introduction: Anti-TNF therapy has revolutionised the treatment of patients with Crohn's disease (CD) and ulcerative colitis (UC). However, primary resistance or loss of efficacy are serious clinical challenges. Therapeutic drug monitoring (TDM) could help to manage these unfavourable therapeutic outcomes. The measurement of anti-TNF drug levels (DL) with point-of-care tests (POCT) is fast, simple tool to guide the therapy. TDM can be performed reactively in patients with active disease and proactively in asymptomatic patients. Nevertheless, the optimal utilization of TDM is still debated.

Aims & Methods: Our aim was to evaluate the impact of proactive and reactive TDM on the medium-term course of inflammatory bowel disease. We enrolled patients with UC and CD who were treated at our department with infliximab or adalimumab and underwent reactive or proactive TDM with POCT method between October 2021 and September 2023. We examined the types of therapeutic decision (dose intensification, switch within or out of class) were performed knowing DL and how the changes have affected the half-yearly outcome. Laboratory findings such as C-reactive protein (CRP), iron, albumin, haemoglobin, platelet, stool calprotectin level and calculated disease activity indices, Crohn's disease activity index (CDAI), Harvey-Bradshaw Index (HBI), partial Mayo score (pMayo) and Simple clinical colitis activity index (SCCAI) were analysed at baseline and after 6 months. Statistical analysis was carried out with Graphpad Prism and SPSS.

Results: 175 patients were enrolled, 80 men, 95 women, median age was 38 (IQR 30-50 years). 81 UC and 94 CD patients. In 79 cases proactive, in 96 cases reactive TDM was performed. In the reactive group the CRP (5.9 vs 12.2 mg/l, $p=0.010$), platelet count (278.3 vs 314.5 G/l, $p=0.024$) and the four activity indices (CDAI $p=0.004$, HBI $p=0.0004$, SCCAI $p<0.0001$, pMayo $p<0.0001$) were significantly higher, the albumin level (46.5 vs 45 g/l, $p=0.019$) was significantly lower compared to the proactive group at baseline. In the reactive group CRP (12.2 vs 5.7 mg/l, $p=0.0083$) and albumin level (46.5 vs 45 g/l $p=0.0186$) and all examined activity indices (CDAI $p<0.0001$, HBI $p=0.0003$, SCCAI $p<0.0001$, pMayo $p=0.0002$) changed significantly after 6 month from baseline. In the proactive group the lowering of SCCAI ($p=0.0232$), pMayo ($p=0.0077$) and CDAI ($p=0.0471$) were significant comparing baseline and 6-month parameters. Between the proactive and reactive groups no significant difference was found at month 6. In 41 (52%) cases in the proactive group subtherapeutic DL was found. Within these cases in CD patients CDAI ($p=0.035$, OR:1.02, 95%CI: 1.0-1.05) had a significant predictive value for the half-yearly outcome, in UC platelet count appeared to be nearly significant ($p=0.097$, OR: 1.07, 95%CI: 0.99-1.15) as a predictive factor. In 41 (52%) of the proactively measured cases no intervention was done, 27 (34%) dose-intensification, 5 (6%) de-escalation, 5 (6%) stop and 2 (3%) switch was carried out. In the reactively measured group 55 patients (57%) had subtherapeutic DL. In the reactive group no therapeutic change happened in 25 cases (26%), 42 (44%) underwent dose-intensification, 29 (30%) had switch (13 within class, 16 out of class).

Conclusion: We found no difference between the proactive and reactive drug level monitoring methods with POCT. Both affected the decision-making process and presented beneficial effect for medium-term and helped to achieve stride therapy goals.

Disclosure: Nothing to disclose.

Introduction: Psychological therapies have been shown to be effective for treatment of patients with disorders of gut-brain interaction like irritable bowel syndrome (IBS). However, these therapies are time and personnel demanding which limits the access to this therapeutic option for many patients. Virtual reality (VR) creates an immersive environment where psychological interventions can be self-administered by the patient at home, thereby facilitating the access of these interventions to a large number of patients with minimal costs.

Aims & Methods: Our aim was to evaluate the effect of a psychological intervention delivered using VR on digestive symptoms in patients with IBS. Thirty-six patients with IBS (mean age 42±2 years, 89 % female) were randomized to receive a VR-based psychological intervention or placebo, using a randomized, single blind, parallel study design. The psychological intervention consisted in a 6-week program that started with a session of psychoeducation using a specifically created VR-video, followed by weekly sessions of group psychotherapy applied on-line by a psychologist. During the 6 treatment weeks, patients were asked to perform 15-30-min VR-sessions at home every day following a pre-designed protocol that incorporated progressive psychological interventions using VR-videos developed by a specialized company (XRHealth, Massachusetts, USA). The placebo group took a pill containing 0.3 g of glucose once daily. The primary outcome was the improvement of gastrointestinal symptoms (assessed by IBS-SSS) at the end of the intervention (6 weeks). Secondary outcomes included psychological comorbidities using the HADS (Hospital Anxiety and Depression Scale) and PSS (Perceived Stress Scale) questionnaires.

Results: Twenty-one patients were randomized to VR and fifteen patients to placebo. After 6 weeks of treatment, patients receiving the psychological intervention had a significantly greater reduction in IBS-SSS scores (score change -39±12) compared to patients on placebo (score change 1±19; $p=0.009$). When analyzing the specific symptoms, abdominal pain had a significant reduction after psychological intervention (score reduction -8±3; $p=0.015$) and a tendency was identified for abdominal bloating (score reduction -6±5; $p=0.097$). Both symptoms remained unchanged after placebo (score change 1±6; $p=0.719$ and -0±6; $p=0.695$, pain and distension, respectively).

In addition, psychological intervention was followed by a greater improvement than placebo in HADS scores for anxiety (score change -2.35 ± 0.56; $p=0.041$ vs score change 0.00 ± 0.85 after placebo) and depression

(score change -1.40± 0.71; $p=0.005$ vs score change 1.36 ± 0.50 after placebo). Stress evaluation using PSS also showed a greater reduction in stress perception in patients on psychological intervention (score change -5.15 ± 1.50) compared with patients on placebo 0.07 ± 1.35 ($p=0.023$).

Conclusion: A psychological intervention delivered at home using virtual reality is superior to placebo in relieving IBS symptoms, an effect that is associated to a reduction in anxiety, depression and stress in patients with IBS. These findings open the door to development of treatments in patients own home, and should facilitate the access to these treatments in large populations of patients. NTC06318572

Contact E-Mail Address: karen.vandenhoute@kuleuven.be

Introduction: The DOMINO diet app (diet) provides superior symptom relief to a spasmolytic agent (otilonium bromide, OB) in primary care Irritable Bowel Syndrome (IBS)¹. While the DOMINO diet aimed to provide a practical approach to lower intake of FODMAPs (fermentable oligo-, di-, monosaccharides and polyols), genetic polymorphisms in the eosinophil trafficking chemokine receptor CCR3 were associated with response to the diet². A correlation between fecal eosinophil-derived neurotoxin (F-EDN) and colonic mucosal eosinophil degranulation was previously reported in IBS³.

Aims & Methods: To assess a role for eosinophil-driven mucosal inflammation as a target for IBS therapy, we assessed changes in F-EDN levels in primary care patients treated with the DOMINO diet and OB, and their correlation with symptoms and inflammatory markers. In the DOMINO study, primary care physician-diagnosed IBS patients (70% fulfilling Rome IV, Rome+) were randomized to diet or OB. Analysis of gene polymorphisms, blood and stool samples were collected from 356 patients (86 IBS-C, 116 IBS-D, and 154 IBS-M) before and after treatment with diet and OB (respectively $n=147$ and 163). We compared and correlated F-EDN levels, demographic parameters, IBS symptom severity scoring (IBS-SSS), laboratory blood tests as well as biomarkers of inflammation in stool (secretory IgA/sIgA, Beta-defensin2, calprotectin). Statistical analysis was conducted using non-parametric tests; data were presented as median with interquartile range.

Results: Baseline F-EDN correlated negatively with presence of CCR3 polymorphism ($r=-0.13$, $p=0.02$), positively with sIgA ($r=0.27$, $p<0.0001$), but showed no significant associations with IBS-SSS scores or other stool parameters. Furthermore, a positive correlation was observed between F-EDN and glucose ($r=0.16$, $p=0.004$), insulin ($r=0.14$, $p=0.01$) and triglyceride ($r=0.12$, $p=0.03$) plasma levels and body weight ($r=0.16/p=0.002$). F-EDN decreased significantly in responders to the diet (≥ 50 -point improvement on IBS-SSS) ($n=104$, $0.44\mu\text{g/g}[0.16;0.88]$ vs. $0.32\mu\text{g/g}[0.15;0.72]$, $p=0.03$), but not to medication ($n=97$, $0.48\mu\text{g/g}[0.16;1.01]$ vs. $0.44\mu\text{g/g}[0.19;0.87]$,

$p=0.57$). In diet responders, baseline F-EDN levels correlated positively with calprotectin and sIgA (respectively $r=0.24$, $p=0.01$ and $r=0.37$, $p<0.001$). The significant decrease in F-EDN after diet was more pronounced in the subset of patients fulfilling Rome IV criteria ($n=86$, $0.47\mu\text{g/g}$ [0.17;0.91] vs. $0.34\mu\text{g/g}$ [0.16;0.75], $p=0.02$). Baseline F-EDN levels in this cohort correlated with the improvement in IBS-SSS ($r=0.21$, $p=0.04$).

Conclusion: In primary care IBS, response to the DOMINO diet, but not to OB, is associated with the presence and decrease of eosinophil-driven intestinal immune activation. Further research will focus on the ability of the DOMINO diet, besides its FODMAP-lowering properties, to improve atypical food allergic reactions involved in IBS pathophysiology.

Introduction: Irritable bowel syndrome is one of the most common Disorders of gut-brain interaction, with diarrhea being the predominant subtype. At present, there are limited drugs for effective management of irritable bowel syndrome.

Compound glutamine entersoluble capsules are composed of traditional chinese medicine formulas Sijunzi Tang and L-glutamine. The Sijunzi Tang, which has been used in traditional complementary and alternative

integrated medicine, has been used for the treatment of irritable bowel syndrome for many years. However, there is a lack of evidence from modern evidence-based medicine, its clinical efficacy and safety need to be confirmed. L-glutamine has the function of repairing damaged intestinal mucosa.

Aims & Methods: This study performed a multicenter randomized double-blind placebo-controlled withdrawal trial to explore the effectiveness and safety of compound glutamine entersoluble capsules in the treatment of diarrhea predominant irritable bowel syndrome.

The selected participants received the investigational drug for four weeks during the first single arm stage. The responding participants were randomly assigned to the compound glutamine entersoluble capsules and placebo groups in a 1:1 ratio for another 4 weeks.

The primary efficacy endpoint of the study was the response rate of both the improvement in abdominal pain and bowel movements after treatment in randomized controlled trial subjects (50% of the treatment course met the requirement of at least 30% improvement in abdominal pain severity (NRS pain score) and a reduction of at least 50% in bowel movement days for Bristol 6 or 7 types).

Results: A total of 558 subjects in 22 centers, of which 493 subjects were successfully screened and entered the placebo introduction period. During the placebo introduction period, there were a total of 493 subjects, of which 481 subjects were successfully rescreened and entered the single arm period. 437 subjects entered the randomized controlled trial period and were randomly divided into a treatment group of 217 subjects and a placebo group of 220 subjects.

For the primary efficacy endpoint, the number of response cases in the experimental group and placebo group were 114 (54.55%) and 89 (41.20%), respectively ($P=0.0059$). For secondary efficacy endpoints: (1) The number of improvements in NRS pain scores in the experimental group and placebo group were 138 (66.03%) and 107 (49.54%), respectively ($P=0.0006$); (2) The number of improved bowel movements in the experimental group and placebo group were 157 (75.12%) and 118 (54.63%), respectively ($P<0.0001$); (3) The median (quartile) relative baseline change of IBS-SSS scale in the experimental group was -47.00 (-97.00, -14.00) points; The median (quartile) relative baseline change in the placebo group was -17.00 (-63.00, 16.00) points, and there was a statistically significant difference between the two groups ($P<0.0001$); (4) The median (quartile) relative baseline change of IBS-QOL in the experimental group was -11.46 (-43.01, 0.00) points; The median (quartile) relative baseline change in the placebo group was -3.57 (-39.43, 0.00) points ($P=0.0007$).

During the randomized controlled trial period, the incidence of all adverse events in the 217 subjects in the trial group was 18.89%, the placebo group was 22.27%, the incidence of TEAEs related to the drug in the trial group was 2.30%, and the placebo group was 3.18%.

Conclusion: Compound glutamine entersoluble capsule can effectively improve the clinical symptoms of diarrhea predominant irritable bowel syndrome with a satisfactory safety.

Disclosure: Nothing to disclose.

Contact E-Mail Address: syl.groen@gmail.com

Introduction: Visceral hypersensitivity is a hallmark of irritable bowel syndrome (IBS). Transient receptor potential (TRP) channels are known as molecules involved in the pathogenesis of visceral hypersensitivity. A putative role for the Transient Receptor Potential Ankyrin 1 (TRPA1) channel in colonic nociceptor activation and mechanosensation has been shown in animal studies. We hypothesize there is a correlation in TRPA1 mRNA expression and the symptom-severity in IBS patients.

Aims & Methods: The main objective of this study was to determine TRPA1 mRNA expression in the colonic mucosa and ascertain its correlation with symptom-severity in IBS patients. Second, difference in TRPA1 mRNA expression between IBS patients and healthy controls along with regional differences in TRPA1 mRNA expression was analyzed. IBS patients (Rome III) and healthy controls were included. Sigmoid biopsies were obtained in all subjects. Additional biopsies of the proximal colon were obtained in 24/30 IBS patients. TRPA1 mRNA levels were measured in duplicate by quantitative reverse-transcriptase–polymerase-chain-reaction (Biorad), using primers from Biolegio and normalized to GAPDH. Levels of mRNA were expressed as relative mRNA values using the $-2^{\Delta\Delta Ct}$ method. A multivariate regression was utilized to compare mRNA-expression between IBS patients vs healthy controls. Symptoms in IBS patients were assessed using the Gastrointestinal Symptom Rating Scale (GSRS).

Results: 30 IBS patients (median age 39.0 yrs, 80% female) and 23 healthy controls (median age 22.7 yrs, 43.5% female) were included. Relative TRPA1 mRNA expression in the sigmoid was significantly higher in IBS patients compared to healthy controls ($P<0.001$), independent of age and gender. There was no significant difference in relative TRPA1 mRNA expression between IBS subtypes ($P>0.05$). Within IBS patients expression of TRPA1 mRNA of sigmoid-biopsies was significantly higher compared to biopsies of the proximal colon ($p<0.001$). No significant correlation between TRPA1 expression in sigmoid or proximal colon in GSRS scales ($n=27$) was found.

Conclusion: In IBS patients relative TRPA1 mRNA expression in colonic biopsies is significantly elevated compared to healthy controls. Furthermore, relative TRPA1 mRNA expression is higher in sigmoid colonic biopsies than in proximal colonic biopsies of IBS patients. These findings suggest a potential for the TRPA1 pathway as a target for IBS treatment in the future. However, no correlation between TRPA1 mRNA expression and symptom severity was found. Therefore, further research towards the clinical relevance of the increased TRPA1 mRNA-expression in IBS-patients along with its location-specific expression is warranted.

ABDOMINAL BLOATING AND DISTENTION IN IRRITABLE BOWEL SYNDROME ARE COMMON AND PARTLY RELATED TO GUT TRANSIT AND VISCERAL HYPERSENSITIVITY

N. Tornkvist¹, H. Törnblom², M. Simrén², A. Josefsson³
¹Sahlgrenska Universitetssjukhuset, Department of Internal Medicine and Clinical Nutrition, Gothenburg, Sweden, ²Inst of medicine, Department of Molecular and Clinical Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, ³Sahlgrenska University Hospital, Department of gastroenterology, Göteborg, Sweden

Contact E-Mail Address: navkiran.tornkvist@gu.se

Introduction: Patients with irritable bowel syndrome (IBS) frequently report bothersome abdominal bloating and/or distention.

Aims & Methods: We aimed to investigate the association of these symptoms to overall symptom characteristics and gut sensorimotor function. We included patients with IBS (Rome II-IV criteria) from studies investigating the association between IBS symptoms and pathophysiologic mechanisms. Validated questionnaires were used to evaluate gastrointestinal (GI) (GSRS-IBS and IBS-SSS), extraintestinal (PHQ-12), and psychological symptoms (HAD). Significant symptoms of abdominal bloating and/or distention were defined as a GSRS-IBS score ≥ 4 (at least moderate) for any of these two symptoms. Abdominal bloating or distention as the most bothersome symptom was defined in those scoring GSRS-IBS questions on bloating or distention higher than all other GI symptoms. Visceral sensory function was measured by a rectal barostat test and oro-anal transit time (OATT) was measured by use of radiopaque markers. Local reference values were used to define visceral hypersensitivity or abnormal OATT.

Results: We included 1100 patients with IBS; median age 35 (IQR 27-47) years and 794 (72%) females. IBS subtype distribution was IBS-C 30%, IBS-D 38%, and IBS-nonCnonD 32%.

Questions on abdominal bloating, abdominal distention, and passing gas had the highest median score, 5 (moderately severe), of all GSRS-IBS items (IQR 4-6 for bloating and passing gas, IQR 3-6 for distention). Significant abdominal bloating and/or distention was reported by 91.6% and 81.2% respectively, with a female predominance (74% and 78% respectively) and were equally distributed across IBS-subtypes ($p=0.09$). Having significant symptoms of abdominal bloating or distention was associated with more extraintestinal symptoms (PHQ-12) and more severe IBS symptoms (IBS-SSS) ($p<0.001$ for both). In addition, significant abdominal bloating was also associated with increased psychological symptoms (HAD), while significant distention was not ($p<0.05$ and $p=0.22$ respectively). There was no association between having significant abdominal bloating/distention and abnormal OATT or visceral hypersensitivity (Table 1).

	Signi- ficant bloating	Not signi- ficant bloating	p- value	Bloating most bother- some symptom	Bloating not most bother- some symptom	p- value	Signi- ficant disten- tion	Not signi- ficant disten- tion	p- value	Distention most bother- some symptom	Disten- tion not most bother- some symptom	p- value
Delayed OATT n (%)	35 (8)	3 (4.6)		5 (25)	33 (6.8)		27 (7)	11 (9.2)		4 (8)	34 (7.5)	
Normal OATT n (%)	300 (68.5)	41 (63.1)	0.24	13 (65)	328 (68)	0.01	267 (69.7)	74 (61.7)	0.26	34 (68)	307 (67.8)	0.95
Accelerated OATT n (%)	96 (28.6)	21 (32.3)		2 (10)	122 (25.3)		89 (23.2)	35 (29.2)		12 (24)	112 (24.7)	
Visceral hypersensi- tivity n (%)	96 (28.6)	4 (13.8)	0.09	88 (25.6)	88 (25.6)	0.016	70 (25.7)	29 (31.5)	0.28	11 (29.3)	88 (27.7)	0.59

Abdominal distention was more common as the most bothersome symptom compared to abdominal bloating (13% vs. 5%), both with a female predominance (76% and 79% respectively). The severity of IBS, extrain-

testinal, and psychological symptoms were similar in patients with and without abdominal bloating or distention as the most bothersome GI symptom ($p=0.09$, 0.45 , and 0.76 for bloating and $p=0.21$, 0.13 , and 0.69 for distention). However, abdominal bloating as the most bothersome GI symptom was associated with delayed OATT and visceral hypersensitivity. No such difference was noted comparing those with and without abdominal distention as the most bothersome GI symptom. Table 1.

Conclusion: The presence of significant bloating or distention in IBS is common and associated to more severe IBS as well as increased symptom burden, regardless of it being the most bothersome symptom or not, while the presence of bothersome abdominal bloating is associated to a deviant gut sensorimotor function. Our results suggest that bloating and distention play an important role in both disease burden and in further understanding pathophysiological mechanisms in IBS.

Introduction: IBS patients are often high healthcare utilizers. Symptom frequency, as well as psychological factors like neuroticism, anxiety, and depression, impact healthcare seeking. Bothersomeness, i.e., how distressing or disruptive symptoms are to a person's daily life, is a potential treatment-seeking motivator in IBS. We aimed to evaluate symptom bothersomeness in IBS and its potential influence on healthcare utilization.

Aims & Methods: Adults in 9 countries (Canada, China, Germany, Japan, Mexico, Poland, Romania, Spain, United States) completed an online survey that included IBS Rome IV Diagnostic Questions, lifetime healthcare utilization (HCU) for IBS (Yes/No); depression and anxiety; negative emotionality/neuroticism (NE), or a person's tendency to experience anxiety, anger, frustration, pessimism, or depressed mood; demographic

questions and the question "Is the [symptom] bothersome to you?" (yes/no) for each: abdominal pain, hard/lumpy stools, and soft/mushy stools. Three separate binary logistic regression models assessed the symptom's frequency, depression, anxiety, NE, sex, and age as predictors of bothersomeness for each of the key IBS symptoms. Three additional regression models evaluated each symptom's bothersomeness and frequency, depression, anxiety, NE, sex, and age as predictors of HCU.

Results: Of 17,663 participants, 1,389 (7.9%) met Rome IV criteria for IBS (mean age 41.6 (SD 14.7) years, 62.3% female; IBS sub-types: 32% C, 29% D, 36% M, 4% U). Of those with IBS, 65.7% had ever visited a doctor because of bowel problems. Abdominal pain was rated bothersome by 93% of people with IBS, hard stools by 80%, and mushy/watery stools by 78%, with no sex differences. Older people (ages 65+) reported only hard stools as more bothersome ($t(1236) = -3.40$, 95%CI: -5.54 to -1.49 , $p<.001$) than people of ages 18-39 or 40-64. Bothersomeness (yes/no) was predicted in regression analyses by higher frequencies of abdominal pain [Odds Ratio (OR) and 95% CI: 2.00 (1.46-2.74)], hard stools [1.33 (1.24-1.43)], and mushy stools [(1.24 (1.16-1.31))], but not by age, sex, or psychological variables. People with IBS were significantly more likely (χ^2) to have ever visited a doctor for bowel problems if they rated their pain ($p = .003$), hard stools ($p = .020$), and mushy stools ($p < .001$), as bothersome. Finding pain and mushy stools bothersome (yes/no) increased the odds of HCU for pain and mushy stools, but not for hard stools in the regression models (Table 1). Higher frequency of pain and hard stools (but not mushy stools) also increased HCU odds, and older people were more likely to consult for all 3 symptoms. Psychological variables and sex were not significant predictors of HCU.

	Dependent variable: Ever sought care for this symptom (yes/no)					
	1. Abdominal pain		2. Hard / lumpy stools		3. Mushy / watery stools	
Predictors:	OR (95% CI)	p	OR (95% CI)	p	OR (95% CI)	p
Symptom bothersomeness	1.82 (1.18-2.79)	.006	1.24 (0.92-1.67)	.160	1.81 (1.37-2.40)	<0.01
Symptom Frequency	1.16 (1.03-1.32)	.019	1.06 (1.00-1.11)	.036		.254
Age	1.02 (1.01-1.02)	<.001	1.01 (1.01-1.02)	.002	1.02 (1.01-1.03)	<.001
Sex		.725		.507		.510
Anxiety Score (PHQ-4)		.423		.562		.489
Depression Score (PHQ-4)		.974		.977		.717
Negative Emotionality Score		.135		.258	.96 (.94-1.00)	.040

Table 1. Binary regression analyses for predicting IBS lifetime doctor consulting for bowel symptoms

Conclusion: For persons with IBS, subjective experience of how bothersome symptoms are is strongly associated with symptom reporting and a driving factor to HCU regardless of gender, psychological distress, or negative emotionality. Providers need to assess symptom bothersomeness in their clinical decision-making.

Disclosure: Nothing to disclose.

TARGETING CONFOCAL LASER ENDOMICROSCOPY-IDENTIFIED GUT BARRIER DYSFUNCTION IN IRRITABLE BOWEL SYNDROME VIA MULTIMODAL INTEGRATIVE THERAPY IMPROVES BARRIER INTEGRITY AND SYMPTOM RELIEF – INSIGHTS FROM AN EXPLORATORY, PROSPECTIVE OBSERVATIONAL CLINICAL TRIAL

M. Bittel^{1,2}, S. Weyrauch^{1,2}, M.-L. Groh^{1,2}, J. Langhorst^{1,2}

Introduction: Irritable bowel syndrome (IBS) imposes a substantial burden on patients and healthcare systems globally, with diverse gut symptoms. Its pathophysiology involves disorders in gut-brain interaction and gut barrier dysfunction related to diet and stress. Confocal laser endomicroscopy (CLE) can detect barrier dysfunctions in vivo. Multimodal integrative mind-body medicine-based (MBM) therapy, including stress management, exercise, relaxation, and nutrition, may enhance gut barrier function, symptoms and patient well-being.

Aims & Methods: This study aims to screen IBS patients for prevalent and food-induced gut barrier dysfunction via CLE and explore the impact of a multimodal integrative therapy on barrier integrity, IBS-symptom severity, -quality of life and psychological well-being.

Methods: IBS patients (N=119) admitted between 1 February 2021 and 1 July 2023 at a Clinic for Internal and Integrative Medicine for a two-week inpatient stay underwent esophagogastroduodenoscopy with confocal laser endomicroscopy (CLE) and local food challenge (standardized protocol for egg white, soy, milk, yeast or wheat) to test for a primary prevalent (1stCLE+) or secondary food-induced (2ndCLE+) duodenal barrier dysfunction – after exclusion of IgE-mediated food allergy and coeliac disease. All IBS patients received a multimodal MBM therapy. Patients with barrier dysfunction were recommended to adhere to an adjuvant pre-clinically-tested barrier-stabilising therapy with myrrh, chamomile and coffee charcoal (MYRRHINIL INTEST® 3x4 dragées/ day), and exclusion of CLE-identified barrier-disrupting foods until a voluntary follow-up CLE (2nd CLE). Pre (=1st CLE) and Post (=2nd CLE) intervention, IBS-symptom severity (IBS-SSS), IBS-quality of life (IBS-QoL) and psychological well-being via clinically validated questionnaires were additionally assessed.

Results: Of the 119 IBS patients included in the study, 62% (n=74) showed duodenal barrier dysfunction [1stCLE+: n=27 (23%); 2ndCLE+: n=47 (39%)]. Of those, N=35 IBS patients (47%) with barrier dysfunction at 1stCLE returned for a voluntary 2nd CLE after 6.3 ± 3.0 months [at 1st CLE: 1stCLE+: n=15 (43%), 2ndCLE+: n=20 (57%); n=25 (71%) female; age 42.9 ± 15.4 yrs, diagnosis age 32.1 ± 15.0 yrs; disease duration 11.1 ± 11.2 yrs].

Of returned IBS patients, n=25 (71%) showed an improved gut barrier integrity, of whom 16 (46%) achieved complete stabilisation of the gut barrier (CLE-).

Pre-intervention, IBS patients were clinically characterized by severe IBS symptom severity (IBS-SSS 304.8 ± 83.4), severely impaired IBS-related quality of life (IBS-QoL 42.7 ± 16.6) and concomitant severe level of anxiety and depression (HADS 19.2 ± 7.7), fatigue (MFI-20 66.8 ± 13.1) and perceived stress (PSS-10 31.3 ± 7.7).

Post-intervention, patients exhibited significant and clinically relevant (MCID) improvement in all of these clinical outcomes (IBS-SSS $p < .001$, IBS-QoL $p < .001$, HADS $p < .001$, MFI-20 $p < .001$, PSS-10 $p = 0.004$), even allowing the severity score level to be reduced from severe to moderate. Patients reported particular improvement in abdominal pain, change in stool frequency and consistency, abdominal cramps and nausea assessed via 5-point Likert scale.

Conclusion: IBS patients have a high prevalence of existing and food-induced duodenal barrier dysfunction (62%). A multimodal integrative therapy showed a stabilisation of the gut barrier in 71% of IBS patients in a 2nd CLE as well as significant and clinically relevant improvement in IBS-related symptom severity, quality of life and psychological well-being.

IMPACT OF MEAL-RELATED SYMPTOMS IN IRRITABLE BOWEL SYNDROME (IBS)

M. Cuffe¹, V. Goodoory¹, C.E. Ng², C. Black^{1,3}, A.C. Ford^{3,1}

¹Leeds Gastroenterology Institute, St James' University Hospital, Leeds, United Kingdom, ²County Durham and Darlington NHS Foundation Trust, Surgery, Darlington, United Kingdom, ³Leeds Institute of Medical Research, St James' University Hospital, Leeds, United Kingdom

Contact E-Mail Address: melanie.cuffe@nhs.net

Introduction: Patients with IBS often report meal-related symptoms. These symptoms can negatively affect IBS-related quality of life, psychological health, and lead to food-avoidant behaviours¹. Developing our understanding of the impact of meal-related symptoms in IBS could lead to better treatment.

Aims & Methods: We aimed to compare the characteristics of patients with and without meal-related symptoms in IBS. Participants were recruited from the NIHR research register ContactME-IBS². We collected data for demographics, gastrointestinal symptoms^{3,4,5}, psychological health⁶, quality of life^{7,8}, and impact on work and daily activities⁹ using validated questionnaires among adults with IBS, as defined using the Rome IV criteria. We dichotomised the cohort according to whether they experienced meal-related symptoms, defined as being present $\geq 50\%$ of the time, or not. We compared the characteristics of the two groups and used logistic regression to explore predictors of meal-related symptoms in IBS.

	Had meal-related symptoms (n = 561)	Did not have meal-related symptoms (n = 191)	P value*
Female (%)	501 (89.3)	154 (80.6)	0.002
Most troublesome symptom (%)			
Abdominal pain	121 (21.6)	48 (25.1)	0.008
Constipation	30 (5.3)	23 (12.0)	
Diarrhoea	90 (16)	27 (14.1)	
Bloating or distension	175 (31.2)	43 (22.5)	
Urgency	145 (25.8)	50 (26.2)	
VSI scores (%)			
Low	151 (26.9)	96 (50.3)	<0.001
Medium	198 (35.3)	49 (25.7)	
High	212 (37.8)	46 (24.1)	
IBS-QOL score (%)			
Low	194 (34.6)	45 (23.6)	<0.001
Medium	196 (34.9)	56 (29.3)	
High	171 (30.5)	90 (47.1)	
Functional dyspepsia (%)			
Epigastric pain syndrome	195 (34.8)	39 (20.4)	<0.001
Postprandial distress syndrome	274 (49.1)	57 (30.2)	
WPAI:IBS, median (IQR)			
Absenteeism	0 (0-2.67)	0 (0-4.7)	0.92
Presenteeism	40 (20-60)	30 (10-60)	0.08
Overall work impairment	33.3 (10-60)	27.4 (6-51.9)	0.04
Activity impairment	50 (20-70)	30 (20-60)	<0.001

Table 1. Characteristics of Individuals with Rome IV IBS according to presence or absence of meal-related symptoms.

*P value for Pearson χ^2 for comparison of categorical data, independent samples t-test for continuous data, and Mann-Whitney U test for all four dimensions of Work Productivity and Activity Impairment: IBS.

Results: Of 752 respondents with Rome IV IBS, 561 (74.6%) were affected by meal-related symptoms. 89.3% of individuals with meal-related symptoms were female vs 80.6% of those without ($p=0.002$). A significantly higher proportion of those with meal-related symptoms reported bloating or distension as their most troublesome symptom (31.2% vs 22.5%, $p=0.008$), and had a higher prevalence of functional dyspepsia, especially postprandial distress syndrome (49.1% vs 30.2%, $p<0.001$). Individuals affected by meal-related symptoms reported higher levels of

gastrointestinal symptom-specific anxiety, had lower levels of IBS-related quality of life, and significantly higher levels of work productivity and activity impairment ($p<0.001$ for all analyses). Logistic regression analysis controlling for all other data showed that females (OR 2.3, 95% CI 1.30 - 4.08) and those with functional dyspepsia, both post-prandial distress syndrome (OR 2.0, 95% CI 1.3 - 3.3) and epigastric pain syndrome (OR 2.0, 95% CI 1.19 - 3.22), were more likely to report IBS meal-related symptoms. Conversely, IBS sufferers with abnormal depression scores were less likely to report meal-related symptoms (OR 0.4, 95% CI 0.20 - 0.72). This could reflect low mood leading to poor appetite. Overall, the model explained 22.8% of the variance of the data.

Conclusion: Individuals with Rome IV IBS who report meal-related symptoms experience significantly worse gastrointestinal symptom-specific anxiety and are more adversely affected at work compared to those without meal-related symptoms. These findings suggest that people with IBS and meal-related symptoms may benefit from early multidisciplinary treatment with dietary and psychological therapies.

COLONIC MOTOR PATTERNS AFTER INTRACOLONIC INFUSION OF FRUCTANS, FRUCTOSE AND MANNITOL IN HEALTHY VOLUNTEERS ASSESSED WITH HIGH-RESOLUTION COLONIC MANOMETRY

A. Verheyden¹, S. Dubrulle¹, T. Vanuytsel¹, J. Tack¹

¹KU Leuven, University Hospital Gasthuisberg, Translational Research center for Gastrointestinal Disorders, Leuven, Belgium

Contact E-Mail Address: annelies.verheyden@kuleuven.be

Introduction: Although irritable bowel syndrome (IBS) is defined as a motility disorder, there is a lack of studies assessing colonic motility in these patients and linking it to symptoms. A recent FODMAP (Fermentable Oligo-, Di-, Monosaccharides, and Polyols) reintroduction study showed that fructans and mannitol triggered IBS symptoms in the majority of patients, while fructose did not, but the mechanism is unclear. Therefore, we set up a study investigating how these FODMAPs trigger colonic motor patterns in healthy volunteers (HV).

Aims & Methods: HV were included in a randomized, double-blind, 3-way crossover study where a 200 mL solution of either fructose, fructans, or mannitol was administered during three study visits, each separated by ≥ 2 weeks of wash-out. Participants followed a low-FODMAP and low-fiber diet for 3 days before each study visit. On the study day, they received a 250mL tap water enema for HRCM catheter placement (36-sensor solid-state) via colonoscopy. After recovery of 1h, colonic pressure waves (PWs) were measured in a fasted state (1h), after a 20-min FODMAP infusion (2h), and after a standardized meal (1h). The number and propagation direction of short PWs (3 sensors), long PWs (≥ 4 sensors), cyclic PWs, and high-amplitude propagating (retrograde) contractions (HA(R)PCs) were analyzed.

Results: A total of 15 study visits from five HV (40%men, 38±8 years, BMI 23.7±1.6 kg/m²) who finished the full protocol were analyzed. Although none of the motor patterns occurred more frequently with one of the FODMAPs in the fasted state, during FODMAP infusion, 1h post-infusion and postprandially, the short anterograde PWs occurred more frequently in the 2h post-infusion period with fructans compared to fructose and mannitol (p=0.03). Additionally, long synchronous PWs occurred more frequently 1h post-infusion with fructans compared to the fasted state (p=0.01) and there was a trend toward a higher occurrence of long synchronous PWs (p=0.054) and cyclic retrograde PWs (p=0.06) with mannitol

Conclusion: At the current number of healthy volunteers finalizing all 3 visits, fructans and to a lesser extent mannitol but not fructose intracolonic infusions are associated with increased occurrence of synchronous and anterograde colonic motor patterns. Triggering of colonic motor patterns may contribute to symptom triggering by these FODMAPs in IBS.

OPIUM TINCTURE HAS ANTI-PROPULSIVE EFFECTS IN CHRONIC DIARRHEA PATIENTS: A RANDOMIZED PLACEBO-CONTROLLED CROSS-OVER TRIAL

L. Davidsen^{1,2}, T. Okdahl^{1,2}, K.L. Høyer³, C.S. Knoph^{1,2}, I.M. Larsen¹, C.L. Hvas³, K. Krogh³, A.M. Drewes^{1,2}

Contact E-Mail Address: l.davidsen@rn.dk

Introduction: Chronic diarrhea is a debilitating disorder affecting up to 5% of the population. Opioids inhibit gastrointestinal motility via μ-opioid receptors in the enteric nervous system, and opioids have been used in the management of diarrhea for centuries. However, a lack of clinical evidence regarding their efficacy, along with concerns about potential opioid-induced sedation and addiction, limits their use in the clinic. Opium tincture (raw opium dissolved in ethanol) has recently shown anti-propulsive effects in a healthy cohort (1), but no evidence of its effects on the enteric and central nervous system (CNS) in chronic diarrhea patients exists.

Aims & Methods: We aimed to investigate the anti-propulsive effects of opium tincture and its secondary effects on the CNS in a randomized, double-blinded, placebo-controlled, cross-over trial in subjects with chronic diarrhea (defined as a minimum of three daily bowel movements for the past week) refractory to loperamide and targeted treatment (if known etiology). Opium tincture or placebo was administered for seven days in two study periods separated by 14 days. The end titration daily dose was 30 drops (~15mg of oral morphine).

Bowel movements were assessed using the Bristol Stool Form Scale, while a wireless motility capsule recorded gastrointestinal transit times. CNS effects in terms of change in pupil size, reaction time, and working memory were also investigated. Signs of addiction were evaluated using the Subjective Opiate Withdrawal Scale.

Results: Eleven subjects (mean age: 45 ±17 years, 46% males) with chronic diarrhea were included (idiopathic: 4; bile acid malabsorption: 3; inflammatory bowel disease: 2; microscopic colitis: 1; irritable bowel syndrome: 1). The number of daily bowel movements was reduced during treatment with opium tincture compared to placebo (overall estimated difference between treatments: -0.7 (-1.1 - -0.3), p=0.002). In line with this, opium tincture prolonged the colonic transit time (opium tincture: median 17h

(interquartile range 15-40h) vs. placebo: 12h (4-16h), p=<0.001). Opium tincture induced miosis in most subjects, but no indication of sedation or addiction was found.

	Opium tincture (n=11)	Placebo (n=11)	p-value
Anti-propulsive effects	Daily bowel movements (#)	2 (1-3)	3 (2-5)
	Stool consistency (BSFS score)	5 (4-6)	5 (5-6)
	Gastric emptying time (hours)	3 (2-4)	3 (2-18)
	Small bowel transit time (hours)	6 (4-7)	7 (3-6)
Central nervous system effects	Colonic transit time (hours)	17 (15-40)	12 (4-16)
	Δ pupil size (mm)	0.1 ±0.5	-0.6 ±0.5
	Δ reaction time (ms)	-0.7 ±21.4	-2.5 ±19.4
	Δ working memory (DST score)	1.2 ±1.4	1.2 ±1.4
	Signs of addiction (SOWS score)	8.8 ±4.9	11.7 ±9.1

Summary data (mean ±standard deviation or median (interquartile range). Delta values (Δ): day 7 minus day 1. [†]Repeated measures mixed model. [‡]Wilcoxon signed-rank test. BSFS: Bristol Stool Form Scale; DST: Digit Span Test; SOWS: Subjective Opiate Withdrawal Scale.

Conclusion: Opium tincture induced anti-propulsive effects in subjects with chronic diarrhea refractory to standard treatment, evident as a reduced number of bowel movements and prolonged colonic transit. No CNS involvement besides miosis was observed. These results suggest that opium tincture is a relevant treatment strategy for selected patients with chronic diarrhea, especially because no evidence of opioid-induced sedation or addiction was found. However, studies on the long-term effects are needed.

PREDICTIVE VALUE OF ULTRASONOGRAPHIC SURROGATE MARKERS OF FIBROSIS: A RETROSPECTIVE COHORT STUDY

P.F. da Silva Mesquita¹, M.M. Estevinho¹, C. Costa¹, A. Ponte¹, T. Freitas¹

¹Centro Hospitalar Vila Nova de Gaia/Espinho, Gastroenterology, Vila Nova de Gaia, Portugal

Contact E-Mail Address: pedro.filipe.silva.mesquita@gmail.com

Introduction: Performance of liver ultrasound (US) in the detection of fibrosis has been compared in the past with histology, however non-invasive tests are today's standard of care. Additionally, most of these studies were conducted in a controlled setting with dedicated sonographers, which does not reflect clinical practice. We aim to determine the specificity and diagnostic accuracy of routine clinical ultrasound surrogate markers in the staging of liver fibrosis against fibroscan, in the real-world setting.

Aims & Methods: Retrospective cohort study of patients who underwent liver US and Fibroscan (Echosens®) within 3 months of each other, in the last 6 months. Patients with clinical signs of decompensated cirrhosis were excluded. Ultrasonographic keywords of chronic liver disease were collected and their accuracy, specificity, and AUROC for liver fibrosis was calculated.

Results: 251 patients met the inclusion criteria. Mean age was 58,2 ($\pm 13,05$) years, and 73% were male. The most common etiologies were MASLD (34,5%), MetAld (19,2%), Alcohol (15,1%), followed by HCV (12,8%) and HBV (12,4%). In our cohort 25,9% of patients had advanced fibrosis ($>10\text{Kpa}$). The most specific signs were severe coarseness of the parenchymal texture 100% (98,02-100%); major structural changes (parenchymal atrophy or left liver lobe/caudate lobe hypertrophy): 96.17% (92.28%-98.45%) and severe steatosis: 89,87% (84,34%-93,67%). The simultaneous presence of an altered liver edge and any degree of coarseness showed a specificity of 82,07% (75,75%-87,32%). Splenomegaly, hepatomegaly/globose liver, steatosis, or coarseness of any degree showed a specificity under 75%. The most accurate signs (considering a prevalence of 2,85% of advance fibrosis) were severe coarseness 97,42% (94,59-99,01%, AUC 93,7%); major structural changes 93.94% (90.23%-96.55%, AUC 66,4%), severe steatosis: 87,30% (82,50%-91,17%, AUC of 51,5%) and the combined presence of an altered liver edge/any degree of coarseness 82,49% (77,18%-87,01%, AUC 69.5%). BMI and the presence of diabetes were strongly correlated with advanced fibrosis.

Conclusion: In summary, ultrasound surrogate markers of fibrosis remain accurate in predicting advanced fibrosis, even in a real-world setting.

Introduction: Despite the increasing diffusion of non-invasive tests for the diagnosis of liver diseases, histological assessment through liver biopsy (LB) is still often mandatory especially in unclear cases. Actually, percutaneous approach (PC-LB) is the gold standard. Nowadays, endoscopic ultrasound-guided liver biopsy (EUS-LB) has emerged as an established method to achieve liver tissue sampling. EUS-LB has several advantages such as: sampling of both liver lobes, it allows to obtain liver tissue sampling in case of ascites and to avoid damage to nearby organs and vessels.

Aims & Methods: e performed a systematic review with meta-analysis (MA) to evaluate the diagnostic outcomes and safety for liver tissue acquisition of PC-LB and EUS-LB in patients with liver diseases and focal liver lesions. Studies that compare diagnostic outcomes of PC-LB and EUS-LB were identified through literature search using MEDLINE, Embase and Scopus until January 2024. MA was performed according to a frequentist approach.

Results: Overall, diagnostic adequacy was 94 % (CI 95%, 0.91-0.98, $I^2 = 83.92\%$, $P < 0.001$) for EUS-LB, while 96 % (CI 95%, 0.93-0.99, $I^2 = 91.58\%$, $P < 0.001$) for PC-LB. Moreover, based on eight studies comparison between the two procedures showed an OR 1.89 (95% CI, 0.44 – 8.12, $I^2 = 62.33\%$, $P = 0.003$) when comparing PC-LB to EUS-LB. Based on four studies, pooled accuracy was OR 2.45 (95% CI, 0.38 – 15.97, $I^2 = 49.74\%$, $P = 0.0114$) when comparing PC-LB to EUS-LB. Regarding safety, based on nine studies, pooled rate of overall adverse events was slightly higher in PC-LB compared to EUS-LB, OR: 1.25 (CI 95%, 0.51 – 3.09 $I^2 = 26.13\%$, $P = 0.212$). Technical success for EUS-LB was 99 % (CI 95%, 0.99 – 1.00, $I^2 = 0\%$, $P = 0.973$) while 100 % (CI 95%, 0.99-1.00, $I^2 = 0\%$, $P = 0.973$) for PC-LB, with an OR 1.11 (95% CI, 0.26-4.70, $I^2 = 0\%$, $P = 0.988$) when comparing PC-LB to EUS-LB. Overall no differences between the two procedures were observed in term of total length specimen with a standardized mean difference of 0.89 (95% CI, -0.87 – 2.64, $I^2 = 98.95\%$, $P < 0.001$) and in term of complete portal tract with a standardized mean difference of 0.50 (95% CI, -0.55 – 1.55, $I^2 = 97.42\%$, $P < 0.001$).

Conclusion: In conclusion, our meta-analysis does not show significant differences between PC-LB and EUS-LB in terms of diagnostic outcomes, albeit EUS-LB is slightly safer than PC-LB.

Introduction: Metabolic Associated Steatotic Liver Disease (MASLD) affects 25-30% of the European population and is projected to rise further. These patients are at increased risk for liver-related complications and higher overall mortality, emphasizing the need for early detection to improve outcomes. While abdominal ultrasound serves as the primary imaging modality for suspected liver disease, its sensitivity for diagnosing mild steatosis is inadequate, and gold-standard methods for quantifying liver steatosis infiltration, such as magnetic resonance imaging or liver biopsy are impractical for widespread use.

Aims & Methods: This study aimed to assess the diagnostic accuracy of the Attenuation Coefficient (ATT) as a complementary method to B-mode ultrasound for early detection of hepatic steatosis. Consecutive patients referred for transient elastography were prospectively enrolled. Liver steatosis was graded using a 4-point scale (normal, mild, moderate, or severe) in B-mode ultrasound for each patient, and ATT was measured in accordance with manufacturer quality criteria instructions (Fujifilm®). Additionally, the Hepato-Renal Index (HRI) was calculated for each patient, and Controlled Attenuation Parameter (CAP, Fibroscan®) was measured.

Results: A total of 128 patients, 61.7% male, with a mean age of 56.8±12.8 years, were included. Among them, 78.1% exhibited at least one cardiometabolic risk factor. The main referral indications were fibrosis assessment in viral hepatitis (42.2%), MASLD (21.9%), and alcoholic liver disease (11.7%). The median vibration-controlled elastography result was 5.8kPa. B-mode ultrasound steatosis assessment classified 44.5% as normal, 10.2% with mild steatosis, 21.1% with moderate steatosis, and 24.2% with severe steatosis. The area under the ROC curve for steatosis detection was 0.796 for HRI, 0.894 for ATT, and 0.896 for CAP, highlighting robust diagnostic performance, particularly for the latter two methods. There was a strong correlation between ATT and CAP ($r=0.710$). Using a CAP>248dB/m to define steatosis, the area under the ROC curve for ATT was 0.890. For an ATT cutoff value ≥ 0.66 , Sensitivity, Specificity, Negative Predictive Value, and Positive Predictive Value were 82.7%, 77.3%, 72.3%, and 86.1%, respectively. The sensitivity of B-mode ultrasound for steatosis detection was 79.5%, increasing to 90.4% when combined with ATT measurement.
